### Overview

The following external parts are needed to demonstrate the design example:

- MAX10 FPGA evaluation kit.
  - A potentiometer must be purchased and soldered onto the kit at R94. More information about purchasing and soldering the potentiometer can be found here [MAX10 FPGA Evaluation Kit User Guide](#). Potentiometer must be purchased and soldered onto the kit. The Evaluation kit user guide shows model to order with finger adjust knob. Part number 3362P-103TLF must be ordered and soldered to the Evaluation kit R94 location.

- Mini-USB cable for providing power to the kit.
- USB-Blaster II cable for programming the device (note this kit gets its program download through the JTAG port. The Blaster cable bridges USB to JTAG).
- Sainsmart LCD keypad Arduino shield. This can be purchased here [Sainsmart](#)
  - Adafruit electret microphone available from adafruit.com. More information about soldering and connecting the microphone can be found in the Appendix.
**Theory of Operation**

The ADC accepts an analog voltage reading from a potentiometer or microphone on the MAX10 FPGA evaluation kit through channel 7. The NIOS II processor is then used to program an LCD to display the equivalent digital voltage reading.

![ADC/LCD Design Block Diagram](image)

**ADC Simple Demo Setup**

1. Place your MAX 10 10M08 Eval kit and sainsmart LCD keypad shield on the bench
2. All switches on the DIPSWITCH on located near bottom edge of the board must be in the DOWN position or the demo will not run. Please make sure all dipswitches are in the down/off position.

3. Pair the Sainsmart LCD’s male pins with the Arduino female connectors on the Eval kit. There is a gap difference between headers on top and bottom such that you cannot insert the Arduino shield in the wrong direction. To insert the Sainsmart LCD shield correctly the Altera logo and the SainSmart logo should be in same direction and orientation. Make sure the LCD shield is pushed down snug with the Arduino female connectors.
Make sure connection is snug.

4. Connect mini-USB cable to the board to power up, the other end to a USB connection on a laptop, computer, or USB power supply.

5. If not previously pre-programmed with the demo design POF, follow these instructions:
The design package includes a pre-compiled version of the design that downloads to the MAX 10 embedded flash. This version of the configuration includes the combined FPGA configuration and NIOS executable. Startup Quartus. Then start the programmer: Tools → Programmer. Once the programmer starts, make sure the link is established to the kit:

Load the pre-canned file which includes both the FPGA configuration: add file → master_image/niosMAX10EvalKit_adc_lcd.pof. Then click start and you can run the demonstration. Note that by loading the .pof file in that directory, you have loaded a non-volatile image into the MAX 10 FPGA. You can also load .sof file in the same master_image directory for a volatile image of the same design (will be lost upon power down).

6. Click the top right blue push button (SW1) next to the JTAG header to begin operation of the design. You will not see anything on the LCD until you hit SW1 at least once, then you will see a Dallas Logic DSN splash screen, followed by the ADC/LCD demo title after another click. One more click and the design is in ADC measure mode.
7. Use a small screwdriver or your fingers (if knob is attached to your POT) to turn the potentiometer and see the voltage meter change up or down. MAX 10 FPGA’s ADC block input channel is measuring the analog voltage and using a Nios II system to display to the LCD. (Note: picture below is using a variable resistor R16, not the potentiometer recommended on R94.

8. If you push the upper right push button SW1 one more time you can change the voltage meter scale to a numeric voltmeter. You can go back to meter mode by pushing the button again.
Optional Microphone Demo Setup
The same design file/POF in the device can be used for a microphone to ADC demonstration. Here are the instructions.

1. 2 male headers must be soldered to the TP5 and TP8 test point through-holes. These will provide power and GND to the microphone.

2. With an assembled Adafruit microphone (see Appendix), connect a cable to V+, GND, and Out on the adafruit PCB.
3. Connect the cable for V+ (red in the above image) to the TP5 test point, the GND cable to the TP8 test point, and the Out cable to the center of the J7 jumper header. You must remove the J7 jumper in order to connect the cable to the J7 center header. This is the same channel input as the POT into the MAX 10 ADC. Note that you must return the jumper
if you want the potentiometer to control the input voltage.

4. Power the board and run the ADC/LCD demo design in meter mode. For this demo you can blow into the microphone or it's good to play a song from your smart phone and put the microphone up to the speaker on your phone. A song with distinct beats will show well on the meter.

Optional Cool Microphone Soundwaves Demo

You are now ready for introduction into the ADC Toolkit (in Beta starting in 14.1). In this part of the demo, we illustrate Tools capabilities and features. This should not be used at this early stage to measure ADC performance. In this demo we can show how everything demonstrated on the LCD can be quickly acquired and displayed by the toolkit.

1. Download one of the following sound wave apps for your smart phone:
   - Android Sound Wave Generator (free) – this one is untested
   - iPhone Tone Generator (free)
2. Launch the app on your phone and turn up sound on phone volume
3. Open the ADC Toolkit from System Console. Click on the Tools menu -> System Debugging Tools -> System Console
4. Click on Load Design… and click on the “master_image/niosMAX10EvalKit_adc_lcd.sof” file that came with this design. System Console does not configure the device using the SOF, but instead extracts debug file information from the SOF format.

5. After loading the SOF file into the system console, the JTAG connection to the toolkit becomes available, click on Launch shown in red below to open it.
6. Select ADC Channel 7 from the scope view and click on “Run” to see the output of the microphone. It should contain a noisy output.

7. Open your iPhone or Android tone generator App and hold the speaker up to the microphone. It’s best to let the phone lie on the desktop next to the phone speaker source. Turn up the volume and run the tones from the app.
8. Sweep from low to high frequency on the application, you will see analog capture in the form of sine waves that increase with frequency as you sweep the Apps tones to higher frequency. See examples below...
9. Click Run on Signal integrity to see FFT results and center frequency.
10. Hit Stop and hit run on the Linearity tab to see a histogram of measured values.
11. If you run the histogram in the Linearity panel, you get the expected bath tub result after accumulating samples from a sine wave.
12. As you go higher in frequency you will find that you stop hearing the sound but the ADC Toolkit still shows waveforms, this is because human audible range will cut off at high frequency but the microphone still captures it. The older the person listening the lower their high frequency cut off will be. The youngest people in the room will always hear higher frequencies than the older folks.
How to compile the hardware
Follow the steps on the Design Store web page to extract and install the evalkit_adc_lcd_controller platform file.

The following steps describe how to setup a project in Quartus II software in order to program the MAX10 FPGA device with the ADC/LCD demo design

**Note – extract platform**

i) Launch Quartus II software and open the project top.qpf using File->Open Project.

ii) Compile the Project by clicking the button.

iii) Launch the Quartus II programmer from the Tools menu or alternatively by clicking the button.

iv) Download the .sof file output_files/top.sof and program the device using the programmer. Alternatively, create a output_files/.pof file by selecting File → Convert Programming Files. Set the Mode from the default 1-bit Passive Serial to Internal Configuration. Highlight SOF data in the input files to convert field and you will see Add File become available to click. Click on add file and add the .sof file located under output_files/top.sof and click generate.

v) You can download the volatile .sof or non-volatile .pof file.

---

How to compile the software
The following steps describe how to use Nios II Software Build Tools for Eclipse software to perform the following tasks;

i) Create a software project (BSP and application) from a sopcinfo file

ii) Add source code (that is used to program the LCD) to the project

iii) Download and run source code on the target processor (NIOS II)

---

1. Open Quartus II on a windows platform
2. Launch Nios II Software Build Tools for Eclipse from the Tools menu
3. Specify the workspace directory for the project and click ok
4. A blank workspace window pops up, right click anywhere in the Project Explorer and select the following to create a new software project; New->Nios II Application and BSP (board support package) from Template.

5. In the window that appears, browse to the location of the platform/<project>.sopcinfo file and add it to the project. Provide a name for the software project i.e. niosMAX10EvalBoard and click Finish.

6. A BSP is created and located at niosMAX10EvalBoard_bsp and an application is created and located at niosMAX10EvalBoard. The application contains source code from the template design “Hello World Small” that needs to be replaced with source code from the MAX10 EVAL DEMO design, the source code is located at the software/src.

7. Select and right click hello_world_small.c under the main project explorer tab and click delete.

8. Right click the project name and left click the import command.

9. Navigate to General → File System
Browse to the location of src, click on the box next to it, add it as shown and click Finish.

You should see main.c and 2 folders: device and drivers added to your project.
10. Compile the project by selecting Build All from the Projects Menu or alternatively Ctrl+B.

11. Program the FPGA device by launching Quartus II programmer from the menu and loading the file output_files/top.sof.

12. Load the executable to the processor by right clicking on the Application project and selecting Run-As Nios II Hardware.

13. In the Run Configurations page under the Target connections tab. Check the options; Ignore mismatched system ID and Ignore mismatched system timestamp. If you don’t see the connection specified, click Refresh Connections. Click Apply followed by Run.

14. Now your hardware image is downloaded to the FPGA through the Quartus programmer and the NIOS code has also been downloaded through Eclipse. You can proceed to the demonstration as discussed in the earlier steps. The method described works well if you are modifying your code. You can maintain the same FPGA download and iterate through code revisions.

**Merging the NIOS executable into the FPGA configuration file**

The master_image directory shipped with the design example .sof and .pof files have the NIOS executable incorporated in them. The prior steps detailing how to build your hardware and
software show you how to compile the hardware without the image loaded in the .sof or .pof file. In those steps, you load the NIOS executable from Eclipse through the Run ➔ NIOSII Hardware step.

This section will allow you to merge the .elf executable into the .sof once your software is stable. In Eclipse, right click the project and select Make Targets. Click on mem_init_generate. You will generate a .hex file that is in the location where your software build is located (e.g): 

```
./platform/software/evalkit_lcd_adc_v14/mem_init/NIOSII_M10_ONCHIP_RAM_16K.hex
```

Next, you need to return to Qsys and change the ONCHIP_RAM_16K component by double-clicking it. The initialize memory content and enable non-default initialization file needs to on. Enter the location where the .hex file is located.

Next, click Generate HDL ➔ Generate. Return to Quartus and click compile and you will generate a new .sof file with the NIOS executable included. Run the programmer and download the new .sof. Run the demonstration as described in the previous steps.

Click generate, and you will see the output_files/top.pof file to download with the programmer. The demonstration will continue to run even after power cycling the development kit.

Appendix A - Microphone soldering instructions

Solder the 5-pin header that comes with the board such that the long end is at the back side of the microphone PCB. The short end of the connectors should be soldered at the front of the PCB. If the pin header has more than 5 pins, cut off the extra pins using wire cutters.
