Unless the License provides otherwise, you may not use, modify, copy, publish, distribute, disclose or transmit this software or the related documents without Intel's prior written permission.

This software and the related documents are provided as is, with no express or implied warranties, other than those that are expressly stated in the License.
This is for version 2021.6 of the compiler.

This document contains information about the Intel® C++ Compiler Classic (icc for Linux* and icl for Windows*) compiler and runtime environment. The Intel® C++ Compiler Classic can be found in the Intel® oneAPI HPC Toolkit, Intel® oneAPI IoT Toolkit, or as a standalone compiler. More information and specifications can be found on the Intel® oneAPI DPC++/C++ Compiler main page.

The following are some important sections of the compiler developer guide:

**Compiler Setup**

- **Compiler Setup** explains how to invoke the compiler on the command line or from within an IDE.

**OpenMP* Support**

- The compiler supports many OpenMP* features, including most of OpenMP* Version TR4: Version 5.0.

**Compiler Options**

- **Compiler Options** provides information about options you can use to affect optimization, code generation, and more.

**Intrinsics**

- **Intrinsics** let you generate more readable code, simplify instruction scheduling, reduce debugging, access the instructions that cannot be generated using the standard constructs of the C and C++ languages, and more.

**Pragmas**

- **Pragmas** provide the compiler with the instructions for specific tasks, such as splitting large loops into smaller ones, enabling or disabling optimization for code, or offloading computation to the target.

**Context Sensitive/F1 Help**

- To use the Context Sensitive/F1 Help feature, visit the Download Documentation: Intel® Compiler (Current and Previous) page and follow the instructions provided there.

**Download Previous Versions of the Developer Guide and Reference**

- Visit the Download Documentation: Intel® Compiler (Current and Previous) page to download PDF or FAR HTML versions of previous compiler documentation.

---

**NOTE** For the best search experience, use a Google Chrome* or Internet Explorer* browser to view your downloaded copy of the Developer Guide and Reference. If you use Mozilla Firefox*, you may encounter an issue where the Search tab does not work. As a workaround, you can use the Contents and Index tabs or a third-party search tool to find your content.
Introducing the Intel® C++ Compiler Classic

Using the Intel® C++ Compiler Classic, you can compile and generate applications that can run on Intel® 64 architecture. You can also create programs for the IA-32 architecture on Windows® and Linux®.

Intel® 64 architecture applications can run on the following:
- Windows operating systems for Intel® 64 architecture-based systems.
- Linux operating systems for Intel® 64 architecture-based systems.
- macOS* operating systems for Intel® 64 architecture-based systems.

IA-32 architecture applications can run on the following:
- Supported Windows operating systems
- Supported Linux operating systems

Unless specified otherwise, assume the information in this document applies to all supported architectures and all operating systems.

You can use the compiler in the command-line or in a supported Integrated Development Environment (IDE):
- Microsoft Visual Studio® (Windows only)
- Eclipse*/CDT (Linux only)
- Xcode* (macOS* only)

See the Release Notes for complete information on supported architectures, operating systems, and IDEs for this release.

Performance and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

Feature Requirements

To use these tools and features, you need licensed versions of the tools and you must have an appropriately supported version of the product edition. For more information, check the product release notes.

NOTE Some features may require additional product installation.

The following table shows components (tools) and where to find additional information on them.

<table>
<thead>
<tr>
<th>Component</th>
<th>More Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel® C++ Compiler Classic</td>
<td>More information on tools and features can be found on the Intel® Developer Zone and the Software Development Tools pages.</td>
</tr>
<tr>
<td>Intel® Advisor</td>
<td></td>
</tr>
<tr>
<td>Intel® Inspector</td>
<td></td>
</tr>
<tr>
<td>Intel® Trace Analyzer and Collector</td>
<td></td>
</tr>
</tbody>
</table>
The following table lists dependent features and their corresponding required products. For certain compiler options, the compilation may fail if the option is specified but the required product is not installed. In this case, remove the option from the command line and recompile.

### Feature Requirements

<table>
<thead>
<tr>
<th>Feature</th>
<th>Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel® oneAPI Threading Building Blocks (oneTBB)</td>
<td>The -tbb, -qtbb, and /Qtbb options require a oneTBB install.</td>
</tr>
<tr>
<td>Intel® oneAPI Math Kernel Library (oneMKL)</td>
<td>The -qmkkl, -ml, and /Qmkkl options require a oneMKL install.</td>
</tr>
<tr>
<td>Intel® oneAPI Data Analytics Library (oneDAL)</td>
<td>The -daal, -qdaal, and /Qdaal options require a oneDAL install.</td>
</tr>
<tr>
<td>Intel® Integrated Performance Primitives Cryptography (Intel® IPP Cryptography)</td>
<td>Use crypto to link to the Intel® IPP Cryptography library.</td>
</tr>
<tr>
<td>Thread Checking</td>
<td>Intel® Inspector</td>
</tr>
<tr>
<td>Trace Analyzing and Collecting</td>
<td>Intel® Trace Analyzer and Collector</td>
</tr>
</tbody>
</table>

Compiler options related to this feature may require a set-up script. For further information, see the product documentation.

Refer to the Release Notes for detailed information about system requirements, late changes to the products, supported architectures, operating systems, and Integrated Development Environments (IDEs).

---

### Get Help and Support

**Windows®**

Documentation is available from within the version of Microsoft Visual Studio®. You must install the documentation on your local system. To use the feature, visit the Download Documentation: Intel® Compiler (Current and Previous) page and follow the instructions provided there. From the Help menu, choose Intel Compilers and Libraries to view the installed user and reference documentation.

**Linux® and macOS®**

On Linux and macOS®, the documentation has limited integration in the Eclipse*/CDT and Xcode®. In both cases, the integrated documentation only provides details about where to find the product documentation on your local system.

**Intel® Software Documentation**

You can find product documentation for many released products at: https://software.intel.com/content/www/us/en/develop/documentation.html
Product Website and Support
To find product information, register your product, or contact Intel, visit: https://software.intel.com/content/www/us/en/develop/support.html
At this site, you will find comprehensive product information, including:
• Links to Get Started, Documentation, Individual Support, and Registration
• Links to information such as white papers, articles, and user forums
• Links to product information
• Links to news and events

Online Service Center
Each purchase of an Intel® Software Development Product includes a year of support services, which includes priority customer support at our Online Service Center. For more information about the Online Service Center visit: https://supporttickets.intel.com/servicecenter

NOTE To access support, you must register your product at the Intel® Registration Center: https://registrationcenter.intel.com/en/products/

Release Notes
For detailed information on system requirements, late changes to the products, supported architectures, operating systems, and Integrated Development Environments (IDE) see the Release Notes for the product.

Forums
You can find helpful information in the Intel Software user forums. You can also submit questions to the forums. To see the list of the available forums, go to https://community.intel.com/t5/Software-Development-Tools/ct-p/software-dev-tools

Related Information

Recommended Additional Reading
You are strongly encouraged to read the following books for in-depth understanding of threading. Each book discusses general concepts of parallel programming by explaining a particular programming technology:
• For information on OpenMP® technology: Chapman, Barbara, Gabriele Jost, Ruud van der Pas, and David J. Kuck (foreword). Using OpenMP: Portable Shared Memory Parallel Programming. MIT Press, October 2007
• For information on Microsoft Win32* Threading (for Windows* users): Akhter, Shameem, and Jason Roberts. Multi-Core Programming: Increasing Performance through Software Multithreading, Intel Press, April 2006

Intel does not endorse these books or recommend them over other books on the same subjects.

Additional Product Information
For additional technical product information including white papers, forums, and documentation, visit https://software.intel.com/content/www/us/en/develop/tools.html
**Additional Language Information**

- For information about the C++ standards, visit the C++ website: http://www.isocpp.org/
- For information about the C standards, visit the C website: http://www.open-std.org/jtc1/sc22/wg14/
- For information about the OpenMP* standards, visit the OpenMP website: http://www.openmp.org/

**Notational Conventions**

Information in this documentation applies to all supported operating systems and architectures unless otherwise specified. This documentation uses the following conventions:

<table>
<thead>
<tr>
<th>THIS TYPE</th>
<th>Indicates language keywords.</th>
</tr>
</thead>
<tbody>
<tr>
<td>this type</td>
<td>Indicates command-line or option arguments.</td>
</tr>
<tr>
<td>This type</td>
<td>Indicates a code example.</td>
</tr>
<tr>
<td>This type</td>
<td>Indicates what you type as input.</td>
</tr>
<tr>
<td>This type</td>
<td>Indicates menu names, menu items, button names, dialog window names, and other user-interface items.</td>
</tr>
</tbody>
</table>

**File > Open**

Menu names and menu items joined by a greater than (>) sign to indicate a sequence of actions. For example, **Click File > Open** indicates that in the **File** menu, you would click **Open** to perform this action.

| {value | value} | Indicates a choice of items or values. You can usually only choose one of the values in the braces. |
| [item] | Indicates items that are optional. |
| item [, item ]... | Indicates that the item preceding the ellipsis (...) can be repeated. |

**Intel® C++**

This term refers to the name of the common compiler language supported by the Intel® C++ Compiler Classic.

**compiler or the compiler**

These terms are used when information is not limited to only one specific compiler, or when it is not necessary to indicate a specific compiler.

**Windows* or Windows operating system**

These terms refer to all supported Microsoft Windows operating systems.

**Linux or Linux operating system**

These terms refer to all supported Linux operating systems.

**macOS* or macOS* operating system**

These terms refer to all supported macOS* operating systems.

**Microsoft Visual Studio***

An asterisk at the end of a word or name indicates it is a third-party product trademark.
compiler option

This term refers to Linux, macOS*, or Windows options, which are used by the compiler to compile applications.

The following conventions are used as shortcuts when referencing compiler option names in text:

- Many options have names that are the same on Linux, macOS*, and Windows, except that the Windows form starts with an initial / and the Linux and macOS* form starts with an initial -. Within text, such option names are shown without the initial character. For example, check.

- Many options have names that are the same on Linux, macOS*, and Windows, except that the Windows form starts with an initial Q. Within text, such option names are shown as \[Q\]option-name.

  For example, if you see a reference to \[Q\]ipo, the Linux and macOS* form of the option is -ipo and the Windows form of the option is /Qipo.

- Several compiler options have similar names except that the Linux and macOS* forms start with an initial q and the Windows form starts with an initial Q. Within text, such option names are shown as \[q or Q\]option-name.

  For example, if you see a reference to \[q or Q\]opt-report, the Linux and macOS* form of the option is -qopt-report and the Windows form of the option is /Qopt-report.

Other dissimilar compiler option names are shown in full.

### Conventions Used in Compiler Options

- **/option or -option**
  
  A slash before an option name indicates the option is available on Windows. A dash before an option name indicates the option is available on Linux and macOS* systems. For example:

  - Windows option: /help
  - Linux and macOS* option: -help

**NOTE** If an option is available on all supported operating systems, no slash or dash appears in the general description of the option. The slash and dash only appear where the option syntax is described.
Indicates that an option requires an argument (parameter). For example, you must specify an argument for the following options:

- Windows option: /tune:processor
- Linux and macOS* option: -mtune=processor

Indicates that an option requires one of the keyword values.

Indicates that the option can be used alone or with an optional keyword.

Indicates that the option can be used alone or with an optional value. For example, in -unroll[=n], the n can be omitted or a valid value can be specified for n.

Indicates that a trailing hyphen disables the option. For example, /Qglobal_hoist-disables the Windows option /Qglobal_hoist.

Indicates that no or no- preceding an option disables the option. For example, in the Windows option /[no]traceback, /traceback enables the option, while /notraceback disables it.

In the Linux and macOS* option -[no-]global_hoist, -global_hoist enables the option, while -no-global_hoist disables it.

In some options, the no appears later in the option name. For example, -fno-common disables the -fcommon option.
Compiler Setup

You can use the Intel® C++ Compiler Classic from the command line, or from the IDEs listed below. These IDEs are described in further detail in their corresponding sections.

Use the Command Line

This section provides information about the Command Line Interface (CLI).

Specifying the Location of Compiler Components

Before you invoke the compiler, you may need to set certain environment variables that define the location of compiler-related components. The Intel® C++ Compiler Classic includes environment configuration scripts to configure your build and development environment variables:

- On Linux*, and macOS*, the file is a shell script called setvars.sh.
- On Windows*, the file is a batch file called setvars.bat.

**NOTE** If you are using older Intel® Parallel Studio XE or Intel® System Studio bits, you need to use compilervars instead of setvars.

The following information is operating system dependent.

**Linux and macOS**:  
Set the environment variables before using the compiler by sourcing the shell script setvars.sh. Depending on the shell, you can use the source command or a . (dot) to source the shell script, according to the following rule for a .sh script:

```
source /<install-dir>/setvars.sh <arg1> <arg2> ... <argn>
./<install-dir>/setvars.sh <arg1> <arg2> ... <argn>
```

Examples: (assuming <install-dir> is /opt/intel/oneapi)

```
prompt> source /opt/intel/oneapi/setvars.sh intel64
prompt> ./opt/intel/oneapi/setvars.sh intel64
```

**NOTE** Type: source /<install-dir>/setvars.sh --help for more setvars usage information.

The compiler environment script file accepts an optional target architecture argument <arg>:

- intel64: Generate code and use libraries for Intel® 64 architecture-based targets.
- ia32: Generate code and use libraries for IA-32 architecture-based targets.
If you want the setvars.sh script to run automatically in all of your terminal sessions, add the source setvars.sh command to your startup file. For example, inside your .bash_profile entry for Intel® 64 architecture targets:

```bash
# set environment vars for Intel® C++ Compiler
source <install-dir>/setvars.sh intel64
```

If the proper environment variables are not set, errors similar to the following may appear when attempting to execute a compiled program:

```bash
# for C++
./a.out: error while loading shared libraries:
libimf.so: cannot open shared object file: No such file or directory
```

**Windows:**

Under normal circumstances, you do not need to run the setvars.bat batch file. The terminal shortcuts in the Windows Start menu, Intel oneAPI command prompt for <target architecture> for Visual Studio <year>, set these variables automatically.

For additional information, see Using the Command Line on Windows.

**NOTE** You need to run the setvars batch file if a command line is opened without using one of the provided Command Prompt menu items in the Start menu, or if you want to use the compiler from a script of your own.

The setvars batch file inserts DLL directories used by the compiler and libraries at the beginning of the existing Path. Because these directories appear first, they are searched before any directories that were part of the original Path provided by Windows (and other applications). This is especially important if the original Path includes directories with files that have the same names as those added by the compiler and libraries.

The setvars batch file takes multiple optional arguments; the following two arguments are recognized for compiler and library initialization:

```
<install-dir>\setvars.bat [<arg1>] [<arg2>]
```

Where `<arg1>` is optional and can be one of the following:

- `intel64`: Generate code and use libraries for Intel® 64 architecture (host and target).
- `ia32`: Generate code and use libraries for IA-32 architecture (host and target).

The `<arg2>` is optional. If specified, it is one of the following:

- `vs2019`: Microsoft Visual Studio® 2019
- `vs2017`: Microsoft Visual Studio 2017

**NOTE** If `<arg1>` is not specified, the script uses the `intel64` argument by default. If `<arg2>` is not specified, the script uses the highest installed version of Microsoft Visual Studio detected during the installation procedure.

**NOTE** Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

Configure Your CPU or GPU System

Invoke the Compiler

Requirements Before Using the Command Line
You may need to set certain environment variables before using the command line. For more information, see Specifying the Location of Compiler Components.

Different Compilers and Drivers
The table below provides the different compiler front-end and driver information.

<table>
<thead>
<tr>
<th>Compiler</th>
<th>Notes</th>
<th>Linux* Driver</th>
<th>Windows* Driver</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intel® C++ Compiler Classic</td>
<td>A C++ compiler with EDG front-end, supporting OpenMP* but not OpenMP offload.</td>
<td>icc for C</td>
<td>icl</td>
</tr>
<tr>
<td></td>
<td></td>
<td>icpc for C++</td>
<td></td>
</tr>
</tbody>
</table>

Use the Compiler from the Command Line
Use the compiler with the OS/language specific invocations below.

**NOTE** You can also use the compiler from within the IDE. For more information on using Microsoft Visual Studio*, see Using Microsoft Visual Studio. For information on using Xcode*, see Using Xcode. For information on using Eclipse*, see Using Eclipse.

**Linux:**
Invoke the compiler using `icc/icpc` to compile IL0 C/C++ source files.

- When you invoke the compiler with `icl`, the compiler builds C source files using C libraries and C include files. If you use `icc` with a C++ source file, it is compiled as a C++ file. Use `icc` to link C object files.
- When you invoke the compiler with `icpc` the compiler builds C++ source files using C++ libraries and C++ include files. If you use `icpc` with a C source file, it is compiled as a C++ file. Use `icpc` to link C++ object files.

The `icc/icpc` command does the following:

- Compiles and links the input source file(s).
- Produces one executable file, `a.out`, in the current directory.

**macOS***:
Invoke the compiler using `icc/icpc` to compile C/C++ source files.

- When you invoke the compiler with `icl`, the compiler builds C source files using C libraries and C include files. If you use `icc` with a C++ source file, it is compiled as a C++ file. Use `icc` to link C object files.
- When you invoke the compiler with `icpc` the compiler builds C++ source files using C++ libraries and C++ include files (`libc++` library is used by default). If you use `icpc` with a C source file, it is compiled as a C++ file. Use `icpc` to link C++ object files.

The `icc/icpc` command does the following:
- Compiles and links the input source file(s).
- Produces one executable file, `a.out`, in the current directory.

**Windows:**

You can invoke the compiler on the command line using the `icl` command. This command:

- Compiles and links the input source file(s).
- Produces object file(s) and assigns the names of the respective source file(s), but with a `.obj` extension.
- Produces one executable file and assigns it the name of the first input file on the command line, but with a `.exe` extension.
- Places all the files in the current directory.

When compilation occurs with the compiler, many tools may be called to complete the task that may reproduce diagnostics unique to the given tool. For instance, the linker may return a message if it cannot resolve a global reference. The `watch` option can help clarify which component is generating the error.

**Command Line Syntax**

When you invoke the compiler, the syntax is: For C/C++ projects:

```bash
// (Linux)
{icc/icpc} [options] file1 [file2...]

// (macOS*)
{icc/icpc} [options] file1 [file2...]

// (Windows)
icl [options] file1 [file2...] [/link link_options]
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>options</td>
<td>Indicates one or more command line options. On Linux and macOS* systems, the compiler recognizes one or more letters preceded by a hyphen (<code>-</code>). On Windows, options are preceded by a slash (<code>/</code>). This includes linker options. Options are not required when invoking the compiler. The default behavior of the compiler implies that some options are ON by default when invoking compiler.</td>
</tr>
<tr>
<td>file1, file2...</td>
<td>Indicates one or more files to be processed by the compiler. You can specify more than one file, using space as a delimiter for multiple files.</td>
</tr>
<tr>
<td>/link (Windows)</td>
<td>All options following <code>/link</code> are passed to the linker. Compiler options must precede <code>link</code> if they are not to be passed to the linker.</td>
</tr>
</tbody>
</table>

**Other Methods for Using the Command Line to Invoke the Compiler**

- **Using makefiles from the Command Line**: Use makefiles to specify a number of files with various paths and to save this information for multiple compilations. For more information on using makefiles, see Using Makefiles to Compile Your Application.
- **Using a Batch File from the Command Line**: Create and use a `.bat` file to consistently execute the compiler with a desired set of options instead of retyping the command each time you need to recompile.

**See Also**

- Specifying the Location of Compiler Components
- Understanding File Extensions
- Using Makefiles to Compile Your Application
- `watch` compiler option
Use the Command Line on Windows*

The compiler provides a shortcut to access the command line with the appropriate environment variables already set.

**NOTE** Instructions and menu options may vary by Windows* version.

To invoke the compiler from the command line:

1. Open the Windows Start menu.
2. Scroll down the list of apps (programs) in the Start menu and find the Intel oneAPI 2021 folder.
3. Left click on the folder name and select your component.

**NOTE** The command prompts shown are dependent on the versions of Microsoft Visual Studio* you have installed on your machine.

4. Right click on the command prompt icon to pin it to your taskbar.

**NOTE** This step is optional.

The command line opens.

You can use any command recognized by the Windows command prompt, plus some additional commands.

Because the command line runs within the context of Windows, you can easily switch between the command line and other applications for Windows or have multiple instances of the command line open simultaneously.

When you are finished working in a command line, use the **exit** command to close and end the session.

File Extensions

**Input File Extensions**

The Intel® C++ Compiler Classic recognizes input files with the extensions listed in the following table:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Interpretation</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>file.c</td>
<td>C source file</td>
<td>Passed to compiler</td>
</tr>
<tr>
<td>file.C</td>
<td>C++ source file</td>
<td>Passed to compiler</td>
</tr>
<tr>
<td>file.CC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.cc</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.cpp</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.cxx</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.lib</td>
<td>Library file</td>
<td>Passed to linker</td>
</tr>
<tr>
<td>(Windows*)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.a</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.so</td>
<td></td>
<td></td>
</tr>
<tr>
<td>(Linux* and macOS*)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>File Name</td>
<td>Interpretation</td>
<td>Action</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------</td>
<td>--------------------</td>
</tr>
<tr>
<td>file.dylib</td>
<td>(macOS*)</td>
<td></td>
</tr>
<tr>
<td>file.i</td>
<td>Preprocessed file</td>
<td>Passed to compiler</td>
</tr>
<tr>
<td>file.obj</td>
<td>(Windows)</td>
<td>Passed to linker</td>
</tr>
<tr>
<td>file.o (Linux and macOS*)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.asm</td>
<td>(Windows)</td>
<td>Passed to assembler</td>
</tr>
<tr>
<td>file.s (Linux and macOS*)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>file.S (Linux and macOS*)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Output File Extensions**

The Intel® C++ Compiler Classic produces output files with the extensions listed in the following table:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file.i</td>
<td>Preprocessed file: Produced with the -P option.</td>
</tr>
<tr>
<td>file.o (Linux and macOS*)</td>
<td>Object file: Produced with the -c (Linux, macOS*, and Windows) object. The /Fo (Windows) or -o (Linux) option allows you to rename the output object file.</td>
</tr>
<tr>
<td>file.obj</td>
<td>(Windows)</td>
</tr>
<tr>
<td>file.s (Linux and macOS*)</td>
<td>Assembly language file: Produced with the -S option. The /Fa (Windows) or -s (Linux) option allows you to rename the output assembly file.</td>
</tr>
<tr>
<td>file.asm</td>
<td>(Windows)</td>
</tr>
<tr>
<td>a.out (Linux and macOS*)</td>
<td>Executable file: Produced by the default compilation. The /Fe (Windows) or -o (Linux) option allows you to rename the output executable file.</td>
</tr>
<tr>
<td>file.exe</td>
<td>(Windows)</td>
</tr>
</tbody>
</table>

**See Also**

Invoke the Compiler
Specify Compiler Files

**Use Makefiles for Compilation**

This topic describes the use of makefiles to compile your application. You can use makefiles to specify a number of files with various paths, and to save this information for multiple compilations.
**Use Makefiles to Store Information for Compilation on Linux* or macOS***

To run `make` from the command line using the Intel® C++ Compiler Classic, make sure that `/usr/bin` and `/usr/local/bin` are in your `PATH` environment variable.

If you use the C shell, you can edit your `.cshrc` file and add the following:

```bash
setenv PATH /usr/bin:/usr/local/bin:$PATH
```

To use the Intel® C++ Compiler Classic, your makefile must include the setting `CC=icc`. Use the same setting on the command line to instruct the makefile to use the compiler. If your makefile is written for GCC*, you need to change the command line options that are not recognized by the compiler. Run `make`, using the following syntax:

```bash
make -f yourmakefile
```

Where `-f` is the `make` command option to specify a particular makefile name.

**Use Makefiles to Store Information for Compilation on Windows***

To use a makefile to compile your source files, use the `nmake` command with the following syntax:

```bash
nmake /f [makefile_name.mak] CPP=[compiler_name] [LINK32=[linker_name]]
```

For C/C++ projects:

```bash
prompt> nmake /f your_project.mak CPP=icl LINK32=link
```

-OR-

```bash
prompt> nmake /f your_project.mak CPP=icl LINK32=xilink
```

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/f</code></td>
<td>The <code>nmake</code> option to specify a makefile.</td>
</tr>
<tr>
<td>your_project.mak</td>
<td>The makefile used to generate object and executable files.</td>
</tr>
<tr>
<td>CPP</td>
<td>The preprocessor/compiler that generates object and executable files.</td>
</tr>
<tr>
<td></td>
<td>(The name of this macro may be different for your makefile.)</td>
</tr>
<tr>
<td>LINK32</td>
<td>The linker that is used.</td>
</tr>
</tbody>
</table>

The `nmake` command creates object files (.obj) and executable files () from the information specified in the `your_project.mak` makefile.

**See Also**

- Modifying Your makefile (Linux* and macOS*)
- Modifying Your makefile (Windows*)

**Use Compiler Options**

A compiler option is a case-sensitive, command line expression used to change the compiler's default operation. Compiler options are not required to compile your program, but they can control different aspects of your application, such as:

- Code generation
- Optimization
- Output file (type, name, location)
- Linking properties
- Size of the executable
• Speed of the executable
See the Option Categories section for the option capabilities included with the Intel® C++ Compiler Classic.

**Command Line Syntax (Linux* and macOS*)**

When you specify compiler options on the command line, the following syntax applies:

```bash
// Linux and macOS*
[invocation] [options] [@response_file] file1 [file2...]
```

The *invocation* is `icc`.

The *options* represents zero or more compiler options and the *file* is any of the following:

- C or C++ source file (`.C`, `.c`, `.cc`, `.cpp`, `.cxx`, `.c++`, `.i`, `.ii`)
- Assembly file (`.s`, `.S`)
- Object file (`.o`)
- Static library (`.a`)

When compiling C language sources, invoke the compiler with `icc`. When compiling C++ language sources or a combination of C and C++, invoke the compiler with `icpc`.

**Command Line Syntax (Windows*)**

When you specify compiler options on the command line, the following syntax applies:

```bash
[invocation] [options] [@response_file] file1 [file2 ...] [/link linker_options]
```

The *invocation* is `icc`.

The *options* represents zero or more compiler options, the *linker_options* represents zero or more linker options, and the *file* is any of the following:

- C or C++ source file (`.c`, `.cc`, `.cpp`, `.cxx`, `.i`)
- Assembly file (`.asm`)
- Object (`.obj`)
- Static library (`.lib`)

The optional *response_file* is a text file that lists the compiler options you want to include during compilation. See **Using Response Files** for additional information.

**Default Operation**

The compiler invokes many options by default. In this example, the compiler includes the option `O2` (and other default options) in the compilation:

```bash
// Linux and macOS*
[invocation] main.c
```

```bash
// Windows
[invocation] main.c
```

The *invocation* is `icc`.

Each time you invoke the compiler, options listed in the corresponding configuration file override any competing default options. For example, if your configuration file includes the `O3` option, the compiler uses `O3` rather than the default `O2` option. Use the configuration file to list the options for the compiler to use for every compilation. See **Using Configuration Files**.

Options specified in the command line environment variable override any competing default options and options listed in the configuration file.
Finally, options used on the command line override any competing options that may be specified elsewhere (default options, options in the configuration file, and options specified in the command line environment variable). If you specify the option O1 on the command line, this option setting takes precedence over competing option defaults and competing options in the configuration files, in addition to the competing options in the command line environment variable.

Certain #pragma statements in your source code can override competing options specified on the command line. For example, if a function in your code is preceded by #pragma optimize("", off), then optimization for that function is turned off, even though O2 optimization is on by default, the O3 is listed in the configuration file, and the O1 is specified on the command line for the rest of the program.

Use Competing Options

The compiler reads command line options from left to right. If your compilation includes competing options, then the compiler uses the one furthest to the right. For example:

For C:

```
// Linux and macOS* icc -xSSSE3 main.c -xSSE4.2 file2.c
// Windows icl /QxSSSE3 main.c /QxSSE4.2 file2.c
```

For C++:

```
// Linux and macOS* icpc -xSSSE3 main.c -xSSE4.2 file2.c
// Windows icl /QxSSSE3 main.c /QxSSE4.2 file2.c
```

The compiler sees [Q]xSSSE3 and [Q]xSSE4.2 as two forms of the same option, where only one form can be used. Since [Q]xSSE4.2 is last (furthest to the right), it will be used.

All options specified on the command line are used to compile each file. The compiler does not compile individual files with specific options. For example:

```
// Linux and macOS*
icc -O3 main.c file1.c -mp1 file2.c
// Windows icl /O3 main.c file1.c /Qprec file2.c
```

It may seem that main.c and file1.c are compiled with the option O3, and file2.c is compiled with the -mp1 (Linux and macOS*) or /Qprec (Windows) option. This is not correct; all files are compiled with both options.

A rare exception to this rule is the -x type option:

For C:

```
// Linux and macOS* icc -x c file1 -x c++ file2 -x assembler file3
```

For C++:

```
// Linux and macOS* icpc -x c file1 -x c++ file2 -x assembler file3
```

The type argument identifies each file type for the compiler.

Use Options with Arguments

Compiler options can be as simple as a single letter, such as the option E. Many options accept or require arguments. The O option, for example, accepts a single-value argument that the compiler uses to determine the degree of optimization. Other options require at least one argument and can accept multiple arguments. For most options that accept arguments, the compiler warns you if your option and argument are not recognized. If you specify O9, the compiler issues a warning, ignores the unrecognized option O9, and proceeds with the compilation.
The `o` option does not require an argument, but there are other options that must include an argument. The `I` option requires an argument that identifies the directory to add to the include file search path. If you use this option without an argument, the compiler will not finish its compilation.

**Other Forms of Options**

You can toggle some options on or off by using the negation convention. For example, the `[-][Q]ipo` option (and many others) includes negation forms, `-no-ipo` (Linux and macOS*) and `/Qipo-` (Windows), to change the state of the option.

**Option Categories**

When you invoke the Intel® C++ Compiler Classic and specify a compiler option, you have a wide range of choices to influence the compiler’s default operation. Intel® C++ Compiler Classic options typically correspond to one or more of the following categories:

- Advanced Optimization
- Code Generation
- Compatibility
- Compiler Diagnostics
- Component Control This content is specific to C++; it does not apply to DPC++.
- Data
- Floating Point
- Inlining
- Interprocedural Optimizations (IPO)
- Language
- Linking/Linker
- Miscellaneous
- OpenMP® and Parallel Processing
- Optimization
- Optimization Report
- Output
- Preprocessor

To see the included options in each category, invoke the compiler from the command line with the `help` category option. For example:

```
//Linux and macOS* icc -help codegen

//Windows
icc /help codegen
```

The help option prints to `stdout` with the names and syntax of the options found in the Code Generation category.

**See Also**

`qopt-report`, `Qopt-report`

**Use Configuration Files**

**Specify Compiler Files**

**Specify Include Files**

The Intel® C++ Compiler Classic searches the default system areas for include files and items specified by the `I` compiler option. The compiler searches directories for include files in the following order:
1. Directories specified by the I option
2. Directories specified in the environment variables
3. Default include directories

Use the X (Windows*) or -nostdinc (Linux*) option to remove the default directories from the include file search path.

For example, to direct the compiler to search the path /alt/include instead of the default path, do the following:

For C/C++ projects:

// Linux and macOS* icpc -X -I/alt/include prog1.cpp
// Windows icl /X /I\alt\include prog1.cpp

Specify Assembly Files

You can use the /Fa option (Windows*) or -S and -o options (Linux* and macOS*) to specify an alternate name for an assembly file. The compiler generates an assembly file named myasm.asm (Windows) or myasm.s (Linux and macOS*).

For C/C++ projects:

// Linux and macOS* icpc -S -omyasm.s x.cpp
// Windows icl /Famyasm x.cpp

Specify Object Files

You can use the /Fo option (Windows*) or -c and -o options (Linux* and macOS*) to specify an alternate name for an object file. In this example, the compiler generates an object file name myobj.obj (Windows) or myobj.o (Linux and macOS*).

For C/C++ projects:

// Linux and macOS* icpc -c -omyobj.o x.cpp
// Windows icl /Fomyobj x.cpp

See Also

- c compiler option
/Fa compiler option
/Fo compiler option
I compiler option
-o compiler option
-S compiler option
X compiler option

Supported Environment Variables

Convert Projects to Use a Selected Compiler

You can use the command-line interface ICProjConvert<version>.exe to transform your Intel® C++ projects into Microsoft Visual C++* projects, or vice versa. The syntax is:

ICProjConvert<version>.exe <sln_file | prj_files> /VC[:"VToolset name"] /IC[:"IToolset name"]> [/q] [/nologo] [/msvc] [/s] [/f]

Where:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>The ICProjConvert version number. Values are: 191 or 192.</td>
</tr>
<tr>
<td>sln_file</td>
<td>A path to the solution file, which should be modified to use a specified project system.</td>
</tr>
<tr>
<td>prj_files</td>
<td>A space separated list of project files (or wildcard), which should be modified to use specified project system.</td>
</tr>
<tr>
<td>/VC</td>
<td>Convert to use the Microsoft Visual C++ project system.</td>
</tr>
<tr>
<td>VCtoolset name</td>
<td>The possible values are v141 (Microsoft Visual Studio* 2017), v142 (Microsoft Visual Studio 2019), or v143 (Microsoft Visual Studio 2022).</td>
</tr>
</tbody>
</table>

**NOTE** Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

| /IC              | Convert to use the Intel® C++ project system.                                                 |
| ICtoolset name   | Such as Intel C++ Compiler 2021.1                                                              |

Depending on the integration version, the supported name values may be different.

| /q               | Starts quiet mode, all information messages (except errors) are hidden.                        |
| /nologo          | Suppresses the startup banner.                                                                 |
| /msvc            | Sets the compiler to Microsoft Visual C++.                                                     |
| /s               | Searches the project files through all subdirectories.                                          |
| /f               | Forces an update to the project even if it has an unsupported type or unsupported properties.   |
| /? or /h         | Shows help.                                                                                     |

**Example**

Issue the command ICProjConvert<version>.exe *.icproj /s /VC to convert all Intel® C++ project files in the current directory and its subdirectories to use Microsoft Visual C++.

**NOTE** If you uninstall the Intel® C++ Compiler Classic, ICProjConvert<version>.exe remains in the folder Program Files (x86)\Common Files\Intel\shared files\ia32\Bin and you can use it to transform Intel® C++ projects back into Microsoft Visual C++.

**Use Eclipse***

The Intel® C++ Compiler for Linux* provides integrations for the compiler to Eclipse* and C/C++ Development Tooling* (CDT) that let you develop, build, and debug your Intel® C++ projects in an integrated development environment (IDE).
Eclipse is an open source software development project dedicated to providing a robust, full-featured, commercial-quality, industry platform for the development of highly integrated tools. It is an extensible, open source integrated development environment (IDE). CDT is a complete C/C++ IDE for the Eclipse platform, which allows you to develop, build, and run projects in a visual, interactive environment. CDT is layered on Eclipse and provides a C/C++ development environment perspective.

**Add the Compiler to Eclipse***

This step is needed only if you are manually installing the Intel® C++ Compiler plug-in for Eclipse*.

To add the Intel® C++ Compiler product extension to your Eclipse configuration:

1. Start Eclipse.
2. Select Help > Install New Software.
3. Next to the Work with field, click the Add button. The Add Repository dialog box opens.
4. Click the Archive button and browse to the <install_dir>/compiler/<version>/linux/ide_support directory. Select the .zip file that starts with com.intel.compiler, then click OK.
5. Select Intel® Software Development Tools > Intel® C++ Compiler Integration, then click OK.
6. Follow the installation instructions.
7. When asked if you want to restart Eclipse, select Yes.

When Eclipse restarts, you can create and work with CDT projects that use the Intel® C++ Compiler.

**Multi-Version Compiler Support**

You can select different versions of the Intel® C++ Compiler for compiling projects with the Eclipse* Integrated Development Environment (IDE). For a list of the currently supported compiler versions by platform, refer to the Release Notes.

If multiple versions of the compiler are installed on the system, Eclipse uses the latest version by default. To select the version of the compiler to build your project:

1. Right click the project and open Properties.
2. In the properties dialog box, select C/C++ Build > Settings.
3. Select the Intel® C++ Compiler Classic for a C++ project tab.
4. Select the row with the desired compiler version.
5. Click Use Selected. Alternatively, click Use Latest to select the latest version of compiler.
6. Click Apply.

The corresponding compiler environment is configured automatically for your project.

Use Settings and Tool Chain Editor to select tools to be used within the toolchain, or set distinct project properties, like compiler options, to be used with different versions of the compiler.

For any project, you can set the compiler environment by specifying it within Eclipse; this overrides any other environment specifications for the compiler.

**Use Cheat Sheets**

The Intel® C++ Compiler Classic integration includes several Eclipse* cheat sheets that can guide you through various compilation and debugging tasks.

To view a list of available cheat sheets and select one:

1. Select Help > Cheat Sheets.
   The Cheat Sheet Selection dialog box opens, displaying a list of available cheat sheets.
2. Select a cheat sheet. Cheat sheets located outside of the Eclipse* integration can be entered in the Select a cheat sheet from a file or Enter the URL of a cheat sheet.
   Intel cheat sheets are located under Intel(R) C++ Compiler. A description of the cheat sheet appears in the lower pane.
3. To open a cheat sheet, click OK.

The Cheat Sheets view opens in the Eclipse window.
Create a Simple Eclipse* Project

The sections below show you how to create a simple project using Eclipse*.

Create a New Eclipse Project

To create a new Eclipse project:

1. Select File > New > Project... The New Project wizard opens.
2. Expand the C/C++ Project tab and select the appropriate project type. Click Next to continue.
3. For Project name, enter hello_world. Deselect the Use default location to specify a directory for the new project.
4. In the Project Type list, expand the Executable project type and select Hello World C++ Project
5. In the Toolchains list, select Intel C++ Compiler Classic. Click Next.

NOTE

• If you need to see the toolchains for the compilers that are not locally installed, uncheck Show project types and toolchains only if they are supported on the platform. You are only able to view and configure these toolchains if the proper compilers are installed.
• If you have multiple versions of the compiler installed, they appear in the project’s properties under C/C++ Build > Settings on the Intel® C++ Compiler Classic tab.

6. The Basic Settings page allows specifying template information, including Author and Copyright notice, which appear as a comment at the top of the generated source file. After entering desired fields, click Next.
7. The Select Configurations page allows specifying deployment platforms and configurations. By default, a Debug and Release configuration is created for the selected toolchain. Select no (Deselect all), multiple, or all (Select all) configurations. To edit project properties, click the Advanced settings button. Click Finish to create the hello_world project.

NOTE Configurations can be created after the project is created by selecting Project > Properties.

8. If the view is not the C/C++ Development Perspective (default), an Open Associated Perspective dialog box opens. In the C/C++ Perspective, click Yes to proceed.

An entry for your hello_world project appears in the Project Explorer view.

Add a C Source File

To add a source file to the hello_world project:

1. Select the hello_world project in the Project Explorer view.

   NOTE The dialog box automatically populates the source folder for the source file to be created. You can change this by entering a new location or selecting Browse.

4. Select a Template from the drop-down list or Configure a new template.
5. Click Finish to add the file to the hello_world project.
6. In the Editor view, add your code for new_source_file.c.
7. When your code is complete, Save your file.
Set Options for a Project or File

You can specify compiler, linker, and archiver options at the project and source file level. Follow these steps to set options for a project or file:

1. Right-click a project or source file in the Project Explorer.
2. Select Properties. The property pages dialog box opens.
3. Select C/C++ Build > Settings.
4. Select the Tool Settings tab and click an option category for Intel C Compiler, Intel C++ Compiler, or Intel C++ Linker for a C++ project, or select Intel® oneAPI DPC++ Compiler or Intel® oneAPI DPC++ Linker for a DPC++ project.
5. Set the options to apply to the project or file.

NOTE

• Some properties use check boxes, drop-down boxes, or dialog boxes to specify compiler options. For a description on options properties, hover over the option to display a tooltip. After setting the desired options in command line syntax, select Apply.
• To specify an option that is not available from the Properties dialog, use C/C++ Build Settings > Settings > <Compiler> > Command Line. The Compiler entry has one of the following values: or Intel® oneAPI DPC++ Compiler. Enter the command line options in the Additional Options field using command-line syntax and select Apply.
• You can specify option settings for one or more configurations by using the Configuration drop-down menu.

6. Click Apply and Close.

The compiler applies the selected options, using the selected configurations, when building. To restore default settings to all properties for the selected configuration, click the Restore Defaults button on any property page.

Exclude Source Files from a Build

To exclude a source file from a build:

1. Right-click a file or folder in the Project Explorer.
2. Select Resource Configurations > Exclude from build. The Exclude from build dialog box opens.
3. Select one or more build configurations to exclude the file or folder from.
4. Click OK.

The compiler excludes that file or folder when it builds using the selected project configuration.

Build a Project

To build your project:

1. Select the hello_world project in the Project Explorer view.
2. Select Project > Build Project.

See the Build results in the Console view.

For a C/C++ project, use:

```bash
**** Build of configuration Debug for project hello_world ****
makes all
Building file: ../src/hello_world.cpp
Invoking: Intel(R) C++ Compiler Classic
icpc -g -O0 -MMD -MP -MF"src/hello_world.d" -MT"src/hello_world.d" -c -o "src/hello_world.o"
"./src/hello_world.cpp"
Finished building: ../src/hello_world.cpp
```
Building target: hello_world
Invoking: Intel C++ Linker
icpc -O0 -o "hello_world" ./src/hello_world.o
Finished building Target: hello_world

Build Finished. 0 errors, 0 warnings.

Detailed descriptions of errors, warnings, and other output can be viewed by selecting the Problems tab.

Run a Project
After building a project, you can run your project by following these steps:
1. Select the hello_world project in the Project Explorer view.
2. Select Run As > Local C/C++ Application.

When the executable runs, the output appears in the Console view.

Error Parser
The Error Parser (selected by default) lets you track compile-time errors in Eclipse. To confirm that the Error Parser is active:
1. Select the hello_world project in the Project Explorer view.
2. Select Project > Properties.
3. In the Properties dialog box, select C/C++ Build > Settings.
4. Click the Error Parsers tab. Make sure that Intel C++ Error Parser is checked, and CDT Visual C Error Parser or Microsoft Visual C Error Parser are not checked.
5. Click OK to update your choices, if you have changed any settings.

Use the Error Parser
The Error Parser automatically detects and manages the diagnostics generated by the Intel® C++ Compiler Classic.

If an error occurring in the hello_world.c program is compiled, for example, #include <stdio.h>, the error is reported in the Problems view next to an error marker.

You can double-click on each error in the Problems view to highlight the source line, which causes the error in the Editor view.

Correct the error, then rebuild your project.

Makefiles
This section provides information about makefile project types and exporting makefiles.

Project Types and Makefiles
When you create a new project in Eclipse*, there are Executable, Shared Library, Static Library, or Makefile project types available for your selection.

- Select Makefile Project if the project already includes a makefile.
- Use Executable, Shared Library, or Static Library Project to build a makefile using options assigned from property pages specific to the Intel® C++ Compiler Classic.
Export Makefiles

Eclipse can build a makefile that includes Intel® C++ Compiler Classic options for created Executables, Shared Libraries, or Static Library Projects. When the project is complete, export the makefile and project source files to another directory, and then build the project from the command line using make.

To export the makefile:

1. Select the project in the Eclipse Project Explorer view.
2. Select File > Export to launch the Export Wizard. The Export dialog box opens, showing the Select screen.
3. Select General > File system, then click Next. The File System screen opens.
4. Check both the hello_world and Release directories in the left-hand pane. Ensure all project sources are checked in the right-hand pane.

**NOTE** Some files in the right-hand pane may be deselected, such as the hello_world.o object file and the hello_world executable. Create directory structure for files in the Options section must be selected to successfully create the export directory. This process applies to project files in the hello_world directory.

5. Use the Browse button to target the export to an existing directory. Eclipse can create a directory for full paths entered in the To directory text box. For example, if the /code/makefile is specified as the export directory, Eclipse creates two new subdirectories:
   - /code/makefile/hello_world
   - /code/makefile/hello_world/Release
6. Click Finish to complete the export.

Run Make

In a terminal window, change to the /cpp/hello_world/Release directory, then run make by typing: make clean all.

You should see the following output:

```
rm -rf ./new_source_file.o ./new_source_file.d hello_world
Building file: ../new_source_file.c
Invoking: Intel(R) C Compiler Classic
Finished building: ../new_source_file.c
Building target: hello_world
Invoking: Intel C++ Linker
icc -o "hello_world" ./new_source_file.o
Finished building target: hello_world
```

This process generates the hello_world executable in the same directory.

Use Intel Libraries with Eclipse*

You can use the compiler with the following Intel Libraries, which may be included as a part of the product:

- Intel® oneAPI Data Analytics Library (oneDAL)
- Intel® Integrated Performance Primitives (Intel® IPP)
- Intel® oneAPI Math Kernel Library (oneMKL)
- Intel® oneAPI Threading Building Blocks (oneTBB)

To access these libraries in Eclipse*, use the property pages:
1. Select your project.
2. Open the property pages from Project > Properties and select C/C++ Build > Settings.
3. Select Intel C/C++ Compiler > Performance Library Build Components

The Use Intel® oneAPI Data Analytics Library (oneDAL) property allows enabling the library and bringing in the associated headers.

- None: Disable Use of oneDAL.
- Use threaded Intel® oneDAL: Link using the threaded version of the library.
- Use non-threaded Intel® oneDAL: Link using the non-threaded version of the library.

The Use Intel® Integrated Performance Primitives Libraries property provides the following options in a drop-down menu:

- None: Disable use of Intel® IPP.
- Use main libraries set: Link using the main libraries set.
- Use non-pic version of libraries: Link using the version of the libraries that do not have position-independent code.
- Use main libraries and cryptography library: Link using main or cryptography libraries.

The Use Intel® oneAPI Math Kernel Library property provides the following options in a drop-down menu:

- None: Disables the use of the oneMKL.
- Use threaded Intel® oneMKL library: Link using the threaded version of the library.
- Use non-threaded Intel® oneMKL library: Link using the non-threaded version of the library.
- Use Intel® oneMKL Cluster and sequential Intel® oneMKL libraries: Link using the oneMKL Cluster Edition libraries and the sequential oneMKL libraries.

NOTE The option value Use Intel® oneMKL Cluster and sequential Intel® oneMKL libraries is only available for Intel C Compiler or Intel C++ Compiler.

The Use Intel® oneAPI Threading Building Blocks on the Property page allows enabling the library and bringing in the associated headers.

For more information, see the oneDAL, Intel® IPP, oneMKL, and oneTBB documentation.

Using Microsoft Visual Studio*

You can use the Intel® C++ Compiler within the Microsoft Visual Studio® integrated development environment (IDE) to develop C++ applications, including static library (.LIB), dynamic link library (.DLL), and main executable (.EXE) applications. This environment makes it easy to create, debug, and execute programs. You can build your source code into several types of programs and libraries, using the IDE or from the command line.

The IDE offers these major advantages:

- Makes application development quicker and easier by providing a visual development environment.
- Provides integration with the native Microsoft Visual Studio debugger.
- Makes other IDE tools available.
Create a New Project

Create a New Project

When you create a project, Microsoft Visual Studio* automatically creates a corresponding solution to contain it. To create a new Intel® C++ project using Microsoft Visual Studio:

**NOTE** Exact steps may vary depending on the version of Microsoft Visual Studio in use.

This content is specific to C++; it does not apply to DPC++.

1. Select **File** > **New** > **Project**.
2. In the left pane, expand **Visual C++** and select **Windows Desktop**.
3. In the right pane, select **Windows Console Application**.
4. Accept or specify a project name in the **Name** field. For this example, use hello32 as the project name.
5. Accept or specify the Location for the project directory. Click **OK**.

The hello32 project assumes focus in the **Solution Explorer** view. The default Microsoft Visual Studio* solution is also named hello32.

Use the Intel® C++ Compiler Classic

To use the compiler with Microsoft Visual C++* (MSVC):

1. Create a MSVC project, or open an existing project.
2. In **Solution Explorer**, select the project(s) to build with Intel® C++ Compiler Classic.
3. Open **Project** > **Properties**.
4. In the left pane, expand the **Configuration Properties** category and select the **General** property page.
5. In the right pane, change the Platform Toolset to `<compiler selection>`.

**NOTE** For C/C++, there are two toolsets: Select **Intel C++ Compiler <major version>** (example 2021) to invoke icx, or select **Intel C++ Compiler <major.minor>** (example 19.2) to invoke icl.

6. To add options, go to **Project** > **Properties** > **C/C++** > **Command Line** and add new options to the **Additional Options** field. Alternatively, you can select options from Intel specific properties. Refer to complete list of options in the Compiler Options section in this documentation.
7. Rebuild, using either **Build** > **Project only** > **Rebuild** for a single project, or **Build** > **Rebuild Solution** for a solution.

Switch Back to the MSVC Compiler

If your project is using the Intel® C++ Compiler Classic, you can switch back to MSVC:

1. Select your project.
2. Right-click and select **Intel Compiler** > **Use Visual C++** from the context menu.

Verify Use of the Intel® C++ Compiler Classic

To verify the use of the Intel® C++ Compiler Classic:

1. Go to **Project** > **Properties** > **C/C++** > **General**.
2. Set **Suppress Startup Banner** to **No**. Click **OK**.
3. Rebuild your application.
4. Look at the Output window.

You should see a message similar to the following when using the Intel® C++ Compiler Classic:

Intel(R) C++ Intel(R) XX Compiler Classic for applications running on XXXX, Version XX.X.X

Unsupported MSVC Project Types
The following project types are not supported:
- Class Library
- CLR Console Application
- CLR Empty Project
- Windows* Forms Application
- Windows Forms Control Library

Tips for Use
- Create a separate configuration for building with Intel® C++ Compiler Classic:
  - After you have created your project and specified it as an Intel project, create a new configuration (for example, rel_intelc based on Release configuration or debug_intelc based on Debug configuration).
  - Add any special optimization options offered by Intel® C++ Compiler Classic only to this new configuration (for example, rel_intelc or debug_intelc) through the project property page.
  - Build with Intel® C++ Compiler Classic.

Select the Compiler Version
If you have multiple versions of the installed, you can select which version you want from the Compiler Selection dialog box:
1. Select a project, then go to Tools > Options > Intel Compilers and Libraries > Compilers.
2. Use the Selected Compiler drop-down menu to select the appropriate version of the compiler.
3. Click OK.

See Also
Use Intel® C++ dialog box

Specify a Base Platform Toolset
By default, when your project uses the Intel® C++ Compiler Classic, the Base Platform Toolset property is set to use that compiler with the build environment. This environment includes paths, libraries, included files, etc., of the toolset specific to the version of Microsoft Visual Studio* you are using.

You can set the general project level property Base Platform Toolset to use one of the non-Intel installed platform toolsets as the base.

For example, if you are using Microsoft Visual Studio 2019, and you selected the Intel® C++ Compiler Classic in the Platform Toolset property, then the Base Platform Toolset uses the Microsoft Visual Studio 2019 environment (v142). If you want to use other environments from Microsoft Visual Studio along with the Intel® C++ Compiler Classic, set the Base Platform Toolset property to:
- v141 for Microsoft Visual Studio 2017
- v142 for Microsoft Visual Studio 2019
- v143 for Microsoft Visual Studio 2022
NOTE
Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

This property displays all installed toolsets, not including Intel toolsets.

To set the Base Platform Toolset:

- Using property pages:
  1. Select the project and open Project > Properties.
  2. In the left pane, select Configuration Properties > General.
  3. In the right pane, find Intel Specific > Base Platform Toolset.
  4. Select a value from the pop-up menu.

- Using the msbuild.exe command line tool, use the /p:PlatformToolset and /p:BasePlatformToolset options.
  Example: When the Platform Toolset property is already set to use the Intel® C++ Compiler Classic, to build a project using the Microsoft Visual Studio 2019 environment use the following command:

```
Msbuild.exe myproject.vcxproj /p:BasePlatformToolset=v142
```

  Example: To set the Platform Toolset property to use the Intel® C++ Compiler Classic and build a project using the Microsoft Visual Studio 2019 environment use the following command:

```
Msbuild.exe myproject.vcxproj /p:PlatformToolset="Intel C++ Compiler 19.2" /p:BasePlatformToolset=v141
```

  For possible values for the /p:BasePlatformToolset property, see the properties described above.

The next time you build your project with the Intel® C++ Compiler Classic, the option you selected is used to specify the build environment.

Using Property Pages

The Intel® C++ Compiler integration with Microsoft Visual Studio® includes support for Property Pages to manage both Intel-specific and general compiler options.

To set compiler options in Microsoft Visual Studio®:

1. Right-click on a project or source file in the Solution Explorer view.
2. Select Properties from the pop-up menu.
3. In the Property Pages dialog box, expand the C/C++ section to view the categories of compiler options.
4. Select a category, then change the compiler options on the corresponding Property Page in the right-hand pane. Some categories contain Intel-specific properties; these categories are marked with [Intel C++]. For example, there is a Code Generation and Code Generation [Intel C++] category. The latter contains properties specific to the Intel® C++ Compiler.
5. Click OK to complete your selection.

The option you selected is used in the compilation the next time you build your project.

Use Intel® Libraries with Microsoft Visual Studio®

You can use the compiler with the following Intel® Libraries, which may be included as a part of the product:

- Intel® oneAPI Data Analytics Library (oneDAL)

  NOTE This library is only available in the x64 configuration.

- Intel® Integrated Performance Primitives (Intel® IPP)
- Intel® oneAPI Threading Building Blocks (oneTBB)
• Intel® oneAPI Math Kernel Library (oneMKL)

Use the property pages to specify Intel Libraries to use with the selected project configuration. The functionality supports Intel® C++ and Microsoft Visual C++® project types.

To specify Intel Libraries, select Project > Properties. In Configuration Properties, select Intel Libraries for oneAPI, then do the following:

1. To use oneDAL change the Use oneDAL settings as follows:

   **NOTE** This library is only available in the x64 configuration.

   - **No**: Disable Use of oneDAL.
   - **Default Linking Method**: Use parallel dynamic oneDAL libraries.
   - **Multi-threaded Static Library**: Use parallel static oneDAL libraries.
   - **Single-threaded Static Library**: Use sequential static oneDAL libraries.
   - **Multi-threaded DLL**: Use parallel dynamic oneDAL libraries.
   - **Single-threaded DLL**: Use sequential dynamic oneDAL libraries.

2. To use Intel® Integrated Performance Primitives, change the Use Intel® IPP settings as follows:

   - **No**: Disable use of Intel® IPP libraries.
   - **Default Linking Method**: Use dynamic Intel® IPP libraries.
   - **Static Library**: Use static Intel® IPP libraries.
   - **Dynamic Library**: Use dynamic Intel® IPP libraries.

3. To use oneTBB in your project, change the Use oneTBB settings as follows:

   - **No**: Disable use of oneTBB libraries.
   - **Use oneTBB**: Set to Yes to use oneTBB in the application.
   - **Instrument for use with Analysis Tools**: Set to Yes to analyze your release mode application (not required for debug mode).

4. To use oneMKL in your project, change the Use oneMKL property settings as follows:

   - **No**: Disable use of oneMKL libraries.
   - **Parallel**: Use parallel oneMKL libraries.
   - **Sequential**: Use sequential oneMKL libraries.
   - **Cluster**: Use cluster libraries.

Additional settings for use with the Microsoft Visual C++® Platform Toolset are available on the Intel Libraries for oneAPI category, found at Tools > Options.

**NOTE** The Use <library> properties in Microsoft Visual Studio mimic the behavior of the /Qmkl, /Qdaal, /Qipp and /Qtbb compiler options. The include and library paths to the performance library, which are installed with the selected compiler, are set up with these properties.

---

**Change the Selected Intel® Performance Libraries**

If you have installed multiple versions of the Intel® Performance Libraries, you can specify which version to use with the Microsoft Visual C++® compiler. To do this:

1. Select Tools > Options.
2. In the left pane, select Intel Compilers and Libraries > Performance Libraries.
3. Select the desired library version from the drop-down boxes in the right pane.

For more information, see the Intel® oneAPI Data Analytics Library (oneDAL), Intel® Integrated Performance Primitives (Intel® IPP), Intel® oneAPI Threading Building Blocks (oneTBB), and Intel® oneAPI Math Kernel Library (oneMKL) documentation.
Include MPI Support

To specify the type of MPI support you want:

1. Open the project’s property pages and select Configuration Properties > Intel Libraries for oneAPI.
2. Set the property Use oneMKL to Cluster.
3. Set the property Use MPI Library to one of the following values:
   - Intel® MPI Library
   - MS-MPI
4. Build the project.

The next time you build your project with the Microsoft Visual C++* compiler, it will include support for the version of MPI that you specified.

Use Guided Auto Parallelism in Microsoft Visual Studio*

The Guided Auto Parallelism (GAP) feature helps you locate portions of your serial code that can be parallelized. When you enable analysis using GAP, the compiler guides you to places in your code where you can increase efficiency through automatic parallelization and vectorization.

**NOTE** GAP is not supported for ifx.

Run Analysis on a Project

You can start analysis from the Microsoft Visual Studio* IDE in several ways:

- From the Tools menu: Select Intel Compiler > Guided Auto Parallelism > Run Analysis...
  Starting analysis in this way results in a one-time run for the current project. The default values are taken from Tools > Options unless you have chosen to override them in the dialog box.
- From the Diagnostics property page: Use the Guided Auto Parallelism Analysis property.
  Specifically, choose Project > Properties > C/C++ > Diagnostics and enable analysis using the Guided Auto Parallelism Analysis property. Enabling analysis in the property page allows you to run an analysis as part of a normal project Build request in Microsoft Visual Studio*. In this mode, GAP-related settings in Tools > Options are ignored, in favor of other GAP-related settings available in the property page.
- From the context menu: Right-click and select Intel Compiler > Guided Auto Parallelism > Run Analysis....
  This is equivalent to using the Guided Auto Parallelism > Run Analysis option on the Tools menu.

To receive advice for auto parallelization, be sure that certain property page settings are correct. Select Project > Properties > C/C++ > Optimization [Intel C++] and set Parallelization to Yes to enable auto-parallelization optimization. You may also need to set the Optimization level at option 02 or higher. To do this, use the Optimization property page.

GAP Scenarios

To illustrate how the various GAP settings work together, consider the following scenarios:
The GAP analysis setting in the property pages is set to Enabled.
The GAP analysis setting in the property pages is set to Disabled, and GAP is run from the Tools menu.
The GAP analysis setting in the property pages is set to Disabled, and GAP options are set in Tools > Options.

### Run Analysis on a File or within a File
Right-click on Guided Auto Parallelism context menu item to run analysis on the following:
- **Single file**: Select a file and right-click.
- **Function (routine)**: Right-click within the function scope.
- **Range of lines**: Select one or more lines for analysis and right-click.

### Use Code Coverage in Microsoft Visual Studio*

The code coverage tool provides the ability to determine how much application code is executed when a specific workload is applied to the application. The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate a report in HTML-format and export data in both text- and XML-formatted files. The reports can be further customized to show color-coded, annotated source-code listings that distinguish between used and unused code.

**NOTE** Code coverage is not supported for ifx.

To start code coverage:
1. Select **Tools > Intel Compiler > Code Coverage**...
2. Specify settings for the various phases.
3. Click **Run**.

The **Output** window shows the results of the coverage and a general summary of information from the code coverage.

### See Also
- Code Coverage dialog box
- Code Coverage Settings dialog box
**Code Coverage Tool**

**Use Profile Guided Optimization in Microsoft Visual Studio**

Profile Guided Optimization (PGO) improves application performance by reorganizing code layouts to reduce instruction-cache problems, shrinking code size, and reducing branch misprediction. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

**NOTE** PGO is not supported for ifx.

To start PGO:
1. Choose **Tools > Intel Compiler > Profile Guided Optimization**...
2. Specify settings for the various phases.
3. Click **Run**.

The **Output** windows show the results of the optimization with a link to the composite log.

**See Also**
Profile Guided Optimization dialog box

**Options: Profile Guided Optimization dialog box**

**Profile Guided Optimization**

**Optimization Reports**

**Enable in Microsoft Visual Studio**

Optimization reports can help you address vectorization and optimization issues.

When you build a solution or project, the compiler generates optimization diagnostics. You can view the optimization reports in the following windows:

- The **Compiler Optimization Report** window, either grouped by loops or in a flat format.
- The **Compiler Inline Report** window.
- The optimization annotations, which are integrated within the source editor.

To enable viewing for the optimization reports:

1. In your project’s property pages, select **Configuration Properties > C/C++ > Diagnostics [Intel C ++]**.
2. Set a non-default value for any of the following options:
   - **Optimization Diagnostics Level**
   - **Optimization Diagnostics Phase**
   - **Optimization Diagnostics Routine**
3. Build your project to generate an optimization report.

When the compiler generates optimization diagnostics, the **Compiler Optimization Report** and the **Compiler Inline Report** windows open. The optimization report annotations appear in the source editor.
NOTE You can specify how you want the optimization reporting to appear with the Optimization Reports dialog box. Access this dialog box by selecting Tools > Options > Intel Compilers and Libraries > Optimization Reports.

View Reports

When the compiler generates optimization diagnostics, the Compiler Optimization Report and the Compiler Inline Report windows open, and optimization report annotations appear in the editor.

The Compiler Optimization Report window displays diagnostics for the following phases of the optimization report:

- PGO
- LNO
- PAR
- VEC
- Offload (Linux* only)
- OpenMP*
- CG

Information appears in this window grouped by loops, or in a flat format. To switch the presentation format, click the gear button on the toolbar of the window, and uncheck Group by loops.

In addition to sorting information by clicking column headers and resizing columns, you can use the windows described in the following table:

<table>
<thead>
<tr>
<th>Do This</th>
<th>To Do This</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double-click a diagnostic.</td>
<td>Jump to the corresponding position in the editor.</td>
</tr>
<tr>
<td>Click a link in the Inlined into column.</td>
<td>Jump to the call site of the function where the loop is inlined.</td>
</tr>
<tr>
<td>Expand or collapse a diagnostic in Group by loops view.</td>
<td>View detailed information for the diagnostic.</td>
</tr>
<tr>
<td>Click on a column header.</td>
<td>Sort the information according to that column.</td>
</tr>
<tr>
<td>Click the filter button.</td>
<td>Select a scope by which to filter the diagnostics that appear in the window.</td>
</tr>
<tr>
<td>Click a Compiler Optimization Report window toolbar button corresponding to an optimization report phase.</td>
<td>Turn filtering diagnostics on or off for an optimization phase.</td>
</tr>
<tr>
<td>Enter text in the search box in the Compiler Optimization Report window toolbar.</td>
<td>Labels on optimization phase filter buttons show how many diagnostics of each phase are in the current scope.</td>
</tr>
<tr>
<td></td>
<td>By default all phases turned on.</td>
</tr>
<tr>
<td></td>
<td>Filter diagnostics using the text pattern.</td>
</tr>
<tr>
<td></td>
<td>Diagnostics are filtered when you stop typing.</td>
</tr>
<tr>
<td></td>
<td>Pressing Enter saves this pattern in the search history.</td>
</tr>
<tr>
<td></td>
<td>To disable filtering, clear the search box.</td>
</tr>
<tr>
<td></td>
<td>To use a pattern from the search history, click on the down arrow next to the search box.</td>
</tr>
</tbody>
</table>
The **Compiler Inline Report** window displays diagnostics for the IPO phase of the optimization report. Information appears in this window in a tree. Each entry in the tree has corresponding information in the right-hand pane under the **Properties** tab and the **Inlining options** tab.

You can use the window as described in the following table:

<table>
<thead>
<tr>
<th>Do This</th>
<th>To Do This</th>
</tr>
</thead>
<tbody>
<tr>
<td>Double-click a diagnostic in the tree, or click on the source position</td>
<td>Jump to the corresponding position in the editor.</td>
</tr>
<tr>
<td>link under the <strong>Properties</strong> tab.</td>
<td></td>
</tr>
<tr>
<td>Click <strong>Just My Code</strong>.</td>
<td>Only display functions from your code, filter all records from files that</td>
</tr>
<tr>
<td></td>
<td>don't belong to the current solution file tree.</td>
</tr>
<tr>
<td>Right-click on a function body in the editor and select <strong>Intel Compiler</strong></td>
<td>View detailed information for the specified function.</td>
</tr>
<tr>
<td>&gt; <strong>Show Inline report for function name</strong>.</td>
<td></td>
</tr>
<tr>
<td>Right-click on a function body in the editor and select <strong>Intel Compiler</strong></td>
<td>Show where the specified function is inlined.</td>
</tr>
<tr>
<td>&gt; <strong>Show where function name in inlined</strong>.</td>
<td></td>
</tr>
<tr>
<td>Enter text in the search box in the <strong>Compiler Inline Report</strong> window</td>
<td>Filter diagnostics using the text pattern.</td>
</tr>
<tr>
<td>toolbar.</td>
<td>Diagnostics are filtered when you stop typing. Pressing Enter saves this</td>
</tr>
<tr>
<td></td>
<td>pattern in the search history.</td>
</tr>
<tr>
<td></td>
<td>To disable filtering, clear the search box.</td>
</tr>
<tr>
<td></td>
<td>To use a pattern from the search history, click on the down arrow next to</td>
</tr>
<tr>
<td></td>
<td>the search box.</td>
</tr>
</tbody>
</table>

The **Viewing Optimization Notes** window in the editor provides context for the diagnostics that the compiler generates:

- In Caller Site
- In Callee Site
- In Caller and Callee Site

You can use optimization notes as described in the following table:

<table>
<thead>
<tr>
<th>Do This</th>
<th>To Do This</th>
</tr>
</thead>
<tbody>
<tr>
<td>Right-click an optimization note</td>
<td>• Expand or collapse the current optimization note, or all of them.</td>
</tr>
<tr>
<td></td>
<td>• Open the <strong>Optimization Reports</strong> dialog box to adjust settings for</td>
</tr>
<tr>
<td></td>
<td>optimization report viewing.</td>
</tr>
<tr>
<td></td>
<td>You can view optimization notes in one of the following locations:</td>
</tr>
<tr>
<td></td>
<td>• <strong>Caller Site</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Callee Site</strong></td>
</tr>
<tr>
<td></td>
<td>• <strong>Caller Site and Callee Site</strong></td>
</tr>
<tr>
<td>Double-click an optimization note heading.</td>
<td>Expand or collapse the current optimization note.</td>
</tr>
<tr>
<td>Double-click a diagnostic detail.</td>
<td>Jump to the corresponding position in the editor.</td>
</tr>
<tr>
<td>Click a hyperlink in the optimization note.</td>
<td>Show where the specified function is inlined.</td>

**Dialog Box Help**
This section provides information about access to dialog boxes and information about compilers, libraries, and converter dialog boxes.

**Options: Compilers dialog box**
To access the Compilers page:

1. Open **Tools > Options**.
2. In the left pane, select **Intel Compilers and Libraries > C++ > Compilers**.

**Compiler Selection for C++ Classic**
**Target Platform:** Select your target platform.

**Platform Toolset/Selected Compiler:** Select your compiler for your platform toolset. The left column lists the platform toolset names. The right column lists combo boxes, which are used to select a compiler. The default value for all combo boxes in current table is `<Latest>`.

**NOTE** The left column contains Intel® C++ Compiler Classic and Intel® oneAPI DPC++/C++ Compiler options. The **Intel C++ Compiler <major.minor>** (example 19.2) selects the Intel® C++ Compiler Classic (**icc**). The **Intel C++ Compiler <major>** (example 2021) selects the Intel® oneAPI DPC+++/C++ Compiler (**icx**).

**Default Options:** Sets the default options for a selected compiler. You may specify this setting for each selected compiler.

**Environment:** Sets custom environment variables. You may specify this setting for each selected compiler.

**NOTE** The Environment selection is only available for **icx**.

**Compiler Information:** Shows the detail description of the selected compiler.

**Reset All:** Sets all contents back to the default value on the dialog.

**See Also**

**Use Intel® C++ Compiler Classic dialog box**
To access the **Use Intel C++ Compiler Classic** dialog box, select one or more files in the Solution Explorer, right-click and select **Use Intel C++ Compiler Classic for selected files(s)**...

Use this dialog box to change the compiler for one or more selected files to the Intel® C++ Compiler Classic.
Select the configuration(s) to update: Select the desired configuration. Choose from Active configuration or All configurations. If you select All configurations, the compiler is changed in all configurations for the currently selected file(s).

Select the Platform Toolset: Select the desired toolset, if multiple platform toolsets are installed.

Use the Intel® C++ Compiler Classic

Options: Intel Libraries for oneAPI dialog box

Use the Intel Libraries for oneAPI dialog box to specify standalone library versions to use with the Microsoft Visual C++* compiler.

To access the Intel Libraries for oneAPI dialog box:

1. Open Tools > Options.
2. Select Intel Compilers and Libraries > Intel Libraries for oneAPI.

In the dialog box, you can select your desired library version from the drop-down box with one of the following values:

- oneDAL
- Intel IPP
- oneTBB
- oneMKL
- Reset All: Use the latest libraries (default)

NOTE To enable or disable the Intel Libraries for oneAPI, use the property pages located in the Configuration Properties category.

Use Intel® Libraries for oneAPI

Options: Converter dialog box

To access the Converter page, click Tools > Options and then select Intel Compilers and Libraries > C++ > Converter.

Use the Converter page to specify which platform toolset to use when upgrading an Intel® C++ solution (.icproj) from an older version of Microsoft Visual Studio* to a C++ project supported by Microsoft Visual Studio 2017 or later (.vcxproj). Once a solution is upgraded, the .icproj file is not used and can be deleted.

NOTE Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

Win32: Select the desired compiler version to be used when converting projects based on IA-32 architecture.

X64: Select the desired compiler version to be used when converting projects based on x64 architecture.
Reset All: Click this button to use the default platform toolsets.

**Options: Optimization Reports dialog box**

To access the Optimization Reports page, click Tools > Options and then select Intel Compilers and Libraries > Optimization Reports. Use this page to specify how you want optimization reporting to appear.

This page, in conjunction with the Diagnostics property page for your project or solution, defines settings for optimization report viewing in Visual Studio*.

**General**

**Always Show Compiler Inline Report**: Specify if the Compiler Inline Report appears after building or rebuilding your solution or project when inline diagnostics are present.

**Always Show Compiler Optimization Report**: Specify if Compiler Optimization Report appears after building or rebuilding your solution or project when optimization diagnostics are present. This option has higher priority than Always Show Compiler Inline Report. If both options are set to True, then this window has focus by default.

**Show Optimization Notes in Text Editor Margin**: Specify if optimization notes appear in the editor as source code annotations.

**Optimization Notes in Text Editor**

**Collapse by Default**: Specify if optimization notes appear expanded or collapsed by default.

**Show Optimization Notes**: Specify if source code annotations appear in the editor.

**Site**: Specify where optimization notes appear in the editor. Select from one of the following options:

- Caller Site
- Callee Site
- Caller and Callee Sites

**See Also**

Optimization Reports: Enabling in Visual Studio*

**Options: Guided Auto Parallelism dialog box**

Use the Guided Auto Parallelism page to specify settings for Guided Auto Parallelism (GAP) analysis.

**NOTE** The Guided Auto Parallelism dialog box is only available for ifort.

To access the Guided Auto Parallelism page click Tools > Options and then select: Intel Compilers and Libraries > C++ > Guided Auto Parallelism.

These settings are used when running analysis using Tools > Intel Compiler > Guided Auto Parallelism > Run Analysis on project...

**Guided Auto Parallelism Options**

**Level of Analysis**: Specify the desired level of analysis. Choose Simple, Moderate, Maximum, or Extreme.

**Suppress compiler warnings**: Check this box to suppress compiler warnings. Selection adds option W0 to the compiler command line.

**Suppress Remark IDs**: Specify one or more remark IDs to suppress. Use a comma to separate IDs.

**Send remarks to a file**: Check this box to send GAP remarks to a specified text file.
Remarks file: Specify the filename to send GAP remarks to.

Show all GAP configuration and informational dialogs: Check this box to display additional dialog boxes when you run an analysis.

Reset All: Click this button to restore the previously selected settings.

Guided Auto Parallelism
Using Guided Auto Parallelism

Configure Analysis dialog box
Use the Configure Analysis dialog box to specify settings for Guided Auto Parallelism (GAP) analysis and run the analysis.

To access this dialog box, click Tools > Intel Compiler > Guided Auto Parallelism > Run Analysis...

Configure Analysis Options
Level of Analysis: Specify the desired level of analysis. Choose Simple, Moderate, Maximum, or Extreme.

Suppress Compiler Warnings: Check this box to suppress compiler warnings. This adds the option W0 to the compiler command line.

Suppress remark IDs: Specify one or more remark IDs to suppress. Use a comma to separate IDs.

Send remarks to a file: Check this box to send GAP remarks to a specified text file.

Remarks file: Specify the filename where GAP remarks will be sent.

Save these settings as the default (in Tools > Options for Guided Auto Parallelism): Check this box to save the specified settings as the default settings.

Show this dialog next time (in Tools > Intel Compiler): Check this box to display this dialog box next time.

When you are done specifying settings, click Run Analysis.

Profile Guided Optimization dialog box

Profile-Guided Optimizations

Profile Guided Optimization dialog box

This topic has information on the following dialog boxes:

- Profile Guided Optimization (PGO) dialog box
- Application Invocations dialog box
- Edit Command dialog box
- Command dialog box

Profile Guided Optimization dialog box

To access the Profile Guided Optimization dialog box, choose Tools > Intel Compiler > Profile Guided Optimization.

Use the Profile Guided Optimization dialog box to set the options for profile guided optimization.

Phase 1 - Instrument: This phase produces an instrumented object file for the profile guided optimization. The command line compiler option for each optimization instrument you choose appears in Compiler Options.

- Enable Function Ordering in the optimized application: Select this checkbox to enable ordering of static and extern routines using profile information. This optimization specifies the order in which the linker should link the functions of your application. This optimization can improve your application performance by improving code locality and by reducing paging.

- Enable Static Data Layout in the optimized application: Select this checkbox to enable ordering of static global data items based on profiling information. This optimization specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.

- Instrument with guards for threaded application: Select this checkbox to produce an instrumented object file that includes the collection of PGO data on applications that use a high level of parallelism.

Selecting an option produces a static profile information file (.spi), but also increases the time needed to do a parallel build.

Deselect the checkbox to skip this phase to save time running profile guided optimization. When you skip this phase, you use the existing profile information when running profile guided optimization. For example, you may want to skip this phase when you change the code to fix a bug and the fix doesn't affect the architecture of the project.

Phase 2 - Run Instrumented Application(s): This phase runs the instrumented application produced in the previous phase as well as other applications in the Applications Invocations dialog box. To add a new application or edit an existing application in the list, click Applications Invocations.

Deselect the checkbox to skip this phase to save time running profile guided optimization. When you skip this phase, you do not run the applications in the list when running profile guided optimization. For example, you might want to skip this phase when you change the code to fix a bug and the fix doesn't affect the architecture of the project.
**Phase 3 - Optimize with Profile Data:** This phase performs the profile guided optimization. Deselect the checkbox to skip this phase.

**Profile Directory:** The directory that contains the profile. Click Edit to edit the profile directory or the Browse button to browse for the profile directory.

**Show this dialog next time:** Deselect this checkbox to run profile guided optimization without displaying this dialog box. The profile guided optimization will use these settings.

**Save Settings:** Click to save your settings.

**Run:** Click to start the profile guided optimization.

**Cancel:** Click to close this dialog box without starting the profile guided optimization.

**Application Invocations dialog box**

To access the Application Invocations dialog box, click Application Invocations... in the Profile Guided Optimization dialog box. Use the Profile Guided Optimization dialog box to configure the application options for your application as well add additional applications when you run profile guided optimization.

The list of applications comes from the debug settings of the Startup Project.

**Merge Environment:** Select this checkbox to merge the application environment with the environment defined by the operating system.

To add, edit, or remove an application, click one of the buttons.

**Add:** Click to add a new application in the Add Command dialog box.

**Duplicate:** Click after selecting an application to copy its settings so that you can use a different setting.

**Edit:** Click after selecting an application to change its settings in the Edit Command dialog box.

**Delete:** Click to remove the selected application from the list.

**OK:** Click to save the settings and close this dialog box.

**Cancel:** Click to discard the settings and close this dialog box.

**Add Command dialog box**

To access the Add Command dialog box, click Add in the Application Invocations dialog box. Use the Add Command dialog box to add a new application in the Application Invocations dialog box.

**Command:** Add a new or edit an existing application. Click Edit to open the Command dialog box with a list of macros. Click Browse to navigate to another directory that contains the application.

**Command Arguments:** Enter the arguments required by the application.

**Working Directory:** Enter a new or edit the working directory for the application. Click Edit to open the Working Directory dialog box with a list of macros. Click Browse to navigate to working directory of the application.

**Environment:** Enter the environment variable required by this application.

**Merge Environment:** Select this checkbox to merge the application environment with the environment defined by the operating system.

**Load from Debugging Settings:** Click to load the debug settings for this application.

**OK:** Click to save the settings and close this dialog box.

**Cancel:** Click to discard the settings and close this dialog box.
NOTE: The **Edit Command** and **Add Command** dialog boxes are similar. To use the **Edit Command** dialog box, substitute **Edit** for **Add** in the selections above.

### Command dialog box

To access the **Command** dialog box, click **Edit** in the **Edit Command** dialog box, or **Add** in the **Add Command** dialog box. Use the **Command** dialog box to specify or change the macro used in the application to run as part of the profile guided optimization.

Select a macro from the list and then click one of the buttons.

- **Macro**: Click to show or close the list of available macros.
- **Insert**: Click to use the selected macro.
- **OK**: Click to save the settings and close this dialog box.
- **Cancel**: Click to discard the settings and close this dialog box.

**Using Xcode* (macOS*)**

### Create an Xcode* Project

To create a new Xcode* project:

1. Launch the Xcode application.
2. Select File > New > Project...
   - The Choose a template for your new project window opens.
3. In the left pane, select macOS > Application.
4. Select a template, for example: Command Line Tool, and click Next.
5. Name your project, for example: Hello World, then enter a string for the **Organization Name** and **Organization Identifier** and select a language. Click Next.
6. Specify a directory for your project, and optionally select Create local git repository for this project to place your project under version control.
7. Click Create.

Xcode creates the named project directory, with an .xcodeproj extension. Your new project directory contains a main.cpp source file and other project files.

Each Xcode project has its own **Project Editor** window that displays project source files, targets, and executables.

**See Also**

### Select the Intel® Compiler

To select the Intel® C++ Compiler Classic:

1. Select the target you want to change and click Build Rules.
2. Add a new rule by clicking Editor > Add Build Rule or pressing the + button.
3. Under Process, choose C source files or C++ source files, depending on your source files.
4. Under Using, select one of the options for the ICC Intel® C++ Compiler:
   - **Major_Version**, such as 2021.1: The most recently installed compiler, even if it is not the latest release.
   - **Latest Release**: The latest released compiler available on your system. This is useful when you have multiple installations of the Intel compiler and want to use the version most recently released by Intel.
   - **Major_Version.n.nnn**: A specific package, such as 2021.1.0.000. This is useful when you have multiple packages of one major version installed.
NOTE If the Intel® Compiler does not show up in the drop-down list, it may mean that the compiler does not support your version of Xcode. To enable the Intel® Compiler in Xcode specify the Xcode path during installation and restart the program. The installer checks for the supported Xcode version and warns you in the case of an unsupported version.

NOTE If you select a tool that does not support the source file type, that source file type is processed by a later rule that specifies that type. For example, even though Objective-C/C++ sources are derived from C sources, they are built by the Intel® C++ Compiler Classic.

See Also
Setting Compiler Options

Build the Target

A single project can contain multiple targets. The active target determines how your project is built. This topic describes how to build the target using the Xcode* IDE and documents the build steps using the xcodebuild command line utility.

NOTE Starting with the 19.0 release of the Intel® C++ Compiler Classic, macOS* 32-bit applications are no longer supported. If you want to compile 32-bit applications, you must use an earlier version of the compiler and you must use Xcode 9.4 or earlier.

Build Using the Xcode IDE

1. Select the target in the project editor under Targets.
2. Select Product > Build.
3. To view the results of your build, click the Log Navigator button.

You can change the compilation order of the files in an Xcode target. To re-order the files listed under a target’s Compile Sources, click a source file and drag it before, or after other compilations.

Build From the Command Line Using the xcodebuild Utility

You can use the xcodebuild utility to build a target. This utility uses the Xcode project settings to build target projects from the command line. If you have previously configured your Xcode project to build with the Intel compiler, xcodebuild invokes it from the command line.

To build from the command line:

1. Check that the Xcode project is configured to use the Intel® C++ Compiler Classic.
2. Launch a terminal window from the finder by selecting Applications > Utilities > Terminal.
3. Change directories to the directory containing the Xcode project file (.xcodeproj).
4. If you have multiple versions of Xcode, use the xcode-select utility to verify the current Xcode version.
5. Issue an xcodebuild command. For example:

   xcodebuild -project HelloWorld.xcodeproj -target HelloWorld -configuration Debug

6. Run the program built in the example from the previous step by entering the following:

   ./build/Debug/HelloWorld

For more information, refer to the xcodebuild man page.
Set the Executable's Architecture

Before building a 64-bit executable from within Xcode, you may need to edit the executable's target architecture. To change the Architectures setting:

1. Click the target you want to change in the project editor under Targets and select the Build Settings tab.
2. Under Architectures, select the desired architecture.

NOTE The Intel® C++ Compiler Classic generates code solely for Intel® architectures.

Set Compiler Options

To use the Xcode* environment to set compiler options, including options specific to Intel® architecture:

1. Select a target.
2. Under the Build Settings tab, click All.
3. Scroll down to the list of ICC Intel® C++ Compiler categories.
4. To set an Intel® C++ Compiler Classic option in the Optimization category, scroll down to display Optimization.
5. Select a Setting, such as Enable Interprocedural Optimization for Single File Compilation, and set the option's state. If the Quick Help inspector is visible, information about the selected option appears under Quick Help.

Tip
Apple* has deprecated the libstdc++ library, make sure you are using the libc++ standard library.

The next time you build your project, the selected options are used in the compilation.

NOTE To view the settings that have changed from the established defaults, select the Levels button under Build Settings.

Run the Executable

Once you have built your Xcode* project, click the Run button. The output from the executable is displayed. This button runs the configuration currently associated with the button. Use the Scheme Editor to change the configuration associated with the button.

Tip To open the Scheme Editor, select Product > Scheme... > Edit Scheme...

Use Dynamic Libraries

Using the Dynamic Libraries does not assume that the Apple* System Integrity Protection feature purges environment variables, such as DYLD_LIBRARY_PATH, when launching the protected process. Refer to the https://developer.apple.com/library/archive/documentation/Security/Conceptual/System_Integrity_Protection_Guide/Introduction/Introduction.html for more information. Xcode must take this into account and set the proper environment variables in the Xcode environment.
You can build your Xcode project with the `-shared-intel` compiler option to link with the Intel dynamic libraries. Build your project with the `-qopenmp` or `-parallel` option to link in `libiomp5.dylib`. If you do this, you need to set Xcode build option Runpath Search path to an appropriate folder with the compiler and performance libraries, or specify the `DYLD_LIBRARY_PATH` environment variable in the Xcode environment.

To add the environment variable:

1. Open the Scheme Editor and select the Run action.
2. On the Arguments tab, under Environment Variables, click the + button.
3. Add DYLD_LIBRARY_PATH. Set the value to the full path to the Intel compiler's /lib directory.

**NOTE** If you build your project with the `-shared-intel`, `-qopenmp`, or `-parallel` compiler option without setting the `DYLD_LIBRARY_PATH` environment variable, a library not found error message results at runtime. Depending on your application, the error message may refer to a library other than the one noted in this example:

```
dyld: Library not loaded: libiomp5.dylib
  Referenced from: /Users/test/hello_world
  Reason: image not found
```

Due to the Apple System Integrity Protection you may need to set the `DYLD_LIBRARY_PATH` explicitly in the launch string, or configure the Runpath Search path build option.

**See Also**
- shared-intel option
- openmp, Qopenmp option
- parallel, Qparallel option

## Use Intel Libraries with Xcode*

You can use the compiler with the following Intel Libraries, which may be included as a part of the product:

- Intel® oneAPI Data Analytics Library (oneDAL)
- Intel® Integrated Performance Primitives (Intel® IPP)
- Intel® oneAPI Threading Building Blocks (oneTBB)
- Intel® oneAPI Math Kernel Library (oneMKL)

To access these libraries in Xcode, select the target and go to Build Settings > Intel® C++ Compiler Performance Library Build Components.

To use oneDAL change the Use Intel® oneAPI Data Analytics Library settings as follows:

- **None**: Disables the use of the oneDAL.
- **Use threaded Intel® oneAPI Data Analytics Library**: Links using the threaded version of the library.
- **Use non-threaded Intel® oneAPI Data Analytics Library**: Links using the non-threaded version of the library.

The **Use Intel® oneAPI Threading Building Blocks Library** property enables the library and brings in the associated headers.

The **Use Intel Integrated Performance Primitives Libraries** property provides the following options in a drop-down menu:

- **None**: Disables the use of the Intel® IPP.
- **Use main libraries set**: Uses all the libraries, except the cryptography libraries.
• **Use main libraries and cryptography library**: Uses the cryptography and main libraries.

  **NOTE** The cryptography libraries are subject to export laws.

The **Use Intel® oneAPI Math Kernel Library** property provides the following options in a drop-down menu:

- **None**: Disables the use of oneMKL.
- **Use threaded Intel® oneAPI Math Kernel Library**: Links using the threaded version of the library.
- **Use non-threaded Intel® oneAPI Math Kernel Library**: Links using the non-threaded version of the library.

For more information, see the oneDAL, Intel® Integrated Performance Primitives, oneTBB, and oneMKL documentation.
There are a number of calling conventions that set the rules on how arguments are passed to a function and how the values are returned from the function.

### Calling Conventions on Windows*

The following table summarizes the supported calling conventions on Windows*:

<table>
<thead>
<tr>
<th>Calling Convention</th>
<th>Compiler Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>__cdecl</td>
<td>/Gd</td>
<td>This is the default calling convention for C/C++ programs. It can be specified on a function with variable arguments.</td>
</tr>
<tr>
<td>__stdcall</td>
<td>/Gz</td>
<td>Standard calling convention used for Win32 API functions.</td>
</tr>
<tr>
<td>__fastcall</td>
<td>/Gr</td>
<td>Fast calling convention that specifies that arguments are passed in registers rather than on the stack.</td>
</tr>
<tr>
<td>__regcall</td>
<td>/Qregcall</td>
<td>Intel® C++ Compiler calling convention that specifies that as many arguments as possible are passed in registers; likewise, __regcall uses registers whenever possible to return values. This calling convention is ignored if specified on a function with variable arguments. For more information about the Intel-compatible vector functions ABI, see the article Vector Function Application Binary Interface at <a href="https://software.intel.com/content/www/us/en/develop/download/vector-simd-function-abi.html">https://software.intel.com/content/www/us/en/develop/download/vector-simd-function-abi.html</a>.</td>
</tr>
<tr>
<td>Calling Convention</td>
<td>Compiler Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td><strong>attribute</strong>((cdecl))</td>
<td>none</td>
<td>Default calling convention for C/C++ programs. Can be specified on a function with variable arguments.</td>
</tr>
<tr>
<td><strong>attribute</strong>((stdcall))</td>
<td>none</td>
<td>Calling convention that specifies the arguments are passed on the stack. Cannot be specified on a function with variable arguments.</td>
</tr>
<tr>
<td><strong>attribute</strong>((regparm (number)))</td>
<td>none</td>
<td>On systems based on IA-32 architecture, the regparm attribute causes the compiler to pass up to number arguments in registers EAX, EDX, and ECX instead of on the stack. Functions that take a variable number of arguments will continue to pass all of their arguments on the stack.</td>
</tr>
<tr>
<td><strong>attribute</strong>((regcall))</td>
<td>-regcall</td>
<td>Intel® C++ Compiler calling convention that specifies that as many arguments as possible are passed in registers; likewise, __regcall uses registers whenever possible to return values. This calling convention is ignored if specified on a function with variable arguments.</td>
</tr>
<tr>
<td><strong>attribute</strong>((vectorcall))</td>
<td>none</td>
<td>Calling convention that specifies that a function passing vector type arguments should utilize vector registers.</td>
</tr>
</tbody>
</table>

**Calling Conventions on Linux* and macOS* **

The following table summarizes the supported calling conventions on Linux* and macOS*:

<table>
<thead>
<tr>
<th>Calling Convention</th>
<th>Compiler Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>attribute</strong>((cdecl))</td>
<td>none</td>
<td>Default calling convention for C/C++ programs. Can be specified on a function with variable arguments.</td>
</tr>
<tr>
<td><strong>attribute</strong>((stdcall))</td>
<td>none</td>
<td>Calling convention that specifies the arguments are passed on the stack. Cannot be specified on a function with variable arguments.</td>
</tr>
<tr>
<td><strong>attribute</strong>((regparm (number)))</td>
<td>none</td>
<td>On systems based on IA-32 architecture, the regparm attribute causes the compiler to pass up to number arguments in registers EAX, EDX, and ECX instead of on the stack. Functions that take a variable number of arguments will continue to pass all of their arguments on the stack.</td>
</tr>
<tr>
<td><strong>attribute</strong>((regcall))</td>
<td>-regcall</td>
<td>Intel® C++ Compiler calling convention that specifies that as many arguments as possible are passed in registers; likewise, __regcall uses registers whenever possible to return values. This calling convention is ignored if specified on a function with variable arguments.</td>
</tr>
<tr>
<td><strong>attribute</strong>((vectorcall))</td>
<td>none</td>
<td>Calling convention that specifies that a function passing vector type arguments should utilize vector registers.</td>
</tr>
</tbody>
</table>
The __regcall Calling Convention

The __regcall calling convention is unique to the Intel® C++ Compiler and requires some additional explanation.

To use __regcall, place the keyword before a function declaration. For example:

```
Example

__regcall int foo (int i, int j);

// Linux* and macOS*
__attribute__((regcall)) foo (int i, int j);
```

Available __regcall Registers

All registers in a __regcall function can be used for parameter passing/returning a value, except those that are reserved by the compiler. The following table lists the registers that are available in each register class depending on the default ABI for the compilation. The registers are used in the order shown in the table.

<table>
<thead>
<tr>
<th>Register Class/Architecture</th>
<th>IA-32 for Linux*</th>
<th>IA-32 for Windows*</th>
<th>Intel® 64 for Linux*</th>
<th>Intel® 64 for Windows*</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPR</td>
<td>EAX, ECX, EDX, EDI</td>
<td>ECX, EDX, EDI, ESI</td>
<td>RAX, RCX, RDX, RDI, RSI, R8, R9, R10, R11, R12, R14, R15</td>
<td>RAX, RCX, RDX, RDI, RSI, R8, R9, R11, R12, R14, R15</td>
</tr>
<tr>
<td>FP</td>
<td>ST0</td>
<td>ST0</td>
<td>ST0</td>
<td>ST0</td>
</tr>

<td>None</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
<tr>
<td>XMM</td>
<td>XMM0 - XMM7</td>
<td>XMM0 - XMM7</td>
<td>XMM0 - XMM15</td>
<td>XMM0 - XMM15</td>
</tr>
<tr>
<td>YMM</td>
<td>YMM0 - YMM7</td>
<td>YMM0 - YMM7</td>
<td>YMM0 - YMM15</td>
<td>YMM0 - YMM15</td>
</tr>
<tr>
<td>ZMM</td>
<td>ZMM0 - ZMM7</td>
<td>ZMM0 - ZMM7</td>
<td>ZMM0 - YMM15</td>
<td>ZMM0 - YMM15</td>
</tr>
</tbody>
</table>

__regcall Data Type Classification

Parameters and return values for __regcall are classified by data type and are passed in the registers of the classes shown in the following table.

```
NOTE All types assigned to XMM, YMM, or ZMM in a non-SSE target are passed in the stack.
```

<table>
<thead>
<tr>
<th>Type (for both unsigned and signed types)</th>
<th>IA-32</th>
<th>Intel® 64</th>
</tr>
</thead>
<tbody>
<tr>
<td>bool, char, int, enum, _Decimal32, long, pointer</td>
<td>GPR</td>
<td>GPR</td>
</tr>
<tr>
<td>short, __mmask{8,16,32,64}</td>
<td>GPR</td>
<td>GPR</td>
</tr>
<tr>
<td>long long, __int64</td>
<td>See Structured Data Type Classification Rules</td>
<td>GPR</td>
</tr>
<tr>
<td>_Decimal64</td>
<td>XMM</td>
<td>GPR</td>
</tr>
</tbody>
</table>
### Type (for both unsigned and signed types)

<table>
<thead>
<tr>
<th>Type (IA-32)</th>
<th>IA-32</th>
<th>Intel® 64</th>
</tr>
</thead>
<tbody>
<tr>
<td>long double</td>
<td>FP</td>
<td>FP</td>
</tr>
<tr>
<td>float, double, float128, _Decimal128</td>
<td>XMM</td>
<td>XMM</td>
</tr>
<tr>
<td>__m128, __m128i, __m128d</td>
<td>XMM</td>
<td>XMM</td>
</tr>
<tr>
<td>__m256, __m256i, __m256d</td>
<td>YMM</td>
<td>YMM</td>
</tr>
<tr>
<td>__m512, __m512i, __m512d</td>
<td>ZMM</td>
<td>ZMM</td>
</tr>
<tr>
<td>complex type, struct, union</td>
<td>See Structured Data Type Classification Rules</td>
<td>See Structured Data Type Classification Rules</td>
</tr>
</tbody>
</table>

**NOTE** For the purpose of structured types, the classification of GPR class is used.

**NOTE** On systems based on IA-32 architecture, these 64-bit integer types (long long, __int64) get classified to the GPR class and are passed in two registers, as if they were implemented as a structure of two 32-bit integer fields.

Types that are smaller in size than registers than registers of their associated class are passed in the lower part of those registers; for example, float is passed in the lower four bytes of an XMM register.

### __regcall Structured Data Type Classification Rules

Structures/unions and complex types are classified similarly to what is described in the x86_64 ABI, with the following exceptions:

- There is no limitation on the overall size of a structure.
- The register classes for basic types are given in Data Type Classifications.
- For systems based on the IA-32 architecture, classification is performed on four-bytes. For systems based on other architectures, classification is performed on eight-bytes.

### __regcall Placement in Registers or on the Stack

After the classification described in Data Type Classifications and Structured Data Type Classification Rules, __regcall parameters and return values are either put into registers specified in Available Registers or placed in memory, according to the following:

- Each chunk (eight bytes on systems based on Intel® 64 architecture or four-bytes on systems based on IA-32 architecture) of a value of Data Type is assigned a register class. If enough registers from Available Registers are available, the whole value is passed in registers, otherwise the value is passed using the stack.
- If the classification were to use one or more register classes, then the registers of these classes from the table in Available Registers are used, in the order given there.
- If no more registers are available in one of the required register classes, then the whole value is put on the stack.
__regcall Registers that Preserve Their Values

The following registers preserve their values across a __regcall call, as long as they were not used for passing a parameter or returning a value:

<table>
<thead>
<tr>
<th>Register Class/ABI</th>
<th>IA-32</th>
<th>Intel® 64 for Linux*</th>
<th>Intel® 64 for Windows*</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPR</td>
<td>ESI, EDI, EBX, EBP, ESP</td>
<td>R12 - R15, RBX, RBP, RSP</td>
<td>R12 - R15, RBX, RBP, RSP</td>
</tr>
<tr>
<td>FP</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
<tr>
<td>MMX</td>
<td>None</td>
<td>None</td>
<td>None</td>
</tr>
<tr>
<td>XMM</td>
<td>XMM4 - XMM7</td>
<td>XMM8 - XMM15</td>
<td>XMM8 - XMM15</td>
</tr>
<tr>
<td>YMM</td>
<td>XMM4 - XMM7</td>
<td>XMM8 - XMM15</td>
<td>XMM8 - XMM15</td>
</tr>
<tr>
<td>ZMM</td>
<td>XMM4 - XMM7</td>
<td>XMM8 - XMM15</td>
<td>XMM8 - XMM15</td>
</tr>
</tbody>
</table>

All other registers do not preserve their values across this call.

Compiler Options

This compiler supports many compiler options you can use in your applications.

In this section, we provide the following:

- An alphabetical list of compiler options that includes their short descriptions
- Lists of deprecated and removed options
- General rules for compiler options and the conventions we use when referring to options
- Details about what appears in the compiler option descriptions
- A description of each compiler option. The descriptions appear under the option’s functional category. Within each category, the options are listed in alphabetical order.

For details about new functionality, such as new compiler options, see the Release Notes for the product.

Alphabetical Option List

The following table lists all the current compiler options in alphabetical order.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A, QA</td>
<td>Specifies an identifier for an assertion.</td>
</tr>
<tr>
<td>alias-const, Qalias-const</td>
<td>Determines whether the compiler assumes a parameter of type pointer-to-const does not alias with a parameter of type pointer-to-non-const.</td>
</tr>
<tr>
<td>align</td>
<td>Determines whether variables and arrays are naturally aligned.</td>
</tr>
<tr>
<td>ansi</td>
<td>Enables language compatibility with the gcc option ansi.</td>
</tr>
<tr>
<td>ansi-alias, Qansi-alias</td>
<td>Enables or disables the use of ANSI aliasing rules in optimizations.</td>
</tr>
<tr>
<td>ansi-alias-check, Qansi-alias-check</td>
<td>Enables or disables the ansi-alias checker.</td>
</tr>
</tbody>
</table>
arch

tells the compiler which features it may target, including which instruction sets it may generate.

auto-ilp32, Qauto-ilp32

instructs the compiler to analyze the program to determine if there are 64-bit pointers that can be safely shrunk into 32-bit pointers and if there are 64-bit longs (on Linux* systems) that can be safely shrunk into 32-bit longs.

auto-p32

instructs the compiler to analyze the program to determine if there are 64-bit pointers that can be safely shrunk to 32-bit pointers.

ax, Qax

tells the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit.

B

specifies a directory that can be used to find include files, libraries, and executables.

Bdynamic

enables dynamic linking of libraries at run time.

bigobj

increases the number of sections that an object file can contain.

Bstatic

enables static linking of a user's library.

Bsymbolic

binds references to all global symbols in a program to the definitions within a user's shared library.

Bsymbolic-functions

binds references to all global function symbols in a program to the definitions within a user's shared library.

C

places comments in preprocessed source output.

c

prevents linking.

check

checks for certain conditions at run time.

check-pointers, Qcheck-pointers

determines whether the compiler checks bounds for memory access through pointers.

check-pointers-dangling, Qcheck-pointers-dangling

determines whether the compiler checks for dangling pointer references.

check-pointers-mpx, Qcheck-pointers-mpx

determines whether the compiler checks bounds for memory access through pointers on processors that support Intel® Memory Protection Extensions (Intel® MPX).

check-pointers-narrowing, Qcheck-pointers-narrowing

determines whether the compiler enables or disables the narrowing of pointers to structure fields.

check-pointers-undimensioned, Qcheck-pointers-undimensioned

determines whether the compiler checks bounds for memory access through arrays that are declared without dimensions.

clang-name

specifies the name of the Clang compiler that should be used to set up the environment for C compilations.

clangxx-name

specifies the name of the Clang++ compiler that should be used to set up the environment for C++ compilations.

complex-limited-range, Qcomplex-limited-range

determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

cxxlib

determines whether the compiler links using the C++ run-time libraries and header files provided by gcc.

D

defines a macro name that can be associated with an optional value.
dD, QdD
Same as option -dM, but outputs #define directives in preprocessed source.

ddebug (Linux* and macOS* )
Enables or disables generation of debugging information.

ddebug (Windows*)
Enables or disables generation of debugging information.

device-math-lib
Enables or disables certain device libraries. This is a deprecated option that may be removed in a future release.

diag, Qdiag
Controls the display of diagnostic information during compilation.

diag-dump, Qdiag-dump
Tells the compiler to print all enabled diagnostic messages.

diag-enable=power, Qdiag-enable:power
Controls whether diagnostics are enabled for possibly inefficient code that may affect power consumption on IA-32 and Intel® 64 architectures.

diag-error-limit, Qdiag-error-limit
Specifies the maximum number of errors allowed before compilation stops.

diag-file, Qdiag-file
Causes the results of diagnostic analysis to be output to a file.

diag-file-append, Qdiag-file-append
Causes the results of diagnostic analysis to be appended to a file.

diag-id-numbers, Qdiag-id-numbers
Determines whether the compiler displays diagnostic messages by using their ID number values.

diag-once, Qdiag-once
Tells the compiler to issue one or more diagnostic messages only once.

dM, QdM
Tells the compiler to output macro definitions in effect after preprocessing.

dN, QdN
Same as option -dD, but outputs #define directives contain only macro names.

dryrun
Specifies that driver tool commands should be shown but not executed.

dumpmachine
Displays the target machine and operating system configuration.

dumpversion
Displays the version number of the compiler.
dynamiclib
Invokes the libtool command to generate dynamic libraries.
dynamic-linker
Specifies a dynamic linker other than the default.
E
Causes the preprocessor to send output to stdout.
early-template-check
Lets you semantically check template function template prototypes before instantiation.

EH
Specifies the model of exception handling to be performed.

EP
Causes the preprocessor to send output to stdout, omitting #line directives.

F ( macOS* )
Adds a framework directory to the head of an include file search path.

F (Windows*)
Specifies the stack reserve amount for the program.

Fa
Specifies that an assembly listing file should be generated.

FA
Specifies the contents of an assembly listing file.

fabi-version
Instructs the compiler to select a specific ABI implementation.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>falias, Oa</td>
<td>Determines whether aliasing is assumed in a program.</td>
</tr>
<tr>
<td>falign-functions, Qfnalign</td>
<td>Tells the compiler to align functions on an optimal byte boundary.</td>
</tr>
<tr>
<td>falign-loops, Qalign-loops</td>
<td>Aligns loops to a power-of-two byte boundary.</td>
</tr>
<tr>
<td>falign-stack</td>
<td>Tells the compiler the stack alignment to use on entry to routines. This option is deprecated and will be removed in a future release.</td>
</tr>
<tr>
<td>fargument-alias, Qalias-args</td>
<td>Determines whether function arguments can alias each other.</td>
</tr>
<tr>
<td>fargument-noalias-global</td>
<td>Tells the compiler that function arguments cannot alias each other and cannot alias global storage.</td>
</tr>
<tr>
<td>fasm-blocks</td>
<td>Enables the use of blocks and entire functions of assembly code within a C or C++ file.</td>
</tr>
<tr>
<td>fast</td>
<td>Maximizes speed across the entire program.</td>
</tr>
<tr>
<td>fast-transcendentals, Qfast-transcendentals</td>
<td>Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.</td>
</tr>
<tr>
<td>fasynchronous-unwind-tables</td>
<td>Determines whether unwind information is precise at an instruction boundary or at a call boundary.</td>
</tr>
<tr>
<td>fblocks</td>
<td>Determines whether Apple* blocks are enabled or disabled.</td>
</tr>
<tr>
<td>fbuiltin, Oi</td>
<td>Enables or disables inline expansion of intrinsic functions.</td>
</tr>
<tr>
<td>FC</td>
<td>Displays the full path of source files passed to the compiler in diagnostics.</td>
</tr>
<tr>
<td>fcode-asm</td>
<td>Produces an assembly listing with machine code annotations.</td>
</tr>
<tr>
<td>fcommon</td>
<td>Determines whether the compiler treats common symbols as global definitions.</td>
</tr>
<tr>
<td>FD</td>
<td>Generates file dependencies related to the Microsoft* C/C++ compiler.</td>
</tr>
<tr>
<td>Fd</td>
<td>Lets you specify a name for a program database (PDB) file created by the compiler.</td>
</tr>
<tr>
<td>fdata-sections, Gw</td>
<td>Places each data item in its own COMDAT section.</td>
</tr>
<tr>
<td>fdefer-pop</td>
<td>Determines whether the compiler always pops the arguments to each function call as soon as that function returns.</td>
</tr>
<tr>
<td>Fe</td>
<td>Specifies the name for a built program or dynamic-link library.</td>
</tr>
<tr>
<td>felimate-unused-debug-types, Qeliminate-unused-debug-types</td>
<td>Controls the debug information emitted for types declared in a compilation unit.</td>
</tr>
<tr>
<td>femit-class-debug-always</td>
<td>Controls the format and size of debug information generated by the compiler for C++ classes.</td>
</tr>
<tr>
<td>fexceptions</td>
<td>Enables exception handling table generation.</td>
</tr>
<tr>
<td>fextend-arguments, Qextend-arguments</td>
<td>Controls how scalar integer arguments are extended in calls to unprototyped and varargs functions.</td>
</tr>
<tr>
<td>ffat-lto-objects</td>
<td>Determines whether a fat link-time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation (-c -ipo).</td>
</tr>
<tr>
<td>ffnalias, Ow</td>
<td>Determines whether aliasing is assumed within functions.</td>
</tr>
</tbody>
</table>
ffreestanding, Qfreestanding
Ensures that compilation takes place in a freestanding environment.

ffriend-injection
Causes the compiler to inject friend functions into the enclosing namespace.

ffunction-sections, Gy
Places each function in its own COMDAT section.

fgnu89-inline
Tells the compiler to use C89 semantics for inline functions when in C99 mode.

fimf-absolute-error, Qimf-absolute-error
Defines the maximum allowable absolute error for math library function results.

fimf-accuracy-bits, Qimf-accuracy-bits
Defines the relative error for math library function results, including division and square root.

fimf-arch-consistency, Qimf-arch-consistency
Ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture.

fimf-domain-exclusion, Qimf-domain-exclusion
Indicates the input arguments domain on which math functions must provide correct results.

fimf-force-dynamic-target, Qimf-force-dynamic-target
Instructs the compiler to use run-time dispatch in calls to math functions.

fimf-max-error, Qimf-max-error
Defines the maximum allowable relative error for math library function results, including division and square root.

fimf-precision, Qimf-precision
Lets you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.

fimf-use-svml, Qimf-use-svml
Instructs the compiler to use the Short Vector Math Library (SVML) rather than the Intel® C++ Compiler Classic Math Library (LIBM) to implement math library functions.

finline
Tells the compiler to inline functions declared with __inline and perform C++ inlining.

finline-functions
Enables function inlining for single file compilation.

finline-limit
Lets you specify the maximum size of a function to be inlined.

finstrument-functions, Qinstrument-functions
Determines whether function entry and exit points are instrumented.

FI
Tells the preprocessor to include a specified file name as the header file.

fixed
Causes the linker to create a program that can be loaded only at its preferred base address.

fjump-tables
Determines whether jump tables are generated for switch statements.

fkeep-static-consts, Qkeep-static-consts
Tells the compiler to preserve allocation of variables that are not referenced in the source.

Fm
Tells the linker to generate a link map file. This is a deprecated option. There is no replacement option.

fma, Qfma
Determines whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor.

fmath-errno
Tells the compiler that errno can be reliably tested after calls to standard math library functions.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fmerge-constants</td>
<td>Determines whether the compiler and linker attempt to merge identical</td>
</tr>
<tr>
<td></td>
<td>constants (string constants and floating-point constants) across</td>
</tr>
<tr>
<td></td>
<td>compilation units.</td>
</tr>
<tr>
<td>fmerge-debug-strings</td>
<td>Causes the compiler to pool strings used in debugging information.</td>
</tr>
<tr>
<td>fminshared</td>
<td>Specifies that a compilation unit is a component of a main program and</td>
</tr>
<tr>
<td></td>
<td>should not be linked as part of a shareable object.</td>
</tr>
<tr>
<td>fmpc-privatize</td>
<td>Enables or disables privatization of all static data for the MultiProcessor</td>
</tr>
<tr>
<td></td>
<td>Computing environment (MPC) unified parallel runtime.</td>
</tr>
<tr>
<td>fms-dialect</td>
<td>Enables support for a language dialect that is compatible with Microsoft*</td>
</tr>
<tr>
<td></td>
<td>Windows*, while maintaining link compatibility with gcc.</td>
</tr>
<tr>
<td>fmudflap</td>
<td>The compiler instruments risky pointer operations to prevent buffer</td>
</tr>
<tr>
<td></td>
<td>overflows and invalid heap use. This is a deprecated option. There is no</td>
</tr>
<tr>
<td></td>
<td>replacement option. You can consider using the Pointer Checker options</td>
</tr>
<tr>
<td></td>
<td>(such as option -check-pointers).</td>
</tr>
<tr>
<td>fno-gnu-keywords</td>
<td>Tells the compiler to not recognize typeof as a keyword.</td>
</tr>
<tr>
<td>fno-implicit-inline-templates</td>
<td>Tells the compiler to not emit code for implicit instantiations of inline</td>
</tr>
<tr>
<td></td>
<td>templates.</td>
</tr>
<tr>
<td>fno-implicit-templates</td>
<td>Tells the compiler to not emit code for non-inline templates that are</td>
</tr>
<tr>
<td></td>
<td>instantiated implicitly.</td>
</tr>
<tr>
<td>fnon-call-exceptions</td>
<td>Allows trapping instructions to throw C++ exceptions.</td>
</tr>
<tr>
<td>fnon-lvalue-assign</td>
<td>Determines whether casts and conditional expressions can be used as</td>
</tr>
<tr>
<td></td>
<td>lvalues.</td>
</tr>
<tr>
<td>fno-operator-names</td>
<td>Disables support for the operator names specified in the standard.</td>
</tr>
<tr>
<td>fno-rtti</td>
<td>Disables support for run-time type information (RTTI).</td>
</tr>
<tr>
<td>fnsplit, Qfnsplit</td>
<td>Enables function splitting.</td>
</tr>
<tr>
<td>Fo</td>
<td>Specifies the name for an object file.</td>
</tr>
<tr>
<td>fomit-frame-pointer, Oy</td>
<td>Determines whether EBP is used as a general-purpose register in</td>
</tr>
<tr>
<td></td>
<td>optimizations.</td>
</tr>
<tr>
<td>fopenmp-device-lib</td>
<td>Enables or disables certain device libraries for an OpenMP* target.</td>
</tr>
<tr>
<td>foptimize-sibling-calls</td>
<td>Determines whether the compiler optimizes tail recursive calls.</td>
</tr>
<tr>
<td>Fp</td>
<td>Lets you specify an alternate path or file name for precompiled header</td>
</tr>
<tr>
<td></td>
<td>files.</td>
</tr>
<tr>
<td>fpack-struct</td>
<td>Specifies that structure members should be packed together.</td>
</tr>
<tr>
<td>fpascal-strings</td>
<td>Tells the compiler to allow for Pascal-style string literals.</td>
</tr>
<tr>
<td>fpermissive</td>
<td>Tells the compiler to allow for non-conformant code.</td>
</tr>
<tr>
<td>fpic</td>
<td>Determines whether the compiler generates position-independent code.</td>
</tr>
<tr>
<td>fpie</td>
<td>Tells the compiler to generate position-independent code. The generated</td>
</tr>
<tr>
<td></td>
<td>code can only be linked into executables.</td>
</tr>
<tr>
<td>fp-model, fp</td>
<td>Controls the semantics of floating-point calculations.</td>
</tr>
<tr>
<td>fp-port, Qfp-port</td>
<td>Rounds floating-point results after floating-point operations.</td>
</tr>
</tbody>
</table>
fprotect-parens, Qprotect-parens
Determine whether the optimizer honors parentheses when floating-point expressions are evaluated.

fp-speculation, Qfp-speculation
Tells the compiler the mode in which to speculate on floating-point operations.

fp-stack-check, Qfp-stack-check
Tells the compiler to generate extra code after every function call to ensure that the floating-point stack is in the expected state.

fp-trap, Qfp-trap
Sets the floating-point trapping mode for the main routine.

fp-trap-all, Qfp-trap-all
Sets the floating-point trapping mode for all routines.

FR
Invokes the Microsoft* C/C++ compiler and tells it to produce a BSCMAKE .sbr file with complete symbolic information.

freg-struct-return
Tells the compiler to return struct and union values in registers when possible.

fshort-enums
Tells the compiler to allocate as many bytes as needed for enumerated types.

fsource-asm
Produces an assembly listing with source code annotations.

fstack-protector
Enables or disables stack overflow security checks for certain (or all) routines.

fstack-security-check
Determines whether the compiler generates code that detects some buffer overruns.

fsyntax-only
Tells the compiler to check only for correct syntax.

ftemplate-depth, Qtemplate-depth
Control the depth in which recursive templates are expanded.

ftls-model
Changes the thread local storage (TLS) model.

ftrapuv, Qtrapuv
Initializes stack local variables to an unusual value to aid error detection.

ftz, Qftz
Flushes denormal results to zero.

funroll-all-loops
Unroll all loops even if the number of iterations is uncertain when the loop is entered.

funsigned-bitfields
Determines whether the default bitfield type is changed to unsigned.

funsigned-char
Change default char type to unsigned.

fuse-ld
Tells the compiler to use a different linker instead of the default linker (ld).

fverbose-asm
Produces an assembly listing with compiler comments, including options and version information.

fvisibility
Specifies the default visibility for global symbols or the visibility for symbols in a file.

fvisibility-inlines-hidden
Causes inline member functions (those defined in the class declaration) to be marked hidden.

fzero-initialized-in-bss, Qzero-initialized-in-bss
Determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.

g
Tells the compiler to generate a level of debugging information in the object file.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GA</td>
<td>Enables faster access to certain thread-local storage (TLS) variables.</td>
</tr>
<tr>
<td>gcc, gcc-sys</td>
<td>Determines whether certain GNU macros are defined or undefined.</td>
</tr>
<tr>
<td>gcc-include-dir</td>
<td>Controls whether the gcc-specific include directory is put into the system include path.</td>
</tr>
<tr>
<td>gcc-name</td>
<td>Lets you specify the name of the GCC compiler that should be used to set up the environment for C compilations.</td>
</tr>
<tr>
<td>Gd</td>
<td>Makes __cdecl the default calling convention.</td>
</tr>
<tr>
<td>gdwarf</td>
<td>Lets you specify a DWARF Version format when generating debug information.</td>
</tr>
<tr>
<td>Ge</td>
<td>Enables stack-checking for all functions. This is a deprecated option. The replacement option is /Gs0.</td>
</tr>
<tr>
<td>GF</td>
<td>Enables read-only string-pooling optimization.</td>
</tr>
<tr>
<td>Gh</td>
<td>Calls a function to aid custom user profiling.</td>
</tr>
<tr>
<td>GH</td>
<td>Calls a function to aid custom user profiling.</td>
</tr>
<tr>
<td>global-hoist, Qglobal-hoist</td>
<td>Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.</td>
</tr>
<tr>
<td>Gm</td>
<td>Enables a minimal rebuild.</td>
</tr>
<tr>
<td>gnu-prefix</td>
<td>Lets you specify a prefix that will be added to the names of gnu utilities called from the compiler.</td>
</tr>
<tr>
<td>GR</td>
<td>Enables or disables C++ Run Time Type Information (RTTI).</td>
</tr>
<tr>
<td>Gr</td>
<td>Makes __fastcall the default calling convention.</td>
</tr>
<tr>
<td>grecord-gcc-switches</td>
<td>Causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.</td>
</tr>
<tr>
<td>GS</td>
<td>Determines whether the compiler generates code that detects some buffer overruns.</td>
</tr>
<tr>
<td>Gs</td>
<td>Lets you control the threshold at which the stack checking routine is called or not called.</td>
</tr>
<tr>
<td>gsplit-dwarf</td>
<td>Creates a separate object file containing DWARF debug information.</td>
</tr>
<tr>
<td>GT</td>
<td>Enables fiber-safe thread-local storage of data.</td>
</tr>
<tr>
<td>guard</td>
<td>Enables the control flow protection mechanism.</td>
</tr>
<tr>
<td>guide, Qguide</td>
<td>Lets you set a level of guidance for auto-vectorization, auto parallelism, and data transformation.</td>
</tr>
<tr>
<td>guide-data-trans, Qguide-data-trans</td>
<td>Lets you set a level of guidance for data transformation.</td>
</tr>
<tr>
<td>guide-file, Qguide-file</td>
<td>Causes the results of guided auto parallelism to be output to a file.</td>
</tr>
<tr>
<td>guide-file-append, Qguide-file-append</td>
<td>Causes the results of guided auto parallelism to be appended to a file.</td>
</tr>
<tr>
<td>guide-opt, Qguide-opt</td>
<td>Tells the compiler to analyze certain code and generate recommendations that may improve optimizations.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>guide-par, Qguide-par</td>
<td>Lets you set a level of guidance for auto parallelism.</td>
</tr>
<tr>
<td>guide-vec, Qguide-vec</td>
<td>Lets you set a level of guidance for auto-vectorization.</td>
</tr>
<tr>
<td>Gv</td>
<td>Tells the compiler to use the vector calling convention (__vectorcall) when passing vector type arguments.</td>
</tr>
<tr>
<td>gxx-name</td>
<td>Lets you specify the name of the g++ compiler that should be used to set up the environment for C++ compilations.</td>
</tr>
<tr>
<td>GZ</td>
<td>Initializes all local variables. This is a deprecated option. The replacement option is /RTC1.</td>
</tr>
<tr>
<td>Gz</td>
<td>Makes __stdcall the default calling convention.</td>
</tr>
<tr>
<td>H, QH</td>
<td>Tells the compiler to display the include file order and continue compilation.</td>
</tr>
<tr>
<td>H (Windows*)</td>
<td>Causes the compiler to limit the length of external symbol names. This is a deprecated option. There is no replacement option.</td>
</tr>
<tr>
<td>help</td>
<td>Displays all supported compiler options or supported compiler options within a specified category of options.</td>
</tr>
<tr>
<td>help-pragma, Qhelp-pragma</td>
<td>Displays all supported pragmas.</td>
</tr>
<tr>
<td>homeparams</td>
<td>Tells the compiler to store parameters passed in registers to the stack.</td>
</tr>
<tr>
<td>hotpatch</td>
<td>Tells the compiler to prepare a routine for hotpatching.</td>
</tr>
<tr>
<td>I</td>
<td>Specifies an additional directory to search for include files.</td>
</tr>
<tr>
<td>I-</td>
<td>Splits the include path.</td>
</tr>
<tr>
<td>icc, Qicl</td>
<td>Determines whether certain Intel®-specific compiler macros are defined or undefined.</td>
</tr>
<tr>
<td>idirafter</td>
<td>Adds a directory to the second include file search path.</td>
</tr>
<tr>
<td>imacros</td>
<td>Allows a header to be specified that is included in front of the other headers in the translation unit.</td>
</tr>
<tr>
<td>inline-calloc, Qinline-calloc</td>
<td>Tells the compiler to inline calls to calloc() as calls to malloc() and memset().</td>
</tr>
<tr>
<td>inline-factor, Qinline-factor</td>
<td>Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.</td>
</tr>
<tr>
<td>inline-forceinline, Qinline-forceinline</td>
<td>Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.</td>
</tr>
<tr>
<td>inline-level, Ob</td>
<td>Specifies the level of inline function expansion.</td>
</tr>
<tr>
<td>inline-max-per-compile, Qinline-max-per-compile</td>
<td>Specifies the maximum number of times inlining may be applied to an entire compilation unit.</td>
</tr>
<tr>
<td>inline-max-per-routine, Qinline-max-per-routine</td>
<td>Specifies the maximum number of times the inliner may inline into a particular routine.</td>
</tr>
<tr>
<td>inline-max-size, Qinline-max-size</td>
<td>Specifies the lower limit for the size of what the inliner considers to be a large routine.</td>
</tr>
<tr>
<td>inline-max-total-size, Qinline-max-total-size</td>
<td>Specifies how much larger a routine can normally grow when inline expansion is performed.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>inline-min-caller-growth</td>
<td>Lets you specify a function size n for which functions of size ≤ n do not contribute to the estimated growth of the caller when inlined.</td>
</tr>
<tr>
<td>inline-min-size, Qinline-min-size</td>
<td>Specifies the upper limit for the size of what the inliner considers to be a small routine.</td>
</tr>
<tr>
<td>intel-extensions, Qintel-extensions</td>
<td>Enables or disables all Intel® C and Intel® C++ language extensions.</td>
</tr>
<tr>
<td>intel-freestanding</td>
<td>Lets you compile in the absence of a gcc environment.</td>
</tr>
<tr>
<td>intel-freestanding-target-os</td>
<td>Lets you specify the target operating system for compilation.</td>
</tr>
<tr>
<td>ip, Qip</td>
<td>Determines whether additional interprocedural optimizations for single-file compilation are enabled.</td>
</tr>
<tr>
<td>ip-no-inlining, Qip-no-inlining</td>
<td>Disables full and partial inlining enabled by interprocedural optimization options.</td>
</tr>
<tr>
<td>ip-no-pinlining, Qip-no-pinlining</td>
<td>Disables partial inlining enabled by interprocedural optimization options.</td>
</tr>
<tr>
<td>ipo, Qipo</td>
<td>Enables interprocedural optimization between files.</td>
</tr>
<tr>
<td>ipo-c, Qipo-c</td>
<td>Tells the compiler to optimize across multiple files and generate a single object file.</td>
</tr>
<tr>
<td>ipo-jobs, Qipo-jobs</td>
<td>Specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).</td>
</tr>
<tr>
<td>ipo-S, Qipo-S</td>
<td>Tells the compiler to optimize across multiple files and generate a single assembly file.</td>
</tr>
<tr>
<td>ipo-separate, Qipo-separate</td>
<td>Tells the compiler to generate one object file for every source file.</td>
</tr>
<tr>
<td>ipp-link, Qipp-link</td>
<td>Controls whether the compiler links to static or dynamic threaded Intel® Integrated Performance Primitives (Intel® IPP) run-time libraries.</td>
</tr>
<tr>
<td>iprefix</td>
<td>Lets you indicate the prefix for referencing directories that contain header files.</td>
</tr>
<tr>
<td>iquote</td>
<td>Adds a directory to the front of the include file search path for files included with quotes but not brackets.</td>
</tr>
<tr>
<td>isystem</td>
<td>Specifies a directory to add to the start of the system include path.</td>
</tr>
<tr>
<td>iwithprefix</td>
<td>Appends a directory to the prefix passed in by -iprefix and puts it on the include search path at the end of the include directories.</td>
</tr>
<tr>
<td>iwithprefixbefore</td>
<td>Similar to -iwithprefix except the include directory is placed in the same place as -I command-line include directories.</td>
</tr>
<tr>
<td>J</td>
<td>Sets the default character type to unsigned.</td>
</tr>
<tr>
<td>Kc++, TP</td>
<td>Tells the compiler to process all source or unrecognized file types as C++ source files. This is a deprecated option. The replacement option for Kc++ is -x c++; the replacement option for /TP is /Tp&lt;file&gt;.</td>
</tr>
<tr>
<td>I</td>
<td>Tells the linker to search for a specified library when linking.</td>
</tr>
<tr>
<td>L</td>
<td>Tells the linker to search for libraries in a specified directory before searching the standard directories.</td>
</tr>
<tr>
<td>LD</td>
<td>Specifies that a program should be linked as a dynamic-link (DLL) library.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>link</td>
<td>Passes user-specified options directly to the linker at compile time.</td>
</tr>
<tr>
<td>m</td>
<td>Tells the compiler which features it may target, including which instruction set architecture (ISA) it may generate.</td>
</tr>
<tr>
<td>M, QM</td>
<td>Tells the compiler to generate makefile dependency lines for each source file.</td>
</tr>
<tr>
<td>m32, m64, Qm32, Qm64</td>
<td>Tells the compiler to generate code for a specific architecture.</td>
</tr>
<tr>
<td>m80387</td>
<td>Specifies whether the compiler can use x87 instructions.</td>
</tr>
<tr>
<td>malign-double</td>
<td>Determines whether double, long double, and long long types are naturally aligned. This option is equivalent to specifying option align.</td>
</tr>
<tr>
<td>malign-mac68k</td>
<td>Aligns structure fields on 2-byte boundaries (m68k compatible).</td>
</tr>
<tr>
<td>malign-natural</td>
<td>Aligns larger types on natural size-based boundaries (overrides ABI).</td>
</tr>
<tr>
<td>malign-power</td>
<td>Aligns based on ABI-specified alignment rules.</td>
</tr>
<tr>
<td>map-opts, Qmap-opts</td>
<td>Maps one or more compiler options to their equivalent on a different operating system.</td>
</tr>
<tr>
<td>march</td>
<td>Tells the compiler to generate code for processors that support certain features.</td>
</tr>
<tr>
<td>masm</td>
<td>Tells the compiler to generate the assembler output file using a selected dialect.</td>
</tr>
<tr>
<td>mauto-arch, Qauto-arch</td>
<td>Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit.</td>
</tr>
<tr>
<td>mbranches-within-32B-boundaries, Qbranches-within-32B-boundaries</td>
<td>Tells the compiler to align branches and fused branches on 32-byte boundaries for better performance.</td>
</tr>
<tr>
<td>mcmode</td>
<td>Tells the compiler to use a specific memory model to generate code and store data.</td>
</tr>
<tr>
<td>mconditional-branch, Qconditional-branch</td>
<td>Lets you identify and fix code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction.</td>
</tr>
<tr>
<td>MD</td>
<td>Tells the linker to search for unresolved references in a multithreaded, dynamic-link run-time library.</td>
</tr>
<tr>
<td>MD, QMD</td>
<td>Preprocess and compile, generating output file containing dependency information ending with extension .d.</td>
</tr>
<tr>
<td>mdynamic-no-pic</td>
<td>Generates code that is not position-independent but has position-independent external references.</td>
</tr>
<tr>
<td>MF, QMF</td>
<td>Tells the compiler to generate makefile dependency information in a file.</td>
</tr>
<tr>
<td>MG, QMG</td>
<td>Tells the compiler to generate makefile dependency lines for each source file.</td>
</tr>
<tr>
<td>minstruction, Qinstruction</td>
<td>Determines whether MOVBE instructions are generated for certain Intel® processors.</td>
</tr>
<tr>
<td>mlong-double</td>
<td>Lets you override the default configuration of the long double data type.</td>
</tr>
</tbody>
</table>
MM, QMM  
Tells the compiler to generate makefile dependency lines for each source file.

MMD, QMMD  
Tells the compiler to generate an output file containing dependency information.

momit-leaf-frame-pointer  
Determines whether the frame pointer is omitted or kept in leaf functions.

MP  
Tells the compiler to add a phony target for each dependency.

mp1, Qprec  
Improves floating-point precision and consistency.

MP-force  
Disables the default heuristics used when compiler option /MP is specified. This lets you control the number of processes spawned.

MQ  
Changes the default target rule for dependency generation.

mregparm  
Lets you control the number registers used to pass integer arguments.

mregparm-version  
Determines which version of the Application Binary Interface (ABI) is used for the regparm parameter passing convention.

mstringop-inline-threshold, Qstringop-inline-threshold  
Tells the compiler to not inline calls to buffer manipulation functions such as memcpy and memset when the number of bytes the functions handle are known at compile time and greater than the specified value.

mstringop-strategy, Qstringop-strategy  
Lets you override the internal decision heuristic for the particular algorithm used when implementing buffer manipulation functions such as memcpy and memset.

MT  
Tells the linker to search for unresolved references in a multithreaded, static run-time library.

MT, QMT  
Changes the default target rule for dependency generation.

mtune, tune  
Performs optimizations for specific processors but does not cause extended instruction sets to be used (unlike -march).

multibyte-chars, Qmultibyte-chars  
Determines whether multi-byte characters are supported.

multiple-processes, MP  
Creates multiple processes that can be used to compile large numbers of source files at the same time.

noBool  
Disables the bool keyword.

no-bss-init, Qnobss-init  
Tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables. This option is deprecated and will be removed in a future release.

nodefaultlibs  
Prevents the compiler from using standard libraries when linking.

no-intel-lib, Qno-intel-lib  
Disables linking to specified Intel® libraries, or to all Intel® libraries.

no-libgcc  
Prevents the linking of certain gcc-specific libraries.

nolib-inline  
Disables inline expansion of standard library or intrinsic functions.

nologo  
Tells the compiler to not display compiler version information.

nostartfiles  
Prevents the compiler from using standard startup files when linking.

nostdinc++  
Do not search for header files in the standard directories for C++, but search the other standard directories.
<table>

<tr>
<td>Ox</td>
<td>Enables maximum optimizations.</td>
</tr>
<tr>
<td>p</td>
<td>Compiles and links for function profiling with gprof(1).</td>
</tr>
<tr>
<td>P</td>
<td>Tells the compiler to stop the compilation process and write the results to a file.</td>
</tr>
<tr>
<td>par-affinity, Qpar-affinity</td>
<td>Specifies thread affinity.</td>
</tr>
<tr>
<td>parallel, Qparallel</td>
<td>Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.</td>
</tr>
<tr>
<td>parallel-source-info, Qparallel-source-info</td>
<td>Enables or disables source location emission when OpenMP* or auto-parallelism code is generated.</td>
</tr>
<tr>
<td>par-loops, Qpar-loops</td>
<td>Lets you select between old or new implementations of parallel loop support.</td>
</tr>
<tr>
<td>par-num-threads, Qpar-num-threads</td>
<td>Specifies the number of threads to use in a parallel region.</td>
</tr>
<tr>
<td>par-runtime-control, Qpar-runtime-control</td>
<td>Generates code to perform run-time checks for loops that have symbolic loop bounds.</td>
</tr>
<tr>
<td>par-schedule, Qpar-schedule</td>
<td>Lets you specify a scheduling algorithm for loop iterations.</td>
</tr>
<tr>
<td>par-threshold, Qpar-threshold</td>
<td>Sets a threshold for the auto-parallelization of loops.</td>
</tr>
<tr>
<td>pc, Qpc</td>
<td>Enables control of floating-point significand precision.</td>
</tr>
<tr>
<td>pch-create</td>
<td>Tells the compiler to create a precompiled header file.</td>
</tr>
<tr>
<td>pch-dir</td>
<td>Tells the compiler the location for precompiled header files.</td>
</tr>
<tr>
<td>pch</td>
<td>Tells the compiler to use appropriate precompiled header files.</td>
</tr>
<tr>
<td>pch-use</td>
<td>Tells the compiler to use a precompiled header file.</td>
</tr>
<tr>
<td>pdbfile</td>
<td>Lets you specify the name for a program database (PDB) file created by the linker.</td>
</tr>
<tr>
<td>pie</td>
<td>Determines whether the compiler generates position-independent code that will be linked into an executable.</td>
</tr>
<tr>
<td>pragma-optimization-level</td>
<td>Specifies which interpretation of the optimization_level pragma should be used if no prefix is specified.</td>
</tr>
<tr>
<td>prec-div, Qprec-div</td>
<td>Improves precision of floating-point divides.</td>
</tr>
<tr>
<td>prec-sqrt, Qprec-sqrt</td>
<td>Improves precision of square root implementations.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>print-multi-lib</code></td>
<td>Prints information about where system libraries should be found.</td>
</tr>
<tr>
<td><code>print-sysroot</code></td>
<td>Prints the target sysroot directory that is used during compilation.</td>
</tr>
<tr>
<td><code>prof-data-order</code></td>
<td>Enables or disables data ordering if profiling information is enabled.</td>
</tr>
<tr>
<td><code>prof-dir</code></td>
<td>Specifies a directory for profiling information output files.</td>
</tr>
<tr>
<td><code>prof-file</code></td>
<td>Specifies an alternate file name for the profiling summary files.</td>
</tr>
<tr>
<td><code>prof-func-groups</code></td>
<td>Enables or disables function grouping if profiling information is enabled.</td>
</tr>
<tr>
<td><code>prof-func-order</code></td>
<td>Enables or disables function ordering if profiling information is enabled.</td>
</tr>
<tr>
<td><code>prof-gen</code></td>
<td>Produces an instrumented object file that can be used in profile guided optimization.</td>
</tr>
<tr>
<td><code>prof-gen-sampling</code></td>
<td>Tells the compiler to generate debug discriminators in debug output. This aids in developing more precise sampled profiling output.</td>
</tr>
<tr>
<td><code>prof-hotness-threshold</code></td>
<td>Lets you set the hotness threshold for function grouping and function ordering.</td>
</tr>
<tr>
<td><code>prof-src-dir</code></td>
<td>Determines whether directory information of the source file under compilation is considered when looking up profile data records.</td>
</tr>
<tr>
<td><code>prof-src-root</code></td>
<td>Lets you use relative directory paths when looking up profile data and specifies a directory as the base.</td>
</tr>
<tr>
<td><code>prof-src-root-cwd</code></td>
<td>Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.</td>
</tr>
<tr>
<td><code>prof-use</code></td>
<td>Enables the use of profiling information during optimization.</td>
</tr>
<tr>
<td><code>prof-use-sampling</code></td>
<td>Lets you use data files produced by hardware profiling to produce an optimized executable.</td>
</tr>
<tr>
<td><code>prof-value-profiling</code></td>
<td>Controls which values are value profiled.</td>
</tr>
<tr>
<td><code>pthread</code></td>
<td>Tells the compiler to use pthreads library for multithreading support.</td>
</tr>
<tr>
<td><code>qcf-protection</code></td>
<td>Enables Control-flow Enforcement Technology (CET) protection, which defends your program from certain attacks that exploit vulnerabilities. This option offers preliminary support for CET.</td>
</tr>
<tr>
<td><code>Qcov-dir</code></td>
<td>Specifies a directory for profiling information output files that can be used with the codecov or tselect tool.</td>
</tr>
<tr>
<td><code>Qcov-file</code></td>
<td>Specifies an alternate file name for the profiling summary files that can be used with the codecov or tselect tool.</td>
</tr>
<tr>
<td><code>Qcov-gen</code></td>
<td>Produces an instrumented object file that can be used with the codecov or tselect tool.</td>
</tr>
<tr>
<td><code>Qcxx-features</code></td>
<td>Enables standard C++ features without disabling Microsoft* features.</td>
</tr>
<tr>
<td><code>qdaal</code></td>
<td>Tells the compiler to link to certain libraries in the Intel® oneAPI Data Analytics Library ( oneDAL ).</td>
</tr>
<tr>
<td><code>Qgcc-dialect</code></td>
<td>Enables support for a limited gcc-compatible dialect on Windows*.</td>
</tr>
<tr>
<td><code>Qinline-dllimport</code></td>
<td>Determines whether dllimport functions are inlined.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Qinstall</td>
<td>Specifies the root directory where the compiler installation was performed.</td>
</tr>
<tr>
<td>qipp, Qipp</td>
<td>Tells the compiler to link to the some or all of the Intel® Integrated</td>
</tr>
<tr>
<td></td>
<td>Performance Primitives (Intel® IPP) libraries.</td>
</tr>
<tr>
<td>Qlocation</td>
<td>Specifies the directory for supporting tools.</td>
</tr>
<tr>
<td>Qlong-double</td>
<td>Changes the default size of the long double data type.</td>
</tr>
<tr>
<td>qmkl, Qmkl</td>
<td>Tells the compiler to link to certain libraries in the Intel® oneAPI Math</td>
</tr>
<tr>
<td></td>
<td>Kernel Library (oneMKL). On Windows systems, you must specify this option</td>
</tr>
<tr>
<td></td>
<td>at compile time.</td>
</tr>
<tr>
<td>Qms</td>
<td>Tells the compiler to emulate Microsoft* compatibility bugs.</td>
</tr>
<tr>
<td>qopenmp, Qopenmp</td>
<td>Enables recognition of OpenMP* features and tells the parallelizer to</td>
</tr>
<tr>
<td></td>
<td>generate multi-threaded code based on OpenMP* directives.</td>
</tr>
<tr>
<td>qopenmp-lib, Qopenmp-lib</td>
<td>Lets you specify an OpenMP* run-time library to use for linking.</td>
</tr>
<tr>
<td>qopenmp-link</td>
<td>Controls whether the compiler links to static or dynamic OpenMP* run-time</td>
</tr>
<tr>
<td></td>
<td>libraries.</td>
</tr>
<tr>
<td>qopenmp-simd, Qopenmp-simd</td>
<td>Enables or disables OpenMP* SIMD compilation.</td>
</tr>
<tr>
<td>qopenmp-stubs, Qopenmp-stubs</td>
<td>Enables compilation of OpenMP* programs in sequential mode.</td>
</tr>
<tr>
<td>qopenmp-threadprivate, Qopenmp-threadprivate</td>
<td>Lets you specify an OpenMP* threadprivate implementation.</td>
</tr>
<tr>
<td>qopt-args-in-regs, Qopt-args-in-regs</td>
<td>Determines whether calls to routines are optimized by passing</td>
</tr>
<tr>
<td></td>
<td>parameters in registers instead of on the stack. This option is deprecated</td>
</tr>
<tr>
<td></td>
<td>and will be removed in a future release.</td>
</tr>
<tr>
<td>qopt-assume-safe-padding, Qopt-assume-safe-padding</td>
<td>Determines whether the compiler assumes that variables and dynamically</td>
</tr>
<tr>
<td></td>
<td>allocated memory are padded past the end of the object.</td>
</tr>
<tr>
<td>qopt-block-factor, Qopt-block-factor</td>
<td>Lets you specify a loop blocking factor.</td>
</tr>
<tr>
<td>qopt-calloc</td>
<td>Tells the compiler to substitute a call to _intel_fast_calloc() for a call to</td>
</tr>
<tr>
<td></td>
<td>calloc().</td>
</tr>
<tr>
<td>qopt-class-analysis, Qopt-class-analysis</td>
<td>Determines whether C++ class hierarchy information is used to analyze</td>
</tr>
<tr>
<td>qopt-dynamic-align, Qopt-dynamic-align</td>
<td>and resolve C++ virtual function calls at compile time.</td>
</tr>
<tr>
<td>Qoption</td>
<td>Passes options to a specified tool.</td>
</tr>
<tr>
<td>qopt-jump-tables, Qopt-jump-tables</td>
<td>Enables or disables generation of jump tables for switch statements.</td>
</tr>
<tr>
<td>qopt-malloc-options</td>
<td>Lets you specify an alternate algorithm for malloc().</td>
</tr>
<tr>
<td>qopt-matmul, Qopt-matmul</td>
<td>Enables or disables a compiler-generated Matrix Multiply (matmul) library</td>
</tr>
<tr>
<td>qopt-mem-layout-trans, Qopt-mem-layout-trans</td>
<td>Controls the level of memory layout transformations performed by the compiler.</td>
</tr>
</tbody>
</table>
Enables or disables the optimization for multiple adjacent gather/scatter type vector memory references.

Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.

Enables or disables prefetch insertion optimization.

Specifies the prefetch distance to be used for compiler-generated prefetches inside loops.

Supports the prefetchW instruction in Intel® microarchitecture code name Broadwell and later.

Selects the method that the register allocator uses to partition each routine into regions.

Tells the compiler to generate an optimization report.

Enables the annotated source listing feature and specifies its format.

Enables the annotated source listing feature and specifies the site where optimization messages appear in the annotated source in inlined cases of loop optimizations.

Determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated.

Specifies that the output for the optimization report goes to a file, stderr, or stdout.

Tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application.

Specifies the format for an optimization report.

Displays the optimizer phases available for report generation and a short description of what is reported at each level.

Specifies whether mangled or unmangled names should appear in the optimization report.

Tells the compiler that optimization report information should be generated in a separate file for each object.

Specifies one or more optimizer phases for which optimization reports are generated.

Tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring.

Enables generation of streaming stores for optimization.

Determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops.

Defines a level of zmm registers usage.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>qoverride-limits, Qoverride-limits</td>
<td>Lets you override certain internal compiler limits that are intended to prevent excessive memory usage or compile times for very large, complex compilation units.</td>
</tr>
<tr>
<td>Qpar-adjust-stack</td>
<td>Tells the compiler to generate code to adjust the stack size for a fiber-based main thread.</td>
</tr>
<tr>
<td>Qpatchable-addresses</td>
<td>Tells the compiler to generate code such that references to statically assigned addresses can be patched.</td>
</tr>
<tr>
<td>Qpchi</td>
<td>Enable precompiled header coexistence to reduce build time.</td>
</tr>
<tr>
<td>Qsafeseh</td>
<td>Registers exception handlers for safe exception handling.</td>
</tr>
<tr>
<td>Qsfalign</td>
<td>Specifies stack alignment for functions. This option is deprecated and will be removed in a future release.</td>

<tr>
<td>qsimd-serialize-fp-reduction, Qsimd-serialize-fp-reduction</td>
<td>Tells the compiler to serialize floating-point reduction when vectorizing SIMD loops.</td>
</tr>
<tr>
<td>qtbb, Qtbb</td>
<td>Tells the compiler to link to the Intel® oneAPI Threading Building Blocks (oneTBB) libraries.</td>
</tr>
<tr>
<td>Quse-msasm-symbols</td>
<td>Tells the compiler to use a dollar sign (&quot;$&quot;) when producing symbol names.</td>
</tr>
<tr>
<td>Qvc</td>
<td>Specifies compatibility with Microsoft* Visual C++* or Microsoft* Visual Studio*.</td>
</tr>
<tr>
<td>Qvla</td>
<td>Determines whether variable length arrays are enabled.</td>
</tr>
<tr>
<td>rcd, Qrcd</td>
<td>Enables fast float-to-integer conversions. This is a deprecated option. There is no replacement option.</td>
</tr>
<tr>
<td>regcall, Qregcall</td>
<td>Tells the compiler that the __regcall calling convention should be used for functions that do not directly specify a calling convention.</td>
</tr>
<tr>
<td>restrict, Qrestrict</td>
<td>Determines whether pointer disambiguation is enabled with the restrict qualifier.</td>
</tr>
<tr>
<td>RTC</td>
<td>Enables checking for certain run-time conditions.</td>
</tr>
<tr>
<td>S</td>
<td>Causes the compiler to compile to an assembly file only and not link.</td>
</tr>
<tr>
<td>save-temps, Qsave-temps</td>
<td>Tells the compiler to save intermediate files created during compilation.</td>
</tr>
<tr>
<td>scalar-rep, Qscalar-rep</td>
<td>Enables or disables the scalar replacement optimization done by the compiler as part of loop transformations.</td>
</tr>
<tr>
<td>shared</td>
<td>Tells the compiler to produce a dynamic shared object instead of an executable.</td>
</tr>
<tr>
<td>shared-intel</td>
<td>Causes Intel-provided libraries to be linked in dynamically.</td>
</tr>
<tr>
<td>shared-libgcc</td>
<td>Links the GNU libgcc library dynamically.</td>
</tr>
<tr>
<td>showIncludes</td>
<td>Tells the compiler to display a list of the include files.</td>
</tr>
<tr>
<td>simd, Qsimd</td>
<td>Enables or disables compiler interpretation of simd pragmas.</td>
</tr>
<tr>
<td>simd-function-pointers, Qsimd-function-pointers</td>
<td>Enables or disables pointers to simd-enabled functions.</td>
</tr>
</tbody>
</table>
sox  
Tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain functions.

static  
Prevents linking with shared libraries.

static-intel  
Causes Intel-provided libraries to be linked in statically.

static-libgcc  
Links the GNU libgcc library statically.

staticlib  
Invokes the libtool command to generate static libraries.

static-libstdc++  
Links the GNU libstdc++ library statically.

std, Qstd  
Tells the compiler to conform to a specific language standard.

stdlib  
Lets you select the C++ library to be used for linking.

strict-ansi  
Tells the compiler to implement strict ANSI conformance dialect.

sysroot  
Specifies the root directory where headers and libraries are located.

T  
Tells the linker to read link commands from a file.

Tc  
Tells the compiler to process all source or unrecognized file types as C source files.

TC  
Tells the compiler to process a file as a C source file.

Tp  
Tells the compiler to process a file as a C++ source file.

traceback  
Tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.

U  
Undefines any definition currently in effect for the specified macro.

u (Linux*)  
Tells the compiler the specified symbol is undefined.

u (Windows*)  
Disables all predefined macros and assertions.

undef  
Disables all predefined macros.

unroll, Qunroll  
Tells the compiler the maximum number of times to unroll loops.

unroll-aggressive, Qunroll-aggressive  
Determines whether the compiler uses more aggressive unrolling for certain loops.

use-asm, Quse-asm  
Tells the compiler to produce objects through the assembler. This is a deprecated option. There is no replacement option.

use-intel-optimized-headers, Quse-intel-optimized-headers  
Determines whether the performance headers directory is added to the include path search list.

use-msasm  
Enables the use of blocks and entire functions of assembly code within a C or C++ file.

V  
Displays the compiler version information.

V (Windows*)  
Places the text string specified into the object file being generated by the compiler.

v  
Specifies that driver tool commands should be displayed and executed.

vd  
Enables or suppresses hidden vtordisp members in C++ objects.

**General Rules for Compiler Options**

This section describes general rules for compiler options and it contains information about how we refer to compiler option names in descriptions.

**General Rules for Compiler Options**

You cannot combine options with a single dash (Linux* and macOS*) or slash (Windows*). For example:

- On Linux* and macOS* systems: This is incorrect: `-Ec`; this is correct: `-E -c`
- On Windows* systems: This is incorrect: `/Ec`; this is correct: `/E /c`

All compiler options are case sensitive. Some options have different meanings depending on their case; for example, option "c" prevents linking, but option "C" places comments in preprocessed source output.

Options specified on the command line apply to all files named on the command line.

Options can take arguments in the form of file names, strings, letters, or numbers. If a string includes spaces, the string must be enclosed in quotation marks. For example:

- On Linux* and macOS* systems, `-unroll [=n]` or `-Uname (string)`
- On Windows* systems, `/Famyfile.s (file name)` or `/V"version 5.0" (string)`

Compiler options can appear in any order.

On Windows* systems, all compiler options must precede `/link` options, if any, on the command line.

Unless you specify certain options, the command line will both compile and link the files you specify.

You can abbreviate some option names, entering as many characters as are needed to uniquely identify the option.

Certain options accept one or more keyword arguments following the option name. For example, the `ax` option accepts several keywords.

To specify multiple keywords, you typically specify the option multiple times.

Compiler options remain in effect for the whole compilation unless overridden by a compiler `#pragma`.

To disable an option, specify the negative form of the option.

On Windows* systems, you can also disable one or more optimization options by specifying option `/Od` last on the command line.

---

**NOTE**

On Windows* systems, the `/Od` option is part of a mutually-exclusive group of options that includes `/Od`, `/O1`, `/O2`, `/O3`, and `/Ox`. The last of any of these options specified on the command line will override the previous options from this group.
If there are enabling and disabling versions of an option on the command line, the last one on the command line takes precedence.

**How We Refer to Compiler Option Names in Descriptions**

The following conventions are used as shortcuts when referencing compiler option names in descriptions:

- Many options have names that are the same on Linux*, macOS*, and Windows*, except that the Windows form starts with an initial / and the Linux and macOS* form starts with an initial -. Within text, such option names are shown without the initial character; for example, `check`.

- Many options have names that are the same on Linux*, macOS*, and Windows*, except that the Windows form starts with an initial Q. Within text, such option names are shown as `[Q]option-name`.

  For example, if you see a reference to `[Q]ipo`, the Linux* and macOS* form of the option is `-ipo` and the Windows form of the option is `/Qipo`.

- Several compiler options have similar names except that the Linux* and macOS* forms start with an initial `q` and the Windows form starts with an initial Q. Within text, such option names are shown as `[q or Q]option-name`.

  For example, if you see a reference to `[q or Q]opt-report`, the Linux* and macOS* form of the option is `-qopt-report` and the Windows form of the option is `/Qopt-report`.

Compiler option names that are more dissimilar are shown in full.

**What Appears in the Compiler Option Descriptions**

This section contains details about what appears in the option descriptions.

Following sections include individual descriptions of all the current compiler options. The option descriptions are arranged by functional category. Within each category, the option names are listed in alphabetical order.

Each option description contains the following information:

- The primary name for the option and a short description of the option.

- **Architecture Restrictions**
  This section only appears if there is a known architecture restriction for the option.

  Restrictions may appear for any of the following architectures:

  - IA-32 architecture
  - Intel® 64 architecture

  Certain operating systems are not available on all the above architectures. For the latest information, please check your Release Notes.

- **Syntax**
  This shows the syntax on Linux* and macOS* systems and the syntax on Windows* systems. If the option has no syntax on one of these systems, that is, the option is not valid on a particular operating system, it will specify "None".

- **Arguments**
  This shows any arguments (parameters) that are related to the option. If the option has no arguments, it will specify "None".

- **Default**
  This shows the default setting for the option.

- **Description**
  This shows the full description of the option. It may also include further information on any applicable arguments.

- **IDE Equivalent**
  This shows information related to the integrated development environment (IDE) Property Pages on Linux*, macOS*, and Windows* systems. It shows on which Property Page the option appears, and under what category it's listed. The Windows* IDE is Microsoft* Visual Studio* .NET; the Linux* IDE is Eclipse*; the macOS* IDE is Xcode*. If the option has no IDE equivalent, it will specify "None".

- **Alternate Options**
This lists any options that are synonyms for the described option. If there are no alternate option names, it will show "None".
Some of the alternate option names are deprecated and may be removed in future releases.
Many options have an older spelling where underscores ("_") instead of hyphens ("-") connect the main option names. The older spelling is a valid alternate option name.

Some option descriptions may also have the following:
- **Example**
  This shows a short example that includes the option
- **See Also**
  This shows where you can get further information on the option or related options.

## Optimization Options

**falias, Oa**  
*Determines whether aliasing is assumed in a program.*

**Syntax**

**Linux OS and macOS:**
- `-falias`
- `-fno-alias`

**Windows OS:**
- `/Oa`
- `/Oa-`

**Arguments**

None

**Default**

- `-falias`
- or `/Oa-`

On Linux* and macOS*, aliasing is assumed in the program. On Windows*, aliasing is not assumed in a program.

**Description**

This option determines whether aliasing is assumed in a program.

If you specify `-fno-alias` or `/Oa`, aliasing is not assumed in a program.

If you specify `-falias` or `/Oa-`, aliasing is assumed in a program. However, this may affect performance.

**IDE Equivalent**

Visual Studio: None

Eclipse: **Data > Assume No Aliasing in Program**

Xcode: **Data > Assume No Aliasing in Program**

**Alternate Options**

None

**See Also**

`ffnalias` compiler option
**fast**

Maximizes speed across the entire program.

**Syntax**

Linux OS:

- `fast`

macOS:

- `fast`

Windows OS:

/`fast`

**Arguments**

None

**Default**

OFF

The optimizations that maximize speed are not enabled.

**Description**

This option maximizes speed across the entire program.

It sets the following options:

- On macOS* systems: `-ipo, -mdynamic-no-pic,-O3,-no-prec-div,-fp-model fast=2, and -xHost`
- On Windows* systems: `/O3, /Qipo, /Qprec-div-, /fp:fast=2, and /QxHost`
- On Linux* systems: `-ipo, -O3, -no-prec-div,-static,-fp-model fast=2, and -xHost`

When option `fast` is specified, you can override the `[Q]xHost` option setting by specifying a different processor-specific `[Q]x` option on the command line. However, the last option specified on the command line takes precedence.

For example:

- On Linux* systems, if you specify option `-fast -xSSE3`, option `-xSSE3` takes effect. However, if you specify `-xSSE3 -fast`, option `-xHost` takes effect.
- On Windows* systems, if you specify option `/fast /QxSSE3`, option `/QxSSE3` takes effect. However, if you specify `/QxSSE3 /fast`, option `/QxHost` takes effect.

For implications on non-Intel processors, refer to the `[Q]xHost` documentation.

---

**NOTE**

Option `fast` sets some aggressive optimizations that may not be appropriate for all applications. The resulting executable may not run on processor types different from the one on which you compile. You should make sure that you understand the individual optimization options that are enabled by option `fast`.

---

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.
**Product and Performance Information**

fp-model, fp compiler option
xHost, QxHost
  compiler option
x, Qx
  compiler option

**fbuiltin, Oi**

*Enables or disables inline expansion of intrinsic functions.*

**Syntax**

**Linux OS:**
- `-fbuiltin[-name]`
- `-fno-builtin[-name]`

**macOS:**
- `-fbuiltin[-name]`
- `-fno-builtin[-name]`

**Windows OS:**
/`Oi[-]`
/Qno-builtin-name

**Arguments**

`name`  
Is a list of one or more intrinsic functions. If there is more than one intrinsic function, they must be separated by commas.

**Default**

ON  
Inline expansion of intrinsic functions is enabled.

**Description**

This option enables or disables inline expansion of one or more intrinsic functions.

If `-fno-builtin-name` or `/Qno-builtin-name` is specified, inline expansion is disabled for the named functions. If `name` is not specified, `-fno-builtin` or `/Oi` disables inline expansion for all intrinsic functions.

For a list of built-in functions affected by `-fbuiltin`, search for "built-in functions" in the appropriate gcc* documentation.
For a list of built-in functions affected by `/Oi`, search for "/Oi" in the appropriate Microsoft* Visual C/C++* documentation.

**IDE Equivalent**
Visual Studio: **Optimization > Enable Intrinsic Functions (/Oi)**
Eclipse: None
Xcode: None

**Alternate Options**
None

**fdefer-pop**
*Determines whether the compiler always pops the arguments to each function call as soon as that function returns.*

**Syntax**

**Linux OS and macOS:**
- `fdefer-pop`
- `fno-defer-pop`

**Windows OS:**
None

**Arguments**
None

**Default**

- `fdefer-pop`  
  The compiler uses default optimizations that may result in deferred clearance of the stack arguments.

**Description**
This option determines whether the compiler always pops the arguments to each function call as soon as that function returns.

If you want the compiler to always pop the arguments to each function call as soon as that function returns, specify `fno-defer-pop`.

For processors that must pop arguments after a function call, the compiler normally lets arguments accumulate on the stack for several function calls and pops them all at once.

**IDE Equivalent**
None

**Alternate Options**
None
**ffnalias, Ow**

*Determines whether aliasing is assumed within functions.*

**Syntax**

**Linux OS and macOS:**
- `-ffnalias`
- `-fno-fnalias`

**Windows OS:**
- `/Ow`
- `/Ow-`

**Arguments**
None

**Default**
- `-ffnalias` or `/Ow`
  Aliasing is assumed within functions.

- or `/Ow` (Default)

**Description**

This option determines whether aliasing is assumed within functions.

If you specify `-fno-fnalias` or `/Ow-`, aliasing is not assumed within functions, but it is assumed across calls.

If you specify `-ffnalias` or `/Ow`, aliasing is assumed within functions.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**

falias  compiler option

**foptimize-sibling-calls**

*Determines whether the compiler optimizes tail recursive calls.*

**Syntax**

**Linux OS:**
- `-foptimize-sibling-calls`
- `-fno-optimize-sibling-calls`

**macOS:**
- `-foptimize-sibling-calls`

- `-fno-optimize-sibling-calls`
-fno-optimize-sibling-calls

**Windows OS:**
None

**Arguments**
None

**Default**
- The compiler optimizes tail recursive calls.

foptimize
esibling-calls

**Description**
This option determines whether the compiler optimizes tail recursive calls. It enables conversion of tail recursion into loops.

If you do not want to optimize tail recursive calls, specify -fno-optimize-sibling-calls.

Tail recursion is a special form of recursion that doesn't use stack space. In tail recursion, a recursive call is converted to a GOTO statement that returns to the beginning of the function. In this case, the return value of the recursive call is only used to be returned. It is not used in another expression. The recursive function is converted into a loop, which prevents modification of the stack space used.

**IDE Equivalent**
None

**Alternate Options**
None

---

**fprotect-parens, Qprotect-parens**
*Determines whether the optimizer honors parentheses when floating-point expressions are evaluated.*

**Syntax**

**Linux OS and macOS:**
- -fprotect-parens
- -fno-protect-parens

**Windows OS:**
/Qprotect-parens
/Qprotect-parens-

**Arguments**
None
Default

- **fno-protect-parens**
  or
  /Qprotect-parens-

Description

This option determines whether the optimizer honors parentheses when determining the order of floating-point expression evaluation.

When option **-fprotect-parens** (Linux* and macOS*) or /Qprotect-parens (Windows*) is specified, the optimizer will maintain the order of evaluation imposed by parentheses in the code.

When option **-fno-protect-parens** (Linux* and macOS*) or /Qprotect-parens- (Windows*) is specified, the optimizer may reorder floating-point expressions without regard for parentheses if it produces faster executing code.

IDE Equivalent

None

Alternate Options

None

Example

Consider the following expression:

\[ A + (B + C) \]

By default, the parentheses are ignored and the compiler is free to re-order the floating-point operations based on the optimization level, the setting of option **-fp-model** (Linux* and macOS*) or /fp (Windows*), etc. to produce faster code. Code that is sensitive to the order of operations may produce different results (such as with some floating-point computations).

However, if **-fprotect-parens** (Linux* and macOS*) or /Qprotect-parens (Windows*) is specified, parentheses around floating-point expressions (including complex floating-point and decimal floating-point) are honored and the expression will be interpreted following the normal precedence rules, that is, \( B + C \) will be computed first and then added to \( A \).

This may produce slower code than when parentheses are ignored. If floating-point sensitivity is a specific concern, you should use option **-fp-model precise** (Linux* and macOS*) or /fp:precise (Windows*) to ensure precision because it controls all optimizations that may affect precision.

See Also

fp-model, fp  compiler option

GF

*Enables read-only string-pooling optimization.*

Syntax

Linux OS:

None

macOS:

None
Windows OS:
/GF

Arguments
None

Default
OFF  Read/write string-pooling optimization is enabled.

Description
This option enables read only string-pooling optimization.

IDE Equivalent
Visual Studio: **Code Generation > Enable String Pooling**
Eclipse: None
Xcode: None

Alternate Options
None

nolib-inline
_Disables inline expansion of standard library or intrinsic functions._

Syntax
Linux OS:
-nolib-inline

macOS:
-nolib-inline

Windows OS:
None

Arguments
None

Default
OFF  The compiler inlines many standard library and intrinsic functions.

Description
This option disables inline expansion of standard library or intrinsic functions. It prevents the unexpected results that can arise from inline expansion of these functions.

IDE Equivalent
Visual Studio: None
Eclipse: **Optimization > Disable Intrinsic Inline Expansion**
Xcode: **Optimization > Disable Intrinsic Inline Expansion**

**Alternate Options**

None

**O**

*Specifies the code optimization for applications.*

**Syntax**

Linux OS:

- `-O [n]`

macOS:

- `-O [n]`

Windows OS:

- `/O [n]`

**Arguments**

*n*  
Is the optimization level. Possible values are 1, 2, or 3. On Linux* and macOS* systems, you can also specify 0.

**Default**

02  
Optimizes for code speed. This default may change depending on which other compiler options are specified. For details, see below.

**Description**

This option specifies the code optimization for applications.

<table>

</tr>
<tr>
<td></td>
<td>Many routines in the shared libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.</td>
</tr>
<tr>
<td><strong>03</strong></td>
<td>Performs 02 optimizations and enables more aggressive loop transformations such as Fusion, Block-Unroll-and-Jam, and collapsing IF statements.</td>
</tr>
</tbody>
</table>
This option may set other options. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release.

When `O3` is used with options `-ax` or `-x` (Linux) or with options `/Qax` or `/Qx` (Windows), the compiler performs more aggressive data dependency analysis than for `O2`, which may result in longer compilation times.

The `O3` optimizations may not cause higher performance unless loop and memory access transformations take place. The optimizations may slow down code in some cases compared to `O2` optimizations.

The `O3` option is recommended for applications that have loops that heavily use floating-point calculations and process large data sets.

Many routines in the shared libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

The last `O` option specified on the command line takes precedence over any others.

`Od` compiler option

**Od**

*Disables all optimizations.*

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/Od

**Arguments**

None
Default
OFF
The compiler performs default optimizations.

Description
This option disables all optimizations. It can be used for selective optimizations, such as a combination of /Od and /Ob1 (disables all optimizations, but enables inlining).

On IA-32 architecture, this option sets the /Oy- option.

IDE Equivalent
Visual Studio: Optimization > Optimization
Eclipse: None
Xcode: None

Alternate Options
Linux and macOS*: -O0
Windows: None

See Also
- compiler option (see O0)

Ofast
Sets certain aggressive options to improve the speed of your application.

Syntax
Linux OS:
-Ofast
macOS:
-Ofast
Windows OS:
None

Arguments
None

Default
OFF
The aggressive optimizations that improve speed are not enabled.

Description
This option improves the speed of your application.

It sets compiler options -O3, -no-prec-div, and -fp-model fast=2.

On Linux* systems, this option is provided for compatibility with gcc.
IDE Equivalent
None

Alternate Options
None

See Also
O compiler option
prec-div, Qprec-div compiler option
fast compiler option
fp-model, fp compiler option

Os
Enables optimizations that do not increase code size; it produces smaller code size than O2.

Syntax
Linux OS:
-Os
macOS:
-Os
Windows OS:
/Os

Arguments
None

Default
OFF Optimizations are made for code speed. However, if O1 is specified, Os is the default.

Description
This option enables optimizations that do not increase code size; it produces smaller code size than O2. It disables some optimizations that increase code size for a small speed benefit.
This option tells the compiler to favor transformations that reduce code size over transformations that produce maximum performance.

IDE Equivalent
Visual Studio: Optimization > Favor Size or Speed
Eclipse: None
Xcode: None

Alternate Options
None

See Also
O compiler option
Ot  compiler option

**Ot**

*Enables all speed optimizations.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**

`/Ot`

**Arguments**
None

**Default**

`/Ot`
Optimizations are made for code speed.
If `Od` is specified, all optimizations are disabled. If `O1` is specified, `Os` is the default.

**Description**

This option enables all speed optimizations.

**IDE Equivalent**

Visual Studio: *Optimization > Favor Size or Speed*
Eclipse: None
Xcode: None

**Alternate Options**
None

**See Also**

`o`  compiler option
`Os`  compiler option

**Ox**

*Enables maximum optimizations.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**

`/Ox`
Windows OS:
/Ox

Arguments
None

Default
OFF  The compiler does not enable optimizations.

Description
The compiler enables maximum optimizations by combining the following options:
- /Ob2
- /Oy
- /Ot
- /Oi

IDE Equivalent
Visual Studio: Optimization > Optimization
Eclipse: None
Xcode: None

Alternate Options
None

Code Generation Options

`arch`
*Tell* s the compiler which features it may target, including which instruction sets it may generate.

Syntax

Linux OS:
None

macOS:
None

Windows OS:
/arch:code

Arguments

code
Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

- ALDERLAKE  May generate instructions for processors that support the specified Intel® processor or microarchitecture code name.
- AMBERLAKE
Keyword **ICELAKE** is deprecated and may be removed in a future release.
This option has been deprecated; it is now the same as specifying IA32.

Generates x86/x87 generic code that is compatible with IA-32 architecture. Disables any default extended instruction settings, and any previously set extended instruction settings. It also disables all feature-specific optimizations and instructions.

This value is only available on IA-32 architecture.

Default

SSE2

The compiler may generate Intel® SSE2 and SSE instructions.

Description

This option tells the compiler which features it may target, including which instruction sets it may generate.

Code generated with these options should execute on any compatible, non-Intel processor with support for the corresponding instruction set.

Options `/arch` and `/Qx` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

If you specify both the `/Qax` and `/arch` options, the compiler will not generate Intel-specific instructions.

IDE Equivalent

Visual Studio

Visual Studio: Code Generation > Enable Enhanced Instruction Set

Eclipse

Eclipse: None

**ax**, Qax

*Tell the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit.*

**Syntax**

**Linux OS:**

-ax*code*

**macOS:**

-ax*code*

**Windows OS:**

/Qax*code*

**Arguments**

*code*

Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. The following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

- ALDERLAKE
- AMBERLAKE
- BROADWELL
- CANNONLAKE
- CASCADELAKE
- COFFEELAKE
- COOPERLAKE
- GOLDMONT
- GOLDMONT-PLUS
- HASWELL
- ICELAKE-CLIENT *(or ICELAKE)*
- ICELAKE-SERVER
- IVYBRIDGE
- KABYLAKE
- KNL
- KNM
- ROCKETLAKE
- SANDYBRIDGE
- SAPPHIRERAPIDS
- SILVERMONT
- SKYLAKE
- SKYLAKE-AVX512
- TIGERLAKE
- TREMONT
- WHISKEYLAKE
- COMMON-AVX512

May generate instructions for processors that support the specified Intel® processor or microarchitecture code name.

**Keywords**

- KNL and SILVERMONT are only available on Windows* and Linux* systems.

- Keyword ICELAKE is deprecated and may be removed in a future release.

May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection Instructions (CDI), as well as the instructions enabled with CORE-AVX2.
CORE-AVX512  May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection Instructions (CDI), Intel® AVX-512 Doubleword and Quadword Instructions (DQI), Intel® AVX-512 Byte and Word Instructions (BWI) and Intel® AVX-512 Vector Length extensions, as well as the instructions enabled with CORE-AVX2.

CORE-AVX2  May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

CORE-AVX-I  May generate Float-16 conversion instructions and the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

AVX  May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

SSE4.2  May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel processors.

SSE4.1  May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.

SSSE3  May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions for Intel® processors. For macOS* systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.

SSE3  May generate Intel® SSE3, SSE2, and SSE instructions for Intel® processors. This value is not available on macOS* systems.

SSE2  May generate Intel® SSE2 and SSE instructions for Intel® processors. This value is not available on macOS* systems.

You can specify more than one code value. When specifying more than one code value, each value must be separated with a comma. See the Examples section below.

Default

OFF  No auto-dispatch code is generated. Feature-specific code is generated and is controlled by the setting of the following compiler options:

- Linux*: -m and -x
- Windows*: /arch and /Qx
- macOS*: -x

Description

This option tells the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit. It also generates a baseline code path. The Intel feature-specific auto-dispatch path is usually more optimized than the baseline path. Other options, such as O3, control how much optimization is performed on the baseline path.
The baseline code path is determined by the architecture specified by options -m or -x (Linux* and macOS*) or options /arch or /Qx (Windows*). While there are defaults for the [Q]x option that depend on the operating system being used, you can specify an architecture and optimization level for the baseline code that is higher or lower than the default. The specified architecture becomes the effective minimum architecture for the baseline code path.

If you specify both the [Q]ax and [Q]x options, the baseline code will only execute on Intel® processors compatible with the setting specified for the [Q]x.

If you specify both the -ax and -m options (Linux and macOS*) or the /Qax and /arch options (Windows), the baseline code will execute on non-Intel processors compatible with the setting specified for the -m or /arch option.

If you specify both the -ax and -march options (Linux and macOS*), or the /Qax and /arch options (Windows), the compiler will not generate Intel-specific instructions. This is because specifying -march disables -ax and specifying /arch disables /Qax.

The [Q]ax option tells the compiler to find opportunities to generate separate versions of functions that take advantage of features of the specified instruction features.

If the compiler finds such an opportunity, it first checks whether generating a feature-specific version of a function is likely to result in a performance gain. If this is the case, the compiler generates both a feature-specific version of a function and a baseline version of the function. At run time, one of the versions is chosen to execute, depending on the Intel® processor in use. In this way, the program can benefit from performance gains on more advanced Intel processors, while still working properly on older processors and non-Intel processors. A non-Intel processor always executes the baseline code path.

You can use more than one of the feature values by combining them. For example, you can specify -axSSE4.1,SSSE3 (Linux and macOS*) or /QaxSSE4.1,SSSE3 (Windows). You cannot combine the old style, deprecated options and the new options. For example, you cannot specify -axSSE4.1,T (Linux and macOS*) or /QaxSSE4.1,T (Windows).

Examples
The following shows an example of how to specify this option:

<table>
<thead>
<tr>
<th>icpc -axSKYLAKE file.cpp</th>
<th>Linux* and macOS* systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>icl /QaxSKYLAKE file.cpp</td>
<td>Windows* systems</td>
</tr>
</tbody>
</table>

The following shows an example of how to specify more than one code value:

<table>
<thead>
<tr>
<th>icpc -axSKYLAKE,BROADWELL file.cpp</th>
<th>Linux* and macOS* systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>icl /QaxBROADWELL,SKYLAKE file.cpp</td>
<td>Windows* systems</td>
</tr>
</tbody>
</table>

Note that the comma-separated list must have no spaces between the names.

EH
Specifies the model of exception handling to be performed.

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/EH<type>
/EH<type>-

Arguments
type

Specifies the exception handling model. Possible values are:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Specifies the asynchronous C++ exception handling model.</td>
</tr>
<tr>
<td>s</td>
<td>Specifies the synchronous C++ exception handling model.</td>
</tr>
<tr>
<td>c</td>
<td>Tells the compiler to assume that extern &quot;C&quot; functions do not throw exceptions.</td>
</tr>
<tr>
<td>r</td>
<td>Tells the compiler to always generate runtime termination checks for all noexcept functions. It forces runtime termination checks in all functions that have a noexcept attribute.</td>
</tr>
</tbody>
</table>

If you specify c, you must also specify a or s.
Default
OFF Some exception handling is performed by default.

Description
This option specifies the model of exception handling to be performed.
If you specify the negative form of the option, it disables the exception handling performed by type or the last type if there are two. For example, if you specify /EHsc-, it is interpreted as /EHs.
For more details about option /EH, see the Microsoft documentation.

IDE Equivalent
Visual Studio: Code Generation > Enable C++ Exceptions
Eclipse: None
Xcode: None

Alternate Options
/EHsc Linux and macOS*: None
Windows: /GX

Qsafeeh compiler option

fasynchronous-unwind-tables
Determines whether unwind information is precise at an instruction boundary or at a call boundary.

Syntax
Linux OS:
-fasynchronous-unwind-tables
-fno-asynchronous-unwind-tables

macOS:
-fasynchronous-unwind-tables
-fno-asynchronous-unwind-tables

Windows OS:
None

Arguments
None

Default
Intel® 64 architecture: The unwind table generated is precise at an instruction boundary, enabling accurate unwinding at any instruction.
IA-32 architecture (Linux* only): The unwind table generated is precise at call boundaries only.

-fno-asynchronous-unwind-tables

**Description**

This option determines whether unwind information is precise at an instruction boundary or at a call boundary. The compiler generates an unwind table in DWARF2 or DWARF3 format, depending on which format is supported on your system.

If **-fno-asynchronous-unwind-tables** is specified, the unwind table is precise at call boundaries only. In this case, the compiler will avoid creating unwind tables for routines such as the following:

- A C++ routine that does not declare objects with destructors and does not contain calls to routines that might throw an exception.
- A C/C++ or Fortran routine compiled without **-fexceptions**, and on Intel® 64 architecture, without **-traceback**.
- A C/C++ or Fortran routine compiled with **-fexceptions** that does not contain calls to routines that might throw an exception.

fexceptions  compiler option

**fdata-sections, Gw**

*Places each data item in its own COMDAT section.*

**Syntax**

**Linux OS:**

-fdata-sections

**macOS:**

-fdata-sections

**Windows OS:**

/Gw

**Arguments**

None

**Default**

OFF  The compiler does not separate functions into COMDATs.

**Description**

This option places each data item in its own COMDAT section.

When using this compiler option, you can add the linker option **-Wl,-gC-sections** (Linux) or **/link /OPT:REF** (Windows), which will remove all unused code.
NOTE
When you put each data item in its own section, it enables the linker to reorder the sections for other possible optimization.

Alternate Options
None

See Also
ffunction-sections, Gy compiler option

fexceptions
Enables exception handling table generation.

Syntax
Linux OS:
- fexceptions
- fno-exceptions
macOS:
- fexceptions
- fno-exceptions
Windows OS:
None

Arguments
None

Default
- fexceptions Exception handling table generation is enabled. Default for C++.
- fno-exceptions Exception handling table generation is disabled. Default for C.

Description
This option enables exception handling table generation. The -fno-exceptions option disables exception handling table generation, resulting in smaller code. When this option is used, any use of exception handling constructs (such as try blocks and throw statements) will produce an error. Exception specifications are parsed but ignored. It also undefines the preprocessor symbol __EXCEPTIONS.

IDE Equivalent
None

Alternate Options
None

ffunction-sections, Gy
Places each function in its own COMDAT section.
Syntax
Linux OS:
-ffunction-sections
macOS:
-ffunction-sections
Windows OS:
/Gy

Arguments
None

Default
OFF The compiler does not separate functions into COMDATs.

Description
This option places each function in its own COMDAT section.
When using this compiler option, you can add the linker option -wL,--gc-sections (Linux) or /link /OPT:REF (Windows), which will remove all unused code.

NOTE
When you put each function in its own section, it enables the linker to reorder the sections for other possible optimization.

IDE Equivalent

fdata-sections, Gw compiler option
fomit-frame-pointer, Oy
Determines whether EBP is used as a general-purpose register in optimizations.

Architecture Restrictions
Option /Oy[-] is only available on IA-32 architecture
Syntax

Linux OS:
- *fomit-frame-pointer*
- *fno-omit-frame-pointer*

macOS:
- *fomit-frame-pointer*
- *fno-omit-frame-pointer*

Windows OS:
/\Oy
/\Oy-

Arguments

None

Default

- *fomit-frame-pointer* or /\Oy
  
  EBP is used as a general-purpose register in optimizations. However, on Linux* and macOS* systems, the default is *fno-omit-frame-pointer* if option -O0 or -g is specified. On Windows* systems, the default is /\Oy- if option /Od is specified.

Description

These options determine whether EBP is used as a general-purpose register in optimizations. Option -fomit-frame-pointer and option /\Oy allows this use. Option -fno-omit-frame-pointer and option /\Oy- disallows it.

Some debuggers expect EBP to be used as a stack frame pointer, and cannot produce a stack backtrace unless this is so. The -fno-omit-frame-pointer and the /\Oy- option directs the compiler to generate code that maintains and uses EBP as a stack frame pointer for all functions so that a debugger can still produce a stack backtrace without doing the following:

- For -fno-omit-frame-pointer: turning off optimizations with -O0
- For /\Oy-: turning off /O1, /O2, or /O3 optimizations

The -fno-omit-frame-pointer option is set when you specify option -O0 or the -g option. The -fomit-frame-pointer option is set when you specify option -O1, -O2, or -O3.

The /\Oy option is set when you specify the /O1, /O2, or /O3 option. Option /\Oy- is set when you specify the /Od option.

Using the -fno-omit-frame-pointer or /\Oy- option reduces the number of available general-purpose registers by 1, and can result in slightly less efficient code.

**NOTE**

For Linux* systems:

There is currently an issue with GCC 3.2 exception handling. Therefore, the compiler ignores this option when GCC 3.2 is installed for C++ and exception handling is turned on (the default).
IDE Equivalent
Visual Studio: **Optimization > Omit Frame Pointers**
Eclipse: **Optimization > Provide Frame Pointer**
Xcode: **Optimization > Provide Frame Pointer**

Alternate Options
Linux and macOS*: `-fp` (this is a deprecated option)
Windows: None

C C++ Calling Conventions

GR
Enables or disables C++ Run Time Type Information (RTTI).

Syntax
Linux OS:
None

macOS:
None
**Windows OS:**

/GR
/GR-

**Arguments**

None

**Default**

/GR C++ Run Time Type Information (RTTI) is enabled.

**Description**

This option enables or disables C++ Run Time Type Information (RTTI).

To disable C++ Run Time Type Information (RTTI), specify option /GR-.

**IDE Equivalent**

Visual Studio: **Language > Enable Run-Time Type Information**

Eclipse: None

Xcode: None

**Alternate Options**

None

**guard**

*Enables the control flow protection mechanism.*

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/guard:keyword

**Arguments**

*keyword* Specifies the the control flow protection mechanism. Possible values are:

*cf[-]* Tells the compiler to analyze control flow of valid targets for indirect calls and to insert code to verify the targets at runtime.

To explicitly disable this option, specify /guard:cf-.

**Default**

OFF The control flow protection mechanism is disabled.
**Description**
This option enables the control flow protection mechanism. It tells the compiler to analyze control flow of valid targets for indirect calls and inserts a call to a checking routine before each indirect call to verify the target of the given indirect call.

The /guard:cf option must be passed to both the compiler and linker.

Code compiled using /guard:cf can be linked to libraries and object files that are not compiled using the option.

This option has been added for Microsoft compatibility. It uses the Microsoft implementation.

**IDE Equivalent**
Visual Studio: **Code Generation > Control Flow Guard**
Eclipse: None
Xcode: None

**Alternate Options**
None

**Gv**
*Tells the compiler to use the vector calling convention (__vectorcall) when passing vector type arguments.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/Gv

**Arguments**
None

**Default**
OFF  The default calling convention is _cdecl.

**Description**
This option tells the compiler to use the vector calling convention (__vectorcall) when passing vector type arguments.

It causes each function in the module to compile as __vectorcall unless the function is declared with a conflicting attribute, or the name of the function is main.

This option has been added for Microsoft compatibility.
For more details about the __vectorcall calling convention, see the Microsoft documentation.
IDE Equivalent
Visual Studio: Advanced > Calling Convention
Eclipse: None
Xcode: None

Alternate Options
None

C C++ Calling Conventions
**hotpatch**
*Tells the compiler to prepare a routine for hotpatching.*

**Syntax**

Linux OS:
- `hotpatch [=n]`

macOS:
None

Windows OS:
`/hotpatch=[n]`

**Arguments**

`n` An integer specifying the number of bytes the compiler should add before the function entry point.

**Default**

**OFF** The compiler does not prepare routines for hotpatching.

**Description**

This option tells the compiler to prepare a routine for hotpatching. The compiler inserts nop padding around function entry points so that the resulting image is hot patchable.

Specifically, the compiler adds nop bytes after each function entry point and enough nop bytes before the function entry point to fit a direct jump instruction on the target architecture.

If `n` is specified, it overrides the default number of bytes that the compiler adds before the function entry point.

**IDE Equivalent**

None

**Alternate Options**

None

**m**
*Tells the compiler which features it may target, including which instruction sets it may generate.*

**Syntax**

Linux OS and macOS:
- `mcode`

Windows OS:
None
**Arguments**

*code*

Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>avx</strong></td>
<td>May generate Intel® Advanced Vector Extensions (Intel® AVX), SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.</td>
</tr>
<tr>
<td><strong>sse4.2</strong></td>
<td>May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.</td>
</tr>
<tr>
<td><strong>sse4.1</strong></td>
<td>May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.</td>
</tr>
<tr>
<td><strong>ssse3</strong></td>
<td>May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.</td>
</tr>
<tr>
<td><strong>sse3</strong></td>
<td>May generate Intel® SSE3, SSE2, and SSE instructions.</td>
</tr>
<tr>
<td><strong>sse2</strong></td>
<td>May generate Intel® SSE2 and SSE instructions. This value is only available on Linux systems.</td>
</tr>
<tr>
<td><strong>sse</strong></td>
<td>This option has been deprecated; it is now the same as specifying <strong>ia32</strong>.</td>
</tr>
<tr>
<td><strong>ia32</strong></td>
<td>Generates x86/x87 generic code that is compatible with IA-32 architecture. Disables any default extended instruction settings, and any previously set extended instruction settings. It also disables all feature-specific optimizations and instructions. This value is only available on Linux* systems using IA-32 architecture.</td>
</tr>
</tbody>
</table>

This compiler option also supports many of the `-m` option settings available with gcc. For more information on gcc `-m` settings, see the gcc documentation.

**Default**

<table>
<thead>
<tr>
<th>Platform</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux* systems:</td>
<td><code>-msse2</code></td>
</tr>
<tr>
<td>macOS* systems:</td>
<td><code>-mssse3</code></td>
</tr>
</tbody>
</table>

For more information on the default values, see Arguments above.

**Description**

This option tells the compiler which features it may target, including which instruction sets it may generate.
Code generated with these options should execute on any compatible, non-Intel processor with support for the corresponding instruction set.

Options -x and -m are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

Linux* systems: For compatibility with gcc, the compiler allows the following options but they have no effect. You will get a warning error, but the instructions associated with the name will not be generated. You should use the suggested replacement options.

<table>
<thead>
<tr>
<th>gcc Compatibility Option (Linux*)</th>
<th>Suggested Replacement Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>-mfma</td>
<td>-march=core-avx2</td>
</tr>
<tr>
<td>-mbmi, -mavx2, -mlzcnt</td>
<td>-march=core-avx2</td>
</tr>
<tr>
<td>-mmovbe</td>
<td>-march=atom -minstruction=movbe</td>

ax, Qax compiler option

arch compiler option

march compiler option

m32, m64 compiler option

**m32, m64, Qm32, Qm64**

* Tells the compiler to generate code for a specific architecture.

**Syntax**

**Linux OS:**

- -m32

- -m64

**macOS:**

- -m64

**Windows OS:**

/Qm32
Arguments
None

Default
OFF
The compiler's behavior depends on the host system.

Description
These options tell the compiler to generate code for a specific architecture.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-m32 or /Qm32</td>
<td>Tells the compiler to generate code for IA-32 architecture.</td>
</tr>
<tr>
<td>-m64 or /Qm64</td>
<td>Tells the compiler to generate code for Intel® 64 architecture.</td>
</tr>
</tbody>
</table>

The -m64 option is the same as macOS* option -arch x86_64. This option is not related to the Intel® C++ Compiler option arch.

On Linux* systems, these options are provided for compatibility with gcc.

IDE Equivalent
None

Alternate Options
None

m80387
Specifies whether the compiler can use x87 instructions.

Syntax

Linux OS:
- m80387
- mno-80387

macOS:
- m80387
- mno-80387

Windows OS:
None

Arguments
None
Default

-m80387 The compiler may use x87 instructions.

Description
This option specifies whether the compiler can use x87 instructions.
If you specify option -mno-80387, it prevents the compiler from using x87 instructions. If the compiler is forced to generate x87 instructions, it issues an error message.

IDE Equivalent
None

Alternate Options
-m[no-]x87

march
Tells the compiler to generate code for processors that support certain features.

Syntax
Linux OS:
-march=processor
macOS:
-march=processor
Windows OS:
None

Arguments

processor

Tells the compiler the code it can generate. Possible values are:

- alderlake
- amberlake
- broadwell
- cannonlake
- cascadelake
- coffeelake
- cooperlake
- goldmont
- goldmont-plus
- haswell
- icelake-client (or icelake)
- icelake-server
- ivybridge
- kabylake
- knl
- knm

May generate instructions for processors that support the specified Intel® processor or microarchitecture code name.

Keywords knl and silvermont are only available on Linux® systems.

Keyword icelake is deprecated and may be removed in a future release.

<td></td>
</tr>
<tr>
<td>pentium</td>
<td></td>
</tr>
</tbody>
</table>

**Default**

pentium4

If no architecture option is specified, value pentium4 is used by the compiler to generate code.
**Description**
This option tells the compiler to generate code for processors that support certain features.
If you specify both the -ax and -march options, the compiler will not generate Intel-specific instructions.

Specifying -march=pentium4 sets -mtune=pentium4.
For compatibility, a number of historical processor values are also supported, but the generated code will not differ from the default.

**masm**
*Tells the compiler to generate the assembler output file using a selected dialect.*

**Syntax**
Linux OS:
- `-masm= dialect`
macOS:
None

Windows OS:
None

**Arguments**

*dialect*  
Is the dialect to use for the assembler output file. Possible values are:

- *att*  
  Tells the compiler to generate the assembler output file using AT&T* syntax.

- *intel*  
  Tells the compiler to generate the assembler output file using Intel syntax.

**Default**

- `-masm=att`
  The compiler generates the assembler output file using AT&T* syntax.

**Description**

This option tells the compiler to generate the assembler output file using a selected dialect.

**IDE Equivalent**

None

**Alternate Options**

None

**mauto-arch, Qauto-arch**

*Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit.*

**Syntax**

**Linux OS and macOS:**

- `-mauto-arch=value`

**Windows OS:**

- `/Qauto-arch:value`

**Arguments**

*value*  
Is any setting you can specify for option `[Q]ax`.

**Default**

- `OFF`  
  No additional execution path is generated.

**Description**

This option tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit. It also generates a baseline code path.
This option cannot be used together with any options that may require Intel-specific optimizations (such as [Q]x or [Q]ax).

IDE Equivalent
None

Alternate Options
None

ax, Qax compiler option

**mbranches-within-32B-boundaries, Qbranches-within-32B-boundaries**
*Tells the compiler to align branches and fused branches on 32-byte boundaries for better performance.*

**Syntax**

**Linux OS:**
- mbranches-within-32B-boundaries
- mno-branches-within-32B-boundaries

**macOS:**
- mbranches-within-32B-boundaries
- mno-branches-within-32B-boundaries

**Windows OS:**
/ Qbranches-within-32B-boundaries
/ Qbranches-within-32B-boundaries-

**Arguments**
None

**Default**
- mno-branches-within-32B-boundaries
  or / Qbranches-within-32B-boundaries-

**Description**
This option tells the compiler to align branches and fused branches on 32-byte boundaries for better performance.

**NOTE**
When you use this option, it may affect binary utilities usage experience, such as debugability.

IDE Equivalent
None
Alternate Options

None

**mconditional-branch, Qconditional-branch**

*Lets you identify and fix code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction.*

**Syntax**

**Linux OS:**

-mconditional-branch=keyword

**macOS:**

-mconditional-branch=keyword

**Windows OS:**

/Qconditional-branch:keyword

**Arguments**

*keyword* Indicates to the compiler what action to take. Possible values are:

- **keep**
  - Tells the compiler to not attempt any vulnerable code detection or fixing. This is equivalent to not specifying the -mconditional-branch option.

- **pattern-report**
  - Tells the compiler to perform a search of vulnerable code patterns in the compilation and report all occurrences to stderr.

- **pattern-fix**
  - Tells the compiler to perform a search of vulnerable code patterns in the compilation and generate code to ensure that the identified data accesses are not executed speculatively. It will also report any fixed patterns to stderr.

  This setting does not guarantee total mitigation, it only fixes cases where all components of the vulnerability can be seen or determined by the compiler. The pattern detection will be more complete if advanced optimization options are specified or are in effect, such as option O3 and option -ipo (or /Qipo).

- **all-fix**
  - Tells the compiler to fix all of the vulnerable code so that it is either not executed speculatively, or there is no observable side-channel created from their speculative execution. Since it is a complete mitigation against Spectre variant 1 attacks, this setting will have the most run-time performance cost.

  In contrast to the pattern-fix setting, the compiler will not attempt to identify the exact conditional branches that may have led to the mis-speculated execution.

- **all-fix-lfence**
  - This is the same as specifying setting all-fix.
**all-fix-cmov**

Tells the compiler to treat any path where speculative execution of a memory load creates vulnerability (if mispredicted). The compiler automatically adds mitigation code along any vulnerable paths found, but it uses a different method than the one used for all-fix (or all-fix-lfence).

This method uses CMOVcc instruction execution, which constrains speculative execution. Thus, it is used for keeping track of the predicate value, which is updated on each conditional branch.

To prevent Spectre v.1 attack, each memory load that is potentially vulnerable is bitwise ORed with the predicate to mask out the loaded value if the code is on a mispredicted path.

This is analogous to the Clang compiler's option to do Speculative Load Hardening.

This setting is only supported on Intel® 64 architecture-based systems.

**Default**

-mconditional-branch=keep

and /Qconditional-branch:keep

The compiler does not attempt any vulnerable code detection or fixing.

**Description**

This option lets you identify code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction. Depending on the setting you choose, vulnerabilities may be detected and code may be generated to attempt to mitigate the security risk.

**IDE Equivalent**

Visual Studio: Code Generation [Intel C++] > Spectre Variant 1 Mitigation

Eclipse: None

Xcode: None

**Alternate Options**

None

**minstruction, Qinstruction**

Determines whether MOVBE instructions are generated for certain Intel processors.

**Syntax**

**Linux OS and macOS:**

-minstruction=[no]movbe

**Windows OS:**

/Qinstruction:[no]movbe
Arguments
None

Default

-minstruction=nomovbe
or /Qinstruction:nomovbe

The compiler does not generate MOVBE instructions for Intel Atom® processors.

Description

This option determines whether MOVBE instructions are generated for Intel Atom® processors. To use this option, you must also specify [Q]xATOM_SSSE3 or [Q]xATOM_SSE4.2.

If -minstruction=movbe or /Qinstruction:movbe is specified, the following occurs:

• MOVBE instructions are generated that are specific to the Intel Atom® processor.
• Generated executables can only be run on Intel Atom® processors or processors that support Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3) or Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) and MOVBE.

If -minstruction=nomovbe or /Qinstruction:nomovbe is specified, the following occurs:

• The compiler optimizes code for the Intel Atom® processor, but it does not generate MOVBE instructions.
• Generated executables can be run on non-Intel Atom® processors that support Intel® SSE3 or Intel® SSE4.2.

IDE Equivalent
None

Alternate Options

x, Qx compiler option

momit-leaf-frame-pointer

Determines whether the frame pointer is omitted or kept in leaf functions.

Syntax

Linux OS:
-momit-leaf-frame-pointer
-mno-omit-leaf-frame-pointer

macOS:
-momit-leaf-frame-pointer
-mno-omit-leaf-frame-pointer

Windows OS:
None

Arguments
None
Default

If you specify option `-fomit-frame-pointer` (or it is set by default), the default is `-momit-leaf-frame-pointer`. If you specify option `-fno-omit-frame-pointer`, the default is `-mno-omit-leaf-frame-pointer`.

Description

This option determines whether the frame pointer is omitted or kept in leaf functions. It is related to option `-f[no-]omit-frame-pointer` and the setting for that option has an effect on this option.

Consider the following option combinations:

<table>
<thead>
<tr>
<th>Option Combination</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-fommit-frame-pointer -momit-leaf-frame-pointer</code></td>
<td>Both combinations are the same as specifying <code>-fommit-frame-pointer</code>.</td>
</tr>
<tr>
<td>or</td>
<td>Frame pointers are omitted for all routines.</td>
</tr>
<tr>
<td><code>-fommit-frame-pointer -mno-omit-leaf-frame-pointer</code></td>
<td>In this case, the frame pointer is omitted for leaf routines, but other routines will keep the frame pointer.</td>
</tr>
<tr>
<td><code>-fno-omit-frame-pointer -momit-leaf-frame-pointer</code></td>
<td>This is the intended effect of option <code>-momit-leaf-frame-pointer</code>.</td>
</tr>
<tr>
<td><code>-fno-omit-frame-pointer -mno-omit-leaf-frame-pointer</code></td>
<td>In this case, <code>-mno-omit-leaf-frame-pointer</code> is ignored since</td>
</tr>
<tr>
<td></td>
<td><code>-fno-omit-frame-pointer</code> retains frame pointers in all routines.</td>
</tr>
<tr>
<td></td>
<td>This combination is the same as specifying <code>-fno-omit-frame-pointer</code>.</td>
</tr>
</tbody>
</table>

This option is provided for compatibility with gcc.

IDE Equivalent

Visual Studio: None

Eclipse: Optimization > Omit frame pointer for leaf routines

Xcode: Optimization > Provide Frame Pointer For Leaf Routines

mregparm

Let you control the number registers used to pass integer arguments.

Architecture Restrictions

Only available on IA-32 architecture
Syntax

Linux OS:
-mregparm=n

macOS:
None

Windows OS:
None

Arguments

$n$

Specifies the number of registers to use when passing integer arguments. You can specify at most 3 registers. If you specify a nonzero value for $n$, you must build all modules, including startup modules, and all libraries, including system libraries, with the same value.

Default

OFF  The compiler does not use registers to pass arguments.

Description

Control the number registers used to pass integer arguments. This option is provided for compatibility with gcc.

IDE Equivalent

None

Alternate Options

None

mregparm-version  compiler option

mregparm-version

Determines which version of the Application Binary Interface (ABI) is used for the regparm parameter passing convention.

Syntax

Linux OS:
-mregparm-version=n

macOS:
macOS:
None

Windows OS:
None
Arguments

\( n \)

Specifies the ABI implementation to use. Possible values are:

- **0**: Tells the compiler to use the most recent ABI implementation.
- **1**: Tells the compiler to use the ABI implementation that is compatible with gcc 3.4.6 and icc 15.0.

**Default**

0

The compiler uses the most recent ABI implementation.

**Description**

This option determines which version of the Application Binary Interface (ABI) is used for the regparm parameter passing convention. This option allows compatibility with previous versions of gcc and icc.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

mregparm compiler option

---

**mstringop-inline-threshold, Qstringop-inline-threshold**

* Tells the compiler to not inline calls to buffer manipulation functions such as memcpy and memset when the number of bytes the functions handle are known at compile time and greater than the specified value.

**Syntax**

**Linux OS:**

-mstringop-inline-threshold=val

**macOS:**

-mstringop-inline-threshold=val

**Windows OS:**

/Qstringop-inline-threshold:val

**Arguments**

\( val \)

Is a positive 32-bit integer. If the size is greater than \( val \), the compiler will never inline it.
Default

OFF  The compiler uses its own heuristics to determine the default.

Description

This option tells the compiler to not inline calls to buffer manipulation functions such as memcpy and memset when the number of bytes the functions handle are known at compile time and greater than the specified val.

IDE Equivalent

None

Alternate Options

None

See Also

mstringop-strategy, Qstringop-strategy  compiler option

**mstringop-strategy, Qstringop-strategy**

*Lets you override the internal decision heuristic for the particular algorithm used when implementing buffer manipulation functions such as memcpy and memset.*

Syntax

Linux OS and macOS:

-mstringop-strategy=alg

Windows OS:

/Qstringop-strategy:alg

Arguments

`alg`  Specifies the algorithm to use. Possible values are:

- `const_size_loop`  Tells the compiler to expand the string operations into an inline loop when the size is known at compile time and it is not greater than threshold value. Otherwise, the compiler uses its own heuristics to decide how to implement the string operation.

- `libcall`  Tells the compiler to use a library call when implementing string operations.

- `rep`  Tells the compiler to use its own heuristics to decide what form of `rep movs | stos` to use when inlining string operations.

Default

varies  If optimization option `Os` is specified, the default is `rep`. Otherwise, the default is `const_size_loop`.

Description

This option lets you override the internal decision heuristic for the particular algorithm used when implementing buffer manipulation functions such as memcpy and memset.
This option may have no effect on compiler-generated string functions, for example, a call to `memcpy` generated by the compiler to implement an array copy or structure copy.

**IDE Equivalent**
None

**mtune, tune**
*Performs optimizations for specific processors but does not cause extended instruction sets to be used (unlike -march).*

**Syntax**

**Linux OS:**
- `mtune=processor`

**macOS:**
- `mtune=processor`

**Windows OS:**
/`tune:processor`

**Arguments**

`processor`  
Is the processor for which the compiler should perform optimizations. Possible values are:

- `generic`  
  Optimizes code for the compiler's default behavior.

- `alderlake`  
  Optimizes code for processors that support the specified Intel® processor or microarchitecture code name.

- `amberlake`  
  Keywords `knl` and `silvermont` are only available on Windows* and Linux* systems.

- `broadwell`  
  Keyword `icelake` is deprecated and may be removed in a future release.

- `cannonlake`  

- `cascadebbake`  

- `coffee lake`  

- `cooperlake`  

- `goldmont`  

- `goldmont-plus`  

- `haswell`  

- `icelake-client (or icelake)`  

- `icelake-server`  

- `ivybridge`

tremont
whiskeylake

**core-avx2**
Optimizes code for processors that support Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

**core-avx-i**
Optimizes code for processors that support Float-16 conversion instructions and the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

**corei7-avx**
Optimizes code for processors that support Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.

**corei7**
Optimizes code for processors that support Intel® SSE4 Efficient Accelerated String and Text Processing instructions. May also generate code for Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSE3, SSE2, SSE, and SSSE3 instructions.

**atom**
Optimizes code for processors that support MOVBE instructions, depending on the setting of option `-minstruction` (Linux* and macOS*) or `/Qinstruction` (Windows*). May also generate code for SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.

**core2**
Optimizes for the Intel® Core™2 processor family, including support for MMX™, Intel® SSE, SSE2, SSE3 and SSSE3 instruction sets.

**pentium-mmx**
Optimizes for Intel® Pentium® with MMX technology.

**pentiumpro**
Optimizes for Intel® Pentium® Pro, Intel Pentium II, and Intel Pentium III processors.

**pentium4m**
Optimizes for Intel® Pentium® 4 processors with MMX technology.

**pentium-m**
Optimizes code for Intel® Pentium® processors. Value `pentium3` is only available on Linux* systems.
Default

generic

Code is generated for the compiler's default behavior.

Description

This option performs optimizations for specific processors but does not cause extended instruction sets to be used (unlike -march).

The resulting executable is backwards compatible and generated code is optimized for specific processors. For example, code generated with -mtune=core2 or /tune:core2 will run correctly on 4th Generation Intel® Core™ processors, but it might not run as fast as if it had been generated using -mtune=haswell or /tune:haswell. Code generated with -mtune=haswell (/tune:haswell) or -mtune=core-avx2 (/tune:core-avx2) will also run correctly on Intel® Core™2 processors, but it might not run as fast as if it had been generated using -mtune=core2 or /tune:core2. This is in contrast to code generated with -march=core-avx2 or /arch:core-avx2, which will not run correctly on older processors such as Intel® Core™2 processors.

march compiler option

fcf-protection, Qcf-protection

Enables Control-flow Enforcement Technology (CET) protection, which defends your program from certain attacks that exploit vulnerabilities. This option offers preliminary support for CET.
Syntax

Linux OS:
- `--fcf-protection [=keyword]`

macOS:
None

Windows OS:
`/Qcf-protection [:keyword]`

Arguments

`keyword` Specifies the level of protection the compiler should perform. Possible values are:

- `shadow_stack` Enables shadow stack protection.
- `branch_tracking` Enables endbranch (EB) generation.
- `full` Enables both shadow stack protection and endbranch (EB) generation. This is the same as specifying this compiler option with no `keyword`.
- `none` Disables Control-flow Enforcement Technology (CET) protection.

Default

- `--fcf-protection=none` or `/Qcf-protection:none` No Control-flow Enforcement protection is performed.

Description

This option enables Control-flow Enforcement Technology (CET) protection, which defends your program from certain attacks that exploit vulnerabilities.

CET protections are enforced on processors that support CET. They are ignored on processors that do not support CET, so they are safe to use in programs that might run on a variety of processors.

Specifying `shadow_stack` helps to protect your program from return-oriented programming (ROP). Return-oriented programming (ROP) is a technique to exploit computer security defenses such as non-executable memory and code signing by gaining control of the call stack to modify program control flow and then execute certain machine instruction sequences.

Specifying `branch_tracking` helps to protect your program from call/jump-oriented programming (COP/JOP). Jump-oriented programming (JOP) is a variant of ROP that uses indirect jumps and calls to emulate return instructions. Call-oriented programming (COP) is a variant of ROP that employs indirect calls.

To get both protections, specify this compiler option with no `keyword`, or specify `-fcf-protection=full` (Linux*) or `/Qcf-protection:full` (Windows*).

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-qcf-protection`

Windows: None
Qcxx-features
Enables standard C++ features without disabling Microsoft features.

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/Qcxx-features

Arguments
None

Default
OFF The compiler enables standard C++ features.

Description
This option enables standard C++ features without disabling Microsoft features within the bounds of what is provided in the Microsoft headers and libraries.
This option has the same effect as specifying /EHsc /GR.

IDE Equivalent
None

Alternate Options
None

Qpatchable-addresses
Tells the compiler to generate code such that references to statically assigned addresses can be patched.

Architecture Restrictions
Only available on Intel® 64 architecture

Syntax
Linux OS:
None

macOS:
None
**Windows OS:**

/Qpatchable-addresses

**Arguments**

None

**Default**

OFF The compiler does not generate patchable addresses.

**Description**

This option tells the compiler to generate code such that references to statically assigned addresses can be patched with arbitrary 64-bit addresses.

Normally, the Windows* system compiler that runs on Intel® 64 architecture uses 32-bit relative addressing to reference statically allocated code and data. That assumes the code or data is within 2GB of the access point, an assumption that is enforced by the Windows object format.

However, in some patching systems, it is useful to have the ability to replace a global address with some other arbitrary 64-bit address, one that might not be within 2GB of the access point.

This option causes the compiler to avoid 32-bit relative addressing in favor of 64-bit direct addressing so that the addresses can be patched in place without additional code modifications. This option causes code size to increase, and since 32-bit relative addressing is usually more efficient than 64-bit direct addressing, you may see a performance impact.

**IDE Equivalent**

None

**Alternate Options**

None

**Qsafeseh**

*Registers exception handlers for safe exception handling.*

**Architecture Restrictions**

Only available on IA-32 architecture

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/Qsafeseh[-]

**Arguments**

None
Exception handlers are enabled for safe exception handling.

Description
Registers exception handlers for safe exception handling. It also marks objects as "compatible with the Registered Exception Handling feature" whether they contain handlers or not. This is important because the Windows linker will only generate the "special registered EH table" if ALL objects that it is building into an image are marked as compatible. If any objects are not marked as compatible, the EH table is not generated. Digital signatures certify security and are required for components that are shipped with Windows, such as device drivers.

IDE Equivalent
None

Alternate Options

/EH compiler option

regcall, Qregcall
*Tells the compiler that the __regcall calling convention should be used for functions that do not directly specify a calling convention.*

Syntax

**Linux OS:**
-regcall

**macOS:**
-regcall

**Windows OS:**
/Qregcall

Arguments
None

Default
OFF The __regcall calling convention will only be used if a function explicitly specifies it.

Description
This option tells the compiler that the __regcall calling convention should be used for functions that do not directly specify a calling convention. This calling convention ensures that as many values as possible are passed or returned in registers.

It ensures that __regcall is the default calling convention for functions in the compilation, unless another calling convention is specified in a declaration.

This calling convention is ignored if it is specified for a function with variable arguments.
Note that all __regcall functions must have prototypes.

**IDE Equivalent**

WHISKEYLAKE

COMMON-AVX512
May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection Instructions (CDI), as well as the instructions enabled with CORE-AVX2. Optimizes for Intel® processors that support Intel® AVX-512 instructions.

CORE-AVX512
May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection Instructions (CDI), Intel® AVX-512 Doubleword and Quadword Instructions (DQI), Intel® AVX-512 Byte and Word Instructions (BWI) and Intel® AVX-512 Vector Length extensions, as well as the instructions enabled with CORE-AVX2. Optimizes for Intel® processors that support Intel® AVX-512 instructions.

CORE-AVX2
May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel® processors that support Intel® AVX2 instructions.

CORE-AVX-I
May generate Float-16 conversion instructions and the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel® processors that support Float-16 conversion instructions and the RDRND instruction.

AVX
May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel® processors that support Intel® AVX instructions.

SSE4.2
May generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions, Intel® SSE4 Vectorizing Compiler and Media Accelerator, and Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel® processors. May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors that support Intel® SSE4.1 instructions.

SSE4.1
May generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel® processors. May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors that support Intel® SSE4.1 instructions.

ATOM_SSE4.2
May generate MOVBE instructions for Intel® processors, depending on the setting of option -minstruction (Linux* and macOS*) or /Qinstruction (Windows*). May also
generate Intel® SSE4.2, SSE3, SSE2, and SSE instructions for Intel processors. Optimizes for Intel Atom® processors that support Intel® SSE4.2 and MOVBE instructions.

This keyword is only available on Windows* and Linux* systems.

ATOM_SSSE3

May generate MOVBE instructions for Intel® processors, depending on the setting of option -minstruction (Linux* and macOS*) or /Qinstruction (Windows*). May also generate SSSE3, Intel® SSE3, SSE2, and SSE instructions for Intel processors. Optimizes for Intel Atom® processors that support Intel® SSE3 and MOVBE instructions.

This keyword is only available on Windows* and Linux* systems.

SSSE3

May generate SSSE3 and Intel® SSE3, SSE2, and SSE instructions for Intel® processors. Optimizes for Intel processors that support SSSE3 instructions. For macOS* systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.

SSE3

May generate Intel® SSE3, SSE2, and SSE instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE3 instructions. This value is not available on macOS* systems.

SSE2

May generate Intel® SSE2 and SSE instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE2 instructions. This value is not available on macOS* systems.

You can also specify a Host. For more information, see option [Q]xHost.

Default

Windows* systems: None
Linux* systems: None
macOS* systems: SSSE3

On Windows systems, if neither /Qx nor /arch is specified, the default is /arch:SSE2.

On Linux systems, if neither -x nor -m is specified, the default is -msse2.

Description

This option tells the compiler which processor features it may target, including which instruction sets and optimizations it may generate. It also enables optimizations in addition to Intel feature-specific optimizations.

The specialized code generated by this option may only run on a subset of Intel® processors.

The resulting executables created from these option code values can only be run on Intel® processors that support the indicated instruction set.

The binaries produced by these code values will run on Intel® processors that support the specified features.

Do not use code values to create binaries that will execute on a processor that is not compatible with the targeted processor. The resulting program may fail with an illegal instruction exception or display other unexpected behavior.
Compiling the function `main()` with any of the `code` values produces binaries that display a fatal run-time error if they are executed on unsupported processors, including all non-Intel processors.

Compiler options `m` and `arch` produce binaries that should run on processors not made by Intel that implement the same capabilities as the corresponding Intel® processors.

The `-x` and `/Qx` options enable additional optimizations not enabled with options `-m` or `/arch` (nor with options `-ax` and `/Qax`).

On Windows systems, options `/Qx` and `/arch` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning. Similarly, on Linux and macOS* systems, options `-x` and `-m` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

**NOTE**
All settings except SSE2 do a CPU check. However, if you specify option `-O0` (Linux* and macOS*) or option `/Od` (Windows*), no CPU check is performed.

---

**xHost, QxHost**

*Tells the compiler to generate instructions for the highest instruction set available on the compilation host processor.*
Syntax

Linux OS and macOS:

-xHost

Windows OS:

/QxHost

Arguments

None

Default

Windows* systems: None
Linux* systems: None
macOS* systems: -xSSSE3

On Windows systems, if neither /Qx nor /arch is specified, the default is /arch:SSE2.

On Linux systems, if neither -x nor -m is specified, the default is -msse2.

Description

This option tells the compiler to generate instructions for the highest instruction set available on the compilation host processor.

The instructions generated by this compiler option differ depending on the compilation host processor.

The following table describes the effects of specifying the [Q]xHost option and it tells whether the resulting executable will run on processors different from the host processor.

Descriptions in the table refer to Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® Advanced Vector Extensions (Intel® AVX), Intel® Streaming SIMD Extensions (Intel® SSE), and Supplemental Streaming SIMD Extensions (SSSE).

Interprocedural Optimization Options

This section contains descriptions for compiler options that pertain to interprocedural optimization.

**ffat-lto-objects**

*Determine* whether a fat link-time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation (-c –ipo).

**Syntax**

Linux OS:

-ffat-lto-objects

-fno-fat-lto-objects

macOS:

None
Windows OS:
None

Arguments
None

Default

-ffat-lto-objects

When -c -ipo is specified, the compiler generates a fat link-time optimization (LTO) object that has both a true object and a discardable intermediate language section.

Description
This option determines whether a fat link time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation (-c -ipo). During an interprocedural optimization compilation (-c -ipo), the following occurs:

- If you specify -ffat-lto-objects, the compiler generates a fat link-time optimization (LTO) object that has both a true object and a discardable intermediate language section. This enables both link-time optimization (LTO) linking and normal linking.
- If you specify -fno-fat-lto-objects, the compiler generates a fat link-time optimization (LTO) object that only has a discardable intermediate language section; no true object is generated. This option may improve compilation time.

Note that these files will be inserted into archives in the form in which they were created.

This option is provided for compatibility with gcc. For more information about this option, see the gcc documentation.

NOTE
Intel's intermediate language representation is not compatible with gcc's intermediate language representation.

IDE Equivalent
None

Alternate Options
None

See Also
ipo, Qipo  compiler option

ip, Qip
Determines whether additional interprocedural optimizations for single-file compilation are enabled.

Syntax

Linux OS and macOS:

- ip
- no-ip
Windows OS:
/Qip
/Qip-

Arguments
None

Default
OFF

Some limited interprocedural optimizations occur, including inline function expansion for calls to functions defined within the current source file. These optimizations are a subset of full intra-file interprocedural optimizations. Note that this setting is not the same as -no-ip (Linux* and macOS*) or /Qip- (Windows*).

Description
This option determines whether additional interprocedural optimizations for single-file compilation are enabled.

The [Q]ip option enables additional interprocedural optimizations for single-file compilation.

Options -no-ip (Linux and macOS*) and /Qip- (Windows) may not disable inlining. To ensure that inlining of user-defined functions is disabled, specify -inline-level=0 or -fno-inline (Linux and macOS*), or specify /Ob0 (Windows). To ensure that inlining of compiler intrinsic functions is disabled, specify -fno-built-in (Linux and macOS*) or /Oi- (Windows).

IDE Equivalent
Visual Studio: Optimization > Interprocedural Optimization
Eclipse: Optimization > Enable Interprocedural Optimizations for Single File Compilation
Xcode: Optimization > Enable Interprocedural Optimization for Single File Compilation

Alternate Options
None

See Also
finline-functions compiler option

ip-no-inlining, Qip-no-inlining
Disables full and partial inlining enabled by interprocedural optimization options.

Syntax

Linux OS and macOS:
-ip-no-inlining

Windows OS:
/Qip-no-inlining

Arguments
None
**Default**

OFF  Inlining enabled by interprocedural optimization options is performed.

**Description**

This option disables full and partial inlining enabled by the following interprocedural optimization options:

- On Linux* and macOS* systems: `-ip` or `-ipo`
- On Windows* systems: `/Qip`, `/Qipo`, or `/Ob2`

It has no effect on other interprocedural optimizations.

On Windows systems, this option also has no effect on user-directed inlining specified by option `/Ob1`.

**IDE Equivalent**

None

**Alternate Options**

None

**ip-no-pinlining, Qip-no-pinlining**

*Disables partial inlining enabled by interprocedural optimization options.*

**Syntax**

**Linux OS and macOS:**
- `-ip-no-pinlining`

**Windows OS:**
- `/Qip-no-pinlining`

**Arguments**

None

**Default**

OFF  Inlining enabled by interprocedural optimization options is performed.

**Description**

This option disables partial inlining enabled by the following interprocedural optimization options:

- On Linux* and macOS* systems: `-ip` or `-ipo`
- On Windows* systems: `/Qip` or `/Qipo`

It has no effect on other interprocedural optimizations.

**IDE Equivalent**

None

**Alternate Options**

None
**ipo, Qipo**

*Enables interprocedural optimization between files.*

**Syntax**

**Linux OS:**
- `-ipo [n]`
- `-no-ipo`

**macOS:**
- `-ipo [n]`
- `-no-ipo`

**Windows OS:**
- `/Qipo [n]`
- `/Qipo-`

**Arguments**

\[n\] Is an optional integer that specifies the number of object files the compiler should create. The integer must be greater than or equal to 0.

**Default**

- `-no-ipo` Multifile interprocedural optimization is not enabled.
- or `/Qipo-`

**Description**

This option enables interprocedural optimization between files. This is also called multifile interprocedural optimization (multifile IPO) or Whole Program Optimization (WPO).

When you specify this option, the compiler performs inline function expansion for calls to functions defined in separate files.

You cannot specify the names for the files that are created.

If \[n\] is 0, the compiler decides whether to create one or more object files based on an estimate of the size of the application. It generates one object file for small applications, and two or more object files for large applications.

If \[n\] is greater than 0, the compiler generates \[n\] object files, unless \[n\] exceeds the number of source files (\[m\]), in which case the compiler generates only \[m\] object files.

If you do not specify \[n\], the default is 0.

---

**NOTE**

When you specify option [Q]ipo with option [q or Q]opt-report, IPO information is generated in the compiler optimization report at link time. After linking, you will see a report named ipo_out.optrpt in the folder where you linked all of the object files.
IDE Equivalent
Visual Studio: Optimization > Interprocedural Optimization
Eclipse: Optimization > Enable Whole Program Optimization
Xcode: None

Alternate Options
None

ipo-c, Qipo-c
Tells the compiler to optimize across multiple files and generate a single object file.

Syntax
Linux OS and macOS:
-ipo-c

Windows OS:
/Qipo-c

Arguments
None

Default
OFF The compiler does not generate a multifile object file.

Description
This option tells the compiler to optimize across multiple files and generate a single object file (named ipo_out.o on Linux* and macOS* systems; ipo_out.obj on Windows* systems).
It performs the same optimizations as the [Q]ipo option, but compilation stops before the final link stage, leaving an optimized object file that can be used in further link steps.

IDE Equivalent
None

Alternate Options
None

See Also
ipo, Qipo compiler option

ipo-jobs, Qipo-jobs
Specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).
Syntax

Linux OS and macOS:
-ipo-jobs n

Windows OS:
/Qipo-jobs:n

Arguments

n
Is the number of commands (jobs) to run simultaneously. The number must be greater than or equal to 1.

Default

-ipo-jobs 1
or/Qipo-jobs:1

One command (job) is executed in an interprocedural optimization parallel build.

Description

This option specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO). It should only be used if the link-time compilation is generating more than one object. In this case, each object is generated by a separate compilation, which can be done in parallel.

This option can be affected by the following compiler options:

- [Q]ipo when applications are large enough that the compiler decides to generate multiple object files.
- [Q]ipo n when n is greater than 1.
- [Q]ipo-separate

Caution

Be careful when using this option. On a multi-processor system with lots of memory, it can speed application build time. However, if n is greater than the number of processors, or if there is not enough memory to avoid thrashing, this option can increase application build time.

IDE Equivalent

None

Alternate Options

None

See Also

ipo, Qipo  compiler option
ipo-separate, Qipo-separate  compiler option

ipo-S, Qipo-S

Tell the compiler to optimize across multiple files and generate a single assembly file.
Syntax

Linux OS and macOS:
-ipo-S

Windows OS:
/Qipo-S

Arguments
None

Default
OFF The compiler does not generate a multifile assembly file.

Description
This option tells the compiler to optimize across multiple files and generate a single assembly file (named ipo_out.s on Linux* and macOS* systems; ipo_out.asm on Windows* systems).

It performs the same optimizations as the [Q]ipo option, but compilation stops before the final link stage, leaving an optimized assembly file that can be used in further link steps.

IDE Equivalent
None

Alternate Options
None

See Also
ipo, Qipo compiler option

ipo-separate, Qipo-separate
*Tells the compiler to generate one object file for every source file.*

Syntax

Linux OS:
-ipo-separate

macOS:
None

Windows OS:
/Qipo-separate

Arguments
None

Default
OFF The compiler decides whether to create one or more object files.
Description
This option tells the compiler to generate one object file for every source file. It overrides any \texttt{ipo} option specification.

IDE Equivalent
None

Alternate Options
None

See Also
\texttt{ipo}, \texttt{Qipo} compiler option

Advanced Optimization Options

\texttt{alias-const, Qalias-const}
\textit{Determines whether the compiler assumes a parameter of type pointer-to-const does not alias with a parameter of type pointer-to-non-const.}

Syntax
\textbf{Linux OS:}
- \texttt{-alias-const}
- \texttt{-no-alias-const}

\textbf{macOS:}
- \texttt{-alias-const}
- \texttt{-no-alias-const}

\textbf{Windows OS:}
\texttt{/Qalias-const}
\texttt{/Qalias-const-}

Arguments
None

Default
\texttt{-no-alias-const} \hspace{1cm} \textbf{The compiler uses standard C/C++ rules for the interpretation of const.}
\texttt{or /Qalias-const-}

Description
This option determines whether the compiler assumes a parameter of type pointer-to-const does not alias with a parameter of type pointer-to-non-const. It implies an additional attribute for const.

This functionality complies with the input/output buffer rule, which assumes that input and output buffer arguments do not overlap. This option allows the compiler to do some additional optimizations with those parameters.
In C99, you can also get the same result if you additionally declare your pointer parameters with the restrict keyword.

**IDE Equivalent**

Visual Studio: None

Eclipse: **Data > Assume Restrict Semantics for Const**

Xcode: **Data > Assume Restrict Semantics for Const**

**Alternate Options**

None

**ansi-alias, Qansi-alias**

*Enables or disables the use of ANSI aliasing rules in optimizations.*

**Syntax**

Linux OS:

- `-ansi-alias`
- `-no-ansi-alias`

macOS:

- `-ansi-alias`
- `-no-ansi-alias`

Windows OS:

- `/Qansi-alias`
- `/Qansi-alias-`

**Arguments**

None

**Default**

Windows* systems: `/Qansi-alias`

Linux* and macOS* systems: `-ansi-alias`

**Description**

This option tells the compiler to assume that the program adheres to ISO C Standard aliasability rules. If your program adheres to the ANSI aliasability rules, this option allows the compiler to optimize more aggressively. If your program does not adhere to these rules, this option may cause the compiler to generate incorrect code.

If you are compiling on a Linux* or an macOS* system and your program does not adhere to the ANSI aliasability rules, you can specify `-no-ansi-alias` to ensure program correctness.
When you specify the \texttt{\texttt{Q}ansi-alias} option, the ansi-alias checker is enabled by default. To disable the ansi-alias checker, you must specify \texttt{-no-ansi-alias-check} (Linux* and macOS*) or \texttt{/Qansi-alias-check-} (Windows*).

**IDE Equivalent**

Visual Studio: Language > Enable Use of ANSI Aliasing Rules in Optimizations

Eclipse: Language > Enable Use of ANSI Aliasing Rules in Optimizations

Xcode: Language > Enable ANSI Aliasing

**Alternate Options**

Linux and macOS*: \texttt{-fstrict-aliasing}

Windows: None

**See Also**

ansi-alias-check, Qansi-alias-check

compiler option

\textbf{ansi-alias-check, Qansi-alias-check}

\textit{Enables or disables the ansi-alias checker.}

**Syntax**

\textbf{Linux OS:}

\texttt{-ansi-alias-check}

\texttt{-no-ansi-alias-check}

\textbf{macOS:}

\texttt{-ansi-alias-check}

\texttt{-no-ansi-alias-check}

\textbf{Windows OS:}

\texttt{/Qansi-alias-check}

\texttt{/Qansi-alias-check-}

**Arguments**

None

**Default**

\texttt{-no-ansi-alias-check} or

\texttt{/Qansi-alias-check-}

The ansi-alias checker is disabled unless option \texttt{-ansi-alias-check} or \texttt{/Qansi-alias-check-} has been specified.

**Description**

This option enables or disables the ansi-alias checker. The ansi-alias checker checks the source code for potential violations of ANSI aliasing rules and disables unsafe optimizations related to the code for those statements that are identified as potential violations.

You can use option \texttt{-Wstrict-aliasing} to identify potential violations.
If the \texttt{Qansi-alias} option has been specified, the ansi-alias checker is enabled by default. You can use the negative form of the option (see Syntax above) to disable the checker.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

ansi-alias, Qansi-alias

\textit{compiler option}

\textit{Wstrict-aliasing}

\textit{compiler option}

\textbf{complex-limited-range, Qcomplex-limited-range}

\textit{Determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.}

**Syntax**

\textbf{Linux OS and macOS:}

\texttt{-complex-limited-range}

\texttt{-no-complex-limited-range}

\textbf{Windows OS:}

\texttt{/Qcomplex-limited-range}

\texttt{/Qcomplex-limited-range-}

**Arguments**

None

**Default**

\texttt{-no-complex-limited-range} \hspace{1cm} Basic algebraic expansions of some arithmetic operations involving data of type COMPLEX are disabled.

\texttt{or/Qcomplex-limited-range-}

**Description**

This option determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

When the option is enabled, this can cause performance improvements in programs that use a lot of COMPLEX arithmetic. However, values at the extremes of the exponent range may not compute correctly.

**IDE Equivalent**

Visual Studio: Floating Point > Limit COMPLEX Range

Eclipse: Floating Point > Limit COMPLEX Range

Xcode: Floating Point > Limit COMPLEX Range
Alternate Options
None

**fargument-alias, Qalias-args**
Determines whether function arguments can alias each other.

**Syntax**

Linux OS and macOS:
- `fargument-alias`
- `fargument-noalias`

Windows OS:
- `/Qalias-args`
- `/Qalias-args-`

**Arguments**
None

**Default**
- `fargument-alias` or `/Qalias-args`

**Description**
This option determines whether function arguments can alias each other. If you specify `fargument-noalias` or `/Qalias-args-`, function arguments cannot alias each other, but they can alias global storage.

On Linux and macOS* systems, you can also disable aliasing for global storage, by specifying option `fargument-noalias-global`.

**IDE Equivalent**
Visual Studio: None
Eclipse: **Data > Enable Argument Aliasing**
Xcode: **Data > Enable Argument Aliasing**

**See Also**
`fargument-noalias-global` compiler option

**fargument-noalias-global**
Tells the compiler that function arguments cannot alias each other and cannot alias global storage.

**Syntax**

Linux OS and macOS:
- `fargument-noalias-global`
Windows OS:
None

Arguments
None

Default
OFF       Function arguments can alias each other and can alias global storage.

Description
This option tells the compiler that function arguments cannot alias each other and they cannot alias global storage.

If you only want to prevent function arguments from being able to alias each other, specify option -fargument-noalias.

IDE Equivalent
None

Alternate Options
None

See Also
fargument-alias, Qalias-args
   compiler option

ffreestanding, Qfreestanding
Ensures that compilation takes place in a freestanding environment.

Syntax
Linux OS:
-ffreestanding

macOS:
-ffreestanding

Windows OS:
/Qfreestanding

Arguments
None

Default
OFF       Standard libraries are used during compilation.

Description
This option ensures that compilation takes place in a freestanding environment. The compiler assumes that the standard library may not exist and program startup may not necessarily be at main. This environment meets the definition of a freestanding environment as described in the C and C++ standard.
An example of an application requiring such an environment is an OS kernel.

**NOTE**
When you specify this option, the compiler will not assume the presence of compiler-specific libraries. It will only generate calls that appear in the source code.

**IDE Equivalent**
None

**Alternate Options**
None

**fjump-tables**

*Determines whether jump tables are generated for switch statements.*

**Syntax**

**Linux OS:**
- `-fjump-tables`
- `-fno-jump-tables`

**macOS:**
- `-fjump-tables`
- `-fno-jump-tables`

**Windows OS:**
None

**Arguments**
None

**Default**
- `-fjump-tables`  
The compiler may use jump tables for switch statements.

**Description**
This option determines whether jump tables are generated for switch statements. Option `-fno-jump-tables` prevents the compiler from generating jump tables for switch statements. This action is performed unconditionally and independent of any generated code performance consideration. Option `-fno-jump-tables` also prevents the compiler from creating switch statements internally as a result of optimizations.

*Use `-fno-jump-tables` with `-fpic` when compiling objects that will be loaded in a way where the jump table relocation cannot be resolved.*

**IDE Equivalent**
None
Alternate Options
None

See Also
fpic compiler option

ftls-model
Changes the thread local storage (TLS) model.

Syntax
Linux OS:
-ftls-model=model
macOS:
-ftls-model=model
Windows OS:
None

Arguments
Determines the TLS model used by the compiler. Possible values are:

model

global-dynamic
Generates a generic TLS code. The code can be used everywhere and the code can access variables defined anywhere else. This setting causes the largest size code to be generated and uses the most run time to produce.

local-dynamic
Generates an optimized TLS code. To use this setting, the thread-local variables must be defined in the same object in which they are referenced.

initial-exec
Generates a restrictive, optimized TLS code. To use this setting, the thread-local variables accessed must be defined in one of the modules available to the program.

local-exec
Generates the most restrictive TLS code. To use this setting, the thread-local variables must be defined in the executable.

Default
OFF The compiler uses default heuristics when determining the thread-local storage model.

Description
This option changes the thread local storage (TLS) model. Thread-local storage is a mechanism by which variables are allocated in a way that causes one instance of the variable per extant thread.
For more information on the thread-storage localization models, see the appropriate GCC* documentation.
For more information on the thread-storage localization models, see the appropriate Clang documentation.
funroll-all-loops
Unroll all loops even if the number of iterations is uncertain when the loop is entered.

Syntax
Linux OS and macOS:
-funroll-all-loops
Windows OS:
None

Arguments
None

Default
OFF
Do not unroll all loops.

Description
Unroll all loops, even if the number of iterations is uncertain when the loop is entered. There may a performance impact with this option.

IDE Equivalent
None

Alternate Options
None

guide, Qguide
Lets you set a level of guidance for auto-vectorization, auto parallelism, and data transformation.

Syntax
Linux OS and macOS:
-guide[=n]
Windows OS:
/Qguide[:n]

Arguments
n
Is an optional value specifying the level of guidance to be provided.
The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If \( n \) is omitted, the default is 4.

**Default**

OFF  
You do not receive guidance about how to improve optimizations for parallelism, vectorization, and data transformation.

**Description**

This option lets you set a level of guidance (advice) for auto-vectorization, auto parallelism, and data transformation. It causes the compiler to generate messages suggesting ways to improve these optimizations.

When this option is specified, the compiler does not produce any objects or executables.

You must also specify the \([Q]parallel\) option to receive auto parallelism guidance.

You can set levels of guidance for the individual guide optimizations by specifying one of the following options:

\begin{itemize}
\item \([Q]guide-data-trans\) Provides guidance for data transformation.
\item \([Q]guide-par\) Provides guidance for auto parallelism.
\item \([Q]guide-vec\) Provides guidance for auto-vectorization.
\end{itemize}

If you specify the \([Q]guide\) option and also specify one of the options setting a level of guidance for an individual guide optimization, the value set for the individual guide optimization will override the setting specified in \([Q]guide\).

If you do not specify \([Q]guide\), but specify one of the options setting a level of guidance for an individual guide optimization, option \([Q]guide\) is enabled with the greatest value passed among any of the three individual guide optimizations specified.

In debug mode, this option has no effect unless option \( O2 \) (or higher) is explicitly specified in the same command line.

**NOTE**

The compiler speculatively performs optimizations as part of guide analysis. As a result, when you use guided auto-parallelism options with options that produce vectorization or auto-parallelizer reports (such as option \([q or Q]opt-report\)), the compiler generates "LOOP WAS VECTORIZED" or similar messages as if the compilation was performed with the recommended changes.

When compilation is performed with the \([Q]guide\) option, you should use extra caution when interpreting vectorizer diagnostics and auto-parallelizer diagnostics.

**NOTE**

You can specify \([Q]diag-disable\) to prevent the compiler from issuing one or more diagnostic messages.

**IDE Equivalent**

Visual Studio: **Diagnostics > Guided Auto Parallelism Analysis**
Eclipse: Compilation Diagnostics > Enable Guided Auto Parallelism Analysis
Xcode: Diagnostics > Enable Guided Auto Parallelism Analysis

Alternate Options
None

guide-opts, Qguide-opts compiler option
diag, Qdiag compiler option
qopt-report, Qopt-report compiler option

guide-data-trans, Qguide-data-trans
*Let* you set a level of guidance for data transformation.

Syntax

Linux OS and macOS:
-guide-data-trans[=n]

Windows OS:
/Qguide-data-trans[:n]

Arguments

\( n \)

Is an optional value specifying the level of guidance to be provided. The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If \( n \) is omitted, the default is 4.

Default

OFF

You do not receive guidance about how to improve optimizations for data transformation.

Description

This option lets you set a level of guidance for data transformation. It causes the compiler to generate messages suggesting ways to improve that optimization.

IDE Equivalent

None

Alternate Options

None
See Also
guide, Qguide  compiler option
guide-par, Qguide-par  compiler option
guide-vec, Qguide-vec  compiler option
guide-file, Qguide-file  compiler option

guide-file, Qguide-file
Causes the results of guided auto parallelism to be output to a file.

Syntax

Linux OS and macOS:
-guide-file [=filename]

Windows OS:
/Qguide-file[:filename]

Arguments

filename  Is the name of the file for output. It can include a path.

Default

OFF  Messages that are generated by guided auto parallelism are output to stderr.

Description

This option causes the results of guided auto parallelism to be output to a file.
This option is ignored unless you also specify one or more of the following options:

- [Q]guide
- [Q]guide-vec
- [Q]guide-data-trans
- [Q]guide-par

If you do not specify a path, the file is placed in the current working directory.
If there is already a file named filename, it will be overwritten.
You can include a file extension in filename. For example, if file.txt is specified, the name of the output file is file.txt. If you do not provide a file extension, the name of the file is filename.guide.
If you do not specify filename, the name of the file is name-of-the-first-source-file.guide. This is also the name of the file if the name specified for filename conflicts with a source file name provided in the command line.

NOTE  If you specify the [Q]guide-file option and you also specify option [Q]guide-file-append, the last option specified on the command line takes precedence.

IDE Equivalent

Visual Studio: Diagnostics > Emit Guided Auto Parallelism Diagnostics to File
Diagnostics > Guided Auto Parallelism Diagnostics File

Eclipse: Compilation Diagnostics > Emit Guided Auto Parallelism diagnostics to File
Compilation Diagnostics > Guided Auto Parallelism Report File

Xcode: Diagnostics > Emit Guided Auto Parallelism diagnostics to File
Diagnostics > Guided Auto Parallelism Report File

Alternate Options
None

Example

The following example shows how to cause guided auto parallelism messages to be output to a file named my_guided_autopar.guide:

-`guide-file=my_guided_autopar` ! Linux and macOS* systems
/Qguide-file=my_guided_autopar ! Windows systems

See Also

guide, Qguide compiler option
guide-file-append, Qguide-file-append compiler option

**guide-file-append, Qguide-file-append**

*Causes the results of guided auto parallelism to be appended to a file.*

Syntax

Linux OS and macOS:

-`guide-file-append[=filename]`

Windows OS:

/Qguide-file-append[::filename]

Arguments

`filename` Is the name of the file to be appended to. It can include a path.

Default

OFF Messages that are generated by guided auto parallelism are output to stderr.

Description

This option causes the results of guided auto parallelism to be appended to a file.

This option is ignored unless you also specify one or more of the following options:

- [Q]guide
- [Q]guide-vec
- [Q]guide-data-trans
- [Q]guide-par

If you do not specify a path, the compiler looks for `filename` in the current working directory.

If `filename` is not found, then a new file with that name is created in the current working directory.
If you do not specify a file extension, the name of the file is *filename.guide*.

If the name specified for *filename* conflicts with a source file name provided in the command line, the name of the file is *name-of-the-first-source-file.guide*.

---

**NOTE**
If you specify the [*Q*]guide-file-append option and you also specify option [*Q*]guide-file, the last option specified on the command line takes precedence.

---

**IDE Equivalent**
None

**Alternate Options**
None

**Example**
The following example shows how to cause guided auto parallelism messages to be appended to a file named *my_messages.txt*:

```bash
-guide-file-append=my_messages.txt       ! Linux and macOS* systems
/Qguide-file-append:my_messages.txt      ! Windows systems
```

**See Also**
guide, *Qguide* compiler option
guide-file, *Qguide-file* compiler option

guide-opts, *Qguide-opts*
*Tells the compiler to analyze certain code and generate recommendations that may improve optimizations.*

**Syntax**

**Linux OS and macOS:**

```
-guide-opts=string
```

**Windows OS:**

```
/Qguide-opts:string
```

**Arguments**

*string*

Is the text denoting the code to analyze. The string must appear within quotes. It can take one or more of the following forms:

<table>
<thead>
<tr>
<th>Form</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>filename</em></td>
</tr>
<tr>
<td><em>filename</em>, routine</td>
</tr>
<tr>
<td><em>filename</em>, range [, range]...</td>
</tr>
<tr>
<td><em>filename</em>, routine, range [, range]...</td>
</tr>
</tbody>
</table>
If you specify more than one of the above forms in a string, a semicolon must appear between each form. If you specify more than one range in a string, a comma must appear between each range. Optional blanks can follow each parameter in the forms above and they can also follow each form in a string.

- **filename** Specifies the name of a file to be analyzed. It can include a path.
  
  If you do not specify a path, the compiler looks for filename in the current working directory.

- **routine** Specifies the name of a routine to be analyzed. You can include an identifying parameter.
  
  The name, including any parameter, must be enclosed in single quotes.
  
  The compiler tries to uniquely identify the routine that corresponds to the specified routine name. It may select multiple routines to analyze, especially if the following is true:
  
  - More than one routine has the specified routine name, so the routine cannot be uniquely identified.
  - No parameter information has been specified to narrow the number of routines selected as matches.

- **range** Specifies a range of line numbers to analyze in the file or routine specified. The range must be specified in integers in the form:
  
  `first_line_number-last_line_number`
  
  The hyphen between the line numbers is required.

**Default**

- **OFF** You do not receive guidance on how to improve optimizations. However, if you specify the [Q]guide option, the compiler analyzes and generates recommendations for all the code in an application.

**Description**

This option tells the compiler to analyze certain code and generate recommendations that may improve optimizations.

This option is ignored unless you also specify one or more of the following options:

- [Q]guide
- [Q]guide-vec
- [Q]guide-data-trans
- [Q]guide-par
When the [Q]guide-opts option is specified, a message is output that includes which parts of the input files are being analyzed. If a routine is selected to be analyzed, the complete routine name will appear in the generated message.

When inlining is involved, you should specify callee line numbers. Generated messages also use callee line numbers.

**IDE Equivalent**

Visual Studio: **Diagnostics > Guided Auto Parallelism Code Selection Options**

Eclipse: **Compilation Diagnostics > Guided Auto Parallelism Code Selection**

Xcode: **Diagnostics > Guided Auto Parallelism Code Selection**

**Alternate Options**

None

**Example**

Consider the following:

```bash
Linux*: -guide-opts="v.c, 1-10; v2.c, 1-40, 50-90, 100-200; v5.c, 300-400; x.c, 'funca(int)', 22-44, 55-77, 88-99; y.c, 'funcb'"
```

Windows*: `/Qguide-opts:"v.c, 1-10; v2.c, 1-40, 50-90, 100-200; v5.c, 300-400; x.c, 'funca(int)', 22-44, 55-77, 88-99; y.c, 'funcb'"`

The above command causes the following to be analyzed:

<table>
<thead>
<tr>
<th>File</th>
<th>Line Numbers</th>
</tr>
</thead>
<tbody>
<tr>
<td>v.c</td>
<td>1 to 10</td>
</tr>
<tr>
<td>v2.c</td>
<td>1 to 40, 50 to 90, and 100 to 200</td>
</tr>
<tr>
<td>v5.c</td>
<td>300 to 400</td>
</tr>
<tr>
<td>x.c</td>
<td>routine funca with parameter (int), 22 to 44, 55 to 77, and 88 to 99</td>
</tr>
<tr>
<td>y.c</td>
<td>routine funcb</td>
</tr>
</tbody>
</table>

**guide-par, Qguide-par**

*Lets you set a level of guidance for auto parallelism.*

**Syntax**

**Linux OS and macOS:**

```
-guide-par[=n]
```

**Windows OS:**

```
/Qguide-par[:n]
```
Arguments

\( n \)

Is an optional value specifying the level of guidance to be provided. The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If \( n \) is omitted, the default is 4.

Default

OFF

You do not receive guidance about how to improve optimizations for parallelism.

Description

This option lets you set a level of guidance for auto parallelism. It causes the compiler to generate messages suggesting ways to improve that optimization.

You must also specify the \([Q]parallel\) option to receive auto parallelism guidance.

IDE Equivalent

None

Alternate Options

None

ipp-link, Qipp-link
Controls whether the compiler links to static or dynamic threaded Intel® Integrated Performance Primitives (Intel® IPP) run-time libraries.

Syntax
Linux OS:
-ipp-link[=lib]

macOS:
-ipp-link[=lib]

Windows OS:
/Qipp-link[:lib]

Arguments
lib

Specifies the Intel® IPP library to use. Possible values are:

static
Tells the compiler to link to the set of static run-time libraries.

dynamic
Tells the compiler to link to the set of dynamic threaded run-time libraries.

Default
dynamic

The compiler links to the Intel® IPP set of dynamic run-time libraries. However, if Linux® option -static is specified, the compiler links to the set of static run-time libraries.
**Description**

This option controls whether the compiler links to static or dynamic threaded Intel® Integrated Performance Primitives (Intel® IPP) run-time libraries.

To use this option, you must also specify the [Q]ipp option.

**qdaal, Qdaal**

_Tells the compiler to link to certain libraries in the Intel® oneAPI Data Analytics Library (oneDAL)._

**Syntax**

**Linux OS:**

-qdaal [=lib]

**macOS:**

-qdaal [=lib]

**Windows OS:**

/Qdaal [:lib]

**Arguments**

_lib_ Indicates which oneDAL library files should be linked. Possible values are:

- _parallel_ Tells the compiler to link using the threaded oneDAL libraries. This is the default if the option is specified with no _lib_.

- _sequential_ Tells the compiler to link using the non-threaded oneDAL libraries.

**Default**

OFF  The compiler does not link to the oneDAL.
Description
This option tells the compiler to link to certain libraries in the Intel® oneAPI Data Analytics Library (oneDAL).
On Linux* and macOS* systems, the associated oneDAL headers are included when you specify this option.

NOTE
On Windows* systems, this option adds directives to the compiled code, which the linker then reads without further input from the driver. You do not need to specify a separate link command.
On Linux* and macOS* systems, the driver must add the library names explicitly to the link command. You must use option -qdaal to perform the link to pull in the dependent libraries.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.
Notice revision #20201201

IDE Equivalent

Using Intel® Performance Libraries

qipp, Qipp
Tells the compiler to link to the some or all of the Intel® Integrated Performance Primitives (Intel® IPP) libraries.

Syntax
Linux OS:
-qipp[=lib]

macOS:
-qipp[=lib]

Windows OS:
/Qipp[:lib]
Arguments

Indicates the Intel® IPP libraries that the compiler should link to. Possible values are:

- **common**: Tells the compiler to link using the main libraries set. This is the default if the option is specified with no \textit{lib}.
- **crypto**: Tells the compiler to link using the Intel® IPP Cryptography libraries.
- **nonpic** (Linux* only): Tells the compiler to link using the version of the libraries that do not have position-independent code.
- **nonpic\_crypto** (Linux only): Tells the compiler to link using the Intel® IPP Cryptography libraries. It uses the version of the libraries that do not have position-independent code.

Default

OFF

The compiler does not link to the Intel® IPP libraries.

Description

The option tells the compiler to link to the some or all of the Intel® Integrated Performance Primitives (Intel® IPP) libraries and include the Intel® IPP headers.

The \texttt{[Q]ipp-link} option controls whether the compiler links to static, dynamic threaded, or static threaded Intel® IPP run-time libraries.

\textbf{NOTE}

On Windows* systems, this option adds directives to the compiled code, which the linker then reads without further input from the driver. You do not need to specify a separate link command.

On Linux* and macOS* systems, the driver must add the library names explicitly to the link command. You must use option \texttt{qipp} to perform the link to pull in the dependent libraries.

Product and Performance Information

ipp-link, Qipp-link compiler option

qmlk, Qmkl
_Tells the compiler to link to certain libraries in the Intel® oneAPI Math Kernel Library (oneMKL). On Windows systems, you must specify this option at compile time._

Syntax
Linux OS:
-qmlk [=lib]

macOS:
-qmlk [=lib]

Windows OS:
/Qmkl[=lib]

Arguments

Indicates which oneMKL library files should be linked. Possible values are:

- **parallel**: Tells the compiler to link using the threaded libraries in oneMKL. This is the default if the option is specified with no `lib`.

- **sequential**: Tells the compiler to link using the sequential libraries in oneMKL.

- **cluster**: Tells the compiler to link using the cluster-specific libraries and the sequential libraries in oneMKL. Cluster-specific libraries are not available for macOS*.

Default
OFF The compiler does not link to the oneMKL library.

Description
This option tells the compiler to link to certain libraries in the Intel® oneAPI Math Kernel Library (oneMKL).
On Linux* and macOS* systems, dynamic linking is the default when you specify `-mkl`. To link with oneMKL statically, you must specify:

```
-qmkl -static-intel
```

On Windows* systems, static linking is the default when you specify `/Qmkl`. To link with oneMKL dynamically, you must specify:

```
/Qmkl /MD
```

For more information about using oneMKL libraries, see the article in Intel® Developer Zone titled: Intel® oneAPI Math Kernel Library Link Line Advisor, which is located in https://software.intel.com/content/www/us/en/develop/tools/oneapi/components/onemkl/link-line-advisor.html.

**NOTE**

On Windows* systems, this option adds directives to the compiled code, which the linker then reads without further input from the driver. On Linux* and macOS* systems, the driver must add the library names explicitly to the link command.

**NOTE**

If you specify option [q or Q]mkl, or `-qmkl=parallel` or `/Qmkl:parallel`, and you also specify option [Q]tbb, the compiler links to the standard threaded version of oneMKL. However, if you specify [q or Q]mkl, or `-qmkl=parallel` or `/Qmkl:parallel`, and you also specify option [Q]tbb and option [q or Q]openmp, the compiler links to the OpenMP* threaded version of oneMKL.

**IDE Equivalent**

Visual Studio: None

Eclipse: Performance Library Build Components > Use Intel® oneAPI Math Kernel Library

Xcode: Performance Library Build Components > Use Intel® oneAPI Math Kernel Library

**Alternate Options**

Linux and macOS*: `-mkl` (this is a deprecated option)

**See Also**

static-intel compiler option

MD compiler option

**qopt-args-in-regs, Qopt-args-in-regs**

Determines whether calls to routines are optimized by passing parameters in registers instead of on the stack.

**Architecture Restrictions**

Only available on IA-32 architecture

**Syntax**

Linux OS:

```
-qopt-args-in-regs[=keyword]
```
macOS:
None

Windows OS:
/Qopt-args-in-regs[:keyword]

**Arguments**

*keyword*  Specifies whether the optimization should be performed and under what conditions. Possible values are:

- **none**  The optimization is not performed. No parameters are passed in registers. They are put on the stack.
- **seen**  Causes parameters to be passed in registers when they are passed to routines whose definition can be seen in the same compilation unit.
- **all**  Causes parameters to be passed in registers, whether they are passed to routines whose definition can be seen in the same compilation unit, or not. This value is only available on Linux* systems.

**Default**

- `-qopt-args-in-regs=seen`  or  
  `/Qopt-args-in-regs:seen`

**Description**

This option determines whether calls to routines are optimized by passing parameters in registers instead of on the stack. It also indicates the conditions when the optimization will be performed.

This option can improve performance for Application Binary Interfaces (ABIs) that require parameters to be passed in memory and compiled without interprocedural optimization (IPO).

Note that on Linux* systems, if all is specified, a small overhead may be paid when calling "unseen" routines that have not been compiled with the same option. This is because the call will need to go through a "thunk" to ensure that parameters are placed back on the stack where the callee expects them.

**IDE Equivalent**

None

**Alternate Options**

None

**qopt-assume-safe-padding, Qopt-assume-safe-padding**

*Determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object.*

**Architecture Restrictions**

Only available on all architectures that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions
Syntax

Linux OS and macOS:
-qopt-assume-safe-padding
-qno-opt-assume-safe-padding

Windows OS:
/Qopt-assume-safe-padding
/Qopt-assume-safe-padding-

Arguments
None

Default
-qno-opt-assume-safe-padding
or/Qopt-assume-safe-padding-

The compiler will not assume that variables and dynamically allocated memory are padded past the end of the object. It will adhere to the sizes specified in your program.

Description
This option determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object.

When you specify option [q or Q]opt-assume-safe-padding, the compiler assumes that variables and dynamically allocated memory are padded. This means that code can access up to 64 bytes beyond what is specified in your program.

The compiler does not add any padding for static and automatic objects when this option is used, but it assumes that code can access up to 64 bytes beyond the end of the object, wherever the object appears in the program. To satisfy this assumption, you must increase the size of static and automatic objects in your program when you use this option.

This option may improve performance of memory operations.

IDE Equivalent
None

Alternate Options
None

qopt-block-factor, Qopt-block-factor
Let you specify a loop blocking factor.

Syntax

Linux OS and macOS:
-qopt-block-factor=n

Windows OS:
/Qopt-block-factor:n
Arguments

\( n \)

Is the blocking factor. It must be an integer. The compiler may ignore the blocking factor if the value is 0 or 1.

Default

OFF

The compiler uses default heuristics for loop blocking.

Description

This option lets you specify a loop blocking factor.

IDE Equivalent

Visual Studio: Diagnostics > Optimization Diagnostic File
Diagnostics > Emit Optimization Diagnostics to File
Eclipse: None
Xcode: None

Alternate Options

None

\texttt{qopt-calloc}

\textit{Tells the compiler to substitute a call to _intel_fast_calloc() for a call to calloc().}

Syntax

Linux OS:
\texttt{-qopt-calloc}
\texttt{-qno-opt-calloc}

macOS:
None

Windows OS:
None

Arguments

None

Default

\texttt{-qno-opt-calloc}

The compiler does not substitute a call to _intel_fast_calloc() for a call to calloc().

Description

This option tells the compiler to substitute a call to _intel_fast_calloc() for a call to calloc().

This option may increase the performance of long-running programs that use calloc() frequently. It is recommended for these programs over combinations of options -\texttt{inline-calloc} and -\texttt{qopt-malloc-options=3} because this option causes less memory fragmentation.
NOTE
Many routines in the LIBIRC library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

**IDE Equivalent**
None

**Alternate Options**
None

### qopt-class-analysis, Qopt-class-analysis

*Determines whether C++ class hierarchy information is used to analyze and resolve C++ virtual function calls at compile time.*

#### Syntax

**Linux OS and macOS:**
- `-qopt-class-analysis`
- `-qno-opt-class-analysis`

**Windows OS:**
- `/Qopt-class-analysis`
- `/Qopt-class-analysis-`

#### Arguments

None

#### Default

- `-qno-opt-class-analysis`
  or `/Qopt-class-analysis-`

#### Description

This option determines whether C++ class hierarchy information is used to analyze and resolve C++ virtual function calls at compile time. The option is turned on by default with the `-ipo` compiler option, enabling improved C++ optimization. If a C++ application contains non-standard C++ constructs, such as pointer down-casting, it may result in different behaviors.

**IDE Equivalent**
None

**Alternate Options**
None

### qopt-dynamic-align, Qopt-dynamic-align

*Enables or disables dynamic data alignment optimizations.*
**Syntax**

**Linux OS:**
- `-qopt-dynamic-align`
- `-qno-opt-dynamic-align`

**macOS:**
- `-qopt-dynamic-align`
- `-qno-opt-dynamic-align`

**Windows OS:**
- `/Qopt-dynamic-align`
- `/Qopt-dynamic-align-`

**Arguments**
None

**Default**
- `-qopt-dynamic-align`
- `/Qopt-dynamic-align`

The compiler may generate code dynamically dependent on alignment. It may do optimizations based on data location for the best performance. The result of execution on some algorithms may depend on data layout.

**Description**

This option enables or disables dynamic data alignment optimizations.

If you specify `-qno-opt-dynamic-align` or `/Qopt-dynamic-align-`, the compiler generates no code dynamically dependent on alignment. It will not do any optimizations based on data location and results will depend on the data values themselves.

When you specify `[q or Q]qopt-dynamic-align`, the compiler may implement conditional optimizations based on dynamic alignment of the input data. These dynamic alignment optimizations may result in different bitwise results for aligned and unaligned data with the same values.

Dynamic alignment optimizations can improve the performance of some vectorized code, especially for long trip count loops, but there is an associated cost of increased code size and compile time. Disabling such optimizations can improve the performance of some other vectorized code. It may also improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

**IDE Equivalent**
None

**Alternate Options**
None

**qopt-jump-tables, Qopt-jump-tables**

*Enables or disables generation of jump tables for switch statements.*
Syntax

Linux OS and macOS:
-qopt-jump-tables=keyword
-qno-opt-jump-tables

Windows OS:
/Qopt-jump-tables:keyword
/Qopt-jump-tables-

Arguments

keyword

Is the instruction for generating jump tables. Possible values are:

**never**
Tells the compiler to never generate jump tables. All switch statements are implemented as chains of if-then-elses. This is the same as specifying -qno-opt-jump-tables (Linux* and macOS*) or /Qopt-jump-tables- (Windows*).

**default**
The compiler uses default heuristics to determine when to generate jump tables.

**large**
Tells the compiler to generate jump tables up to a certain pre-defined size (64K entries).

**n**
Must be an integer. Tells the compiler to generate jump tables up to n entries in size.

Default

-qopt-jump-tables=default
/Qopt-jump-tables:default

The compiler uses default heuristics to determine when to generate jump tables for switch statements.

Description

This option enables or disables generation of jump tables for switch statements. When the option is enabled, it may improve performance for programs with large switch statements.

IDE Equivalent

None

Alternate Options

None

qopt-malloc-options

*Let you specify an alternate algorithm for malloc*. 
Syntax

Linux OS and macOS:
-qopt-malloc-options=n

Windows OS:
None

Arguments

\( n \) Specifies the algorithm to use for malloc(). Possible values are:

0
Tells the compiler to use the default algorithm for malloc(). This is the default.

1
Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x10000000.

2
Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x40000000.

3
Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=0 and M_TRIM_THRESHOLD=-1.

4
Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=0, M_TRIM_THRESHOLD=-1, M_TOP_PAD=4096.

Default

-qopt-malloc-options=0 The compiler uses the default algorithm when malloc() is called. No call is made to mallopt().

Description

This option lets you specify an alternate algorithm for malloc().

If you specify a non-zero value for \( n \), it causes alternate configuration parameters to be set for how malloc() allocates and frees memory. It tells the compiler to insert calls to mallopt() to adjust these parameters to malloc() for dynamic memory allocation. This may improve speed.

IDE Equivalent

mallopt function (defined in malloc.h)
**qopt-matmul, Qopt-matmul**

*Enables or disables a compiler-generated Matrix Multiply (matmul) library call.*

**Syntax**

**Linux OS:**
- `-qopt-matmul`
- `-qno-opt-matmul`

**macOS:**
None

**Windows OS:**
- `/Qopt-matmul`
- `/Qopt-matmul-`

**Arguments**

None

**Default**

- `-qno-opt-matmul` or `/Qopt-matmul-`  
  The matmul library call optimization does not occur unless this option is enabled or certain other compiler options are specified (see below).

**Description**

This option enables or disables a compiler-generated Matrix Multiply (MATMUL) library call.

The `[q or Q]opt-matmul` option tells the compiler to identify matrix multiplication loop nests (if any) and replace them with a matmul library call for improved performance. The resulting executable may improve performance on Intel® microprocessors.

**NOTE**

This option is dependent upon the OpenMP® library. If your product does not support OpenMP, this option will have no effect.

This option has no effect unless option `O2` or higher is set.

**NOTE**

Many routines in the MATMUL library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

**IDE Equivalent**

**Visual Studio**

Visual Studio: **Optimization > Enable Matrix Multiply Library Call**
**Eclipse**
Eclipse: **Optimization > Optimize Matrix Multiplication**

**Xcode**
Xcode: None

**Alternate Options**
None

**See Also**

**qopt-mem-layout-trans, Qopt-mem-layout-trans**
*Controls the level of memory layout transformations performed by the compiler.*

**Syntax**

**Linux OS and macOS:**
-qopt-mem-layout-trans[=n]
-qno-opt-mem-layout-trans

**Windows OS:**
/Qopt-mem-layout-trans[:n]
/Qopt-mem-layout-trans-

**Arguments**

- **n**
  - Disables memory layout transformations. This is the same as specifying -qno-opt-mem-layout-trans (Linux* and macOS*) or /Qopt-mem-layout-trans- (Windows*).
  - Enables basic memory layout transformations.
  - Enables more memory layout transformations. This is the same as specifying [q or Q]opt-mem-layout-trans with no argument.
  - Enables more memory layout transformations like copy-in/copy-out of structures for a region of code. You should only use this setting if your system has more than 4GB of physical memory per core.
Enables more aggressive memory layout transformations. You should only use this setting if your system has more than 4GB of physical memory per core.

**Default**

-qopt-mem-layout-trans=2

or
/Qopt-mem-layout-trans:2

**Description**

This option controls the level of memory layout transformations performed by the compiler. This option can improve cache reuse and cache locality.

**IDE Equivalent**

None

**Alternate Options**

None

**qopt-multi-version-aggressive, Qopt-multi-version-aggressive**

* Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.

**Syntax**

**Linux OS:**

-qopt-multi-version-aggressive

-qno-opt-multi-version-aggressive

**macOS:**

-qopt-multi-version-aggressive

-qno-opt-multi-version-aggressive

**Windows OS:**

/Qopt-multi-version-aggressive

/Qopt-multi-version-aggressive-

**Arguments**

None
**Default**

- `qno-opt-multi-version-aggressive` or `/Qopt-multi-version-aggressive-

The compiler uses default heuristics when checking for pointer aliasing and scalar replacement.

**Description**

This option tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement. This option may improve performance.

The performance can be affected by certain options, such as `/arch` or `/Qx` (Windows*) or `-m` or `-x` (Linux* and macOS*).

**IDE Equivalent**

None

**Alternate Options**

None

**qopt-multiple-gather-scatter-by-shuffles, Qopt-multiple-gather-scatter-by-shuffles**

*Enables or disables the optimization for multiple adjacent gather/scatter type vector memory references.*

**Syntax**

Linux OS:

- `-qopt-multiple-gather-scatter-by-shuffles`
- `-qno-opt-multiple-gather-scatter-by-shuffles`

macOS:

- `-qopt-multiple-gather-scatter-by-shuffles`
- `-qno-opt-multiple-gather-scatter-by-shuffles`

Windows OS:

/`Qopt-multiple-gather-scatter-by-shuffles`
/`Qopt-multiple-gather-scatter-by-shuffles-

**Arguments**

None

**Default**

*varies*

When this option is not specified, the compiler uses default heuristics for optimization.

**Description**

This option controls the optimization for multiple adjacent gather/scatter type vector memory references. This optimization hint is useful for performance tuning. It tries to generate more optimal software sequences using shuffles.
If you specify this option, the compiler will apply the optimization heuristics. If you specify
-qno-opt-multiple-gather-scatter-by-shuffles
or /Qopt-multiple-gather-scatter-by-shuffles-, the compiler will not apply the optimization.

NOTE
Optimization is affected by optimization compiler options, such as [Q]x, -march (Linux* or
macOS*), and /arch (Windows*).

qopt-prefetch, Qopt-prefetch
Enables or disables prefetch insertion optimization.

Syntax

Linux OS and macOS:
-qopt-prefetch=[n]
-qno-opt-prefetch

Windows OS:
/Qopt-prefetch[:n]
/Qopt-prefetch-

Arguments

n

Is the level of software prefetching optimization desired. Possible values are:

0
Disables software prefetching. This is the same as specifying -qno-opt-prefetch (Linux* and macOS*) or /Qopt-prefetch-(Windows*).
Enables different levels of software prefetching. If you do not specify a value for \( n \), the default is 2. Use lower values to reduce the amount of prefetching.

**Default**

-qno-opt-prefetch
or /Qopt-prefetch-

**Prefetch insertion optimization is disabled.**

**Description**

This option enables or disables prefetch insertion optimization. The goal of prefetching is to reduce cache misses by providing hints to the processor about when data should be loaded into the cache.

This option enables prefetching when higher optimization levels are specified.

**IDE Equivalent**

Visual Studio: None

Eclipse: **Optimization > Enable Prefetch Insertion**

Xcode: **Optimization > Enable Prefetch Insertion**

**Alternate Options**

None

**See Also**

qopt-prefetch-distance, Qopt-prefetch-distance  compiler option

---

**qopt-prefetch-distance, Qopt-prefetch-distance**

*Specifies the prefetch distance to be used for compiler-generated prefetches inside loops.*

**Syntax**

**Linux OS:**

-qopt-prefetch-distance=n1[, n2]

**macOS:**

None

**Windows OS:**

/Qopt-prefetch-distance:n1[, n2]

**Arguments**

\( n1, n2 \)

Is the prefetch distance in terms of the number of (possibly-vectorized) iterations. Possible values are non-negative numbers \( \geq 0 \).

\( n2 \) is optional.

\( n1 = 0 \) turns off all compiler issued prefetches from memory to L2. \( n2 = 0 \) turns off all compiler issued prefetches from L2 to L1. If \( n2 \) is specified and \( n1 > 0 \), \( n1 \) should be \( \geq n2 \).
**Default**
OFF
The compiler uses default heuristics to determine the prefetch distance.

**Description**
This option specifies the prefetch distance to be used for compiler-generated prefetches inside loops. The unit ($n1$ and optionally $n2$) is the number of iterations. If the loop is vectorized by the compiler, the unit is the number of vectorized iterations.

The value of $n1$ will be used as the distance for prefetches from memory to L2 (for example, the vprefetch1 instruction). If $n2$ is specified, it will be used as the distance for prefetches from L2 to L1 (for example, the vprefetch0 instruction).

This option is ignored if option `-qopt-prefetch=0 (Linux*) or /Qopt-prefetch:0 (Windows*) is specified.

**IDE Equivalent**
None

**Alternate Options**
None

**Example**
Consider the following Linux* examples:

- `-qopt-prefetch-distance=64,32`

  The above causes the compiler to use a distance of 64 iterations for memory to L2 prefetches, and a distance of 32 iterations for L2 to L1 prefetches.

- `-qopt-prefetch-distance=24`

  The above causes the compiler to use a distance of 24 iterations for memory to L2 prefetches. The distance for L2 to L1 prefetches will be determined by the compiler.

- `-qopt-prefetch-distance=0,4`

  The above turns off all memory to L2 prefetches inserted by the compiler inside loops. The compiler will use a distance of 4 iterations for L2 to L1 prefetches.

- `-qopt-prefetch-distance=16,0`

  The above causes the compiler to use a distance of 16 iterations for memory to L2 prefetches. No L2 to L1 loop prefetches are issued by the compiler.

**See Also**
`qopt-prefetch`, `Qopt-prefetch` compiler option
`prefetch` pragma

**qopt-prefetch-issue-excl-hint, Qopt-prefetch-issue-excl-hint**

*Supports the prefetchW instruction in Intel® microarchitecture code name Broadwell and later.*

**Syntax**

**Linux OS:**

- `-qopt-prefetch-issue-excl-hint`
macOS:
None

Windows OS:
/Qopt-prefetch-issue-excl-hint

Arguments
None

Default
OFF

The compiler does not support the PREFETCHW instruction for this microarchitecture.

Description
This option supports the PREFETCHW instruction in Intel® microarchitecture code name Broadwell and later. When you specify this option, you must also specify option [q or Q]opt-prefetch.
The prefetch instruction is merely a hint and does not affect program behavior. If executed, this instruction moves data closer to the processor and invalidates any other cached copy in anticipation of the line being written to in the future.

IDE Equivalent
None

Alternate Options
None

qopt-prefetch/Qopt-prefetch compiler option

qopt-ra-region-strategy, Qopt-ra-region-strategy
Selects the method that the register allocator uses to partition each routine into regions.

Syntax
Linux OS and macOS:
-qopt-ra-region-strategy[=keyword]

Windows OS:
/Qopt-ra-region-strategy[:keyword]

Arguments

<table>
<thead>
<tr>
<th>keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routine</td>
<td>Creates a single region for each routine.</td>
</tr>
<tr>
<td>block</td>
<td>Partitions each routine into one region per basic block.</td>
</tr>
</tbody>
</table>
Partitions each routine into one region per trace.

Partitions each routine into one region per loop.

The compiler determines which method is used for partitioning.

**Default**

- `-qopt-ra-region-strategy=default`
  - `or /Qopt-ra-region-strategy:default`

The compiler determines which method is used for partitioning. This is also the default if `keyword` is not specified.

**Description**

This option selects the method that the register allocator uses to partition each routine into regions.

When setting `default` is in effect, the compiler attempts to optimize the tradeoff between compile-time performance and generated code performance.

This option is only relevant when optimizations are enabled (option 01 or higher).

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

- compiler option

**qopt-streaming-stores, Qopt-streaming-stores**

*Enables generation of streaming stores for optimization.*

**Syntax**

**Linux OS and macOS:**

- `-qopt-streaming-stores=keyword`
  - `-qno-opt-streaming-stores`

**Windows OS:**

- `/Qopt-streaming-stores=keyword`
  - `/Qopt-streaming-stores-`

**Arguments**

- `keyword`

  Specifies whether streaming stores are generated. Possible values are:
always

Enables generation of streaming stores for optimization. The compiler optimizes under the assumption that the application is memory bound.

When this option setting is specified, it is your responsibility to also insert any fences as required to ensure correct memory ordering within a thread or across threads. One typical way to do this is to insert a __mm_sfence() intrinsic call just after the loops (such as the initialization loop) where the compiler may insert streaming store instructions.

never

Disables generation of streaming stores for optimization. Normal stores are performed. This is the same as specifying -qno-opt-streaming-stores (Linux*) or /Qopt-streaming-stores=always (Windows*).

auto

Lets the compiler decide which instructions to use.

Default

-qopt-streaming-stores=auto
or /Qopt-streaming-stores:auto

The compiler decides whether to use streaming stores or normal stores.

Description

This option enables generation of streaming stores for optimization. This method stores data with instructions that use a non-temporal buffer, which minimizes memory hierarchy pollution.

This option may be useful for applications that can benefit from streaming stores.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows a way to insert fences when specifying -qopt-streaming-stores=always or /Qopt-streaming-stores:always:

```c
void simple1(double * restrict a, double * restrict b, double * restrict c, double *d, int n) {
    int i, j;

    #pragma omp parallel for
    for (j=0; j<n; j++) {
        a[j] = 1.0;
        b[j] = 2.0;
        c[j] = 0.0;
    }
```

ax, Qax  compiler option
x, Qx  compiler option

qopt-subscript-in-range, Qopt-subscript-in-range
Determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops.

Syntax
Linux OS and macOS:
-qopt-subscript-in-range
-qno-opt-subscript-in-range

Windows OS:
/Qopt-subscript-in-range
/Qopt-subscript-in-range-

Arguments
None

Default
-qno-opt-subscript-in-range
or
/Qopt-subscript-in-range-

Description
This option determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops.

If you specify [q or Q]opt-subscript-in-range, the compiler assumes that there are no "large" integers being used or being computed inside loops. A "large" integer is typically \(2^{31}\).

This feature can enable more loop transformations.

IDE Equivalent
None

Alternate Options
None
Example
The following example shows how these options can be useful. Variable `m` is declared as type long (64-bits) and all other variables inside the subscript are declared as type int (32-bits):

```
A[i + j + (n + k) * m]
```

qopt-zmm-usage, Qopt-zmm-usage
 Defines a level of zmm registers usage.

Syntax
Linux OS and macOS:
- `qopt-zmm-usage=keyword`

Windows OS:
/`Qopt-zmm-usage:keyword`

Arguments
`keyword` Specifies the level of zmm registers usage. Possible values are:

- `low`
  Tells the compiler that the compiled program is unlikely to benefit from zmm registers usage. It specifies that the compiler should avoid using zmm registers unless it can prove the gain from their usage.

- `high`
  Tells the compiler to generate zmm code without restrictions.

Default
`varies`
The default is low when you specify `[Q]xCORE-AVX512`.
The default is high when you specify `[Q]xCOMMON-AVX512`.

Description
This option may provide better code optimization for Intel® processors that are on the Intel® microarchitecture formerly code-named Skylake.

This option defines a level of zmm registers usage. The `low` setting causes the compiler to generate code with zmm registers very carefully, only when the gain from their usage is proven. The `high` setting causes the compiler to use much less restrictive heuristics for zmm code generation.

It is not always easy to predict whether the `high` or the `low` setting will yield better performance. Programs that enjoy high performance gains from the use of xmm or ymm registers may expect performance improvement by moving to use zmm registers. However, some programs that use zmm registers may not gain as much or may even lose performance. We recommend that you try both option values to measure the performance of your programs.

This option is ignored if you do not specify an option that enables Intel® AVX-512, such as `[Q]xCORE-AVX512` or option `[Q]xCOMMON-AVX512`.

This option has no effect on loops that use pragma omp simd simdlen(n) or on functions that are generated by vector specifications specific to CORE-AVX512.

IDE Equivalent
None
Alternate Options
None

See Also
x, Qx compiler option
For more information about simd loops specification and vector function specification, see pragmas omp simd and omp declare simd in the OpenMP* TR4: Version 5.0 specification.

qoverride-limits, Qoverride-limits
*Let you override certain internal compiler limits that are intended to prevent excessive memory usage or compile times for very large, complex compilation units.*

Syntax
Linux OS and macOS:
-qoverride-limits

Windows OS:
/Qoverride-limits

Arguments
None

Default
OFF Certain internal compiler limits are not overridden. These limits are determined by default heuristics.

Description
This option provides a way to override certain internal compiler limits that are intended to prevent excessive memory usage or compile times for very large, complex compilation units.

If this option is not used and your program exceeds one of these internal compiler limits, some optimizations will be skipped to reduce the memory footprint and compile time. If you chose to create an optimization report by specifying [q or Q]opt-report, you may see a related diagnostic remark as part of the report.

Specifying this option may substantially increase compile time and/or memory usage.

**NOTE**
If you use this option, it is your responsibility to ensure that sufficient memory is available. If there is not sufficient available memory, the compilation may fail.

This option should only be used where there is a specific need; it is not recommended for inexperienced users.

IDE Equivalent
None

Alternate Options
None
**qtbb, Qtbb**
*Tells the compiler to link to the Intel® oneAPI Threading Building Blocks (oneTBB) libraries.*

**Syntax**

**Linux OS:**
- `-qtbb`

**macOS:**
- `-qtbb`

**Windows OS:**
- `/Qtbb`

**Arguments**
None

**Default**
OFF The compiler does not link to the oneTBB libraries.

**Description**
This option tells the compiler to link to the Intel® oneAPI Threading Building Blocks (oneTBB) libraries and include the oneTBB headers.

**NOTE**
On Windows* systems, this option adds directives to the compiled code, which the linker then reads without further input from the driver. You do not need to specify a separate link command.

On Linux* and macOS* systems, the driver must add the library names explicitly to the link command. You must use option `-qtbb` to perform the link to pull in the dependent libraries.

**IDE Equivalent**

**Visual Studio**
Visual Studio: None

**Eclipse**
Eclipse: *Performance Library Build Components > Use Intel® oneAPI Threading Building Blocks*

**Xcode**
Xcode: *Performance Library Build Components > Use Intel® oneAPI Threading Building Blocks*

**Alternate Options**
Linux: `-tbb` (this is a deprecated option)
**Qvla**

*Determines whether variable length arrays are enabled.*

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/Qvla
/Qvla-

**Arguments**

None

**Default**

/Qvla-  Variable length arrays are disabled.

**Description**

This option determines whether variable length arrays (a C99 feature) are enabled. To enable variable length arrays, you must specify /Qvla.

**IDE Equivalent**

None

**Alternate Options**

None

---

**scalar-rep, Qscalar-rep**

*Enables or disables the scalar replacement optimization done by the compiler as part of loop transformations.*

**Syntax**

**Linux OS and macOS:**

-scalar-rep
-no-scalar-rep

**Windows OS:**

/Qscalar-rep
/Qscalar-rep-
**Arguments**
None

**Default**
-scalar-rep or /Qscalar-rep

**Description**
Scalar replacement is performed during loop transformation at optimization levels of O2 and above.

This option enables or disables the scalar replacement optimization done by the compiler as part of loop transformations. This option takes effect only if you specify an optimization level of O2 or higher.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
O compiler option

**simd, /Qsimd**
Enables or disables compiler interpretation of simd pragmas.

**Syntax**

**Linux OS and macOS:**
- simd
- no-simd

**Windows OS:**
/Qsimd
/Qsimd-

**Arguments**
None

**Default**
-simd or /Qsimd

**Description**
SIMD pragmas are enabled.

This option enables or disables compiler interpretation of simd pragmas.

To disable interpretation of simd pragmas, specify -no-simd (Linux* and macOS*) or /Qsimd- (Windows*). Note that the compiler may still vectorize loops based on its own heuristics (leading to generation of SIMD instructions) even when -no-simd (or /Qsimd-) is specified.
To disable all compiler vectorization, use the "-no-vec -no-simd" (Linux* and macOS*) or "/Qvec- /Qsimd-" (Windows*) compiler options. The option -no-vec (and /Qvec-) disables all auto-vectorization, including vectorization of array notation statements. The option -no-simd (and /Qsimd-) disables vectorization of loops that have simd pragmas.

**NOTE**
If you specify option -mia32 (Linux*) or option /arch:IA32 (Windows*), simd pragmas are disabled by default and vector instructions cannot be used. Therefore, you cannot explicitly enable SIMD pragmas by specifying option /Qsimd.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
vec, Qvec  compiler option
Function Annotations and the SIMD Directive for Vectorization
simd pragma

**simd-function-pointers, Qsimd-function-pointers**
Enables or disables pointers to simd-enabled functions.

**Syntax**

**Linux OS and macOS:**
- simd-function-pointers
- no-simd-function-pointers

**Windows OS:**
/Qsimd-function-pointers
/Qsimd-function-pointers-

**Arguments**
None

**Default**
-no-simd-function-pointers Points to simd-enabled functions are disabled. Vector specifications can only be placed in function declarations and definitions.

**Description**
This option enables or disables pointers to simd-enabled functions.

When option [Q]simd-function-pointers is specified, it defines simd-enabled (vector) function pointers by placing vector specifications with all usual clauses in function pointer declarations. The vector specifications must be indicated in an attribute vector declaration or in pragma omp declare simd.
These pointers can enable indirect calls to appropriate vector versions of the function from a simd loop or another simd-enabled function.

**IDE Equivalent**

None

**Alternate Options**

None

**unroll, Qunroll**

*Tells the compiler the maximum number of times to unroll loops.*

**Syntax**

Linux OS:

- `-unroll [=n]`

macOS:

- `-unroll [=n]`

Windows OS:

- `/Qunroll [=n]`

**Arguments**

`n` Is the maximum number of times a loop can be unrolled. To disable loop enrolling, specify 0.

**Default**

- `-unroll` The compiler uses default heuristics when unrolling loops.
  
or
  `/Qunroll`

**Description**

This option tells the compiler the maximum number of times to unroll loops.

If you do not specify `n`, the optimizer determines how many times loops can be unrolled.

**IDE Equivalent**

Visual Studio: **Optimization > Loop Unrolling**

Eclipse: **Optimization > Loop Unroll Count**

Xcode: **Optimization > Loop Unrolling**

**Alternate Options**

Linux and macOS*: `-funroll-loops`

Windows: None
**unroll-aggressive, Qunroll-aggressive**
*Determines whether the compiler uses more aggressive unrolling for certain loops.*

**Syntax**

**Linux OS:**
- -unroll-aggressive
- -no-unroll-aggressive

**macOS:**
- -unroll-aggressive
- -no-unroll-aggressive

**Windows OS:**
- /Qunroll-aggressive
- /Qunroll-aggressive-

**Arguments**

None

**Default**

- -no-unroll-aggressive
  
  The compiler uses default heuristics when unrolling loops.
  
  or /Qunroll-aggressive-

**Description**

This option determines whether the compiler uses more aggressive unrolling for certain loops. The positive form of the option may improve performance.

This option enables aggressive, complete unrolling for loops with small constant trip counts.

**IDE Equivalent**

None

**Alternate Options**

None

**use-intel-optimized-headers, Quse-intel-optimized-headers**
*Determines whether the performance headers directory is added to the include path search list.*

**Syntax**

**Linux OS:**
- -use-intel-optimized-headers

**macOS:**
- -use-intel-optimized-headers

*Compiler Reference*
Windows OS:
/Quse-intel-optimized-headers

Arguments
None

Default
-no-use-intel-optimized-headers
or /Quse-intel-optimized-headers-
The performance headers directory is not added to the include path search list.

Description
This option determines whether the performance headers directory is added to the include path search list.
The performance headers directory is added if you specify [Q]use-intel-optimized-headers. Appropriate libraries are also linked in, as needed, for proper functionality.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

vec, Qvec
Enables or disables vectorization.

Syntax
Linux OS:
-vec
-no-vec

macOS:
-vec
-no-vec

Windows OS:
/Qvec
/Qvec-

Arguments
None

Default
-vec
or/Qvec

Vectorization is enabled if option O2 or higher is in effect.

Description
This option enables or disables vectorization.
To disable vectorization, specify -no-vec (Linux* and macOS*) or /Qvec- (Windows*).
To disable interpretation of SIMD pragmas, specify -no-simd (Linux* and macOS*) or /Qsimd- (Windows*).
To disable all compiler vectorization, use the "-no-vec -no-simd" (Linux* and macOS*) or "/Qvec- /Qsimd-" (Windows*) compiler options. The option -no-vec (and /Qvec-) disables all autovectorization, including vectorization of array notation statements. The option -no-simd (and /Qsimd-) disables vectorization of loops that have SIMD pragmas.

NOTE
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as /arch (Windows), -m (Linux and macOS*), or [Q]x.

vec-guard-write, Qvec-guard-write
Tells the compiler to perform a conditional check in a vectorized loop.
Syntax
Linux OS and macOS:
-vec-guard-write
-no-vec-guard-write

Windows OS:
/Qvec-guard-write
/Qvec-guard-write-

Arguments
None

Default
-vec-guard-write or /Qvec-guard-write

The compiler performs a conditional check in a vectorized loop.

Description
This option tells the compiler to perform a conditional check in a vectorized loop. This checking avoids unnecessary stores and may improve performance.

IDE Equivalent
None

Alternate Options
None

vec-threshold, Qvec-threshold
Sets a threshold for the vectorization of loops.

Syntax
Linux OS and macOS:
-vec-threshold[n]

Windows OS:
/Qvec-threshold[[[::]n]

Arguments

n
Is an integer whose value is the threshold for the vectorization of loops. Possible values are 0 through 100.

If n is 0, loops get vectorized always, regardless of computation work volume.

If n is 100, loops get vectorized when performance gains are predicted based on the compiler analysis data. Loops get vectorized only if profitable vector-level parallel execution is almost certain.
The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, \( n=50 \) directs the compiler to vectorize only if there is a 50% probability of the code speeding up if executed in vector form.

**Default**

-vec-threshold100
or /Qvec-threshold100

Loops get vectorized only if profitable vector-level parallel execution is almost certain. This is also the default if you do not specify \( n \).

**Description**

This option sets a threshold for the vectorization of loops based on the probability of profitable execution of the vectorized loop in parallel. This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time. The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

**IDE Equivalent**

Visual Studio: **Optimization > Threshold For Vectorization**
Eclipse: **Optimization > Enable Maximum Vector-level Parallelism**
Xcode: **Optimization > Enable Maximum Vector-level Parallelism**

**Alternate Options**

None

**vecabi, Qvecabi**

Determines which vector function application binary interface (ABI) the compiler uses to create or call vector functions.

**Syntax**

Linux OS and macOS:
-vecabi=keyword

Windows OS:
/Qvecabi:keyword

**Arguments**

*keyword*

Specifies which vector function ABI to use. Possible values are:

- **compat**
  
  Tells the compiler to use the compatibility vector function ABI. This ABI includes Intel®-specific features.

- **cmdtarget**
  
  Tells the compiler to generate an extended set of vector functions. The option is very similar to setting compat. However, for compat, only one vector function is created,
while for cmdtarget, several vector functions are created for each vector specification. Vector variants are created for targets specified by compiler options \([Q]x\) and/or \([Q]ax\). No change is made to the source code.

**gcc**

Tells the compiler to use the gcc vector function ABI. Use this setting only in cases when you want to link with modules compiled by gcc. This setting is not available on Windows* systems.

**legacy**

Tells the compiler to use the legacy vector function ABI. Use this setting if you need to keep the generated vector function binary backward compatible with the vectorized binary generated by older versions of the Intel® compilers (V13.1 or older).

**Default**

**compat**

The compiler uses the compatibility vector function ABI.

**Description**

This option determines which vector function application binary interface (ABI) the compiler uses to create or call vector functions.

**NOTE**

To avoid possible link-time and run-time errors, use identical \([Q]\text{vecabi}\) settings when compiling all files in an application that define or use vector functions, including libraries. If setting cmdtarget is specified, options \([Q]x\) and/or \([Q]ax\) must have identical values.

Be careful using setting cmdtarget with libraries or program modules/routines with vector function definitions that cannot be recompiled. In such cases, setting cmdtarget may cause link errors.

On Linux* systems, since the default is compat, you must specify legacy if you need to keep the generated vector function binary backward compatible with the vectorized binary generated by the previous version of Intel® compilers.

When cmdtarget is specified, the additional vector function versions are created by copying each vector specification and changing target processor in the copy. The number of vector functions is determined by the settings specified in options \([Q]x\) and/or \([Q]ax\).

For example, suppose we have the following function declaration:

```c
__declspec (vector(processor(core_2_duo_sse4_1))) int foo(int a);
```

and the following options are specified: \(-axAVX,\text{CORE-AVX2}\)

The following table shows the different results for the above declaration and option specifications when setting compat or setting cmdtarget is used:
compat
One vector version is created for Intel® SSE4.1 (by vector function specification).

cmdtarget
Four vector versions are created for the following targets:
- Intel® SSE2 (default because no -x option is used)
- Intel® SSE4.1 (by vector function specification)
- Intel® AVX (by the first -ax option value)
- Intel® AVX2 (by the second -ax option value)

For more information about the Intel®-compatible vector functions ABI, see the downloadable PDF titled: Vector Function Application Binary Interface, at https://software.intel.com/content/www/us/en/develop/download/vector-simd-function-abi.html

For more information about the GCC vector functions ABI, see the item Libmvec - vector math library document in the GLIBC wiki at sourceware.org.

Profile Guided Optimization Options
This section contains descriptions for compiler options that pertain to profile-guided optimization.

finstrument-functions, Qinstrument-functions
Determines whether function entry and exit points are instrumented.

Syntax

Linux OS and macOS:
- finstrument-functions
- fno-instrument-functions

Windows OS:
/finstrument-functions
/Qinstrument-functions-

Arguments
None
**Default**

`-fno-instrument-functions`  
or  
`/Qinstrument-functions-`

**Description**

This option determines whether function entry and exit points are instrumented. It may increase execution time.

The following profiling functions are called with the address of the current function and the address of where the function was called (its "call site"):

- This function is called upon function entry:
  ```c
  void __cyg_profile_func_enter (void *this_fn,  
  void *call_site);
  ```

- This function is called upon function exit:
  ```c
  void __cyg_profile_func_exit (void *this_fn,  
  void *call_site);
  ```

These functions can be used to gather more information, such as profiling information or timing information. Note that it is the user's responsibility to provide these profiling functions.

If you specify `-finstrument-functions` (Linux* and macOS*) or `/Qinstrument-functions` (Windows*), function inlining is disabled. If you specify `-fno-instrument-functions` or `/Qinstrument-functions-`, inlining is not disabled.

On Linux and macOS* systems, you can use the following attribute to stop an individual function from being instrumented:

```c
__attribute__((__no_instrument_function__))
```

It also stops inlining from being disabled for that individual function.

This option is provided for compatibility with gcc.

**IDE Equivalent**

None

**Alternate Options**

None

**fnsplit, Qfnsplit**

*Enables function splitting.*

**Syntax**

**Linux OS:**

```c
-fnsplit[=n]
-no-fnsplit
```

**macOS:**

None
Windows OS:
/Qfnsplit[:n]
/Qfnsplit-

Arguments

$n$

Is an optional positive integer indicating the threshold number.
The blocks can be placed into a different code segment if they are only reachable via a conditional branch whose taken probability is less than the specified $n$. Branch taken probability is heuristically calculated by the compiler and can be observed in assembly listings.
The range for $n$ is $0 \leq n \leq 100$.

Default

OFF

Function splitting is not enabled. However, function grouping is still enabled.

Description

This option enables function splitting. If you specify [Q]fnsplit with no $n$, you must also specify option [Q]prof-use, or the option will have no effect and no function splitting will occur.

If you specify $n$, function splitting is enabled and you do not need to specify option [Q]prof-use.

To disable function splitting when you use option [Q]prof-use, specify /Qfnsplit- (Windows*) or -no-fnsplit (Linux*).

NOTE

Function splitting is generally not supported when exception handling is turned on for C/C++ routines in the stack of called routines. See also -fexceptions (Linux*) and the C/C++ option /EH (Windows*).

IDE Equivalent

Visual Studio: Code Generation > Disable Function Splitting
Eclipse: None
Xcode: None

Alternate Options

Linux: -freorder-blocks-and-partition (a gcc option)
Windows: None

Gh

Calls a function to aid custom user profiling.

Syntax

Linux OS and macOS:

None
Windows OS:
/Gh

Arguments
None

Default
OFF  The compiler uses the default libraries.

Description
This option calls the __penter function to aid custom user profiling. The prototype for __penter is not included in any of the standard libraries or Intel-provided libraries. You do not need to provide a prototype unless you plan to explicitly call __penter.

IDE Equivalent
None

Alternate Options
None

See Also
GH  compiler option

GH
Calls a function to aid custom user profiling.

Syntax
Linux OS and macOS:
None

Windows OS:
/GH

Arguments
None

Default
OFF  The compiler uses the default libraries.

Description
This option calls the __pexit function to aid custom user profiling. The prototype for __pexit is not included in any of the standard libraries or Intel-provided libraries. You do not need to provide a prototype unless you plan to explicitly call __pexit.

IDE Equivalent
None
Alternate Options
None

See Also
Gh  compiler option

p
Compiles and links for function profiling with gprof(1).

Syntax
Linux OS and macOS:

-p

Windows OS:
None

Arguments
None

Default
OFF  Files are compiled and linked without profiling.

Description
This option compiles and links for function profiling with gprof(1).

When you specify this option, inlining is disabled. However, you can override this by specifying pragma forceinline, declspec forceinline (Windows*), attribute always_inline (Linux* and macOS*), or a compiler option such as [Q]inline-forceinline.

IDE Equivalent
None

Alternate Options
Linux and macOS*: -qp (this is a deprecated option)

Windows: None

prof-data-order, Qprof-data-order
Enables or disables data ordering if profiling information is enabled.

Syntax

Linux OS:

-prof-data-order
-no-prof-data-order

macOS:
None
**Windows OS:**
/Qprof-data-order
/Qprof-data-order-

**Arguments**
None

**Default**
-no-prof-data-order
or
/Qprof-data-order-

**Description**
This option enables or disables data ordering if profiling information is enabled. It controls the use of profiling information to order static program data items.

For this option to be effective, you must do the following:
- For instrumentation compilation, you must specify option [Q]prof-gen setting globdata.
- For feedback compilation, you must specify the [Q]prof-use option. You must not use multi-file optimization by specifying options such as [Q]ipo or [Q]ipo-c.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
prof-gen, Qprof-gen
compiler option
prof-use, Qprof-use
compiler option
prof-func-order, Qprof-func-order
compiler option

prof-dir, Qprof-dir
Specifies a directory for profiling information output files.

**Syntax**

**Linux OS and macOS:**
-prof-dir dir

**Windows OS:**
/Qprof-dir:dir
Arguments

\textit{dir} 
Is the name of the directory. You can specify a relative pathname or an absolute pathname.

Default

OFF 
Profiling output files are placed in the directory where the program is compiled.

Description

This option specifies a directory for profiling information output files (*.dyn and *.dpi). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Option /Qprof-dir is equivalent to option /Qcov-dir. If you specify both options, the last option specified on the command line takes precedence.

IDE Equivalent

Visual Studio: \textbf{General > Profile Directory}
Eclipse: \textbf{Optimization > Profile Directory}
Xcode: None

Alternate Options

None

\textbf{prof-file, Qprof-file}

\textit{Specifies an alternate file name for the profiling summary files.}

Syntax

\textbf{Linux OS and macOS:}

- \texttt{-prof-file filename}

\textbf{Windows OS:}

/\texttt{Qprof-file:filename}

Arguments

\textit{filename} 
Is the name of the profiling summary file.

Default

OFF 
The profiling summary files have the file name pgopti.*

Description

This option specifies an alternate file name for the profiling summary files. The \textit{filename} is used as the base name for files created by different profiling passes.

If you add this option to profmerge, the .dpi file will be named \textit{filename}.dpi instead of pgopti.dpi.
If you specify this option with option \texttt{[Q]prof-use}, the .dpi file will be named \textit{filename}.dpi instead of pgopti.dpi.

Option \texttt{/Qprof-file} is equivalent to option \texttt{/Qcov-file}. If you specify both options, the last option specified on the command line takes precedence.

\textbf{NOTE}

When you use option \texttt{[Q]prof-file}, you can only specify a file name. If you want to specify a path (relative or absolute) for \textit{filename}, you must also use option \texttt{[Q]prof-dir}.

\textbf{IDE Equivalent}

None

\textbf{Alternate Options}

None

\textbf{See Also}

\texttt{prof-gen, Qprof-gen} compiler option
\texttt{prof-use, Qprof-use} compiler option
\texttt{prof-dir, Qprof-dir} compiler option

\textbf{prof-func-groups}

\textit{Enables or disables function grouping if profiling information is enabled.}

\textbf{Syntax}

\textbf{Linux OS:}

- \texttt{-prof-func-groups}
- \texttt{-no-prof-func-groups}

\textbf{macOS:}

None

\textbf{Windows OS:}

None

\textbf{Arguments}

None

\textbf{Default}

- \texttt{-no-prof-func-groups} Function grouping is disabled.

\textbf{Description}

This option enables or disables function grouping if profiling information is enabled.

A "function grouping" is a profiling optimization in which entire routines are placed either in the cold code section or the hot code section.
If profiling information is enabled by option `-prof-use`, option `-prof-func-groups` is set and function grouping is enabled. However, if you explicitly enable `-prof-func-order`, function ordering is performed instead of function grouping.

If you want to disable function grouping when profiling information is enabled, specify `-no-prof-func-groups`.

To set the hotness threshold for function grouping, use option `-prof-hotness-threshold`.

**IDE Equivalent**

None

**See Also**

`prof-use`, `Qprof-use` compiler option
`prof-func-order`, `Qprof-func-order` compiler option
`prof-hotness-threshold`, `Qprof-hotness-threshold` compiler option

**prof-func-order, Qprof-func-order**

*Enables or disables function ordering if profiling information is enabled.*

**Syntax**

**Linux OS:**

- `-prof-func-order`
- `-no-prof-func-order`

**macOS:**

None

**Windows OS:**

`/Qprof-func-order`
`/Qprof-func-order-`

**Arguments**

None

**Default**

- `-no-prof-func-order`
  or
  `/Qprof-func-order-`

**Description**

This option enables or disables function ordering if profiling information is enabled.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify option `[Q]prof-gen setting srcpos`.
- For feedback compilation, you must specify `[Q]prof-use`. You must not use multi-file optimization by specifying options such as `[Q]ipo` or `[Q]ipo-c`. 

237
If you enable profiling information by specifying option [Q]prof-use, option [Q]prof-func-groups is set and function grouping is enabled. However, if you explicitly enable the [Q]prof-func-order option, function ordering is performed instead of function grouping.

On Linux* systems, this option is only available for Linux linker 2.15.94.0.1, or later.

To set the hotness threshold for function grouping and function ordering, use option [Q]prof-hotness-threshold.

**IDE Equivalent**
None

**Alternate Options**
None

**Example**
The following example shows how to use this option on a Windows system:

```
icl /Qprof-gen:globdata file1.c file2.c /Fe instrumented.exe
./instrumented.exe
icl /Qprof-use /Qprof-func-order file1.c file2.c /Fe feedback.exe
```

The following example shows how to use this option on a Linux system:

```
icc -prof-gen:globdata file1.c file2.c -o instrumented
./instrumented.exe
icc -prof-use -prof-func-order file1.c file2.c -o feedback
```

**See Also**
prof-hotness-threshold, Qprof-hotness-threshold

**prof-gen, Qprof-gen**
*Produces an instrumented object file that can be used in profile guided optimization.*

**Syntax**

**Linux OS and macOS:**

- `prof-gen[=keyword[, keyword],...]`
- `no-prof-gen`

**Windows OS:**

`/Qprof-gen[=keyword[,keyword],...]`

`/Qprof-gen-`
Arguments

keyword

Specifies details for the instrumented file. Possible values are:

- **default**
  Produces an instrumented object file. This is the same as specifying the \([Q]\text{prof-gen}\) option with no keyword.

- **srcpos**
  Produces an instrumented object file that includes extra source position information.

- **globdata**
  Produces an instrumented object file that includes information for global data layout.

- **[no]threadsafe**
  Produces an instrumented object file that includes the collection of PGO data on applications that use a high level of parallelism. If \([Q]\text{prof-gen}\) is specified with no keyword, the default is nothreadsafe.

Default

- **-no-prof-gen or /Qprof-gen-**
  Profile generation is disabled.

Description

This option produces an instrumented object file that can be used in profile guided optimization. It gets the execution count of each basic block.

You can specify more than one setting for \([Q]\text{prof-gen}\). For example, you can specify the following:

- `-prof-gen=srcpos -prof-gen=threadsafe` (Linux* and macOS*)
- `-prof-gen=srcpos, threadsafe` (this is equivalent to the above)

- `/Qprof-gen:srcpos /Qprof-gen:threadsafe` (Windows*)
- `/Qprof-gen:srcpos, threadsafe` (this is equivalent to the above)

If you specify keyword **srcpos** or **globdata**, a static profile information file (.spi) is created. These settings may increase the time needed to do a parallel build using `-prof-gen`, because of contention writing the .spi file.

These options are used in phase 1 of the Profile Guided Optimizer (PGO) to instruct the compiler to produce instrumented code in your object files in preparation for instrumented execution.

When the \([Q]\text{prof-gen}\) option is used to produce an instrumented binary file for profile generation, some optimizations are disabled. Those optimizations are not disabled for any subsequent profile-guided compilation with option \([Q]\text{prof-use}\) that makes use of the generated profiles.

IDE Equivalent

Visual Studio: **General > Profile Guided Optimization**

General > Code Coverage Build Options

Eclipse: **Optimization > Profile Guided Optimization**

Xcode: None

Alternate Options

None
See Also
prof-use, Qprof-use
compiler option
Profile an Application with Instrumentation

prof-gen-sampling
Tells the compiler to generate debug discriminators in debug output. This aids in developing more precise sampled profiling output. This option is deprecated and will be removed in a future release.

Syntax
Linux OS:
-prof-gen-sampling
macOS:
None
Windows OS:
None

Arguments
None

Default
OFF
The compiler does not generate debug discriminators in the debug output.

Description
This option tells the compiler to generate debug discriminators in debug output. Debug discriminators are used to distinguish code from different basic blocks that have the same source position information. This aids in developing more precise sampled hardware profiling output.

To build an executable suitable for generating hardware profiled sampled output, compile with the following options:

```
-prof-gen-sampling -g
```

To use the data files produced by hardware profiling, compile with option -prof-use-sampling.

IDE Equivalent
None

Alternate Options
None

See Also
prof-use-sampling compiler option
g compiler option
Profile an Application with Instrumentation
**prof-hotness-threshold, Qprof-hotness-threshold**

*Lets you set the hotness threshold for function grouping and function ordering.*

**Syntax**

Linux OS:
- `prof-hotness-threshold=n`

macOS:
None

Windows OS:
`/Qprof-hotness-threshold:n`

**Arguments**

`n`  
Is the hotness threshold. `n` is a percentage having a value between 0 and 100 inclusive. If you specify 0, there will be no hotness threshold setting in effect for function grouping and function ordering.

**Default**

OFF  
The compiler’s default hotness threshold setting of 10 percent is in effect for function grouping and function ordering.

**Description**

This option lets you set the hotness threshold for function grouping and function ordering.

The "hotness threshold" is the percentage of functions in the application that should be placed in the application’s hot region. The hot region is the most frequently executed part of the application. By grouping these functions together into one hot region, they have a greater probability of remaining resident in the instruction cache. This can enhance the application’s performance.

For this option to take effect, you must specify option `[Q]prof-use` and one of the following:

- On Linux systems: `-prof-func-groups` or `-prof-func-order`
- On Windows systems: `/Qprof-func-order`

**IDE Equivalent**

None

**Alternate Options**

None

prof-src-dir, Qprof-src-dir

Determines whether directory information of the source file under compilation is considered when looking up profile data records.

Syntax

**Linux OS and macOS:**
- -prof-src-dir
- -no-prof-src-dir

**Windows OS:**
- /Qprof-src-dir
- /Qprof-src-dir-

**Arguments**

None

**Default**

[Q]prof-src-dir

Directory information is used when looking up profile data records in the .dpi file.

**Description**

This option determines whether directory information of the source file under compilation is considered when looking up profile data records in the .dpi file. To use this option, you must also specify the [Q]prof-use option.

If the option is enabled, directory information is considered when looking up the profile data records within the .dpi file. You can specify directory information by using one of the following options:

- Linux and macOS*: -prof-src-root or -prof-src-root-cwd
- Windows: /Qprof-src-root or /Qprof-src-root-cwd

If the option is disabled, directory information is ignored and only the name of the file is used to find the profile data record.

Note that option [Q]prof-src-dir controls how the names of the user's source files get represented within the .dyn or .dpi files. Option [Q]prof-dir specifies the location of the .dyn or the .dpi files.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

prof-use, Qprof-use

compiler option

prof-src-root, Qprof-src-root

compiler option

prof-src-root-cwd, Qprof-src-root-cwd

compiler option
prof-src-root, Qprof-src-root

Lets you use relative directory paths when looking up profile data and specifies a directory as the base.

Syntax

Linux OS and macOS:
- prof-src-root=dir

Windows OS:
/Qprof-src-root:dir

Arguments

dir

Is the base for the relative paths.

Default

OFF

The setting of relevant options determines the path used when looking up profile data records.

Description

This option lets you use relative directory paths when looking up profile data in .dpi files. It lets you specify a directory as the base. The paths are relative to a base directory specified during the [Q]prof-gen compilation phase.

This option is available during the following phases of compilation:

- Linux* and macOS* systems: -prof-gen and -prof-use phases
- Windows* systems: /Qprof-gen and /Qprof-use phases

When this option is specified during the [Q]prof-gen phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the [Q]prof-use phase, it specifies a root directory that replaces the root directory specified at the [Q]prof-gen phase for forming the lookup keys.

To be effective, this option or option [Q]prof-src-root-cwd must be specified during the [Q]prof-gen phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

IDE Equivalent

None

Alternate Options

None

Example

Consider the initial [Q]prof-gen compilation of the source file c:\user1\feature_foo\myproject\common\glob.c shown below:

Windows*: icl /Qprof-gen /Qprof-src-root=c:\user1\feature_foo\myproject -c common\glob.c

Linux* and macOS*: icc -prof-gen -prof-src-root=c:\user1\feature_foo\myproject -c common\glob.c
For the \texttt{prof-use} phase, the file \texttt{glob.c} could be moved into the directory \texttt{c:\user2\feature_bar\myproject\common\glob.c} and profile information would be found from the .dpi when using the following:

\begin{verbatim}
Windows*: icl /Qprof-use /Qprof-src-root=c:\user2\feature_bar\myproject -c common\glob.c
Linux* and macOS*: icc -prof-use -prof-src-root=c:\user2\feature_bar\myproject -c common\glob.c
\end{verbatim}

If you do not use option \texttt{prof-src-root} during the \texttt{prof-gen} phase, by default, the \texttt{prof-use} compilation can only find the profile data if the file is compiled in the \texttt{c:\user1\feature_foo\my_project\common} directory.

\textbf{See Also}

\texttt{prof-gen}, \texttt{Qprof-gen}

\texttt{prof-use}, \texttt{Qprof-use}

\texttt{prof-src-root-cwd}, \texttt{Qprof-src-root-cwd}

\textbf{prof-src-root-cwd, Qprof-src-root-cwd}

\emph{Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.}

\textbf{Syntax}

\texttt{Linux OS and macOS:}

\texttt{-prof-src-root-cwd}

\texttt{Windows OS:}

\texttt{/Qprof-src-root-cwd}

\textbf{Arguments}

None

\textbf{Default}

OFF \hspace{1cm} The setting of relevant options determines the path used when looking up profile data records.

\textbf{Description}

This option lets you use relative directory paths when looking up profile data in .dpi files. It specifies the current working directory as the base. To use this option, you must also specify option \texttt{prof-use}.

This option is available during the following phases of compilation:

- Linux* and macOS* systems: \texttt{-prof-gen} and \texttt{-prof-use} phases
- Windows* systems: \texttt{/Qprof-gen} and \texttt{/Qprof-use} phases

When this option is specified during the \texttt{prof-gen} phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the \texttt{prof-use} phase, it specifies a root directory that replaces the root directory specified at the \texttt{prof-gen} phase for forming the lookup keys.
To be effective, this option or option [Q]prof-src-root must be specified during the [Q]prof-gen phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

**IDE Equivalent**

compiler option
prof-src-root, Qprof-src-root  
compiler option

**prof-use, Qprof-use**  
Enables the use of profiling information during optimization.

**Syntax**

**Linux OS and macOS:**

- `-prof-use[=keyword]`
- `-no-prof-use`

**Windows OS:**

- `/Qprof-use[:keyword]`
- `/Qprof-use-`

**Arguments**

- **keyword**
  
  Specifies additional instructions. Possible values are:

  - **weighted**
    
    Tells the profmerge utility to apply a weighting to the .dyn file values when creating the .dpi file to normalize the data counts when the training runs have different execution durations. This argument only has an effect when the compiler invokes the profmerge utility to create the .dpi file. This argument does not have an effect if the .dpi file was previously created without weighting.

  - **[no]merge**
    
    Enables or disables automatic invocation of the profmerge utility. The default is `merge`. Note that you cannot specify both `weighted` and `merge`.
If you try to specify both values, a warning will be displayed and `nomerge` takes precedence.

Enables the use of profiling information during optimization. The profmerge utility is invoked by default. This value is the same as specifying `[Q]prof-use` with no argument.

**Default**

- `-no-prof-use`

or

`/Qprof-use-`

**Description**

This option enables the use of profiling information (including function splitting and function grouping) during optimization. It enables option `/Qfnsplit` (Windows*) and `-fnsplit` (Linux* and macOS*).

This option instructs the compiler to produce a profile-optimized executable and it merges available profiling output files into a `pgopti.dpi` file.

Note that there is no way to turn off function grouping if you enable it using this option.

To set the hotness threshold for function grouping and function ordering, use option `[Q]prof-hotness-threshold`.

**IDE Equivalent**

Visual Studio: **General > Profile Guided Optimization**

Eclipse: **Optimization > Profile Guided Optimization**

Xcode: None

**Alternate Options**

None

**See Also**

prof-hotness-threshold, `Qprof-hotness-threshold`

prof-gen, `Qprof-gen`

Profile an Application with Instrumentation

**prof-use-sampling**

*Let you use data files produced by hardware profiling to produce an optimized executable. This option is deprecated and will be removed in a future release.*

**Syntax**

Linux OS:

`-prof-use-sampling=list`
macOS:
None

Windows OS:
None

Arguments

*list*  
Is a list of one or more data files. If you specify more than one data file, they must be separated by colons.

Default

OFF  
Data files produced by hardware profiling will not be used to produce an optimized executable.

Description

This option lets you use data files produced by hardware profiling to produce an optimized executable. These data files are named and produced by using Intel® VTune™.

The executable should have been produced using the following options:

```
prof-gen-sampling -g
```

IDE Equivalent

None

Alternate Options

None

See Also

prof-gen-sampling  compiler option
Profile an Application with Instrumentation

prof-value-profiling, Qprof-value-profiling

*Controls which values are value profiled.*

Syntax

Linux OS and macOS:

```
-prof-value-profiling [=keyword]
```

Windows OS:

```
/Qprof-value-profiling[ :keyword]
```

Arguments

*keyword*  
Controls which type of value profiling is performed. Possible values are:

- none  
Prevents all types of value profiling.

- nodivid
  e  
Prevents value profiling of non-compile time constants used in division or remainder operations.
**noindca** Prevents value profiling of function addresses at indirect call sites.

**ll** Enables all types of value profiling.

You can specify more than one keyword, but they must be separated by commas.

**Default**

**all** All value profile types are enabled and value profiling is performed.

**Description**

This option controls which features are value profiled.

If this option is specified with option `[Q]prof-gen`, it turns off instrumentation of operations of the specified type. This also prevents feedback of values for the operations.

If this option is specified with option `[Q]prof-use`, it turns off feedback of values collected of the specified type.

If you specify level 2 or higher for option `[q or Q]opt-report`, the value profiling specialization information will be reported within the PGO optimization report.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

prof-gen, Qprof-gen compiler option

qopt-report, Qopt-report compiler option

**Qcov-dir**

Specifies a directory for profiling information output files that can be used with the codecov or tselect tool.

**Syntax**

**Linux OS and macOS:**

None

**Windows OS:**

/Qcov-dir:dir

**Arguments**

`dir` Is the name of the directory.

**Default**

OFF Profiling output files are placed in the directory where the program is compiled.
**Description**

This option specifies a directory for profiling information output files (*.dyn and *.dpi) that can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Option `/Qcov-dir` is equivalent to option `/Qprof-dir`. If you specify both options, the last option specified on the command line takes precedence.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

/Qcov-gen
  compiler option
/Qcov-file
  compiler option

**Qcov-file**

*Specifies an alternate file name for the profiling summary files that can be used with the codecov or tselect tool.*

**Syntax**

**Linux OS and macOS:**

None

**Windows OS:**

/Qcov-file:filename

**Arguments**

`filename`  
Is the name of the profiling summary file.

**Default**

OFF  
The profiling summary files have the file name pgopti.*.

**Description**

This option specifies an alternate file name for the profiling summary files. The file name can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect).

The `filename` is used as the base name for the set of files created by different profiling passes.

If you specify this option with option `/Qcov-gen`, the .spi and .spl files will be named `filename.spi` and `filename.spl` instead of pgopti.spi and pgopti.spl.

Option `/Qcov-file` is equivalent to option `/Qprof-file`. If you specify both options, the last option specified on the command line takes precedence.
IDE Equivalent
None

Alternate Options
None

See Also
Qcov-gen
  compiler option
Qcov-dir
  compiler option

Qcov-gen
 Produces an instrumented object file that can be used with the codecov or tselect tool.

Syntax
Linux OS and macOS:

None

Windows OS:
/Qcov-gen
/Qcov-gen-

Arguments
None

Default
/Qcov-gen The instrumented object file is not produced.

Description
This option produces an instrumented object file that can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect). The instrumented code is included in the object file in preparation for instrumented execution.

This option also creates a static profile information file (.spi) that can be used with the codecov or tselect tool.

Option /Qcov-gen should be used to minimize the instrumentation overhead if you are interested in using the instrumentation only for code coverage. You should use /Qprof-gen:srcpos if you intend to use the collected data for code coverage and profile feedback.

IDE Equivalent
Visual Studio: General > Code Coverage Build Options
Eclipse: None
Xcode: None

Alternate Options
None
**See Also**
Qcov-dir
   compiler option
Qcov-file
   compiler option

**Optimization Report Options**

**qopt-report, Qopt-report**
*Tells the compiler to generate an optimization report.*

**Syntax**

Linux OS and macOS:
-qopt-report [=n]

Windows OS:
/Qopt-report[:n]

**Arguments**

\( n \) (Optional) Indicates the level of detail in the report. You can specify values 0 through 5.

If you specify zero, no report is generated.

For levels \( n=1 \) through \( n=5 \), each level includes all the information of the previous level, as well as potentially some additional information. Level 5 produces the greatest level of detail. If you do not specify \( n \), the default is level 2, which produces a medium level of detail.

**Default**

OFF No optimization report is generated.

**Description**

This option tells the compiler to generate a collection of optimization report files, one per object; this is the same output produced by option 
[q or Q]opt-report-per-object.

If you prefer another form of output, you can specify option [q or Q]opt-report-file.

If you specify a level \( (n) \) higher than 5, a warning will be displayed and you will get a level 5 report.

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* and macOS*) or /Qopt-report-phase:all (Windows*).

For a description of the information that each \( n \) level provides, see the Example section in option [q or Q]opt-report-phase.

**IDE Equivalent**

Visual Studio: **Diagnostics > Optimization Diagnostic Level**

Eclipse: **Compilation Diagnostics > Optimization Diagnostic Level**

Xcode: **Diagnostics > Optimization Diagnostic Level**
Alternate Options

None

Example

If you only want reports about certain diagnostics, you can use this option with option [q or Q]opt-report-phase. The phase you specify determines which diagnostics you will receive. For example, the following examples show how to get reports about certain specific diagnostics.

<table>
<thead>
<tr>
<th>To get this specific report</th>
<th>Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td>Auto-parallelizer diagnostics</td>
<td>Linux* and macOS*: -qopt-report -qopt-report-phase=par</td>
</tr>
<tr>
<td></td>
<td>Windows*: /Qopt-report /Qopt-report-phase:par</td>
</tr>
<tr>
<td>OpenMP parallelizer diagnostics</td>
<td>Linux* and macOS*: -qopt-report -qopt-report-phase=openmp</td>
</tr>
<tr>
<td></td>
<td>Windows*: /Qopt-report /Qopt-report-phase:openmp</td>
</tr>
<tr>
<td>Vectorizer diagnostics</td>
<td>Linux* and macOS*: -qopt-report -qopt-report-phase=vec</td>
</tr>
<tr>
<td></td>
<td>Windows*: /Qopt-report /Qopt-report-phase:vec</td>
</tr>
</tbody>
</table>

qopt-report-annotate, Qopt-report-annotate

Enables the annotated source listing feature and specifies its format.

Syntax

Linux OS and macOS:

- `qopt-report-annotate[=keyword]`

Windows OS:

/`Qopt-report-annotate[=keyword]`

Arguments

<table>
<thead>
<tr>
<th><code>keyword</code></th>
<th>Specifies the format for the annotated source listing. You can specify one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>text</code></td>
<td>Indicates that the listing should be in text format. This is the default if you do not specify <code>keyword</code>.</td>
</tr>
<tr>
<td><code>html</code></td>
<td>Indicates that the listing should be in html format.</td>
</tr>
</tbody>
</table>
Default

OFF No annotated source listing is generated

Description

This option enables the annotated source listing feature and specifies its format. The feature annotates source files with compiler optimization reports.

By default, one annotated source file is output per object. The annotated file is written to the same directory where the object files are generated. If the object file is a temporary file and an executable is generated, annotated files are placed in the directory where the executable is placed. You cannot generate annotated files to a directory of your choosing.

However, you can output annotated listings to stdout, stderr, or to a file if you also specify option [q or Q]opt-report-file.

By default, this option sets option [q or Q]opt-report with default level 2.

The following shows the file extension and listing details for the two possible keywords.

<table>
<thead>
<tr>
<th>Format</th>
<th>Listing Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>The annotated source listing has an .annot extension. It includes line numbers and compiler diagnostics placed after correspondent lines. IPO footnotes are inserted at the end of annotated file.</td>
</tr>
<tr>
<td>html</td>
<td>The annotated source listing has an .annot.html extension. It includes line numbers and compiler diagnostics placed after correspondent lines (as the text format does). It also provides hyperlinks in compiler messages and quick navigation with the routine list. IPO footnotes are displayed as tooltips.</td>
</tr>
</tbody>
</table>

IDE Equivalent

None

Alternate Options

qopt-report-annotate-position, Qopt-report-annotate-position compiler option

qopt-report-annotate-position, Qopt-report-annotate-position

Enables the annotated source listing feature and specifies the site where optimization messages appear in the annotated source in inlined cases of loop optimizations.

Syntax

Linux OS:
-qopt-report-annotate-position=keyword

macOS:
-qopt-report-annotate-position=keyword
Windows OS:
/Qopt-report-annotate-position:keyword

Arguments

keyword Specifies the site where optimization messages appear in the annotated source. You can specify one of the following:

caller Indicates that the messages should appear in the caller site.
callee Indicates that the messages should appear in the callee site.
both Indicates that the messages should appear in both the caller and the callee sites.

Default
OFF No annotated source listing is generated

Description
This option enables the annotated source listing feature and specifies the site where optimization messages appear in the annotated source in inlined cases of loop optimizations.

This option enables option [q or Q]opt-report-annotate if it is not explicitly specified.

If annotated source listing is enabled and this option is not passed to compiler, loop optimizations are placed in caller position by default.

IDE Equivalent
None

Alternate Options
None

See Also
qopt-report, Qopt-report compiler option
goqopt-report-annotate, Qopt-report-annotate compiler option

goqopt-report-embed, Qopt-report-embed
Determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated.

Syntax

Linux OS and macOS:
-qopt-report-embed
-qno-opt-report-embed

Windows OS:
/Qopt-report-embed
/Qopt-report-embed-
Arguments
None

Default
OFF When an assembly file is being generated, special loop information annotations will not be embedded in the assembly file.

However, if option \(-g\) (Linux* and macOS*) or \(/Zi\) (Windows*) is specified, special loop information annotations will be embedded in the assembly file unless option \(-qno-opt-report-embed\) (Linux and macOS*) or \(/Qopt-report-embed-\) (Windows) is specified.

Description
This option determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated. Specify the positive form of the option to include the annotations in the assembly file.

If an object file (or executable) is being generated, the annotations will be embedded in the object file (or executable).

If you use this option, you do not have to specify option \([q\ or \ Q]\)opt-report.

Alternate Options
None

See Also
qopt-report, Qopt-report compiler option

qopt-report-file, Qopt-report-file
Specifies that the output for the optimization report goes to a file, stderr, or stdout.

Syntax
Linux OS and macOS:
-qopt-report-file=keyword

Windows OS:
/Qopt-report-file:keyword

Arguments

\textit{keyword} Specifies the output for the report. You can specify one of the following:

- \textit{filename} Specifies the name of the file where the output should go.
- \textit{stderr} Indicates that the output should go to stderr.
- \textit{stdout} Indicates that the output should go to stdout.

Default
OFF No optimization report is generated.
Description
This option specifies that the output for the optimization report goes to a file, stderr, or stdout. If you use this option, you do not have to specify option \[q or Q\]opt-report.
When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* and macOS*) or /Qopt-report-phase:all (Windows*).

IDE Equivalent
Visual Studio: **Diagnostics > Optimization Diagnostic File**
**Diagnostics > Emit Optimization Diagnostic to File**
Eclipse: **Compilation Diagnostics > Emit Optimization Diagnostics to File**
**Compilation Diagnostics > Optimization Diagnostics File**
Xcode: None

Alternate Options
None

See Also
**qopt-report, Qopt-report** compiler option

**qopt-report-filter, Qopt-report-filter**
* Tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application.

Syntax
Linux OS and macOS:
-qopt-report-filter=string
Windows OS:
/Qopt-report-filter:string

Arguments
\*string

Is the information to search for. The *string* must appear within quotes. It can take one or more of the following forms:

<table>
<thead>
<tr>
<th>filename</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename, routine</td>
</tr>
<tr>
<td>filename, range [, range]...</td>
</tr>
<tr>
<td>filename, routine, range [, range]...</td>
</tr>
</tbody>
</table>

If you specify more than one of the above forms in a string, a semicolon must appear between each form. If you specify more than one *range* in a string, a comma must appear between each *range*. Optional blanks can follow each parameter in the forms above and they can also follow each form in a string.

filename

Specifies the name of a file to be found. It can include a path.
If you do not specify a path, the compiler looks for the filename in the current working directory.

**routine**

Specifies the name of a routine to be found. You can include an identifying parameter. The name, including any parameter, must be enclosed in single quotes.

The compiler tries to uniquely identify the routine that corresponds to the specified routine name. It may select multiple routines to analyze, especially if more than one routine has the specified routine name, so the routine cannot be uniquely identified.

**range**

Specifies a range of line numbers to be found in the file or routine specified. The range must be specified in integers in the form: `first_line_number-last_line_number`
The hyphen between the line numbers is required.

**Default**

OFF No optimization report is generated.

**Description**

This option tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application. Optimization reports will only be generated for the routines that contain the specified `string`.

On Linux* and macOS*, if you specify both `-qopt-report-routine=string1` and `-qopt-report-filter=string2`, it is treated as `-qopt-report-filter=string1;string2`. On Windows*, if you specify both `/Qopt-report-routine:string1` and `/Qopt-report-filter:string2`, it is treated as `/Qopt-report-filter:string1;string2`.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

`qopt-report`, `Qopt-report` compiler option
**qopt-report-format, Qopt-report-format**

*Specifies the format for an optimization report.*

**Syntax**

Linux OS and macOS:

```bash
-qopt-report-format=keyword
```

Windows OS:

```bash
/Qopt-report-format:keyword
```

**Arguments**

`keyword` Specifies the format for the report. You can specify one of the following:

- `text` Indicates that the report should be in text format.
- `vs` Indicates that the report should be in Visual Studio* (IDE) format. The Visual Studio IDE uses the information to visualize the optimization report in the context of your program source code.

**Default**

OFF No optimization report is generated.

**Description**

This option specifies the format for an optimization report. If you use this option, you must specify either `text` or `vs`.

If you do not specify this option and another option causes an optimization report to be generated, the default format is `text`.

If the `[q or Q]opt-report-file` option is also specified, it will affect where the output goes:

- If `filename` is specified, output goes to the specified file.
- If `stdout` is specified, output goes to stdout.
- If `stderr` is specified, output goes to stderr.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all (Linux* and macOS*) or /Qopt-report-phase:all (Windows*)`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

qopt-report, Qopt-report compiler option
qopt-report-file, Qopt-report-file compiler option
**qopt-report-help, Qopt-report-help**

Displays the optimizer phases available for report generation and a short description of what is reported at each level.

**Syntax**

Linux OS and macOS:

-qopt-report-help

Windows OS:

/Qopt-report-help

**Arguments**

None

**Default**

OFF  
No optimization report is generated.

**Description**

This option displays the optimizer phases available for report generation using [q or Q]opt-report-phase, and a short description of what is reported at each level. No compilation is performed.

To indicate where output should go, you can specify one of the following options:

- [q or Q]opt-report-file
- [q or Q]opt-report-per-object

If you use this option, you do not have to specify option [q or Q]opt-report.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

- qopt-report, Qopt-report compiler option
- qopt-report-phase, Qopt-report-phase compiler option
- qopt-report-file, Qopt-report-file compiler option
- qopt-report-per-object, Qopt-report-per-object compiler option

**qopt-report-per-object, Qopt-report-per-object**

Tells the compiler that optimization report information should be generated in a separate file for each object.

**Syntax**

Linux OS and macOS:

-qopt-report-per-object
**Windows OS:**

/Qopt-report-per-object

**Arguments**

None

**Default**

OFF  No optimization report is generated.

**Description**

This option tells the compiler that optimization report information should be generated in a separate file for each object.

If you specify this option for a single-file compilation, a file with a .optrpt extension is produced for every object file or assembly file that is generated by the compiler. For a multifile Interprocedural Optimization (IPO) compilation, one file is produced for each of the N true objects generated in the compilation. If only one true object file is generated, the optimization report file generated is called ipo_out.optrpt. If multiple true object files are generated (N>1), the names used are ipo_out1.optrpt, ipo_out2.optrpt, … ipo_outN.optrpt.

The .optrpt files are written to the target directory of the compilation process. If an object or assembly file is explicitly generated, the corresponding .optrpt file is written to the same directory where the object file is generated. If the object file is just a temporary file and an executable is generated, the corresponding .optrpt files are placed in the directory in which the executable is placed.

If you use this option, you do not have to specify option [q or Q]opt-report.

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* and macOS*) or /Qopt-report-phase:all (Windows*).

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

qopt-report, Qopt-report compiler option

qopt-report-phase, Qopt-report-phase

Specifies one or more optimizer phases for which optimization reports are generated.

**Syntax**

**Linux OS and macOS:**

-qopt-report-phase[=list]

**Windows OS:**

/Qopt-report-phase[:list]
Arguments

(list) (Optional) Specifies one or more phases to generate reports for. If you specify more than one phase, they must be separated with commas. The values you can specify are:

- **cg**: The phase for code generation
- **ipo**: The phase for Interprocedural Optimization
- **loop**: The phase for loop nest optimization
- **openmp**: The phase for OpenMP
- **par**: The phase for auto-parallelization
- **pgo**: The phase for Profile Guided Optimization
- **tcollect**: The phase for trace collection
- **vec**: The phase for vectorization
- **all**: All optimizer phases. This is the default if you do not specify list.

Default

OFF.No optimization report is generated.

Description

This option specifies one or more optimizer phases for which optimization reports are generated. For certain phases, you also need to specify other options:

- If you specify phase cg, you must also specify option O1, O2 (default), or O3.
- If you specify phase ipo, you must also specify option [Q]ipo.
- If you specify phase loop, you must also specify option O2 (default) or O3.
- If you specify phase openmp, you must also specify option [q or Q]openmp.
- If you specify phase par, you must also specify option [Q]parallel.
- If you specify phase pgo, you must also specify option [Q]prof-use.
- If you specify phase tcollect, you must also specify option [Q]tcollect.
- If you specify phase vec, you must also specify option O2 (default) or O3. If you are interested in explicit vectorization by OpenMP* SIMD, you must also specify option [q or Q]openmp.

To find all phase possibilities, specify option [q or Q]opt-report-help.

If you use this option, you do not have to specify option [q or Q]opt-report.

However, if you want to get more details for each phase, specify option [q or Q]opt-report=n along with this option and indicate the level of detail you want by specifying an appropriate value for n. (See also the Example section below.)

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* and macOS*) or /Qopt-report-phase:all (Windows*).

IDE Equivalent

Visual Studio: **Diagnostics > Optimization Diagnostic Phase**

Eclipse: **Compilation Diagnostics > Optimization Diagnostic Phase**
Xcode: Diagnostics > Optimization Diagnostic Phase

Alternate Options

None

Example

The following shows examples of the details you may receive when you specify one of the optimizer phases and a particular level \((n)\) for option \([q \text{ or } Q]\text{opt-report}\). Note that details may change in future releases.

<table>
<thead>
<tr>
<th>Optimizer phase</th>
<th>The level specified in option ([q \text{ or } Q]\text{opt-report})</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cg</td>
<td>1</td>
<td>Generates a list of which intrinsics were lowered and which memcall optimizations were performed.</td>
</tr>
<tr>
<td>ipo</td>
<td>1</td>
<td>For each compiled routine, generates a list of the routines that were inlined into the routine, called directly by the routine, and whose calls were deleted.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Generates level 1 details, values for important inlining command line options, and a list of the routines that were discovered to be dead and eliminated.</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>Generates level 2 details, whole program information, the sizes of inlined routines, and the reasons routines were not inlined.</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>Generates level 3 details, detailed footnotes on the reasons why routines are not inlined, and what action the user can take to get them inlined.</td>
</tr>
<tr>
<td>loop</td>
<td>1</td>
<td>Reports high-level details about which optimizations have been performed on the loop nests (along with the line number). Most of the loop optimizations (like fusion, unroll, unroll &amp; jam, collapsing, rerolling etc) only support this level of detail.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Generates level 1 details, and provides more detail on the metrics and types of references (like prefetch distance, indirect prefetches etc) used in optimizations. Only a few</td>
</tr>

<td>openmp</td>
<td>1</td>
<td>Reports loops, regions, sections, and tasks successfully parallelized.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Generates level 1 details, and messages indicating successful handling of master constructs, single constructs, critical constructs, ordered constructs, atomic pragmas, and so forth.</td>
</tr>
<tr>
<td>par</td>
<td>1</td>
<td>Reports which loops were parallelized.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Generates level 1 details, and reports which loops were not parallelized along with a short reason.</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>Generates level 2 details, and prints the memory locations that are categorized as private, shared, reduction, etc..</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>For this phase, this is the same as specifying level 3.</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>Generates level 4 details, and dependency edges that inhibit parallelization.</td>
</tr>
<tr>
<td>pgo</td>
<td>1</td>
<td>During profile feedback, generates report status of feedback (such as, profile used, no profile available, or unable to use profile) for each routine compiled.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Generates level 1 details, and reports which value profile specializations took place for indirect calls and arithmetic operations.</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>Generates level 2 details, and reports which indirect calls had profile data, but did not meet the internal threshold limits for the percentage or execution count.</td>
</tr>
<tr>
<td>Optimizer phase</td>
<td>The level specified in option [q or Q]opt-report</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>tcollect</td>
<td>1</td>
<td>Generates a list of routines and whether each was selected for trace collection.</td>
</tr>
<tr>
<td>vec</td>
<td>1</td>
<td>Reports which loops were vectorized.</td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>Generates level 1 details and reports which loops were not vectorized along with short reason.</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>Generates level 2 details, and vectorizer loop summary information.</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>Generates level 3 details, and greater detail about vectorized and non-vectorized loops.</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>Generates level 4 details, and details about any proven or assumed data dependences.</td>
</tr>

**qopt-report-routine, Qopt-report-routine**

*Tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring.*

**Syntax**

**Linux OS and macOS:**

-qopt-report-routine=substring

**Windows OS:**

/Qopt-report-routine:substring

**Arguments**

substr 

Is the text (string) to look for.

**Default**

OFF

No optimization report is generated.

**Description**

This option tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring.
You can also specify a sequence of substrings separated by commas. If you do this, the compiler will generate an optimization report for each of the routines whose name contains one or more of these substrings.

If you use this option, you do not have to specify option \([q \text{ or } Q]\)opt-report.

When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* and macOS*) or /Qopt-report-phase:all (Windows*).

**IDE Equivalent**

Visual Studio: Diagnostics > Optimization Diagnostic Routine

Eclipse: Compilation Diagnostics > Optimization Diagnostic Routine

Xcode: None

**Alternate Options**

None

**See Also**

qopt-report, Qopt-report compiler option

### qopt-report-names, Qopt-report-names

Specifies whether mangled or unmangled names should appear in the optimization report.

**Syntax**

**Linux OS and macOS:**

```
-qopt-report-names=keyword
```

**Windows OS:**

```
/Qopt-report-names:keyword
```

**Arguments**

`keyword` Specifies the form for the names. You can specify one of the following:

- **mangled** Indicates that the optimization report should contain mangled names.
- **unmangled** Indicates that the optimization report should contain unmangled names.

**Default**

OFF No optimization report is generated.

**Description**

This option specifies whether mangled or unmangled names should appear in the optimization report. If you use this option, you must specify either mangled or unmangled.

If this option is not specified, unmangled names are used by default.

If you specify mangled, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing.

If you specify unmangled, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing.
If you use this option, you do not have to specify option [q or Q]opt-report.
When optimization reporting is enabled, the default is -qopt-report-phase=all (Linux* and macOS*) or /Qopt-report-phase:all (Windows*).

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
qopt-report, Qopt-report  compiler option

tcollect, Qtcollect
*Inserts instrumentation probes calling the Intel® Trace Collector API.*

**Syntax**

**Linux OS:**
-tcollect[lib]

**macOS:**
None

**Windows OS:**
/Qtcollect[:lib]

**Arguments**

*lib*  
Is one of the Intel® Trace Collector libraries; for example, VT, VTcs, VTmc, or VTfs. If you do not specify *lib*, the default library is VT.

**Default**
OFF  
Instrumentation probes are not inserted into compiled applications.

**Description**

This option inserts instrumentation probes calling the Intel® Trace Collector API.

This trace analyzing/collection feature requires installation of another product. For more information, see Feature Requirements.

This option provides a flexible and convenient way of instrumenting functions of a compiled application. For every function, the entry and exit points are instrumented at compile time to let the Intel® Trace Collector record functions beyond the default MPI calls. For non-MPI applications (for example, threaded or serial), you must ensure that the Intel® Trace Collector is properly initialized (VT_initialize/VT_init).

**Caution**
Be careful with full instrumentation because this feature can produce very large trace files.
IDE Equivalent
None

Alternate Options
None

See Also
tcollect-filter, Qtcollect-filter
- compiler option

**tcollect-filter, Qtcollect-filter**

*Lets you enable or disable the instrumentation of specified functions. You must also specify option \[Q\]tcollect.*

**Syntax**

**Linux OS:**

- `tcollect-filter` *filename*

**macOS:**

None

**Windows OS:**

`/Qtcollect-filter:filename`

**Arguments**

`filename`

Is a configuration file that lists filters, one per line. Each filter consists of a regular expression string and a switch. Strings with leading or trailing white spaces must be quoted. Other strings do not have to be quoted. The switch value can be ON, on, OFF, or off.

**Default**

OFF Functions are not instrumented. However, if option `-tcollect` (Linux) or `/Qtcollect` (Windows) is specified, the filter setting is ".* ON" and all functions get instrumented.

**Description**

This option lets you enable or disable the instrumentation of specified functions.

To get instrumentation with a specified filter (or filters), you must specify both option \[Q\]tcollect and option \[Q\]tcollect-filter.

During instrumentation, the regular expressions in the file are matched against the function names. The switch specifies whether matching functions are to be instrumented or not. Multiple filters are evaluated from top to bottom with increasing precedence.

The names of the functions to match against are formatted as follows:

- C++ function names are demangled and the C++ class hierarchy is used. Function parameters are stripped to keep the function names shorter.
- The source file name is followed by a colon-separated function name. Source file names should contain the full path, if available. For example:

```plaintext
/home/joe/src/foo.c:FOO_bar
```
• Classes and function names are separated by double colons. For example:

```
/home/joe/src/foo.cpp:app::foo::bar
```

You can use option [q or Q]opt-report to get a full list of file and function names that the compiler recognizes from the compilation unit. This list can be used as the basis for filtering in the configuration file.

This trace analyzing/collecting feature requires installation of another product. For more information, see Feature Requirements.

**IDE Equivalent**

None

**Alternate Options**

None

Consider the following filters in a configuration file:

```
.'.*' OFF '.*vector.*' ON
```

The above will cause instrumentation of only those functions having the string 'vector' in their names. No other function will be instrumented. Note that reversing the order of the two lines will prevent instrumentation of all functions.

To get a list of the file or routine strings that can be matched by the regular expression filters, generate an optimization report with tcollect information. For example:

```
Windows: icl /Qtcollect /Qopt-report /Qopt-report-phase:tcollect
Linux: icc -tcollect -qopt-report -qopt-report-phase=tcollect
```

**OpenMP* Options and Parallel Processing Options**

This section contains descriptions for compiler options that pertain to offload compilation, OpenMP*, or parallel processing.

**device-math-lib**

*Enables or disables certain device libraries. This is a deprecated option that may be removed in a future release.*

**Syntax**

**Linux OS:**

```
-device-math-lib=library
-no-device-math-lib=library
```

**macOS:**

None
Windows OS:
/device-math-lib:library
/no-device-math-lib:library

Arguments

Possible values are:

- fp32: Links the fp32 device math library.
- fp64: Links the fp64 device math library.

To link more than one library, include a comma between the library names.
For example, if you want to link both the fp32 and fp64 device libraries, specify: fp32, fp64

Default

fp32, fp64: Both the fp32 and fp64 device libraries are linked.

Description

This option enables or disables certain device libraries.

IDE Equivalent

None

Alternate Options

None

See Also

fopenmp-device-lib compiler option

fmpc-privatize

Enables or disables privatization of all static data for the MultiProcessor Computing environment (MPC) unified parallel runtime.

Architecture Restrictions

Only available on Intel® 64 architecture

Syntax

Linux OS:
-fmpc-privatize
-fno-mpc-privatize

macOS:

None

Windows OS:

None
Arguments
None

Default
- fno-mpc-privatize

The privatization of all static data for the MPC unified parallel runtime is disabled.

Description
This option enables or disables privatization of all static data for the MultiProcessor Computing environment (MPC) unified parallel runtime.

Option -fmpc-privatize causes calls to extended thread-local-storage (TLS) resolution, run-time routines that are not supported on standard Linux* distributions.

This option requires installation of another product. For more information, see Feature Requirements.

IDE Equivalent
None

Alternate Options
None

fopenmp-device-lib
Enables or disables certain device libraries for an OpenMP* target.

Syntax
Linux OS:
-fopenmp-device-lib=library[,library,...]
fno-openmp-device-lib=library[,library,...]

macOS:
None

Windows OS:
-fopenmp-device-lib=library[,library,...]
fopenmp-device-lib=library[,library,...]

Arguments

library
Possible values are:

libm-fp32 Enables linking to the fp32 device math library.
libm-fp64 Enables linking to the fp64 device math library.
libc Enables linking to the C library.
all

Enables linking to libraries libm-fp32, libm-fp-64, and libc.

To link more than one library, include a comma between the library names. For example, if you want to link both the libm-fp32 device library and the C library, specify: libm-fp32,libc.

Do not add spaces between library names.

Note that if you specify "all", it supersedes any additional value you may specify.

Default

OFF Disables linking to device libraries for this target.

Description

This option enables or disables certain device libraries for an OpenMP* target.

If you specify fno-openmp-device-lib=library, linking to the specified library is disabled for the OpenMP* target.

Alternate Options

None

par-affinity, Qpar-affinity

Specifies thread affinity.

Syntax

Linux OS:
-par-affinity=[modifier,...]type[,permute][,offset]

macOS:

None

Windows OS:
/Qpar-affinity:[modifier,...]type[,permute][,offset]

Arguments

c

modifier

Is one of the following values: granularity={fine|thread|core|tile}, [no]respect, [no]verbose, [no]warnings, proclist=proc_list. The default is granularity=core, respect, and noverbose. For information on value proclist, see Thread Affinity Interface.

t

type

Indicates the thread affinity. This argument is required and must be one of the following values: compact, disabled, explicit, none, scatter, logical, physical. The default is none. Values logical and physical are deprecated. Use compact and scatter, respectively, with no permute value.
**permute**

Is a positive integer. You cannot use this argument with type setting explicit, none, or disabled. The default is 0.

**offset**

Is a positive integer. You cannot use this argument with type setting explicit, none, or disabled. The default is 0.

**Default**

OFF  
The thread affinity is determined by the run-time environment.

**Description**

This option specifies thread affinity, which binds threads to physical processing units. It has the same effect as environment variable KMP_AFFINITY.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:

- You have specified option [Q]parallel or option [q or Q]openmp (or both).
- You are compiling the main program.

**NOTE**

This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

parallel, Qparallel compiler option  
qopt-report, Qopt-report compiler option

**par-loops, Qpar-loops**

*Let you select between old or new implementations of parallel loop support.*

**Syntax**

**Linux OS and macOS:**

-par-loops=keyword

**Windows OS:**

/Qpar-loops:keyword

**Arguments**

*keyword*  
Specifies which implementation to use. Possible values are:
**new**

Enables the new implementation of parallel-loop support. As a result, parallel C++ range-based loops and collapsing complex loop stacks will not result in compilation errors. This is the default.

**old**

Enables the old implementation of parallel-loop support. This is the same implementation that was supported in 18.0 and earlier releases.

**default**

This is the same as specifying `new`.

---

**Default**

- `-par-loops=new`
- `/Qpar-loops:new`

The compiler uses the new implementation of parallel-loop support. Note that this setting may not yet be as stable as setting "old" since the implementation is new.

**Description**

This option lets you select between old or new implementations of parallel loop support.

The new implementation handles parallel C++ range-based loops, and also collapsing of OpenMP* parallel loops with complicated bounds expressions, for which the previous implementation reported errors.

If your code has a parallel loop that is not handled by the previous implementation, we recommend that you enable use of the new implementation.

**IDE Equivalent**

None

**Alternate Options**

None

**par-num-threads, Qpar-num-threads**

Specifies the number of threads to use in a parallel region.

**Syntax**

**Linux OS and macOS:**

- `-par-num-threads=n`

**Windows OS:**

- `/Qpar-num-threads:n`

**Arguments**

- `n`

  Is the number of threads to use. It must be a positive integer.

**Default**

- `OFF`

  The number of threads to use is determined by the run-time environment.
Description
This option specifies the number of threads to use in a parallel region. It has the same effect as environment variable OMP_NUM_THREADS.
This option overrides the environment variable when both are specified.
This option only has an effect if the following is true:
• You have specified option [Q]parallel or option [q or Q]openmp (or both).
• You are compiling the main program.

IDE Equivalent
None

Alternate Options
None

See Also
parallel, Qparallel compiler option
qopt-report, Qopt-report compiler option

par-runtime-control, Qpar-runtime-control
Generates code to perform run-time checks for loops that have symbolic loop bounds.

Syntax
Linux OS and macOS:
-par-runtime-control[n]
-no-par-runtime-control
Windows OS:
/Qpar-runtime-control[n]
/Qpar-runtime-control-

Arguments

\( n \)

Is a value denoting what kind of runtime checking to perform. Possible values are:

0
Performs no runtime check based on auto-parallelization. This is the same as specifying -no-par-runtime-control (Linux* and macOS*) or /Qpar-runtime-control- (Windows*).

1
Generates runtime check code under conservative mode. This is the default if you do not specify \( n \).

2
Generates runtime check code under heuristic mode.
Generates runtime check code under aggressive mode.

Default

-no-par-runtime-control
or/Qpar-runtime-control-

The compiler uses default heuristics when checking loops.

Description

This option generates code to perform run-time checks for loops that have symbolic loop bounds.
If the granularity of a loop is greater than the parallelization threshold, the loop will be executed in parallel.
If you do not specify this option, the compiler may not parallelize loops with symbolic loop bounds if the compile-time granularity estimation of a loop can not ensure it is beneficial to parallelize the loop.

NOTE

This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

IDE Equivalent

None

Alternate Options

None

par-schedule, Qpar-schedule

Lets you specify a scheduling algorithm for loop iterations.

Syntax

Linux OS and macOS:

-par-schedule-keyword[=n]

Windows OS:

/Qpar-schedule-keyword[][n]

Arguments

keyword

Specifies the scheduling algorithm or tuning method. Possible values are:

auto

Lets the compiler or run-time system determine the scheduling algorithm.

static

Divides iterations into contiguous pieces.

static-balanced

Divides iterations into even-sized chunks.

static-steal

Divides iterations into even-sized chunks, but allows threads to steal parts of chunks from neighboring threads.
dynamic
gets a set of iterations dynamically.
guided
specifies a minimum number of iterations.
guided-analytical
divides iterations by using exponential
distribution or dynamic distribution.
runtime
defers the scheduling decision until run time.

\( n \)
is the size of the chunk or the number of iterations for each chunk.
this setting can only be specified for static, dynamic, and guided.
for more information, see the descriptions of each keyword below.

**default**

**static-balanced** iterations are divided into even-sized chunks and the chunks are assigned to the threads in the
team in a round-robin fashion in the order of the thread number.

**description**

this option lets you specify a scheduling algorithm for loop iterations.
it specifies how iterations are to be divided among the threads of the team.

this option is only useful when specified with option \([Q]\)parallel.

this option affects performance tuning and can provide better performance during auto-parallelization.
it does nothing if it is used with option \([q \text{ or } Q]\)openmp.

<table>
<thead>
<tr>
<th>option</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>([Q])par-schedule-auto</td>
<td>lets the compiler or run-time system determine the scheduling algorithm. any possible mapping may occur for iterations to threads in the team.</td>

<tr>
<td>([Q])par-schedule-static</td>
<td>divides iterations into contiguous pieces (chunks) of size ( n ). the chunks are assigned to threads in the team in a round-robin fashion in the order of the thread number. note that the last chunk to be assigned may have a smaller number of iterations. if no ( n ) is specified, the iteration space is divided into chunks that are approximately equal in size, and each thread is assigned at most one chunk.</td>
</tr>
<tr>
<td>([Q])par-schedule-static-balanced</td>
<td>divides iterations into even-sized chunks. the chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.</td>
</tr>
<tr>
<td>([Q])par-schedule-static-steal</td>
<td>divides iterations into even-sized chunks, but when a thread completes its chunk, it can steal parts of chunks assigned to neighboring threads. each thread keeps track of ( L ) and ( U ), which represent the lower and upper bounds of its chunks respectively. iterations are executed starting from the lower bound, and simultaneously, ( L ) is updated to represent the new lower bound.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>[Q]par-schedule-dynamic</td>
<td>Can be used to get a set of iterations dynamically. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations. Each chunk contains ( n ) iterations, except for the last chunk to be assigned, which may have fewer iterations. If no ( n ) is specified, the default is 1.</td>
</tr>
<tr>
<td>[Q]par-schedule-guided</td>
<td>Can be used to specify a minimum number of iterations. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. For a chunk of size 1, the size of each chunk is proportional to the number of unassigned iterations divided by the number of threads, decreasing to 1. For an ( n ) with value ( k ) (greater than 1), the size of each chunk is determined in the same way with the restriction that the chunks do not contain fewer than ( k ) iterations (except for the last chunk to be assigned, which may have fewer than ( k ) iterations). If no ( n ) is specified, the default is 1.</td>
</tr>
<tr>
<td>[Q]par-schedule-guided-analytical</td>
<td>Divides iterations by using exponential distribution or dynamic distribution. The method depends on run-time implementation. Loop bounds are calculated with faster synchronization and chunks are dynamically dispatched at run time by threads in the team.</td>
</tr>
<tr>
<td>[Q]par-schedule-runtime</td>
<td>Defers the scheduling decision until run time. The scheduling algorithm and chunk size are then taken from the setting of environment variable OMP_SCHEDULE.</td>
</tr>
</tbody>
</table>

**NOTE**
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

**IDE Equivalent**
None

**Alternate Options**
None
par-threshold, Qpar-threshold
Sets a threshold for the auto-parallelization of loops.

Syntax
Linux OS and macOS:
-par-threshold[n]

Windows OS:
/Qpar-threshold[[:]:n]

Arguments

n
Is an integer whose value is the threshold for the auto-parallelization of loops. Possible values are 0 through 100.

If n is 0, loops get auto-parallelized always, regardless of computation work volume.

If n is 100, loops get auto-parallelized when performance gains are predicted based on the compiler analysis data. Loops get auto-parallelized only if profitable parallel execution is almost certain.

The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, n=50 directs the compiler to parallelize only if there is a 50% probability of the code speeding up if executed in parallel.

Default

-par-threshold100
or/Qpar-threshold100
Loops get auto-parallelized only if profitable parallel execution is almost certain. This is also the default if you do not specify n.

Description
This option sets a threshold for the auto-parallelization of loops based on the probability of profitable execution of the loop in parallel. To use this option, you must also specify option [Q]parallel.

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

NOTE
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

IDE Equivalent
Visual Studio: None
Eclipse: Optimization > Auto-Parallelization Threshold
Xcode: Optimization > Auto-Parallelization Threshold
Alternate Options
None

**parallel, Qparallel**
*Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.*

**Syntax**

**Linux OS and macOS:**

- `--parallel`

**Windows OS:**

`/Qparallel` (or `/Qpar`)

**Arguments**

None

**Default**

OFF  Multithreaded code is not generated for loops that can be safely executed in parallel.

**Description**

This option tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

To use this option, you must also specify option **O2** or **O3**.

This option sets option `[q or Q]opt-matmul` if option **O3** is also specified.

---

**NOTE**

On macOS* systems, when you enable automatic parallelization, you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

---

**NOTE**

Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` or `/Qx` (Windows*) or `-m` or `-x` (Linux* and macOS*).

---

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

-qopt-matmul, Qopt-matmul compiler option

parallel-source-info, Qparallel-source-info

Enables or disables source location emission when OpenMP* or auto-parallelism code is generated.

**Syntax**

**Linux OS and macOS:**

- `parallel-source-info[=n]`
- `no-parallel-source-info`

**Windows OS:**

- `/Qparallel-source-info`
- `/Qparallel-source-info[=n]`

**Arguments**

$n$

<table>
<thead>
<tr>
<th>$n$</th>
<th>Is the level of source location emission. Possible values are:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Disables the emission of source location information when OpenMP* code or auto-parallelism code is generated. This is the same as specifying <code>no-parallel-source-info</code> (Linux* and macOS*) or <code>/Qparallel-source-info</code> (Windows*).</td>
</tr>
<tr>
<td>1</td>
<td>Tells the compiler to emit routine name and line information. This is the same as specifying <code>[Q]parallel-source-info</code> with no $n$.</td>
</tr>
<tr>
<td>2</td>
<td>Tells the compiler to emit path, file, routine name, and line information.</td>
</tr>
</tbody>
</table>
When OpenMP* code or auto-parallelism code is generated, the routine name and line information is emitted.

**Description**

This option enables or disables source location emission when OpenMP code or auto-parallelism code is generated. It also lets you set the level of emission.

**IDE Equivalent**

None

**Alternate Options**

None

**qopenmp, Qopenmp**

Enables the parallelizer to generate multi-threaded code based on OpenMP* directives.

**Syntax**

Linux OS and macOS:

-qopenmp

-qno-openmp

Windows OS:

/Qopenmp

/Qopenmp-

**Arguments**

None

**Default**

-qno-openmp

or

/Qopenmp-

**Description**

This option enables the parallelizer to generate multi-threaded code based on OpenMP* directives. The code can be executed in parallel on both uniprocessor and multiprocessor systems.

This option works with any optimization level. Specifying no optimization (-O0 on Linux* or /Od on Windows*) helps to debug OpenMP applications.

**NOTE**

On macOS* systems, when you enable OpenMP* API, you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.
NOTE
Options that use OpenMP* API are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors versus non-Intel microprocessors include: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

qopenmp-stubs, Qopenmp-stubs compiler option

qopenmp-lib, Qopenmp-lib
* Lets you specify an OpenMP* run-time library to use for linking.*

Syntax
Linux OS:
-qopenmp-lib=type
macOS:
-qopenmp-lib=type
Windows OS:
/Qopenmp-lib:type

Arguments

<table>
<thead>
<tr>
<th>type</th>
<th>Specifies the type of library to use; it implies compatibility levels. Currently, the only possible value is:</th>
</tr>
</thead>
</table>
**compat**

Tells the compiler to use the compatibility OpenMP* run-time library (libiomp). This setting provides compatibility with object files created using Microsoft* and GNU* compilers.

### Default

-qopenmp-lib=compat

or/Qopenmp-lib:compat

The compiler uses the compatibility OpenMP* run-time library (libiomp).

### Description

This option lets you specify an OpenMP* run-time library to use for linking.

The compatibility OpenMP run-time libraries are compatible with object files created using the Microsoft* OpenMP run-time library (vcomp) or the GNU OpenMP run-time library (libgomp).

To use the compatibility OpenMP run-time library, compile and link your application using the compat setting for option [q or Q]openmp-lib. To use this option, you must also specify one of the following compiler options:

- **Linux* systems:** -qopenmp or -qopenmp-stubs
- **Windows* systems:** /Qopenmp or /Qopenmp-stubs

On Windows* systems, the compatibility OpenMP* run-time library lets you combine OpenMP* object files compiled with the Microsoft* C/C++ compiler with OpenMP* object files compiled with the Intel® C, Intel® C+++, or Intel® Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

On Linux* systems, the compatibility Intel OpenMP* run-time library lets you combine OpenMP* object files compiled with the GNU* gcc or gfortran compilers with similar OpenMP* object files compiled with the Intel® C, Intel® C++, or Intel® Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

**NOTE**
The compatibility OpenMP run-time library is not compatible with object files created using versions of the Intel compilers earlier than 10.0.

**NOTE**
On Windows* systems, this option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker. On Linux* and macOS* systems, this option is processed by the icc/icpc command that initiates linking, adding library names explicitly to the link command.

### IDE Equivalent

None

### Alternate Options

None

### See Also

qopenmp, Qopenmp compiler option

qopenmp-stubs, Qopenmp-stubs compiler option
qopenmp-link
Controls whether the compiler links to static or dynamic OpenMP* run-time libraries.

Syntax

Linux OS:
-qopenmp-link=library

macOS:
-qopenmp-link=library

Windows OS:
None

Arguments

library
Specifies the OpenMP library to use. Possible values are:

static
Tells the compiler to link to static OpenMP run-time libraries. Note that static OpenMP libraries are deprecated.

dynamic
Tells the compiler to link to dynamic OpenMP run-time libraries.

Default

-qopenmp-link=dynamic
The compiler links to dynamic OpenMP* run-time libraries. However, if Linux* option -static is specified, the compiler links to static OpenMP run-time libraries.

Description

This option controls whether the compiler links to static or dynamic OpenMP* run-time libraries.

To link to the static OpenMP run-time library (RTL) and create a purely static executable, you must specify -qopenmp-link=static. However, we strongly recommend you use the default setting, -qopenmp-link=dynamic.

NOTE
Compiler options -static-intel and -shared-intel (Linux* and macOS*) have no effect on which OpenMP run-time library is linked.

NOTE
On Linux* systems, -qopenmp-link=dynamic cannot be used in conjunction with option -static. If you try to specify both options together, an error will be displayed.
NOTE
On Linux systems, the OpenMP runtime library depends on using libpthread and libc (libgcc when compiled with gcc). Libpthread and libc (libgcc) must both be static or both be dynamic. If both libpthread and libc (libgcc) are static, then the static version of the OpenMP runtime should be used. If both libpthread and libc (libgcc) are dynamic, then either the static or dynamic version of the OpenMP runtime may be used.

IDE Equivalent

Alternate Options
None

qopenmp-simd, Qopenmp-simd
*Enables or disables OpenMP* SIMD compilation.

Syntax
Linux OS:
-qopenmp-simd
-qno-openmp-simd

macOS:
-qopenmp-simd
-qno-openmp-simd

Windows OS:
/Qopenmp-simd
/Qopenmp-simd-

Arguments
None

Default
-qopenmp-simd or /Qopenmp-simd

OpenMP* SIMD compilation is enabled if option O2 or higher is in effect.

OpenMP* SIMD compilation is always disabled at optimization levels of O1 or lower.

When option O2 or higher is in effect, OpenMP SIMD compilation can only be disabled by specifying option -qno-openmp-simd or /Qopenmp-simd-. It is not disabled by specifying option -qno-openmp or /Qopenmp-.

Description
This option enables or disables OpenMP* SIMD compilation.
You can use this option if you want to enable or disable the SIMD support with no impact on other OpenMP features. In this case, no OpenMP runtime library is needed to link and the compiler does not need to generate OpenMP runtime initialization code.

If you specify this option with the [q or Q]openmp option, it can impact other OpenMP features.

**IDE Equivalent**

None

**Alternate Options**

None

**Example**

Consider the following:

```
-qno-openmp -qopenmp-simd    ! Linux or macOS*
/Qopenmp- /Qopenmp-simd      ! Windows
```

The above is equivalent to specifying only [q or Q]openmp-simd. In this case, only SIMD support is provided, the OpenMP* library is not linked, and only the !$OMP directives related to SIMD are processed.

Consider the following:

```
-qopenmp -qopenmp-simd       ! Linux or macOS*
/Qopenmp /Qopenmp-simd       ! Windows
```

In this case, SIMD support is provided, the OpenMP library is linked, and OpenMP runtime initialization code is generated. Note that when you specify [q or Q]openmp, it implies [q or Q]openmp-simd.

**See Also**

qopenmp, Qopenmp  compiler option

qopenmp-stubs, Qopenmp-stubs

*Enables compilation of OpenMP* programs in sequential mode.*

**Syntax**

**Linux OS:**

```
-qopenmp-stubs
```

**macOS:**

```
-qopenmp-stubs
```

**Windows OS:**

```
/Qopenmp-stubs
```

**Arguments**

None

**Default**

OFF  The library of OpenMP* function stubs is not linked.
Description
This option enables compilation of OpenMP* programs in sequential mode. The OpenMP directives are ignored and a stub OpenMP library is linked.

IDE Equivalent
Visual Studio: Language > OpenMP Support
Eclipse: Language > Process OpenMP Directives
Xcode: Language > Process OpenMP Directives

Alternate Options
None

See Also
qopenmp, Qopenmp compiler option

qopenmp-threadprivate, Qopenmp-threadprivate
Let's you specify an OpenMP* threadprivate implementation.

Syntax
Linux OS:
-qopenmp-threadprivate=type
macOS:
None
Windows OS:
/Qopenmp-threadprivate:type

Arguments
type
Specifies the type of threadprivate implementation. Possible values are:

legacy
Tells the compiler to use the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel® compiler. This setting does not provide compatibility with the implementation used by other compilers.

compat
Tells the compiler to use the compatibility OpenMP* threadprivate implementation based on applying the __declspec(thread) attribute to each threadprivate variable. The limitations of the attribute on a given platform also apply to the threadprivate implementation. This setting provides compatibility with the implementation provided by the Microsoft* and GNU* compilers.
Default

-qopenmp-threadprivate=legacy

or/Qopenmp-threadprivate:legacy

The compiler uses the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel compiler.

Description

This option lets you specify an OpenMP* threadprivate implementation.

The threadprivate implementation of the legacy OpenMP run-time library may not be compatible with object files created using OpenMP run-time libraries supported in other compilers.

To use this option, you must also specify one of the following compiler options:

- Linux* systems: -qopenmp or -qopenmp-stubs
- Windows* systems: /Qopenmp or /Qopenmp-stubs

The value specified for this option is independent of the value used for the [q or Q]openmp-lib option.

NOTE

On macOS* systems, legacy is the only type of threadprivate supported. Option -qopenmp-threadprivate is not recognized by the compiler.

IDE Equivalent

None

Alternate Options

None

Qpar-adjust-stack

Tells the compiler to generate code to adjust the stack size for a fiber-based main thread.

Syntax

Linux OS and macOS:

None

Windows OS:

/Qpar-adjust-stack:n

Arguments

n

Is the stack size (in bytes) for the fiber-based main thread. It must be a number equal to or greater than zero.

Default

/Qpar-adjust-stack:0

No adjustment is made to the main thread stack size.
Description
This option tells the compiler to generate code to adjust the stack size for a fiber-based main thread. This can reduce the stack size of threads.

For this option to be effective, you must also specify option /Qparallel.

IDE Equivalent
None

Alternate Options
None

See Also
parallel, Qparallel compiler option

Floating-Point Options

fast-transcendentals, Qfast-transcendentals
Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.

Syntax
Linux OS and macOS:
-fast-transcendentals
-no-fast-transcendentals

Windows OS:
/Qfast-transcendentals
/Qfast-transcendentals-

Arguments
None

Default
If you do not specify option -[no-]fast-transcendentals or option /Qfast-transcendentals[-]:
- The default is ON if option -fp-model fast or /fp:fast is specified or is in effect.
- The default is OFF if a value-safe setting is specified for -fp-model or /fp (such as "precise", "source", etc.).

Description
This option enables the compiler to replace calls to transcendental functions with implementations that may be faster but less precise.
It allows the compiler to perform certain optimizations on transcendental functions, such as replacing individual calls to sine in a loop with a single call to a less precise vectorized sine library routine. These optimizations can cause numerical differences that would not otherwise exist if you are also compiling with a value-safe option such as -fp-model precise (Linux* and macOS*) or /fp:precise (Windows).

For example, you may get different results if you specify option O0 versus option O2, or you may get different results from calling the same function with the same input at different points in your program. If these kinds of numerical differences are problematic, consider using option -fimf-use-svml (Linux* and macOS*) or /Qimf-use-svml (Windows) as an alternative. When used with a value-safe option such as -fp-model precise or /fp:precise, option -fimf-use-svml or /Qimf-use-svml provides many of the positive performance benefits of [Q]fast-transcendentals without negatively affecting numeric consistency. For more details, see the description of option -fimf-use-svml and /Qimf-use-svml.

This option does not affect explicit Short Vector Math Library (SVML) intrinsics. It only affects scalar calls to the standard math library routines.

You cannot use option -fast-transcendentals with option -fp-model strict and you cannot use option /Qfast-transcendentals with option /fp:strict.

This option determines the setting for the maximum allowable relative error for math library function results (max-error) if none of the following options are specified:

- -fimf-accuracy-bits (Linux* and macOS*) or /Qimf-accuracy-bits (Windows*)
- -fimf-max-error (Linux and macOS*) or /Qimf-max-error (Windows)
- -fimf-precision (Linux and macOS*) or /Qimf-precision (Windows)

This option enables extra optimization that only applies to Intel® processors.

fimf-absolute-error, Qimf-absolute-error

Defines the maximum allowable absolute error for math library function results.

<table>
<thead>
<tr>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux OS:</td>
</tr>
<tr>
<td>-fimf-absolute-error=value[:funclist]</td>
</tr>
</tbody>
</table>
macOS:
-fimf-absolute-error=value[:funclist]

Windows OS:
/Qimf-absolute-error:value[:funclist]

Arguments

value
Is a positive, floating-point number. Errors in math library function results may exceed the maximum relative error (max-error) setting if the absolute-error is less than or equal to value.

The format for the number is [digits] [.digits] [ { e | E }[sign]digits]

funclist
Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use
-fimf-absolute-error=0.00001:sin,sinf
(or /Qimf-absolute-error:0.00001:sin,sinf) to specify the maximum allowable absolute error for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify
-fimf-absolute-error=0.00001:/
or /Qimf-absolute-error:0.00001:/. 

Default

Zero (“0”) An absolute-error setting of 0 means that the function is bound by the relative error setting. This is the default behavior.

Description

This option defines the maximum allowable absolute error for math library function results.

This option can improve run-time performance, but it may decrease the accuracy of results.

This option only affects functions that have zero as a possible return value, such as log, sin, asin, etc.

The relative error requirements for a particular function are determined by options that set the maximum relative error (max-error) and precision. The return value from a function must have a relative error less than the max-error value, or an absolute error less than the absolute-error value.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-absolute-error=0.00001:sin
or /Qimf-absolute-error:0.00001:sin, or -fimf-absolute-error=0.00001:sqrtf
or /Qimf-absolute-error:0.00001:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.
NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

### `fimf-accuracy-bits`, `Qimf-accuracy-bits` compiler option

defines the relative error for math library function results, including division and square root.

#### Syntax

**Linux OS:**

```
-fimf-accuracy-bits=bits[:funclist]
```

**macOS:**

```
-fimf-accuracy-bits=bits[:funclist]
```

**Windows OS:**

```
/Qimf-accuracy-bits=bits[:funclist]
```

#### Arguments

- **bits**
  
  Is a positive, floating-point number indicating the number of correct bits the compiler should use.

  The format for the number is `[digits] [.digits] [ { e | E }[sign]digits].`

- **funclist**
  
  Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.
Precision-specific variants like sin and sinf are considered different functions, so you would need to use
-fimf-accuracy-bits=23:sin,sinf
(or /Qimf-accuracy-bits:23:sin,sinf) to specify the relative error for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify
-fimf-accuracy-bits=10.0:/f
or /Qimf-accuracy-bits:10.0:/f.

Default

-fimf-precision= medium
or /Qimf-precision: medium

Description

This option defines the relative error, measured by the number of correct bits, for math library function results.

The following formula is used to convert bits into ulps: ulps = \(2^{p-1-bits}\), where \(p\) is the number of the target format mantissa bits (24, 53, and 64 for single, double, and long double, respectively).

This option can affect run-time performance and the accuracy of results.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in the following:

- -fimf-accuracy-bits=23:sinf,cosf,logf or /Qimf-accuracy-bits:23:sinf,cosf,logf
- -fimf-accuracy-bits=52:sqrt,/,trunc or /Qimf-accuracy-bits:52:sqrt,/,trunc
- -fimf-accuracy-bits=10:powf or /Qimf-accuracy-bits:10:powf

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- -fimf-precision (Linux* and macOS*) or /Qimf-precision (Windows*)
- -fimf-max-error (Linux* and macOS*) or /Qimf-max-error (Windows*)
- -fimf-accuracy-bits (Linux and macOS*) or /Qimf-accuracy-bits (Windows)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.

If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- [Q]fast-transcendentals
- [Q]prec-div
- [Q]prec-sqrt
- **-fp-model (Linux and macOS*) or /fp (Windows)**

---

**NOTE**
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

---

**fimf-arch-consistency, Qimf-arch-consistency**

Ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture.

---

**Syntax**

**Linux OS:**

- `fimf-arch-consistency=value[:funclist]`

**macOS:**

- `fimf-arch-consistency=value[:funclist]`

**Windows OS:**

/`Qimf-arch-consistency:value[:funclist]`

---

**Arguments**

- **value**
  
  Is one of the logical values "true" or "false".

- **funclist**
  
  Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.
Precision-specific variants like sin and sinf are considered different functions, so you would need to use
-fimf-arch-consistency=true:sin,sinf
(or /Qimf-arch-consistency:true:sin,sinf) to specify consistent results for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify
-fimf-arch-consistency=true:/
or /Qimf-arch-consistency:true:/.

Default
false

Implementations of some math library functions may produce slightly different results on implementations of the same architecture.

Description
This option ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture (for example, across different microarchitectural implementations of IA-32 architecture). Consistency is only guaranteed for a single binary. Consistency is not guaranteed across different architectures. For example, consistency is not guaranteed across IA-32 architecture and Intel® 64 architecture.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-arch-consistency=true:sin
or /Qimf-arch-consistency:true:sin, or -fimf-arch-consistency=false:sqrtf
or /Qimf-arch-consistency:false:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

The -fimf-arch-consistency (Linux* and macOS*) and /Qimf-arch-consistency (Windows*) option may decrease run-time performance, but the option will provide bit-wise consistent results on all Intel® processors and compatible, non-Intel processors, regardless of micro-architecture. This option may not provide bit-wise consistent results between different architectures.

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

fimf-domain-exclusion, Qimf-domain-exclusion
Indicates the input arguments domain on which math functions must provide correct results.

Syntax
Linux OS:
-fimf-domain-exclusion=classlist[:funclist]
macOS:
-fimf-domain-exclusion=classlist[:funclist]
Windows OS:
/Qimf-domain-exclusion=classlist[:funclist]

Arguments
classlist

Is one of the following:

- One or more of the following floating-point value classes you can exclude from the function domain without affecting the correctness of your program. The supported class names are:

  extremes
  This class is for values which do not lie within the usual domain of arguments for a given function.

  nans
  This means "x=Nan".

  infinities
  This means "x=infinities".

  denormals
  This means "x=denormal".

  zeros
  This means "x=0".

Each classlist element corresponds to a power of two. The exclusion attribute is the logical or of the associated powers of two (that is, a bitmask).
The following shows the current mapping from classlist mnemonics to numerical values:

<table>
<thead>
<tr>
<th>classlist mnemonic</th>
<th>numerical value</th>
</tr>
</thead>
<tbody>
<tr>
<td>extremes</td>
<td>1</td>
</tr>
<tr>
<td>nans</td>
<td>2</td>
</tr>
<tr>
<td>infinities</td>
<td>4</td>
</tr>
<tr>
<td>denormals</td>
<td>8</td>
</tr>
<tr>
<td>zeros</td>
<td>16</td>
</tr>
<tr>
<td>none</td>
<td>0</td>
</tr>
<tr>
<td>all</td>
<td>31</td>
</tr>
<tr>
<td>common</td>
<td>15</td>
</tr>
<tr>
<td>other combinations</td>
<td>bitwise OR of the used values</td>
</tr>
</tbody>
</table>

You must specify the integer value that corresponds to the class that you want to exclude.

Note that on excluded values, unexpected results may occur.

- One of the following short-hand tokens:
  
  - **none**
    
      This means that none of the supported classes are excluded from the domain. To indicate this token, specify 0, as in
      
      -fimf-domain-exclusion=0
      
      (or /Qimf-domain-exclusion:0).

  - **all**
    
      This means that all of the supported classes are excluded from the domain. To indicate this token, specify 31, as in
      
      -fimf-domain-exclusion=31
      
      (or /Qimf-domain-exclusion:31).

  - **common**
    
      This is the same as specifying extremes, nans, infinities, denormals. To indicate this token, specify 15 (1 + 2 + 4 + 8), as in
      
      -fimf-domain-exclusion=15
      
      (or /Qimf-domain-exclusion:15).

  - **funclist**

    Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.

    Precision-specific variants like sin and sinf are considered different functions, so you would need to use
    
    -fimf-domain-exclusion=4:sin,sinf
    
    (or /Qimf-domain-exclusion:4:sin,sinf) to specify infinities for both the single-precision and double-precision sine functions.

    You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example, you can specify:
-fimf-domain-exclusion=4 or /Qimf-domain-exclusion:4
-fimf-domain-exclusion=5:/,powf
or /Qimf-domain-exclusion:5:/,powf
-fimf-domain-exclusion=23:log,logf,/,sin,cosf
or /Qimf-domain-exclusion:23:log,logf,/,sin,cosf

If you don’t specify argument funclist, the domain restrictions apply to all math library functions.

Default

Zero ("0") The compiler uses default heuristics when calling math library functions.

Description

This option indicates the input arguments domain on which math functions must provide correct results. It specifies that your program will function correctly if the functions specified in funclist do not produce standard conforming results on the number classes.

This option can affect run-time performance and the accuracy of results. As more classes are excluded, faster code sequences can be used.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin, as in -fimf-domain-exclusion=denormals:sin
or /Qimf-domain-exclusion:denormals:sin, or -fimf-domain-exclusion=extremes:sqrtf
or /Qimf-domain-exclusion:extremes:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

NOTE

Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

Notice revision #20201201

IDE Equivalent

None

Alternate Options

None

Example

Consider the following single-precision sequence for function exp2f:

<table>
<thead>
<tr>
<th>Operation:</th>
<th>y = exp2f(x)</th>
</tr>
</thead>
</table>
The following shows the 2-instruction sequence without the fix-up:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vcvtfxpntps2dq</td>
<td>zmm1 {k1}, zmm0, 0x50 // zmm1 &lt;-- rndToInt(2^24 * x)</td>
</tr>
<tr>
<td>vexp223ps</td>
<td>zmm1 {k1}, zmm1 // zmm1 &lt;-- exp2(x)</td>
</tr>
</tbody>
</table>

However, the above 2-instruction sequence will not correctly process NaNs. To process NaNs correctly, the following fix-up must be included following the above instruction sequence:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vpxord</td>
<td>zmm2, zmm2, zmm2 // zmm2 &lt;-- 0</td>
</tr>
<tr>
<td>vfixupnanps</td>
<td>zmm1 {k1}, zmm0, zmm2 {aaaa} // zmm1 &lt;-- QNaN(x) if x is NaN &lt;F&gt;</td>
</tr>
</tbody>
</table>

If the `vfixupnanps` instruction is not included, the sequence correctly processes any arguments except NaN values. For example, the following options generate the 2-instruction sequence:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-fimf-domain-exclusion=2:exp2f</td>
<td>NaN’s are excluded (2 corresponds to NaNs)</td>
</tr>
<tr>
<td>-fimf-domain-exclusion=6:exp2f</td>
<td>NaN’s and infinities are excluded (4 corresponds to infinities; 2 + 4 = 6)</td>
</tr>
<tr>
<td>-fimf-domain-exclusion=7:exp2f</td>
<td>NaN’s, infinities, and extremes are excluded (1 corresponds to extremes; 2 + 4 + 1 = 7)</td>
</tr>
<tr>
<td>-fimf-domain-exclusion=15:exp2f</td>
<td>NaN’s, infinities, extremes, and denormals are excluded (8 corresponds to denormals; 2 + 4 + 1 + 8=15)</td>
</tr>
</tbody>
</table>

If the `vfixupnanps` instruction is included, the sequence correctly processes any arguments including NaN values. For example, the following options generate the 4-instruction sequence:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-fimf-domain-exclusion=1:exp2f</td>
<td>only extremes are excluded (1 corresponds to extremes)</td>
</tr>
<tr>
<td>-fimf-domain-exclusion=4:exp2f</td>
<td>only infinities are excluded (4 corresponds to infinities)</td>
</tr>
<tr>
<td>-fimf-domain-exclusion=8:exp2f</td>
<td>only denormals are excluded (8 corresponds to denormals)</td>
</tr>
<tr>
<td>-fimf-domain-exclusion=13:exp2f</td>
<td>only extremes, infinities and denormals are excluded (1 + 4 + 8 = 13)</td>
</tr>
</tbody>

-fimf-force-dynamic-target, Qimf-force-dynamic-target

Instructs the compiler to use run-time dispatch in calls to math functions.

Syntax

Linux OS:

-fimf-force-dynamic-target[=funclist]

macOS:

-fimf-force-dynamic-target[=funclist]

Windows OS:

/Qimf-force-dynamic-target[:funclist]
Arguments

funclist

Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use

-fimf-dynamic-target=sin,sinf

(or /Qimf-dynamic-target:sin,sinf) to specify run-time dispatch for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example, you can specify -fimf-dynamic-target=/ or /Qimf-dynamic-target:/. 

Default

OFF

Run-time dispatch is not forced in math libraries calls. The compiler can choose to call a CPU-specific version of a math function if one is available.

Description

This option instructs the compiler to use run-time dispatch in calls to math functions. When this option set to ON, it lets you force run-time dispatch in math libraries calls.

By default, when this option is set to OFF, the compiler often optimizes math library calls using the target CPU architecture-specific information available at compile time through the [Q]x and arch compiler options.

If you want to target multiple CPU families with a single application or you prefer to choose a target CPU at run time, you can force run-time dispatch in math libraries by using this option.

**fimf-max-error, Qimf-max-error**

Defines the maximum allowable relative error for math library function results, including division and square root.

**Syntax**

**Linux OS:**

- `fimf-max-error=ulps[:funclist]`

**macOS:**

- `fimf-max-error=ulps[:funclist]`

**Windows OS:**

/\Qimf-max-error:ulps[:funclist]

**Arguments**

- **ulps**
  
  Is a positive, floating-point number indicating the maximum allowable relative error the compiler should use.
  
  The format for the number is `[digits] [.digits] [ { e | E }[sign]digits].`

- **funclist**
  
  Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.
  
  Precision-specific variants like sin and sinf are considered different functions, so you would need to use
  `fimf-max-error=4.0:sin,sinf`
  (or `/Qimf-max-error=4.0:sin,sinf`) to specify the maximum allowable relative error for both the single-precision and double-precision sine functions.
  
  You also can specify the symbol `/f` to denote single-precision divides, symbol `/` to denote double-precision divides, symbol `/l` to denote extended-precision divides, and symbol `/q` to denote quad-precision divides. For example you can specify `fimf-max-error=4.0:/` or `/Qimf-max-error:4.0:/`.

**Default**

- `fimf-max-error=ulps[:funclist]`
  
  The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.
  
  medium
  or `/Qimf-max-error:medium`

**Description**

This option defines the maximum allowable relative error, measured in ulps, for math library function results. This option can affect run-time performance and the accuracy of results.
If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in -fimf-max-error=4.0:sin or /Qimf-max-error:4.0:sin, or -fimf-max-error=4.0:sqrtf or /Qimf-max-error:4.0:sqrtf.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- -fimf-precision (Linux* and macOS*) or /Qimf-precision (Windows*)
- -fimf-max-error (Linux* and macOS*) or /Qimf-max-error (Windows*)
- -fimf-accuracy-bits (Linux and macOS*) or /Qimf-accuracy-bits (Windows)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.

If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- [Q]fast-transcendentals
- [Q]prec-div
- [Q]prec-sqrt
- -fp-model (Linux and macOS*) or /fp (Windows)

**NOTE**
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.
**fimf-precision, Qimf-precision**

*Let you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.*

**Syntax**

**Linux OS:**

- `fimf-precision[=value[:funclist]]`

**macOS:**

- `fimf-precision[=value[:funclist]]`

**Windows OS:**

- `/Qimf-precision[=value[:funclist]]`

**Arguments**

`value` Is one of the following values denoting the desired accuracy:

- **high**
  - This is equivalent to `max-error = 1.0`.

- **medium**
  - This is equivalent to `max-error = 4`; this is the default setting if the option is specified and `value` is omitted.

- **low**
  - This is equivalent to `accuracy-bits = 11` for single-precision functions; `accuracy-bits = 26` for double-precision functions.

In the above explanations, `max-error` means option `-fimf-max-error` (Linux* and macOS*) or `/Qimf-max-error` (Windows*); `accuracy-bits` means option `-fimf-accuracy-bits` (Linux* and macOS*) or `/Qimf-accuracy-bits` (Windows*).

`funclist` Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.

Precision-specific variants like `sin` and `sinf` are considered different functions, so you would need to use `-fimf-precision=high:sin,sinf` (or `/Qimf-precision:high:sin,sinf`) to specify high precision for both the single-precision and double-precision sine functions.

You also can specify the symbol `/f` to denote single-precision divides, symbol `/` to denote double-precision divides, symbol `/l` to denote extended-precision divides, and symbol `/q` to denote quad-precision divides. For example you can specify `-fimf-precision=low:/` or `/Qimf-precision:low:/` and `-fimf-precision=low:/f` or `/Qimf-precision:low:/f`.  

303
**Default**

**medium**  The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.

**Description**

This option lets you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.

This option can be used to improve run-time performance if reduced accuracy is sufficient for the application, or it can be used to increase the accuracy of math library functions selected by the compiler.

In general, using a lower precision can improve run-time performance and using a higher precision may reduce run-time performance.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in `fimf-precision=low:sin` or `/Qimf-precision:low:sin`, or `fimf-precision=high:sqrtf` or `/Qimf-precision:high:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, `sinf` applies only to the single-precision sine function, `sin` applies only to the double-precision sine function, `sinl` applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- `-fimf-precision` (Linux* and macOS*) or `/Qimf-precision` (Windows*)
- `-fimf-max-error` (Linux* and macOS*) or `/Qimf-max-error` (Windows*)
- `-fimf-accuracy-bits` (Linux and macOS*) or `/Qimf-accuracy-bits` (Windows)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.

If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- `[Q]`fast-transcendentals
- `[Q]`prec-div
- `[Q]`prec-sqrt
- `-fp-model` (Linux and macOS*) or `/fp` (Windows)

**NOTE**

Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

fimf-use-svml, Qimf-use-svml compiler option

fimf-use-svml, Qimf-use-svml

Instructs the compiler to use the Short Vector Math Library (SVML) rather than the Intel® C++ Compiler Classic Math Library (LIBM) to implement math library functions.

Syntax

Linux OS:
-fimf-use-svml=value[:funclist]

macOS:
-fimf-use-svml=value[:funclist]

Windows OS:
/Qimf-use-svml:value[:funclist]

Arguments

funclist

Is an optional list of one or more math library functions to which the attribute should be applied. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use
-fimf-use-svmlt=true:sin,sinf
(or /Qimf-use-svml:truesin,sinf) to specify that both the single-precision and double-precision sine functions should use SVML.

Default

false  Math library functions are implemented using the Intel® C++ Compiler Classic Math Library, though other compiler options such as -fast-transcendentals or /Qfast-transcendentals may give the compiler the flexibility to implement math library functions with either LIBM or SVML.
Description
This option instructs the compiler to implement math library functions using the Short Vector Math Library (SVML). When you specify `-fimf-use-svml=true` or `/Qimf-use-svml:true`, the specific SVML variant chosen is influenced by other compiler options such as `-fimf-precision` (Linux* and macOS*) or `/Qimf-precision` (Windows*) and `-fp-model` (Linux and macOS*) or `/fp` (Windows). This option has no effect on math library functions that are implemented in LIBM but not in SVML.

In value-safe settings of option `-fp-model` (Linux and macOS*) or option `/fp` (Windows) such as precise, this option causes a slight decrease in the accuracy of math library functions, because even the high accuracy SVML functions are slightly less accurate than the corresponding functions in LIBM. Additionally, the SVML functions might not accurately raise floating-point exceptions, do not maintain errno, and are designed to work correctly only in round-to-nearest-even rounding mode.

The benefit of using `-fimf-use-svml=true` or `/Qimf-use-svml:true` with value-safe settings of `-fp-model` (Linux and macOS*) or `/fp` (Windows) is that it can significantly improve performance by enabling the compiler to efficiently vectorize loops containing calls to math library functions.

If you need to use SVML for a specific math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sqrtf, as in `-fimf-use-svml=true:sin` or `/Qimf-use-svml:true:sin`, or `-fimf-use-svml=false:sqrtf` or `/Qimf-use-svml:false:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, `sinf` applies only to the single-precision sine function, `sin` applies only to the double-precision sine function, `sinl` applies only to the extended-precision sine function, etc.

**NOTE**
If you specify option `-mia32` (Linux*) or option `/arch:IA32` (Windows*), vector instructions cannot be used. Therefore, you cannot use Linux* option `-mia32` with option `-fimf-use-svml=true`, and you cannot use Windows* option `/arch:IA32` with option `/Qimf-use-svml:true`.

**NOTE**
Since SVML functions may raise unexpected floating-point exceptions, be cautious about using features that enable trapping on floating-point exceptions. For example, be cautious about specifying option `-fimf-use-svml=true` with option `-fp-trap`, or option `/Qimf-use-svml:true` with option `/Qfp-trap`. For some inputs to some math library functions, such option combinations may cause your program to trap unexpectedly.

fp-trap, Qfp-trap compiler option

fma, Qfma
*Determine* whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor.

Syntax
Linux OS:
- fma
- no-fma

macOS:
- fma
- no-fma

Windows OS:
/Qfma
/Qfma-

Arguments
None

Default
- fma
or/Qfma

If the instructions exist on the target processor, the compiler generates fused multiply-add (FMA) instructions.

However, if you specify -fp-model strict (Linux* and macOS*) or /fp:strict (Windows*), but do not explicitly specify -fma or /Qfma, the default is -no-fma or /Qfma-.

Description
This option determines whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor. When the [Q]fma option is specified, the compiler may generate FMA instructions for combining multiply and add operations. When the negative form of the [Q]fma option is specified, the compiler must generate separate multiply and add instructions with intermediate rounding.

This option has no effect unless setting CORE-AVX2 or higher is specified for option [Q]x,-march (Linux and macOS*), or /arch (Windows).

IDE Equivalent
None

See Also
fp-model, fp compiler option
**fp-model, fp**  
Controls the semantics of floating-point calculations.

### Syntax

**Linux OS:**
- `-fp-model=keyword`

**macOS:**
- `-fp-model=keyword`

**Windows OS:**
- `/fp:keyword`

### Arguments

**keyword**  
Specifies the semantics to be used. Possible values are:

- `precise`
  
  Disables optimizations that are not value-safe on floating-point data.

- `fast[=1|2]`
  
  Enables more aggressive optimizations on floating-point data.

- `consistent`
  
  The compiler uses default heuristics to determine results for different optimization levels or between different processors of the same architecture.

- `strict`
  
  Enables precise and except, disables contractions, and enables `pragma stdc_fenv_access`.

- `source`
  
  Rounds intermediate results to source-defined precision.

- `double`
  
  Rounds intermediate results to 53-bit (double) precision.

- `extended`
  
  Rounds intermediate results to 64-bit (extended) precision.

- `[no-]except`  
  
  Determines whether strict floating-point exception semantics are honored. (Linux* and macOS*) or `except[-]` (Windows* )

### Default

- `-fp-model=fast=1` or `/fp:fast=1`
  
  The compiler uses more aggressive optimizations on floating-point calculations.

### Description

This option controls the semantics of floating-point calculations.

The **keywords** can be considered in groups:

- **Group A:** `precise, fast, strict`
• **Group B:** source, double, extended
• **Group C:** except (or negative forms -no-except or /except-)
• **Group D:** consistent

You can specify more than one keyword. However, the following rules apply:

• You cannot specify fast and except together in the same compilation. You can specify any other combination of group A, group B, and group C. Since fast is the default, you must not specify except without a group A or group B keyword.
• You should specify only one keyword from group A and only one keyword from group B. If you try to specify more than one keyword from either group A or group B, the last (rightmost) one takes effect.
• If you specify except more than once, the last (rightmost) one takes effect.
• If you specify consistent and any other keyword from another group, the last (rightmost) one may not fully override the heuristics set by consistent.

The floating-point (FP) environment is a collection of registers that control the behavior of FP machine instructions and indicate the current FP status. The floating-point environment may include rounding-mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.

</tr>
</tbody>
</table>
The -fp-model and /fp options determine the setting for the maximum allowable relative error for math library function results (max-error) if none of the following options are specified (the following options are only available for ifort):

- -fimf-accuracy-bits (Linux* and macOS*) or /Qimf-accuracy-bits (Windows*)
- -fimf-max-error (Linux and macOS*) or /Qimf-max-error (Windows)
- -fimf-precision (Linux and macOS*) or /Qimf-precision (Windows)
- [Q]fast-transcendentals

**NOTE**
In Microsoft* Visual Studio, when you create a Microsoft* Visual C++ project, option /fp:precise is set by default. It sets the floating-point model to improve consistency for floating-point operations by disabling certain optimizations that may reduce performance. To set the option back to the general default /fp:fast, change the IDE project property for Floating Point Model to Fast.

The article titled: Consistency of Floating-Point Results using the Intel® Compiler, which is located in https://software.intel.com/content/www/us/en/develop/articles/consistency-of-floating-point-results-using-the-intel-compiler.html

**fp-port, Qfp-port**

Rounds floating-point results after floating-point operations.

**Syntax**

Linux OS:
- `fp-port`
- `no-fp-port`

macOS:
- `fp-port`
- `no-fp-port`

Windows OS:
- `/Qfp-port`
- `/Qfp-port`

**Arguments**

None

**Default**

`-no-fp-port` or `/Qfp-port`

The default rounding behavior depends on the compiler's code generation decisions and the precision parameters of the operating system.

**Description**

This option rounds floating-point results after floating-point operations.

This option is designed to be used with the `-mia32` (Linux*) or `/arch:IA32` (Windows*) option on a 32-bit compiler. Under those conditions, the compiler implements floating-point calculations using the x87 instruction set, which uses an internal precision that may be higher than the precision specified in the program.

By default, the compiler may keep results of floating-point operations in this higher internal precision. Rounding to program precision occurs at unspecified points. This provides better performance, but the floating-point results are less deterministic. The [Q]fp-port option rounds floating-point results to user-specified precision at assignments and type conversions. This has some impact on speed.

When compiling for newer architectures, the compiler implements floating-point calculations with different instructions, such as Intel® SSE and SSE2. These Intel® Streaming SIMD Extensions round directly to single precision or double precision at every instruction. In these cases, option [Q]fp-port has no effect.

**IDE Equivalent**

Floating-point Operations

**fp-speculation, Qfp-speculation**
*Tells the compiler the mode in which to speculate on floating-point operations.*

**Syntax**

Linux OS:
- `-fp-speculation=mode`

macOS:
- `-fp-speculation=mode`

Windows OS:
- `/Qfp-speculation:mode`

**Arguments**

`mode`

Is the mode for floating-point operations. Possible values are:

- `fast`
  - Tells the compiler to speculate on floating-point operations.

- `safe`
  - Tells the compiler to disable speculation if there is a possibility that the speculation may cause a floating-point exception.

- `strict`
  - Tells the compiler to disable speculation on floating-point operations.

- `off`
  - This is the same as specifying strict. This feature is only available for ifort.

**Default**

- `-fp-speculation=fast` or `/Qfp-speculation:fast`

The compiler speculates on floating-point operations. This is also the behavior when optimizations are enabled. However, if you specify no optimizations (`-00` on Linux*; `/Od` on Windows*), the default is `-fp-speculation=safe` (Linux*) or `/Qfp-speculation:safe` (Windows*).

**Description**

This option tells the compiler the mode in which to speculate on floating-point operations.
Disabling speculation may prevent the vectorization of some loops containing conditionals. For an example, see the article titled: Diagnostic 15326: loop was not vectorized: implied FP exception model prevents vectorization, which is located in https://software.intel.com/content/www/us/en/develop/articles/fdiag15326.html.

IDE Equivalent
Visual Studio: Optimization > Floating-Point Speculation
Eclipse: Floating Point > Floating-Point Speculation
Xcode: Floating Point > Floating-Point Speculation

Alternate Options
None

fp-stack-check, Qfp-stack-check
Tells the compiler to generate extra code after every function call to ensure that the floating-point stack is in the expected state.

Syntax
Linux OS and macOS:
-fp-stack-check
Windows OS:
/Qfp-stack-check

Arguments
None

Default
OFF
There is no checking to ensure that the floating-point (FP) stack is in the expected state.

Description
This option tells the compiler to generate extra code after every function call to ensure that the floating-point (FP) stack is in the expected state.

By default, there is no checking. So when the FP stack overflows, a NaN value is put into FP calculations and the program's results differ. Unfortunately, the overflow point can be far away from the point of the actual bug. This option places code that causes an access violation exception immediately after an incorrect call occurs, thus making it easier to locate these issues.

IDE Equivalent
Visual Studio: None
Eclipse: Floating Point > Check Floating-point Stack
Xcode: Floating Point > Check Floating-point Stack

Alternate Options
None
**fp-trap, Qfp-trap**

*Sets the floating-point trapping mode for the main routine.*

**Syntax**

**Linux OS:**

- `fp-trap=mode[,mode,...]`

**macOS:**

- `fp-trap=mode[,mode,...]`

**Windows OS:**

- `/Qfp-trap:mode[,mode,...]`

**Arguments**

<table>
<thead>
<tr>
<th>mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[no]divzero</td>
<td>Enables or disables the IEEE trap for division by zero.</td>
</tr>
<tr>
<td>[no]inexact</td>
<td>Enables or disables the IEEE trap for inexact result.</td>
</tr>
<tr>
<td>[no]invalid</td>
<td>Enables or disables the IEEE trap for invalid operation.</td>
</tr>
<tr>
<td>[no]overflow</td>
<td>Enables or disables the IEEE trap for overflow.</td>
</tr>
<tr>
<td>[no]underflow</td>
<td>Enables or disables the IEEE trap for underflow.</td>
</tr>
<tr>
<td>[no]denormal</td>
<td>Enables or disables the trap for denormal.</td>
</tr>
<tr>
<td>all</td>
<td>Enables all of the above traps.</td>
</tr>
<tr>
<td>none</td>
<td>Disables all of the above traps.</td>
</tr>
<tr>
<td>common</td>
<td>Sets the most commonly used IEEE traps: division by zero, invalid operation, and overflow.</td>
</tr>
</tbody>
</table>

**Default**

- `fp-trap=none`  
  or `/Qfp-trap:none`

**Description**

This option sets the floating-point trapping mode for the main routine. It does not set a handler for floating-point exceptions.
The [no] form of a mode value is only used to modify the meaning of mode values all and common, and can only be used with one of those values. The [no] form of the option by itself does not explicitly cause a particular trap to be disabled.

Use mode value inexact with caution. This results in the trap being enabled whenever a floating-point value cannot be represented exactly, which can cause unexpected results.

If mode value underflow is specified, the compiler ignores the FTZ (flush-to-zero) bit state of Intel® Streaming SIMD Extensions (Intel® SSE) floating-point units.

When a DAZ (denormals are zero) bit is set in an Intel® SSE floating-point unit control word, a denormal operand exception is never generated.

To set the floating-point trapping mode for all routines, specify the [Q]fp-trap-all option.

**NOTE**
The negative form of the [Q]ftz option can be used to set or reset the FTZ and the DAZ hardware flags.

**IDE Equivalent**

Visual Studio: Code Generation > Unmask Floating Point Exceptions

Configuration Properties->C/C++ > Unmask Floating Point Exceptions

Eclipse: Floating Point > Initial Exception Mask

Xcode: Floating Point > Set Initial Exception Mask

**Alternate Options**

None

**See Also**

ftz, Qftz compiler option
fp-trap-all, Qfp-trap-all compiler option

**fp-trap-all, Qfp-trap-all**
Sets the floating-point trapping mode for all routines.

**Syntax**

Linux OS:

-fp-trap-all=mode[,mode,...]

macOS:

-fp-trap-all=mode[,mode,...]

Windows OS:

/Qfp-trap-all:mode[,mode,...]

**Arguments**

`mode`

Is the floating-point trapping mode. If you specify more than one mode value, the list is processed sequentially from left to right. Possible values are:
Enables or disables the IEEE trap for division by zero.

Enables or disables the IEEE trap for inexact result.

Enables or disables the IEEE trap for invalid operation.

Enables or disables the IEEE trap for overflow.

Enables or disables the IEEE trap for underflow.

Enables or disables the trap for denormal.

Enables all of the above traps.

Disables all of the above traps.

Sets the most commonly used IEEE traps: division by zero, invalid operation, and overflow.

Default

-no-divzero
-no-inexact
-no-invalid
-no-overflow
-no-underflow
-no-denormal
-all
-none
-common

No traps are enabled for all routines.

-or

/Qfp-trap-all:none

Description

This option sets the floating-point trapping mode for the main routine. It does not set a handler for floating-point exceptions.

The [no] form of a mode value is only used to modify the meaning of mode values all and common, and can only be used with one of those values. The [no] form of the option by itself does not explicitly cause a particular trap to be disabled.

Use mode value inexact with caution. This results in the trap being enabled whenever a floating-point value cannot be represented exactly, which can cause unexpected results.

If mode value underflow is specified, the compiler ignores the FTZ (flush-to-zero) bit state of Intel Streaming SIMD Extensions (Intel SSE) floating-point units.

When a DAZ (denormals are zero) bit is set in an Intel SSE floating-point unit control word, a denormal operand exception is never generated.

To set the floating-point trapping mode for the main routine only, specify the [Q]fp-trap option.

NOTE

The negative form of the [Q]ftz option can be used to set or reset the FTZ and the DAZ hardware flags.

IDE Equivalent

None
Alternate Options

None

See Also

ftz, Qftz compiler option
fp-trap, Qfp-trap compiler option

ftz, Qftz

*Flushes denormal results to zero.*

Syntax

Linux OS and macOS:

- -ftz
- -no-ftz

Windows OS:

/Qftz
/Qftz-

Arguments

None

Default

- -ftz or /Qftz

Denormal results are flushed to zero.

Every optimization option o level, except o0, sets [Q]ftz.

Description

This option flushes denormal results to zero when the application is in the gradual underflow mode. It may improve performance if the denormal values are not critical to your application's behavior.

The [Q]ftz option has no effect during compile-time optimization.

The [Q]ftz option sets or resets the FTZ and the DAZ hardware flags. If FTZ is ON, denormal results from floating-point calculations will be set to the value zero. If FTZ is OFF, denormal results remain as is. If DAZ is ON, denormal values used as input to floating-point instructions will be treated as zero. If DAZ is OFF, denormal instruction inputs remain as is. Systems using Intel® 64 architecture have both FTZ and DAZ. FTZ and DAZ are not supported on all IA-32 architectures.

When the [Q]ftz option is used in combination with an SSE-enabling option on systems using IA-32 architecture (for example, the [Q]xSSE2 option), the compiler will insert code in the main routine to set FTZ and DAZ. When [Q]ftz is used without such an option, the compiler will insert code to conditionally set FTZ/DAZ based on a run-time processor check.

If you specify option -no-ftz (Linux and macOS*) or option /Qftz- (Windows), it prevents the compiler from inserting any code that might set FTZ or DAZ.

Option [Q]ftz only has an effect when the main program is being compiled. It sets the FTZ/DAZ mode for the process. The initial thread and any threads subsequently created by that process will operate in FTZ/DAZ mode.
If this option produces undesirable results of the numerical behavior of your program, you can turn the FTZ/DAZ mode off by specifying \texttt{-no-ftz} or \texttt{/Qftz-} in the command line while still benefiting from the \texttt{O3} optimizations.

\textbf{NOTE}

Option \texttt{[Q]ftz} is a performance option. Setting this option does not guarantee that all denormals in a program are flushed to zero. The option only causes denormals generated at run time to be flushed to zero.

\textbf{IDE Equivalent}

Visual Studio: \textit{Optimization} > \textit{Flush Denormal Results to Zero}

Eclipse: \textit{Floating-Point} > \textit{Flush Denormal Results to Zero}

Xcode: \textit{Floating-Point} > \textit{Flush Denormal Results to Zero}

\textit{Enables stack-checking for all functions. This is a deprecated option. The replacement option is /Gs0.}

\textbf{Syntax}

\textbf{Linux OS and macOS:}

None

\textbf{Windows OS:}

/Ge

\textbf{Arguments}

None

\textbf{Default}

OFF Stack-checking for all functions is disabled.

\textbf{Description}

This option enables stack-checking for all functions.

\textbf{IDE Equivalent}

None

\textbf{Alternate Options}

Linux and macOS*: None

Windows: /Gs0
**mp1, Qprec**  
*Improves floating-point precision and consistency.*

**Syntax**

**Linux OS:**
-mp1

**macOS:**
-mp1

**Windows OS:**
/Qprec

**Arguments**

None

**Default**

OFF  

The compiler provides good accuracy and run-time performance at the expense of less consistent floating-point results.

**Description**

This option improves floating-point consistency. It ensures the out-of-range check of operands of transcendental functions and improves the accuracy of floating-point compares.

This option prevents the compiler from performing optimizations that change NaN comparison semantics and causes all values to be truncated to declared precision before they are used in comparisons. It also causes the compiler to use library routines that give better precision results compared to the X87 transcendental instructions.

This option disables fewer optimizations and has less impact on performance than option -fp-model precise (Linux* and macOS*) or option /fp:precise (Windows*).

**IDE Equivalent**

Visual Studio: None

Eclipse: None

Xcode: **FloatingPoint > Improve Floating-Point Consistency**

**Alternate Options**

None

**See Also**

**pc, Qpc**  
*Enables control of floating-point significand precision.*

**Syntax**

**Linux OS:**
-pcn
macOS:
-\texttt{pcn}

Windows OS:
/\texttt{Qpcn}

**Arguments**

\( n \)

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>32</td>
<td>Rounds the significand to 24 bits (single precision).</td>
</tr>
<tr>
<td>64</td>
<td>Rounds the significand to 53 bits (double precision).</td>
</tr>
<tr>
<td>80</td>
<td>Rounds the significand to 64 bits (extended precision).</td>
</tr>
</tbody>
</table>

**Default**

-\texttt{pc80}

or/\texttt{Qpc64}

On Linux* and macOS* systems, the floating-point significand is rounded to 64 bits. On Windows* systems, the floating-point significand is rounded to 53 bits.

**Description**

This option enables control of floating-point significand precision.

Some floating-point algorithms are sensitive to the accuracy of the significand, or fractional part of the floating-point value. For example, iterative operations like division and finding the square root can run faster if you lower the precision with the this option.

Note that a change of the default precision control or rounding mode, for example, by using the [\texttt{Q}pc32](#) option or by user intervention, may affect the results returned by some of the mathematical functions.

**IDE Equivalent**

None

**Alternate Options**

None

**prec-div, Qprec-div**

*Improves precision of floating-point divides.*

**Syntax**

Linux OS and macOS:

-\texttt{prec-div}

-\texttt{no-prec-div}

Windows OS:

/\texttt{Qprec-div}

/\texttt{Qprec-div-}
Arguments
None

Default
OFF
Default heuristics are used. The default is not as accurate as full IEEE division, but it is slightly more accurate than would be obtained when \texttt{/Qprec-div} or \texttt{-no-prec-div} is specified.

If you need full IEEE precision for division, you should specify \texttt{[Q]prec-div}.

Description
This option improves precision of floating-point divides. It has a slight impact on speed. At default optimization levels, the compiler may change floating-point division computations into multiplication by the reciprocal of the denominator. For example, $A/B$ is computed as $A \times (1/B)$ to improve the speed of the computation.

However, sometimes the value produced by this transformation is not as accurate as full IEEE division. When it is important to have fully precise IEEE division, use this option to disable the floating-point division-to-multiplication optimization. The result is more accurate, with some loss of performance.

If you specify \texttt{-no-prec-div} (Linux* and macOS*) or \texttt{/Qprec-div-} (Windows*), it enables optimizations that give slightly less precise results than full IEEE division.

Option \texttt{[Q]prec-div} is implied by option \texttt{-fp-model precise} (Linux* and macOS*) and option \texttt{/fp:precise} (Windows*).

IDE Equivalent
None

Alternate Options
None

See Also
\texttt{fp-model}, \texttt{fp} compiler option

\texttt{prec-sqrt}, \texttt{Qprec-sqrt}

\textit{Improves precision of square root implementations.}

Syntax

\textbf{Linux OS and macOS:}

\begin{itemize}
  \item \texttt{-prec-sqrt}
  \item \texttt{-no-prec-sqrt}
\end{itemize}

\textbf{Windows OS:}

\begin{itemize}
  \item \texttt{/Qprec-sqrt}
  \item \texttt{/Qprec-sqrt-}
\end{itemize}

Arguments
None
The compiler uses a faster but less precise implementation of square root. However, the default is -prec-sqrt or /Qprec-sqrt if any of the following options are specified: /Od, /fp:precise, or /Qprec on Windows* systems; -O0 or -mplt on Linux* and macOS* systems.

**Description**
This option improves precision of square root implementations. It has a slight impact on speed. This option inhibits any optimizations that can adversely affect the precision of a square root computation. The result is fully precise square root implementations, with some loss of performance.

**IDE Equivalent**
None

**Alternate Options**
None

`qsimd-honor-fp-model, Qsimd-honor-fp-model`
*Tells the compiler to obey the selected floating-point model when vectorizing SIMD loops.*

**Syntax**

*Linux OS:*
- -qsimd-honor-fp-model
- -qno-simd-honor-fp-model

*macOS:*
- -qsimd-honor-fp-model
- -qno-simd-honor-fp-model

*Windows OS:*
/qsimd-honor-fp-model
/Qsimd-honor-fp-model-

**Arguments**
None

**Default**
- -qno-simd-honor-fp-model
  or /Qsimd-honor-fp-model-
The compiler performs vectorization of SIMD loops even if it breaks the floating-point model setting.

**Description**
The OpenMP* SIMD specification and the setting of compiler option -fp-model (Linux* and macOS*) or /fp (Windows*) can contradict in requirements. When contradiction occurs, the default behavior of the compiler is to follow the OpenMP* specification and therefore vectorize the loop.
This option lets you override this default behavior - it causes the compiler to follow the -fp-model (or /fp) specification. This means that the compiler will serialize the loop.

**NOTE**
This option does not affect automatic vectorization of loops. By default, the compiler uses -fp-model (Linux* and macOS*) or /fp (Windows*) settings for this.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
qsimd-serialize-fp-reduction, Qsimd-serialize-fp-reduction compiler option
fp-model, fp compiler option
simd pragma

**qsimd-serialize-fp-reduction, Qsimd-serialize-fp-reduction**
*Tells the compiler to serialize floating-point reduction when vectorizing SIMD loops.*

**Syntax**

**Linux OS:**
-qsimd-serialize-fp-reduction
-qno-simd-serialize-fp-reduction

**macOS:**
-qsimd-serialize-fp-reduction
-qno-simd-serialize-fp-reduction

**Windows OS:**
/Qsimd-serialize-fp-reduction
/Qsimd-serialize-fp-reduction-

**Arguments**
None

**Default**
- The compiler does not attempt to serialize floating-point reduction in SIMD loops.

**Description**
The OpenMP* SIMD reduction specification and the setting of compiler option -fp-model (Linux* and macOS*) or /fp (Windows*) can contradict in requirements. When contradiction occurs, the default behavior of the compiler is to follow OpenMP* specification and therefore vectorize the loop, including floating-point reduction.
This option lets you override this default behavior - it causes the compiler to follow the -fp-model (or /fp) specification. This means that the compiler will serialize the floating-point reduction while vectorizing the rest of the loop.

NOTE
When [q or Q]simd-honor-fp-model is specified and OpenMP* SIMD reduction specification is the only thing causing serialization of the entire loop, addition of option [q or Q]simd-serialize-fp-reduction will result in vectorization of the entire loop except for reduction calculation, which will be serialized.

NOTE
This option does not affect automatic vectorization of loops. By default, the compiler uses -fp-model (Linux* and macOS*) or /fp (Windows*) settings for this.

IDE Equivalent
None

simd pragma

rcd, Qrcd
Enables fast float-to-integer conversions. This is a deprecated option. There is no replacement option.

Syntax
Linux OS:
-rcd
macOS:
-rcd
Windows OS:
/Qrcd

Arguments
None

Default
OFF Floating-point values are truncated when a conversion to an integer is involved.
Description
This option enables fast float-to-integer conversions. It can improve the performance of code that requires
floating-point-to-integer conversions.

The system default floating-point rounding mode is round-to-nearest. However, the C language requires
floating-point values to be truncated when a conversion to an integer is involved. To do this, the compiler
must change the rounding mode to truncation before each floating-point-to-integer conversion and change it
back afterwards.

This option disables the change to truncation of the rounding mode for all floating-point calculations,
including floating point-to-integer conversions. This option can improve performance, but floating-point
conversions to integer will not conform to C semantics.

IDE Equivalent
None

Alternate Options
Linux and macOS*: None
Windows: /QIfist (this is a deprecated option)

Inlining Options

fgnu89-inline
Tells the compiler to use C89 semantics for inline
functions when in C99 mode.

Syntax
Linux OS:
-fgnu89-inline

macOS:
-fgnu89-inline

Windows OS:
None

Arguments
None

Default
OFF

Description
This option tells the compiler to use C89 semantics for inline functions when in C99 mode.

IDE Equivalent
None
Alternate Options
None

**finline**
*Tells the compiler to inline functions declared with \_\_inline and perform C++ inlining.*

**Syntax**

**Linux OS:**
- `finline`
- `fno-inline`

**macOS:**
- `finline`
- `fno-inline`

**Windows OS:**
None

**Arguments**
None

**Default**
- `fno-inline`  
  The compiler does not inline functions declared with __inline.

**Description**
This option tells the compiler to inline functions declared with __inline and perform C++ inlining.

**IDE Equivalent**
None

**Alternate Options**

**Linux and macOS:** `-inline-level`

**Windows:** `/Ob`

**finline-functions**
*Enables function inlining for single file compilation.*

**Syntax**

**Linux OS:**
- `finline-functions`
- `fno-inline-functions`

**macOS:**
- `finline-functions`
-fno-inline-functions

**Windows OS:**
None

**Arguments**
None

**Default**
-ffunction-inline

Interprocedural optimizations occur. However, if you specify -O0, the default is OFF.

**Description**
This option enables function inlining for single file compilation.
It enables the compiler to perform inline function expansion for calls to functions defined within the current source file.
The compiler applies a heuristic to perform the function expansion. To specify the size of the function to be expanded, use the -finline-limit option.

**IDE Equivalent**
None

**Alternate Options**
Linux and macOS*: -inline-level=2
Windows: /Ob2

**See Also**
ip, Qip  compiler option
finline-limit  compiler option

**finline-limit**

Lets you specify the maximum size of a function to be inlined.

**Syntax**

**Linux OS and macOS:**
-finline-limit=n

**Windows OS:**
None

**Arguments**

n  Must be an integer greater than or equal to zero. It is the maximum number of lines the function can have to be considered for inlining.

**Default**
OFF  The compiler uses default heuristics when inlining functions.
Description
This option lets you specify the maximum size of a function to be inlined. The compiler inlines smaller functions, but this option lets you inline large functions. For example, to indicate a large function, you could specify 100 or 1000 for \( n \).

Note that parts of functions cannot be inlined, only whole functions.

This option is a modification of the \(-\text{finline-functions}\) option, whose behavior occurs by default.

IDE Equivalent
None

Alternate Options
None

See Also
\texttt{finline-functions\ compiler option}

\texttt{inline-calloc, Qinline-calloc}

*Tells the compiler to inline calls to calloc() as calls to malloc() and memset().*

Architectures
All

Syntax

\textbf{Linux OS and macOS:}
- \texttt{-inline-calloc}
- \texttt{-no-inline-calloc}

\textbf{Windows OS:}
- \texttt{/Qinline-calloc}
- \texttt{/Qinline-calloc-}

Arguments
None

Default
\texttt{-no-inline-calloc}

The compiler inlines calls to calloc() as calls to malloc().

or \texttt{/Qinline-calloc-}

Description
This option tells the compiler to inline calls to calloc() as calls to malloc() and memset(). This enables additional memset() optimizations. For example, it can enable inlining as a sequence of store operations when the size is a compile time constant.
NOTE
Many routines in the supplied libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors

Alternate Options
None

**inline-factor, Qinline-factor**
Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.

**Syntax**

Linux OS and macOS:
- -inline-factor=n
- -no-inline-factor

Windows OS:
/Qinline-factor:n
/Qinline-factor-

**Arguments**

n Is a positive integer specifying the percentage value. The default value is 100 (a factor of 1).

**Default**

- -inline-factor=100
or/Qinline-factor:100

The compiler uses a percentage multiplier of 100.

**Description**

This option specifies the percentage multiplier that should be applied to all inlining options that define upper limits:

- [Q]inline-max-size
- [Q]inline-max-total-size
- [Q]inline-max-per-routine
- [Q]inline-max-per-compile
The Qinline-factor option takes the default value for each of the above options and multiplies it by \( n \) divided by 100. For example, if 200 is specified, all inlining options that define upper limits are multiplied by a factor of 2. This option is useful if you do not want to individually increase each option limit.

If you specify -no-inline-factor (Linux* and macOS*) or /Qinline-factor- (Windows*), the following occurs:

- Every function is considered to be a small or medium function; there are no large functions.
- There is no limit to the size a routine may grow when inline expansion is performed.
- There is no limit to the number of times some routine may be inlined into a particular routine.
- There is no limit to the number of times inlining can be applied to a compilation unit.

To see compiler values for important inlining limits, specify option [q or Q]opt-report.

**Caution**

When you use this option to increase default limits, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

inline-max-size, Qinline-max-size compiler option
inline-max-total-size, Qinline-max-total-size compiler option

qopt-report, Qopt-report compiler option

**inline-forceinline, Qinline-forceinline**

*Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.*

**Syntax**

**Linux OS and macOS:**

- -inline-forceinline

**Windows OS:**

/Qinline-forceinline

**Default**

OFF  The compiler uses default heuristics for inline routine expansion.

**Description**

This option instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.
Without this option, the compiler treats functions declared with the inline keyword as merely being recommended for inlining. When this option is used, it is as if they were declared with the keyword __forceinline keyword.

**NOTE**
Because C++ member functions whose definitions are included in the class declaration are considered inline functions by default, using this option will also make these member functions "forceinline" functions.

To see compiler values for important inlining limits, specify option [q or Q]opt-report.

**Caution**
When you use this option to change the meaning of inline to "forceinline", the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
qopt-report, Qopt-report compiler option

**inline-level, Ob**
Specifies the level of inline function expansion.

**Syntax**

**Linux OS and macOS:**
- -inline-level=n

**Windows OS:**
/Obn

**Arguments**

n Is the inline function expansion level. Possible values are 0, 1, and 2.

**Default**
- -inline-level=2 or /Ob2 This is the default if option -O2 is specified or is in effect by default. On Windows* systems, this is also the default if option -O3 is specified.
- -inline-level=0 or /Ob0 This is the default if option -O0 (Linux* and macOS*) or /Od (Windows*) is specified.

**Description**
This option specifies the level of inline function expansion. Inlining procedures can greatly improve the run-time performance of certain programs.
**Option** | **Description**
--- | ---
-`inline-level=0` or `/Ob0` | Disables inlining of user-defined functions. Note that statement functions are always inlined.
-`inline-level=1` or `/Ob1` | Enables inlining when an inline keyword or an inline attribute is specified. Also enables inlining according to the C++ language.
-`inline-level=2` or `/Ob2` | Enables inlining of any function at the compiler’s discretion.

**IDE Equivalent**

Visual Studio: **Optimization > Inline Function Expansion**

Eclipse: **Optimization > Inline Function Expansion**

Xcode: **Optimization > Inline Function Expansion**

**Alternate Options**

None

**`inline-max-per-compile`, `Qinline-max-per-compile`**

*Specifies the maximum number of times inlining may be applied to an entire compilation unit.*

**Syntax**

**Linux OS and macOS:**

- `-inline-max-per-compile=n`
- `-no-inline-max-per-compile`

**Windows OS:**

- `/Qinline-max-per-compile=n`
- `/Qinline-max-per-compile-`

**Arguments**

\( n \)

Is a positive integer that specifies the number of times inlining may be applied.

**Default**

- `-no-inline-max-per-compile` or `/Qinline-max-per-compile-`

The compiler uses default heuristics for inline routine expansion.

**Description**

This option the maximum number of times inlining may be applied to an entire compilation unit. It limits the number of times that inlining can be applied.

For compilations using Interprocedural Optimizations (IPO), the entire compilation is a compilation unit. For other compilations, a compilation unit is a file.

If you specify `-no-inline-max-per-compile` *(Linux* and *macOS*) or `/Qinline-max-per-compile-` *(Windows*)*, there is no limit to the number of times inlining may be applied to a compilation unit.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`. 
Caution
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent
None

inline-factor, Qinline-factor compiler option
qopt-report, Qopt-report compiler option

inline-max-per-routine, Qinline-max-per-routine
Specifies the maximum number of times the inliner may inline into a particular routine.

Syntax
Linux OS and macOS:
-inline-max-per-routine=n
-no-inline-max-per-routine

Windows OS:
/Qinline-max-per-routine=n
/Qinline-max-per-routine-

Arguments
n
Is a positive integer that specifies the maximum number of times the inliner may inline into a particular routine.

Default
-no-inline-max-per-routine
or/Qinline-max-per-routine-
The compiler uses default heuristics for inline routine expansion.

Description
This option specifies the maximum number of times the inliner may inline into a particular routine. It limits the number of times that inlining can be applied to any routine.

If you specify -no-inline-max-per-routine (Linux* and macOS*) or /Qinline-max-per-routine- (Windows*), there is no limit to the number of times some routine may be inlined into a particular routine.

To see compiler values for important inlining limits, specify option [q or Q]opt-report.
Caution
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent
None

Alternate Options
None

See Also
inline-factor, Qinline-factor compiler option
qopt-report, Qopt-report compiler option

**inline-max-size, Qinline-max-size**

Specifies the lower limit for the size of what the inliner considers to be a large routine.

**Syntax**

**Linux OS and macOS:**
- `-inline-max-size=n`
- `-no-inline-max-size`

**Windows OS:**
- `/Qinline-max-size=n`
- `/Qinline-max-size-`

**Arguments**

\( n \)

Is a positive integer that specifies the minimum size of what the inliner considers to be a large routine.

**Default**

- `-inline-max-size`
- `/Qinline-max-size`

The compiler sets the maximum size \( n \) dynamically, based on the platform.

**Description**

This option specifies the lower limit for the size of what the inliner considers to be a large routine (a function). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be medium and large-size routines.

The inliner prefers to inline small routines. It has a preference against inlining large routines. So, any large routine is highly unlikely to be inlined.

If you specify `-no-inline-max-size (Linux* and macOS*)` or `/Qinline-max-size- (Windows*)`, there are no large routines. Every routine is either a small or medium routine.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

**Caution**
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

**IDE Equivalent**

**inline-max-total-size, Qinline-max-total-size**
Specifies how much larger a routine can normally grow when inline expansion is performed.

**Syntax**
Linux OS and macOS:
- -inline-max-total-size=n
  -no-inline-max-total-size

Windows OS:
/Qinline-max-total-size=n
/Qinline-max-total-size-

**Arguments**

\( n \)
Is a positive integer that specifies the permitted increase in the routine’s size when inline expansion is performed.

**Default**

- -no-inline-max-total-size
  or/Qinline-max-total-size-
The compiler uses default heuristics for inline routine expansion.

**Description**
This option specifies how much larger a routine can normally grow when inline expansion is performed. It limits the potential size of the routine. For example, if 2000 is specified for \( n \), the size of any routine will normally not increase by more than 2000.

If you specify -no-inline-max-total-size (Linux* and macOS*) or/Qinline-max-total-size- (Windows*), there is no limit to the size a routine may grow when inline expansion is performed.

To see compiler values for important inlining limits, specify option \([q \text{ or } Q]\)opt-report.
Caution
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent
None

Alternate Options
None

See Also
inline-factor, Qinline-factor compiler option
qopt-report, Qopt-report compiler option

inline-min-caller-growth, Qinline-min-caller-growth
Lets you specify a function size $n$ for which functions of size $\leq n$ do not contribute to the estimated growth of the caller when inlined.

Syntax
Linux OS and macOS:
-inline-min-caller-growth=n

Windows OS:
/Qinline-min-caller-growth=n

Arguments
$n$
Is a non-negative integer. When $n > 0$, functions with a size of $n$ are treated as if they are size 0.

Default
-inline-min-caller-growth=0
or /Qinline-min-caller-growth=0
The compiler treats functions as if they have size zero.

Description
This option lets you specify a function size $n$ for which functions of size $\leq n$ do not contribute to the estimated growth of the caller when inlined. It allows you to inline functions that the compiler would otherwise consider too large to inline.

NOTE
We recommend that you choose a value of $n \leq 10$; otherwise, compile time and code size may greatly increase.

IDE Equivalent
None
Alternate Options
None

**inline-min-size, Qinline-min-size**

*Specifies the upper limit for the size of what the inliner considers to be a small routine.*

**Syntax**

**Linux OS and macOS:**

- `-inline-min-size=n`
- `-no-inline-min-size`

**Windows OS:**

- `/Qinline-min-size=n`
- `/Qinline-min-size-`

**Arguments**

`n` Is a positive integer that specifies the maximum size of what the inliner considers to be a small routine.

**Default**

- `-no-inline-min-size`
  or `/Qinline-min-size-`

  The compiler uses default heuristics for inline routine expansion.

**Description**

This option specifies the upper limit for the size of what the inliner considers to be a small routine (a function). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be small and medium-size routines.

The inliner has a preference to inline small routines. So, when a routine is smaller than or equal to the specified size, it is very likely to be inlined.

If you specify `-no-inline-min-size` (Linux* and macOS*) or `/Qinline-min-size-` (Windows*), there is no limit to the size of small routines. Every routine is a small routine; there are no medium or large routines.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

---

**Caution**

When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

---

Qinline-dllimport
Determines whether dllimport functions are inlined.

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/Qinline-dllimport
/Qinline-dllimport-

Arguments
None

Default
/Qinline-dllimport The dllimport functions are inlined.

Description
This option determines whether dllimport functions are inlined. To disable dllimport functions from being inlined, specify /Qinline-dllimport-.

IDE Equivalent
None

Alternate Options
None

Output, Debug, and Precompiled Header Options
This section contains descriptions for compiler options that pertain to output, debugging, or precompiled headers (PCH).

c
Prevents linking.

Syntax
Linux OS:
-c

macOS:
-c

c
Windows OS:
/c

Arguments
None

Default
OFF Linking is performed.

Description
This option prevents linking. Compilation stops after the object file is generated.
The compiler generates an object file for each C or C++ source file or preprocessed source file. It also takes
an assembler file and invokes the assembler to generate an object file.

IDE Equivalent
None

Alternate Options
None

debug (Linux® and macOS®)
Enables or disables generation of debugging information.

Syntax
Linux OS:
- debug [keyword]

macOS:
- debug [keyword]

Windows OS:
None

Arguments

keyword Is the type of debugging information to be generated. Possible values are:

none Disables generation of debugging information.

full or all Generates complete debugging information.

minimal Generates line number information for debugging.

[no]emit_column Determines whether the compiler generates column number information for debugging.
Determines whether the compiler generates source position information at the expression level of granularity.

Determines whether the compiler generates enhanced debug information for inlined code.

Determines whether the compiler generates a DWARF debug_pubnames section.

Determines whether the compiler generates enhanced debug information useful for breakpoints and stepping.

Determines whether the compiler generates enhanced debug information useful in finding scalar local variables.

Generates complete debugging information and also sets keyword values semantic-stepping and variable-locations.

Determines whether the compiler generates parallel debug code instrumentations useful for thread data sharing and reentrant call detection.

For information on the non-default settings for these keywords, see the Description section.

**Default**

Normally, the default is `-debug none` and no debugging information is generated. However, on Linux*, the `-debug inline-debug-info` option will be enabled by default if you compile with optimizations (option `-O2` or higher) and debugging is enabled (option `-g`).

**Description**

This option enables or disables generation of debugging information.

By default, enabling debugging, will disable optimization. To enable both debugging and optimization use the `-debug` option together with one of the optimization level options (`-O3`, `-O2` or `-O3`).

Keywords `semantic-stepping`, `inline-debug-info`, `variable-locations`, and `extended` can be used in combination with each other. If conflicting keywords are used in combination, the last one specified on the command line has precedence.

<td><code>-debug variable-locations</code></td>
<td>Generates enhanced debug information useful in finding scalar local variables. It uses a feature of the Dwarf object module known as &quot;location lists&quot;.</td>
</tr>
<tr>
<td></td>
<td>This feature allows the run-time locations of local scalar variables to be specified more accurately; that is, whether, at a given position in the code, a variable value is found in memory or a machine register.</td>
</tr>
<tr>
<td><code>-debug extended</code></td>
<td>Sets keyword values semantic-stepping and variable-locations. It also tells the compiler to include column numbers in the line information.</td>
</tr>
<tr>
<td></td>
<td>Generates complete debugging information and also sets keyword values semantic-stepping and variable-locations. This is a more powerful setting than <code>-debug full</code> or <code>-debug all</code>.</td>
</tr>
<tr>
<td><code>-debug parallel</code></td>
<td>Generates parallel debug code instrumentations needed for the thread data sharing and reentrant call detection. For shared data and reentrancy detection, option <code>-qopenmp</code> must be set.</td>
</tr>
</tbody>
</table>

On Linux* systems, debuggers read debug information from executable images. As a result, information is written to object files and then added to the executable by the linker.

On macOS* systems, debuggers read debug information from object files. As a result, the executables don't contain any debug information. Therefore, if you want to be able to debug on these systems, you must retain the object files.

**IDE Equivalent**

Visual Studio: None

Eclipse: **Advanced Debugging > Enable Parallel Debug Checks** (`-debug parallel`)

**Debug > Enable Expanded Line Number Information** (`-debug expr-source-pos`)

Xcode: None
Alternate Options

For `-debug full`, `-debug all`, or `-debug`
- **Linux and macOS**: `-g`
- **Windows**: `/debug:full`, `/debug:all`, or `/debug`

For `-debug variable-locations`
- **Linux and macOS**: `-fvar-tracking`
- **Windows**: None

For `-debug semantic-stepping`
- **Linux and macOS**: `-fvar-tracking-assignments`
- **Windows**: None

debug (Windows*) compiler option
qopenmp, Qopenmp compiler option

debug (Windows*)
*Enables or disables generation of debugging information.*

Syntax

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
`/debug[:keyword]`

Arguments

**keyword**

Is the type of debugging information to be generated. Possible values are:

- **none**
  - Determines whether the compiler generates source position information at the expression level of granularity.

- **full or all**
  - Generates complete debugging information.

- **minimal**
  - Generates line number information for debugging.

- **partial**
  - Deprecated. Generates global symbol table information needed for linking.

- `[no]expr-source-pos`
  - Determines whether the compiler generates source position information at the expression level of granularity.

- `[no]inline-debug-info`
  - Determines whether the compiler generates enhanced debug information for inlined code.

For information on the non-default settings for these keywords, see the Description section.
Default

/debug:none  This is the default on the command line and for a release configuration in the IDE.
/debug:all   This is the default for a debug configuration in the IDE.

Description

This option enables or disables generation of debugging information. It is passed to the linker.

By default, enabling debugging, will disable optimization. To enable both debugging and optimization use the /debug option together with one of the optimization level options (/O3, /O2 or /O1).

If conflicting keywords are used in combination, the last one specified on the command line has precedence.

dbg (Linux* and macOS*) compiler option
**Fa**
Specifies that an assembly listing file should be generated.

**Syntax**

**Linux OS:**
- Fa[filename|dir]

**macOS:**
- Fa[filename|dir]

**Windows OS:**
/Fa[filename|dir]

**Arguments**

*filename*  
Is the name of the assembly listing file.

*dir*  
Is the directory where the file should be placed. It can include *filename*.

**Default**
OFF  
No assembly listing file is produced.

**Description**
This option specifies that an assembly listing file should be generated (optionally named *filename*).

**IDE Equivalent**
Visual Studio: **Output Files > ASM List Location**
Eclipse: **Output > Generate Assembler Source and Binary Files**
Xcode: **Output Files > Filename for Generated Assembler Listing, Output > Generate Assembler Listing**

**Alternate Options**
Linux and macOS*: -S
Windows: /S

**FA**
Specifies the contents of an assembly listing file.

**Syntax**

**Linux OS:**
None

**macOS:**
None
Windows OS:
/FA[specifier]

Arguments

specifier

Denotes the contents of the assembly listing file. Possible values are c, s, or cs.

Default

OFF

No source or machine code annotations appear in the assembly listing file, if one is produced.

Description

These options specify what information, in addition to the assembly code, should be generated in the assembly listing file.

To use this option, you must also specify option /Fa, which causes an assembly listing to be generated.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/FA</td>
<td>Produces an assembly listing without source or machine code annotations.</td>
</tr>
<tr>
<td>/FAc</td>
<td>Produces an assembly listing with machine code annotations.</td>
</tr>
<tr>
<td>/FAs</td>
<td>Produces an assembly listing with source code annotations. Note that if you use alternate option -fsource-asm, you must also specify the -S option.</td>
</tr>
<tr>
<td>/FAscs</td>
<td>Produces an assembly listing with source and machine code annotations.</td>
</tr>
</tbody>
</table>

IDE Equivalent

Visual Studio: Output Files > Assembler Output

Eclipse: None

Xcode: None

Alternate Options

/FAc

Linux and macOS*: -fcode-asm

Windows: None

/FAs

Linux and macOS*: -fsource-asm

Windows: None

fasm-blocks

Enables the use of blocks and entire functions of assembly code within a C or C++ file.

Syntax

Linux OS:

-fasm-blocks
**macOS:**
- `fasm-blocks`

**Windows OS:**
None

**Arguments**
None

**Default**
OFF  
The compiler allows a GNU*-style inline assembly format.

**Description**
This option enables the use of blocks and entire functions of assembly code within a C or C++ file. It allows a Microsoft* MASM-style inline assembly block not a GNU*-style inline assembly block. On macOS* systems, this option is provided for compatibility with the Apple* GNU compiler.

**IDE Equivalent**
None

**Alternate Options**
- `-use-msasm`

**FC**
*Displays the full path of source files passed to the compiler in diagnostics.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
`/FC`

**Arguments**
None

**Default**
OFF  
The compiler does not display the full path of source files passed to the compiler in diagnostics.

**Description**
Displays the full path of source files passed to the compiler in diagnostics. This option is supported with Microsoft Visual Studio .NET 2003* or newer.
IDE Equivalent
Visual Studio: Advanced > Use Full Paths

Alternate Options
None

`fcode-asm`

*Produces an assembly listing with machine code annotations.*

Syntax

Linux OS and macOS:

`-fcode-asm`

Windows OS:

None

Arguments

None

Default

OFF

No machine code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with machine code annotations.

The assembly listing file shows the hex machine instructions at the beginning of each line of assembly code. The file cannot be assembled; the file name is the name of the source file with an extension of `.cod`.

To use this option, you must also specify option `-S`, which causes an assembly listing to be generated.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/FAc`

S compiler option

**Fd**

* Lets you specify a name for a program database (PDB) file created by the compiler.*

Syntax

Linux OS:

None
**macOS:**
None

**Windows OS:**

/Fd[:filename]

**Arguments**

*filename*  
Is the name for the PDB file. It can include a path. If you do not specify a file extension, the extension .pdb is used.

**Default**

OFF  
No PDB file is created unless you specify option /Zi. If you specify option /Zi and /Fd, the default filename is vcx0.pdb, where *x* represents the version of Visual C++, for example vc100.pdb.

**Description**

This option lets you specify a name for a program database (PDB) file that is created by the compiler. A program database (PDB) file holds debugging and project state information that allows incremental linking of a Debug configuration of your program. A PDB file is created when you build with option /Zi. Option /Fd has no effect unless you specify option /Zi.

**IDE Equivalent**

Visual Studio: **Output Files > Program Database File Name**
Eclipse: None
Xcode: None

**Alternate Options**

None

**See Also**

Zi, Z7, ZI  compiler option
pdbfile  compiler option

**FD**

*Generates file dependencies related to the Microsoft*®* C/C++ compiler.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**

/FD
Arguments
None

Default
OFF  The compiler does not generate Microsoft C/C++-related file dependencies.

Description
This option generates file dependencies related to the Microsoft C/C++ compiler. It invokes the Microsoft C/C++ compiler and passes the option to it.

IDE Equivalent
None

Alternate Options
None

Fe
Specifies the name for a built program or dynamic-link library.

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/Fe[::]filename|dir

Arguments
filename  Is the name for the built program or dynamic-link library.

dir  Is the directory where the built program or dynamic-link library should be placed. It can include file.

Default
OFF  The name of the file is the name of the first source file on the command line with file extension .exe, so file.f becomes file.exe.

Description
This option specifies the name for a built program (.EXE) or a dynamic-link library (.DLL).
You can use this option to specify an alternate name for an executable file. This is especially useful when compiling and linking a set of input files. You can use the option to give the resulting file a name other than that of the first input file (source or object) on the command line.
IDE Equivalent
None

Alternate Options
Linux and macOS*: -o
Windows: None

Example
In the following example, the command produces an executable file named outfile.exe as a result of compiling and linking three files: one object file and two C++ source files.

```prompt> icl /Feoutfile.exe file1.obj file2.cpp file3.cpp```

By default, this command produces an executable file named file1.exe.

See Also
- compiler option

~~feliminate-unused-debug-types, Qeliminate-unused-debug-types~~
Controls the debug information emitted for types declared in a compilation unit.

Syntax

- **Linux OS:**
  - -feliminate-unused-debug-types
  - -fno-eliminate-unused-debug-types

- **macOS:**
  - -feliminate-unused-debug-types
  - -fno-eliminate-unused-debug-types

- **Windows OS:**
  - /Qeliminate-unused-debug-types
  - /Qeliminate-unused-debug-types-

Arguments
None

Default
- -feliminate-unused-debug-types or /Qeliminate-unused-debug-types-
  The compiler emits debug information only for types that are actually used by a variable/parameter/etc..

Description
This option controls the debug information emitted for types declared in a compilation unit.

If you specify -fno-eliminate-unused-debug-types (Linux and macOS*) or /Qeliminate-unused-debug-types-, it will cause the compiler to emit debug information for all types present in the sources. This option may cause a large increase in the size of the debug information.
IDE Equivalent
None

Alternate Options
None

**femit-class-debug-always**
*Controls the format and size of debug information generated by the compiler for C++ classes.*

**Syntax**

**Linux OS:**
- `-femit-class-debug-always`
- `-fno-emit-class-debug-always`

**macOS:**
None

**Windows OS:**
None

**Arguments**
None

**Default**
- `-fno-emit-class-debug-always` Causes the compiler to reduce the amount of debug information generated for C++ classes.

**Description**

When emission of debug information is enabled, this option will control the format and size of debug information generated by the compiler for C++ classes. It tells the compiler to generate full debug information, or it tells the compiler to reduce the amount of debug information it generates.

When you specify the `-femit-class-debug-always` option, the compiler emits debug information for a C++ class into each object file where the class is used. This option is useful for tools that are not able to resolve incomplete type descriptions. Note that this option may cause a large increase in the size of the debug information generated.

When you specify the `-fno-emit-class-debug-always` option, the compiler does not emit full debug information for every instance of C++ class use. In general, this reduces the size of the debugging information generated for C++ applications without impacting debugging ability when used with debuggers that have corresponding support, such as gdb.

**IDE Equivalent**
None

**Alternate Options**
None
**fmerge-constants**
*Determines whether the compiler and linker attempt to merge identical constants (string constants and floating-point constants) across compilation units.*

**Syntax**

Linux OS:
- `-fmerge-constants`
- `-fno-merge-constants`

macOS:
None

Windows OS:
None

**Arguments**
None

**Default**

The compiler and linker attempt to merge identical constants across compilation units if the compiler and linker support it.

**Description**

This option determines whether the compiler and linker attempt to merge identical constants (string constants and floating-point constants) across compilation units.

If you do not want the compiler and linker to attempt to merge identical constants across compilation units, specify `-fno-merge-constants`.

**IDE Equivalent**
None

**Alternate Options**
None

**fmerge-debug-strings**
*Causes the compiler to pool strings used in debugging information.*

**Syntax**

Linux OS:
- `-fmerge-debug-strings`
- `-fno-merge-debug-strings`

macOS:
None

None

**fmerge-debug-strings**
*Causes the compiler to pool strings used in debugging information.*

**Syntax**

Linux OS:
- `-fmerge-debug-strings`
- `-fno-merge-debug-strings`

macOS:
None

None
Windows OS:
None

Arguments
None

Default
-fmerge-debug-strings

The compiler will pool strings used in debugging information.

Description
This option causes the compiler to pool strings used in debugging information. The linker will automatically retain this pooling.

This option can reduce the size of debug information, but it may produce slightly slower compile and link times.

This option is only turned on by default if you are using gcc 4.3 or later, where this setting is also the default, since the generated debug tables require binutils version 2.17 or later to work reliably.

If you do not want the compiler to pool strings used in debugging information, specify option -fno-merge-debug-strings.

IDE Equivalent
None

Alternate Options
None

Fo
Specifies the name for an object file.

Syntax
Linux OS:
See option o.

macOS:
See option o.

Windows OS:
/Fo[[:]filename|dir]

Arguments

filename
Is the name for the object file.

dir
Is the directory where the object file should be placed. It can include filename.

Default
OFF  An object file has the same name as the name of the first source file and a file extension of .obj.
Description
This option specifies the name for an object file.

IDE Equivalent
Visual Studio: **Output Files > Object File Name**

Alternate Options
None

See Also
- compiler option

Fp
*Let you specify an alternate path or file name for precompiled header files.*

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/Fp{filename|dir}/

Arguments

*filename*  
Is the name for the precompiled header file.

*dir*  
Is the directory where the precompiled header file should be placed. It can include *filename*.

Default
OFF  
The compiler does not create or use precompiled headers unless you tell it to do so.

Description
This option lets you specify an alternate path or file name for precompiled header files.

IDE Equivalent
Visual Studio: **Precompiled Headers > Precompiled Header Output File**
Eclipse: None
Xcode: None

Alternate Options
None
FR
Invokes the Microsoft C/C++ compiler and tells it to produce a BSCMAKE .sbr file with complete symbolic information.

Syntax
Linux OS and macOS:
None

Windows OS:
/FR[filename|dir]

Arguments
filename
Is the name for the BSCMAKE .sbr file.
dir
Is the directory where the file should be placed. It can include filename.

Default
OFF
The compiler does not invoke the Microsoft C/C++ compiler to produce a .sbr file.

Description
This option invokes the Microsoft C/C++ compiler and tells it to produce a BSCMAKE .sbr file with complete symbolic information.
You can provide a name for the file. If you do not specify a file name, the .sbr file gets the same base name as the source file.
A synonym for option /FR is option /Fr. Option /Fr is a deprecated option.

IDE Equivalent
Visual Studio: Browse Information > Browse Information File
Browse Information > Enable Browse Information

Eclipse: None
Xcode: None

Alternate Options
None

fsource-asm
Produces an assembly listing with source code annotations.

Syntax
Linux OS and macOS:
-fsource-asm
Windows OS:
None

Arguments
None

Default
OFF
No source code annotations appear in the assembly listing file, if one is produced.

Description
This option produces an assembly listing file with source code annotations. The assembly listing file shows the source code as interspersed comments.
To use this option, you must also specify option -S, which causes an assembly listing to be generated.

IDE Equivalent
None

Alternate Options
None

See Also
S compiler option

ftrapuv, Qtrapuv

Initializes stack local variables to an unusual value to aid error detection.

Syntax
Linux OS:
-ftrapuv

macOS:
-ftrapuv

Windows OS:
/Qtrapuv

Arguments
None

Default
OFF
The compiler does not initialize local variables.

Description
This option initializes stack local variables to an unusual value to aid error detection. Normally, these local variables should be initialized in the application. It also unmasks the floating-point invalid exception.
The option sets any uninitialized local variables that are allocated on the stack to a value that is typically interpreted as a very large integer or an invalid address. References to these variables are then likely to cause run-time errors that can help you detect coding errors.

This option sets option -g (Linux* and macOS*) and /Zi or /Z7 (Windows*), which changes the default optimization level from O2 to O0 (Linux and macOS*) or /Od (Windows). You can override this effect by explicitly specifying an O option setting.

If option O2 and option -ftrapuv (Linux and macOS*) or /Qtrapuv (Windows) are used together, you should specify option -fp-speculation_safe (Linux and macOS*) or /Qfp-speculation:safe (Windows) to prevent exceptions resulting from speculated floating-point operations from being trapped.

For more details on using options -ftrapuv and /Qtrapuv with compiler option O, see the article in Intel® Developer Zone titled Don’t optimize when using -ftrapuv for uninitialized variable detection, which is located in https://software.intel.com/en-us/articles/dont-optimize-when-using-ftrapuv-for-uninitialized-variable-detection/.

Another way to detect uninitialized local scalar variables is by specifying keyword uninit for option check.

**IDE Equivalent**

Visual Studio: None

Eclipse: **Run-Time > Initialize Stack Variables to an Unusual Value**

Xcode: **Code Generation > Initialize Stack Variables to an Unusual Value**

**Alternate Options**

None

**See Also**

O compiler option

check compiler option (see setting uninit)

**fverbose-asm**

*Produces an assembly listing with compiler comments, including options and version information.*

**Syntax**

**Linux OS:**

-fverbose-asm

-fno-verbose-asm

**macOS:**

-fverbose-asm

-fno-verbose-asm

**Windows OS:**

None

**Arguments**

None
Default
-\texttt{-fno-verbose-asm}

No source code annotations appear in the assembly listing file, if one is produced.

Description
This option produces an assembly listing file with compiler comments, including options and version information.

To use this option, you must also specify -\texttt{S}, which sets -\texttt{fverbose-asm}.

If you do not want this default when you specify -\texttt{S}, specify -\texttt{-fno-verbose-asm}.

IDE Equivalent
None

Alternate Options
None

See Also
- \texttt{s} compiler option

\textbf{g}
\textit{Tells the compiler to generate a level of debugging information in the object file.}

Syntax

\textbf{Linux OS:}
\begin{verbatim}
-\texttt{g[n]}
\end{verbatim}

\textbf{macOS:}
\begin{verbatim}
-\texttt{g[n]}
\end{verbatim}

\textbf{Windows OS:}
See option Zi, Z7, ZI.

Arguments

\textit{n}

Is the level of debugging information to be generated. Possible values are:

\begin{itemize}
  \item \texttt{0} Disables generation of symbolic debug information.
  \item \texttt{1} Produces minimal debug information for performing stack traces.
  \item \texttt{2} Produces complete debug information. This is the same as specifying -\texttt{g} with no \textit{n}.
  \item \texttt{3} Produces extra information that may be useful for some tools.
\end{itemize}
Default
-g or -g2

The compiler produces complete debug information.

Description
Option -g tells the compiler to generate symbolic debugging information in the object file, which increases the size of the object file.

The compiler does not support the generation of debugging information in assembleable files. If you specify this option, the resulting object file will contain debugging information, but the assembleable file will not.

This option turns off option -O2 and makes option -O0 the default unless option -O2 (or higher) is explicitly specified in the same command line.

Specifying the -g or -O0 option sets the -fno-omit-frame-pointer option. On Linux*, the -debug inline-debug-info option will be enabled by default if you compile with optimizations (option -O2 or higher) and debugging is enabled (option -g).

NOTE
When option -g is specified, debugging information is generated in the DWARF Version 3 format. Older versions of some analysis tools may require applications to be built with the -gdwarf-2 option to ensure correct operation.

IDE Equivalent
Visual Studio: None
Eclipse: General > Include Debug Information
Xcode: General > Generate Debug Information

Alternate Options
Linux: None
Windows: /Zi, /Z7, /ZI

See Also
gdwarf compiler option
Zi, Z7, ZI compiler option
debug (Linux* and macOS*) compiler option

gdwarf
Let you specify a DWARF Version format when generating debug information.

Syntax
Linux OS:
-gdwarf-n

macOS:
-gdwarf-n

Windows OS:
None
Arguments

\( n \)

Is a value denoting the DWARF Version format to use. Possible values are:

- 2
  Generates debug information using the DWARF Version 2 format.
- 3
  Generates debug information using the DWARF Version 3 format.
- 4
  Generates debug information using the DWARF Version 4 format. This setting is only available on Linux*.

Default

OFF

No debug information is generated. However, if compiler option \(-g\) is specified, debugging information is generated in the DWARF Version 3 format.

Description

This option lets you specify a DWARF Version format when generating debug information.

Note that older versions of some analysis tools may require applications to be built with the \(-gdwarf-2\) option to ensure correct operation.

IDE Equivalent

None

Alternate Options

None

See Also

\( g \) compiler option

Gm

*Enables a minimal rebuild.*

Syntax

Linux OS:

None

macOS:

None

Windows OS:

/Gm

Arguments

None
**Default**
OFF  Minimal rebuilds are disabled.

**Description**
This option enables a minimal rebuild.

**IDE Equivalent**
Visual Studio: **Code Generation > Enable Minimal Rebuild**
Eclipse: None
Xcode: None

**Alternate Options**
None

**grecord-gcc-switches**
*Causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.*

**Syntax**

**Linux OS:**
```
-grecord-gcc-switches
```

**macOS:**
None

**Windows OS:**
None

**Arguments**
None

**Default**
OFF  The command line options that were used to invoke the compiler are not appended to the DW_AT_producer attribute in DWARF debugging information.

**Description**
This option causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.

The options are concatenated with whitespace separating them from each other and from the compiler version.

**IDE Equivalent**
None
Alternate Options

None

**gsplit-dwarf**

*Creates a separate object file containing DWARF debug information.*

**Syntax**

Linux OS:

- `gsplit-dwarf`

macOS:

None

Windows OS:

None

**Arguments**

None

**Default**

OFF

No separate object file containing DWARF debug information is created.

**Description**

This option creates a separate object file containing DWARF debug information. It causes debug information to be split between the generated object (.o) file and the new DWARF object (.dwo) file.

The DWARF object file is not used by the linker, so this reduces the amount of debug information the linker must process and it results in a smaller executable file.

For this option to perform correctly, you must use binutils-2.24 or later. To debug the resulting executable, you must use gdb-7.6.1 or later.

**NOTE**

If you use the split executable with a tool that does not support the split DWARF format, it will behave as though the DWARF debug information is absent.

**IDE Equivalent**

None

**Alternate Options**

None

**map-opts, Qmap-opts**

*Maps one or more compiler options to their equivalent on a different operating system.*
Syntax

Linux OS:
-map-opts

macOS:
None

Windows OS:
/Qmap-opts

Arguments
None

Default
OFF No platform mappings are performed.

Description
This option maps one or more compiler options to their equivalent on a different operating system. The result is output to stdout.

On Windows systems, the options you provide are presumed to be Windows options, so the options that are output to stdout will be Linux equivalents.

On Linux systems, the options you provide are presumed to be Linux options, so the options that are output to stdout will be Windows equivalents.

The tool can be invoked from the compiler command line or it can be used directly.

No compilation is performed when the option mapping tool is used.

This option is useful if you have both compilers and want to convert scripts or makefiles.

NOTE
Compiler options are mapped to their equivalent on the architecture you are using. For example, if you are using a processor with IA-32 architecture, you will only see equivalent options that are available on processors with IA-32 architecture.

IDE Equivalent
None

Alternate Options
None

Example
The following command line invokes the option mapping tool, which maps the Linux options to Windows-based options, and then outputs the results to stdout:

```batch
icc -map-opts -xP -O2
```

The following command line invokes the option mapping tool, which maps the Windows options to Linux-based options, and then outputs the results to stdout:

```batch
icl /Qmap-opts /QxP /O2
```
See Also
Compiler Option Mapping Tool

-o
Specifies the name for an output file.

Syntax
Linux OS:
-o filename
macOS:
-o filename
Windows OS:
See option Fo.

Arguments
filename Is the name for the output file. The space before filename is optional.

Default
OFF The compiler uses the default file name for an output file.

Description
This option specifies the name for an output file as follows:
• If -c is specified, it specifies the name of the generated object file.
• If -S is specified, it specifies the name of the generated assembly listing file.
• If -P is specified, it specifies the name of the generated preprocessor file.
Otherwise, it specifies the name of the executable file.

IDE Equivalent
None

Alternate Options
Linux and macOS*: None
Windows: /Fe

See Also
Fo compiler option
Fe compiler option

pch
Tells the compiler to use appropriate precompiled header files.
Syntax

Linux OS and macOS:

-pch

Windows OS:

None

Arguments

None

Default

OFF

The compiler does not create or use precompiled headers unless you tell it to do so.

Description

This option tells the compiler to use appropriate precompiled header (PCH) files. If none are available, they are created as sourcefile.pchi. This option is supported for multiple source files.

The -pch option will use PCH files created from other sources if the headers files are the same. For example, if you compile source1.cpp using -pch, then source1.pchi is created. If you then compile source2.cpp using -pch, the compiler will use source1.pchi if it detects the same headers.

Caution

Depending on how you organize the header files listed in your sources, this option may increase compile times.

IDE Equivalent

Visual Studio: None

Eclipse: Precompiled Headers > Automatic Processing for Precompiled Headers

Xcode: None

Alternate Options

None

Example

Consider the following command line:

```bash
icpc -pch source1.cpp source2.cpp
```

It produces the following output when .pchi files exist:

```
"source1.cpp": using precompiled header file "source1.pchi"
"source2.cpp": using precompiled header file "source2.pchi"
```

It produces the following output when .pchi files do not exist:

```
"source1.cpp": creating precompiled header file "source1.pchi"
"source2.cpp": creating precompiled header file "source2.pchi"
```

-pch-create  compiler option

-pch-dir  compiler option
-pch-use compiler option

**pch-create**
*Tells the compiler to create a precompiled header file.*

**Syntax**

**Linux OS and macOS:**
- *-pch-create* *filename*

**Windows OS:**
None

**Arguments**

*filename*  
Is the name for the precompiled header file. A space must appear before the file name. It can include a path.

**Default**

OFF  
The compiler does not create or use precompiled headers unless you tell it to do so.

**Description**

This option tells the compiler to create a precompiled header (PCH) file. It is supported only for single source file compilations.

Note that the .pchi extension is not automatically appended to the file name.  
This option cannot be used in the same compilation as the *-pch-use* option.  
On Windows* systems, option *-pch-create* is equivalent to the */Yc* option.

**IDE Equivalent**

None

**Alternate Options**

Linux and macOS*: None  
Windows: */Yc*

**Example**

Consider the following command line:
```
icpc -pch-create /pch/foo.pchi foo.cpp
```
This creates the precompiled header file "/pch/foo.pchi".

**See Also**

pch-use compiler option

**pch-dir**
*Tells the compiler the location for precompiled header files.*
Syntax

Linux OS and macOS:

-pch-dir dir

Windows OS:

None

Arguments

dir

Is the path for precompiled header files. The path must exist.

Default

OFF

The compiler does not create or use precompiled headers unless you tell it to do so.

Description

This option tells the compiler the location for precompiled header files. It denotes where to find precompiled header files, and where new PCH files should be placed.

This option can be used with the -pch, -pch-create, and -pch-use options.

IDE Equivalent

Visual Studio: None

Eclipse: Precompiled Headers > Precompiled Headers' File Directory

Xcode: Precompiled Headers > Prefix Header

Alternate Options

None

Example

Consider the following command line:

icpc -pch -pch-dir /pch source32.cpp

It produces the following output:

"source32.cpp": creating precompiled header file /pch/source32.pch1

See Also

pch  compiler option

pch-create  compiler option

pch-use  compiler option

pch-use

Tells the compiler to use a precompiled header file.

Syntax

Linux OS and macOS:

-pch-use filename
Windows OS:
None

Arguments

filename

Is the name of the precompiled header file to use. A space must appear before the file name. It can include a path.

Default

OFF

The compiler does not create or use precompiled headers unless you tell it to do so.

Description

This option tells the compiler to use a precompiled header (PCH) file.
It is supported for multiple source files when all source files use the same .pchi file.
This option cannot be used in the same compilation as the -pch-create option.
To learn how to optimize compile times using the PCH options, see "Using Precompiled Header Files" in the User's Guide.
On Windows* systems, option -pch-use is equivalent to the /Yu option.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None
Windows: /Yu

Example

Consider the following command line:

icpc -pch-use /pch/source32.pchi source.cpp

It produces the following output:

"source.cpp": using precompiled header file /pch/source32.pchi

See Also

-pch-create compiler option

pdbfile

Lets you specify the name for a program database (PDB) file created by the linker.

Syntax

Linux OS:
None

macOS:
None
Windows OS:
/pdbfile[:filename]

Arguments
filename Is the name for the PDB file. It can include a path. If you do not specify a file extension, the extension .pdb is used.

Default
OFF No PDB file is created unless you specify option /Zi. If you specify option /Zi the default filename is executablename.pdb.

Description
This option lets you specify the name for a program database (PDB) file created by the linker. This option does not affect where the compiler outputs debug information.

To use this option, you must also specify option /debug:full or /Zi.

If filename is not specified, the default file name used is the name of your file with an extension of .pdb.

IDE Equivalent
None

Alternate Options
None

print-multi-lib
Prints information about where system libraries should be found.

Syntax
Linux OS:
-print-multi-lib

macOS:
-print-multi-lib

Windows OS:
None

Arguments
None
**Default**

OFF  
No information is printed unless the option is specified.

**Description**

This option prints information about where system libraries should be found, but no compilation occurs. On Linux* systems, it is provided for compatibility with gcc.

**IDE Equivalent**

None

**Alternate Options**

None

**Qpchi**

_Enable precompiled header coexistence to reduce build time._

**Syntax**

Linux OS:

None

macOS:

None

Windows OS:

/Qpchi
/Qpchi-

**Arguments**

None

**Default**

ON  
The compiler enables precompiled header coexistence.

**Description**

This option enables precompiled header (PCH) files generated by the Intel® C++ compiler and those generated by the Microsoft Visual C++* compiler to coexist, which reduces build time.

If build time is not an issue and you do not want an additional set of PCH files on your system, specify /Qpchi-.

**IDE Equivalent**

None

**Alternate Options**

None
**Quse-msasm-symbols**
*Tells the compiler to use a dollar sign ("$") when producing symbol names.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/Quse-msasm-symbols

**Arguments**
None

**Default**
OFF
The compiler uses a period (".") when producing symbol names

**Description**
This option tells the compiler to use a dollar sign ("$") when producing symbol names.
Use this option if you require symbols in your .asm files to contain characters that are accepted by the MS assembler.

**IDE Equivalent**
None

**Alternate Options**
None

**RTC**
*Enables checking for certain run-time conditions.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/RTC<option>

**Arguments**

<option>
Specifies the condition to check. Possible values are 1, s, u, or c.
Default

OFF  No checking is performed for these run-time conditions.

Description

This option enables checking for certain run-time conditions. Using the /RTC option sets __MSVC_RUNTIME_CHECKS = 1.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/RTC1</td>
<td>This is the same as specifying /RTCsu.</td>
</tr>
<tr>
<td>/RTCs</td>
<td>Enables run-time checks of the stack frame.</td>
</tr>
<tr>

**use-asm, Quse-asm**

*Tells the compiler to produce objects through the assembler. This is a deprecated option. There is no replacement option.*

**Syntax**

**Linux OS and macOS:**

-use-asm

-no-use-asm

**Windows OS:**

/Quse-asm

/Quse-asm-

**Arguments**

None

**Default**

OFF The compiler produces objects directly.

**Description**

This option tells the compiler to produce objects through the assembler.

**IDE Equivalent**

None

**Alternate Options**

None

**use-msasm**

*Enables the use of blocks and entire functions of assembly code within a C or C++ file.*
Syntax

Linux OS:
-use-msasm

macOS:
-use-msasm

Windows OS:
None

Arguments
None

Default
OFF The compiler allows a GNU*-style inline assembly format.

Description
This option enables the use of blocks and entire functions of assembly code within a C or C++ file. It allows a Microsoft* MASM-style inline assembly block not a GNU*-style inline assembly block.

IDE Equivalent
None

Alternate Options
-fasm-blocks

V (Windows*)

Places the text string specified into the object file being generated by the compiler.

Syntax

Linux OS and macOS:
None

Windows OS:
/Vstring

Arguments

string Is the text string to go into the object file.

Default
OFF No text string is placed in the object file.

Description
Places the text string specified into the object file (.obj) being generated by the compiler.
This option places the text string specified into the object file (.obj) being generated by the compiler. The string also gets propagated into the executable file.

For example, this option is useful if you want to place the version number or copyright information into the object and executable.

If the string contains a space or tab, the string must be enclosed by double quotation marks ("'). A backslash (\') must precede any double quotation marks contained within the string.

**IDE Equivalent**
None

**Alternate Options**
None

**Y-**
*Tells the compiler to ignore all other precompiled header files.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/Y-

**Arguments**
None

**Default**
OFF The compiler recognizes precompiled header files when certain compiler options are specified.

**Description**
This option tells the compiler to ignore all other precompiled header files.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
Yc compiler option
Yu compiler option
**Yc**
*Tells the compiler to create a precompiled header file.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/\Yc[filename]

**Arguments**

`filename` Is the name of a C/C++ header file, which is included in the source file using an `#include` preprocessor directive.

**Default**

OFF  The compiler does not create or use precompiled headers unless you tell it to do so.

**Description**

This option tells the compiler to create a precompiled header (PCH) file. It is supported only for single source file compilations.

When `filename` is specified, the compiler creates a precompiled header file from the headers in the C/C++ program up to and including the C/C++ header specified.

If you do not specify `filename`, the compiler compiles all code up to the end of the source file, or to the point in the source file where a `hdrstop` occurs. The default name for the resulting file is the name of the source file with extension `.pchi`.

This option cannot be used in the same compilation as the `/Yu` option.

On Linux* and macOS*, option `/Yc` is equivalent to the `-pch-create` option.

**IDE Equivalent**

Visual Studio: **Precompiled Headers** > **Precompiled Header File**
Eclipse: None
Xcode: None

**Alternate Options**

Linux and macOS*: `-pch-create`
Windows: None

**Example**

If option `/Fp` is used, it names the PCH file. For example, consider the following command lines:

```
icl /c /Ycheader.h /Fpprecomp foo.cpp
icl /c /Yc /Fpprecomp foo.cpp
```
In both cases, the name of the PCH file is "precomp.pchi".
If the header file name is specified, the file name is based on the header file name. For example:

```
icl /c /Ycheader.h foo.cpp
```
In this case, the name of the PCH file is "header.pchi".
If no header file name is specified, the file name is based on the source file name. For example:

```
icl /c /Yc foo.cpp
```
In this case, the name of the PCH file is "foo.pchi".

**See Also**
- Yu compiler option
- Fp compiler option

**Yd**

*Tells the compiler to add complete debugging information in all object files created from a precompiled header file when option /Zi or /Z7 is specified. This is a deprecated option. There is no replacement option.*

**Syntax**

**Linux OS and macOS:**

None

**Windows OS:**

/Yd

**Arguments**

None

**Default**

OFF

If /Zi or /Z7 is specified when you are compiling with a precompiled header file using /Yc or /Yu, only one .obj file contains the common debugging information.

**Description**

This option tells the compiler that complete debugging information should be added to all object files created from a precompiled header (PCH) file when option /Zi or /Z7 is specified. It affects precompiled header files that were created by specifying the /Yc option.

Option /Yd has no effect unless option /Zi or /Z7 is specified.

When option /Zi or /Z7 is specified and option /Yd is omitted, the compiler stores common debugging information in only the first object (.obj) file created from the PCH file. This information is not inserted into any .obj files subsequently created from the PCH file, only cross-references to the information are inserted.

**IDE Equivalent**

None

**Alternate Options**

None
**Yu**
*Tells the compiler to use a precompiled header file.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/Yu*[filename]*

**Arguments**

*filename* is the name of a C/C++ header file, which is included in the source file using an #include preprocessor directive.

**Default**

**OFF** The compiler does not use precompiled header files unless it is told to do so.

**Description**

This option tells the compiler to use a precompiled header (PCH) file. It is supported for multiple source files when all source files use the same .pchi file.

The compiler treats all code occurring before the header file as precompiled. It skips to just beyond the #include directive associated with the header file, uses the code contained in the PCH file, and then compiles all code after *filename*.

If you do not specify *filename*, the compiler will use a PCH with a name based on the source file name. If you specify option /FP, it will use the PCH specified by that option.

When this option is specified, the compiler ignores all text, including declarations preceding the #include statement of the specified file.

This option cannot be used in the same compilation as the /Ye option.

On Linux* and macOS* systems, option /Yu is equivalent to the -pch-use option.

**IDE Equivalent**

Visual Studio: **Precompiled Headers > Precompiled Header**

Eclipse: None

Xcode: None

**Alternate Options**

Linux and macOS*: -pch-use

Windows: None
**Example**

Consider the following command line:

```
icl /c /Yuheader.h bar.cpp
```

In this case, the name of the PCH file used is "header.pchi".

In the following command line, no filename is specified:

```
icl /Yu bar.cpp
```

In this case, the name of the PCH file used is "bar.pchi".

In the following command line, no filename is specified, but option /Fp is specified:

```
icl /Yu /Fpprecomp bar.cpp
```

In this case, the name of the PCH file used is "precomp.pchi".

**See Also**

Yc  compiler option

**Zi, Z7, ZI**

*Tells the compiler to generate full debugging information in either an object (.obj) file or a project database (PDB) file.*

**Syntax**

**Linux OS:**
See option g.

**macOS:**
See option g.

**Windows OS:**

```
/zi
/z7
/ZI
```

**Arguments**

None

**Default**

OFF  No debugging information is produced.

**Description**

Option /Z7 tells the compiler to generate symbolic debugging information in the object (.obj) file for use with the debugger. No .pdb file is produced by the compiler.

Option /ZI is a synonym for option /zi.

The /Zi option tells the compiler to generate symbolic debugging information in a program database (PDB) file for use with the debugger. Type information is placed in the .pdb file, and not in the .obj file, resulting in smaller object files in comparison to option /Z7.
When option /zi is specified, two PDB files are created:

- The compiler creates the program database project.pdb. If you compile a file without a project, the compiler creates a database named vc\x0.pdb, where \x represents the major version of Visual C++, for example vc140.pdb.
  
  This file stores all debugging information for the individual object files and resides in the same directory as the project makefile. If you want to change this name, use option /Fd.

- The linker creates the program database executablename.pdb.

  This file stores all debug information for the .exe file and resides in the debug subdirectory. It contains full debug information, including function prototypes, not just the type information found in vc\x0.pdb.

Both PDB files allow incremental updates. The linker also embeds the path to the .pdb file in the .exe or .dll file that it creates.

The compiler does not support the generation of debugging information in assemblable files. If you specify these options, the resulting object file will contain debugging information, but the assemblable file will not.

These options turn off option /O2 and make option /Od the default unless option /O2 (or higher) is explicitly specified in the same command line.

For more information about the /Zi, /zi, and /ZI options, see the Microsoft documentation.

**IDE Equivalent**

Visual Studio: **General > Generate Debug Information**

Eclipse: None

Xcode: None

**Alternate Options**

Linux: -g

Windows: None

**See Also**

Fd  compiler option

g  compiler option
ddebug (Windows*)  compiler option

**Zo**

Enables or disables generation of enhanced debugging information for optimized code.

**Syntax**

**Linux OS and macOS:**

None

**Windows OS:**

/zo

/zo-

**Arguments**

None
Default
OFF The compiler does not generate enhanced debugging information for optimized code.

Description
This option enables or disables the generation of additional debugging information for local variables and inlined routines when code optimizations are enabled. It should be used with option /zi or /Z7 to allow improved debugging of optimized code.

Option /Zo enables generation of this enhanced debugging information. Option /zo- disables this functionality.

For more information on code optimization, see option /O.

IDE Equivalent
None

Alternate Options
None

See Also
Zi, Z7, ZI compiler option
debug (Windows*) compiler option
O compiler option

Preprocessor Options

A, QA
Specifies an identifier for an assertion.

Syntax
Linux OS and macOS:
-Aname[ (value)]

Windows OS:
/QAname[ (value)]

Arguments
name Is the identifier for the assertion.
value Is an optional value for the assertion. If a value is specified, it must be within quotes, including the parentheses delimiting it.

Default
OFF Assertions have no identifiers or symbol names.

Description
This option specifies an identifier (symbol name) for an assertion. It is equivalent to an #assert preprocessing directive.
Note that this option is not the positive form of the C++ `/QA-` option.
On Linux* systems, because GCC has deprecated assertions, this option has no effect.

**IDE Equivalent**
Visual Studio: None
Eclipse: None
Xcode: **Preprocessor > Undefine All Preprocessor Definitions**

**Alternate Options**
None

**Example**
To make an assertion for the identifier fruit with the associated values orange and banana use the following command.

On Windows* systems:
```
icl /QA"fruit(orange,banana)" prog1.cpp
```

On Linux* systems:
```
icpc -A"fruit(orange,banana)" prog1.cpp
```

On macOS* systems:
```
icl++ -A"fruit(orange,banana)" prog1.cpp
icpc -A"fruit(orange,banana)" prog1.cpp
```

**B**
Specifies a directory that can be used to find include files, libraries, and executables.

**Syntax**

<table>
<thead>
<tr>
<th>OS</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Linux OS:</strong></td>
<td><code>-B dir</code></td>
</tr>
<tr>
<td><strong>macOS:</strong></td>
<td><code>-B dir</code></td>
</tr>
<tr>
<td><strong>Windows OS:</strong></td>
<td>None</td>
</tr>
</tbody>
</table>

**Arguments**

- `dir`  
  Is the directory to be used. If necessary, the compiler adds a directory separator character at the end of `dir`.

**Default**

- **OFF**  
  The compiler looks for files in the directories specified in your PATH environment variable.

**Description**

This option specifies a directory that can be used to find include files, libraries, and executables.
The compiler uses `dir` as a prefix.

For include files, the `dir` is converted to `-I/`\texttt{dir}/include. This command is added to the front of the includes passed to the preprocessor.

For libraries, the `dir` is converted to `-L/`\texttt{dir}. This command is added to the front of the standard `-L` inclusions before system libraries are added.

For executables, if `dir` contains the name of a tool, such as `ld` or `as`, the compiler will use it instead of those found in the default directories.

The compiler looks for include files in `dir`/include while library files are looked for in `dir`.

On Linux* systems, another way to get the behavior of this option is to use the environment variable `GCC_EXEC_PREFIX`.

**IDE Equivalent**

None

**Alternate Options**

None

**C**

*Places comments in preprocessed source output.*

**Syntax**

**Linux OS:**

\[-C\]

**macOS:**

\[-C\]

**Windows OS:**

\[/C\]

**Arguments**

None

**Default**

OFF  

No comments are placed in preprocessed source output.

**Description**

This option places (or preserves) comments in preprocessed source output. Comments following preprocessing directives, however, are not preserved.

**IDE Equivalent**

Visual Studio: **Preprocessor > Keep Comments**

Eclipse: None

Xcode: None
Alternate Options

None

Example

The following commands cause the compiler to preserve comments in the prog1.i preprocessed file.

On Windows* systems:

icl /C /P prog1.cpp prog2.cpp

On Linux* systems:

icpc -C -P prog1.cpp prog2.cpp

On macOS* systems:

icpc -C -P prog1.cpp prog2.cpp

D

Defines a macro name that can be associated with an optional value.

Syntax

Linux OS:

-Dname[=value]

macOS:

-Dname[=value]

Windows OS:

/Dname[=value]

Arguments

name

Is the name of the macro.

value

Is an optional integer or an optional character string delimited by double quotes; for example, Dname=string.

Default

OFF Only default symbols or macros are defined.

Description

Defines a macro name that can be associated with an optional value. This option is equivalent to a #define preprocessor directive.

If a value is not specified, name is defined as "1".

IDE Equivalent

Visual Studio: Preprocessor > Preprocessor Definitions

Eclipse: Preprocessor > Preprocessor Definitions

Xcode: Preprocessor > Preprocessor Definitions
Alternate Options

None

Example

To define a macro called SIZE with the value 100, enter the following command:

On Windows* systems:
```
icl /DSIZE=100 prog1.cpp
```

On Linux* systems:
```
icpc -DSIZE=100 prog1.cpp
```

On macOS* systems:
```
icpc -DSIZE=100 prog1.cpp
```

If you define a macro, but do not assign a value, the compiler defaults to 1 for the value of the macro.

See Also

Additional Predefined Macros

dD, QdD

Same as option -dM, but outputs #define directives in preprocessed source.

Syntax

Linux OS:
```
-dD
```

macOS:
```
-dD
```

Windows OS:
```
/QdD
```

Arguments

None

Default

OFF The compiler does not output #define directives.

Description

Same as -dM, but outputs #define directives in preprocessed source. To use this option, you must also specify the E option.

IDE Equivalent

None

Alternate Options

None
**dM, QdM**
*Tells the compiler to output macro definitions in effect after preprocessing.*

**Syntax**

**Linux OS:**
- `-dM`

**macOS:**
- `-dM`

**Windows OS:**
- `/QdM`

**Arguments**
None

**Default**
OFF The compiler does not output macro definitions after preprocessing.

**Description**
This option tells the compiler to output macro definitions in effect after preprocessing. To use this option, you must also specify option `E`.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
E compiler option

---

**dN, QdN**
*Same as option `-D`, but output `#define` directives contain only macro names.*

**Syntax**

**Linux OS and macOS:**
- `-dN`

**Windows OS:**
- `/QdN`

**Arguments**
None
Default
OFF  The compiler does not output #define directives.

Description
Same as -dD, but output #define directives contain only macro names. To use this option, you must also specify option E.

IDE Equivalent
None

Alternate Options
None

E
Causes the preprocessor to send output to stdout.

Syntax
Linux OS:
-E

macOS:
-E

Windows OS:
/E

Arguments
None

Default
OFF  Preprocessed source files are output to the compiler.

Description
This option causes the preprocessor to send output to stdout. Compilation stops when the files have been preprocessed.

When you specify this option, the compiler’s preprocessor expands your source module and writes the result to stdout. The preprocessed source contains #line directives, which the compiler uses to determine the source file and line number.

IDE Equivalent
None

Alternate Options
None
**Example**

To preprocess two source files and write them to `stdout`, enter the following command:

On Windows* systems:

```
icl /E prog1.cpp prog2.cpp
```

On Linux* systems:

```
icpc -E prog1.cpp prog2.cpp
```

On macOS* systems:

```
icl++ -E prog1.cpp prog2.cpp
icpc -E prog1.cpp prog2.cpp
```

**EP**

*Causes the preprocessor to send output to stdout, omitting #line directives.*

**Syntax**

**Linux OS:**

```
-EP
```

**macOS:**

```
-EP
```

**Windows OS:**

```
/EP
```

**Arguments**

None

**Default**

OFF  Preprocessed source files are output to the compiler.

**Description**

This option causes the preprocessor to send output to `stdout`, omitting #line directives.

If you also specify option `P` or Linux* option `F`, the preprocessor will write the results (without #line directives) to a file instead of `stdout`.

**IDE Equivalent**

Visual Studio: **Preprocessor > Preprocess Suppress Line Numbers**

Eclipse: None

Xcode: None

**Alternate Options**

None
Example

To preprocess to stdout omitting #line directives, enter the following command:

On Windows* systems:

```plaintext
icl /EP prog1.cpp prog2.cpp
```

On Linux* and macOS* systems:

```plaintext
icpc -EP prog1.cpp prog2.cpp
```

FI

*Tells the preprocessor to include a specified file name as the header file.*

Syntax

Linux OS:

None

macOS:

None

Windows OS:

```plaintext
/IFI filename
```

Arguments

`filename`  
Is the file name to be included as the header file.

Default

OFF  
The compiler uses default header files.

Description

This option tells the preprocessor to include a specified file name as the header file. The file specified with `/FI` is included in the compilation before the first line of the primary source file.

IDE Equivalent

Visual Studio:  *Advanced > Forced Include File*

Eclipse: None

Xcode: None

Alternate Options

None

*gcc, gcc-sys*

Determines whether certain GNU macros are defined or undefined.
**Syntax**

Linux OS:
- `-gcc`
- `-no-gcc`
- `-gcc-sys`

macOS:
- `-gcc`
- `-no-gcc`
- `-gcc-sys`

Windows OS:
None

**Arguments**

None

**Default**

- `-gcc` The compiler defines the GNU macros `__GNUC__`, `__GNUC_MINOR__`, and `__GNUC_PATCHLEVEL__`

**Description**

This option determines whether the GNU macros `__GNUC__`, `__GNUC_MINOR__`, and `__GNUC_PATCHLEVEL__` are defined or undefined.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-gcc</code></td>
<td>Defines GNU macros.</td>
</tr>
<tr>
<td><code>-no-gcc</code></td>
<td>Undefines GNU macros.</td>
</tr>
<tr>
<td><code>-gcc-sys</code></td>
<td>Defines GNU macros only during compilation of system headers.</td>
</tr>
</tbody>
</table>

**IDE Equivalent**

Visual Studio: None

Eclipse: *Preprocessor* > *gcc Predefined Macro Enablement*

Xcode: *Preprocessor* > *Predefine gcc Macros*

**Alternate Options**

None

**gcc-include-dir**

* Controls whether the gcc-specific include directory is put into the system include path.*

**Syntax**

Linux OS:
- `-gcc-include-dir`
-no-gcc-include-dir

**macOS:**
None

**Windows OS:**
None

**Arguments**
None

**Default**

The gcc-specific include directory is put into the system include path.

**Description**
This option controls whether the gcc-specific include directory is put into the system include path.

If you specify `-no-gcc-include-dir`, the gcc-specific include directory will not be put into the system include path.

**IDE Equivalent**
None

**Alternate Options**
None

**H, QH**
*Tells the compiler to display the include file order and continue compilation.*

**Syntax**

**Linux OS:**
- `H`

**macOS:**
- `H`

**Windows OS:**
/`QH`

**Arguments**
None

**Default**
OFF  Compilation occurs as usual.

**Description**
This option tells the compiler to display the include file order and continue compilation.

IDE Equivalent
None

Alternate Options
None

\textbf{I}
\begin{itemize}
  \item \textit{Specifies an additional directory to search for include files.}
\end{itemize}

\textbf{Syntax}
\begin{itemize}
  \item Linux OS: \texttt{-I \textit{dir}}
  \item macOS: \texttt{-I \textit{dir}}
  \item Windows OS: \texttt{/I \textit{dir}}
\end{itemize}

\textbf{Arguments}
\begin{itemize}
  \item \textit{dir} \hspace{1cm} Is the additional directory for the search.
\end{itemize}

\textbf{Default}
\begin{itemize}
  \item OFF \hspace{1cm} The default directory is searched for include files.
\end{itemize}

\textbf{Description}
This option specifies an additional directory to search for include files. To specify multiple directories on the command line, repeat the include option for each directory.

\textbf{IDE Equivalent}
Visual Studio: \textbf{General > Additional Include Directories}
Eclipse: \textbf{Preprocessor > Additional Include Directories}
Xcode: \textbf{Preprocessor > Additional Include Directories}

\textbf{Alternate Options}
None

\textbf{I-}
\begin{itemize}
  \item \textit{Splits the include path.}
\end{itemize}

\textbf{Syntax}
\begin{itemize}
  \item Linux OS: \texttt{-I-}
\end{itemize}
macOS:
-I-

Windows OS:
/I-

**Arguments**
None

**Default**
OFF
The default directory is searched for include files.

**Description**
This option splits the include path. It prevents the use of the current directory as the first search directory for '
#include "file"'.

If you specify directories using the I option before you specify option I-, the directories are searched only for the case of '#include "file"'; they are not searched for '#include <file>'.

If you specify directories using the I option after you specify option I-, these directories are searched for all '#include' directives.

This option has no effect on option nostdinc++, which searches the standard system directories for header files.

This option is provided for compatibility with gcc.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
I compiler option
nostdinc++ compiler option

**icc, Qicl**
*Determines whether certain Intel compiler macros are defined or undefined.*

**Syntax**
Linux OS:
-icc
-no-icc

macOS:
-icc
-no-icc
**Windows OS:**

/Qicl
/Qicl-

**Arguments**

None

**Default**

-icc or /Qicl

**Description**

This option determines whether certain Intel compiler macros are defined or undefined. If you specify option `-no-icc` or `/Qicl-`, the compiler undefines the __INTEL_COMPILER macros. These macros are defined by default or by specifying `-icc` or `/Qicl`.

**IDE Equivalent**

None

**Alternate Options**

None

**idirafter**

*Adds a directory to the second include file search path.*

**Syntax**

**Linux OS:**

-`idirafterdir`

**macOS:**

-`idirafterdir`

**Windows OS:**

None

**Arguments**

`dir`  
Is the name of the directory to add.

**Default**

OFF  
Include file search paths include certain default directories.

**Description**

This option adds a directory to the second include file search path (after `-I`).

396
imacros
Allows a header to be specified that is included in front of the other headers in the translation unit.

Syntax

Linux OS:
-`-imacros filename`

macOS:
-`-imacros filename`

Windows OS:
None

Arguments

`filename` Name of header file.

Default

OFF

Description

Allows a header to be specified that is included in front of the other headers in the translation unit.

iprefix

Lets you indicate the prefix for referencing directories that contain header files.

Syntax

Linux OS:
-`-iprefix prefix`

macOS:
-`-iprefix prefix`
Windows OS:
None

**Arguments**

*prefix*  
Is the prefix to use.

**Default**

*OFF*  
No prefix is included.

**Description**

Options for indicating the prefix for referencing directories containing header files. Use *prefix* with option `-iwithprefix` as a prefix.

**IDE Equivalent**

None

**Alternate Options**

None

*iquote*

*Adds a directory to the front of the include file search path for files included with quotes but not brackets.*

**Syntax**

**Linux OS:**

 `-iquote dir`

**macOS:**

 `-iquote dir`

**Windows OS:**

None

**Arguments**

*dir*  
Is the name of the directory to add.

**Default**

*OFF*  
The compiler does not add a directory to the front of the include file search path.

**Description**

Add directory to the front of the include file search path for files included with quotes but not brackets.

**IDE Equivalent**

None
Alternate Options
None

**isystem**
Specifies a directory to add to the start of the system include path.

**Syntax**

Linux OS:
-isystemdir

macOS:
isystemdir

Windows OS:
None

**Arguments**
[dir]
Is the directory to add to the system include path.

**Default**
OFF
The default system include path is used.

**Description**
This option specifies a directory to add to the system include path. The compiler searches the specified directory for include files after it searches all directories specified by the -I compiler option but before it searches the standard system directories.

On Linux* systems, this option is provided for compatibility with gcc.

**IDE Equivalent**
None

Alternate Options
None

**iwithprefix**
Appends a directory to the prefix passed in by -iprefix and puts it on the include search path at the end of the include directories.

**Syntax**

Linux OS:
-iwithprefixdir

macOS:
iwithprefixdir
**Windows OS:**
None

**Arguments**

\(dir\) Is the include directory.

**Default**

OFF

**Description**

This option appends a directory to the prefix passed in by \(-iprefix\) and puts it on the include search path at the end of the include directories.

**IDE Equivalent**

None

**Alternate Options**

None

---

**iwithprefixbefore**

Similar to \(-iwithprefix\) except the include directory is placed in the same place as \(-I\) command-line include directories.

**Syntax**

**Linux OS:**

\(-iwithprefixbefore\) \(dir\)

**macOS:**

\(-iwithprefixbefore\) \(dir\)

**Windows OS:**

None

**Arguments**

\(dir\) Is the include directory.

**Default**

OFF

**Description**

Similar to \(-iwithprefix\) except the include directory is placed in the same place as \(-I\) command-line include directories.

**IDE Equivalent**

None
Alternate Options
None

Kc++, TP
*Tells the compiler to process all source or unrecognized file types as C++ source files. This is a deprecated option. The replacement option for Kc++ is -x c++; the replacement option for /TP is /Tp<file>.*

Syntax
Linux OS:
-Kc++

macOS:
-Kc++

Windows OS:
/TP

Arguments
None

Default
OFF The compiler uses default rules for determining whether a file is a C++ source file.

Description
This option tells the compiler to process all source or unrecognized file types as C++ source files.

IDE Equivalent
Visual Studio: Advanced > Compile As
Eclipse: None
Xcode: None

Alternate Options
Linux and macOS*: -x c++
Windows: /Tp

M, QM
*Tells the compiler to generate makefile dependency lines for each source file.*

Syntax
Linux OS:
-M

macOS:
-M
Windows OS:
/QM

**Arguments**
None

**Default**
OFF  The compiler does not generate makefile dependency lines for each source file.

**Description**
This option tells the compiler to generate makefile dependency lines for each source file, based on the #include lines found in the source file.

**IDE Equivalent**
None

**Alternate Options**
None

**MD, QMD**
Preprocess and compile, generating output file containing dependency information ending with extension .d.

**Syntax**

Linux OS:
-MD

macOS:
-MD

Windows OS:
/QMD

**Arguments**
None

**Default**
OFF  The compiler does not generate dependency information.

**Description**
Preprocess and compile, generating output file containing dependency information ending with extension .d.

**IDE Equivalent**
None

**Alternate Options**
None
**MF, QMF**
*Tells the compiler to generate makefile dependency information in a file.*

**Syntax**

**Linux OS:**

- `MF filename`

**macOS:**

- `MF filename`

**Windows OS:**

- `/QMF filename`

**Arguments**

*filename*  
Is the name of the file where the makefile dependency information should be placed.

**Default**

**OFF**  
The compiler does not generate makefile dependency information in files.

**Description**

This option tells the compiler to generate makefile dependency information in a file. To use this option, you must also specify `/QM` or `/QMM`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

QM  
compiler option

QMM  
compiler option

---

**MG, QMG**
*Tells the compiler to generate makefile dependency lines for each source file.*

**Syntax**

**Linux OS:**

- `MG`

**macOS:**

- `MG`

**Windows OS:**

- `/QMG`
Arguments
None

Default
OFF  The compiler does not generate makefile dependency information in files.

Description
This option tells the compiler to generate makefile dependency lines for each source file. It is similar to `/QM`, but it treats missing header files as generated files.

IDE Equivalent
None

Alternate Options
None

See Also
QM  compiler option

**MM, QMM**
*Tells the compiler to generate makefile dependency lines for each source file.*

Syntax
Linux OS:

```
-MM
```

macOS:

```
-MM
```

Windows OS:

```
/QMM
```

Arguments
None

Default
OFF  The compiler does not generate makefile dependency information in files.

Description
This option tells the compiler to generate makefile dependency lines for each source file. It is similar to `/QM`, but it does not include system header files.

IDE Equivalent
None

Alternate Options
None
See Also

QM compiler option

MMD, QMMD
Tell the compiler to generate an output file containing dependency information.

Syntax

Linux OS:
- MMD

macOS:
- MMD

Windows OS:
/ QMMD

Arguments
None

Default
OFF  The compiler does not generate an output file containing dependency information.

Description
This option tells the compiler to preprocess and compile a file, then generate an output file (with extension .d) containing dependency information.

It is similar to / QMD, but it does not include system header files.

IDE Equivalent
None

Alternate Options
None

MP
Tell the compiler to add a phony target for each dependency.

Syntax

Linux OS:
- MP

macOS:
- MP

Windows OS:
None (see below)
Arguments
None

Default
OFF  The compiler does not generate dependency information unless it is told to do so.

Description
This option tells the compiler to add a phony target for each dependency.
Note that this option is not related to Windows* option /MP.

IDE Equivalent
None

Alternate Options
None

MQ
Changes the default target rule for dependency generation.

Syntax
Linux OS:
-MQtarget
macOS:
-MQtarget
Windows OS:
None

Arguments

target  Is the target rule to use.

Default
OFF  The default target rule applies to dependency generation.

Description
This option changes the default target rule for dependency generation. It is similar to -MT, but quotes special Make characters.

IDE Equivalent
None

Alternate Options
None
**MT, QMT**

*Changes the default target rule for dependency generation.*

**Syntax**

**Linux OS:**

```
-MT target
```

**macOS:**

```
-MT target
```

**Windows OS:**

```
/QMT target
```

**Arguments**

*target*  

Is the target rule to use.

**Default**

**OFF**  

The default target rule applies to dependency generation.

**Description**

This option changes the default target rule for dependency generation.

**IDE Equivalent**

None

**Alternate Options**

None

---

**n ostdinc++**

*Do not search for header files in the standard directories for C++, but search the other standard directories.*

**Syntax**

**Linux OS:**

```
-nostdinc++
```

**macOS:**

```
-nostdinc++
```

**Windows OS:**

None

**Arguments**

None
Default

OFF

Description
Do not search for header files in the standard directories for C++, but search the other standard directories.

IDE Equivalent
None

Alternate Options
None

P
Tells the compiler to stop the compilation process and write the results to a file.

Syntax
Linux OS:
  -P
macOS:
  -P
Windows OS:
  /P

Arguments
None

Default
OFF Normal compilation is performed.

Description
This option tells the compiler to stop the compilation process after C or C++ source files have been preprocessed and write the results to files named according to the compiler’s default file-naming conventions.

On Linux systems, this option causes the preprocessor to expand your source module and direct the output to a .i file instead of stdout. Unlike the -E option, the output from -P on Linux does not include #line number directives. By default, the preprocessor creates the name of the output file using the prefix of the source file name with a .i extension. You can change this by using the -o option.

IDE Equivalent
Visual Studio: Preprocessor > Generate Preprocessed File
Eclipse: None
Xcode: None
Alternate Options
Linux and macOS*: -F
Windows: None

pragma-optimization-level
Specifies which interpretation of the optimization_level pragma should be used if no prefix is specified.

Syntax
Linux OS:
-pragma-optimization-level=interpretation
macOS:
-pragma-optimization-level=interpretation
Windows OS:
None

Arguments

* interpretation
Compiler-specific interpretation of optimization_level pragma. Possible values are:

Intel Specify the Intel interpretation.
GCC Specify the GCC interpretation.

Default
-pragma-optimization-level=Intel
Use the Intel interpretation of the optimization_level pragma.

Description
Specifies which interpretation of the optimization_level pragma should be used if no prefix is specified.

IDE Equivalent
None

Alternate Options
None

u (Windows*)
Disables all predefined macros and assertions.

Syntax
Linux OS:
None
macOS:
None
**Windows OS:**

/u

**Arguments**

None

**Default**

OFF Defined preprocessor values are in effect until they are undefined.

**Description**

This option disables all predefined macros and assertions.

**IDE Equivalent**

Visual Studio: **Preprocessor > Undefine All Preprocessor Definitions**

Eclipse: None

Xcode: None

**Alternate Options**

None

**U**

_Undefines any definition currently in effect for the specified macro._

**Syntax**

**Linux OS:**

- `Uname`

**macOS:**

- `Uname`

**Windows OS:**

/Uname

**Arguments**

(name) Is the name of the macro to be undefined.

**Default**

OFF Macro definitions are in effect until they are undefined.

**Description**

This option undefines any definition currently in effect for the specified macro. It is equivalent to an `#undef` preprocessing directive.

On Windows systems, use the /u option to undefine all previously defined preprocessor values.
**IDE Equivalent**

Visual Studio: Preprocessor > Undefine Preprocessor Definitions

Eclipse: Preprocessor > Undefine Preprocessor Definitions

Xcode: Preprocessor > Undefine Preprocessor Definitions

**Alternate Options**

None

**Example**

To undefine a macro, enter the following command:

On Windows* systems:

```
icl -Uia64 prog1.cpp
```

On Linux* systems:

```
icpc -Uia64 prog1.cpp
```

On macOS* systems:

```
icpc -Uia64 prog1.cpp
```

If you attempt to undefine an ANSI C macro, the compiler will emit an error:

```
invalid macro undefinition: <name of macro>
```

**See Also**

**undef**

*Disables all predefined macros.*

**Syntax**

**Linux OS:**

```
-undef
```

**macOS:**

```
-undef
```

**Windows OS:**

None

**Arguments**

None

**Default**

OFF Defined macros are in effect until they are undefined.

**Description**

This option disables all predefined macros.

**IDE Equivalent**

None
Alternate Options

None

X

Removes standard directories from the include file search path.

Syntax

Linux OS:
- X

macOS:
- X

Windows OS:
/ X

Arguments

None

Default

OFF Standard directories are in the include file search path.

Description

This option removes standard directories from the include file search path. It prevents the compiler from searching the default path specified by the INCLUDE environment variable.

On Linux* and macOS* systems, specifying -X (or -noinclude) prevents the compiler from searching in /usr/include for files specified in an INCLUDE statement.

You can use this option with the I option to prevent the compiler from searching the default path for include files and direct it to use an alternate path.

IDE Equivalent

Visual Studio: **Preprocessor > Ignore Standard Include Path**

Eclipse: **Preprocessor > Ignore Standard Include Path**

Xcode: **Preprocessor > Ignore Standard Include Path**

Alternate Options

Linux and macOS*: -nostdinc

Windows: None

See Also

I compiler option
Component Control Options

Qinstall
Specifies the root directory where the compiler installation was performed.

Syntax
Linux OS:
-Qinstall\dir
macOS:
-Qinstall\dir
Windows OS:
None

Arguments
\dir
Is the root directory where the installation was performed.

Default
OFF
The default root directory for compiler installation is searched for the compiler.

Description
This option specifies the root directory where the compiler installation was performed. It is useful if you want to use a different compiler or if you did not use the compilervars shell script to set your environment variables.

IDE Equivalent
None

Alternate Options
None

Qlocation
Specifies the directory for supporting tools.

Syntax
Linux OS:
-Qlocation,string,dir
macOS:
-Qlocation,string,dir
Windows OS:
/Qlocation,string,dir
**Arguments**

*string*  
Is the name of the tool.

*dir*  
Is the directory (path) where the tool is located.

**Default**

**OFF**  
The compiler looks for tools in a default area.

**Description**

This option specifies the directory for supporting tools.

*string* can be any of the following:

- c - Indicates the Intel® C++ compiler.
- cpp (or fpp) - Indicates the Intel® C++ preprocessor.
- cxxinc - Indicates C++ header files.
- cinc - Indicates C header files.
- asm - Indicates the assembler.
- link - Indicates the linker.
- prof - Indicates the profiler.
- On Windows* systems, the following is also available:
  - masm - Indicates the Microsoft assembler.
- On Linux* and macOS* systems, the following are also available:
  - as - Indicates the assembler.
  - gas - Indicates the GNU assembler. This setting is for Linux* only.
  - ld - Indicates the loader.
  - gld - Indicates the GNU loader. This setting is for Linux* only.
  - lib - Indicates an additional library.
  - crt - Indicates the crt%.o files linked into executables to contain the place to start execution.

On Windows and macOS* systems, you can also specify a tool command name.

The following shows an example on macOS* systems:

```
-Qlocation,ld,/usr/bin               ! This tells the driver to use /usr/bin/ld for the loader
-Qlocation,ld,/usr/bin/gld           ! This tells the driver to use /usr/bin/gld as the loader
```

The following shows an example on Windows* systems:

```
/Qlocation,link,"c:\Program Files\tools\"
/Qlocation,link,"c:\Program Files\tools\my_link.exe" ! This tells the driver to use c:\Program Files\tools\my_link.exe as the loader
```

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

*Qoption  compiler option*
Qoption

*Passes options to a specified tool.*

**Syntax**

**Linux OS:**

- `Qoption, string, options`

**macOS:**

- `Qoption, string, options`

**Windows OS:**

/`Qoption, string, options`

**Arguments**

- `string`  
  Is the name of the tool.

- `options`  
  Are one or more comma-separated, valid options for the designated tool.

  Note that certain tools may require that options appear within quotation marks (" ").

**Default**

OFF  
No options are passed to tools.

**Description**

This option passes options to a specified tool.

If an argument contains a space or tab character, you must enclose the entire argument in quotation marks (" "). You must separate multiple arguments with commas.

`string` can be any of the following:

- `cpp` - Indicates the Intel compiler preprocessor.
- `c` - Indicates the C++ compiler.
- `asm` - Indicates the assembler.
- `link` - Indicates the linker.
- `prof` - Indicates the profiler.
- On Windows* systems, the following is also available:
  - `masm` - Indicates the Microsoft assembler.
- On Linux* and macOS* systems, the following are also available:
  - `as` - Indicates the assembler.
  - `gas` - Indicates the GNU assembler.
  - `ld` - Indicates the loader.
  - `gld` - Indicates the GNU loader.
  - `lib` - Indicates an additional library.
  - `crt` - Indicates the crt%.o files linked into executables to contain the place to start execution.

**IDE Equivalent**

None
Alternate Options
None

See Also
Qlocation compiler option

Language Options

ansi
Enables language compatibility with the gcc option ansi.

Syntax
Linux OS:
-ansi
macOS:
-ansi
Windows OS:
None

Arguments
None

Default
OFF GNU C++ is more strongly supported than ANSI C.

Description
This option enables language compatibility with the gcc option -ansi and provides the same level of ANSI standard conformance as that option.
This option sets option fmath-errno.
If you want strict ANSI conformance, use the -strict-ansi option.

IDE Equivalent
Visual Studio: None
Eclipse: Language > ANSI Conformance
Xcode: Language > C Language Dialect and Language > C++ Language Dialect

Alternate Options
None

check
Checks for certain conditions at run time.
**Syntax**

**Linux OS and macOS:**
- check=keyword[, keyword...]

**Windows OS:**
/ check:keyword[, keyword...]

**Arguments**

`keyword` Specifies the conditions to check. Possible values are:

- [no]conversions
  Determines whether checking occurs for converting to smaller types. Keyword `conversions` enables this checking.

- [no]stack
  Determines whether checking occurs on the stack frame. Keyword `stack` enables this checking. If `stack` is specified, the stack is checked for buffer overruns and buffer underruns. This option also enforces local variables initialization and stack pointer verification.

- [no]uninit
  Determines whether checking occurs for uninitialized variables. Keyword `uninit` enables this checking. If a variable is read before it is written, a run-time error routine will be called.

  Run-time checking of undefined variables is only implemented on local, scalar variables. It is not implemented on dynamically allocated variables, extern variables or static variables. It is not implemented on structs, classes, unions or arrays.

**Default**

- noconversions
- nostack
- nouninit

**No checking is performed for the above run-time conditions.**

**Description**

This option checks for certain conditions at run time.

On Windows* systems, this option disables any default or specified optimizations and applies the /Od level of optimization. If you specified optimizations, the compiler emits warning diagnostics for the disabled optimizations.

On Linux* and macOS* systems, this option may disable some optimizations.
NOTE
This option requires library support. Depending on the platform, the required library is either in your operating system run-time environment or in your compiler package.

IDE Equivalent
Visual Studio: None
Eclipse: Runtime > Check Stack Frame (-check=stack)
Runtime > Check Type Conversions (-check=conversions)
Runtime > Check Uninitialized Variables (-check=uninit)
Xcode: Runtime > Check Stack Frame (-check=stack)
Runtime > Check Type Conversions (-check=conversions)
Runtime > Check Uninitialized Variables (-check=uninit)

Alternate Options
check:conversions
Linux and macOS*: None
Windows: /RTCc
check:stack
Linux and macOS*: None
Windows: /RTCc
check:uninit
Linux and macOS*: None
Windows: /RTCc

early-template-check
Lets you semantically check template function template prototypes before instantiation.

Syntax
Linux OS and macOS:
-early-template-check
-no-early-template-check
Windows OS:
None

Arguments
None

Default
-no-early-template-check
The prototype instantiation of function templates and function members of class templates is deferred.
Description
Lets you semantically check template function template prototypes before instantiation. On Linux* platforms, gcc 3.4 (or newer) compatibility modes must be in effect. For all macOS* platforms, gcc 4.0 (or newer) is required.

IDE Equivalent
None

Alternate Options
None

fblocks
Determines whether Apple* blocks are enabled or disabled.

Syntax
Linux OS:
None

macOS:
-fblocks
-fno-blocks

Windows OS:
None

Arguments
None

Default
-fblocks Apple* blocks are enabled.

Description
This option determines whether Apple* blocks (block variable declarations) are enabled or disabled.
If you want to disable Apple* blocks, specify -fno-blocks.
To use this feature, macOS* 10.6 or greater is required.

IDE Equivalent
None

Alternate Options
None

ffriend-injection
Causes the compiler to inject friend functions into the enclosing namespace.
Syntax

Linux OS and macOS:
-ffriend-injection
-fno-friend-injection

Windows OS:
None

Arguments

None

Default

-fno-friend-injection

The compiler does not inject friend functions into the enclosing namespace. A friend function that is not declared in an enclosing scope can only be found using argument-dependent lookup.

Description

This option causes the compiler to inject friend functions into the enclosing namespace, so they are visible outside the scope of the class in which they are declared.

On Linux systems, in gcc versions 4.1 or later, this is not the default behavior. This option allows compatibility with gcc 4.0 or earlier.

IDE Equivalent

None

Alternate Options

None

fno-gnu-keywords

*Tells the compiler to not recognize typeof as a keyword.*

Syntax

Linux OS:
-fno-gnu-keywords

macOS:
-fno-gnu-keywords

Windows OS:
None

Arguments

None

Default

OFF

Keyword typeof is recognized.
Description
Tells the compiler to not recognize `typeof` as a keyword.

IDE Equivalent
None

Alternate Options
None

fno-implicit-inline-templates
_Tells the compiler to not emit code for implicit instantiations of inline templates._

Syntax
Linux OS:
- `fno-implicit-inline-templates`

macOS:
- `fno-implicit-inline-templates`

Windows OS:
None

Arguments
None

Default
OFF  The compiler handles inlines so that compilations, with and without optimization, will need the same set of explicit instantiations.

Description
This option tells the compiler to not emit code for implicit instantiations of inline templates.

IDE Equivalent
None

Alternate Options
None

fno-implicit-templates
_Tells the compiler to not emit code for non-inline templates that are instantiated implicitly._

Syntax
Linux OS:
- `fno-implicit-templates`
macOS:
-fno-implicit-templates

Windows OS:
None

Arguments
None

Default
OFF  The compiler handles inlines so that compilations, with and without optimization, will need the same set of explicit instantiations.

Description
This option tells the compiler to not emit code for non-inline templates that are instantiated implicitly, but to only emit code for explicit instantiations.

IDE Equivalent
None

Alternate Options
None

fno-operator-names
Disables support for the operator names specified in the standard.

Syntax
Linux OS:
-fno-operator-names

macOS:
-fno-operator-names

Windows OS:
None

Arguments
None

Default
OFF

Description
Disables support for the operator names specified in the standard.

IDE Equivalent
None
Alternate Options
None

**fno-rtti**
*Disables support for run-time type information (RTTI).*

**Syntax**
Linux OS:
- *fno-rtti*
macOS:
- *fno-rtti*
Windows OS:
None

**Arguments**
None

**Default**
OFF Support for run-time type information (RTTI) is enabled.

**Description**
This option disables support for run-time type information (RTTI).

**IDE Equivalent**
Visual Studio: None
Eclipse: None
Xcode: *Language > Enable C++ Runtime Types*

Alternate Options
None

**fnon-lvalue-assign**
*Determines whether casts and conditional expressions can be used as lvalues.*

**Syntax**
Linux OS and macOS:
- *fnon-lvalue-assign*
  - *fno-non-lvalue-assign*
Windows OS:
None
Arguments
None

Default

-fnon-lvalue-assign

The compiler allows casts and conditional expressions to be used as lvalues.

Description
This option determines whether casts and conditional expressions can be used as lvalues.

IDE Equivalent
None

Alternate Options
None

fpermissive
*Tells the compiler to allow for non-conformant code.*

Syntax
Linux OS:
-fpermissive

macOS:
-fpermissive

Windows OS:
None

Arguments
None

Default
OFF

Description
Tells the compiler to allow for non-conformant code.

IDE Equivalent
None

Alternate Options
None

fshort-enums
*Tells the compiler to allocate as many bytes as needed for enumerated types.*
Syntax
Linux OS:
-fshort-enums
macOS:
-fshort-enums
Windows OS:
None

Arguments
None

Default
OFF
The compiler allocates a default number of bytes for enumerated types.

Description
This option tells the compiler to allocate as many bytes as needed for enumerated types.

IDE Equivalent
Visual Studio: None
Eclipse: Data > Associate as Many Bytes as Needed for Enumerated Types
Xcode: Data > Allocate enumerated types

Alternate Options
None

fsyntax-only
_Tells the compiler to check only for correct syntax._

Syntax
Linux OS:
-fsyntax-only
macOS:
-fsyntax-only
Windows OS:
None

Arguments
None

Default
OFF
Normal compilation is performed.
**Description**
This option tells the compiler to check only for correct syntax. No object file is produced.

**IDE Equivalent**
None

**Alternate Options**
Linux and macOS*: None
Windows: /zs

**ftemplate-depth, Qtemplate-depth**
*Control the depth in which recursive templates are expanded.*

**Syntax**

**Linux OS:**
-ftemplate-depth=n

**macOS:**
-ftemplate-depth=n

**Windows OS:**
/Qtemplate-depth:n

**Arguments**

n
The number of recursive templates that are expanded.

**Default**
OFF
The compiler uses default heuristics for the depth of expansion.

**Description**
Control the depth in which recursive templates are expanded. On Linux*, this option is supported only by invoking the compiler with icpc.

**IDE Equivalent**
None

**Alternate Options**
None

**funsigned-bitfields**
*Determines whether the default bitfield type is changed to unsigned.*
Syntax
Linux OS:
-funsigned-bitfields
-fno-unsigned-bitfields

macOS:
-funsigned-bitfields
-fno-unsigned-bitfields

Windows OS:
None

Arguments
None

Default
The default bitfield type is signed.

Description
This option determines whether the default bitfield type is changed to unsigned.

IDE Equivalent
Visual Studio: None
Eclipse: Data > Change Default Bitfield Type to unsigned
Xcode: Data > Unsigned bitfield Type

Alternate Options
None

funsigned-char
Change default char type to unsigned.

Syntax
Linux OS:
-funsigned-char

macOS:
-funsigned-char

Windows OS:
None

Arguments
None
Default
OFF  Do not change default char type to unsigned.

Description
Change default char type to unsigned.

IDE Equivalent
Visual Studio: None
Eclipse: Data > Change default char type to unsigned
Xcode: Data > Unsigned char Type

Alternate Options
None

GZ
Initializes all local variables. This is a deprecated option. The replacement option is /RTC1.

Syntax
Linux OS:
None
macOS:
None
Windows OS:
/GZ

Arguments
None

Default
OFF  The compiler does not initialize local variables.

Description
This option initializes all local variables to a non-zero value. To use this option, you must also specify option /Od.

IDE Equivalent
None

Alternate Options
Linux and macOS*: None
Windows: /RTC1
H (Windows*)

*Causes the compiler to limit the length of external symbol names. This is a deprecated option. There is no replacement option.*

Syntax

Linux OS and macOS:
None

Windows OS:
/Hn

Arguments

\( n \)  
Is the maximum number of characters for external symbol names.

Default

OFF  
The compiler follows default rules for the length of external symbol names.

Description

This option causes the compiler to limit the length of external symbol names to a maximum of \( n \) characters.

IDE Equivalent

None

Alternate Options

None

help-pragmas, Qhelp-pragmas

*Displays all supported pragmas.*

Syntax

Linux OS:
- -help-pragmas

macOS:
- -help-pragmas

Windows OS:
/Qhelp-pragmas

Arguments

None

Default

OFF  
No list is displayed unless this compiler option is specified.
Description
This option displays all supported pragmas and shows their syntaxes.

IDE Equivalent
None

Alternate Options
None

**intel-extensions, Qintel-extensions**

*Enables or disables all Intel® C and Intel® C++ language extensions.*

Syntax

**Linux OS and macOS:**
- -intel-extensions
- -no-intel-extensions

**Windows OS:**
-/Qintel-extensions
-/Qintel-extensions-

Arguments
None

Default
OFF  The Intel® C and Intel® C++ language extensions are enabled.

Description
This option enables or disables all Intel® C and Intel® C++ language extensions.

If you specify the negative form of the option (see above), it disables all Intel® C and Intel® C++ language extensions.

Note that certain settings for the [Q]std compiler option can enable or disable decimal floating-point support:

- The following [Q]std settings enable decimal floating-point support: c89, gnu89 (Linux* only), gnu99 (Linux* only)
- The following [Q]std setting disables decimal floating-point support: c99

IDE Equivalent

Visual Studio: **Language > Disable All Intel Language Extensions**

Eclipse: **Language > Disable All Intel Language Extensions**

Xcode: **Language > Enable Intel C/C++ language extensions**

Alternate Options
None
See Also
std, Qstd  compiler option

J
Sets the default character type to unsigned.

Syntax
Linux OS:
None
macOS:
None
Windows OS:
/J

Arguments
None

Default
OFF  The default character type is signed

Description
This option sets the default character type to unsigned. This option has no effect on character values that are explicitly declared signed. This option sets _CHAR_UNSIGNED = 1.

IDE Equivalent
Visual Studio: Language > Default Char Unsigned
Eclipse: None
Xcode: None

Alternate Options
None

restrict, Qrestrict
Determines whether pointer disambiguation is enabled with the restrict qualifier.

Syntax
Linux OS:
-restrict
-no-restrict
macOS:
-restrict
-no-restrict
Windows OS:
/Qrestrict
/Qrestrict-

Arguments
None

Default
-no-restrict

or
/Qrestrict-

Description
This option determines whether pointer disambiguation is enabled with the restrict qualifier. Option -restrict and /Qrestrict enable the recognition of the restrict keyword as defined by the ANSI standard.

By qualifying a pointer with the restrict keyword, you assert that an object accessed by the pointer is only accessed by that pointer in the given scope. You should use the restrict keyword only when this is true. When the assertion is true, the restrict option will have no effect on program correctness, but may allow better optimization.

IDE Equivalent
Visual Studio: Language > Recognize The Restrict Keyword
Eclipse: Language > Recognize The Restrict Keyword
Xcode: Language > Recognize RESTRICT keyword

Alternate Options
None

See Also
std, Qstd compiler option

std, Qstd
Tells the compiler to conform to a specific language standard.

Syntax
Linux OS:
-std=val

macOS:
-std=val

Windows OS:
/Qstd:val
/std:val (For Microsoft* compatibility)
Arguments

Specifies the specific language standard to conform to.

The following values apply to Linux* -std and Windows* /Qstd:

- **c++2b**: Enables support for the Working Draft for ISO C++ 2023 DIS standard.
- **c++20**: Enables support for the 2020 ISO C++ DIS standard.
- **c++17**: Enables support for the 2017 ISO C++ standard with amendments.
- **c++14**: Enables support for the 2014 ISO C++ standard with amendments.
- **c++11**: Enables support for the 2011 ISO C++ standard with amendments.
- **c++98 and c++03**: Enables support for the 1998 ISO C++ standard with amendments.
- **c2x**: Enables support for the Working Draft for ISO C2x standard.
- **c18 and c17**: Enables support for the 2017 ISO C standard. Support for c17 can also be enabled by value iso9899:2017. Support for c18 can also be enabled by value iso9899:2018.
- **c11**: Enables support for the 2011 ISO C standard. Support for this standard can also be enabled by value iso9899:2011.
- **c99**: Enables support for the 1999 ISO C standard. Support for this standard can also be enabled by value iso9899:1999.
- **c90 and c89**: Enables support for the 1990 ISO C standard. Support for this standard can also be enabled by value iso9899:1990.

The following values apply only to Linux -std:

- **gnu++2b**: Enables support for the Working Draft for ISO C++ 2023 DIS standard plus GNU extensions.
- **gnu++20**: Enables support for the 2020 ISO C++ DIS standard plus GNU extensions.
- **gnu++17**: Enables support for the 2017 ISO C++ standard with amendments plus GNU extensions.
- **gnu++14**: Enables support for the 2014 ISO C++ standard with amendments plus GNU extensions.
- **gnu++11**: Enables support for the 2011 ISO C++ standard with amendments plus GNU extensions.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>gnu++98 and gnu++03</td>
<td>Enables support for the 1998 ISO C++ standard with amendments plus GNU extensions.</td>
</tr>

<td>gnu2x</td>
<td>Enables support for the Working Draft for ISO C2x standard plus GNU extensions.</td>
</tr>
<tr>
<td>gnu18 and gnu17</td>
<td>Enables support for the 2017 ISO C standard plus GNU extensions.</td>
</tr>
<tr>
<td>gnu11</td>
<td>Enables support for the 2011 ISO C standard plus GNU extensions.</td>
</tr>
<tr>
<td>gnu99</td>
<td>Enables support for the 1999 ISO C standard plus GNU extensions.</td>
</tr>
<tr>
<td>gnu90 and gnu89</td>
<td>Enables support for the 1990 ISO C standard plus GNU extensions.</td>
</tr>
</tbody>
</table>

For possible values for Microsoft*-compatible Windows* /std, see the Microsoft* documentation.

**Default**

Default for Windows option **/Qstd:**

- **OFF**
  - The compiler does not conform to a specific language standard.
- **c++14**
  - Currently, the compiler conforms to the 2014 ISO C++ standard. For the latest information, see the Microsoft* documentation.

Default for Linux option **-std** on icc (Classic C compiler):

- **c99** or **c11**
  - If using GCC5.x or higher, the compiler conforms to c99, which is the 1999 ISO C standard. If using GCC5.0 or lower, the compiler conforms to c11, which is the 2011 ISO C standard.

Default for Linux option **-std** on icpc (Classic C++ compiler):

- **varies**
  - If using GCC5.x or lower, the compiler conforms to c++98, which is the 1998 ISO C++ standard. If using GCC6.0 to GCC11.0, the compiler conforms to c++14, which is the 2014 ISO C++ standard. If using GCC11.1 or higher, the compiler conforms to c++17, which is the 2017 ISO C++ standard.

**Description**

This option tells the compiler to conform to a specific language standard.

**IDE Equivalent**

**Visual Studio**

Visual Studio: **Language > C/C++ Language Support**

**Eclipse**

Eclipse: **Language > ANSI Conformance**

**Xcode**

Xcode: **Language > C Language Dialect and C++ Language Dialect**

**Alternate Options**

None
**strict-ansi**
*Tells the compiler to implement strict ANSI conformance dialect.*

**Syntax**

**Linux OS:**
- `strict-ansi`

**macOS:**
- `strict-ansi`

**Windows OS:**
None

**Arguments**
None

**Default**
OFF  The compiler conforms to default standards.

**Description**
This option tells the compiler to implement strict ANSI conformance dialect. On Linux* systems, if you need to be compatible with gcc, use the `-ansi` option.

This option sets option `fmath-errno`, which tells the compiler to assume that the program tests `errno` after calls to math library functions. This restricts optimization because it causes the compiler to treat most math functions as having side effects.

**IDE Equivalent**
Visual Studio: None

Eclipse: **Language > ANSI Conformance**

Xcode: **Language > C Language Dialect and Language > C++ Language Dialect**

**Alternate Options**
None

**vd**
*Enables or suppresses hidden vtordisp members in C++ objects.*

**Syntax**

**Linux OS:**
None

**macOS:**
None
Windows OS:
/vdn

Arguments

Possible values are:

\( n \)

- **0**: Suppresses the creation of the hidden `vtordisp` members in C++ objects.
- **1**: Enables the creation of hidden `vtordisp` members in C++ objects when they are necessary.
- **2**: Enables the hidden `vtordisp` members for all virtual base classes with virtual functions. This setting is recommended in the following cases:
  - When the only virtual function in your virtual base class is a destructor
  - When you want to ensure correct performance of the `dynamic_cast` operator on a partially-constructed object

Default

/vd1

The compiler enables the creation of hidden `vtordisp` members in C++ objects when they are necessary.

Description

This option enables or suppresses hidden `vtordisp` members in C++ objects.

This is a compatibility option for the Microsoft Visual C++* option `/vdn`. For full details about this compiler option, see the Microsoft* documentation.

IDE Equivalent

None

Alternate Options

None

vmb

Selects the smallest representation that the compiler uses for pointers to members.

Syntax

Linux OS:
None

macOS:
None
Windows OS:
/vmb

Arguments
None

Default
OFF The compiler uses default rules to represent pointers to members.

Description
This option selects the smallest representation that the compiler uses for pointers to members. Use this option if you define each class before you declare a pointer to a member of the class.

IDE Equivalent
None

Alternate Options
None

/vmg
Selects the general representation that the compiler uses for pointers to members.

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/vmg

Arguments
None

Default
OFF The compiler uses default rules to represent pointers to members.

Description
This option selects the general representation that the compiler uses for pointers to members. Use this option if you declare a pointer to a member before you define the corresponding class.

IDE Equivalent
None

Alternate Options
None
**vmm**

*Enables pointers to class members with single or multiple inheritance.*

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/vmm

**Arguments**

None

**Default**

OFF  
The compiler uses default rules to represent pointers to members.

**Description**

This option enables pointers to class members with single or multiple inheritance. To use this option, you must also specify option `/vmg`.

**IDE Equivalent**

None

**Alternate Options**

None

---

**vms**

*Enables pointers to members of single-inheritance classes.*

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/vms

**Arguments**

None
Default

OFF The compiler uses default rules to represent pointers to members.

Description

This option enables pointers to members of single-inheritance classes. To use this option, you must also specify option /v/mg.

IDE Equivalent

None

Alternate Options

None

x (type option)

All source files found subsequent to -x type will be recognized as a particular type.

Syntax

Linux OS:
-x type

macOS:
-x type

Windows OS:
None

Arguments

type is the type of source file. Possible values are:

c++ C++ source file

c++-header C++ header file

c++-cpp-output C++ pre-processed file

c C source file

c-header C header file

cpp-output C pre-processed file

assembler Assembly file

assembler-with-cpp Assembly file that needs to be preprocessed

none Disable recognition, and revert to file extension

Default

none Disable recognition and revert to file extension.
Description
All source files found subsequent to \(-x\)type will be recognized as a particular type.

IDE Equivalent
None

Alternate Options
None

Example
Suppose you want to compile the following C and C++ source files whose extensions are not recognized by the compiler:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Language</th>
</tr>
</thead>
<tbody>
<tr>
<td>file1.c99</td>
<td>C</td>
</tr>
<tr>
<td>file2.cplusplus</td>
<td>C++</td>
</tr>
</tbody>
</table>

We will also include these files whose extensions are recognized:

<table>
<thead>
<tr>
<th>File Name</th>
<th>Language</th>
</tr>
</thead>
<tbody>

The command-line invocation using the \(-x\) option follows:

```
icpc -x c file1.c99 -x c++ file2.cplusplus -x none file3.c file4.cpp```

Za
Disables Microsoft Visual C++ compiler language extensions.

Syntax

Linux OS and macOS:
None

Windows OS:
/Za

Arguments
None

Default
OFF The compiler provides support for extended ANSI C.

Description
Disables Microsoft Visual C++ compiler language extensions.
IDE Equivalent
Visual Studio: **Language > Disable Language Extensions**
Eclipse: None
Xcode: None

Alternate Options
None

See Also
Ze compiler option
Zc compiler option

Zc
*Lets you specify ANSI C standard conformance for certain language features.*

Syntax

Linux OS:
None

macOS:
None

Windows OS:

/\Zc:arg1[,arg2]

Arguments

arg

Is the language feature for which you want standard conformance.
The settings are compatible with Microsoft® settings for option /Zc.
For a list of supported settings, see the table in the Description section of this topic.

Default

varies

See the table in the Description section of this topic.

Description

This option lets you specify ANSI C standard conformance for certain language features.
If you do not want the default behavior for one or more of the settings, you must specify the negative form of the setting. For example, if you do not want the forScope or wchar_t default behavior, you should specify /Zc:forScope-,wchar_t-.

The following table shows the supported Microsoft settings for option /Zc.

<table>
<thead>
<tr>
<th>/Zc setting name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto[-]</td>
<td>Enforces compliance to the new standard meaning for auto (default). Disabled by /Zc:auto-.</td>
</tr>
<tr>
<td>/Zc setting name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| forScope[-]      | Enforces standard compliance in for-loop scope (default). Disabled by /Zc:forScope-.
| inline[-]        | Controls inline expansion. Disabled by /Zc:inline- (default).
| strictStrings[-] | Enforces const qualification for string literals. Disabled by /Zc:strictStrings- (default).
| threadSafeInit[-]| Enables thread-safe initialization of local statics (default). Disabled by /Zc:threadSafeInit-.
| throwingNew[-]   | Enables link with the operator new implementation. Disabled by /Zc:throwingNew- (default).
| trigraphs[-]     | Enables trigraph character sequences. Disabled by /Zc:trigraphs- (default).
| wchar_t[-]       | Specifies that wchar_t is a native data type (default). Disabled by /Zc:wchar_t-.

**IDE Equivalent**

Visual Studio: **Language > Treat wchar_t as Built-in Type / Force Conformance In For Loop Scope**

**Language > Enforce type conversion rules (rvalueCast)**

Eclipse: None

Xcode: None

**Alternate Options**

None

**Ze**

*Enables Microsoft Visual C++* compiler language extensions. This is a deprecated option. There is no replacement option.

**Syntax**

**Linux OS and macOS:**

None

**Windows OS:**

/Zc

**Arguments**

None

**Default**

ON The compiler provides support for extended ANSI C.
**Zg**

_Tells the compiler to generate function prototypes._

_This is a deprecated option. There is no replacement option._

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/\_Zg

**Arguments**

None

**Default**

OFF  The compiler does not create function prototypes.

**Description**

This option tells the compiler to generate function prototypes.

**IDE Equivalent**

None

**Alternate Options**

None

**Zp**

_Specifies alignment for structures on byte boundaries._
**Syntax**

Linux OS:

-Zp[n]

macOS:

-Zp[n]

Windows OS:

/Zp[n]

**Arguments**

*n*  
Is the byte size boundary. Possible values are 1, 2, 4, 8, or 16.

**Default**

Zp16  
Structures are aligned on either size boundary 16 or the boundary that will naturally align them.

**Description**

This option specifies alignment for structures on byte boundaries.  
If you do not specify *n*, you get Zp16.

**IDE Equivalent**

Visual Studio: Code Generation > Struct Member Alignment

Eclipse: Data > Structure Member Alignment

Xcode: Data > Structure Member Alignment

**Alternate Options**

None

**Zs**

*Tells the compiler to check only for correct syntax.*

**Syntax**

Linux OS:

None

macOS:

None

Windows OS:

/Zs

**Arguments**

None

**Default**

OFF  
Normal compilation is performed.
Description
This option tells the compiler to check only for correct syntax.

IDE Equivalent
None

Alternate Options
Linux: -syntax, -fsyntax-only
Windows: None

Data Options

align
Determines whether variables and arrays are naturally aligned.

Architecture Restrictions
Only available on IA-32 architecture

Syntax
Linux OS:
-align
-noalign

macOS:
-align
-noalign

Windows OS:
None

Arguments
None

Default
-noalign Variables and arrays are aligned according to the gcc model, which means they are aligned to 4-byte boundaries.

Description
This option determines whether variables and arrays are naturally aligned. Option -align forces the following natural alignment:

<table>
<thead>
<tr>
<th>Type</th>
<th>Alignment</th>
</tr>
</thead>
<tbody>
<tr>
<td>double</td>
<td>8 bytes</td>
</tr>
<tr>
<td>long long</td>
<td>8 bytes</td>
</tr>
<tr>
<td>Type</td>
<td>Alignment</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------</td>
</tr>
<tr>
<td>long double</td>
<td>16 bytes</td>
</tr>
</tbody>
</table>

If you are not interacting with system libraries or other libraries that are compiled without `-align`, this option can improve performance by reducing misaligned accesses. This option can also be specified as `-m[no-]align-double`. The options are equivalent.

**Caution**
If you are interacting with compatible libraries, this option can improve performance by reducing misaligned accesses. However, if you are interacting with noncompatible libraries or libraries that are compiled without option `-align`, your application may not perform as expected.

**IDE Equivalent**
None

**Alternate Options**
None

**auto-ilp32, Qauto-ilp32**
*Instructs the compiler to analyze the program to determine if there are 64-bit pointers that can be safely shrunk into 32-bit pointers and if there are 64-bit longs (on Linux* systems) that can be safely shrunk into 32-bit longs.*

**Architecture Restrictions**
Only available on Intel® 64 architecture

**Syntax**

**Linux OS and macOS:**
- `-auto-ilp32`

**Windows OS:**
- `/Qauto-ilp32`

**Arguments**
None

**Default**
OFF

The optimization is not attempted.

**Description**
This option instructs the compiler to analyze the program to determine if there are 64-bit pointers that can be safely shrunk into 32-bit pointers and if there are 64-bit longs (on Linux* systems) that can be safely shrunk into 32-bit longs.

On macOS* systems, you must also specify option `-no-pie` for the optimization to occur.
For this option to be effective, the compiler must be able to optimize using the `ipo` option and must be able to analyze all library calls or external calls the program makes. This option has no effect on Linux* systems unless you specify setting SSE3 or higher for option `-x`.

This option requires that the size of the program executable never exceeds $2^{32}$ bytes and all data values can be represented within 32 bits. If the program can run correctly in a 32-bit system, these requirements are implicitly satisfied. If the program violates these size restrictions, unpredictable behavior may occur.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

- `auto-p32` compiler option
- `pie` compiler option
- `ipo`, `Qipo` compiler option
- `parallel`, `Qparallel` compiler option
- `x`, `Qx` compiler option

### auto-p32

*Instructs the compiler to analyze the program to determine if there are 64-bit pointers that can be safely shrunk to 32-bit pointers.*

**Architecture Restrictions**

Only available on Intel® 64 architecture

**Syntax**

**Linux OS and macOS:**

```
-auto-p32
```

**Windows OS:**

None

**Arguments**

None

**Default**

OFF The optimization is not performed.

**Description**

This option instructs the compiler to analyze and transform the program so that 64-bit pointers are shrunk to 32-bit pointers, wherever it is legal and safe to do so.

On macOS* systems, you must also specify option `-no-pie` for the optimization to occur.
For this option to be effective, the compiler must be able to optimize using the -ipo option and it must be able to analyze all library calls or external calls the program makes. This option has no effect unless you specify setting SSE3 or higher for option -x.

The application cannot exceed a 32-bit address space; otherwise, unpredictable results can occur.

**check-pointers, Qcheck-pointers**

Determines whether the compiler checks bounds for memory access through pointers.

**Syntax**

**Linux OS:**

- check-pointers=keyword

**macOS:**

None

**Windows OS:**

/Qcheck-pointers:keyword

**Arguments**

*keyword*

Specifies what type of bounds checking occurs. Possible values are:

- none
  - Disables bounds checking. This is the default.
- rw
  - Checks bounds for reads and writes through pointers.
- write
  - Checks bounds for only writes through pointers.

**Default**

- check-pointers=none
  - or /Qcheck-pointers:none
  - No bounds checking occurs for memory access through pointers.
**Description**

This option determines whether the compiler checks bounds for memory access through pointers. It enables checking of all indirect accesses through pointers, and all array accesses.

The compiler may optimize these checks away when it can determine that an access is safe.

When `rw` or `write` is specified, the `check-pointers-undimensioned` option is set and dimensioned and undimensioned arrays are checked.

If you do not want undimensioned arrays checked, you must specify option the negative form of the option (see Syntax above).

This pointer checker feature requires installation of another product. For more information, see Feature Requirements.

**IDE Equivalent**

Visual Studio: **Code Generation > Check Pointers**

Eclipse: **Code Generation > Check Pointers**

Xcode: None

**Alternate Options**

None

**See Also**

  - compiler option
- `check-pointers-dangling`, `Qcheck-pointers-dangling`
  - compiler option

**check-pointers-dangling, Qcheck-pointers-dangling**

Determines whether the compiler checks for dangling pointer references.

**Syntax**

**Linux OS:**

- `-check-pointers-dangling=keyword`

**macOS:**

None

**Windows OS:**

- `/Qcheck-pointers-dangling:keyword`

**Arguments**

- `keyword`

  Specifies what type of dangling pointer checking occurs. Possible values are:

  - `none`
    - Disables checking for dangling pointer references. This is the default.
  - `heap`
    - Checks for dangling pointer references on the heap.
Checks for dangling pointer references on the stack.

all  Checks for dangling pointer references on the heap and the stack.

Default

-check-pointers-dangling=none  No checking occurs for dangling pointer references.
or
/Qcheck-pointers-dangling:none

Description
This option determines whether the compiler checks for dangling pointer references.
To use this option, you must also specify the [Q]check-pointers option.
This pointer checker feature requires installation of another product. For more information, see Feature Requirements.

IDE Equivalent
Visual Studio: Code Generation > Check Dangling Pointers
Eclipse: Code Generation > Check Dangling Pointers
Xcode: None

Alternate Options
None

See Also
check-pointers, Qcheck-pointers

check-pointers-mpx, Qcheck-pointers-mpx
Determines whether the compiler checks bounds for memory access through pointers on processors that support Intel® Memory Protection Extensions (Intel® MPX).

Syntax
Linux OS:
-check-pointers-mpx=keyword

macOS:
None

Windows OS:
/Qcheck-pointers-mpx:keyword

Arguments
keyword  Specifies what type of bounds checking occurs. Possible values are:
Disables bounds checking. This is the default.

rw
Checks bounds for reads and writes through pointers.

write
Checks bounds for only writes through pointers.

Default

-nocheck-pointers-mpx=none  or /Qcheck-pointers-mpx:none
No bounds checking occurs for memory access through pointers on processors that support Intel® MPX.

Description
This option determines whether the compiler checks bounds for memory access through pointers on processors that support Intel® MPX. It enables checking of all indirect accesses through pointers, and all array accesses.

The compiler may optimize these checks away when it can determine that an access is safe.

If you specify option [Q]check-pointers along with option [Q]check-pointers-mpx, option [Q]check-pointers-mpx takes precedence.

If you specify [Q]check-pointers-mpx, you cannot specify option [Q]check-pointers-dangling.

NOTE
This feature requires supporting hardware, OS, and library support. Intel® MPX bounds exceptions are hardware exceptions that are handled by the OS and run-time library, similar to the way that a null pointer exception is handled. Pointer Checker detailed reports and report control functions are not enabled with Intel® MPX, because these require overriding the OS exception handling.

For more details, see the document titled: Intel® Memory Protection Extensions Enabling Guide, which is located at http://intel.ly/1QIUdjN

This pointer checker feature requires installation of another product. For more information, see Feature Requirements.

IDE Equivalent
Visual Studio: Code Generation > Check Pointers
Eclipse: Code Generation > Check Pointers
Xcode: None

Alternate Options
None

See Also
check-pointers, Qcheck-pointers
compiler option
check-pointers-undimensioned, Qcheck-pointers-undimensioned
compiler option
check-pointers-narrowing, Qcheck-pointers-narrowing

Determines whether the compiler enables or disables the narrowing of pointers to structure fields.

Syntax

Linux OS:
- check-pointers-narrowing
- no-check-pointers-narrowing

macOS:
None

Windows OS:
/Qcheck-pointers-narrowing
/Qcheck-pointers-narrowing-

Arguments

None

Default

- check-pointers-narrowing
  or /Qcheck-pointers-narrowing

The compiler enables the narrowing of pointers to structure fields.

Description

This option determines whether the compiler enables or disables the narrowing of pointers to structure fields. Narrowing restricts a field pointer so that it can only legally point to that field.

To use this option, you must also specify the [Q]check-pointers option.

Disabling this feature can improve Pointer Checker compatibility with non-ANSI compliant code.

To disable the narrowing of pointers to structure fields, specify the negative form of the option (see Syntax above).

This pointer checker feature requires installation of another product. For more information, see Feature Requirements.

IDE Equivalent

None

Alternate Options

None

See Also

check-pointers, Qcheck-pointers
  compiler option
check-pointers-undimensioned, Qcheck-pointers-undimensioned

Determines whether the compiler checks bounds for memory access through arrays that are declared without dimensions.

**Syntax**

**Linux OS:**
- `-check-pointers-undimensioned`
- `-no-check-pointers-undimensioned`

**macOS:**
None

**Windows OS:**
/Qcheck-pointers-undimensioned
/Qcheck-pointers-undimensioned-

**Arguments**

None

**Default**

- `-check-pointers-undimensioned`
  or
  /Qcheck-pointers-undimensioned

  Bounds checking occurs for memory access through arrays that are declared without dimensions. This checking occurs for both dimensioned and undimensioned arrays.

**Description**

This option determines whether the compiler checks bounds for memory access through arrays that are declared without dimensions.

To use this option, you must also specify the [Q]check-pointers option.

This pointer checker feature requires installation of another product. For more information, see Feature Requirements.

The default setting, [Q]check-pointers-undimensioned, can cause link time errors for multiple definitions for non-standard code and it can cause linker warnings for undefined symbols when linking library code that has not been compiled with pointer checking enabled. In both of these cases, the symbols will contain the string `cp_array_end`.

To prevent these issues, disable the checking of undimensioned arrays, by specifying the negative form of the option (see Syntax above).

Note that even if you specify the negative form of the option, dimensioned arrays are always checked.

**IDE Equivalent**

**Windows**

Visual Studio: Code Generation > Turn off Checking for Undimensioned Arrays

**Linux**

Eclipse: Code Generation > Turn off Checking for Undimensioned Arrays
OS X
Xcode: None

Alternate Options
None

See Also
check-pointers, Qcheck-pointers
  compiler option

falign-functions, Qfnalign
* Tells the compiler to align functions on an optimal byte boundary. *

Syntax

Linux OS and macOS:
-falign-functions[\=n]
-fno-align-functions

Windows OS:
/Qfnalign[:n]
/Qfnalign-

Arguments

$n$

Is an optional positive integer initialization expression indicating the number of bytes for the minimum alignment boundary. It tells the compiler to align functions on a power-of-2 byte boundary. If you do not specify $n$, the compiler aligns the start of functions on 16-byte boundaries.

The $n$ must be a positive integer less than or equal to 4096. If you specify a value that is not a power of 2, $n$ will be rounded up to the nearest power of 2. For example, if 23 is specified for $n$, functions will be aligned on 32 byte boundaries.

Default

-fno-align-functions
or /Qfnalign-

The compiler aligns functions on 2-byte boundaries. This is the same as specifying -falign-functions=2 (Linux* and macOS*) or /Qfnalign:2 (Windows*).

Description

This option tells the compiler to align functions on an optimal byte boundary. If you do not specify $n$, the compiler aligns the start of functions on 16-byte boundaries.

IDE Equivalent
None

Alternate Options
None
**falign-loops, Qalign-loops**  
*Aligns loops to a power-of-two byte boundary.*

**Syntax**

**Linux OS and macOS:**

```bash
-falign-loops [=n]
-fno-align-loops
```

**Windows OS:**

```bash
/Qalign-loops [:n]
/Qalign-loops-
```

**Arguments**

$n$ is the optional number of bytes for the minimum alignment boundary. It must be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on.  

If you specify 1 for $n$, no alignment is performed; this is the same as specifying the negative form of the option.  

If you do not specify $n$, the default alignment is 16 bytes.

**Default**

- `fno-align-loops`

  or

- `/Qalign-loops-`

**Description**

This option aligns loops to a power-of-two boundary. This alignment may improve performance.  
It can be affected by the pragma `code_align` and attribute `code_align`.  

If code is compiled with the `falign-loops=m` (Linux* and macOS*) or `/Qalign-loops:m` (Windows*) option and a `code_align:n` pragma precedes a loop, the loop is aligned on a max (m, n) byte boundary. If a function is modified by a `code_align:k` pragma and a `code_align:n` pragma precedes a loop, then both the function and the loop are aligned on a max (k, n) byte boundary.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

`falign-functions, Qfnalign`  compiler option

**falign-stack**

*Tells the compiler the stack alignment to use on entry to routines.*
Architecture Restrictions
Only available on IA-32 architecture

Syntax
Linux OS:
-falign-stack=mode

macOS:
None

Windows OS:
None

Arguments
mode

Is the method to use for stack alignment. Possible values are:

- **assume-4-byte**
  Tells the compiler to assume the stack is aligned on 4-byte boundaries. The compiler can dynamically adjust the stack to 16-byte alignment if needed.

- **maintain-16-byte**
  Tells the compiler to not assume any specific stack alignment, but attempt to maintain alignment in case the stack is already aligned. The compiler can dynamically align the stack if needed. This setting is compatible with gcc.

- **assume-16-byte**
  Tells the compiler to assume the stack is aligned on 16-byte boundaries and to continue to maintain 16-byte alignment. This setting is compatible with gcc.

Default
-falign-stack=assume-16-byte

The compiler assumes the stack is aligned on 16-byte boundaries and continues to maintain 16-byte alignment.

Description
This option tells the compiler the stack alignment to use on entry to routines.

IDE Equivalent
None

Alternate Options
None

fcommon
Determines whether the compiler treats common symbols as global definitions.
**Syntax**

**Linux OS:**
- `-fcommon`
- `-fno-common`

**macOS:**
- `-fcommon`
- `-fno-common`

**Windows OS:**
None

**Arguments**
None

**Default**
- `-fcommon` The compiler does not treat common symbols as global definitions.

**Description**
This option determines whether the compiler treats common symbols as global definitions and to allocate memory for each symbol at compile time.

The option `-fno-common` tells the compiler to treat common symbols as global definitions. When using this option, you can only have a common variable declared in one module; otherwise, a link time error will occur for multiple defined symbols.

Normally, a file-scope declaration with no initializer and without the `extern` or `static` keyword "int i;" is represented as a common symbol. Such a symbol is treated as an external reference. However, if no other compilation unit has a global definition for the name, the linker allocates memory for it.

**IDE Equivalent**
Visual Studio: None
Eclipse: Data > Allow gprel Addressing of Common Data Variables
Xcode: Data > Allow gprel Addressing of Common Data Variables

**Alternate Options**
None

**fextend-arguments, Qextend-arguments**

Controls how scalar integer arguments are extended in calls to unprototyped and varargs functions.

**Syntax**

**Linux OS and macOS:**
- `-fextend-arguments=n`

**Windows OS:**
- `/Qextend-arguments:n`
Arguments

Specifies the extension for the integer parameters. Possible values are:

32  Causes unprototyped integer parameters to be extended to 32 bits.
64  Causes unprototyped integer parameters to be extended to 64 bits. This value is only available on Intel® 64 architecture.

Default

Unprototyped integer parameters are extended to 32 bits.

-fextend-arguments=32  or /Qextend-arguments:32

Description

This option controls how scalar integer arguments are extended in calls to unprototyped and varargs functions.

IDE Equivalent

None

Alternate Options

None

fkeep-static-consts, Qkeep-static-consts

Tells the compiler to preserve allocation of variables that are not referenced in the source.

Syntax

Linux OS:
-fkeep-static-consts
-fno-keep-static-consts

macOS:
-fkeep-static-consts
-fno-keep-static-consts

Windows OS:
/Qkeep-static-consts
/Qkeep-static-consts-

Arguments

None
Default

- fno-keep-static-consts
  or /Qkeep-static-consts-

If a variable is never referenced in a routine, the variable is discarded unless optimizations are disabled by option -O0 (Linux* and macOS*) or /Od (Windows*).

Description

This option tells the compiler to preserve allocation of variables that are not referenced in the source.
The negated form can be useful when optimizations are enabled to reduce the memory usage of static data.

IDE Equivalent

None

Alternate Options

None

fmath-errno

*Tells the compiler that errno can be reliably tested after calls to standard math library functions.*

Syntax

Linux OS:

- fmath-errno
- fno-math-errno

macOS:

- fmath-errno
- fno-math-errno

Windows OS:

None

Arguments

None

Default

- fno-math-errno

The compiler assumes that the program does not test errno after calls to standard math library functions.

Description

This option tells the compiler to assume that the program tests errno after calls to math library functions. This restricts optimization because it causes the compiler to treat most math functions as having side effects.

Option -fno-math-errno tells the compiler to assume that the program does not test errno after calls to math library functions. This frequently allows the compiler to generate faster code. Floating-point code that relies on IEEE exceptions instead of errno to detect errors can safely use this option to improve performance.
fminshared
Specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

Syntax
Linux OS and macOS:
-fminshared

Windows OS:
None

Arguments
None

Default
OFF Source files are compiled together to form a single object file.

Description
This option specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

This option allows the compiler to optimize references to defined symbols without special visibility settings. To ensure that external and common symbol references are optimized, you need to specify visibility hidden or protected by using the -fvisibility, -fvisibility-hidden, or -fvisibility-protected option.

Also, the compiler does not need to generate position-independent code for the main program. It can use absolute addressing, which may reduce the size of the global offset table (GOT) and may reduce memory traffic.

IDE Equivalent
None

Alternate Options
None

See Also
fvisibility compiler option
**fmudflap**

The compiler instruments risky pointer operations to prevent buffer overflows and invalid heap use. This is a deprecated option. There is no replacement option. You can consider using the Pointer Checker options (such as option `-check-pointers`).

**Syntax**

**Linux OS:**

- `-fmudflap`

**macOS:**

None

**Windows OS:**

None

**Arguments**

None

**Default**

OFF The compiler does not instrument risky pointer operations.

**Description**

The compiler instruments risky pointer operations to prevent buffer overflows and invalid heap use. It requires gcc 4.0 or newer.

When using this compiler option, you must specify linker option `-lmudflap` in the link command line to resolve references to the `libmudflap` library.

**IDE Equivalent**

None

**Alternate Options**

None

---

**fpack-struct**

Specifies that structure members should be packed together.

**Syntax**

**Linux OS:**

- `-fpack-struct`

**macOS:**

- `-fpack-struct`

**Windows OS:**

None
Arguments
None

Default
OFF

Description
Specifies that structure members should be packed together.

**NOTE**
Using this option may result in code that is not usable with standard (system) c and C++ libraries.

IDE Equivalent
None

Alternate Options
Linux and macOS*: `-Zp1`
Windows: None

**fpascal-strings**
*Tells the compiler to allow for Pascal-style string literals.*

Architecture Restrictions
Only available on IA-32 architecture

Syntax
**Linux OS:**
`-fpascal-strings`

**macOS:**
None

**Windows OS:**
None

Arguments
None

Default
OFF

The compiler does not allow for Pascal-style string literals.

Description
Tells the compiler to allow for Pascal-style string literals.
IDE Equivalent
Visual Studio: None
Eclipse: None
Xcode: **Data > Recognize Pascal Strings**

Alternate Options
None

**fpic**
*Determines whether the compiler generates position-independent code.*

Syntax
Linux OS:
- `fpic`
- `fno-pic`

macOS:
- `fpic`
- `fno-pic`

Windows OS:
None

Arguments
None

Default
- `fno-pic` The compiler does not generate position-independent code.

Description
This option determines whether the compiler generates position-independent code.

Option `-fpic` specifies full symbol preemption. Global symbol definitions as well as global symbol references get default (that is, preemptable) visibility unless explicitly specified otherwise.

Option `-fpic` must be used when building shared objects.

This option can also be specified as `-fPIC`.

IDE Equivalent
Visual Studio: None
Eclipse: **Code Generation > Generate Position Independent Code**
Xcode: None

Alternate Options
None
**fpie**
*Tells the compiler to generate position-independent code. The generated code can only be linked into executables.*

**Syntax**

**Linux OS:**

- `-fpie`

**macOS:**

None

**Windows OS:**

None

**Arguments**

None

**Default**

OFF

The compiler does not generate position-independent code for an executable-only object.

**Description**

This option tells the compiler to generate position-independent code. It is similar to `-fpic`, but code generated by `-fpie` can only be linked into an executable.

Because the object is linked into an executable, this option causes better optimization of some symbol references.

To ensure that run-time libraries are set up properly for the executable, you should also specify option `-pie` to the compiler driver on the link command line.

Option `-fpie` can also be specified as `-fPIE`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

`fpic`  
compiler option

`pie`  
compiler option

**freg-struct-return**
*Tells the compiler to return struct and union values in registers when possible.*
Architecture Restrictions
Only available on IA-32 architecture

Syntax
Linux OS:
-\texttt{-freg-struct-return}

macOS:
None

Windows OS:
None

Arguments
None

Default
OFF

Description
This option tells the compiler to return \texttt{struct} and \texttt{union} values in registers when possible.

IDE Equivalent
None

Alternate Options
None

\texttt{fstack-protector}
\textit{Enables or disables stack overflow security checks for certain (or all) routines.}

Syntax
Linux OS:
-\texttt{-fstack-protector[-keyword]}
-\texttt{-fno-stack-protector[-keyword]}

macOS:
-\texttt{-fstack-protector[-keyword]}
-\texttt{-fno-stack-protector[-keyword]}

Windows OS:
None

Arguments
\textit{keyword} Possible values are:
When option `-fstack-protector-strong` is specified, it enables stack overflow security checks for routines with any type of buffer.

When option `-fstack-protector-all` is specified, it enables stack overflow security checks for every routine.

If no `-keyword` is specified, option `-fstack-protector` enables stack overflow security checks for routines with a string buffer.

Default

`-fno-stack-protector`,
`-fno-stack-protector-strong`

No stack overflow security checks are enabled for the relevant routines.

`-fno-stack-protector-all`

No stack overflow security checks are enabled for any routines.

Description

This option enables or disables stack overflow security checks for certain (or all) routines. A stack overflow occurs when a program stores more data in a variable on the execution stack than is allocated to the variable. Writing past the end of a string buffer or using an index for an array that is larger than the array bound could cause a stack overflow and security violations.

The `-fstack-protector` options are provided for compatibility with gcc. They use the gcc/glibc implementation when possible. If the gcc/glibc implementation is not available, they use the Intel implementation.

For an Intel-specific version of this feature, see option `-fstack-security-check`.

IDE Equivalent

None

Alternate Options

None

See Also

`fstack-security-check` compiler option
`GS` compiler option

`fstack-security-check`

Determines whether the compiler generates code that detects some buffer overruns.

Syntax

Linux OS:

- `-fstack-security-check`
- `-fno-stack-security-check`

macOS:

- `-fstack-security-check`
- `-fno-stack-security-check`
**Windows OS:**
None

**Arguments**
None

**Default**

-`-fno-stack-security-check`  
The compiler does not detect buffer overruns.

**Description**
This option determines whether the compiler generates code that detects some buffer overruns that overwrite the return address. This is a common technique for exploiting code that does not enforce buffer size restrictions.

This option always uses an Intel implementation.

For a gcc-compliant version of this feature, see option `fstack-protector`.

**IDE Equivalent**
None

**Alternate Options**

Linux and macOS*: None

Windows: `/GS`

**See Also**

`fstack-protector` compiler option

`GS` compiler option

**fvisibility**

*Specifies the default visibility for global symbols or the visibility for symbols in a file.*

**Syntax**

**Linux OS:**

- `-fvisibility=keyword`
- `-fvisibility-keyword=filename`

**macOS:**

- `-fvisibility=keyword`
- `-fvisibility-keyword=filename`

**Windows OS:**
None

**Arguments**

`keyword`  
Specifies the visibility setting. Possible values are:
Sets visibility to default.

Sets visibility to extern.

Sets visibility to hidden.

Sets visibility to internal.

Sets visibility to protected. This value is not available on macOS* systems.

**filename**

Is the pathname of a file containing the list of symbols whose visibility you want to set. The symbols must be separated by whitespace (spaces, tabs, or newlines).

**Default**

```
-fvisibility=default
```

The compiler sets visibility of symbols to default.

**Description**

This option specifies the default visibility for global symbols (syntax `-fvisibility=keyword`) or the visibility for symbols in a file (syntax `-fvisibility-keyword=filename`).

Visibility specified by `-fvisibility-keyword=filename` overrides visibility specified by `-fvisibility=keyword` for symbols specified in a file.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-fvisibility=default</code></td>
<td>Sets visibility of symbols to default. This means other components can reference the symbol, and the symbol definition can be overridden (preempted) by a definition of the same name in another component.</td>
</tr>
<tr>
<td><code>-fvisibility-default=filename</code></td>
<td></td>
</tr>
<tr>
<td><code>-fvisibility=extern</code></td>
<td>Sets visibility of symbols to extern. This means the symbol is treated as though it is defined in another component. It also means that the symbol can be overridden by a definition of the same name in another component.</td>
</tr>
<tr>
<td><code>-fvisibility-extern=filename</code></td>
<td></td>
</tr>
<tr>
<td><code>-fvisibility=hidden</code></td>
<td>Sets visibility of symbols to hidden. This means that other components cannot directly reference the symbol. However, its address may be passed to other components indirectly.</td>
</tr>
<tr>
<td><code>-fvisibility-hidden=filename</code></td>
<td></td>
</tr>
<tr>
<td><code>-fvisibility=internal</code></td>
<td>Sets visibility of symbols to internal. This means that the symbol cannot be referenced outside its defining component, either directly or indirectly. The affected functions can never be called from another module, including through function pointers.</td>
</tr>
<tr>
<td><code>-fvisibility-internal=filename</code></td>
<td></td>
</tr>
<tr>
<td><code>-fvisibility=protected</code></td>
<td>Sets visibility of symbols to protected. This means other components can reference the symbol, but it cannot be overridden by a definition of the same name in another component. This value is not available on macOS* systems.</td>
</tr>
<tr>
<td><code>-fvisibility-protected=filename</code></td>
<td></td>
</tr>
</tbody>
</table>
If an `-fvisibility` option is specified more than once on the command line, the last specification takes precedence over any others.

If a symbol appears in more than one visibility `filename`, the setting with the least visibility takes precedence.

The following shows the precedence of the visibility settings (from greatest to least visibility):

- `extern`
- `default`
- `protected`
- `hidden`
- `internal`

Note that `extern` visibility only applies to functions. If a variable symbol is specified as `extern`, it is assumed to be `default`.

### IDE Equivalent

#### Windows
Visual Studio: None

#### Linux
Eclipse: **Data > Default Symbol Visibility**

#### OS X
Xcode: **Data > Default Symbol Visibility**

### Alternate Options
None

### Example

A file named `prot.txt` contains symbols a, b, c, d, and e. Consider the following:

```bash
-fvisibility-protected=prot.txt
```

This option sets protected visibility for all the symbols in the file. It has the same effect as specifying `fvisibility=protected` in the declaration for each of the symbols.

### `-fvisibility-inlines-hidden`

*Causes inline member functions (those defined in the class declaration) to be marked hidden.*

### Architecture Restrictions

Only available on IA-32 architecture

### Syntax

#### Linux OS:

`-fvisibility-inlines-hidden`

#### macOS:

None

#### Windows OS:

None
Arguments
None

Default
OFF The compiler does not cause inline member functions to be marked hidden.

Description
Causes inline member functions (those defined in the class declaration) to be marked hidden. This option is particularly useful for templates.

IDE Equivalent
None

Alternate Options
None

fzero-initialized-in-bss, Qzero-initialized-in-bss
Determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.

Syntax
Linux OS:
-fzero-initialized-in-bss
-fno-zero-initialized-in-bss

macOS:
-fzero-initialized-in-bss
-fno-zero-initialized-in-bss

Windows OS:
/Qzero-initialized-in-bss
/Qzero-initialized-in-bss-

Arguments
None

Default
-fno-zero-initialized-in-bss or /Qzero-initialized-in-bss -

Variables explicitly initialized with zeros are placed in the BSS section. This can save space in the resulting code.

Description
This option determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.

If option -fno-zero-initialized-in-bss (Linux* and macOS*) or /Qzero-initialized-in-bss- (Windows*) is specified, the compiler places in the DATA section any variables that are initialized to zero.

<td>Eclipse: None</td>
<td></td>
<td></td>
<td></td>
<td>Xcode: None</td>
<td></td>
</tr>
</tbody>
</table>
Syntax

Linux OS:
None

macOS:
None

Windows OS:
/Gs[n]

Arguments

\( n \)

Is the number of bytes that local variables and compiler temporaries can occupy before stack checking is activated. This is called the threshold.

Default

/Gs

Stack checking occurs for routines that require more than 4KB (4096 bytes) of stack space. This is also the default if you do not specify \( n \).

Description

This option lets you control the threshold at which the stack checking routine is called or not called. If a routine's local stack allocation exceeds the threshold \( (n) \), the compiler inserts a \_chkstk()\ call into the prologue of the routine.

IDE Equivalent

None

Alternate Options

None

GS

\textit{Determines whether the compiler generates code that detects some buffer overruns.}

Syntax

Linux OS:
None

macOS:
None

Windows OS:
/GS[:keyword]
/GS-

Arguments

\textit{keyword}\n
Specifies the level of stack protection heuristics used by the compiler. Possible values are:
**Tells the compiler to ignore buffer overruns. This is the same as specifying /GS-.**

**partial**

Tells the compiler to provide a stack protection level that is compatible with Microsoft* Visual Studio 2008.

**strong**

Tells the compiler to provide full stack security level checking. This setting is compatible with more recent Microsoft* Visual Studio stack protection heuristics. This is the same as specifying /GS with no keyword.

**Default**

/GS- The compiler does not detect buffer overruns.

**Description**

This option determines whether the compiler generates code that detects some buffer overruns that overwrite a function's return address, exception handler address, or certain types of parameters.

This option has been added for Microsoft compatibility.

Following Visual Studio 2008, the Microsoft implementation of option /GS became more extensive (for example, more routines are protected). The performance of some programs may be impacted by the newer heuristics. In such cases, you may see better performance if you specify /GS:partial.

For more details about option /GS, see the Microsoft documentation.

**IDE Equivalent**

Visual Studio: **Code Generation > Security Check**

Eclipse: None

Xcode: None

**Alternate Options**

Linux and macOS*: `-fstack-security-check`

Alternate Options
None

**malign-double**

*Determined whether double, long double, and long long types are naturally aligned. This option is equivalent to specifying option align.*

Architecture Restrictions
Only available on IA-32 architecture

Syntax

**Linux OS:**
- `malign-double`
- `mno-align-double`

**macOS:**
None

**Windows OS:**
None

Arguments
None

Default

- `mno-align-double`

Types are aligned according to the gcc model, which means they are aligned to 4-byte boundaries.

Description
For details, see the `align` option.

IDE Equivalent
None

Alternate Options
None

**malign-mac68k**

*Aligns structure fields on 2-byte boundaries (m68k compatible).*

Syntax

**Linux OS:**
None
**malign-mac68k**

*macOS:*

-malign-mac68k

*Windows OS:*

None

**Arguments**

None

**Default**

OFF  The compiler does not align structure fields on 2-byte boundaries.

**Description**

This option aligns structure fields on 2-byte boundaries (m68k compatible).

**IDE Equivalent**

None

**Alternate Options**

None

---

**malign-natural**

Aligns larger types on natural size-based boundaries (overrides ABI).

*Syntax*

Aligns based on ABI-specified alignment rules.

Syntax
Linux OS:
None

macOS:
-malign-power

Windows OS:
None

Arguments
None

Default
ON
The compiler aligns based on ABI-specified alignment rules.

Description
Aligns based on ABI-specified alignment rules.

IDE Equivalent
None

Alternate Options
None

mcmodel
Tells the compiler to use a specific memory model to generate code and store data.

Architecture Restrictions
Only available on Intel® 64 architecture

Syntax
Linux OS:
-mcmodel=mem_model

macOS:
None

Windows OS:
None
Arguments

**mem_model**

Is the memory model to use. Possible values are:

- **small**
  - Tells the compiler to restrict code and data to the first 2GB of address space. All accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.

- **medium**
  - Tells the compiler to restrict code to the first 2GB; it places no memory restriction on data. Accesses of code can be done with IP-relative addressing, but accesses of data must be done with absolute addressing.

- **large**
  - Places no memory restriction on code or data. All accesses of code and data must be done with absolute addressing.

Default

- `-mcmodel=small`
  - On systems using Intel® 64 architecture, the compiler restricts code and data to the first 2GB of address space. Instruction Pointer (IP)-relative addressing can be used to access code and data.

Description

This option tells the compiler to use a specific memory model to generate code and store data. It can affect code size and performance. If your program has global and static data with a total size smaller than 2GB, `-mcmodel=small` is sufficient. Global and static data larger than 2GB requires `-mcmodel=medium` or `-mcmodel=large`. Allocation of memory larger than 2GB can be done with any setting of `-mcmodel`.

IP-relative addressing requires only 32 bits, whereas absolute addressing requires 64-bits. IP-relative addressing is somewhat faster. So, the `small` memory model has the least impact on performance.

**NOTE**

When you specify option `-mcmodel=medium` or `-mcmodel=large`, it sets option `-shared-intel`. This ensures that the correct dynamic versions of the Intel run-time libraries are used.

If you specify option `-static-intel` while `-mcmodel=medium` or `-mcmodel=large` is set, an error will be displayed.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to compile using `-mcmodel`:

```
icl -shared-intel -mcmodel=medium -o prog prog.c
```

See Also

`shared-intel` compiler option
fpic  compiler option

mdynamic-no-pic
Generates code that is not position-independent but has position-independent external references.

Syntax
Linux OS:
None

macOS:
-mdynamic-no-pic

Windows OS:
None

Arguments
None

Default
OFF  All references are generated as position independent.

Description
This option generates code that is not position-independent but has position-independent external references.
The generated code is suitable for building executables, but it is not suitable for building shared libraries.
This option may reduce code size and produce more efficient code. It overrides the \texttt{-fpic} compiler option.

IDE Equivalent
None

Alternate Options
None

See Also
fpic  compiler option

mlong-double
Lets you override the default configuration of the long double data type.

Syntax
Linux OS:
-mlong-double-n

macOS:
None
**Windows OS:**

None

**Arguments**

\[
n\]

Specifies the size of the long double data type. Possible values are:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>Specifies that the size of the long double data type is 64 bits.</td>
</tr>
<tr>
<td>80</td>
<td>Specifies that the size of the long double data type is 80 bits. This is the default.</td>
</tr>
<tr>
<td>128</td>
<td>Specifies that the size of the long double data type is 128 bits.</td>
</tr>
</tbody>
</table>

**Default**

-mlong-double-80  Specifies that the size of the long double data type is 80 bits.

**Description**

This option lets you override the default configuration of the long double data type.

When you specify `-mlong-double-64`, the size of the long double data type is 8 bytes and the macro `__LONG_DOUBLE_64__` is defined.

When you specify `-mlong-double-80`, the size of the long double data type is 12 bytes on IA-32 architecture and 16 bytes on Intel® 64 architecture.

This option has no effect on floating-point significand precision. That must be specified by using the `-pc64` or `-pc80` option.

Note that this option has no effect when you pass arguments. When you pass arguments, the 64-bit long double data type is treated as the double data type and it is always 64-bit.

Remember to include the math.h and complex.h header files when you use this option.

The following restrictions apply to this option:

- `__builtin_*` functions using the long double type should not be used in the non-default mode with Intel compiler libraries.
- Long double functions from the `std` namespace should not be called from C++ sources when the non-default mode is set.

**IDE Equivalent**

None

**Alternate Options**

Linux and macOS*: None

Windows: `/Qlong-double`

**See Also**

pc, Qpc

compiler option
**no-bss-init, Qnobss-init**
*Tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables.*

**Syntax**

Linux OS and macOS:
- `-no-bss-init`

Windows OS:
- `/Qnobss-init`

**Arguments**

None

**Default**

OFF

Uninitialized variables and explicitly zero-initialized variables are placed in the BSS section.

**Description**

This option tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables.

**IDE Equivalent**

Visual Studio: None

Eclipse: **Data > Disable Placement of Zero-initialized and Uninitialized Variables in .bss - place in .data instead**

Xcode: **Data > Allocate Zero-initialized Variables to .data**

**Alternate Options**

---

**noBool**

*Disables the bool keyword.*

**Syntax**

Linux OS:

None

**macOS:**

None

**Windows OS:**

None

**Arguments**

None
Default
OFF  The bool keyword is enabled.

Description
This option disables the bool keyword.

IDE Equivalent
None

Alternate Options
None

Qlong-double
Changes the default size of the long double data type.

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/Qlong-double

Arguments
None

Default
OFF  The default size of the long double data type is 64 bits.

Description
This option changes the default size of the long double data type to 80 bits.
However, the alignment requirement of the data type is 16 bytes, and its size must be a multiple of its alignment, so the size of a long double on Windows* is also 16 bytes. Only the lower 10 bytes (80 bits) of the 16 byte space will have valid data stored in it.
NOTE
Using the Qlong-double command-line option on Windows* platforms requires that any source code using double extended precision floating-point types (FP80) be carefully segregated from source code that was not written in a way that considers or supports their use. When this option is used, source code that makes assumptions or has requirements on the size or layout of an FP80 value may experience a variety of failures at compile time, link time, or run time.

The Microsoft* C Standard Library and Microsoft* C++ Standard Template Library do not support FP80 datatypes. In all circumstances where you want to use this option, please check with your library vendor to determine whether they support FP80 datatype formats.

For example, the Microsoft* compiler and Microsoft*-provided library routines (such as printf or long double math functions) do not provide support for 80-bit floating-point values and should not be called from code compiled with the Qlong-double command-line option.

Starting with the Microsoft Visual Studio 2019 version 16.10 release, you may get compilation errors when using options /std:c++latest together with /Qlong-double in programs that directly or indirectly include the <complex>, <xutility>, or the <cmath> header. To see an example of this, see the Example section below.

IDE Equivalent
None

Alternate Options
None

Example
In the Note above, we mention an issue with using the options /std:c++latest together with /Qlong-double in programs that directly or indirectly include the <complex>, <xutility>, or the <cmath> headers. The following shows an example of this issue:

```cpp
#include <iostream>
#include <complex>

int main()
{long double ld2 = 1256789.98765432106L;int iMan = isnan(ld2);std::cout << "Hello World!\n"; }

ksh-3.2$ icl -c -EHsc -GR -std:c++latest /Qlong-double /MD test1.cpp

Qsfalign
Specifies stack alignment for functions.

Architecture Restrictions
Only available on IA-32 architecture

Syntax
Linux OS:
None
macOS:
None
Windows OS:
/Qsfalign[n]

Arguments
n
Is the byte size of aligned variables. Possible values are:

8

Specifies that alignment should occur for functions with 8-byte aligned variables. At this setting the compiler aligns the stack to 16 bytes if there is any 16-byte or 8-byte data on the stack. For 8-byte data, the compiler only aligns the stack if the alignment will produce a performance advantage.

16

Specifies that alignment should occur for functions with 16-byte aligned variables. At this setting, the compiler only aligns the stack for 16-byte data. No attempt is made to align for 8-byte data.

Default
/Qsfalign8  Alignment occurs for functions with 8-byte aligned variables.
Description
This option specifies stack alignment for functions. It lets you disable the normal optimization that aligns a stack for 8-byte data.
If you do not specify \texttt{n}, stack alignment occurs for all functions. If you specify \texttt{/Qsfalign-}, no stack alignment occurs for any function.

IDE Equivalent
None

Alternate Options
None

Compiler Diagnostic Options

diag, Qdiag
\textit{Controls the display of diagnostic information during compilation.}

Syntax

\textbf{Linux OS and macOS:}
\begin{verbatim}
-diag-type=diag-list
\end{verbatim}

\textbf{Windows OS:}
\begin{verbatim}
/Qdiag-type:diag-list
\end{verbatim}

Arguments

type

\begin{itemize}
\item \texttt{enable} \quad Enables a diagnostic message or a group of messages. If you specify \texttt{-diag-enable=all} (Linux* and macOS*) or \texttt{/Qdiag-enable:all} (Windows*), all diagnostic messages shown in \texttt{diag-list} are enabled.
\item \texttt{disable} \quad Disables a diagnostic message or a group of messages. If you specify \texttt{-diag-disable=all} (Linux* and macOS*) or \texttt{/Qdiag-disable:all} (Windows*), all diagnostic messages shown in \texttt{diag-list} are disabled.
\item \texttt{error} \quad Tells the compiler to change diagnostics to errors.
\item \texttt{warning} \quad Tells the compiler to change diagnostics to warnings.
\item \texttt{remark} \quad Tells the compiler to change diagnostics to remarks (comments).
\end{itemize}
Is a diagnostic group or ID value. Possible values are:

- **driver**: Specifies diagnostic messages issued by the compiler driver.
- **port-linux**: Specifies diagnostic messages for language features that may cause errors when porting to Linux* systems. This diagnostic group is only available on Windows* systems.
- **port-win**: Specifies diagnostic messages for GNU extensions that may cause errors when porting to Windows. This diagnostic group is only available on Linux and macOS* systems.
- **thread**: Specifies diagnostic messages that help in thread-enabling a program.
- **vec**: Specifies diagnostic messages issued by the vectorizer.
- **par**: Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).
- **openmp**: Specifies diagnostic messages issued by the OpenMP* parallelizer.
- **warn**: Specifies diagnostic messages that have a "warning" severity level.
- **error**: Specifies diagnostic messages that have an "error" severity level.
- **remark**: Specifies diagnostic messages that are remarks or comments.
- **cpu-dispatch**: Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default.
- **id[,id,...]**: Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each id.
- **tag[,tag,...]**: Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each tag.

The diagnostic messages generated can be affected by certain options, such as `[Q]x, /arch (Windows) or -m (Linux and macOS*)`. 

---

*Intel® C++ Compiler Classic Developer Guide and Reference*
The compiler issues certain diagnostic messages by default.

**Description**
This option controls the display of diagnostic information during compilation. Diagnostic messages are output to stderr unless the `[-Q]diag-file` option is specified.

To control the diagnostic information reported by the vectorizer, use options `[-q or -Q]opt-report` and `[-q or -Q]opt-report-phase`, phase `vec`.

To control the diagnostic information reported by the auto-parallelizer, use options `[-q or -Q]opt-report` and `[-q or -Q]opt-report-phase`, phase `par`.

**IDE Equivalent**
Visual Studio: **Diagnostics > Disable Specific Diagnostics** (`/Qdiag-disable:id`)

**Advanced > Disable Specific Warnings** (`/Qdiag-disable`)

Eclipse: **Compilation Diagnostics > Disable Specific Diagnostics**

Xcode: **Diagnostics > Disable Specific Diagnostics**

**Alternate Options**

| Enable Vec | Linux and macOS*: `-qopt-report; -qopt-report -qopt-report-phase=vec` |
| Windows: `/Qopt-report; /Qopt-report /Qopt-report-phase:vec` |

| Disable Vec | Linux and macOS*: `-qopt-report=0 -qopt-report-phase=vec` |
| Windows: `/Qopt-report:0 /Qopt-report-phase:vec` |

| Enable Par | Linux and macOS*: `-qopt-report; -qopt-report-phase=par` |
| Windows: `/Qopt-report; /Qopt-report /Qopt-report-phase:par` |

| Disable Par | Linux and macOS*: `-qopt-report=0 -qopt-report-phase=par` |
| Windows: `/Qopt-report:0 /Qopt-report-phase:par` |

**Example**
The following example shows how to enable diagnostic IDs 117, 230 and 450:

```
-diag-enable=117,230,450       ! Linux and macOS* systems
/Qdiag-enable:117,230,450       ! Windows systems
```

The following example shows how to change vectorizer diagnostic messages to warnings:

```
-diag-enable=vec -diag-warning=vec     ! Linux and macOS* systems
/Qdiag-enable:vec /Qdiag-warning:vec     ! Windows systems
```

Note that you need to enable the vectorizer diagnostics before you can change them to warnings.
The following example shows how to disable all auto-parallelizer diagnostic messages:

```
-diag-disable=par       ! Linux and macOS* systems
/Qdiag-disable:par      ! Windows systems
```

The following example shows how to change all diagnostic warnings and remarks to errors:

```
-diag-error=warn,remark ! Linux and macOS* systems
/Qdiag-error:warn,remark ! Windows systems
```

The following example shows how to get a list of only vectorization diagnostics:

```
-diag-dump -diag-disable=all -diag-enable=vec       ! Linux and macOS* systems
/Qdiag-dump /Qdiag-disable:all /Qdiag-enable:vec    ! Windows systems
```

### See Also

diag-dump, Qdiag-dump  
compiler option

diag-id-numbers, Qdiag-id-numbers  
compiler option

diag-file, Qdiag-file  
compiler option

goopt-report, Qopt-report  
compiler option

\*x, Qx  
compiler option

diag-dump, Qdiag-dump

*Tells the compiler to print all enabled diagnostic messages.*

### Syntax

**Linux OS and macOS:**

```
-diag-dump
```

**Windows OS:**

```
/Qdiag-dump
```

### Arguments

None

### Default

OFF

The compiler issues certain diagnostic messages by default.

### Description

This option tells the compiler to print all enabled diagnostic messages. The diagnostic messages are output to stdout.

This option prints the enabled diagnostics from all possible diagnostics that the compiler can issue, including any default diagnostics.

*If diag-list is specified for the [Q]diag-enable option, the print out will include the diag-list diagnostics.*

### IDE Equivalent

None

### Alternate Options

None
Example

The following example adds vectorizer diagnostic messages to the printout of default diagnostics:

- `~diag-enable vec -diag-dump`  ! Linux and macOS* systems
  `/Qdiag-enable:vec /Qdiag-dump`  ! Windows systems

See Also
diag, Qdiag  compiler option

diag-enable=power, Qdiag-enable:power
Controls whether diagnostics are enabled for possibly inefficient code that may affect power consumption on IA-32 and Intel® 64 architectures.

Syntax

**Linux OS and macOS:**
- `-diag-enable=power`
- `-diag-disable=power`

**Windows OS:**
- `/Qdiag-enable:power`
- `/Qdiag-disable:power`

Arguments
None

Default

- `-diag-disable=power`  
  or `/Qdiag-disable:power`  
  Power consumption diagnostics are disabled.

Description
This option controls whether diagnostics are enabled for possibly inefficient code that may affect power consumption on IA-32 and Intel® 64 architectures.

If you specify option `-diag-enable=power` (Linux* and macOS*) or `/Qdiag-enable:power` (Windows*), the compiler will detect various API calls with argument values in ranges known to be inefficient for power consumption. The diagnostic issued will point out the problem argument; for example, "power inefficient use of 'Sleep' with argument in range [0;10]."

IDE Equivalent
None

Alternate Options
None

diag-error-limit, Qdiag-error-limit
Specifies the maximum number of errors allowed before compilation stops.
Syntax

Linux OS and macOS:
- `diag-error-limit=n`
- `no-diag-error-limit`

Windows OS:
/`Qdiag-error-limit:n`
/`Qdiag-error-limit-`

Arguments

$n$  
Is the maximum number of error-level or fatal-level compiler errors allowed.

Default

30  
A maximum of 30 error-level and fatal-level messages are allowed.

Description

This option specifies the maximum number of errors allowed before compilation stops. It indicates the maximum number of error-level or fatal-level compiler errors allowed for a file specified on the command line.

If you specify the negative form of the `[Q]diag-error-limit` option on the command line, there is no limit on the number of errors that are allowed.

If the maximum number of errors is reached, a warning message is issued and the next file (if any) on the command line is compiled.

IDE Equivalent

Visual Studio: **Diagnostics > Error Limit**

Eclipse: **Compilation Diagnostics > Set Error Limit**

Xcode: **Diagnostics > Error Limit**

Alternate Options

Linux and macOS*: `-wn` (this is a deprecated option)

Windows: `/Qwn` (this is a deprecated option)

diag-file, `Qdiag-file`

*Causes the results of diagnostic analysis to be output to a file.*

Syntax

Linux OS:
- `diag-file[=filename]`

macOS:

None
Windows OS:
/Qdiag-file[:filename]

Arguments

filename Is the name of the file for output.

Default

OFF Diagnostic messages are output to stderr.

Description

This option causes the results of diagnostic analysis to be output to a file. The file is placed in the current working directory.

You can include a file extension in filename. For example, if file.txt is specified, the name of the output file is file.txt. If you do not provide a file extension, the name of the file is filename.diag.

If filename is not specified, the name of the file is name-of-the-first-source-file.diag. This is also the name of the file if the name specified for file conflicts with a source file name provided in the command line.

NOTE

If you specify the [Q]diag-file option and you also specify the [Q]diag-file-append option, the last option specified on the command line takes precedence.

IDE Equivalent

Visual Studio: Diagnostics > Diagnostics File
Diagnostics > Emit Diagnostics to File

Eclipse: Compilation Diagnostics > Diagnostics File

Xcode: Diagnostics > Diagnostics File, Diagnostics > Emit Diagnostics to File

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be output to a file named my_diagnostics.diag:

-ddiag-file=my_diagnostics ! Linux systems
/Qdiag-file:my_diagnostics ! Windows systems

See Also
diag-file-append, Qdiag-file-append compiler option

diag-file-append, Qdiag-file-append
Causes the results of diagnostic analysis to be appended to a file.
Syntax

Linux OS:
- `diag-file-append[=filename]`

macOS:
None

Windows OS:
/`Qdiag-file-append[:filename]`

Arguments

`filename`  Is the name of the file to be appended to. It can include a path.

Default

OFF  Diagnostic messages are output to `stderr`.

Description

This option causes the results of diagnostic analysis to be appended to a file. If you do not specify a path, the driver will look for `filename` in the current working directory.

If `filename` is not found, then a new file with that name is created in the current working directory. If the name specified for file conflicts with a source file name provided in the command line, the name of the file is `name-of-the-first-source-file.diag`.

**NOTE**

If you specify the `[Q]diag-file-append` option and you also specify the `[Q]diag-file` option, the last option specified on the command line takes precedence.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be appended to a file named `my_diagnostics.txt`:

- `diag-file-append=my_diagnostics.txt` ! Linux systems
  
/`Qdiag-file-append=my_diagnostics.txt` ! Windows systems

See Also

diag-file, Qdiag-file  compiler option

diag-id-numbers, Qdiag-id-numbers

*Determines whether the compiler displays diagnostic messages by using their ID number values.*
Syntax

**Linux OS and macOS:**
- `-diag-id-numbers`
- `-no-diag-id-numbers`

**Windows OS:**
/`Qdiag-id-numbers`
/`Qdiag-id-numbers-`

Arguments
None

Default
`-diag-id-numbers`

The compiler displays diagnostic messages by using their ID number values.

or `/Qdiag-id-numbers`

Description
This option determines whether the compiler displays diagnostic messages by using their ID number values. If you specify the negative form of the `[Q]diag-id-numbers` option, mnemonic names are output for driver diagnostics only.

IDE Equivalent
None

Alternate Options
None

See Also
`diag, Qdiag` compiler option

---

diag-once, Qdiag-once

* Tells the compiler to issue one or more diagnostic messages only once.

Syntax

**Linux OS and macOS:**
- `-diag-once-id[,id,...]`

**Windows OS:**
/`Qdiag-once:id[,id,...]`

Arguments

* `id`  
  Is the ID number of the diagnostic message. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each `id`. 
Default
OFF The compiler issues certain diagnostic messages by default.

Description
This option tells the compiler to issue one or more diagnostic messages only once.

IDE Equivalent
None

Alternate Options
Linux: -wo (this is a deprecated option)
Windows: /Qwo (this is a deprecated option)

fnon-call-exceptions
Allows trapping instructions to throw C++ exceptions.

Syntax
Linux OS and macOS:
-ffnon-call-exceptions
-ffno-non-call-exceptions

Windows OS:
None

Arguments
None

Default
-ffno-non-call-exceptions

C++ exceptions are not thrown from trapping instructions.

Description
This option allows trapping instructions to throw C++ exceptions. It allows hardware signals generated by trapping instructions to be converted into C++ exceptions and caught using the standard C++ exception handling mechanism. Examples of such signals are SIGFPE (floating-point exception) and SIGSEGV (segmentation violation).

You must write a signal handler that catches the signal and throws a C++ exception. After that, any occurrence of that signal within a C++ try block can be caught by a C++ catch handler of the same type as the C++ exception thrown within the signal handler.

Only signals generated by trapping instructions (that is, memory access instructions and floating-point instructions) can be caught. Signals that can occur at any time, such as SIGALRM, cannot be caught in this manner.

IDE Equivalent
None
Alternate Options
None

**traceback**
*Tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.*

**Syntax**

**Linux OS and macOS:**
- `-traceback`
- `-notraceback`

**Windows OS:**
- `/traceback`
- `/notraceback`

**Arguments**
None

**Default**
`notraceback` No extra information is generated in the object file to produce traceback information.

**Description**
This option tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time. This is intended for use with C code that is to be linked into a Fortran program.

When the severe error occurs, source file, routine name, and line number correlation information is displayed along with call stack hexadecimal addresses (program counter trace).

Note that when a severe error occurs, advanced users can also locate the cause of the error using a map file and the hexadecimal addresses of the stack displayed when the error occurs.

This option increases the size of the executable program, but has no impact on run-time execution speeds. It functions independently of the debug option.

On Windows* systems, **traceback** sets the `/Oy` option, which forces the compiler to use EBP as the stack frame pointer.

On Windows* systems, the linker places the traceback information in the executable image, in a section named ".trace". To see which sections are in an image, use the command:

```
link -dump -summary your_app_name.exe
```

To see more detailed information, use the command:

```
link -dump -headers your_app_name.exe
```

On Linux* systems, to display the section headers in the image (including the header for the .trace section, if any), use the command:

```
objdump -h your_app_name.exe
```
On macOS* systems, to display the section headers in the image, use the command:

```
otool -l your_app_name.exe
```

**IDE Equivalent**

Visual Studio: None

Eclipse: **Runtime > Generate Traceback Information**

Xcode: **Runtime > Generate Traceback Information**

**Alternate Options**

None

**w**

*Disables all warning messages.*

**Syntax**

**Linux OS:**

`-w`

**macOS:**

`-w`

**Windows OS:**

`/w`

**Arguments**

None

**Default**

OFF

Default warning messages are enabled.

**Description**

This option disables all warning messages.

**IDE Equivalent**

Visual Studio: **General > Warning Level**

Eclipse: **General > Warning Level**

Xcode: **General > Warning Level**

**Alternate Options**

Linux and macOS*: `-w0`

Windows: `/w0`

**w, W**

*S-specifies the level of diagnostic messages to be generated by the compiler.*
Syntax

**Linux OS:**
\(-wn\)

**macOS:**
\(-wn\)

**Windows OS:**
\(/Wn\)

Arguments

\(n\)

Is the level of diagnostic messages to be generated. Possible values are:

- **0**: Enables diagnostics for errors. Disables diagnostics for warnings.
- **1**: Enables diagnostics for warnings and errors. On Linux* and macOS* systems, additional warnings are enabled. On Windows* systems, this setting is equivalent to level 1 \((n = 1)\).
- **2**: Enables diagnostics for warnings and errors. On Linux* and macOS* systems, additional warnings are enabled. On Windows* systems, this setting is equivalent to level 1 \((n = 1)\).
- **3**: Enables diagnostics for remarks, warnings, and errors. Additional warnings are also enabled above level 2 \((n = 2)\). This level is recommended for production purposes.
- **4**: Enables diagnostics for all level 3 \((n = 3)\) warnings plus informational warnings and remarks, which in most cases can be safely ignored. This value is only available on Windows* systems.
- **5**: Enables diagnostics for all remarks, warnings, and errors. This setting produces the most diagnostic messages. This value is only available on Windows* systems.

**Default**

\(n=1\)

The compiler displays diagnostics for warnings and errors.

**Description**

This option specifies the level of diagnostic messages to be generated by the compiler.

On Windows systems, option /W4 is equivalent to option /Wall.

The \(-wn\), /Wn, and Wall options can override each other. The last option specified on the command line takes precedence.
**IDE Equivalent**
Visual Studio: General > Warning Level
Eclipse: General > Warning Level
Xcode: General > Warning Level

**Alternate Options**
None

**See Also**
Wall compiler option

**Wabi**
*Determines whether a warning is issued if generated code is not C++ ABI compliant.*

**Syntax**

**Linux OS:**
- Wabi
- Wno-abi

**macOS:**
- Wabi
- Wno-abi

**Windows OS:**
None

**Arguments**
None

**Default**
- Wno-abi

**Description**
This option determines whether a warning is issued if generated code is not C++ ABI compliant.

**IDE Equivalent**
None

**Alternate Options**
None

**Wall**
*Enables warning and error diagnostics.*
Syntax

Linux OS:
- `Wall`

macOS:
- `Wall`

Windows OS:
/`Wall`

Arguments
None

Default
OFF

Only default warning diagnostics are enabled.

Description
This option enables many warning and error diagnostics.

On Windows* systems, this option is equivalent to the `/W4` option. It enables diagnostics for all level 3 warnings plus informational warnings and remarks.

However, on Linux* and macOS* systems, this option is similar to gcc option `-Wall`. It displays all errors and some of the warnings that are typically reported by gcc option `-Wall`. If you want to display all warnings, specify the `-w2` or `-w3` option. If you want to display remarks and comments, specify the `'-Wremarks` option.

The `'-Wall`, `-wn`, and `/Wn` options can override each other. The last option specified on the command line takes precedence.

IDE Equivalent
None

Alternate Options
None

See Also
`diag`, `Qdiag` compiler option

`Wremarks` compiler option

`w`, `W` compiler option

**Wbrief**

*Tells the compiler to display a shorter form of diagnostic output.*

Syntax

Linux OS and macOS:
- `Wbrief`

Windows OS:
/`WL`
**Arguments**

None

**Default**

OFF  The compiler displays its normal diagnostic output.

**Description**

This option tells the compiler to display a shorter form of diagnostic output. In this form, the original source line is not displayed and the error message text is not wrapped when too long to fit on a single line.

**IDE Equivalent**

None

**Alternate Options**

Linux and macOS*: None

Windows: /WL

---

**Wcheck**

*Tells the compiler to perform compile-time code checking for certain code.*

**Syntax**

Linux OS and macOS:

-Wcheck

Windows OS:

/Wcheck

**Arguments**

None

**Default**

OFF  No compile-time code checking is performed.

**Description**

This option tells the compiler to perform compile-time code checking for certain code. It specifies to check for code that exhibits non-portable behavior, represents a possible unintended code sequence, or possibly affects operation of the program because of a quiet change in the ANSI C Standard.

**IDE Equivalent**

Visual Studio: None

Eclipse: Compilation Diagnostics > Allow Usage Messages

Xcode: Diagnostics > Allow Usage Messages

**Alternate Options**

None
**Wcheck-unicode-security**

_Determines whether the compiler performs source code checking for Unicode vulnerabilities._

**Syntax**

**Linux OS:**

- -Wcheck-unicode-security
- -Wno-check-unicode-security

**macOS:**

- -Wcheck-unicode-security
- -Wno-check-unicode-security

**Windows OS:**

/Wcheck-unicode-security
/Wno-check-unicode-security

**Arguments**

None

**Default**

_Wno-check-unicode-security_

_The compiler does not perform source code checking for Unicode vulnerabilities._

**Description**

This option determines whether the compiler performs source code checking for Unicode vulnerabilities.

Option _Wcheck-unicode-security_ enables Unicode checking. The compiler will detect and warn about Unicode constructs that can be exploited by using bi-directional formatting codes, zero-width characters in strings, and use of zero-width characters and homoglyphs in identifiers.

Option _Wno-check-unicode-security_ disables Unicode checking.

**IDE Equivalent**

**Windows**

Visual Studio: _C/C++ > Diagnostics [Intel C++] > Check Unicode Security_

**Linux**

Eclipse: _Intel C++ Compiler Classic > Compilation Diagnostics > Check Unicode Security_

**Alternate Options**

None

**Wcomment**

_Determines whether a warning is issued when /* appears in the middle of a */ */ comment._
Syntax

Linux OS:
- Wcomment
- Wno-comment

macOS:
- Wcomment
- Wno-comment

Windows OS:
None

Arguments
None

Default
- Wno-comment

No warning is issued when /* appears in the middle of a /* */ comment.

Description
This option determines whether a warning is issued when /* appears in the middle of a /* */ comment.

IDE Equivalent
None

Alternate Options
None

Wcontext-limit, Qcontext-limit
Set the maximum number of template instantiation contexts shown in diagnostic.

Syntax

Linux OS and macOS:
- Wcontext-limit=n

Windows OS:
/Qcontext-limit:n

Arguments

n
Number of template instantiation contexts.

Default
OFF

Description
Set maximum number of template instantiation contexts shown in diagnostic.
**IDE Equivalent**
None

**Alternate Options**
None

**wd, Qwd**
Disables a soft diagnostic. This is a deprecated option. The replacement option is [Q]diag-disable.

**Syntax**

**Linux OS and macOS:**
- `wdn[,n]...`

**Windows OS:**
- `/Qwdn[,n]...`

**Arguments**

$n$ Is the number of the diagnostic to disable.

**Default**
OFF  The compiler returns soft diagnostics as usual.

**Description**
This option disables the soft diagnostic that corresponds to the specified number. If you specify more than one $n$, each $n$ must be separated by a comma.

**IDE Equivalent**
Visual Studio: Advanced > Disable Specific Warnings
Eclipse: None
Xcode: None

**Alternate Options**

Linux and macOS*: `-diag-disable`
Windows: `/Qdiag-disable`

**Wdeprecated**
Determines whether warnings are issued for deprecated C++ headers.

**Syntax**

**Linux OS:**
- `-Wdeprecate`
- `-Wno-deprecated`

503
macOS:
- Wdeprecated
- Wno-deprecated

Windows OS:
None

Arguments
None

Default
- Wdeprecated

The compiler issues warnings for deprecated C++ headers.

Description
This option determines whether warnings are issued for deprecated C++ headers. It has no effect in C compilation mode.

Option -Wdeprecated enables these warnings by defining the __DEPRECATED macro for preprocessor.

To disable warnings for deprecated C++ headers, specify -Wno-deprecated.

IDE Equivalent
None

Alternate Options
None

we, Qwe
Changes a soft diagnostic to an error. This is a deprecated option. The replacement option is [Q]diagnostic.

Syntax
Linux OS and macOS:
- we Ln[,Ln,...]

Windows OS:
/Qwe Ln[,Ln,...]

Arguments

Ln
Is the number of the diagnostic to be changed.

Default
OFF
The compiler returns soft diagnostics as usual.

Description
This option overrides the severity of the soft diagnostic that corresponds to the specified number and changes it to an error.
Soft diagnostics are diagnostic messages that don't prevent the production of an object file; for example, warnings and remarks.

If you specify more than one \( Ln \), each \( Ln \) must be separated by a comma.

To see the suggested replacement for this option, see Deprecated and Removed Compiler Options.

**IDE Equivalent**

None

**Alternate Options**

Linux and macOS*: \(-\text{diag-error}\)

Windows: \(/\text{diag-error}\)

**Weffc++, Qeffc++**

*Enables warnings based on certain C++ programming guidelines.*

**Syntax**

**Linux OS:**

\[-\text{Weffc++}\]

**macOS:**

\[-\text{Weffc++}\]

**Windows OS:**

\(/[\text{Qeffc++}\]

**Arguments**

None

**Default**

OFF Diagnostics are not enabled.

**Description**

This option enables warnings based on certain programming guidelines developed by Scott Meyers in his books on effective C++ programming. With this option, the compiler emits warnings for these guidelines:

- Use \texttt{const} and \texttt{inline} rather than \#define. Note that you will only get this in user code, not system header code.
- Use \texttt{<iostream>} rather than \texttt{<stdio.h>}
- Use \texttt{new} and \texttt{delete} rather than \texttt{malloc} and \texttt{free}
- Use C++ style comments in preference to C style comments. C comments in system headers are not diagnosed.
- Use \texttt{delete} on pointer members in destructors. The compiler diagnoses any pointer that does not have a delete.
- Make sure you have a user copy constructor and assignment operator in classes containing pointers.
- Use initialization rather than assignment to members in constructors.
- Make sure the initialization list ordering matches the declaration list ordering in constructors.
- Make sure base classes have virtual destructors.
- Make sure \texttt{operator=} returns \*this.
• Make sure prefix forms of increment and decrement return a `const` object.
• Never overload operators `&&`, `||`, and `.`.

**NOTE**
The warnings generated by this compiler option are based on the following books from Scott Meyers:
• Effective C++ Second Edition - 50 Specific Ways to Improve Your Programs and Designs
• More Effective C++ - 35 New Ways to Improve Your Programs and Designs

### IDE Equivalent

Visual Studio: None

Eclipse: **Compilation Diagnostics > Enable Warnings for Style Guideline Violations**

Xcode: **Diagnostics > Report Effective C++ Violations**

### Alternate Options

None

### `Werror, WX`

*Changes all warnings to errors.*

#### Syntax

**Linux OS:**

`-Werror`

**macOS:**

`-Werror`

**Windows OS:**

`/WX`

#### Arguments

None

#### Default

**OFF**

The compiler returns diagnostics as usual.

#### Description

This option changes all warnings to errors.

### IDE Equivalent

Visual Studio: **General > Treat Warnings As Errors**

Eclipse: **Compilation Diagnostics > Treat Warnings As Errors**

Xcode: **Diagnostics > Treat Warnings As Errors**

### Alternate Options

Linux and macOS*: `-diag-error warn`

**Werror-all**
*Causes all warnings and currently-enabled remarks to be reported as errors.*

**Syntax**

**Linux OS:**
- `Werror-all`

**macOS:**
- `Werror-all`

**Windows OS:**
- `/Werror-all`

**Arguments**
None

**Default**
OFF  
The compiler returns diagnostics as usual.

**Description**
This option causes all warnings and currently-enabled remarks to be reported as errors.
To enable display of remarks, specify option `-Wremarks`.

**IDE Equivalent**
None

**Alternate Options**

Linux and macOS*: `-diag-error warn, remark`

Windows: `/Qdiag-error:warn, remark`

**See Also**
diag, Qdiag
  compiler option
Wremarks
  compiler option

**Wextra-tokens**
*Determines whether warnings are issued about extra tokens at the end of preprocessor directives.*

**Syntax**

**Linux OS:**
- `Wextra-tokens`
- `Wno-extra-tokens`
- `-Wextra-tokens`
- `-Wno-extra-tokens`

macOS:
- Wextra-tokens
- Wno-extra-tokens

Windows OS:
None

Arguments
None

Default
- Wno-extra-tokens

Description
The compiler does not warn about extra tokens at the end of preprocessor directives.

IDE Equivalent
None

Alternate Options
None

Wformat
Determines whether argument checking is enabled for calls to printf, scanf, and so forth.

Syntax
Linux OS:
- Wformat
- Wno-format

macOS:
- Wformat
- Wno-format

Windows OS:
None

Arguments
None

Default
- Wno-format

Description
Argument checking is not enabled for calls to printf, scanf, and so forth.

This option determines whether argument checking is enabled for calls to printf, scanf, and so forth.
**IDE Equivalent**
None

**Alternate Options**
None

**Wformat-security**
*Determines whether the compiler issues a warning when the use of format functions may cause security problems.*

**Syntax**

**Linux OS:**
- `-Wformat-security`
- `-Wno-format-security`

**macOS:**
- `-Wformat-security`
- `-Wno-format-security`

**Windows OS:**
None

**Arguments**
None

**Default**

- `-Wno-format-security`
  No warning is issued when the use of format functions may cause security problems.

**Description**
This option determines whether the compiler issues a warning when the use of format functions may cause security problems.

When `-Wformat-security` is specified, it warns about uses of format functions where the format string is not a string literal and there are no format arguments.

**IDE Equivalent**
None

**Alternate Options**
None

**Wic-pointer**
*Determines whether warnings are issued for conversions between pointers to distinct scalar types with the same representation.*
Syntax

**Linux OS and macOS:**
- `-Wic-pointer`
- `-Wno-ic-pointer`

**Windows OS:**
None

**Arguments**
None

**Default**
- `-Wic-pointer`

The compiler issues warnings for conversions between pointers to distinct scalar types with the same representation.

**Description**
This option determines whether warnings are issued for conversions between pointers to distinct scalar types with the same representation.

For example, consider the following:

```c
void f(int *p) { long *q = p; }
```

In this case, by default, the compiler issues a warning because of the conversion from pointer to `int` to pointer to `long`.

However, if you specify `-Wno-ic-pointer`, and `long` and `int` values have the same representation on the target platform, the warning will not be issued.

**IDE Equivalent**
None

**Alternate Options**
None

**Winline**
*Warns when a function that is declared as inline is not inlined.*

**Syntax**

**Linux OS and macOS:**
- `-Winline`

**Windows OS:**
None

**Arguments**
None
**Default**

OFF  
No warning is produced when a function that is declared as inline is not inlined.

**Description**

This option warns when a function that is declared as inline is not inlined.

To see diagnostic messages, including a message about why a particular function was not inlined, you should generate an optimization report by specifying option `-qopt-report=5`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

`qopt-report`, `Qopt-report`  compiler option

**WL**

*Tells the compiler to display a shorter form of diagnostic output.*

**Syntax**

*Linux OS and macOS:*

See `Wbrief`.

*Windows OS:*

`/WL`

**Arguments**

None

**Default**

OFF  
The compiler displays its normal diagnostic output.

**Description**

This option tells the compiler to display a shorter form of diagnostic output. In this form, the original source line is not displayed and the error message text is not wrapped when too long to fit on a single line.

**IDE Equivalent**

None

**Alternate Options**

*Linux and macOS*: `-Wbrief`

*Windows*: None
Wmain

Determine whether a warning is issued if the return type of main is not expected.

Syntax

Linux OS:
- Wmain
- Wno-main

macOS:
- Wmain
- Wno-main

Windows OS:
None

Arguments
None

Default
-Wno-main

No warning is issued if the return type of main is not expected.

Description

This option determines whether a warning is issued if the return type of main is not expected.

IDE Equivalent
None

Alternate Options
None

Wmissing-declarations

Determine whether warnings are issued for global functions and variables without prior declaration.

Syntax

Linux OS:
- Wmissing-declarations
- Wno-missing-declarations

macOS:
- Wmissing-declarations
- Wno-missing-declarations

Windows OS:
None
Arguments
None

Default
-Wno-missing-declarations

No warnings are issued for global functions and variables without prior declaration.

Description
This option determines whether warnings are issued for global functions and variables without prior declaration.

IDE Equivalent
None

Alternate Options
None

Wmissing-prototypes
Determines whether warnings are issued for missing prototypes.

Syntax
Linux OS:
-Wmissing-prototypes
-Wno-missing-prototypes

macOS:
-Wmissing-prototypes
-Wno-missing-prototypes

Windows OS:
None

Arguments
None

Default
-Wno-missing-prototypes

No warnings are issued for missing prototypes.

Description
Determines whether warnings are issued for missing prototypes.

If -Wmissing-prototypes is specified, it tells the compiler to detect global functions that are defined without a previous prototype declaration.

IDE Equivalent
None
Alternate Options

None

\textbf{wn, Qwn}

*Controls the number of errors displayed before compilation stops. This is a deprecated option. The replacement option is [Q]diag-error-limit.*

\textbf{Syntax}

\textbf{Linux OS and macOS:}

\texttt{-wn} \texttt{n}

\textbf{Windows OS:}

\texttt{/Qwn} \texttt{n}

\textbf{Arguments}

\texttt{n} \hspace{1cm} Is the number of errors to display.

\textbf{Default}

100 \hspace{1cm} The compiler displays a maximum of 100 errors before aborting compilation.

\textbf{Description}

This option controls the number of errors displayed before compilation stops.

\textbf{IDE Equivalent}

\textbf{Visual Studio:} Diagnostics > Error Limit

\textbf{Eclipse:} Compilation Diagnostics > Set Error Limit

\textbf{Xcode:} Diagnostics > Error Limit

\textbf{Alternate Options}

\textbf{Linux and macOS*:} -diag-error-limit

\textbf{Windows:} /Qdiag-error-limit

\textbf{Wnon-virtual-dtor}

*Tells the compiler to issue a warning when a class appears to be polymorphic, yet it declares a non-virtual one.*

\textbf{Syntax}

\textbf{Linux OS and macOS:}

\texttt{-Wnon-virtual-dtor}

\textbf{Windows OS:}

None
**Arguments**
None

**Default**
OFF The compiler does not issue a warning.

**Description**
Tells the compiler to issue a warning when a class appears to be polymorphic, yet it declares a non-virtual one. This option is supported in C++ only.

**IDE Equivalent**
Visual Studio: None
Eclipse: None
Xcode: **Diagnostics > Report Non-Virtual Destructor**

**Alternate Options**
None

**wo, Qwo**
Tells the compiler to issue one or more diagnostic messages only once. This is a deprecated option. The replacement option is \[Q\]diag-once id.

**Syntax**
**Linux OS and macOS:**
-wo\[Ln[,Ln,...]\]

**Windows OS:**
/Qwo\[Ln[,Ln,...]\]

**Arguments**
\(Ln\) Is the number of the diagnostic.

**Default**
OFF

**Description**
Specifies the ID number of one or more messages. If you specify more than one \(Ln\), each \(Ln\) must be separated by a comma.

**IDE Equivalent**
None

**Alternate Options**
Linux and macOS*: -diag-once id
Windows: /Qdiag-once:id
**Wp64**
*Tells the compiler to display diagnostics for 64-bit porting.*

**Syntax**

**Linux OS and macOS:**

- `-Wp64`

**Windows OS:**

- `/Wp64`

**Arguments**

None

**Default**

OFF  The compiler does not display diagnostics for 64-bit porting.

**Description**

This option tells the compiler to display diagnostics for 64-bit porting.

**IDE Equivalent**

Visual Studio: **General > Detect 64-bit Portability Issues**

Eclipse: None

Xcode: None

**Alternate Options**

None

**Wpch-messages**
*Determines whether the compiler shows precompiled header (PCH) informational messages.*

**Syntax**

**Linux OS and macOS:**

- `-Wpch-messages`

- `-Wno-pch-messages`

**Windows OS:**

- `/Wpch-messages`

- `/Wpch-messages-`

**Arguments**

None
**Wpch-messages**

The compiler shows precompiled header (PCH) informational messages.

**Description**

This option determines whether the compiler shows precompiled header (PCH) informational messages. By default, these messages are displayed.

To suppress the display of the PCH informational messages, specify `-Wno-pch-messages` (Linux* and macOS*) or /Wpch-messages- (Windows*).

**IDE Equivalent**

Visual Studio: **Precompiled Headers [Intel C++] > Disable Precompiled Header Messages**

Eclipse: **Precompiled Headers > Disable Precompiled Header Messages**

Xcode: **Precompiled Headers > Disable Precompiled Header Messages**

**Alternate Options**

None

---

**Wpointer-arith**

Determines whether warnings are issued for questionable pointer arithmetic.

**Syntax**

**Linux OS:**

- `-Wpointer-arith`
- `-Wno-pointer-arith`

**macOS:**

- `-Wpointer-arith`
- `-Wno-pointer-arith`

**Windows OS:**

None

**Arguments**

None

**Default**

`-Wno-pointer-arith`

No warnings are issued for questionable pointer arithmetic.

**Description**

Determines whether warnings are issued for questionable pointer arithmetic.

**IDE Equivalent**

None
Alternate Options

None

Wport
_Tells the compiler to issue portability diagnostics._

Syntax

Linux OS and macOS:
None

Windows OS:
/Wport

Arguments

None

Default

OFF  The compiler issues default diagnostics.

Description

This option tells the compiler to issue portability diagnostics.

IDE Equivalent

None

Alternate Options

None

wr, Qwr
_Changes a soft diagnostic to an remark. This is a deprecated option. The replacement option is [Q]diag-remark._

Syntax

Linux OS and macOS:
-wrLn[,Ln,...]

Windows OS:
/QwrLn[,Ln,...]

Arguments

Ln  Is the number of the diagnostic to be changed.

Default

OFF  The compiler returns soft diagnostics as usual.
Description
This option overrides the severity of the soft diagnostic that corresponds to the specified number and changes it to a remark.
Soft diagnostics are diagnostic messages that don't prevent the production of an object file; for example, warnings and remarks.
If you specify more than one \( Ln \), each \( Ln \) must be separated by a comma.

IDE Equivalent
None

Alternate Options
Linux and macOS*: -diag-remark
Windows: /Qdiag-remark

Wremarks
*Tells the compiler to display remarks and comments.*

Syntax
Linux OS and macOS:
- `Wremarks`

Windows OS:
None

Arguments
None

Default
OFF
Default warning messages are enabled.

Description
This option tells the compiler to display remarks and comments.
If you want to display warnings and errors, specify the `Wall`, `-wn`, or `/Wn` option.

IDE Equivalent
None

Alternate Options
None

See Also
diag, Qdiag  compiler option
Wall  compiler option
w, W  compiler option
**Wreorder**
*Tells the compiler to issue a warning when the order of member initializers does not match the order in which they must be executed.*

**Syntax**

**Linux OS:**

-Wreorder

**macOS:**

-Wreorder

**Windows OS:**

None

**Arguments**

None

**Default**

OFF  The compiler does not issue a warning.

**Description**

This option tells the compiler to issue a warning when the order of member initializers does not match the order in which they must be executed. This option is supported for C++ only.

**IDE Equivalent**

None

**Alternate Options**

None

---

**Wreturn-type**

*Determines whether warnings are issued when a function is declared without a return type, when the definition of a function returning void contains a return statement with an expression, or when the closing brace of a function returning non-void is reached.*

**Syntax**

**Linux OS:**

-Wreturn-type

-Wno-return-type

**macOS:**

-Wreturn-type

-Wno-return-type
Windows OS:
None

Arguments
None

Default
ON for one condition

Description
A warning is issued when the closing brace of a function returning non-void is reached.

This option determines whether warnings are issued for the following:
- When a function is declared without a return type
- When the definition of a function returning void contains a return statement with an expression
- When the closing brace of a function returning non-void is reached

Specify -Wno-return-type if you do not want to see warnings about the above diagnostics.

IDE Equivalent
None

Alternate Options
None

Wshadow
Determines whether a warning is issued when a variable declaration hides a previous declaration.

Syntax
Linux OS:
-Wshadow
-Wno-shadow

macOS:
-Wshadow
-Wno-shadow

Windows OS:
None

Arguments
None

Default
-Wno-shadow

No warning is issued when a variable declaration hides a previous declaration.
Description
This option determines whether a warning is issued when a variable declaration hides a previous declaration.
Same as -w01599.

IDE Equivalent
None

Alternate Options
None

Wsign-compare
*Determines whether warnings are issued when a comparison between signed and unsigned values could produce an incorrect result when the signed value is converted to unsigned.*

Syntax
Linux OS:
-Wsign-compare
-Wno-sign-compare

macOS:
-Wsign-compare
-Wno-sign-compare

Windows OS:
None

Arguments
None

Default
-Wno-sign-compare

The compiler does not issue these warnings

Description
This option determines whether warnings are issued when a comparison between signed and unsigned values could produce an incorrect result when the signed value is converted to unsigned.

On Linux* systems, this option is provided for compatibility with gcc.

IDE Equivalent
None

Alternate Options
None
**Wstrict-aliasing**

*Determines whether warnings are issued for code that might violate the optimizer’s strict aliasing rules.*

**Syntax**

**Linux OS:**

- `-Wstrict-aliasing`
- `-Wno-strict-aliasing`

**macOS:**

- `-Wstrict-aliasing`
- `-Wno-strict-aliasing`

**Windows OS:**

None

**Arguments**

None

**Default**

- `-Wno-strict-aliasing`

No warnings are issued for code that might violate the optimizer’s strict aliasing rules.

**Description**

This option determines whether warnings are issued for code that might violate the optimizer’s strict aliasing rules. These warnings will only be issued if you also specify option `-ansi-alias` or option `-fstrict-aliasing`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

ansi-alias, Qansi-alias

compiler option

**Wstrict-prototypes**

*Determines whether warnings are issued for functions declared or defined without specified argument types.*

**Syntax**

**Linux OS:**

- `-Wstrict-prototypes`
- `-Wno-strict-prototypes`

- `-Wno-strict-prototypes`
macOS:
-\texttt{-Wstrict-prototypes}
-\texttt{-Wno-strict-prototypes}

Windows OS:
None

Arguments
None

Default
-\texttt{-Wno-strict-prototypes}

No warnings are issued for functions declared or defined without specified argument types.

Description
This option determines whether warnings are issued for functions declared or defined without specified argument types.

IDE Equivalent
None

Alternate Options
None

Wtrigraphs
\textit{Determines whether warnings are issued if any trigraphs are encountered that might change the meaning of the program.}

Syntax
Linux OS:
-\texttt{-Wtrigraphs}
-\texttt{-Wno-trigraphs}

macOS:
-\texttt{-Wtrigraphs}
-\texttt{-Wno-trigraphs}

Windows OS:
None

Arguments
None

Default
-\texttt{-Wno-trigraphs}

No warnings are issued if any trigraphs are encountered that might change the meaning of the program.
Description
This option determines whether warnings are issued if any trigraphs are encountered that might change the meaning of the program.

IDE Equivalent
None

Alternate Options
None

Wuninitialized
_Determines whether a warning is issued if a variable is used before being initialized._

Syntax

Linux OS:
- `Wuninitialized`
- `Wno-uninitialized`

macOS:
- `Wuninitialized`
- `Wno-uninitialized`

Windows OS:
None

Arguments
None

Default
- `Wno-uninitialized`
  No warning is issued if a variable is used before being initialized.

Description
This option determines whether a warning is issued if a variable is used before being initialized. Equivalent to `-ww592 and -wd592`.

IDE Equivalent
None

Alternate Options
- `ww592` and `wd592`

Wunknown-pragmas
_Determines whether a warning is issued if an unknown #pragma directive is used._
**Syntax**

**Linux OS:**  
-Wunknown-pragmas  
-Wno-unknown-pragmas  

**macOS:**  
-Wunknown-pragmas  
-Wno-unknown-pragmas  

**Windows OS:**  
None

**Arguments**  
None

**Default**  
-Wunknown-pragmas  

A warning is issued if an unknown `#pragma` directive is used.

**Description**  
This option determines whether a warning is issued if an unknown `#pragma` directive is used.

**IDE Equivalent**  
None

**Alternate Options**  
None

---

**Wunused-function**  
*Determine whether a warning is issued if a declared function is not used.*

**Syntax**

**Linux OS:**  
-Wunused-function  
-Wno-unused-function  

**macOS:**  
-Wunused-function  
-Wno-unused-function  

**Windows OS:**  
None

**Arguments**  
None
**Default**

`-Wunused-function` No warning is issued if a declared function is not used.

**Description**

This option determines whether a warning is issued if a declared function is not used.

**IDE Equivalent**

None

**Alternate Options**

None

**Wunused-variable**

Determines whether a warning is issued if a local or non-constant static variable is unused after being declared.

**Syntax**

**Linux OS:**

`-Wunused-variable`

`-Wunused-variable`

**macOS:**

`-Wunused-variable`

`-Wunused-variable`

**Windows OS:**

None

**Arguments**

None

**Default**

`-Wunused-variable` No warning is issued if a local or non-constant static variable is unused after being declared.

**Description**

This option determines whether a warning is issued if a local or non-constant static variable is unused after being declared.

**IDE Equivalent**

None

**Alternate Options**

None
**ww, Qww**
Changes a soft diagnostic to an warning. This is a deprecated option. The replacement option is [Q]diag-warning.

**Syntax**

Linux OS and macOS:

```
-ww Ln[,Ln,...]
```

Windows OS:

```
/Qww Ln[,Ln,...]
```

**Arguments**

`Ln` Is the number of the diagnostic to be changed.

**Default**

**OFF** The compiler returns soft diagnostics as usual.

**Description**

This option overrides the severity of the soft diagnostic that corresponds to the specified number and changes it to an warning.

Soft diagnostics are diagnostic messages that don't prevent the production of an object file; for example, warnings and remarks.

If you specify more than one `Ln`, each `Ln` must be separated by a comma.

**IDE Equivalent**

None

**Alternate Options**

Linux and macOS*: `-diag-warning`

Windows: `/Qdiag-warning`

**Wwrite-strings**

*Issues a diagnostic message if const char * is converted to (non-const) char *.

**Syntax**

Linux OS:

```
-Wwrite-strings
```

macOS:

```
-Wwrite-strings
```

Windows OS:

None
Arguments
None

Default
OFF No diagnostic message is issued if const char * is converted to (non-const) char*.

Description
This option issues a diagnostic message if const char* is converted to (non-const) char *.

IDE Equivalent
None

Alternate Options
None

Compatibility Options

clang-name
Specifies the name of the Clang compiler that should be used to set up the environment for C compilations.

Syntax
Linux OS and macOS:
-clang-name=name

Windows OS:
None

Arguments

name Is the name of the Clang compiler to use. It can include the path where the Clang compiler is located.

Default
OFF The compiler uses the PATH setting to find the Clang compiler and resolve environment settings.

Description
This option specifies the name of the Clang compiler that should be used to set up the environment for C compilations. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.

This option is helpful when you are referencing a non-standard Clang installation.

The C++ equivalent to option -clang-name is -clangxx-name.

NOTE
This option applies to the Intel compiler running in a CLANG environment. It does not apply to the Intel CLANG-based compiler.
IDE Equivalent
None

Alternate Options
None

Example
If the following option is specified, the compiler looks for the Clang compiler named `foobar` in the PATH setting:

```
-clang-name=foobar
```

If the following option is specified, the compiler looks for the Clang compiler named `foobar` in the path specified:

```
-clang-name=/a/b/foobar
```

See Also
`clangxx-name` compiler option

`clangxx-name`
Specifies the name of the Clang++ compiler that should be used to set up the environment for C++ compilations.

Syntax
**Linux OS and macOS:**

```
-clangxx-name=name
```

**Windows OS:**

None

Arguments

`name`
Is the name of the Clang++ compiler to use. It can include the path where the Clang++ compiler is located.

Default

`OFF`
The compiler uses the PATH setting to find the Clang++ compiler and resolve environment settings.

Description
This option specifies the name of the Clang++ compiler that should be used to set up the environment for C++ compilations. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.

The C equivalent to option `-clangxx-name` is `-clang-name`.

**NOTE**
This option applies to the Intel compiler running in a CLANG environment. It does not apply to the Intel CLANG-based compiler.
IDE Equivalent
None

Alternate Options
None

Example
If the following option is specified, the compiler looks for the Clang++ compiler named foobar in the PATH setting:

-clangxx-name=foobar

If the following option is specified, the compiler looks for the Clang++ compiler named foobar in the path specified:

-clangxx-name=/a/b/foobar

See Also
clang-name compiler option

fabi-version
Instructs the compiler to select a specific ABI implementation.

Syntax
Linux OS:
-fabi-version=n
macOS:
-fabi-version=n
Windows OS:
None

Arguments

Is the ABI implementation. Possible values are:

<table>
<thead>
<tr>
<th>n</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Requests the latest ABI implementation.</td>
</tr>
<tr>
<td>1</td>
<td>Requests the ABI implementation used in gcc 3.2 and gcc 3.3.</td>
</tr>
<tr>
<td>2</td>
<td>Requests the ABI implementation used in gcc 3.4 and higher.</td>
</tr>
</tbody>
</table>

Default
Varies The compiler uses the ABI implementation that corresponds to the installed version of gcc.

Description
This option tells the compiler to select a specific ABI implementation. This option is compatible with gcc option -fabi-version. If you have multiple versions of gcc installed, the compiler may change the value of n depending on which gcc is detected in your path.
NOTE
gcc 3.2 and 3.3 are not fully ABI-compliant, but gcc 3.4 is highly ABI-compliant.

Caution
Do not mix different values for `-fabi-version` in one link.

IDE Equivalent
Visual Studio: None
Eclipse: Preprocessor > gcc Compatibility Options
Xcode: None

Alternate Options
None

fms-dialect
Enables support for a language dialect that is compatible with Microsoft Windows*, while maintaining link compatibility with GCC*.

Syntax
Linux OS:
`-fms-dialect [=ver]`

macOS:
None

Windows OS:
None

Arguments

`ver` Indicates that the language dialect should be compatible with a certain version of Microsoft Visual Studio*. Possible values are:

14.2 Specifies the dialect should be compatible with Microsoft Visual Studio 2019.

14.1 Specifies the dialect should be compatible with Microsoft Visual Studio 2017.

NOTE
Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.
Default
OFF The compiler does not support a language dialect that is compatible with Microsoft Windows.

Description
This option enables support for a limited language dialect that is compatible with Microsoft Windows, while maintaining link compatibility with GCC. It allows portability of code written on Windows that uses Microsoft extensions or language features. The code will be compiled with syntax and semantics similar to that used by the Microsoft Windows compiler, while continuing to produce object files that are link-compatible with the object files and libraries produced by the GCC compiler and/or by the Intel Compiler without this option.

The -fms-dialect option is intended to be used as an aid in porting code written on Windows. It is not intended to enable an all-encompassing capability for porting all such code written on Windows seamlessly. For example, even with this option enabled, there remains a need to support GCC-compatible syntax and semantics for some language constructs in order to generate object files that are link-time compatible with those produced by the GCC compiler and/or by the Intel compiler without this option.

IDE Equivalent
None

Alternate Options
Linux and macOS*: None
Windows: /Qgcc-dialect

See Also
/Qgcc-dialect compiler option

gcc-name
Lets you specify the name of the gcc compiler that should be used to set up the environment for C compilations.

Syntax
Linux OS:
-gcc-name=name

macOS:
None

Windows OS:
None

Arguments
name Is the name of the gcc compiler to use. It can include the path where the gcc compiler is located.

Default
OFF The compiler uses the PATH setting to find the gcc compiler and resolve environment settings.
Description
This option lets you specify the name of the gcc compiler that should be used to set up the environment for C compilations. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.

This option is helpful when you are referencing a non-standard gcc installation, or you have multiple gcc installations on your system. The compiler will match gcc version values to the gcc compiler you specify.

The C++ equivalent to option `-gcc-name` is `-gxx-name`.

IDE Equivalent
Visual Studio: None
Eclipse: **Preprocessor > Nonstandard gcc Installation**
Xcode: None

Alternate Options
None

Example
If the following option is specified, the compiler looks for the gcc compiler named `foobar` in the PATH setting:

```
-gcc-name=foobar
```

If the following option is specified, the compiler looks for the gcc compiler named `foobar` in the path specified:

```
-gcc-name=/a/b/foobar
```

See Also
`gxx-name` compiler option

`gnu-prefix` compiler option

**Let you specify a prefix that will be added to the names of gnu utilities called from the compiler.**

Syntax
Linux OS:
```
-gnu-prefix=prefix
```

macOS:
None

Windows OS:
None

Arguments
`prefix` is a string that prepends the name of gnu tools called from the compiler. The value depends on the gnu toolchain used for a particular operating system. For example, for Wind River* Linux 6.x, the `prefix` value will be `x86_64-wrs-linux-`. You must append a hyphen to `prefix` only if the toolchain prefix ends with a hyphen.
You can specify a short name or a pathname:

- **short name:** `-gnu-prefix=prefix`

  In this case, the compiler calls `prefix<gnu_utility>`, instead of `<gnu_utility>`. The utility with this name should be in the PATH environment variable.

- **pathname:** `-gnu-prefix=/directory_name/prefix`

  In this case, the compiler calls `/directory_name/prefix<gnu_utility>`. The utility with this name will be invoked by its full pathname.

**Default**

**OFF**

The compiler calls gnu utilities by their short names, and looks for them in the path specified by the PATH environment variable.

**Description**

This option lets you specify a prefix that will be added to the names of gnu utilities called from the compiler. This option is available for Linux*-targeted compilers but the host may be either Windows* or Linux*.

If you specify option `-gnu-prefix` with option `-gcc-name` (or `-gxx-name`), the following occurs:

- If a name specified in `-gcc-name` (or `-gxx-name`) contains a full path to a binary then option `-gnu-prefix` has no effect on the specified name; other binutils will have the prefix.
- Otherwise, option `-gnu-prefix` is applied to the name specified in `-gcc-name` (or `-gxx-name`).

The above approach provides flexibility to specify an alternative gcc name outside of the default toolchain. At the same time, if a short name is provided in option `-gcc-name`, it is assumed to be a part of the default toolchain and a prefix will be added.

Instead of using option `-gnu-prefix`, you can create symlinks for the short names of gnu utilities in the toolchain and add them to the PATH. For example, `ld--> i686-wrs-linux-gnu-ld`.

---

**NOTE**

Even though this option is not supported for a Windows-to-Windows native compiler, it is supported for a Windows-host to Linux-target compiler.

---

**IDE Equivalent**

None

**Alternate Options**

None

**Example**

Consider that you are setting up the compiler to produce an application for a Wind River* Linux 6.

Assume that your gnu cross toolchain for the target operating system is located in the following directory:

```
/WRL/60/x86_64-linux/usr/bin/x86_64-wrs-linux
```

and gnu utilities in the toolchain have `prefix`x86_64-wrs-linux-.
Assume your sysroot for the target operating system is located in the following directory:

```bash
/WRL/60/qemux86-64
```

To compile your application for Wind River* Linux 6, you must enter the following commands:

```bash
export PATH=/WRL/60/x86_64-linux/usr/bin/x86_64-wrs-linux:PATH
icc --sysroot/WRL/60/qemux86-64 -gnu-prefix=x86_64-wrs-linux- app.c
```

The following examples show what happens when you specify both `-gcc-name` and `-gnu-prefix`.

**Example 1:**

Command line: `-gcc-name=foobar -gnu-prefix=em64t-
Actual gcc name used in the compiler: em64t-foobar
ld name used in the icc: em64t-ld

**Example 2:**

Command line: `-gcc-name=/a/b/foobar -gnu-prefix=em64t-
Actual gcc name used in the compiler: /a/b/foobar
ld name used in the icc: em64t-ld

**See Also**

- `gcc-name` compiler option
- `gxx-name` compiler option
- `sysroot` compiler option

**gxx-name**

*Let's you specify the name of the g++ compiler that should be used to set up the environment for C++ compilations.*

**Syntax**

**Linux OS:**

```
-gxx-name=name
```

**macOS:**

None

**Windows OS:**

None

**Arguments**

`name` is the name of the g++ compiler to use. It can include the path where the g++ compiler is located.

**Default**

OFF The compiler uses the PATH setting to find the g++ compiler and resolve environment settings.

**Description**

This option lets you specify the name of the g++ compiler that should be used to set up the environment for C++ compilations. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.
This option is helpful if you have multiple gcc++ installations on your system. The compiler will match gcc++ version values to the gcc++ compiler you specify.

The C equivalent to option `-gxx-name` is `-gcc-name`.

**NOTE**
When compiling a C++ file with `icc`, g++ is used to get the environment.

**IDE Equivalent**
None

**Alternate Options**
None

**Example**
If the following option is specified, the compiler looks for the g++ compiler named `foobar` in the PATH setting:

```
-gxx-name=foobar
```

If the following option is specified, the compiler looks for the g++ compiler named `foobar` in the path specified:

```
-gxx-name=/a/b/foobar
```

**See Also**
`gcc-name` compiler option

**`Qgcc-dialect`**
Enables support for a limited gcc-compatible dialect on Windows*.

**Syntax**

**Linux OS and macOS:**
None

**Windows OS:**

```
/Qgcc-dialect:ver
```

**Arguments**

`ver`

Indicates the version of the gcc compiler that the limited language dialect should be compatible with. It must be a three-digit number with a value of 440 or higher. The number will be normalized to reflect the gcc compiler version numbering scheme. For example, if you specify 450, it indicates gcc version 4.5.0.

**Default**

`OFF` The compiler does not support a language dialect that is compatible with the gcc compiler.
Description

This option enables support for a limited gcc-compatible dialect on Windows*. It allows portability of code written for the gcc compiler.

This option enables a limited gnu-compatible compiler dialect on Windows. The code will be compiled with syntax and semantics similar to that used by gcc, while continuing to produce object files that are link-compatible with the object files and libraries on Windows (that is, object files and libraries produced by the Microsoft compiler and/or by the Intel compiler without this option).

The /Qgcc-dialect option is intended to be used as an aid in porting code written for the gcc compiler. It is not intended to enable an all-encompassing capability for porting all such code written for the gcc compiler seamlessly. For example, even with this option enabled, there remains a need to support Windows-compatible syntax and semantics for some language constructs in order to generate object files that are link-time compatible with those produced by the Windows compiler and/or by the Intel compiler without this option.

*Tells the compiler to emulate Microsoft compatibility bugs.*

Syntax

Linux OS and macOS:

None

Windows OS:

/Qms n

Arguments

n

Possible values are:

0

Instructs the compiler to disable some Microsoft compatibility bugs. It tells the compiler to emulate the fewest number of Microsoft compatibility bugs.

1

Instructs the compiler to enable most Microsoft compatibility bugs. It tells the compiler to emulate more Microsoft compatibility bugs than /Qms0.
Instructs the compiler to generate code that is Microsoft compatible. The compiler emulates the largest number of Microsoft compatibility bugs.

**Default**

/Qms1

The compiler emulates most Microsoft compatibility bugs.

**Description**

This option tells the compiler to emulate Microsoft compatibility bugs.

**Caution**

When using /Qms0, your program may not compile if it depends on Microsoft headers with compatibility bugs that are disabled with this option. Use /Qms1 if your compilation fails.

**IDE Equivalent**

None

**Alternate Options**

None

**Qvc**

Specifies compatibility with Microsoft Visual C++* (MSVC) or Microsoft Visual Studio*.

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/Qvc14.2
/Qvc14.1

**Arguments**

None

**Default**

When the compiler is installed, it detects which version of Microsoft Visual Studio is on your system. Qvc defaults to the form of the option that is compatible with that version. When multiple versions of Microsoft Visual Studio are installed, the compiler installation lets you select which version you want to use. In this case, Qvc defaults to the version you choose.
Description
This option specifies compatibility with MSVC or Microsoft Visual Studio.

<table>

**NOTE**
Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

IDE Equivalent
None

Alternate Options
None

stdlib
*Lets you select the C++ library to be used for linking.*

Syntax

Linux OS:
None

macOS:
-stdlib[=keyword]

Windows OS:
None

Arguments

*keyword*  
Is the function information to include. Possible values are:

- libc++  
  Links using the libc++ library.

- libstdc++  
  Links using the GNU libstdc++ library.

Default

-stdlib=libc++

The compiler links using the libc++ library.

Description

This option lets you select the C++ library to be used for linking. This option is processed by the command that initiates linking, adding library names explicitly to the link command.

Currently, if you do not specify this option, the libc++ headers and library are used.
NOTE
The IDE provides another possible setting for option `-stdlib`, which lets you choose the compiler default rather than a specific library.

**IDE Equivalent**
Visual Studio: None
Eclipse: None
Xcode: Language > C++ standard library > libstdc++
Language > C++ standard library > libc++
Language > C++ standard library > compiler-default

**Alternate Options**
None

**vmv**
*Enables pointers to members of any inheritance type.*

**Syntax**
Linux OS:
None
macOS:
None
Windows OS:
```
/vmv
```

**Arguments**
None

**Default**
OFF
The compiler uses default rules to represent pointers to members.

**Description**
This option enables pointers to members of any inheritance type. To use this option, you must also specify option `/vmg`.

**IDE Equivalent**
None

**Alternate Options**
None

**Linking or Linker Options**
This section contains descriptions for compiler options that pertain to linking or to the linker.
**Bdynamic**

*Enables dynamic linking of libraries at run time.*

**Syntax**

**Linux OS:**

-Bdynamic

**macOS:**

None

**Windows OS:**

None

**Arguments**

None

**Default**

OFF  Limited dynamic linking occurs.

**Description**

This option enables dynamic linking of libraries at run time. Smaller executables are created than with static linking.

This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.

All libraries on the command line following option -Bdynamic are linked dynamically until the end of the command line or until a -Bstatic option is encountered. The -Bstatic option enables static linking of libraries.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

Bstatic compiler option

---

**Bstatic**

*Enables static linking of a user's library.*

**Syntax**

**Linux OS:**

-Bstatic

**macOS:**

None

**Windows OS:**

None
Windows OS:
None

Arguments
None

Default
OFF  Default static linking occurs.

Description
This option enables static linking of a user's library.
This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.
All libraries on the command line following option -Bstatic are linked statically until the end of the command line or until a -Bdynamic option is encountered. The -Bdynamic option enables dynamic linking of libraries.

IDE Equivalent
None

Alternate Options
None

See Also
Bdynamic  compiler option

Bsymbolic
Binds references to all global symbols in a program to the definitions within a user's shared library.

Syntax
Linux OS:
-Bsymbolic

macOS:
None

Windows OS:
None

Arguments
None

Default
OFF  When a program is linked to a shared library, it can override the definition within the shared library.
Description

This option binds references to all global symbols in a program to the definitions within a user's shared library.

This option is only meaningful on Executable Linkage Format (ELF) platforms that support shared libraries.

Caution

This option can have unintended side-effects of disabling symbol preemption in the shared library.

IDE Equivalent

None

Alternate Options

None

See Also

Bsymbolic-functions  compiler option

Bsymbolic-functions

Binds references to all global function symbols in a program to the definitions within a user's shared library.

Syntax

Linux OS:
-Bsymbolic-functions

macOS:
None

Windows OS:
None

Arguments

None

Default

OFF  When a program is linked to a shared library, it can override the definition within the shared library.

Description

This option binds references to all global function symbols in a program to the definitions within a user's shared library.

This option is only meaningful on Executable Linkage Format (ELF) platforms that support shared libraries.
**Caution**

This option can have unintended side-effects of disabling symbol preemption in the shared library.

Bs symbolic compiler option

**cxxlib**

*Determines whether the compiler links using the C++ run-time libraries and header files provided by gcc.*

**Syntax**

**Linux OS:**

- `cxxlib [=dir]`
- `cxxlib-nostd`
- `no-cxxlib`

**macOS:**

None

**Windows OS:**

None

**Arguments**

`dir`  
Is an optional top-level location for the gcc binaries and libraries.

**Default**

**C++:** `-cxxlib`  
**C:** `-no-cxxlib`

For C++, the compiler uses the run-time libraries and headers provided by gcc. For C, the compiler uses the default run-time libraries and headers and does not link to any additional C++ run-time libraries and headers. However, if you specify compiler option `-std=gnu++98`, the default is `-cxxlib`.

**Description**

This option determines whether the compiler links using the C++ run-time libraries and header files provided by gcc.

If you specify `dir` for `cxxlib`, the compiler uses `dir/bin/gcc` to setup the environment.

Option `-cxxlib=dir` can be used with option `-gcc-name=name` to specify the location `dir/bin/name`.

Option `-cxxlib-nostd` prevents the compiler from linking with the standard C++ library.
IDE Equivalent
Visual Studio: None
Eclipse: Preprocessor > gcc Compatibility Options
Xcode: None

Alternate Options
None

gcc-name compiler option

dynamic-linker
*Specifies a dynamic linker other than the default.*

Syntax
Linux OS:
-dynamic-linker file

macOS:
None

Windows OS:
None

Arguments
file

Is the name of the dynamic linker to be used.

Default
OFF

The default dynamic linker is used.

Description
This option lets you specify a dynamic linker other than the default.

IDE Equivalent
None

Alternate Options
None

dynamiclib
*Invokes the libtool command to generate dynamic libraries.*

Syntax
Linux OS:
None
macOS:
-dynamiclib

Windows OS:
None

Arguments
None

Default
OFF The compiler produces an executable.

Description
This option invokes the libtool command to generate dynamic libraries.
When passed this option, the compiler uses the libtool command to produce a dynamic library instead of an executable when linking.
To build static libraries, you should specify option -staticlib or libtool -static <objects>.

IDE Equivalent
None

Alternate Options
None

See Also
staticlib
compiler option

F (Windows*)
 specifies the stack reserve amount for the program.

Syntax
Linux OS:
None

macOS:
None

Windows OS:
/Fn

Arguments
n
Is the stack reserve amount. It can be specified as a decimal integer or as a hexadecimal constant by using a C-style convention (for example, /F0x1000).
Default
OFF The stack size default is chosen by the operating system.

Description
This option specifies the stack reserve amount for the program. The amount \((n)\) is passed to the linker. Note that the linker property pages have their own option to do this.

IDE Equivalent
None

Alternate Options
None

F (macOS*)
*Adds a framework directory to the head of an include file search path.*

Syntax

**Linux OS:**
None

**macOS:**

\(-F\)dir

**Windows OS:**
None

Arguments

**dir** Is the name for the framework directory.

Default
OFF The compiler does not add a framework directory to the head of an include file search path.

Description
This option adds a framework directory to the head of an include file search path.

IDE Equivalent
None

Alternate Options
None

fixed
*Causes the linker to create a program that can be loaded only at its preferred base address.*
Syntax
Linux OS: None
macOS: None
Windows OS: /fixed

Arguments
None

Default
OFF The compiler uses default methods to load programs.

Description
This option is passed to the linker, causing it to create a program that can be loaded only at its preferred base address.

IDE Equivalent
None

Alternate Options
None

**Fm**
*Tells the linker to generate a link map file. This is a deprecated option. There is no replacement option.*

Syntax
Linux OS: None
macOS: None
Windows OS: /Fm[filename|dir]

Arguments

- `filename` Is the name for the link map file.
- `dir` Is the directory where the link map file should be placed. It can include *file*.

Default
OFF No link map is generated.
**Description**
This option tells the linker to generate a link map.

**IDE Equivalent**
None

**Alternate Options**
None

**fuse-ld**
*Tells the compiler to use a different linker instead of the default linker (ld).*

**Syntax**

*Linux OS:*
- `-fuse-ld=keyword`

*macOS:*
- `-fuse-ld=keyword`

*Windows OS:*
None

**Arguments**

*keyword* Possible values are:

- `bfd`  
  Tells the compiler to use the bfd linker.
- `gold`  
  Tells the compiler to use the gold linker.

**Default**

Id  

The compiler uses the ld linker by default.

**Description**
This option tells the compiler to use a different linker instead of default linker (ld).
This option is provided for compatibility with gcc.

**IDE Equivalent**
None

**Alternate Options**
None

**l**
*Tells the linker to search for a specified library when linking.*
Syntax

Linux OS:
-\texttt{lstring}

macOS:
-\texttt{lstring}

Windows OS:
None

Arguments

\texttt{string} \hspace{1cm} Specifies the library (libstring) that the linker should search.

Default

OFF \hspace{1cm} The linker searches for standard libraries in standard directories.

Description

This option tells the linker to search for a specified library when linking.

When resolving references, the linker normally searches for libraries in several standard directories, in directories specified by the \texttt{L} option, then in the library specified by the \texttt{l} option.

The linker searches and processes libraries and object files in the order they are specified. So, you should specify this option following the last object file it applies to.

IDE Equivalent

None

Alternate Options

None

See Also

\texttt{L} \hspace{.5cm} compiler option

\textbf{L}

\textit{Tells the linker to search for libraries in a specified directory before searching the standard directories.}

Syntax

Linux OS:
-\texttt{Ldir}

macOS:
-\texttt{Ldir}

Windows OS:
None
Arguments

dir

Is the name of the directory to search for libraries.

Default

OFF

The linker searches the standard directories for libraries.

Description

This option tells the linker to search for libraries in a specified directory before searching for them in the standard directories.

IDE Equivalent

None

Alternate Options

None

l compiler option

LD

Specifies that a program should be linked as a dynamic-link (DLL) library.

Syntax

Linux OS:

None

macOS:

None

Windows OS:

/ld
/ldd

Arguments

None

Default

OFF

The program is not linked as a dynamic-link (DLL) library.

Description

This option specifies that a program should be linked as a dynamic-link (DLL) library instead of an executable (.exe) file. You can also specify /ldd, where d indicates a debug version.

IDE Equivalent

None
Alternate Options
None

**link**
*Passes user-specified options directly to the linker at compile time.*

**Syntax**
Linux OS:
None

macOS:
None

Windows OS:
/link

**Arguments**
None

**Default**
OFF No user-specified options are passed directly to the linker.

**Description**
This option passes user-specified options directly to the linker at compile time.
All options that appear following /link are passed directly to the linker.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
Xlinker compiler option

**MD**
*Tells the linker to search for unresolved references in a multithreaded, dynamic-link run-time library.*

**Syntax**
Linux OS:
None

macOS:
None
**Windows OS:**

/MD
/MDd

**Arguments**

None

**Default**

OFF  The linker searches for unresolved references in a multi-threaded, static run-time library.

**Description**

This option tells the linker to search for unresolved references in a multithreaded, dynamic-link (DLL) run-time library. You can also specify /MDd, where d indicates a debug version.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

**IDE Equivalent**

Visual Studio:  **Code Generation > Runtime Library**
Eclipse: None
Xcode: None

**Alternate Options**

None

**MT**

_Tells the linker to search for unresolved references in a multithreaded, static run-time library._

**Syntax**

**Linux OS:**

None

**macOS:**

None

**Windows OS:**

/MT
/MTd

**Arguments**

None

**Default**

/MT  The linker searches for unresolved references in a multi-threaded, static run-time library.
**Description**

This option tells the linker to search for unresolved references in a multithreaded, static run-time library. You can also specify `/MTd`, where `d` indicates a debug version.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

**IDE Equivalent**

Visual Studio: **Code Generation > Runtime Library**

Eclipse: None

Xcode: None

**Alternate Options**

None

Qvc compiler option

---

**no-libgcc**

*Prevents the linking of certain gcc-specific libraries.*

**Syntax**

**Linux OS:**

`-no-libgcc`

**macOS:**

None

**Windows OS:**

None

**Arguments**

None

**Default**

OFF

**Description**

This option prevents the linking of certain gcc-specific libraries.

This option is not recommended for general use.

**IDE Equivalent**

None

**Alternate Options**

None
**nodefaultlibs**

*Prevents the compiler from using standard libraries when linking.*

**Syntax**

**Linux OS:**

`-nodefaultlibs`

**macOS:**

`-nodefaultlibs`

**Windows OS:**

None

**Arguments**

None

**Default**

OFF  The standard libraries are linked.

**Description**

This option prevents the compiler from using standard libraries when linking. On Linux* systems, it is provided for GNU compatibility.

**IDE Equivalent**

Visual Studio: None

Eclipse: **Libraries > Use no system libraries**

Xcode: None

**Alternate Options**

None

**See Also**

`nostdlib`  compiler option

**no-intel-lib, Qno-intel-lib**

*Disables linking to specified Intel® libraries, or to all Intel® libraries.*

**Syntax**

**Linux OS:**

`-no-intel-lib [=library]`

**macOS:**

None

**Windows OS:**

`/Qno-intel-lib[::library]`
Arguments

library Indicates which Intel® library should not be linked. Possible values are:

libirc Disables linking to the Intel® C/C++ library.
libimf Disables linking to the Intel® C++ Compiler Classic Math library. This value is only available for Linux*.
libsvml Disables linking to the Intel® Short Vector Math library.
libirng Disables linking to the Random Number Generator library.
libipgo Disables linking to the Profile-Guided Optimization library.

If you specify more than one library, they must be separated by commas.
If library is omitted, the compiler will not link to any of the Intel® libraries shown above.

Default

OFF If this option is not specified, the compiler uses default heuristics for linking to libraries.

Description
This option disables linking to specified Intel® libraries, or to all Intel® libraries.

IDE Equivalent
None

Alternate Options
None

nostartfiles
Prevents the compiler from using standard startup files when linking.

Syntax

Linux OS:
-nostartfiles
macOS:
-nostartfiles
Windows OS:
None

Arguments
None

Default
OFF The compiler uses standard startup files when linking.
**Description**
This option prevents the compiler from using standard startup files when linking.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
nostdlib compiler option

### nostdlib
*Prevents the compiler from using standard libraries and startup files when linking.*

**Syntax**

**Linux OS:**
- `-nostdlib`

**macOS:**
- `-nostdlib`

**Windows OS:**
None

**Arguments**
None

**Default**
OFF  The compiler uses standard startup files and standard libraries when linking.

**Description**
This option prevents the compiler from using standard libraries and startup files when linking. On Linux* systems, it is provided for GNU compatibility.

This option is not related to option `-stdlib`.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
nodefaultlibs compiler option
nostartfiles compiler option
pie

Determines whether the compiler generates position-independent code that will be linked into an executable.

Syntax

Linux OS:

- pie
- no-pie

macOS:

- pie
- no-pie

Windows OS:

None

Arguments

None

Default

varies

On Linux* and on macOS* versions less than 10.7, the default is -no-pie. On macOS* 10.7 or greater, the default is -pie.

Description

This option determines whether the compiler generates position-independent code that will be linked into an executable. To enable generation of position-independent code that will be linked into an executable, specify -pie.

To disable generation of position-independent code that will be linked into an executable, specify -no-pie.

IDE Equivalent

None

Alternate Options

None

See Also

fpic

compiler option

pthread

Tells the compiler to use pthreads library for multithreading support.

Syntax

Linux OS:

- pthread
**macOS:**
- `pthread`

**Windows OS:**
None

**Arguments**
None

**Default**
OFF  
The compiler does not use pthreads library for multithreading support.

**Description**
Tells the compiler to use pthreads library for multithreading support.

**IDE Equivalent**
None

**Alternate Options**
None

**shared**
*Tells the compiler to produce a dynamic shared object instead of an executable.*

**Syntax**

**Linux OS:**
- `--shared`

**macOS:**
None

**Windows OS:**
None

**Arguments**
None

**Default**
OFF  
The compiler produces an executable.

**Description**
This option tells the compiler to produce a dynamic shared object (DSO) instead of an executable. This includes linking in all libraries dynamically and passing `--shared` to the linker.

You must specify option `fpic` for the compilation of each object file you want to include in the shared library.

**IDE Equivalent**
None
Alternate Options
None

See Also
dynamiclib compiler option
fpic compiler option
Xlinker compiler option

shared-intel
Causes Intel-provided libraries to be linked in dynamically.

Syntax
Linux OS:
-shared-intel

macOS:
-shared-intel

Windows OS:
None

Arguments
None

Default
OFF Intel® libraries are linked in statically, with the exception of Intel's OpenMP* runtime support library, which is linked in dynamically unless you specify option -qopenmp-link=static.

Description
This option causes Intel-provided libraries to be linked in dynamically. It is the opposite of -static-intel.
This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command.
If you specify option -mcmode=medium or -mcmode=large, it sets option -shared-intel.

NOTE
On macOS* systems, when you set "Intel Runtime Libraries" to "Dynamic", you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

IDE Equivalent
Visual Studio: None
Eclipse: None
Xcode: Runtime > Intel Runtime Libraries
**Alternate Options**
None

**See Also**
- static-intel  compiler option
- qopenmp-link  compiler option

---

**shared-libgcc**

*Links the GNU libgcc library dynamically.*

**Syntax**

**Linux OS:**
- `--shared-libgcc`

**macOS:**
None

**Windows OS:**
None

**Arguments**
None

**Default**

`--shared-libgcc`  The compiler links the `libgcc` library dynamically.

**Description**

This option links the GNU `libgcc` library dynamically. It is the opposite of option `static-libgcc`.

This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command.

This option is useful when you want to override the default behavior of the `static` option, which causes all libraries to be linked statically.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
- static-intel  compiler option
- static-libgcc  compiler option

---

**static**

*Prevents linking with shared libraries.*
Syntax
Linux OS:
- static
macOS:
None
Windows OS:
None

Arguments
None

Default
OFF  The compiler links with shared libraries except as otherwise specified by -static-intel or its default.

Description
This option prevents linking with shared libraries. It causes the executable to link all libraries statically.

NOTE
This option does not cause static linking of libraries for which no static version is available, such as the OpenMP run-time libraries on Windows*. These libraries can only be linked dynamically.

IDE Equivalent
Visual Studio: None
Eclipse: Libraries > Link with static libraries
Xcode: None

Alternate Options
None

See Also
static-intel compiler option

static-intel
Causes Intel-provided libraries to be linked in statically.
Windows OS:
None

Arguments
None

Default
ON Intel® libraries are linked in statically, with the exception of Intel's OpenMP* runtime support library, which is linked in dynamically unless you specify option -qopenmp-link=static.

Description
This option causes Intel-provided libraries to be linked in statically with certain exceptions (see the Default above). It is the opposite of -shared-intel.

This option is processed by the icc/icpc command that initiates linking, adding library names explicitly to the link command.

If you specify option -static-intel while option -mcmode=medium or -mcmode=large is set, an error will be displayed.

If you specify option -static-intel and any of the Intel-provided libraries have no static version, a diagnostic will be displayed.

IDE Equivalent
Visual Studio: None
Eclipse: None
Xcode: Runtime > Intel Runtime Libraries

Alternate Options
None

shared-intel compiler option
gopenmp-link compiler option

static-libgcc
Links the GNU libgcc library statically.

Syntax
Linux OS:
-static-libgcc
macOS:
None
Windows OS:
None

Arguments
None
**Default**

**OFF**  The compiler links the GNU `libgcc` library dynamically.

**Description**

This option links the GNU `libgcc` library statically. It is the opposite of option `-shared-libgcc`.

This option is processed by the icc or icpc command that initiates linking, adding library names explicitly to the link command.

This option is useful when you want to override the default behavior, which causes the library to be linked dynamically.

---

**NOTE**

If you want to use traceback, you must also link to the static version of the `libgcc` library. This library enables printing of backtrace information.

---

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

- `shared-libgcc`  compiler option
- `static-libstdc++`  compiler option

---

**static-libstdc++**

*Links the GNU `libstdc++` library statically.*

**Syntax**

**Linux OS:**

- `-static-libstdc++`

**macOS:**

None

**Windows OS:**

None

**Arguments**

None

**Default**

**OFF**  The compiler links the GNU `libstdc++` library dynamically.

**Description**

This option links the GNU `libstdc++` library statically. This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command.
This option is useful when you want to override the default behavior, which causes the library to be linked dynamically.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

static-libgcc compiler option

### staticlib

*Invokes the libtool command to generate static libraries.*

**Syntax**

**Linux OS:**

None

**macOS:**

-`-staticlib`

**Windows OS:**

None

**Arguments**

None

**Default**

**OFF**  The compiler produces an executable.

**Description**

This option invokes the `libtool` command to generate static libraries. This option is processed by the command that initiates linking, adding library names explicitly to the link command.

When passed this option, the compiler uses the `libtool` command to produce a static library instead of an executable when linking.

To build dynamic libraries, you should specify option `-dynamiclib` or `libtool -dynamic <objects>`.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

dynamiclib compiler option
T
Tells the linker to read link commands from a file.

Syntax
Linux OS:
- T filename

macOS:
None

Windows OS:
None

Arguments

filename Is the name of the file.

Default
OFF The linker does not read link commands from a file.

Description
This option tells the linker to read link commands from a file.

IDE Equivalent
None

Alternate Options
None

u (Linux*)
Tells the compiler the specified symbol is undefined.

Syntax
Linux OS:
- u symbol

macOS:
- u symbol

Windows OS:
None

Arguments
None

Default
OFF Standard rules are in effect for variables.
Description
This option tells the compiler the specified symbol is undefined.

IDE Equivalent
None

Alternate Options
None

`v`
Specifies that driver tool commands should be displayed and executed.

Syntax
Linux OS:
-v [filename]

macOS:
-v [filename]

Windows OS:
None

Arguments
filename Is the name of a source file to be compiled. A space must appear before the file name.

Default
OFF No tool commands are shown.

Description
This option specifies that driver tool commands should be displayed and executed.
If you use this option without specifying a source file name, the compiler displays only the version of the compiler.

IDE Equivalent
None

Alternate Options
None

See Also
dryrun compiler option

Wa
Passes options to the assembler for processing.
Syntax

Linux OS:
-Wa,option1[,option2,...]

macOS:
-Wa,option1[,option2,...]

Windows OS:
None

Arguments

option
Is an assembler option. This option is not processed by the driver and is directly passed to the assembler.

Default

OFF
No options are passed to the assembler.

Description

This option passes one or more options to the assembler for processing. If the assembler is not invoked, these options are ignored.

IDE Equivalent

None

Alternate Options

None

Wl

Passes options to the linker for processing.

Syntax

Linux OS:
-Wl,option1[,option2,...]

macOS:
-Wl,option1[,option2,...]

Windows OS:
None

Arguments

option
Is a linker option. This option is not processed by the driver and is directly passed to the linker.

Default

OFF
No options are passed to the linker.
**Description**
This option passes one or more options to the linker for processing. If the linker is not invoked, these options are ignored.
This option is equivalent to specifying option `-Qoption,link,options`.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
`Qoption` compiler option

**Wp**
*Passes options to the preprocessor.*

**Syntax**

**Linux OS:**
- `Wp,option1[,option2,...]`

**macOS:**
- `Wp,option1[,option2,...]`

**Windows OS:**
None

**Arguments**

<table>
<thead>
<tr>
<th><code>option</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>Is a preprocessor option. This option is not processed by the driver and is directly passed to the preprocessor.</td>
</tr>
</tbody>
</table>

**Default**
OFF
No options are passed to the preprocessor.

**Description**
This option passes one or more options to the preprocessor. If the preprocessor is not invoked, these options are ignored.
This option is equivalent to specifying option `-Qoption,cpp,options`.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
`Qoption` compiler option
Xlinker

Passes a linker option directly to the linker.

Syntax

Linux OS:
-Xlinker option

macOS:
-Xlinker option

Windows OS:
None

Arguments

don option

Is a linker option.

Default

OFF

No options are passed directly to the linker.

Description

This option passes a linker option directly to the linker. If -Xlinker -shared is specified, only -shared is passed to the linker and no special work is done to ensure proper linkage for generating a shared object.
-Xlinker just takes whatever arguments are supplied and passes them directly to the linker.

If you want to pass compound options to the linker, for example "-L $HOME/lib", you must use the following method:

-Xlinker -L -Xlinker $HOME/lib

IDE Equivalent

Visual Studio: None

Eclipse: Linker > Miscellaneous > Other Options

Xcode: None

Alternate Options

None

shared compiler option
link compiler option

ZI

Causes library names to be omitted from the object file.
**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/zl

**Arguments**
None

**Default**
OFF

Default or specified library names are included in the object file.

**Description**

This option causes library names to be omitted from the object file.

**IDE Equivalent**

Visual Studio: **Advanced > Omit Default Library Names**

Eclipse: None

Xcode: None

**Alternate Options**
None

**Miscellaneous Options**

This section contains descriptions for compiler options that do not pertain to a specific category.

**bigobj**

*Increases the number of sections that an object file can contain.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/bigobj

**Arguments**
None
Default

OFF An object file can hold up to 65,536 (2**16) addressable sections.

Description
This option increases the number of sections that an object file can contain. It increases the address capacity to 4,294,967,296 (2**32).
This option may be helpful for .obj files that can hold more sections, such as machine generated code or code that makes heavy use of template libraries.

IDE Equivalent
None

Alternate Options
None

dryrun
Specifies that driver tool commands should be shown but not executed.

Syntax
Linux OS:
-dryrun
macOS:
-dryrun
Windows OS:
None

Arguments
None

Default

OFF No tool commands are shown, but they are executed.

Description
This option specifies that driver tool commands should be shown but not executed.

IDE Equivalent
None

Alternate Options
None

See Also
v compiler option
dumpmachine

Displays the target machine and operating system configuration.

Syntax

Linux OS:
-dumpmachine

macOS:
-dumpmachine

Windows OS:
None

Arguments
None

Default
OFF
The compiler does not display target machine or operating system information.

Description
This option displays the target machine and operating system configuration. No compilation is performed.

IDE Equivalent
None

Alternate Options
None

See Also
dumpversion  compiler option

dumpversion
Displays the version number of the compiler.

Syntax

Linux OS:
-dumpversion

macOS:
-dumpversion

Windows OS:
None

Arguments
None
Default

OFF The compiler does not display the compiler version number.

Description
This option displays the version number of the compiler. It does not compile your source files.

IDE Equivalent
None

Alternate Options
None

Example
Consider the following command:

```
icc -dumpversion
```

If the above is specified when using version 18.0 of the compiler, the compiler displays "18.0".

See Also
dumpmachine compiler option
global-hoist, Qglobal-hoist

Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.

Syntax

Linux OS:
- -global-hoist
- -no-global-hoist

macOS:
- -global-hoist
- -no-global-hoist

Windows OS:

- /Qglobal-hoist
- /Qglobal-hoist-

Arguments

None

Default

- -global-hoist
or /Qglobal-hoist

Certain optimizations are enabled that can move memory loads.
Description
This option enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source. In most cases, these optimizations are safe and can improve performance.

The negative form of the option is useful for some applications, such as those that use shared or dynamically mapped memory, which can fail if a load is moved too early in the execution stream (for example, before the memory is mapped).

IDE Equivalent
None

Alternate Options
None

help
Displays all supported compiler options or supported compiler options within a specified category of options.

Syntax
Linux OS:
-help[category]

macOS:
-help[category]

Windows OS:
/help[category]

Arguments

category
Is a category or class of options to display. Possible values are:

    advanced
        Displays advanced optimization options that allow fine tuning of compilation or allow control over advanced features of the compiler.

    codegen
        Displays Code Generation options.

    compatibility
        Displays options affecting language compatibility.

    component
        Displays options for component control.

    data
        Displays options related to interpretation of data in programs or the storage of data.

    deprecated
        Displays options that have been deprecated.

    diagnostics
        Displays options that affect diagnostic messages displayed by the compiler.
float
help
inline
ipo
language
link
misc
openmp
opt
output
pgo
preproc
reports

**Default**

OFF  No list is displayed unless this compiler option is specified.

**Description**

This option displays all supported compiler options or supported compiler options within a specified category of options. If you specify category, it will display all available (supported) compiler options in the specified category.

On Linux* systems, this option can also be specified as --help.

**IDE Equivalent**

None

**Alternate Options**

Linux and macOS*: None

Windows: /?

**intel-freestanding**

*Let you compile in the absence of a gcc environment.*
**Syntax**

**Linux OS:**
-intel-freestanding[=ver]

**macOS:**
None

**Windows OS:**
None

**Arguments**

*ver*  
Is a three-digit number that is used to determine the gcc version that the compiler should be compatible with for compilation. It also sets the corresponding GNUC macros.

The number will be normalized to reflect the gcc compiler version numbering scheme. For example, if you specify 493, it indicates the compiler should be compatible with gcc version 4.9.3.

**Default**

OFF  
The compiler uses default heuristics when choosing the gcc environment.

**Description**

This option lets you compile in the absence of a gcc environment. It disables any external compiler calls (such as calls to gcc) that the compiler driver normally performs by default.

This option also removes any default search locations for header and library files. So, for successful compilation and linking, you must provide these search locations.

This option does not affect ld, as, or cpp. They will be used for compilation as needed.

---

**NOTE**

This option does not imply option -nostdinc -nostdlib. If you want to assure a clean environment for compilation (including removal of Intel-specific header locations and libs), you should specify -nostdinc and/or -nostdlib.

---

**NOTE**

This option is supported for any Linux-target compiler, including a Windows-host to Linux-target compiler.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

intel-freestanding-target-os  compiler option
nostdlib  compiler option
nostdinc  compiler option, which is an alternate option for option X

**intel-freestanding-target-os**

*Lets you specify the target operating system for compilation.*

**Syntax**

Linux OS:

```
-intel-freestanding-target-os=os
```

macOS:

None

Windows OS:

None

**Arguments**

`os`  
Is the target operating system for the Linux compiler. Currently, the only possible value is linux.

**Default**

OFF  
The installed gcc determines the target operating system.

**Description**

This option lets you specify the target operating system for compilation. It sets option `-intel-freestanding`.

**NOTE**

This option is supported for any Linux-target compiler, including a Windows-host to Linux-target compiler.

**IDE Equivalent**

None

**Alternate Options**

None

**See Also**

intel-freestanding  compiler option

**MP-force**

*Disables the default heuristics used when compiler option /MP is specified. This lets you control the number of processes spawned.*
Syntax

Linux OS:
None

macOS:
None

Windows OS:
/MP-force

Arguments
None

Default
OFF

Default heuristics are used when option /MP is specified.

Description
This option disables the default heuristics used when compiler option /MP:n is specified. You must specify it when you specify option /MP:n.

Option /MP:n sets the maximum number of processes that can be used to compile large numbers of source files at the same time. However, default heuristics may cause the number of processes to be less than specified.

Option /MP-force ensures that n will be the maximum number of processes spawned regardless of other heuristics which may limit the number of processes.

IDE Equivalent
None

Alternate Options
None

See Also
multiple-processes, MP compiler option

multibyte-chars, Qmultibyte-chars
Determines whether multi-byte characters are supported.

Syntax

Linux OS:
- multibyte-chars
- no-multibyte-chars

macOS:
- multibyte-chars
- no-multibyte-chars
Windows OS:
/Qmultibyte-chars
/Qmultibyte-chars-

**Arguments**
None

**Default**
-multibyte-chars
or
/Qmultibyte-chars

**Description**
This option determines whether multi-byte characters are supported.

**IDE Equivalent**
Visual Studio: None
Eclipse: Language > Support Multibyte Characters in Source
Xcode: Language > Support Multibyte Characters in Source

**Alternate Options**
None

**multiple-processes, MP**
*Creates multiple processes that can be used to compile large numbers of source files at the same time.*

**Syntax**

**Linux OS:**
-multiple-processes[=n]

**macOS:**
-multiple-processes[=n]

**Windows OS:**
/MP[=n]

**Arguments**

\( n \)

**Default**
OFF

A single process is used to compile source files.
Description
This option creates multiple processes that can be used to compile large numbers of source files at the same time. It can improve performance by reducing the time it takes to compile source files on the command line.
This option causes the compiler to create one or more copies of itself, each in a separate process. These copies simultaneously compile the source files.
If n is not specified for this option, the default value is as follows:
- On Windows* systems, the value is based on the setting of the NUMBER_OF_PROCESSORS environment variable.
- On Linux* and macOS* systems, the value is 2.
This option applies to compilations, but not to linking or link-time code generation.
To override default heuristics, specify option /MP-force. It ensures that n will be the maximum number of processes created regardless of other heuristics that may limit the number of processes.

IDE Equivalent
Visual Studio: General > Multi-processor Compilation
Eclipse: None
Xcode: None

Alternate Options
None

See Also
MP-force compiler option

nologo
_Tells the compiler to not display compiler version information._

Syntax
Linux OS:
None
macOS:
None
Windows OS:
/nologo

Arguments
None

Default
OFF

Description
Tells the compiler to not display compiler version information.
IDE Equivalent
Visual Studio: **General > Suppress Startup Banner**
Eclipse: None
Xcode: None

Alternate Options
None

**print-sysroot**
*Prints the target sysroot directory that is used during compilation.*

**Syntax**

**Linux OS:**
- `print-sysroot`

**macOS:**
None

**Windows OS:**
None

**Arguments**
None

**Default**
OFF

Nothing is printed.

**Description**
This option prints the target sysroot directory that is used during compilation.
This is the target sysroot directory that is specified in an environment file or in option `--sysroot`. This option is only effective if a target sysroot has been specified.
This option is provided for compatibility with gcc.

**NOTE**
Even though this option is not supported for a Windows-to-Windows native compiler, it is supported for a Windows-host to Linux-target compiler.

IDE Equivalent
None

Alternate Options
None

See Also
`sysroot` compiler option
**save-temps, Qsave-temps**  
*Tells the compiler to save intermediate files created during compilation.*

**Syntax**

**Linux OS:**
- `-save-temps`
- `-no-save-temps`

**macOS:**
- `-save-temps`
- `-no-save-temps`

**Windows OS:**
- `/Qsave-temps`
- `/Qsave-temps`-

**Arguments**

None

**Default**

Linux* and macOS* systems: `-no-save-temps`  
Windows* systems: .obj files are saved

On Linux and macOS* systems, the compiler deletes intermediate files after compilation is completed. On Windows systems, the compiler saves only intermediate object files after compilation is completed.

**Description**

This option tells the compiler to save intermediate files created during compilation. The names of the files saved are based on the name of the source file; the files are saved in the current working directory.

If option `[Q]save-temps` is specified, the following occurs:

- The object `.o` file (Linux and macOS*) or `.obj` file (Windows) is saved.
- The assembler `.s` file (Linux and macOS*) or `.asm` file (Windows) is saved if you specified the `[Q]use-asm` option.

If `-no-save-temps` is specified on Linux or macOS* systems, the following occurs:

- The `.o` file is put into `/tmp` and deleted after calling `ld`.  
- The preprocessed file is not saved after it has been used by the compiler.

If `/Qsave-temps`- is specified on Windows systems, the following occurs:

- The `.obj` file is not saved after the linker step.  
- The preprocessed file is not saved after it has been used by the compiler.

**NOTE**

This option only saves intermediate files that are normally created during compilation.
**IDE Equivalent**
None

**Alternate Options**
None

**Example**
If you compile program `my_foo.c` on a Linux or macOS* system and you specify option `--save-temps` and option `--use-asm`, the compilation will produce files `my_foo.o` and `my_foo.s`.

If you compile program `my_foo.c` on a Windows system and you specify option `/Qsave-temps` and option `/Quse-asm`, the compilation will produce files `my_foo.o` and `my_foo.asm`.

**showIncludes**
*Tells the compiler to display a list of the include files.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/showIncludes

**Arguments**
None

**Default**
OFF The compiler does not display a list of the include files.

**Description**
This option tells the compiler to display a list of the include files. Nested include files (files that are included from the files that you include) are also displayed.

**IDE Equivalent**
Visual Studio: Advanced > Show Includes
Eclipse: None
Xcode: None

**Alternate Options**
None

**SOX**
*Tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain functions.*
**Syntax**

**Linux OS:**
- `sox[=keyword[,keyword]]`
- `-no-sox`

**macOS:**
None

**Windows OS:**
None

**Arguments**

`keyword`  
Is the function information to include. Possible values are:

- `inline`  
  Includes a list of the functions that were inlined in each object.

- `profile`  
  Includes a list of the functions that were compiled with the `-prof-use` option and for which the `.dpi` file had profile information, and an indication for each as to whether the profile information was USED (matched) or IGNORED (mismatched).

**Default**

- `-no-sox`  
The compiler does not save these informational strings in the object file.

**Description**

This option tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain functions. The information is embedded as a string in each object file or assembly output.

If you specify option `sox` with no `keyword`, the compiler saves the compiler options and version number used in the compilation of the objects that make up the executable.

When you specify this option, the size of the executable on disk is increased slightly. Each `keyword` you specify increases the size of the executable. When you link the object files into an executable file, the linker places each of the information strings into the header of the executable. It is then possible to use a tool, such as a strings utility, to determine what options were used to build the executable file.

**IDE Equivalent**

None

**Alternate Options**

None

**Example**

The following commands are equivalent:

- `sox=profile -sox=inline`
- `sox=profile,inline`
You can use the negative form of the option to disable and reset the option. For example:

```
-sox=profile -no-sox -sox=inline ! This means -sox=inline
```

See Also
prof-use, Qprof-use compiler option

sysroot
Specifies the root directory where headers and libraries are located.

Syntax

**Linux OS:**

```
--sysroot=dir
```

**macOS:**

None

**Windows OS:**

None

Arguments

`dir`

Specifies the local directory that contains copies of target libraries in the corresponding subdirectories.

Default

Off

The compiler uses default settings to search for headers and libraries.

Description

This option specifies the root directory where headers and libraries are located.

For example, if the headers and libraries are normally located in `/usr/include` and `/usr/lib` respectively, `--sysroot=/mydir` will cause the compiler to search in `/mydir/usr/include` and `/mydir/usr/lib` for the headers and libraries.

This option is provided for compatibility with gcc.

**NOTE**

Even though this option is not supported for a Windows-to-Windows native compiler, it is supported for a Windows-host to Linux-target compiler.

IDE Equivalent

None

Alternate Options

None

print-sysroot compiler option
**Tc**
*Tells the compiler to process a file as a C source file.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/Tc filename

**Arguments**

`filename` Is the file name to be processed as a C source file.

**Default**
OFF The compiler uses default rules for determining whether a file is a C source file.

**Description**
This option tells the compiler to process a file as a C source file.

**IDE Equivalent**
None

**Alternate Options**
None

**See Also**
TC compiler option

**TC**
*Tells the compiler to process all source or unrecognized file types as C source files.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/TC
**Arguments**
None

**Default**
OFF The compiler uses default rules for determining whether a file is a C source file.

**Description**
This option tells the compiler to process all source or unrecognized file types as C source files.

**IDE Equivalent**
Visual Studio: **Advanced > Compile As**
Eclipse: None
Xcode: None

**Alternate Options**
None

**See Also**
TP compiler option
Tc compiler option

**Tp**
*Tell the compiler to process a file as a C++ source file.*

**Syntax**

**Linux OS:**
None

**macOS:**
None

**Windows OS:**
/Tp filename

**Arguments**
filename Is the file name to be processed as a C++ source file.

**Default**
OFF The compiler uses default rules for determining whether a file is a C++ source file.

**Description**
This option tells the compiler to process a file as a C++ source file.

**IDE Equivalent**
None
Alternate Options
None

See Also
TP  compiler option
Tc  compiler option

V
Displays the compiler version information.

Syntax
Linux OS:
-V
macOS:
-V
Windows OS:
/QV

Arguments
None

Default
OFF  The compiler version information is not displayed.

Description
This option displays the startup banner, which contains the following compiler information:

- The name of the compiler and its applicable architecture
- The major and minor version of the compiler, the update number, and the package number (for example, Version 12.1.0.047)
- The specific build and build date (for example, Build <builddate>)
- The copyright date of the software

This option can be placed anywhere on the command line.

IDE Equivalent
Visual Studio: None
Eclipse: General > Show Startup Banner
Xcode: General > Show Startup Banner

Alternate Options
None

version
Tells the compiler to display GCC-style version information.
Syntax
Linux OS:
--version
macOS:
--version
Windows OS:
None

Arguments
None

Default
OFF

Description
Tells the compiler to display GCC-style version information.

IDE Equivalent
None

Alternate Options
None

watch
*Tells the compiler to display certain information to the console output window.*

Syntax
Linux OS:
-watch[=keyword[, keyword...]]
-watch

macOS:
-watch[=keyword[, keyword...]]
-watch

Windows OS:
/watch[=keyword[, keyword...]]
/watch

Arguments

\texttt{keyword} Determines what information is displayed. Possible values are:

\begin{itemize}
  \item \texttt{none} Disables cmd and source.
\end{itemize}
Determines whether driver tool commands are displayed and executed.

Determines whether the name of the file being compiled is displayed.

Enables cmd and source.

**Default**

**nowatch**
Pass information and source file names are not displayed to the console output window.

**Description**
Tells the compiler to display processing information (pass information and source file names) to the console output window.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>watch</code>&lt;keyword&gt;</td>

**Deprecated and Removed Compiler Options**

This topic lists deprecated and removed compiler options and suggests replacement options, if any are available.

For more information on compiler options, see the detailed descriptions of the individual option descriptions in this section.

**Deprecated Options**

Occasionally, compiler options are marked as "deprecated." Deprecated options are still supported in the current release, but are planned to be unsupported in future releases.

The following two tables list options that are currently deprecated.
Note that deprecated options are not limited to these lists.

### Deprecated Linux* and macOS* Options

### Removed Options

Some compiler options are no longer supported and have been removed. If you use one of these options, the compiler issues a warning, ignores the option, and then proceeds with compilation.

The following two tables list options that are no longer supported.

Note that removed options are not limited to these lists.

### Removed Linux* and macOS* Options

**Product and Performance Information**
Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).
Notice revision #20201201

**Display Option Information**
To display a list of all available compiler options, specify option `help` on the command line.
To display functional groupings of compiler options, specify a functional category for option `help`. For example, to display a list of options that affect diagnostic messages, enter one of the following commands:

- `-help diagnostics`  ! Linux and macOS* systems
- `/help diagnostics`  ! Windows systems

For details on other categories you can specify, see `help`.

**Alternate Compiler Options**
This topic lists alternate names for compiler options and show the primary option name. Some of the alternate option names are deprecated and may be removed in future releases.
For more information on compiler options, see the detailed descriptions of the individual, primary options.
Some of these options are deprecated. For more information, see [Deprecated and Removed Options](#).

Portability and GCC*-Compatible Warning Options

This section discusses portability options and GCC*-compatible warning options.

Portability Options

A challenge in porting applications from one compiler to another is making sure that there is support for the compiler options you use to build your application. The Intel® C++ Compiler Classic supports many of the options that are valid on other compilers you may be using.

Listed below are compiler options that are supported by the Intel® C++ Compiler Classic and the following:

- the Microsoft* C++ Compiler
- the GCC* Compiler

Options that are unique to either compiler are not listed in this topic.

Options Equivalent to Microsoft C++ Options (Windows*)

The following table lists compiler options that are supported by both the Intel® C++ Compiler Classic and the Microsoft C++ Compiler.

For complete details about these options, such as the possible values for <n> when it appears below, see the Microsoft Visual Studio C++ documentation.

GCC*-Compatible Warning Options

The Intel® C++ Compiler Classic recognizes many GCC*-compatible warning options, but we do not document many of them.

In general, if a GCC-compatible option is accepted by the compiler, but not documented, the implementation of the option is the same as described in the GCC documentation.

To find the GCC documentation about GCC warning options, you can do any of the following:

- Check the GCC website (http://gcc.gnu.org/onlinedocs/gcc/)
- On Linux*, enter the command `man gcc`
- Search the web for "gcc warning options"

Floating-Point Operations

This section contains information about floating-point operations, including IEEE floating-point operations, and it provides guidelines that can help you improve the performance of floating-point applications.

Programming Tradeoffs in Floating-Point Applications

In general, the programming objectives for floating-point applications fall into the following categories:

- **Accuracy**: The application produces results that are close to the correct result.
- **Reproducibility and portability**: The application produces consistent results across different runs, different sets of build options, different compilers, different platforms, and different architectures.
- **Performance**: The application produces fast, efficient code.

Based on the goal of an application, you will need to make tradeoffs among these objectives. For example, if you are developing a 3D graphics engine, performance may be the most important factor to consider, with reproducibility and accuracy as secondary concerns.

The compiler provides several options that allow you to tune your applications based on specific objectives. Broadly speaking, there are the floating-point specific options, such as the `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) option, and the fast-but-low-accuracy options, such as the `[Q]limf-max-error` option.

The compiler optimizes and generates code differently when you specify these different compiler options. Select appropriate compiler options by carefully balancing your programming objectives and making tradeoffs among these objectives. Some of these options may influence the choice of math routines that are invoked.

Many routines in the `libirc`, `libm`, and `svml` library are more highly optimized for Intel microprocessors than for non-Intel microprocessors.

Using Floating-Point Options

Take the following code as an example:

```
Example

float t0, t1, t2;
...
 t0=t1+t2+4.0f+0.1f;
```
If you specify the `-fp-model extended` (Linux and macOS*) or `/fp:extended` (Windows) option in favor of accuracy, the compiler generates the following assembly code:

```
fld       DWORD PTR _t1
fadd      DWORD PTR _t2
fadd      DWORD PTR _Cnst4.0
fadd      DWORD PTR _Cnst0.1
fstp      DWORD PTR _t0
```

This code maximizes accuracy because it utilizes the highest mantissa precision available on the target platform. The code performance might suffer when managing the x87 stack, and it might yield results that cannot be reproduced on other platforms that do not have an equivalent extended precision type.

If you specify the `-fp-model source` (Linux and macOS*) or `/fp:source` (Windows) option in favor of reproducibility and portability, the compiler generates the following assembly code:

```
movss     xmm0, DWORD PTR _t1
addss     xmm0, DWORD PTR _t2
addss     xmm0, DWORD PTR _Cnst4.0
addss     xmm0, DWORD PTR _Cnst0.1
movss     DWORD PTR _t0, xmm0
```

This code maximizes portability by preserving the original order of the computation, and by using the IEEE single-precision type for all computations. It is not as accurate as the previous implementation, because the intermediate rounding error is greater compared to extended precision. It is not the highest performance implementation, because it does not take advantage of the opportunity to pre-compute \(4.0f + 0.1f\).

If you specify the `-fp-model fast` (Linux and macOS*) or `/fp:fast` (Windows) option in favor of performance, the compiler generates the following assembly code:

```
movss     xmm0, DWORD PTR _Cnst4.1
addss     xmm0, DWORD PTR _t1
addss     xmm0, DWORD PTR _t2
movss     DWORD PTR _t0, xmm0
```

This code maximizes performance using Intel® Streaming SIMD Extensions (Intel® SSE) instructions and pre-computing \(4.0f + 0.1f\). It is not as accurate as the first implementation, due to the greater intermediate rounding error. It does not provide reproducible results like the second implementation, because it must reorder the addition to pre-compute \(4.0f + 0.1f\). All compilers, on all platforms, at all optimization levels do not reorder the addition in the same way.

For many other applications, the considerations may be more complicated.

**Using Fast-But-Low-Accuracy Options**

The fast-but-low-accuracy options provide an easy way to control the accuracy of mathematical functions and utilize performance/accuracy tradeoffs offered by the Intel® oneAPI Math Kernel Library (oneMKL). You can specify accuracy, via a command line interface, for all math functions or a selected set of math functions at the level more precise than low, medium, or high.

You specify the accuracy requirements as a set of function attributes that the compiler uses for selecting an appropriate function implementation in the math libraries. Examples using the attribute, `max-error`, are presented here. For example, use the following option to specify the relative error of two ULPs for all single, double, long double, and quad precision functions:

```
-fimf-max-error=2
```

To specify twelve bits of accuracy for a `sin` function, use:

```
-fimf-accuracy-bits=12:sin
```
To specify relative error of ten ULPs for a \( \sin \) function, and four ULPs for other math functions called in the source file you are compiling, use:

\[-fimf-max-error=10: \sin -fimf-max-error=4\]

On Windows systems, the compiler defines the default value for the max-error attribute depending on the /fp option and /Qfast-transcendentals settings. In /fp:fast mode, or if fast but less accurate math functions are explicitly enabled by /Qfast-transcendentals-, then the compiler sets a max-error=4.0 for the call. Otherwise, it sets a max-error=0.6.

**Dispatching of Math Routines**

The compiler optimizes calls to routines from the *libm* and *svml* libraries into direct CPU-specific calls, when the compilation configuration specifies the target CPU where the code is tuned, and if the set of instructions available for the code compilation is not narrower than the set of instructions available in the tuning target CPU.

For example:

- The code containing calls to the \( \exp() \) library function and compiled with -mtune=corei7-avx (specifies tuning target CPU that supports Intel\(^\circledR\) Advanced Vector Extensions (Intel\(^\circledR\) AVX)) and -QxCORE-AVX2/-march=core-avx2 (specifies Intel\(^\circledR\) Advanced Vector Extensions 2 (Intel\(^\circledR\) AVX2) instructions set) call the \( \exp() \) routine that is optimized for processors with Intel\(^\circledR\) AVX support. This code provides the best performance for these processors.
- The same code, compiled with -mtune=core-avx2 and -QxAVX/-march=corei7-avx, calls a library dispatch routine that picks the optimal CPU specific version of the \( \exp() \) routine in runtime. Dispatching cannot be avoided because the instruction set does not allow the use of Intel\(^\circledR\) AVX2. Dynamic dispatching provides the best performance with the Intel\(^\circledR\) AVX2 CPU.

In the second example, if some portions of code extend the available instructions set by means of the _allow_cpu_features() or the _may_i_use_cpu_feature() intrinsic, then the compiler might produce direct calls to Intel\(^\circledR\) AVX2 specific versions of \( \exp() \).

The dispatching optimization applies to the \( \exp() \) routine, and to the other math routines with CPU specific implementations in the libraries. The dispatching optimization can be disabled using the -fimf-force-dynamic-target (or Qimf-force-dynamic-target) option. This option specifies a list of math routines that are improved with a dynamic dispatcher.

fimf-max-error, Qimf-max-error compiler option

**Floating-point Optimizations**

Application performance is an important goal of the Intel\(^\circledR\) C++ Compiler, even at default optimization levels. A number of optimizations involve transformations that might affect the floating-point behavior of the application, such as evaluation of constant expressions at compile time, hoisting invariant expressions out of loops, or changes in the order of evaluation of expressions. These optimizations usually help the compiler to produce the most efficient code possible. However, the optimizations might be contrary to the floating-point requirements of the application.

Some optimizations are not consistent with strict interpretation of the ANSI or ISO standards for C and C++. Such optimizations can cause differences in rounding and small variations in floating-point results that may be more or less accurate than the ANSI-conformant result.

The Intel\(^\circledR\) C++ Compiler provides the -fp-model (Linux* and macOS*) or /fp (Windows*) option, which allows you to control the optimizations performed when you build an application. The option allows you to specify the compiler rules for:
• **Value safety:** Whether the compiler may perform transformations that could affect the result. For example, in the SAFE mode, the compiler won't transform \(x/x\) to 1.0 because the value of \(x\) at runtime might be a zero or a NaN. The UNSAFE mode is the default.

• **Floating-point expression evaluation:** How the compiler should handle the rounding of intermediate expressions. For example, when double precision is specified, the compiler interprets the statement
  \[
  t0=4.0f+0.1f+t1+t2; \text{ as } t0=(\text{float})(4.1+(\text{double})t1+(\text{double})t2);
  \]

• **Floating-point contractions:** Whether the compiler should generate fused multiply-add (FMA) instructions on processors that support them. When enabled, the compiler may generate FMA instructions for combining multiply and add operations; when disabled, the compiler must generate separate multiply and add instructions with intermediate rounding.

• **Floating-point environment access:** Whether the compiler must account for the possibility that the program might access the floating-point environment, either by changing the default floating-point control settings or by reading the floating-point status flags. This is disabled by default. You can use the `-fp-model:strict (Linux* and macOS*) /fp:strict (Windows*)` option to enable it.

• **Precise floating-point exceptions:** Whether the compiler should account for the possibility that floating-point operations might produce an exception. This is disabled by default. You can use `-fp-model:strict (Linux* and macOS*) or /fp:strict (Windows*)` or `-fp-model:except (Linux* and macOS*) or /fp:except (Windows*)` to enable it.

Consider the following example:

```c
double a=1.5; int x=0; ...
__try {
  int t0=a; //raises inexact
  x=1;
  a*=2;
} __except (1) {
  printf("SEH Exception: x=%d\n", x);
}
```

Without precise floating-point exceptions, the result is `SEH Exception: x=1`; with precision floating-point exceptions, the result is `SEH Exception: x=0`.

The following table describes the impact of different keywords of the option on compiler rules and optimizations:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value Safety</th>
<th>Floating-Point Expression Evaluation</th>
<th>Floating-Point Contractions</th>
<th>Floating-Point Environment Access</th>
<th>Precise Floating-Point Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>precise</td>
<td>Safe</td>

<td>Unaffected</td>
<td>Unaffected</td>
<td>No</td>
</tr>
</tbody>
</table>

**NOTE**

It is illegal to specify the `except` keyword in an unsafe safety mode.
Based on the objectives of an application, you can choose to use different sets of compiler options and keywords to enable or disable certain optimizations, so that you can get the desired result.

**See Also**
Using -fp-model (/fp) Option

### Use the -fp-model, /fp Option

The -fp-model (Linux* and macOS*) or /fp (Windows*) option allows you to control the optimizations on floating-point data. You can use this option to tune the performance, level of accuracy, or result consistency for floating-point applications across platforms and optimization levels.

For applications that do not require support for denormalized numbers, the -fp-model or /fp option can be combined with the [Q]ftz option to flush denormalized results to zero in order to obtain improved runtime performance on processors based on all Intel® architectures.

You can use keywords to specify the semantics to be used. The keywords specified for this option may influence the choice of math routines that are invoked. Many routines in the *libirc*, *libm*, and *libsvml* libraries are more highly optimized for Intel microprocessors than for non-Intel microprocessors. Possible values of the keywords are as follows:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>precise</td>
<td>Enables value-safe optimizations on floating-point data.</td>
</tr>
<tr>
<td>fast[=1</td>
<td>2]</td>
</tr>
</tbody>
</table>
| consistent      | Enables consistent, reproducible results for different optimization levels or between different processors of the same architecture. This setting is equivalent to the use of the following options:  
Windows*: /fp:precise /Qfma- /Qimf-arch-consistency:true  
Linux* and macOS*: -fp-model precise -no-fma -fimf-arch-consistency=true |
| strict          | Enables precise and except, disables contractions, and enables pragma stdc fenv_access. |
| source          | Rounds intermediate results to source-defined precision and enables value-safe optimizations. |
| double          | Rounds intermediate results to 53-bit (double) precision and enables value-safe optimizations. |
| extended        | Rounds intermediate results to 64-bit (extended) precision and enables value-safe optimizations. |
| [no-]except     | Determines whether strict floating-point exception semantics are used.       |
| (Linux* and macOS*) or except[-] (Windows*) |                                                                 |

The default value of the option is -fp-model fast=1 or /fp:fast=1, which means that the compiler uses more aggressive optimizations on floating-point calculations.

**NOTE**
Using the default option keyword -fp-model fast or /fp:fast, you may get significant differences in your result depending on whether the compiler uses x87 or SSE/AVX instructions to implement floating-point operations. Results are more consistent when the other option keywords are used.

Several examples are provided to illustrate the usage of the keywords. These examples show:
- A small example of source code.

**NOTE**
The same source code is considered in all the included examples.

- The semantics that are used to interpret floating-point calculations in the source code.
- One or more possible ways the compiler may interpret the source code.

**NOTE**
There are several ways the compiler may interpret the code; we show just some of these possibilities.

**-fp-model fast or /fp:fast**

Example source code:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| float t0, t1, t2;  
| ...  
| t0 = 4.0f + 0.1f + t1 + t2; |

When this option is specified, the compiler applies the following semantics:

- Additions may be performed in any order.
- Intermediate expressions may use **single, double, or extended double precision**.
- The constant addition may be pre-computed, assuming the default rounding mode.

Using these semantics, some possible ways the compiler may interpret the original code are given below:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
</table>
| float t0, t1, t2;  
| ...  
| t0 = (float)((double)t1 + (double)t2) + 4.1f; |
| float t0, t1, t2;  
| ...  
| t0 = (t1 + t2) + 4.1f; |
| float t0, t1, t2;  
| ...  
| t0 = (t1 + 4.1f) + t2; |

**-fp-model extended or /fp:extended**

This setting is equivalent to **-fp-model precise** on Linux* operating systems based on the IA-32 architecture.

Example source code:

| float t0, t1, t2;  
| ...  
| t0 = 4.0f + 0.1f + t1 + t2; |

When this option is specified, the compiler applies the following semantics:

- Additions are performed in program order
- Intermediate expressions use **extended double precision**
The constant addition may be pre-computed, assuming the default rounding mode

Using these semantics, a possible way the compiler may interpret the original code is shown below:

```c
float t0, t1, t2;
...
t0 = (float)(((long double)4.1 + (long double)t1) + (long double)t2);
```

- **fp-model source or /fp:source**

This setting is equivalent to `-fp-model precise` or `/fp:precise` on systems based on the Intel® 64 architecture.

**Source code example**

```c
float t0, t1, t2;
...
t0 = 4.0f + 0.1f + t1 + t2;
```

When this option is specified, the compiler applies the following semantics:

- Additions are performed in program order.
- Intermediate expressions use the precision specified in the source code, that is, single precision.
- The constant addition may be pre-computed, assuming the default rounding mode.

Using these semantics, a possible way the compiler may interpret the original code is shown below:

**Example**

```c
float t0, t1, t2;
...
t0 = ((4.1f + t1) + t2);
```

- **fp-model double or /fp:double**

This setting is equivalent to `-fp-model precise` or `/fp:precise` on Windows systems based on the IA-32 architecture.

**Example source code**

```c
float t0, t1, t2;
...
t0 = 4.0f + 0.1f + t1 + t2;
```

When this option is specified, the compiler applies the following semantics:

- Additions are performed in program order
- Intermediate expressions use double precision
- The constant addition may be pre-computed, assuming the default rounding mode

Using these semantics, a possible way the compiler may interpret the original code is shown below:

```c
float t0, t1, t2;
...
t0 = (float)(((double)4.1 + (double)t1) + (double)t2);
```
**-fp-model strict or /fp:strict**

<table>
<thead>
<tr>
<th>Source code example</th>
</tr>
</thead>
<tbody>
<tr>
<td>float t0, t1, t2;</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>t0 = 4.0f + 0.1f + t1 + t2;</td>
</tr>
</tbody>
</table>

When this option is specified, the compiler applies the following semantics:

- Additions are performed in program order
- Expression evaluation matches expression evaluation under keyword `precise`.
- The constant addition is not pre-computed because there is no way to tell what rounding mode will be active when the program runs.

Using these semantics, a possible way the compiler may interpret the original code is shown below:

<table>
<thead>
<tr>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>float t0, t1, t2;</td>
</tr>
<tr>
<td>...</td>
</tr>
<tr>
<td>t0 = (float)(((long double)4.0f + (long double)0.1f) + (long double)t1) + (long double)t2);</td>
</tr>
</tbody>
</table>

---

**Denormal Numbers**

A normalized number is a number for which both the exponent (including bias) and the most significant bit of the mantissa are non-zero. For such numbers, all the bits of the mantissa contribute to the precision of the representation.

The smallest normalized single-precision floating-point number greater than zero is about 1.1754943 \(\times 10^{-38}\). Smaller numbers are possible, but those numbers must be represented with a zero exponent and a mantissa whose leading bit(s) are zero, which leads to a loss of precision. These numbers are called denormalized numbers or denormals (newer specifications refer to these as subnormal numbers).

Denormal computations use hardware and/or operating system resources to handle denormals; these can cost hundreds of clock cycles. Denormal computations take much longer to calculate than normal computations.

There are several ways to avoid denormals and increase the performance of your application:

- Scale the values into the normalized range.
- Use a higher precision data type with a larger range.
- Flush denormals to zero.

Reducing Impact of Denormal Exceptions

Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture

Institute of Electrical and Electronics Engineers, Inc*. (IEEE) web site for information about the current floating-point standards and recommendations
Floating-Point Environment

The floating-point environment is a collection of registers that control the behavior of the floating-point machine instructions and indicate the current floating-point status. The floating-point environment can include rounding mode controls, exception masks, flush-to-zero (FTZ) controls, exception status flags, and other floating-point related features.

For example, bit 15 of the MXCSR register enables the flush-to-zero mode, which controls the masked response to an single-instruction multiple-data (SIMD) floating-point underflow condition.

The floating-point environment affects most floating-point operations; therefore, correct configuration to meet your specific needs is important. For example, the exception mask bits define which exceptional conditions will be raised as exceptions by the processor. In general, the default floating-point environment is set by the operating system. You don't need to configure the floating-point environment unless the default floating-point environment does not suit your needs.

There are several methods available if you want to modify the default floating-point environment. For example, you can use inline assembly, compiler built-in functions, library functions, or command line options.

Changing the default floating-point environment affects runtime results only. This does not affect any calculations that are pre-computed at compile time.

If strict reproducibility and consistency are important do not change the floating point environment without also using either -fp-model strict (Linux* or macOS*) or /fp:strict (Windows*) option or pragma fenv_access.

Set the FTZ and DAZ Flags

In Intel® processors, the flush-to-zero (FTZ) and denormals-are-zero (DAZ) flags in the MXCSR register are used to control floating-point calculations. Intel® Streaming SIMD Extensions (Intel® SSE) and Intel® Advanced Vector Extensions (Intel® AVX) instructions, including scalar and vector instructions, benefit from enabling the FTZ and DAZ flags. Floating-point computations using the Intel® SSE and Intel® AVX instructions are accelerated when the FTZ and DAZ flags are enabled. This improves the application's performance.

Use the [Q]ftz option to flush denormal results to zero when the application is in the gradual underflow mode. This option may improve performance if the denormal values are not critical to the application's behavior. The [Q]ftz option, when applied to the main program, sets the FTZ and the DAZ hardware flags. The negative forms of the [Q]ftz option (-no-ftz for Linux* and macOS*, and /Qftz- for Windows*) leave the flags as they are.

The following table describes how the compiler processes denormal values based on the status of the FTZ and DAZ flags:

<table>
<thead>
<tr>
<th>Flag</th>
<th>When set to ON, the compiler...</th>
<th>When set to OFF, the compiler...</th>
<th>Supported on</th>
</tr>
</thead>
<tbody>
<tr>
<td>FTZ</td>
<td>...sets denormal results from floating-point calculations to zero.</td>
<td>...does not change the denormal results.</td>
<td>Intel® 64 and some IA-32 architectures</td>
</tr>
<tr>
<td>DAZ</td>
<td>...treats denormal values used as input to floating-point instructions as zero.</td>
<td>...does not change the denormal instruction inputs.</td>
<td>Intel® 64 and some IA-32 architectures</td>
</tr>
</tbody>
</table>

• FTZ and DAZ are not supported on all IA-32 architectures. The FTZ flag is supported only on IA-32 architectures that support Intel® SSE instructions.
• On systems based on the IA-32 and Intel® 64 architectures, FTZ only applies to Intel® SSE and Intel® AVX instructions. If the application generates denormals using x87 instructions, FTZ does not apply.
• **DAZ** and **FTZ** flags are not compatible with the IEEE 754 standard, and should only be enabled when compliance to the IEEE standard is not required.

Options for **[Q]ftz** are performance options. Setting these options does not guarantee that all denormals in a program are flushed to zero. They only cause denormals generated at run-time to be flushed to zero.

On Intel® 64 and IA-32 systems, the compiler, by default, inserts code into the main routine to set the **FTZ** and **DAZ** flags. When the **[Q]ftz** option is used on IA-32 systems with the option `-msse2` or `/arch:sse2`, the compiler inserts code to that conditionally sets the **FTZ/DAZ** flags based on a run-time processor check. Using the negative form of **[Q]ftz** prevents the compiler from inserting any code that sets **FTZ** or **DAZ** flags.

When the **[Q]ftz** option is used in combination with an Intel® SSE-enabling option on systems based on the IA-32 architecture (for example, `-msse2` or `/arch:sse2`), the compiler inserts code in the main routine to set **FTZ** and **DAZ**. When the option **[Q]ftz** is used without an Intel® SSE-enabling option, the compiler inserts code that conditionally sets **FTZ** or **DAZ** based on a run-time processor check. The negative form of **[Q]ftz** prevents the compiler from inserting any code that might set **FTZ** or **DAZ**.

The **[Q]ftz** option only has an effect when the main program is being compiled. It sets the **FTZ/DAZ** mode for the process. The initial thread, and any subsequently created threads, operate in the **FTZ/DAZ** mode.

On systems based on Intel® 64 and IA-32 architectures, every optimization option **O** level, except **O0**, sets **[Q]ftz**.

If this option produces undesirable results of the numerical behavior of the program, turn the **FTZ/DAZ** mode off by using the negative form of **[Q]ftz** in the command line while still benefiting from the **O3** optimizations.

Manually set the flags with the following macros:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable FTZ</td>
<td><code>_MM_SET_FLUSH_ZERO_MODE(_MM_FLUSH_ZERO_ON)</code></td>
</tr>
<tr>
<td>Enable DAZ</td>
<td><code>_MM_SET_DENORMALS_ZERO_MODE(_MM_DENORMALS_ZERO_ON)</code></td>
</tr>
</tbody>
</table>

The prototypes for these macros are in **xmmintrin.h** (**FTZ**) and **pmmintrin.h** (**DAZ**).

**ftz**, **Qftz** compiler option

### Checking the Floating-point Stack State

On systems based on the IA-32 architecture, when an application calls a function that returns a floating-point value, the returned floating-point value is supposed to be on the top of the floating-point stack. If the return value is not used, the compiler must pop the value off of the floating-point stack in order to keep the floating-point stack in the correct state.

On systems based on Intel® 64 architecture, floating-point values are usually returned in the **xmm0** register. The floating-point stack is used only when the return value is a long double on Linux* and macOS* systems.

If the application calls a function without defining or incorrectly defining the function’s prototype, the compiler cannot determine if the function must return a floating-point value. Consequently, the return value is not popped off the floating-point stack if it is not used. This can cause the floating-point stack to overflow.

The overflow of the stack results in two undesirable situations:

- A NaN value gets involved in the floating-point calculations
- The program results become unpredictable; the point where the program starts making errors can be arbitrarily far away from the point of the actual error.

For systems based on the IA-32 and Intel® 64 architectures, the **[Q]fp-stack-check** option checks whether a program makes a correct call to a function that should return a floating-point value. If an incorrect call is detected, the option places a code that marks the incorrect call in the program. The **[Q]fp-stack-check** option marks the incorrect call and makes it easy to find the error.
NOTE
The \([Q]\)fp-stack-check option causes significant code generation after every function/subroutine call to ensure that the floating-point stack is maintained in the correct state. Therefore, using this option slows down the program being compiled. Use the option only as a debugging aid to find floating point stack underflow/overflow problems, which can be otherwise hard to find.

Tuning Performance
This section describes several programming guidelines that can help you improve the performance of floating-point applications, including:

- Handling Floating-point Array Operations in a Loop Body
- Reducing the Impact of Denormal Exceptions
- Avoiding Mixed Data Type Arithmetic Expressions
- Using Efficient Data Types

Handling Floating-point Array Operations in a Loop Body
Following the guidelines below will help auto-vectorization of the loop.

- Statements within the loop body may contain float or double operations (typically on arrays). The following arithmetic operations are supported: addition, subtraction, multiplication, division, negation, square root, MAX, MIN, and mathematical functions such as SIN and COS.
- Writing to a single-precision scalar/array and a double scalar/array within the same loop decreases the chance of auto-vectorization due to the differences in the vector length (that is, the number of elements in the vector register) between float and double types. If auto-vectorization fails, try to avoid using mixed data types.

NOTE
The special $\_m64$, $\_m128$, and $\_m256$ datatypes are not vectorizable. The loop body cannot contain any function calls. Use of the Intel® Streaming SIMD Extensions (Intel® SSE) and Intel® Advanced Vector Extensions (Intel® AVX) intrinsics (for example, mm_add_ps) is not allowed.

Reducing the Impact of Denormal Exceptions
Denormalized floating-point values are those that are too small to be represented in the normal manner; that is, the mantissa cannot be left-justified. Denormal values require hardware or operating system interventions to handle the computation, so floating-point computations that result in denormal values may have an adverse impact on performance.

There are several ways to handle denormals to increase the performance of your application:

- Scale the values into the normalized range
- Use a higher precision data type with a larger range
- Flush denormals to zero

For example, you can translate them to normalized numbers by multiplying them using a large scalar number, doing the remaining computations in the normal space, then scaling back down to the denormal range. Consider using this method when the small denormal values benefit the program design.
Consider using a higher precision data type with a larger range; for example, by converting variables declared as `float` to be declared as `double`. Understand that making the change can potentially slow down your program. Storage requirements will increase, which will increase the amount of time for loading and storing data from memory. Higher precision data types can also decrease the potential throughput of Intel® Streaming SIMD Extensions (Intel® SSE) and Intel® Advanced Vector Extensions (Intel® AVX) operations.

If you change the type declaration of a variable, you might also need to change associated library calls, unless these are generic; for example, `cos()` instead of `cosf()`.. Another strategy that might result in increased performance is to increase the amount of precision of intermediate values using the `-fp-model [double|extended]` option. However, this strategy might not eliminate all denormal exceptions, so you must experiment with the performance of your application. You should verify that the gain in performance from eliminating denormals is greater than the overhead of using a data type with higher precision and greater dynamic range.

In many cases, denormal numbers can be treated safely as zero without adverse effects on program results. Depending on the target architecture, use flush-to-zero (FTZ) options.

### IA-32 and Intel® 64 Architectures

IA-32 and Intel® 64 architectures take advantage of the FTZ (flush-to-zero) and DAZ (denormals-are-zero) capabilities of Intel® Streaming SIMD Extensions (Intel® SSE) instructions.

By default, the Intel® C++ Compiler inserts code into the main routine to enable FTZ and DAZ at optimization levels higher than `O0`. To enable FTZ and DAZ at `O0`, compile the source file containing `main()` PROGRAM using compiler option `[Q]ftz`. When the `[Q]ftz` option is used on IA-32-based systems with the option `-mia32 (Linux*)` or `/arch:IA32 (Windows*)`, the compiler inserts code to conditionally enable FTZ and DAZ flags based on a run-time processor check. IA-32 is not available on macOS*.

---

**NOTE**

After using flush-to-zero, ensure that your program still gives correct results when treating denormal values as zero.

### Avoiding Mixed Data Type Arithmetic Expressions

Avoid mixing integer and floating-point (float, double, or long double) data in the same computation. Expressing all numbers in a floating-point arithmetic expression (assignment statement) as floating-point values eliminates the need to convert data between fixed and floating-point formats. Expressing all numbers in an integer arithmetic expression as integer values also achieves this. This improves run-time performance.

For example, assuming that `I` and `J` are both `int` variables, expressing a constant number (2.0) as an integer value (2) eliminates the need to convert the data. The following examples demonstrate inefficient and efficient code.

**Inefficient code:**

```c++
int I, J;
I = J / 2.0;
```

**Efficient code:**

```c++
int I, J;
I = J / 2;
```

### Using Efficient Data Types

In cases where more than one data type can be used for a variable, consider selecting the data types based on the following hierarchy, listed from most to least efficient:
• char
• short
• int
• long
• long long
• float
• double
• long double

NOTE
In an arithmetic expression, you should avoid mixing integer and floating-point data.

You can use integer data types (int, int long, etc.) in loops to improve floating point performance. Convert the data type to integer data types, process the data, then convert the data to the old type.

IEEE Floating-point Operations

Understanding the IEEE Standard for Floating-point Arithmetic, IEEE 754-2008
This version of the compiler uses a close approximation to the IEEE Standard for Floating-point Arithmetic, version IEEE 754-2008, unless otherwise stated. This standard is common to many microcomputer-based systems due to the availability of fast processors that implement the required characteristics.

This section outlines the characteristics of the IEEE 754-2008 standard and its implementation in the compiler. Except as noted, the description refers to both the IEEE 754-2008 standard and the compiler implementation.

Floating-point Formats
This IEEE 754-2008 standard specifies formats and methods for Floating-point representation in computer systems, and recommends formats for data interchange. The exception conditions are defined, and the standard handling of these conditions is specified below. The binary counterpart Floating-point exception functions are described in ISO C99. The decimal Floating-point exception functions are defined in the fenv.h header file. The compiler supports decimal floating point types in C and C++. The decimal floating point formats are defined in the IEEE 754-2008 standard.

In C, these decimal floating types are supported:
• _Decimal32
• _Decimal64
• _Decimal128

In C++ for Windows* and Linux*, these decimal classes are supported:
• decimal32
• decimal64
• decimal128
NOTE To use this feature in C++ on Linux*, GCC* 4.5 or later is required.

The decimal Floating-point is not supported in C++ for macOS*.

To ensure correct decimal Floating-point behavior, you must define `__STDC_WANT_DEC_FP__` before any standard headers are included. This is required for the declaration of decimal macros and library functions in order to ensure correct decimal Floating-point results at run-time.

**Example: Linux***

```cpp
#include <iostream>
#define __STDC_WANT_DEC_FP__
#include <decimal/decimal>

typedef std::decimal::decimal32 _Decimal32;
typedef std::decimal::decimal64 _Decimal64;
typedef std::decimal::decimal128 _Decimal128;
#include <dfp754.h>

using namespace std;
using namespace std::decimal;

int main() {
    std::decimal::decimal32 d = 4.7df;
    std::cout << decimal_to_long_double(d) << std::endl;
    return 0;
}
```

**Example: Windows***

```cpp
#include <iostream>
#define __STDC_WANT_DEC_FP__
#include <decimal>
#include <dfp754.h>

using namespace std;
using namespace std::decimal;

int main() {
    std::decimal::decimal32 d = 4.7df;
    std::cout << decimal_to_long_double(d) << std::endl;
    return 0;
}
```

**Functions to Check Decimal Floating-point Status**

Use these Floating-point exception functions to detect exceptions that occur during decimal Floating-point arithmetic:

**Floating-point Functions**

<table>
<thead>
<tr>
<th>Function</th>
<th>Brief Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>fe_dec_feclearexcept()</code></td>
<td>Clears the supported Floating-point exceptions.</td>
</tr>
<tr>
<td><code>fe_dec_fegetexceptflag</code></td>
<td>Stores an implementation-defined representation of the states of the Floating-point status flags.</td>
</tr>
<tr>
<td><code>fe_dec_feraiseexcept</code></td>
<td>Raises the supported Floating-point exceptions.</td>
</tr>
<tr>
<td><code>fe_dec_fesetexceptflag</code></td>
<td>Sets the Floating-point status flags.</td>
</tr>
</tbody>
</table>
### Function

<table>
<thead>
<tr>
<th>Function</th>
<th>Brief Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fe_dec_fetestexcept()</td>
<td>Determines which of a specified subset of the floating point exception flags are currently set.</td>
</tr>
</tbody>
</table>

### Special Values

The following list provides a brief description of the special values that the Intel® C++ Compiler supports.

- **Signed Zero**: The sign of zero is the same as the sign of a nonzero number. Comparisons consider +0 to be equal to -0. A signed zero is useful in certain numerical analysis algorithms, but in most applications the sign of zero is invisible.

- **Denormalized Numbers**: Denormalized numbers (denormals) fill the gap between the smallest positive and the smallest negative normalized number, otherwise only (+/-) 0 occurs in the interval. Denormalized numbers extend the range of computable results by allowing for gradual underflow.

  This content is specific to C++; it does not apply to DPC++. Systems based on the IA-32 architecture support a Denormal Operand status flag. When this is set, at least one of the input operands to a Floating-point operation is a denormal. The Underflow status flag is set when a number loses precision and becomes a denormal.

- **Signed Infinity**: Infinities are the result of arithmetic in the limiting case of operands with arbitrarily large magnitude. They provide a way to continue when an overflow occurs. The sign of an infinity is simply the sign you obtain for a finite number in the same operation as the finite number approaches an infinite value.

  By retrieving the status flags, you can differentiate between an infinity that results from an overflow and one that results from division by zero. The compiler treats infinity as signed by default. The output value of infinity is +Infinity or -Infinity.

- **Not a Number**: Not a Number (NaN) may result from an invalid operation. For example, \(0/0\) and \(\text{SQRT}(-1)\) result in NaN. In general, an operation involving a NaN produces another NaN. Because the fraction of a NaN is unspecified, there are many possible NaNs.

  The compiler treats all NaNs identically, but there are two classes of NaNs:

  - Signaling NaNs: Have an initial mantissa bit of 0. They usually raise an invalid exception when used in an operation.
  - Quiet NaNs: Have an initial mantissa bit of 1.

  The floating-point hardware usually converts a signaling NaN into a quiet NaN during computational operations. An invalid exception is raised and the resulting Floating-point value is a quiet NaN.

### Attributes

Attributes are a way to provide additional information about a declaration to the compiler. The C++11 attribute syntax is consistent with the C2x standard.

#### Use Attributes

The compiler supports three ways to add attributes to your program:

- **Gnu Syntax**

  ```c
  __attribute__((attribute_name(arguments)))
  ```

- **Microsoft Syntax**

  ```c
  __declspec(attribute_name(argument))
  ```
C++11 Standardized Attribute Syntax (part of the C++11 language standard)

```
[[attribute_name(arguments)]]
[[attribute-namespace :: attribute_name(arguments)]]
```

Some attributes are available for both Intel® microprocessors and non-Intel microprocessors but they may perform additional optimizations for Intel® microprocessors than they perform for non-Intel microprocessors. Refer to the individual attribute name for a detailed description.

**align**

*Directs the compiler to align the variable to a specified boundary and a specified offset.*

**Syntax**

**Windows* OS:**

```
__declspec(align(n[, off]))
```

**Linux* OS:**

```
__attribute__((aligned(n[, off])))
__attribute__((align(n[, off])))
```

For portability on Linux* OS, you should use the syntax form `__attribute__((aligned(n[, off])))`. This form is compatible with the GNU compiler.

**Arguments**

- **n**
  Specifies the alignment. The compiler will align the variable to an n-byte boundary.

- **off**
  Optional. Specifies the offset. If this argument is omitted, the value is 0.

**Description**

This keyword directs the compiler to align the variable to an n-byte boundary with offset off within each n-byte boundary. The address of the variable is `address mod n=off`.

**NOTE**

If you require 8-byte alignment, we recommend you specify 16 for n, instead of 8. When 8 is used, the compiler interprets the value as a suggestion and you may not get the requested 8-byte alignment, depending on various heuristics.

**align_value**

*Provides the ability to add a pointer alignment value to a pointer typedef declaration.*

**Syntax**

**Windows* OS:**

```
__declspec(align_value(alignment))
```

**Linux* OS:**

```
__attribute__((align_value(alignment)))
```

Compiler Reference

625
Arguments

alignment Specifies the alignment (8, 16, 32, 64, 128, 256,...) for what the pointer points to.

Description
This keyword can be added to a pointer typedef declaration to specify the alignment value of pointers declared for that pointer type.

This indicates to the compiler that the data referenced by the designated pointer is aligned by the indicated value, and the compiler can generate code based on that assumption. If this attribute is used incorrectly, and the data is not aligned to the designated value, the behavior is undefined.

avoid_false_share

Provides the ability to pad and/or align the defined variable such that it will not be subject to false cache line sharing with any other variable.

Syntax
Windows* OS:
_declspec(avoid_false_share(identifier))variable definition

Linux* OS:
_attribute__((avoid_false_share(identifier)))variable definition

Arguments

identifier Specifies the string that will be used to identify one or more variables. Variables with the same identifier do not need protection from false sharing.

variable definition Specifies the variable to be padded or aligned.

Description
This keyword indicates to the compiler that it should allocate the variable through padding and/or alignment such that it will not share the cache line with other variables unless they share the same identifier. This keyword must occur on a variable definition in function, global, or namespace scope. It is not permitted on a non-static class member or on a function argument.

If you specify an identifier, the variable definition does not need to be protected from false sharing with other variables that are similarly declared with the same identifier. If the variable definition is in function scope, the scope of the identifier is the current function. If the variable definition is in namespace or global scope, the scope of the identifier is the current compilation unit.

This keyword is supported for scalars and arrays and is not supported for structure fields, function arguments, functions, and references.

code_align

Specifies the byte alignment for a routine.
Syntax

Windows* OS:

__declspec(code_align(n))

Linux* OS, macOS*:

__attribute__((code_align(n)))

Arguments

n

Optional. A positive integer indicating the number of bytes for the minimum desired alignment boundary. Its value must be a power of 2, between 1 and 4096, such as 1, 2, 4, 8, and so on.

If you specify 1 for n, no alignment is performed. If you do not specify n, the default alignment is 16 bytes.

Description

This keyword must be placed on the routine to be aligned.

If anything inside the routine requires specific alignment k, the final routine alignment will be max(n,k).

cpu_dispatch, cpu_specific attribute

Processor Targeting

**concurrency_safe**

Guides the compiler to parallelize more loops and straight-line code.

Syntax

Windows* OS:

__declspec(concurrency_safe(clause))

Linux* OS:

__attribute__((concurrency_safe(clause)))

Arguments

clause

Is one of the following:

**cost(cycles):** Specifies the execution cycles of the annotated function for the compiler to perform parallelization profitability analysis while compiling its enclosing loops or blocks. The value of cycles is a 2-byte unsigned integer (unsigned short); its maximal value is 2^16-1. If the cycle count is greater than 2^16-1, you should use **profitable**.

---
**profitable**: Specifies that the loops or blocks that contain calls to the annotated function are profitable to parallelize.

**Description**
This keyword indicates to the compiler that there are no incorrect side-effects and no illegal (or improperly synchronized) memory access interferences among multiple invocations of the annotated function or between an invocation of this annotated function and other statements in the program, if they are executed concurrently.

For every function that is marked with this keyword, you must ensure that its side effects (if any) are acceptable (or expected), and the memory access interferences are properly synchronized.

**const**

*Indicates that a function has no effect other than returning a value and that it uses only its arguments to generate that return value.*

**Syntax**

**Windows** OS:

```c
__declspec(const)
```

**Linux** OS:

```c
__attribute__((const))
```

**Arguments**

None

**Description**

This keyword is equivalent to the gcc attribute `const` and applies to function declarations.

**cpu_dispatch, cpu_specific**

*Provides the ability to write one or more versions of a function that execute only on a list of targeted processors (cpu_dispatch). Provides the ability to declare that a version of a function is targeted at particular type(s) of processors (cpu_specific).*

**Syntax**

**Windows** OS:

```c
__declspec(cpu_dispatch(cpuid, cpuid, ...))
__declspec(cpu_specific(cpuid))
```

**Linux** OS:

```c
__attribute__((cpu_dispatch(cpuid, cpuid, ...)))
__attribute__((cpu_specific(cpuid)))
```
Arguments

**cpuid**

Possible values are:

- **atom**: Intel® Atom™ processors with Intel® Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3)
- **atom_sse4_2**: Intel® Atom™ processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2)
- **atom_sse4_2_movbe**: Intel® Atom™ processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) with MOVBE instructions enabled
- **broadwell**: This is a synonym for **core_5th_gen_avx**
- **core_2nd_gen_avx**: 2nd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX)
- **core_3rd_gen_avx**: 3rd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX) including the RDRND instruction
- **core_4th_gen_avx**: 4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction
- **core_4th_gen_avx_tsx**: 4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)
- **core_5th_gen_avx**: 5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions
- **core_5th_gen_avx_tsx**: 5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)
- **core_aes_pclmulqdq**: Intel® Core™ processors with support for Advanced Encryption Standard (AES) instructions and carry-less multiplication instruction
- **core_i7_sse4_2**: Intel® Core™ i7 processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) instructions
- **generic**: Other Intel processors for IA-32 or Intel® 64 architecture or compatible processors not provided by Intel Corporation
- **haswell**: This is a synonym for **core_4th_gen_avx**
- **pentium**: Intel® Pentium® processor
- **pentium_4**: Intel® Pentium® 4 processors
- **pentium_4_sse3**: Intel® Pentium® 4 processor with Intel® Streaming SIMD Extensions 3 (Intel® SSE3) instructions, Intel® Core™ Duo processors, Intel® Core™ Solo processors
- **pentium_ii**: Intel® Pentium® II processors
pentium_iii: Intel® Pentium® III processors
pentium_iii_no_xmm_regs: Intel® Pentium® III processors with no XMM registers
pentium_m: Intel® Pentium® M processors
pentium_mmx: Intel® Pentium® processors with MMX™ technology
pentium_pro: Intel® Pentium® Pro processors

Description
Use the cpu_dispatch keyword to provide a list of targeted processors, along with an empty function body/function stub.

Use the cpu_specific keyword to declare each function version targeted at particular type(s) of processors
These feature are available only for Intel processors based on IA-32 or Intel® 64 architecture. They are not available for non-Intel processors. Applications built using the manual processor dispatch feature may be more highly optimized for Intel processors than for non-Intel processors.

Processor Targeting

mpx

Directs the compiler to pass Intel® Memory Protection Extensions (Intel® MPX) bounds information along with any pointer-typed parameters.

Syntax
Windows* OS:
__declspec(mpx)

Arguments
None

Description
When a function declared with this keyword is called, any pointer-typed parameters passed to the function will also have Intel® MPX bounds information passed. If the called function returns a pointer-typed object, the compiler will expect the function to return Intel® MPX bounds information along with the pointer object.
Similarly, if this keyword is applied to a function definition, the function will expect the caller to pass Intel® MPX bounds information along with any pointer-type parameters. If the function returns a pointer-typed object, Intel® MPX bounds information will be returned with the object.

NOTE
The usage of this attribute is intended for Windows code that contains hand-written Intel® MPX enhancements based on Intel® MPX inline assembly or calls to Intel® MPX intrinsics, and where the user does not wish to enable automatic Intel® MPX code generation.
**target**

Specifies a target for called functions or variables.

**Syntax**

**Windows* OS:**

```c
__declspec(target(target-name))
```

**Linux* OS:**

```c
__attribute__((target(target-name)))
```

**Arguments**

`target-name`

Specifies the target name. Possible values are:

- `arch=corei7`
- `arch=core2`
- `arch=atom`
- `mmx`
- `sse`
- `sse2`
- `sse3`
- `ssse3`
- `sse4`
- `sse4a`
- `sse4.1`
- `sse4.2`
- `popcnt`
- `aes`
- `pclmul`
- `avx`
- `avx2`
- `avx512f`

**Description**

This keyword specifies that the called function or variable is also available on the target. Only functions or variables marked with this attribute are available on the target, and only these functions can be called on the target.

**vector**

Provides the ability to vectorize user-defined functions and loops.

**Syntax**

**Windows* OS:**

```c
__declspec(vector(clauses))
```

**Linux* OS:**

```c
__attribute__((vector(clauses)))
```
Arguments

classes

Is one of the following:

processor clause, in the form processor(cpubid). This clause creates a vector version of the function for the given target processor (cpuid). See cpu_dispatch, cpu_specific for a list of supported values. The default processor is determined by the implicit or explicit process- or architecture-specific flag in the compiler command line.

vector length clause, in the form vectorlength(n), where n is a vectorlength (vl) and must be an integer with the value 2, 4, 8, or 16. This clause tells the compiler that each routine invocation at the call site should execute the computation equivalent to n times the scalar function execution.

linear clause, in the form linear(param1:step1 [, param2:step2] ...), where param is a scalar variable and step is a compile-time integer constant expression. This clause tells the compiler that for each consecutive invocation of the routine in a serial execution, the value of param1 is incremented by step1, param2 is incremented by step2, and so on. If more than one step is specified for a particular variable, a compile-time error occurs. Multiple linear clauses are merged as a union.

uniform clause, in the form uniform(param [, param,...), where param is a formal parameter of the specified function. This clause tells the compiler that the values of the specified arguments can be broadcast to all iterations as a performance optimization.

mask clause, in the form [no]mask. This clause tells the compiler to generate a masked vector version of the routine.

Description

This keyword combines with the map operation at the call site to provide the data parallel semantics. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced.

vector_variant

Specifies a vector variant function that corresponds to its original C/C++ scalar function. This vector variant function can be invoked under vector context at call sites.

Syntax

Windows* OS:
__declspec(vector_variant(clauses))

Linux* OS:
__attribute__((vector_variant(clauses)))

Arguments

classes

Is the following:
implements clause, in the form implements (<function declarator>) [, <simd-clauses>]), where function declarator is the original scalar function, and simd-clauses is one or more of the clauses allowed for the vector attribute. The simd-clauses are optional.

Description

This attribute provides a means for programmers to describe the association between the vector variant function and its corresponding scalar function. The compiler will use the vector variant to replace the scalar call for a vectorized loop.

The following are restrictions for this attribute:

- A vector variant function can have only one vector_variant annotation.
- A vector variant annotation can have only one implements clause.
- A vector variant annotation applies to only one vector variant function, which must not have both mask and nomask clauses specified. It can be specified with either mask or nomask; the default is nomask.
- A vector variant function should have the __regcall attribute.

If the user-defined vector variant function is a variant with mask, the mask argument should be the last argument.

Example

The following shows an example of a vector variant function:

```c
#include <immintrin.h>
__declspec(noinline)
float MyAdd(float* a, int b) { return *a + b; }
__declspec(vector_variant(implements(MyAdd(float *a, int b)),
    linear(a), vectorlength(8),
    nomask, processor(core_2nd_gen_avx)))
__m256 __regcall MyAddVec(float* v_a, __m128i v_b, __m128i v_b2) {
    __m256i t96 = _mm256_castsi128_si256(v_b);
    __m256i tmp = _mm256_insertf128_si256(t96, v_b2, 1);
    __m256 t95 = _mm256_cvtepi32_ps(tmp);
    return _mm256_add_ps(*((__m256*)v_a), t95);
}

float x[2000], y[2000];
float foo(float y[]) {
    #pragma omp simd
    for (int k=0; k< 2000; k++) {
        x[k] = MyAdd(&y[k], k);
    }
    return x[0] + x[1999];
}
```

If the return value contains more than one register, the following technique can be used for the correct definition of the function:

```c
#include <immintrin.h>

typedef struct {
    __m256d r1;
    __m256d r2;
} __m256dx2;

__declspec(noinline)
double MyAdd(double* a, int b) { return *a + b; }

__declspec(vector_variant(implements(MyAdd(double *a, int b)),
```
linear(a), vectorlength(8),
nomask, processor(core_2nd_gen_avx))

__m256dx2 __regcall MyAddVec(double* v_a, __m128i v_b, __m128i v_b2) {
    __m256d t1 = _mm256_cvtepi32_pd(v_b);
    __m256d t2 = _mm256_cvtepi32_pd(v_b2);
    __m256dx2 ret;
    ret.r1 = _mm256_mul_pd(t1,*((__m256d*)v_a));
    ret.r2 = _mm256_mul_pd(t2,*((__m256d*)v_a)+1));
    return ret;
}

__declspec(align(32)) double x[2000], y[2000];
double foo(double* y) {
    #pragma omp simd
    for (int k=0; k< 2000; k++) {
        x[k] = MyAdd(y, k);
        y++;
    }
    return x[0] + x[1999];
}

Intrinsics

This intrinsics section provides an introduction and information on Intel specific intrinsics. The Intel®
Intrinsics Guide provides detailed information and a lookup tool for viewing the available Intel intrinsics.

The following is some general information:

- Intrinsics are assembly-coded functions that let you use C++ function calls and variables in place of
  assembly instructions.
- Intrinsics can be used only on the host.
- Intrinsics are expanded inline eliminating function call overhead. Providing the same benefit as using
  inline assembly, intrinsics improve code readability, assist instruction scheduling, and help reduce
  debugging.
- Intrinsics provide access to instructions that cannot be generated using the standard constructs of the C
  and C++ languages.

NOTE
When developing and debugging your program with the Intel® C++ Compiler Classic, compile your
sources with -D__INTEL_COMPILER_USE_INTRINSIC_PROTOTYPES to take advantage of improved
compile-time checking of the intrinsics functions. When done be sure to remove this option as it
significantly increases compile time.
Availability of Intrinsics on Intel Processors

Not all Intel® processors support all intrinsics. For information on which intrinsics are supported on Intel® processors, visit the Product Specification, Processors page. The Processor Spec Finder tool links directly to all processor documentation and the datasheets list the features, including intrinsics, supported by each processor.

Details about Intrinsics

All instructions use the following features:

- Registers
- Data Types

Registers

Intel® processors provide special register sets for different instructions.

- Intel® MMX™ instructions use eight 64-bit registers (mm0 to mm7) which are aliased on the floating-point stack registers.
- Intel® Streaming SIMD Extensions (Intel® SSE) and the Advanced Encryption Standard (AES) instructions use eight 128-bit registers (xmm0 to xmm7).
- Intel® Advanced Vector Extensions (Intel® AVX) instructions use 256-bit registers which are extensions of the 128-bit SIMD registers.
- Intel® Advanced Vector Extensions 512 (Intel® AVX-512) instructions use 512-bit registers.

Because each of these registers can hold more than one data element, the processor can process more than one data element simultaneously. This processing capability is also known as single-instruction multiple data processing (SIMD).

For each computational and data manipulation instruction in the new extension sets, there is a corresponding C intrinsic that implements that instruction directly. This frees you from managing registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that your executable runs faster.

Data Types

Intrinsic functions use new C data types as operands, representing the new registers that are used as the operands to these intrinsic functions.

The following table details for which instructions each of the new data types are available. A 'Yes' indicates that the data type is available for that group of intrinsics; an 'NA' indicates that the data type is not available for that group of intrinsics.

__m64 Data Type
The __m64 data type is used to represent the contents of an MMX register, which is the register that is used by the MMX™ technology intrinsics. The __m64 data type can hold eight 8-bit values, four 16-bit values, two 32-bit values, or one 64-bit value.

__m128 Data Types
The __m128 data type is used to represent the contents of a SSE register used by the Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics.
Conventionally, the __m128 data type can hold four 32-bit floating-point values, while the __m128d data type can hold two 64-bit floating-point values, and the __m128i data type can hold sixteen 8-bit, eight 16-bit, four 32-bit, or two 64-bit integer values.
The compiler aligns __m128d and __m128i local and global data to 16-byte boundaries on the stack. To align integer, float, or double arrays, use the __declspec(align) statement.

Accessing __m128i Data
To access 8-bit data on IA-32 and Intel® 64 architecture-based systems, use the mm_extract intrinsics as follows:

```c
#define _mm_extract_epi8(x, imm) \
    (((imm) & 0x1) == 0) ?   \
        _mm_extract_epi16((x), (imm) >> 1) & 0xff : \
        _mm_extract_epi16(_mm_srli_epi16((x), 8), (imm) >> 1))
```
To access 16-bit data, use:

```c
int _mm_extract_epi16(__m128i a, int imm)
```
To access 32-bit data, use:

```c
#define _mm_extract_epi32(x, imm) \
    _mm_cvtsi128_si32(_mm_srli_si128((x), 4 * (imm)))
```

To access 64-bit data (Intel® 64 architecture only), use:

```c
#define _mm_extract_epi64(x, imm) \
    _mm_cvtsi128_si64(_mm_srli_si128((x), 8 * (imm)))
```

### __m256 Data Types

The **__m256** data type is used to represent the contents of the extended SSE register - the **YMM** register, used by the Intel® AVX intrinsics.

The **__m256** data type can hold eight 32-bit floating-point values, while the **__m256d** data type can hold four 64-bit double precision floating-point values, and the **__m256i** data type can hold thirty-two 8-bit, sixteen 16-bit, eight 32-bit, or four 64-bit integer values. See Details for Intel® AVX Intrinsics for more information.

### __m512 Data Types

The **__m512** data type is used to represent the contents of the extended SSE register - the **ZMM** register, used by the Intel® AVX-512 intrinsics.

The **__m512** data type can hold sixteen 32-bit floating-point values, while the **__m512d** data type can hold eight 64-bit double precision floating-point values, and the **__m512i** data type can hold sixty-four 8-bit, thirty-two 16-bit, sixteen 32-bit, or eight 64-bit integer values. See Overview: Intrinsics for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Instructions for more information.

### Data Types Usage Guidelines

These data types are not basic ANSI C data types. You must observe the following usage restrictions:

- Use data types as objects in aggregates, such as unions, to access the byte elements and structures.

See Also

__declspec(align) declaration

### Naming and Usage Syntax

Most intrinsic names use the following notational convention:

```c
__mm_<intrin_op>_<suffix>
```

The following table explains each item in the syntax.

<table>
<thead>
<tr>
<th><strong>&lt;intrin_op&gt;</strong></th>
<th>Indicates the basic operation of the intrinsic; for example, add for addition and sub for subtraction.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>&lt;suffix&gt;</strong></td>
<td>Denotes the type of data the instruction operates on. The first one or two letters of each suffix denote whether the data is packed (p), extended packed (ep), or scalar (s). The remaining letters and numbers denote the type, with notation as follows:</td>
</tr>
<tr>
<td></td>
<td>• s single-precision floating point</td>
</tr>
<tr>
<td></td>
<td>• d double-precision floating point</td>
</tr>
<tr>
<td></td>
<td>• i128 signed 128-bit integer</td>
</tr>
</tbody>
</table>

Intel® C++ Compiler Classic Developer Guide and Reference

638
• i64 signed 64-bit integer
• u64 unsigned 64-bit integer
• i32 signed 32-bit integer
• u32 unsigned 32-bit integer
• i16 signed 16-bit integer
• u16 unsigned 16-bit integer
• i8 signed 8-bit integer
• u8 unsigned 8-bit integer

A number appended to a variable name indicates the element of a packed object. For example, r0 is the lowest word of r. Some intrinsics are "composites" because they require more than one instruction to implement them.

The packed values are represented in right-to-left order, with the lowest value being used for scalar operations. Consider the following example operation:

```c
double a[2] = {1.0, 2.0};
__m128d t = _mm_load_pd(a);
```

The result is the same as either of the following:

```c
__m128d t = _mm_set_pd(2.0, 1.0);
__m128d t = _mm_setr_pd(1.0, 2.0);
```

In other words, the xmm register that holds the value t appears as follows:

\[
\begin{array}{c}
127 \\
2.0 \\
1.0 \\
0
\end{array}
\]

The "scalar" element is 1.0. Due to the nature of the instruction, some intrinsics require their arguments to be immediates (constant integer literals).

### Intrinsics for All Intel® Architectures

Most of the intrinsics documented in this section function for all supported Intel® architectures. Some of the intrinsics documented in this section function across a subset of Intel® architectures.

#### Integer Arithmetic Intrinsics

The following table lists and describes integer arithmetic intrinsics that you can use across Intel® architectures.

<table>
<thead>
<tr>
<th>Intrinsic Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>int abs(int)</code></td>
<td>Returns the absolute value of an integer.</td>
</tr>
<tr>
<td><code>long labs(long)</code></td>
<td>Returns the absolute value of a long integer.</td>
</tr>
<tr>
<td><code>unsigned long _lrotl(unsigned long value, int shift)</code></td>
<td>Implements 64-bit left rotate of value by shift positions.</td>
</tr>
<tr>
<td><code>unsigned long _lrotr(unsigned long value, int shift)</code></td>
<td>Implements 64-bit right rotate of value by shift positions.</td>
</tr>
<tr>
<td><code>unsigned int _rotl(unsigned int value, int shift)</code></td>
<td>Implements 32-bit left rotate of value by shift positions.</td>
</tr>
<tr>
<td><code>unsigned int _rotr(unsigned int value, int shift)</code></td>
<td>Implements 32-bit right rotate of value by shift positions.</td>
</tr>
</tbody>
</table>

#### Intrinsics for IA-32 and Intel® 64 Architectures

<table>
<thead>
<tr>
<th>Intrinsic Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>unsigned short _rotwl(unsigned short value, int shift)</code></td>
<td>Implements 16-bit left rotate of value by shift positions.</td>
</tr>
<tr>
<td><code>unsigned short _rotwr(unsigned short value, int shift)</code></td>
<td>Implements 16-bit right rotate of value by shift positions.</td>
</tr>
</tbody>
</table>

**NOTE**

Passing a constant `shift` value in the rotate intrinsics results in higher performance.

### Floating-point Intrinsics

The following table lists and describes floating point intrinsics that you can use across all Intel® and compatible architectures. Floating-point intrinsic functions may invoke library functions that are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.
<table>
<thead>
<tr>
<th>Intrinsic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>double fabs(double)</td>
<td>Returns the absolute value of a floating-point value.</td>
</tr>
<tr>
<td>double log(double)</td>
<td>Returns the natural logarithm ( \ln(x) ), ( x&gt;0 ), with double precision.</td>
</tr>
<tr>
<td>float logf(float)</td>
<td>Returns the natural logarithm ( \ln(x) ), ( x&gt;0 ), with single precision.</td>
</tr>
<tr>
<td>double log10(double)</td>
<td>Returns the base 10 logarithm ( \log_{10}(x) ), ( x&gt;0 ), with double precision.</td>
</tr>
<tr>
<td>float log10f(float)</td>
<td>Returns the base 10 logarithm ( \log_{10}(x) ), ( x&gt;0 ), with single precision.</td>
</tr>
<tr>
<td>double exp(double)</td>
<td>Returns the exponential function with double precision.</td>
</tr>
<tr>
<td>float expf(float)</td>
<td>Returns the exponential function with single precision.</td>
</tr>
<tr>
<td>double pow(double, double)</td>
<td>Returns the value of ( x ) to the power ( y ) with double precision.</td>
</tr>
<tr>
<td>float powf(float, float)</td>
<td>Returns the value of ( x ) to the power ( y ) with single precision.</td>
</tr>
<tr>
<td>double sin(double)</td>
<td>Returns the sine of ( x ) with double precision.</td>
</tr>
<tr>
<td>float sinf(float)</td>
<td>Returns the sine of ( x ) with single precision.</td>
</tr>
<tr>
<td>double cos(double)</td>
<td>Returns the cosine of ( x ) with double precision.</td>
</tr>
<tr>
<td>float cosf(float)</td>
<td>Returns the cosine of ( x ) with single precision.</td>
</tr>
<tr>
<td>double tan(double)</td>
<td>Returns the tangent of ( x ) with double precision.</td>
</tr>
<tr>
<td>float tanf(float)</td>
<td>Returns the tangent of ( x ) with single precision.</td>
</tr>
<tr>
<td>double acos(double)</td>
<td>Returns the inverse cosine of ( x ) with double precision.</td>
</tr>
<tr>
<td>float acosf(float)</td>
<td>Returns the inverse cosine of ( x ) with single precision.</td>
</tr>
<tr>
<td>double acosh(double)</td>
<td>Compute the inverse hyperbolic cosine of the argument with double precision.</td>
</tr>
<tr>
<td>float acoshf(float)</td>
<td>Compute the inverse hyperbolic cosine of the argument with single precision.</td>
</tr>
<tr>
<td>double asin(double)</td>
<td>Compute inverse sine of the argument with double precision.</td>
</tr>
<tr>
<td>float asinf(float)</td>
<td>Compute inverse sine of the argument with single precision.</td>
</tr>
<tr>
<td>double asinh(double)</td>
<td>Compute inverse hyperbolic sine of the argument with double precision.</td>
</tr>
<tr>
<td>float asinhf(float)</td>
<td>Compute inverse hyperbolic sine of the argument with single precision.</td>
</tr>
<tr>
<td>double atan(double)</td>
<td>Compute inverse tangent of the argument with double precision.</td>
</tr>
<tr>
<td>float atanf(float)</td>
<td>Compute inverse tangent of the argument with single precision.</td>
</tr>
<tr>
<td>double atanh(double)</td>
<td>Compute inverse hyperbolic tangent of the argument with double precision.</td>
</tr>
<tr>
<td>Intrinsic</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>float atanhf(float)</td>
<td>Compute inverse hyperbolic tangent of the argument with single precision.</td>
</tr>
<tr>
<td>double cabs(double complex z)</td>
<td>Computes absolute value of complex number. The intrinsic argument is a complex number made up of two double precision elements, one real and one imaginary. The input parameter z is made up of two values of double type passed together as a single argument.</td>
</tr>
<tr>
<td>float cabsf(float complex z)</td>
<td>Computes absolute value of complex number. The intrinsic argument is a complex number made up of two single precision elements, one real and one imaginary. The input parameter z is made up of two values of float type passed together as a single argument.</td>
</tr>
<tr>
<td>double ceil(double)</td>

<tr>
<td>float coshf(float)</td>
<td>Computes the hyperbolic cosine of single precision argument.</td>
</tr>
<tr>
<td>float fabsf(float)</td>
<td>Computes absolute value of single precision argument.</td>
</tr>
<tr>
<td>double floor(double)</td>
<td>Computes the largest integral value of the double precision argument not greater than the argument.</td>
</tr>
<tr>
<td>float floorf(float)</td>
<td>Computes the largest integral value of the single precision argument not greater than the argument.</td>
</tr>
<tr>
<td>double fmod(double)</td>
<td>Computes the floating-point remainder of the division of the first argument by the second argument with double precision.</td>
</tr>
<tr>
<td>float fmodf(float)</td>
<td>Computes the floating-point remainder of the division of the first argument by the second argument with single precision.</td>
</tr>
<tr>
<td>double hypot(double, double)</td>
<td>Computes the length of the hypotenuse of a right angled triangle with double precision.</td>
</tr>
<tr>
<td>float hypotf(float, float)</td>
<td>Computes the length of the hypotenuse of a right angled triangle with single precision.</td>
</tr>
<tr>
<td>double rint(double)</td>
<td>Computes the integral value represented as double using the IEEE rounding mode.</td>
</tr>
<tr>
<td>float rintf(float)</td>
<td>Computes the integral value represented with single precision using the IEEE rounding mode.</td>
</tr>
<tr>
<td>double sinh(double)</td>
<td>Computes the hyperbolic sine of the double precision argument.</td>
</tr>
<tr>
<td>float sinhf(float)</td>
<td>Computes the hyperbolic sine of the single precision argument.</td>
</tr>
<tr>
<td>float sqrtf(float)</td>
<td>Computes the square root of the single precision argument.</td>
</tr>
<tr>
<td>double tanh(double)</td>
<td>Computes the hyperbolic tangent of the double precision argument.</td>
</tr>
</tbody>
</table>
### Intrinsic Description

<table>
<thead>
<tr>
<th>Intrinsic</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>float tanhf(float)</td>
<td>Computes the hyperbolic tangent of the single precision argument.</td>
</tr>
</tbody>
</table>

### String and Block Copy Intrinsics

The following table lists and describes string and block copy intrinsics that you can use on systems based on IA-32 and Intel® 64 architectures. They may invoke library functions that are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

**NOTE**

`strncpy()` and `strncmp()` functions are implemented as intrinsics depending on compiler version and compiler switches like optimization level.

<table>
<thead>
<tr>
<th>Intrinsic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>char * _strset(char *, _int32)</td>
<td>Sets all characters in a string to a fixed value.</td>
</tr>
<tr>
<td>int memcmp(const void *cs, const void *ct, size_t n)</td>
<td>Compares two regions of memory. Return: • &lt;0 if cs&lt;ct • 0 if cs=ct • &gt;0 if cs&gt;ct</td>
</tr>
<tr>
<td>void *memcpy(void *s, const void *ct, size_t n)</td>
<td>Copies from memory. Returns s.</td>
</tr>
<tr>
<td>void *memset(void *s, int c, size_t n)</td>
<td>Sets memory to a fixed value. Returns s.</td>
</tr>
<tr>
<td>char *strcat(char *s, const char *ct)</td>
<td>Appends to a string. Returns s.</td>
</tr>
<tr>
<td>int strcmp(const char *, const char *)</td>
<td>Compares two strings. Return &lt;0 if cs&lt;ct, 0 if cs=ct, or &gt;0 if cs&gt;ct.</td>
</tr>
<tr>
<td>char *strcpy(char *s, const char *ct)</td>
<td>Copies a string. Returns s.</td>
</tr>
<tr>
<td>size_t strlen(const char *cs)</td>
<td>Returns the length of string cs.</td>
</tr>
<tr>
<td>int strncmp(char *, char *, int)</td>
<td>Compare two strings, but only specified number of characters.</td>
</tr>
<tr>
<td>int strncpy(char *, char *, int)</td>
<td>Copies a string, but only specified number of characters.</td>
</tr>
</tbody>
</table>

### Miscellaneous Intrinsics

The following tables list and describe intrinsics that you can use across all Intel® architectures, except where noted. These intrinsics are available for both Intel® and non-Intel microprocessors but they may perform additional optimizations for Intel® microprocessors than they perform for non-Intel microprocessors.
NOTE
Casting functions for various INT and FP types for use in intrinsic functions across Intel® architectures only change the type; they do not convert between integer and floating point values.

</tbody>
</table>
_may_i_use_cpu_feature
Queries the processor dynamically at the source level (this intrinsic does not perform a vendor check) to determine if processor-specific features are available.

Syntax
extern int _may_i_use_cpu_feature(unsigned __int64);

Arguments

unsigned __int64

An unsigned __int64 bitset representing one or more cpuid features. The arguments for feature query accepted by this intrinsic is:

- FEATURE_GENERIC_IA32
- FEATURE_FPU
- FEATURE_CMOV
- FEATURE_MMX
- FEATURE_FXSAVE
- FEATURE_SSE
- FEATURE_SSE2
- FEATURE_SSE3
- FEATURE_SSSE3
- FEATURE_SSE4_1
- FEATURE_SSE4_2
- FEATURE_POPCNT
- FEATURE_MOVBE
- FEATURE_PCLMULQDQ
- FEATURE_AES
- FEATURE_F16C
- FEATURE_AVX
- FEATURE_RDRND
- FEATURE_FMA
- FEATURE_BMI
- FEATURE_LZCNT
- FEATURE_HLE
- FEATURE_RTM
- FEATURE_AVX2
- FEATURE_ADX
- FEATURE_RDSEED
**Description**

This intrinsic queries the processor on which it is running to check the availability of the given features. This check is dynamically performed at the point in the source where it is called. For example:

```cpp
if (_may_i_use_cpu_feature(_FEATURE_SSE4_2)) {
    Use SSE4.2 intrinsics;
} Else {
    Use generic code;
}
```

The `_may_i_use_feature` intrinsic, in this case, dynamically checks if the code is being executed on a processor that supports SSE4.2, and returns `true` if it is supported, or `false`. The `_may_i_use_feature` also accepts multiple features within a single argument, for example:

```cpp
if (_may_i_use_cpu_feature(_FEATURE_SSE |
    _FEATURE_SSE2 |
    _FEATURE_SSE3 |
    _FEATURE_SSSE3 |
    _FEATURE_MOVBE) &&
    !_may_i_use_cpu_feature(_FEATURE_SSE4_1)) {
    printf("You are running on an Atom processor."
});
```

This intrinsic does not perform processor vendor checks that other features do (`-m <cpu> type option`).

**Returns**

Result of the feature query, true or false (1 or 0) for whether the set of features is available on the machine on which the intrinsic is executed.

**See Also**

- compiler option
- Processor Targeting

[Q]ax

compiler option
**_allow_cpu_features_**
*Tells the compiler that the code region may be targeted for processors with the specified features. The compiler may then generate optimized code for the specified features.*

**Syntax**
`extern void _allow_cpu_features(unsigned __int64);`

**Arguments**
*unsigned __int64*  
an unsigned __int64 bitset representing one or more cpuid features:
- _FEATURE_GENERIC_IA32
- _FEATURE_FPU
- _FEATURE_CMOV
- _FEATURE_MMX
- _FEATURE_FXSAVE
- _FEATURE_SSE
- _FEATURE_SSE2
- _FEATURE_SSE3
- _FEATURE_SSSE3
- _FEATURE_SSE4_1
- _FEATURE_SSE4_2

- _FEATURE_POPCNT
- _FEATURE_PCLMULQDQ
- _FEATURE_AES
- _FEATURE_F16C
- _FEATURE_AVX
- _FEATURE_RDRND
- _FEATURE_FMA
- _FEATURE_BMI
- _FEATURE_LZCNT
- _FEATURE_HLE
- _FEATURE_RTM
- _FEATURE_AVX2
- _FEATURE_ADX
- _FEATURE_RDSEED
FEATURE_AVX512DQ
FEATURE_AVX512F
FEATURE_AVX512ER
FEATURE_AVX512PF
FEATURE_AVX512CD
FEATURE_AVX512BW
FEATURE_AVX512VL
FEATURE_SHA
FEATURE_MPX
FEATURE_AVX512IFMA52
FEATURE_AVX512VBMI
FEATURE_AVX512_4FMAPS
FEATURE_AVX512_4VNNIW

Description

Use this intrinsic function to use the specified processor feature at a code block level. The function only affects the scope of the code following the function call. Ensure that the code block will run only on processors with the specified features. If the code runs on a processor without the specified feature, the program may fail with an illegal instruction exception.

The function accepts a single argument that is a bitmask. In cases where one ISA depends on another, the higher ISA typically implies the lower. For example, the following arguments produce the same assembly code:

- FEATURE_SSE2|FEATURE_AVX|FEATURE_AVX512F
- FEATURE_AVX512F

The argument can only add features to those specified by the [Q]x or -m (Linux* and macOS*) or /arch (Windows*) options, it cannot remove features.

This function does not itself cause the compiler to generate multiple code paths. To do that, you need to use _may_i_use_cpu_feature().

NOTE
See the Release Notes for the latest information about this function.

To use specified processor features at a function level, use the cpu_dispatch or the cpu_specific attribute or the optimization_parameter pragma.

To use specified processor features at the file level, use the [Q]x compiler option.

The following example demonstrates how to use this intrinsic function to allow the compiler to generate the necessary code to use the Advanced Vector Extensions (AVX) and Streaming SIMD Extensions 2 (SSE2) features in the processor.

```c
#include <string.h>
#include <immintrin.h>

#define MAXIMGS  20
#define MAXNAME  512
```
typedef struct {
    int x;                  /* image X axis size */
    int y;                  /* image Y axis size */
    int bpp;                /* image bits */
    char name[MAXNAME];     /* image full filename */
    unsigned char * data;  /* pointer to raw byte image data */
} rawimage;

extern rawimage * imagelist[MAXIMGS];
extern int numimages;

rawimage* CreateImage(char * filename)
{
    rawimage* newimage = NULL;
    int i, len, intable;

    intable=0;
    if (numimages!=0) {
        _allow_cpu_features(_FEATURE_SSE2 | _FEATURE_AVX);
        for (i=0; i<numimages; i++) {
            if (!strcmp(filename, imagelist[i]->name)) {
                newimage=imagelist[i];
                intable=1;
            }
        }
    }

    if (!intable) {
        newimage=(rawimage *)malloc(sizeof(rawimage));
        if (newimage != NULL) {
            strcpy(newimage->name, filename);
            imagelist[numimages]=newimage; /* add new one to the table */
            numimages++; /* increment the number of images */
        }
    }

    return newimage;
}

Returns
Returns nothing.

Data Alignment, Memory Allocation Intrinsics, and Inline Assembly

This section describes features that support usage of the intrinsics.

Alignment Support

Aligning data improves the performance of intrinsics. When using the Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics, you should align data to 16 bytes in memory operations. Specifically, you must align __m128 objects as addresses passed to the _mm_load and _mm_store intrinsics. If you want to declare arrays of floats and treat them as __m128 objects by casting, you need to ensure that the float arrays are properly aligned.

Use __declspec(align) to direct the compiler to align data more strictly than it otherwise would. For example, a data object of type int is allocated at a byte address which is a multiple of 4 by default. By using __declspec(align), you can direct the compiler to instead use an address which is a multiple of 8, 16, or 32 (with the following restriction on IA-32 architecture: 16-byte addresses can be locally or statically allocated).

You can use this data alignment support as an advantage in optimizing cache line usage. By clustering small objects that are commonly used together into a struct, and forcing the struct to be allocated at the beginning of a cache line, you can effectively guarantee that each object is loaded into the cache as soon as any one is accessed, resulting in a significant performance benefit.

For 16-byte alignment, you can use the macro _MM_ALIGN16, which other compilers can support by including header files. This macro enables you to write portable code that does not rely on compiler support for __declspec(align).

See Also
__declspec(align) declaration

Programming Example includes example of _MM_ALIGN16

Allocating and Freeing Aligned Memory Blocks

To allocate and free aligned blocks of memory use the _mm_malloc and _mm_free intrinsics. These intrinsics are based on malloc and free, which are in the libirc.a library. You need to include malloc.h. The syntax for these intrinsics is as follows:

```c
void* _mm_malloc (size_t size, size_t align )
void _mm_free (void *p)
```

The _mm_malloc routine takes an extra parameter, which is the alignment constraint. This constraint must be a power of two. The pointer that is returned from _mm_malloc is guaranteed to be aligned on the specified boundary.

NOTE
Memory that is allocated using _mm_malloc must be freed using _mm_free. Calling free on memory allocated with _mm_malloc or calling _mm_free on memory allocated with malloc will cause unpredictable behavior.
Inline Assembly

Microsoft* Style Inline Assembly

The Intel® C++ Compiler supports Microsoft-style inline assembly on Windows*. The Intel® C++ Compiler supports Microsoft-style inline assembly on Linux* when used with the -use-msasm option. See the Microsoft documentation for the proper syntax.

GNU*-like Style Inline Assembly (IA-32 architecture and Intel® 64 architecture only)

The Intel® C++ Compiler supports GNU-like style inline assembly. The syntax is as follows:

```
asm-keyword [ volatile-keyword ] ( asm-template [ asm-interface ] ) ;
```

The Intel® C++ Compiler also supports mixing UNIX* and Microsoft* style asms. Use the __asm__ keyword for GNU-style ASM when using the -use_msasm switch.

**NOTE**
The Intel® C++ Compiler supports gcc-style inline ASM if the assembler code uses AT&T* System V/386 syntax.

<table>
<thead>
<tr>
<th>Syntax Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asm-keyword</td>
<td>Assembly statements begin with the keyword asm. Alternatively, either __asm or <strong>asm</strong> may be used for compatibility. When mixing UNIX* and Microsoft* style asm, use the <strong>asm</strong> keyword. The compiler only accepts the <strong>asm</strong> keyword. The asm and __asm keywords are reserved for Microsoft* style assembly statements.</td>
</tr>
<tr>
<td>volatile-keyword</td>
<td>If the optional keyword volatile is given, the asm is volatile. Two volatile asm statements are never moved past each other, and a reference to a volatile variable is not moved relative to a volatile asm. Alternate keywords __volatile and <strong>volatile</strong> may be used for compatibility.</td>
</tr>
<tr>
<td>asm-template</td>
<td>The asm-template is a C language ASCII string that specifies how to output the assembly code for an instruction. Most of the template is a fixed string; everything but the substitution-directives, if any, is passed through to the assembler. The syntax for a substitution directive is a %% followed by one or two characters.</td>
</tr>
</tbody>
</table>
| asm-interface    | The asm-interface consists of three parts:  
1. An optional output-list  
2. An optional input-list  
3. An optional clobber-list  
These are separated by colon (:) characters. If the output-list is missing, but an input-list is given, the input list may be preceded by two colons (::) to take the place of the missing output-list. If the asm-interface is omitted altogether, the asm statement is considered volatile regardless of whether a volatile-keyword was specified. |
<table>
<thead>
<tr>
<th>Syntax Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>output-list</td>
<td>An output-list consists of one or more output-specs separated by commas. For the purposes of substitution in the asm-template, each output-spec is numbered. The first operand in the output-list is numbered 0, the second is 1, and so on. Numbering is continuous through the output-list and into the input-list. The total number of operands is limited to 30 (i.e. 0-29).</td>
</tr>
<tr>
<td>input-list</td>
<td>Similar to an output-list, an input-list consists of one or more input-specs separated by commas. For the purposes of substitution in the asm-template, each input-spec is numbered, with the numbers continuing from those in the output-list.</td>
</tr>
<tr>
<td>clobber-list</td>
<td>A clobber-list tells the compiler that the asm uses or changes a specific machine register that is either coded directly into the asm or is changed implicitly by the assembly instruction. The clobber-list is a comma-separated list of clobber-specs.</td>
</tr>
<tr>
<td>input-spec</td>
<td>The input-specs tell the compiler about expressions whose values may be needed by the inserted assembly instruction. In order to describe fully the input requirements of the asm, you can list input-specs that are not actually referenced in the asm-template.</td>
</tr>
<tr>
<td>clobber-spec</td>
<td>Each clobber-spec specifies the name of a single machine register that is clobbered. The register name may optionally be preceded by a %. You can specify any valid machine register name. It is also legal to specify &quot;memory&quot; in a clobber-spec. This prevents the compiler from keeping data cached in registers across the asm statement.</td>
</tr>
</tbody>
</table>

When compiling an assembly statement on Linux*, the compiler simply emits the asm-template to the assembly file after making any necessary operand substitutions. The compiler then calls the GNU* assembler to generate machine code. In contrast, on Windows* the compiler itself must assemble the text contained in the asm-template string into machine code. In essence, the compiler contains a built-in assembler.

The compiler’s built-in assembler supports the GNU* .byte directive but does not support other functionality of the GNU* assembler, so there are limitations in the contents of the asm-template. The following assembler features are not currently supported.

- Directives other than the .byte directive
- Symbols*

**NOTE**
* Direct symbol references in the asm-template are not supported. To access a C++ object, use the asm-interface with a substitution directive.

**Example**

Incorrect method for accessing a C++ object:

```c
__asm__("addl $5, _x");
```

Proper method for accessing a C++ object:

```c
__asm__("addl $5, %0 : "+rm" (x));
```
Additionally, there are some restrictions on the usage of labels. The compiler only allows local labels, and only references to labels within the same assembly statement are permitted. A local label has the form "N: " where N is a non-negative integer. N does not have to be unique, even within the same assembly statement. To reference the most recent definition of label N, use "Nf ". To reference the next definition of label N, use "Nf ". In this context, "b " means backward and "f " means forward. For more information, refer to the GNU assembler documentation.

GNU-style inline assembly statements on Windows* use the same assembly instruction format as on Linux* which is often referenced as AT&T* assembly syntax. This means that destination operands are on the right and source operands are on the left. This operand order is the reverse of Intel assembly syntax.

Due to the limitations of the compiler’s built-in assembler, many assembly statements that compile and run on Linux* will not compile on Windows*. On the other hand, assembly statements that compile and run on Windows* should also compile and run on Linux*.

This feature provides a high-performance alternative to Microsoft-style inline assembly statements when portability between operating systems is important. Its intended use is in small primitives where high-performance integration with the surrounding C++ code is essential.

```c
#ifdef _WIN64
#define INT64_PRINTF_FORMAT "I64"
#else
#define __int64 long long
#define INT64_PRINTF_FORMAT "L"
#endif
#include <stdio.h>
typedef struct {
  __int64 lo64;
  __int64 hi64;
} my_i128;
#define ADD128(out, in1, in2)                      
  __asm__("addq %2, %0; adcq %3, %1" :           
    "=r"(out.lo64), "=r"(out.hi64) :       
    "emr" (in2.lo64), "emr"(in2.hi64),     
    "0" (in1.lo64), "1" (in1.hi64));

extern int
main() {  
  my_i128 val1, val2, result;
  val1.lo64 = ~0;
  val1.hi64 = 0;
  val2.hi64 = 65;
  ADD128(result, val1, val2);
  printf("0x%016" INT64_PRINTF_FORMAT "x%016" INT64_PRINTF_FORMAT "x\n",
         val1.hi64, val1.lo64);
  printf("0x%016" INT64_PRINTF_FORMAT "x%016" INT64_PRINTF_FORMAT "x\n",
         val2.hi64, val2.lo64);
  printf("+0x%016" INT64_PRINTF_FORMAT "x%016" INT64_PRINTF_FORMAT "x\n",
         result.hi64, result.lo64);
  return 0;
}
```
This example, written for Intel® 64 architecture, shows how to use a GNU-style inline assembly statement to add two 128-bit integers. In this example, a 128-bit integer is represented as two __int64 objects in the my_i128 structure. The inline assembly statement used to implement the addition is contained in the ADD128 macro, which takes three my_i128 arguments representing three 128-bit integers. The first argument is the output. The next two arguments are the inputs. The example compiles and runs using the Intel® C++ Compiler on Linux® or Windows*, producing the following output.

```
0x0000000000000000ffffffffffffffff
+ 0x00000000000000410000000000000001
-----------------------------
+ 0x00000000000000420000000000000000
```

In the GNU-style inline assembly implementation, the asm interface specifies all the inputs, outputs, and side effects of the asm statement, enabling the compiler to generate very efficient code.

```
mov       r13, 0xffffffffffffffff
mov       r12, 0x0000000000000000
add       r13, 1
adc       r12, 65
```

It is worth noting that when the compiler generates an assembly file on Windows*, it uses Intel syntax even though the assembly statement was written using AT&T* assembly syntax.

The compiler moves in1.lo64 into a register to match the constraint of operand 4. Operand 4's constraint of "0" indicates that it must be assigned the same location as output operand 0. And operand 0's constraint is "=r", indicating that it must be assigned an integer register. In this case, the compiler chooses r13. In the same way, the compiler moves in1.hi64 into register r12.

The constraints for input operands 2 and 3 allow the operands to be assigned a register location ("r"), a memory location ("m"), or a constant signed 32-bit integer value ("e"). In this case, the compiler chooses to match operands 2 and 3 with the constant values 1 and 65, enabling the add and adc instructions to utilize the "register-immediate" forms.

The same operation is much more expensive using a Microsoft-style inline assembly statement, because the interface between the assembly statement and the surrounding C++ code is entirely through memory. Using Microsoft* assembly, the ADD128 macro might be written as follows.

```
#define ADD128(out, in1, in2)                      
{                                              
__asm mov rax, in1.lo64                    
__asm mov rdx, in1.hi64                    
__asm add rax, in2.lo64                    
__asm adc rdx, in2.hi64                    
__asm mov out.lo64, rax                    
__asm mov out.hi64, rdx                    
}                                            
```

The compiler must add code before the assembly statement to move the inputs into memory, and it must add code after the assembly statement to retrieve the outputs from memory. This prevents the compiler from exploiting some optimization opportunities. Thus, the following assembly code is produced.

```
mov       QWORD PTR [rsp+32], -1
mov       QWORD PTR [rsp+40], 0
mov       QWORD PTR [rsp+48], 1
mov       QWORD PTR [rsp+56], 65

; Begin ASM
mov       rax, QWORD PTR [rsp+32]
```
The operation that took only four instructions and no memory references using GNU-style inline assembly takes twelve instructions with twelve memory references using Microsoft-style inline assembly.

**Intrinsics for Managing Extended Processor States and Registers**

The Intel® C++ Compiler Classic provides twelve intrinsics for managing the extended processor states and extended registers. These intrinsics are available for IA-32 and Intel® 64 architectures running on supported operating systems.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

The intrinsics map directly to the hardware system instructions described in "Intel® 64 and IA-32 Architectures Software Developer's Manual, volumes 1, 2a, and 2b" and "Intel® Advanced Vector Extensions Programming Reference".

**Functional Overview**

The intrinsics for managing the extended processor states and extended registers include:

- Two intrinsics to read from and write to the specified extended control register. These intrinsics map to `XGETBV` and `XSETBV` instructions.
- Four intrinsics to save and restore the current state of the x87 FPU, MMX, XMM, and MXCSR registers. These intrinsics map to `FXSAVE`, `FXSAVE64`, `FXRSTOR`, and `FXRSTOR64` instructions.
- Six intrinsics to save and restore the current state of the x87 FPU, MMX, XMM, YMM, and MXCSR registers. These intrinsics map to `XSAVE`, `XSAVE64`, `XSAVEOPT`, `XSAVEOPT64`, `XRSTOR`, and `XRSTOR64` instructions.

**Intrinsics for Reading and Writing the Content of Extended Control Registers**

This group of intrinsics includes two intrinsics to read from and write to extended control registers (XCRs). Currently, the only such register defined is XCRO, XFEATURE_ENABLED_MASK register. This register specifies the set of processor states that the operating system enables on that processor, for example x87 FPU states, SSE states, and other processor extended states that Intel® 64 architecture may introduce in the future.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```
_xgetbv()
Reads the content of an extended control register.

Syntax
extern unsigned __int64 _xgetbv(unsigned int xcr);

Arguments
xcr
An extended control register to be read. Currently, only the value '0' is allowed.

Description
This intrinsic reads from extended control registers. Currently, the only control register allowed/defined is (XCR0) XFEATURE_ENABLED_MASK register. The corresponding constant is defined in the immintrin.h file to refer to this register:

#define _XCR_XFEATURE_ENABLED_MASK 0

This intrinsic maps to XGETBV instruction.

Returns
Returns the content of a specified extended control register.

_xsetbv()
Writes the given value to a specified extended control register.

Syntax
extern void _xsetbv(unsigned int xcr, unsigned __int64 val);

Arguments
xcr
An extended control register to be written. Currently, only the value '0' is allowed.
Value to be written to the specified extended control register.

**Description**

This intrinsic writes the given value to the specified extended control register. Currently, the only control register allowed/defined is (XCR0) XFEATURE_ENABLED_MASK register. The corresponding constant is defined in the immintrin.h file to refer to this register:

```c
#define _XCR_XFEATURE_ENABLED_MASK 0
```

This intrinsic maps to XSETBV instruction.

**Intrinsics for Saving and Restoring the Extended Processor States**

To use any of these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

**Intrinsics that map to FXSAVE[64] and FXRSTOR[64] instructions**

This group of intrinsics includes four intrinsics to save and restore the current state of the x87 FPU, MMX, XMM, and MXCSR registers.

These intrinsics accept a memory reference to a 16-byte aligned 512-byte memory chunk. The layout of the memory is shown below in Table 1.

**Table 1 - FXSAVE save area layout.**
Intrinsics that map to XSAVE[64], XSAVEOPT[64], and XRSTOR[64] instructions

This group of intrinsics includes six intrinsics to fully or partially save and restore the current state of the x87 FPU, MMX, XMM, YMM, and MXCSR registers.

These intrinsics accept a memory reference to a 64-byte aligned memory. The layout of the register fields for the first 512 bytes is the same as the FXSAVE save area layout. The intrinsics saving the states do not write to bytes 464:511. The save area layout is shown in Tables 2a and 2b below.

The second operand is a save/restore mask specifying the saved/restored extended states. The value of the mask is anded with XFEATURE_ENABLED_MASK(XCR0). A particular extended state is saved/restored only if the corresponding bit of both save/restore mask and XFEATURE_ENABLED_MASK is set to '1'.

_fxsave()
Saves the states of x87 FPU, MMX, XMM, and MXCSR registers to memory.

Syntax
extern void _fxsave(void *mem);

Arguments

mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.
Description
Saves the states of x87 FPU, MMX, XMM, and MXCSR registers to memory. This intrinsic maps to FXSAVE instruction.

fxsave64()
Saves the states of x87 FPU, MMX, XMM, and MXCSR registers to memory.

Syntax
extern void _fxsave64(void *mem);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.

Description
Saves the states of x87 FPU, MMX, XMM, and MXCSR registers to memory. This intrinsic maps to FXSAVE64 instruction.

fxrstor()
Restores the states of x87 FPU, MMX, XMM, and MXCSR registers from memory.

Syntax
extern void _fxrstor(void *mem);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.

Description
Restores the states of x87 FPU, MMX, XMM, and MXCSR registers from memory. This intrinsic maps to FXRSTOR instruction.

fxrstor64()
Restores the states of x87 FPU, MMX, XMM, and MXCSR registers from memory.

Syntax
extern void _fxrstor64(void *mem);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.
Description
Restores the states of x87 FPU, MMX, XMM, and MXCSR registers from memory. This intrinsic maps to FXRSTOR64 instruction.

_xsave()/_xsavec()/_xsaves()
_Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory._

Syntax
extern void _xsave(void *mem, unsigned __int64 save_mask);
extern void _xsavec(void *mem, unsigned __int64 save_mask);
extern void _xsaves(void *mem, unsigned __int64 save_mask);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.

save_mask A bit mask specifying the extended states to be saved.

Description
Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory. The xsave intrinsic maps to XSAVE instruction, the xsavec intrinsic maps to XSAVEC instruction, and the xsaves intrinsic maps to XSAVES instruction. See the Intel® 64 and IA-32 Architectures Software Developer's Manual for information on how the three instructions differ.

_xsave64()/_xsavec64()/_xsaves64()
_Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory._

Syntax
extern void _xsave64(void *mem, unsigned __int64 save_mask);
extern void _xsavec64(void *mem, unsigned __int64 save_mask);
extern void _xsaves64(void *mem, unsigned __int64 save_mask);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.

save_mask A bit mask specifying the extended states to be saved.

Description
Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory. The xsave64 intrinsic maps to XSAVE64 instruction, the xsavec64 intrinsic maps to XSAVEC64 instruction, and the xsaves64 intrinsic maps to XSAVES64 instruction. See the Intel® 64 and IA-32 Architectures Software Developer's Manual for information on how the three instructions differ.
_xsaveopt()
Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory, optimizing the save operation if possible.

Syntax
extern void _xsaveopt(void *mem, unsigned __int64 save_mask);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.
save_mask A bit mask specifying the extended states to be saved.

Description
Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory, optimizing the save operation if possible. This intrinsic maps to XSAVEOPT instruction.

_xsaveopt64()
Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory, optimizing the save operation if possible.

Syntax
extern void _xsaveopt64(void *mem, unsigned __int64 save_mask);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.
save_mask A bit mask specifying the extended states to be saved.

Description
Saves the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers to memory, optimizing the save operation if possible. This intrinsic maps to XSAVEOPT64 instruction.

_xrstor()/_xrstors()
Restores the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers from memory.

Syntax
extern void _xrstor(void *mem, unsigned __int64 rstor_mask);
extern void _xrstors(const void *mem, unsigned __int64 rstor_mask);

Arguments
mem A memory reference to FXSAVE area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.
**xrstor64()**/**xrstors64()**

Restores the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers from memory.

**Syntax**

```c
extern void _xrstor64(void *mem, unsigned __int64 rstor_mask);
extern void _xrstors64(const void *mem, unsigned __int64 rstor_mask);
```

**Arguments**

- **mem**
  - A memory reference to **FXSAVE** area. The 512-bytes memory addressed by the reference must be 16-bytes aligned.

- **rstor_mask**
  - A bit mask specifying the extended states to be restored.

**Description**

Restores the states of x87 FPU, MMX, XMM, YMM, and MXCSR registers from memory. The xrstor intrinsic maps to **XRSTOR** instruction, and the xrstors intrinsic maps to **XRSTORS** instruction. See the Intel® 64 and IA-32 Architectures Software Developer’s Manual for information on how the instructions differ.

---

**Intrinsics for the Short Vector Random Number Generator Library**

The Short Vector Random Number Generator (SVRNG) library provides intrinsics for the IA-32 and Intel® 64 architectures running on supported operating systems. The SVRNG library partially covers both standard C++ (as referenced here: http://www.cplusplus.com/reference/random/) and the random number generation functionality of the Intel® oneAPI Math Kernel Library (oneMKL). The SVRNG library allows users to produce random numbers using a combination of engines and distributions. Engines are basic generators which produce uniformly distributed 32-bit or 64-bit unsigned integer numbers. Distributions transform the sequences of numbers generated by an engine into sequences of numbers with specific random variable distributions, such as uniform, normal, binomial and others. The distributions support single- or double-precision floating point and 32-bit signed integer outputs.

Both scalar and vector implementations are available for SVRNG generation functions. Scalar versions return native C++ data types: float, double, and both 32- and 64-bit integers. Vector versions produce packed results using SIMD-vector registers via corresponding data types as outlined in **Data Types and Calling Conventions**. Scalar versions called in loops can be vectorized by the compiler.

Unlike simple random number generators such as **rand()**, SVRNG engines and distributions require initialization routines which allocate memory and pre-compute constants required for fast vector generation. Finalization routines are provided to deallocate memory. Some engines support skip-ahead and leap-frog techniques for use in parallel computing environment. The **Parallel Computation Support** section discusses
how these are used to obtain a random number sequence in parallel that is identical to the random number sequence that is generated in the sequential case. Error handling in SVRNG is done via status set and get functions. Additionally NULL pointers are returned on errors when possible.

SVRNG SIMD-vector functions and corresponding vectorized scalar calls are highly optimized for the following instructions sets:

- Intel® Streaming SIMD Extensions 2 (Intel® SSE2) (default)
- Intel® Advanced Vector Extensions 2 (Intel® AVX2)
- Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Instructions (on Intel® Many Integrated Core Architecture (Intel® MIC Architecture) and elsewhere)

Further Reference

The following documents are referenced in this section to provide further detail:

Data Types and Calling Conventions

Data types specific to the Short Vector Random Number Generator (SVRNG) Library

There are two types of SVRNG functions: the initialization and service routines and generation functions. The initialization and service routines introduce two new data types:

```cpp
svrng_engine_t
```

A pointer to the engine-specific data structure created by the engine initialization routine. The structure contains pre-computed constants necessary for fast and precise random number vector generation by the engine. The structure size is engine-dependent.

```cpp
svrng_distribution_t
```

A pointer to the distribution-specific data structure created by the distribution initialization routine. The structure contains pre-computed loop invariant constants to perform distribution transformations efficiently. The structure size is distribution-dependent.

While scalar SVRNG generation functions return native "C" data types (float, double, 32-bit and 64-bit integers), the SIMD-vector versions produce 1, 2, 4, 8, 16, or 32 packed results in one or several SIMD-vector registers. A set of SVRNG-specific vector types have been introduced to return these packed results. These types are CPU-specific and mapped to different numbers of SIMD-registers depending on the architecture where the program runs:

</tbody>
</table>
Note that SVRNG does not have optimizations specific to the Intel® Advanced Vector Extensions (Intel® AVX) instruction set. On hardware that supports Intel® AVX the Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instruction default versions are called, so you must use the Intel® SSE2 data types to interpret the results.

**SVRNG calling conventions**

All SVRNG routines use the regcall calling convention which provides the most use of hardware vector registers for passing parameters and returning results. See the "C/C++ Calling Conventions" section and the "_vectorcall and __regcall demystified" article referenced in the Introduction. This avoids unnecessary memory spills and fills of registers and improves performance.

In addition this convention provides the opportunity to deploy the "vector variant" declaration feature specific to the Intel® compiler. The declaration specifies a vector variant function that corresponds to its original C/C++ + scalar function. This vector variant function can be invoked in vector context at the site of the call. See the vector_variant section for more detail. All SIMD-vector SVRNG intrinsics (except packed length = 1) are declared in the svrng.h header file as vector_variant to support automatic vectorization.

vector_variant

**Usage Model**

A typical usage model for using the intrinsics in the Short Vector Random Number Generator (SVRNG) library is the same as for standard C++ or Intel® oneAPI Math Kernel Library (oneMKL) vector statistics random number generator and looks something like the following:

- Include svrng.h header file
- Create and initialize basic SVRNG generator engine, create and initialize distribution (if necessary).
- Call one or more SVRNG generation function.
- Process the output.
- Delete the SVRNG engines and distributions.

On Windows*, users will need to explicitly link the static or dynamic libraries: static: libirng.lib, dynamic: libirngmd.lib. On Linux* and macOS* the compiler driver will link automatically.

The following example demonstrates generation of a random stream that is output of basic generator engine MT19937 with seed equal to 777. The engine is used to generate two arrays: 1024 uniformly distributed random numbers between \(<a = 0.0, b = 4.0>\) via scalar generator call which should be vectorized by the compiler and 1024 normally distributed with parameters \(<\text{mean} = 2.0, \text{standard deviation} = 1.0>\) random numbers in blocks by 16 elements via direct call of SIMD-vector implementation. Delete engines and distributions after completing the generation. Check status for possible errors happened. The purpose of the example is to calculate the sample mean for both distributions with the given parameters.

```c
#include <stdio.h>
#include <svrng.h>

int main( void )
{
  int i, st = SVRNG_STATUS_OK;
  double res1[1024], res2[1024];
  double sum1 = 0, sum2 = 0;
  double mean1, mean2;
  svrng_engine_t engine;
  svrng_distribution_t distr1, distr2;
```
/* Create mt19937 engine */
engine = svrng_new_mt19937_engine( 777 );

/* Create uniform distribution */
distr1 = svrng_new_uniform_distribution_double( 0.0, 4.0 );

/* Create normal distribution */
distr2 = svrng_new_normal_distribution_double( 2.0, 1.0 );

/* Scalar generator call, can be vectorized by compiler */
#pragma ivdep
#pragma vector always
for( i = 0; i < 1024; i ++ ) {
    res1[i] = svrng_generate_double( engine, distr1 );
}

/* Direct call to SIMD-vector implementation */
/* generating 16 packed elements */
for( i = 0; i < 1024; i += 16 ) {
    *((svrng_double16_t*)(&res2[i])) =
        svrng_generate16_double( engine, distr2 );
}

/* Compute mean values */
for( i = 0; i < 1024; i++ ) {
    sum1 += res1[i];
    sum2 += res2[i];
}

mean1 = sum1 / 1024.0;
mean2 = sum2 / 1024.0;

/* Printing results */
printf( "Sample mean of uniform distribution = %f\n", mean1 );
printf( "Sample mean of normal  distribution = %f\n", mean2 );

/* Check for resulted status */
st = svrng_get_status();

if(st != SVRNG_STATUS_OK) {
    printf("FAILED: status error %d returned\n", st);
}

/* Delete distributions */
svrng_delete_distribution( distr1 );
svrng_delete_distribution( distr2 );

/* Delete engine */
svrng_delete_engine( engine );

return st;
Another example demonstrates the "skip-ahead" technique which ensures identical random number sequences in cases of parallel and sequential generation for certain engines. The rand0 engine is being created and copied to T "threads" with the "skip-ahead" adjustments applied. Each "thread" generates N uniformly distributed unsigned integer random values and then all LEN=T*N numbers are compared to the sequential call:

```c
#include <stdio.h>
#include <stdint.h>
#include <svrng.h>

#define LEN 1024
#define T 8
#define N (LEN/T)

int main( void ) {
    uint32_t       seq_res[LEN+32], parallel_res[LEN+32];
    svrng_engine_t seq_engine;
    svrng_engine_t parallel_engine[T];
    int            l, n, t, errs = 0, st = SVRNG_STATUS_OK;

    /* Create sequential engine and distr */
    seq_engine = svrng_new_rand0_engine( 777 );

    /* Copy existing sequential engine to new T parallel ones */
    /* with t*N offsets using skipahead method */
    for( t = 0; t < T; t++ ) {
        int thr_offset = t*N;
        parallel_engine[t] = svrng_copy_engine( seq_engine );
        parallel_engine[t] = svrng_skipahead_engine( parallel_engine[t], thr_offset );
    }

    /* Sequential loop using scalar function (can be vectorized) */
    #pragma ivdep
    #pragma vector always
    for( l = 0; l < LEN; l++ ) {
        seq_res[l] = svrng_generate_uint( seq_engine );
    }

    /* Parallel loop using SIMD-vector function, */
    /* may be spreaded by threads */
    for( t = 0; t < T; t++ ) {
        for( n = 0; n < N; n += 8 ) {
            *((svrng_uint8_t*)(&(parallel_res[t*N+n]))) = svrng_generate8_uint( parallel_engine[t] );
        }
    }

    /* Compare seq and parallel results */
    for(l = 0; l < LEN; l++) {
        if( parallel_res[l] != seq_res[l] ) {
            errs++;
        }
    }

    /* Check for resulted status */
    st = svrng_get_status();
}
```
/* Print overall result */
if(st != SVRNG_STATUS_OK) {
    printf("FAILED: status error %d returned\n", st);
}
else if(errs) {
    printf("FAILED: %d skipahead errors\n", errs);
}
else {
    printf("PASSED\n");
}

/* Delete engines */
svrng_delete_engine( seq_engine );
for( t = 0; t < T; t++ ) {
    svrng_delete_engine(parallel_engine[t]);
}

return (errs-st);

Engine Initialization and Finalization

Unlike the simple rand() function, vector random number generators in the Short Vector Random Number Generator (SVRNG) library require the initialization of an engine before the first generator run. This is due to the fact that a number of initialization values called the vector state of the engine must be pre-computed to perform effective vector generation. Once computed that vector state is retained and updated in memory as more numbers are generated. When no more random numbers are needed, that memory can be deallocated.

The next few topics provide the functions used to allocate memory, initialize, and deallocate memory for all supported SVRNG engines.

The SVRNG library supports the following engines from the C++11 standard and the Intel® oneAPI Math Kernel Library (oneMKL) vector statistics random number generator collection:

• **rand0** (C++11 standard)
• **rand** (C++11 standard)
• **mcg31m1** (oneMKL)
• **mcg59** (oneMKL)
• **mt19937** (oneMKL and C++11 standard)

For more information on the figures of merit for these random number generator engines read the Basic Random Generator Properties and Testing Results section of the Notes for Intel® oneAPI Math Kernel Library Vector Statistics document (see the introduction).

For each engine there is a simple and extended version of the initialization function. Simple initialization has one parameter, the seed, and constructs the rest of the vector state to generate the proper sequence for the engine type. The extended versions of the initialization functions, with the _ex suffix, use multiple constants to set generator state values. The application notes in the description of each engine provide more detail on how these constants are used. The usual case for extended initialization requires enough constants to fill a SIMD register with 64-bit values on the system which the program is intended to run. The following table sums up the width (SIMD_WIDTH) of the SIMD registers used by the instructions sets for which the SVRNG intrinsics are optimized:

<table>
<thead>
<tr>
<th>Instruction set</th>
<th>SIMD_WIDTH</th>

Introduction

**svrng_new_rand0_engine/svrng_new_rand0_ex**

Routines for allocating memory for a rand0 engine and initializing with one or multiple seeds

**Syntax**

```c
svrng_engine_t svrng_new_rand0_engine( uint32_t seed )
svrng_engine_t svrng_new_rand0_engine_ex( int num, uint32_t *pseed )
```

**Input Parameters**

- `seed` Initial condition for the engine.
- `num` Number of initialization values for the extended routine. May be 0 (seed set to 1), 1 (seed set to pseed[0]), or SIMD_WIDTH.
- `pseed` Pointer to an array with initialization values for the extended routine.

**Description**

The `svrng_new_rand0_engine` function allocates memory for the rand0 engine originated from C++11 standard and initializes it using one seed value. The extended version of the function, `svrng_new_rand0_engine_ex`, accepts several values for complex initialization cases where the user needs to fill the whole vector state with their own constants.

**Status flags set**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SVRNG_STATUS_ERROR_MEMORY_ALLOC</code></td>
<td>Memory allocation failure</td>
</tr>
<tr>
<td><code>SVRNG_STATUS_ERROR_BAD_PARAM1</code></td>
<td>Bad parameter: num</td>
</tr>
<tr>
<td><code>SVRNG_STATUS_ERROR_BAD_PARAM2</code></td>
<td>Bad parameter: pseed</td>
</tr>
</tbody>
</table>

**Return Values**

A pointer to an initialized engine or NULL on error.

**Application Notes**

The rand0 engine is a simple 32-bit multiplicative congruential pseudo-random number generator represented by formula:
\[ x_{i+1} = (a \cdot x_i) \mod m \]

multiplier \( a = 16807 (=7^{5}) \)

modulus \( m = 2147483647 (=2^{31}-1) \)

Range: \([0, MAX), \text{where } MAX = m\)

**svrng\_new\_rand\_engine/svrng\_new\_rand\_ex**

*Routines for allocating memory for a rand engine and initializing with one or multiple seeds*

**Syntax**

svrng\_engine\_t svrng\_new\_rand\_engine( uint32\_t seed )

svrng\_engine\_t svrng\_new\_rand\_engine\_ex( int num, uint32\_t *pseed )

**Input Parameters**

- **seed**
  - Initial condition for the engine.

- **num**
  - Number of initialization values for the extended routine. May be 0 (seed set to 1), 1 (seed set to pseed[0]), or SIMD\_WIDTH.

- **pseed**
  - Pointer to an array with initialization values for the extended routine.

**Description**

The *svrng\_new\_rand\_engine* function allocates memory for the rand engine (originated from C++ 11 standard) and initializes it using one *seed* value. The extended version of the function, *svrng\_new\_rand\_engine\_ex*, accepts several values for complex initialization cases where the user needs to fill the whole vector state with their own constants.

**Status flags set**

</table>

**Return Values**

A pointer to an initialized engine or NULL on error.

**Application Notes**

The rand is a simple 32-bit multiplicative congruential pseudo-random number generator represented by formula:

\[ x_{i+1} = (a \cdot x_i) \mod m \]

multiplier \( a = 48271 \)

modulus \( m = 2147483647 (=2^{31}-1) \)

Range: \([0, MAX), \text{where } MAX = m\)
svrng_new_mcg31m1_engine/svrng_new_mcg31m1_ex
Routines for allocating memory for a mcg31m1 engine and initializing with one or multiple seeds

Syntax
svrng_engine_t svrng_new_mcg31m1_engine( uint32_t seed )
svrng_engine_t svrng_new_mcg31m1_engine_ex( int num, uint32_t *pseed )

Input Parameters
seed
   Initial condition for the engine.
num
   Number of initialization values for the extended routine. May be 0 (seed set to 1), 1 (seed set to pseed[0]), or SIMD_WIDTH.
pseed
   Pointer to an array with initialization values for the extended routine.

Description
The svrng_new_mcg31m1_engine function allocates memory for the mcg31m1 engine (originated from C++ 11 standard) and initializes it using one seed value. The extended version of the function, svrng_new_mcg31m1_engine_ex, accepts several values for complex initialization cases where the user needs to fill the whole vector state with their own constants.

Status flags set

<tr>
<td>SVRNG_STATUS_ERROR_BAD_PARAM2</td>
<td>Bad parameter: pseed</td>
</tr>
</tbody>
</table>

Return Values
A pointer to an initialized engine or NULL on error.

Application Notes
The mcg31m1 is a simple 32-bit multiplicative congruential pseudo-random number generator represented by formula:

\[ x_{i+1} = (ax_i) \mod m \]

multiplier \( a = 1132489760 \)
modulus \( m = 2147483647 (=2^{31}-1) \) Range: \([0,MAX)\), where \( MAX = m \)

svrng_new_mcg59_engine/svrng_new_mcg59_ex
Routines for allocating memory for a mcg59 engine and initializing with one or multiple seeds
Syntax

svrng_engine_t svrng_new_mcg59_engine( uint32_t seed )
svrng_engine_t svrng_new_mcg59_engine_ex( int num, uint32_t *pseed )

Input Parameters

- **seed**: Initial condition for the engine.
- **num**: Number of initialization values for the extended routine. May be 0 (seed set to 1), 1 (seed set to pseed[0]), or SIMD_WIDTH.
- **pseed**: Pointer to an array with initialization values for the extended routine.

Description

The `svrng_new_mcg59_engine` function allocates memory for the mcg59 engine (originated from C++ 11 standard) and initializes it using one `seed` value. The extended version of the function, `svrng_new_mcg59_engine_ex`, accepts several values for complex initialization cases where the user needs to fill the whole vector state with their own constants.

<td>Bad parameter: num</td>
</tr>
<tr>
<td><code>SVRNG_STATUS_ERROR_BAD_PARAM2</code></td>
<td>Bad parameter: pseed</td>
</tr>
</tbody>
</table>

Return Values

A pointer to an initialized engine or NULL on error.

Application Notes

The mcg59 is a simple 64-bit multiplicative congruential pseudo-random number generator represented by formula:

\[ x_{i+1} = (a \cdot x_i) \mod m \]

multiplier \( a = 13^{13} \)

modulus \( m = 2^{59} \) Range: \([0,\text{MAX})\), where \( \text{MAX} = m \)

**svrng_new_mt19937_engine/svrng_new_mt19937_ex**

Routines for allocating memory for an mt19937 engine and initializing with one or multiple seeds

Syntax

svrng_engine_t svrng_new_mt19937_engine( uint32_t seed )
svrng_engine_t svrng_new_mt19937_engine_ex( int num, uint32_t *pseed )

Compiler Reference

675
Input Parameters

- **seed**: Initial condition for the engine.
- **num**: Number of initialization values for the extended routine. num >= 0. See VSL Notes for further details on extended initialization of the mt19937 engine.
- **pseed**: Pointer to an array with initialization values for the extended routine.

Description

The `svrng_new_mt19937_engine` function allocates memory for the mt19937 engine (from C++ 11 standard) and initializes it using one `seed` value. The extended version of the function, `svrng_new_mt19937_engine_ex`, accepts several values for complex initialization cases. Because the mt19937 engine has 19937 bits of state in memory, its initialization differs from the other engines. See the Notes for Intel® oneAPI Math Kernel Library Vector Statistics document for detailed information on this engine.

Status flags set

<table>

</tr>
<tr>
<td><code>SVRNG_STATUS_ERROR_BAD_PARAM2</code></td>
<td>Bad parameter: pseed</td>
</tr>
</tbody>
</table>

Return Values

A pointer to an initialized engine or NULL on error.

Application Notes

The mt19937 is a Mersenne Twister pseudo-random generator of 32-bit numbers with a state size of 19937 bits that is a modification of twisted generalized feedback shift register generator. Range: [0,MAX), where MAX = 2^{32}.

NULL pointer.

Distribution Initialization and Finalization

The Short Vector Random Number Generator (SVRNG) library supports the following distributions:

- **uniform** *(single and double floating point and 32-bit integer)*
- **normal** *(single and double floating point)*

SVRNG distributions must be initialized before random numbers can be generated. The initialization and finalization routines in this section allocate memory, pre-compute loop-invariant values and broadcast scalar constants for fast vector generation. Update functions are also provided to re-compute these numbers without memory re-allocation. More detail on the figures of merit for these distributions can be found in the Figures of Merit for Random Number Generators and Testing of Distribution Random Number Generators sections of the *Notes for Intel® oneAPI Math Kernel Library Vector Statistics* document referenced in the Introduction.

See Also

Introduction

`svrng_new_uniform_distribution_[int|float|double]/svrng_update_uniform_distribution_[int|float|double]`

*Allocates and initializes constants for the uniform distribution with specified parameters*

Syntax

```c
svrng_distribution_t svrng_new_uniform_distribution_int( int a, int b )
svrng_distribution_t svrng_new_uniform_distribution_float( float a, float b )
svrng_distribution_t svrng_new_uniform_distribution_double( double a, double b )
svrng_distribution_t svrng_update_uniform_distribution_int( svrng_distribution_t distr, int a, int b )
svrng_distribution_t svrng_update_uniform_distribution_float( svrng_distribution_t distr, float a, float b )
svrng_distribution_t svrng_update_uniform_distribution_double( svrng_distribution_t distr, double a, double b )
```

Input Parameters

- `a` : Left bound of interval
- `b` : Right bound of interval
- `distr` : Pointer to the distribution to be updated
Description
The *svrng_new_uniform_distribution_[int|float|double]* function allocates memory for a uniform distribution and pre-computes and broadcasts loop-invariant constants required for vector generation of uniformly distributed values over the interval \([a, b)\), where \(a, b\) are the real left and right bounds of the interval respectively with \(a < b\). 32-bit int, float and double types are supported. The *svrng_update_uniform_distribution_[int|float|double]* functions give the same result, but by modifying existing distributions instead of allocating memory for new distributions.

Status flags set

<table>
<thead>

<td>(a \geq b)</td>
</tr>
<tr>
<td><strong>SVRNG_STATUS_ERROR_BAD_DISTR</strong></td>
<td>Bad distribution (NULL pointer)</td>
</tr>
</tbody>
</table>

Return Values
A pointer to the distribution created or updated by the function, or NULL on error.

`svrng_new_normal_distribution_[float|double]/svrng_update_normal_distribution_[float|double]`
Allocates and initializes constants for the normal distribution with specified parameters

Syntax

```c
svrng_distribution_t svrng_new_normal_distribution_float( float mean, float stddev )
svrng_distribution_t svrng_new_normal_distribution_double( double mean, double stddev )
svrng_distribution_t svrng_update_normal_distribution_float( svrng_distribution_t distr, float mean, float stddev )
svrng_distribution_t svrng_update_normal_distribution_double( svrng_distribution_t distr, double mean, double stddev )
```

Input Parameters

- **mean**       Mean value of the normal distribution.
- **stddev**     Standard deviation of the normal distribution
- **distr**      Pointer to the distribution to be updated

Description
The *svrng_new_normal_distribution_[float|double]* functions allocate memory for a normal distribution of either 32- or 64-bit floating point numbers with the specified mean and positive, real stddev using the ICDF method. The function pre-computes and broadcasts loop-invariant constants required for vector generation. The *svrng_update_normal_distribution_[float|double]* functions give the same result, but by modifying existing distributions instead of allocating memory for new distributions.
Status flags set

<table>
<thead>
<tr>

<tr>
<td>SVRNG_STATUS_ERROR_BAD_PARAM2</td>
<td>Bad parameter: stddev</td>
</tr>
<tr>
<td>SVRNG_STATUS_ERROR_BAD_DISTR</td>
<td>Bad distribution (NULL pointer)</td>
</tr>
</tbody>
</table>

Return Values
A pointer to the distribution created or updated by the function, or NULL on error.

svrng_delete_distribution
Deallocates memory for the specified distribution

Syntax
svrng_distribution_t svrng_delete_distribution( svrng_distribution_t distr)

Input Parameters
distr
Pointer to the distribution to be deallocated.

Description
The svrng_delete_distribution function deallocates memory for the specified distribution.

Status flags set

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SVRNG_STATUS_ERROR_BAD_DISTR</td>
<td>distr is a NULL pointer.</td>
</tr>
</tbody>
</table>

Return Values
NULL pointer.

Random Values Generation
Once the engines and distributions are created by the appropriate initialization routines, the SVRNG generation functions may be called. Both scalar and vector implementations are available. Scalar functions return random values of native "C" types such as int32_t, uint32_t, uint64_t, float, and double, while vector functions produce packed results in SIMD registers through CPU-specific types (see the "Data Types and Calling Conventions" sections). Calls to scalar SVRNG intrinsics in loops can be vectorized by the compiler via the "vector_variant" feature when the svrng.h header file is used. The compiler vectorizer replaces scalar calls by a corresponding SIMD version.

See Also
Data Types and Calling Conventions
svrng_generate[1|2|4|8|16|32]_[uint|ulong]
Generates uniform random bits over the a specified range

Syntax

```c
uint32_t svrng_generate_uint( svrng_engine_t engine )
svrng_uint1_t svrng_generate1_uint( svrng_engine_t engine )
svrng_uint2_t svrng_generate2_uint( svrng_engine_t engine )
svrng_uint4_t svrng_generate4_uint( svrng_engine_t engine )
svrng_uint8_t svrng_generate8_uint( svrng_engine_t engine )
svrng_uint16_t svrng_generate16_uint( svrng_engine_t engine )
svrng_uint32_t svrng_generate32_uint( svrng_engine_t engine )
uint64_t svrng_generate_ulong( svrng_engine_t engine )
svrng_ulong1_t svrng_generate1_ulong( svrng_engine_t engine )
svrng_ulong2_t svrng_generate2_ulong( svrng_engine_t engine )
svrng_ulong4_t svrng_generate4_ulong( svrng_engine_t engine )
svrng_ulong8_t svrng_generate8_ulong( svrng_engine_t engine )
svrng_ulong16_t svrng_generate16_ulong( svrng_engine_t engine )
svrng_ulong32_t svrng_generate32_ulong( svrng_engine_t engine )
```

Input Parameters

`engine` Pointer to the engine.

Description

The `svrng_generate[n]_[uint|ulong]` functions generate uniform random bits over the range \([0, \text{MAX})\) with engine-dependent maximum value. The uint versions are available for 32-bit engines only ( `rand0`, `rand`, `mcg31m1`, `mt19937` ), the ulong versions are available for 64-bit engines only ( `mcg59` ). The number `n` if specified expresses the number of packed unsigned integer elements in returned SIMD registers.

Status flags set

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SVRNG_STATUS_ERROR_UNSUPPORTED</code></td>
<td>Unmatched engine and result type. See the Description section for supported combinations.</td>
</tr>
<tr>
<td><code>SVRNG_STATUS_ERROR_BAD_ENGINE</code></td>
<td>Bad engine (NULL pointer)</td>
</tr>
</tbody>
</table>

Return Values

Unsigned integer random value(s). The `svrng_generate_[uint|ulong]` functions return a single unsigned 32- or 64-bit integer random value. The `svrng_generate[n]_[uint|ulong]` functions, for `n`=1, 2, 4, 8, 16, or 32 return as many unsigned, 32- or 64-bit integer random values packed in a SIMD register.
svrng_generate[1|2|4|8|16|32]_[int|float|double]
Generates distributed random values for the specified engine and distribution

Syntax

```c
int32_t svrng_generate_int( svrng_engine_t engine, svrng_distribution_t distr )
svrng_int1_t svrng_generate1_int( svrng_engine_t engine, svrng_distribution_t distr )
svrng_int2_t svrng_generate2_int( svrng_engine_t engine, svrng_distribution_t distr )
svrng_int4_t svrng_generate4_int( svrng_engine_t engine, svrng_distribution_t distr )
svrng_int8_t svrng_generate8_int( svrng_engine_t engine, svrng_distribution_t distr )
svrng_int16_t svrng_generate16_int( svrng_engine_t engine, svrng_distribution_t distr )
svrng_int32_t svrng_generate32_int( svrng_engine_t engine, svrng_distribution_t distr )
float svrng_generate_float( svrng_engine_t engine, svrng_distribution_t distr )
svrng_float1_t svrng_generate1_float( svrng_engine_t engine, svrng_distribution_t distr )
svrng_float2_t svrng_generate2_float( svrng_engine_t engine, svrng_distribution_t distr )
svrng_float4_t svrng_generate4_float( svrng_engine_t engine, svrng_distribution_t distr )
svrng_float8_t svrng_generate8_float( svrng_engine_t engine, svrng_distribution_t distr )
svrng_float16_t svrng_generate16_float( svrng_engine_t engine, svrng_distribution_t distr )
svrng_float32_t svrng_generate32_float( svrng_engine_t engine, svrng_distribution_t distr )
double svrng_generate_double( svrng_engine_t engine, svrng_distribution_t distr )
svrng_double1_t svrng_generate1_double( svrng_engine_t engine, svrng_distribution_t distr )
svrng_double2_t svrng_generate2_double( svrng_engine_t engine, svrng_distribution_t distr )
svrng_double4_t svrng_generate4_double( svrng_engine_t engine, svrng_distribution_t distr )
svrng_double8_t svrng_generate8_double( svrng_engine_t engine, svrng_distribution_t distr )
svrng_double16_t svrng_generate16_double( svrng_engine_t engine, svrng_distribution_t distr )
svrng_double32_t svrng_generate32_double( svrng_engine_t engine, svrng_distribution_t distr )
```

Input Parameters

- **engine**: Pointer to the engine.
distr

Pointer to the distribution.

Description

The `svrng_generate[n][int|float|double]` functions generate distributed random values based on the input engine and distribution specified. The output types that are supported—int, float, or double—depend on the distribution used. The number \( n \) if specified expresses the number of packed elements desired in the returned SIMD registers.

Status flags set

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SVRNG_STATUS_ERROR_UNSUPPORTED</code></td>
<td>Unmatched engine and result type. See the Description section for supported combinations.</td>

<td>Bad engine (NULL pointer)</td>
</tr>
<tr>
<td><code>SVRNG_STATUS_ERROR_BAD_DISTR</code></td>
<td>Bad distribution (NULL pointer)</td>
</tr>
</tbody>
</table>

Return Values

The `svrng_generate_{int|long|double}` functions return a single random value of the specified type. The `svrng_generate[n]_{int|long|double}` functions, for \( n=1, 2, 4, 8, 16, \) or 32, return as many signed random values packed in a SIMD register.

Service Routines

There are two types of service routines available to support the short vector random number generator library:

1. Functions for parallel computations
2. Error handling functions

Parallel Computation Support

One of the basic requirements for the random number sequences generated by the engines is their mutual independence and lack of inter-correlation. Even if you want random number samplings to be correlated, such correlation should be controllable. The Short Vector Random Number Generator (SVRNG) library provides two techniques: skip-ahead and leap-frog.

Skip-ahead

The skip-ahead method splits the original sequence into \( k \) non-overlapping blocks, where \( k \) is the number of independent sequences. Each of the sequences generates random numbers only from the corresponding block of contiguous random numbers.
The leap-frog method splits the original sequence into \( k \) disjoint subsequences in such a way that the first stream would generate the random numbers \( x_1, x_{k+1}, x_{2k+1}, x_{3k+1}, \ldots \), the second stream would generate the random numbers \( x_2, x_k+2, x_{2k+2}, x_{3k+2}, \ldots \), and, finally, the \( k \)-th stream would generate the random numbers \( x_k, x_{2k}, x_{3k}, \ldots \). The multi-dimensional uniformity properties of each subsequence deteriorate seriously as \( k \) grows so this method is only useful if \( k \) is less than about 25.

The following sequence outlines the typical usage model for creating independent sequences of random numbers in a parallel computation environment:

- Create the original engine
- Create a copy of the original engine in each thread
- Apply one of techniques above to re-initialize the individual engines to provide an independent sequence on each thread

For detailed information on the use of SVRNG intrinsics in a parallel computation environment see the Random Streams and RNGs in Parallel Computation section of the Notes for Intel® oneAPI Math Kernel Library Vector Statistics document listed in Intrinsics for the Short Vector Random Number Generator Library.

Note: Currently skip-ahead and leap-frog methods are supported by the rand0, rand, mcg31m1, and mcg59 engines. The skip-ahead and leap-frog methods of splitting a stream are not yet implemented for the mt19937 engine, but mt19937 naturally provides parallel support during initialization. See the MT19937 section of the Notes for Intel® oneAPI Math Kernel Library Vector Statistics document listed in the introduction.

Intrinsics for the Short Vector Random Number Generator Library
**svrng_copy_engine**

Allocates memory for a new engine and copies over all parameters

**Syntax**

```c
svrng_engine_t svrng_copy_engine( svrng_engine_t orig_engine )
```

**Input Parameters**

- `orig_engine` Pointer to the engine to be copied

**Description**

The `svrng_copy_engine` function allocates memory for a new engine then copies all parameters from original engine to the new engine.

**Status flags set**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SVRNG_STATUS_ERROR_MEMORY_ALLOC</strong></td>
<td>Memory allocation failure</td>
</tr>
<tr>
<td><strong>SVRNG_STATUS_ERROR_BAD_ENGINE</strong></td>
<td>Bad engine (NULL pointer)</td>
</tr>
</tbody>
</table>

**Return Values**

Pointer to the newly created copy of the original engine, or NULL on error.

**svrng_skipahead_engine**

Re-initialize engine parameters for use of the skip-ahead method

**Syntax**

```c
svrng_engine_t svrng_skipahead_engine( svrng_engine_t orig_engine, long long nskip )
```

**Input Parameters**

- `orig_engine` Pointer to the engine to be re-initialized using the skip-ahead technique
- `nskip` Number of skipped elements

**Description**

Re-initializes engine parameters using the block-splitting ("skip-ahead") method. The function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is `nskip`, then the original random sequence may be split by this function into non-overlapping blocks of `nskip` size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited.
### Status flags set

<table>

<td>Bad engine (NULL pointer)</td>
</tr>
<tr>
<td><code>SVRNG_STATUS_ERROR_BAD_PARAM2</code></td>
<td>Bad parameter: nskip</td>
</tr>
</tbody>
</table>

### Return Values

Pointer to the same input engine or NULL on error

#### svrng_leapfrog_engine

*Re-initialize engine parameters for use of the leap-frog method*

#### Syntax

```c
svrng_engine_t svrng_leapfrog_engine( svrng_engine_t orig_engine, int k, int nstreams )
```

#### Input Parameters

- `orig_engine`  
  Pointer to the engine to be re-initialized using the leap-frog technique.
- `k`            
  Index of the computational node, or sequence number.
- `nstreams`     
  Largest number of computational nodes, or stride.

#### Description

The `svrng_leapfrog_engine` function re-initializes the engine parameters using the leap-frog method. The leap-frogged engine generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the `nstreams` buffers without generating the original random sequence with subsequent manual distribution.

</tr>
<tr>
<td>SVRNG_STATUS_ERROR_UNSUPPORTED</td>
<td>Function or method not supported</td>
</tr>
</tbody>
</table>

svrng_set_status

Sets the status variable to a specified value and returns the previous status value

Syntax

```c
int32_t svrng_set_status( int32_t new_status )
```

Input Parameters

`new_status` The new status.

Description

The `svrng_set_status` function sets the status variable to a specific constant value and returns the previous status value. See the Error Handling page for a table of values defined in `svrng.h`.

Return Values

Returns the previous status value.

svrng_get_status

Returns the current status value
Syntax

```c
int32_t svrng_get_status()
```

Description

The `svrng_get_status` function returns the current status value.

Return Values

The current status value.

Intrinsics for Intel® Advanced Matrix Extensions (Intel(R) AMX) Instructions

Intel® Advanced Matrix Extensions (Intel® AMX) is a new 64-bit programming paradigm consisting of two components:
- A set of 2-dimensional registers (tiles) representing sub-arrays from a larger 2-dimensional memory image
- An accelerator that is able to operate on tiles; the first implementation of this accelerator is called TMUL (tile matrix multiply unit).

The following sections show intrinsics that are available for Intel(R) Advanced Matrix Extension Instructions.

Intrinsic for Intel® Advanced Matrix Extensions AMX-BF16 Instructions

This intrinsic supports tile computational operations on bfloat16 numbers.
_tile_dpbf16ps

</table>

Description

Compute dot-product of BF16 (16-bit) floating-point pairs in tiles "a" and "b", accumulating the intermediate single-precision (32-bit) floating-point elements with elements in "dst", and store the 32-bit result back to tile "dst".

Technology

AMX

Category

Application-Targeted

Operation

```c
FOR m := 0 TO dst.rows - 1
    tmp := dst.row[m]
    FOR k := 0 TO (a.colsb / 4) - 1
        FOR n := 0 TO (dst.colsb / 4) - 1
            tmp.fp32[n] += FP32(a.row[m].bf16[2*k+0]) * FP32(b.row[k].bf16[2*n+0])
            tmp.fp32[n] += FP32(a.row[m].bf16[2*k+1]) * FP32(b.row[k].bf16[2*n+1])
        ENDFOR
    ENDFOR
write_row_and_zero(dst, m, tmp, dst.colsb)
ENDFOR
zero_upper_rows(dst, dst.rows)
zero_tileconfig_start()
```

Intrinsics for Intel® Advanced Matrix Extensions AMX-INT8 Instructions

These intrinsics support tile computational operations on 8-bit integers.

_tile_dpbssd

Synopsis

```c
void _tile_dpbssd(___tile dst, ___tile a, ___tile b)
```

**Instruction**

TDPBSSD tmm, tmm, tmm

**CPUID flags**

AMXINT8

**Description**

Compute dot-product of bytes in tiles with a source/destination accumulator. Multiply groups of 4 adjacent pairs of signed 8-bit integers in "a" with corresponding signed 8-bit integers in "b", producing 4 intermediate 32-bit results. Sum these 4 results with the corresponding 32-bit integer in "dst", and store the 32-bit result back to tile "dst".

**Intrinsics for Intel(R) Advanced Matrix Extensions AMX-TILE Instructions**

These intrinsics support tile architecture.

**_tile_loadconfig**

**Synopsis**

```c
void _tile_loadconfig (const void * mem_addr)
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Tile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header file</td>
<td><code>#include &lt;immintrin.h&gt;</code></td>
</tr>
<tr>
<td>Instruction</td>
<td>LDTILECFG m512</td>
</tr>
<tr>
<td>CPUID flags</td>
<td>AMXTILE</td>
</tr>
</tbody>
</table>

**Description**

Load tile configuration from a 64-byte memory location specified by "mem_addr". The tile configuration format is specified below, and includes the tile type palette, the number of bytes per row, and the number of rows. If the specified palette_id is zero, that signifies the init state for both the tile config and the tile data, and the tiles are zeroed. Any invalid configurations will result in #GP fault.

**Technology**

AMX
Category
Application-Targeted

Operation

// format of memory payload. each field is a byte.
// 0: palette_id
// 1: startRow (8b)
// 2-15: reserved (must be zero)
// 16-17: tile0.colsb -- bytes_per_row
// 18-19: tile1.colsb
// 20-21: tile2.colsb
// ...
// 46-47: tile15.colsb
// 48: tile0.rows
// 49: tile1.rows
// 50: tile2.rows
// ...
// 63: tile15.rows

_tile_loadd

Synopsis

void _tile_loadd (__tile dst, const void * base, int stride)

<table>
<thead>
<tr>
<th>Type</th>
<th>Tile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header file</td>
<td>#include &lt;immintrin.h&gt;</td>
</tr>
<tr>
<td>Instruction</td>
<td>TILELOADD tmm, sibmem</td>
</tr>
<tr>
<td>CPUID flags</td>
<td>AMXTILE</td>
</tr>
</tbody>
</table>

Description

Load tile rows from memory specified by "base" address and "stride" into destination tile "dst" using the tile configuration previously configured via "_tile_loadconfig".

Technology

AMX

Category

Application-Targeted

Operation

start := tileconfig.startRow
IF start == 0 // not restarting, zero incoming state
   tilezero(dst)
FI

nbytes := dst.colsb
DO WHILE start < dst.rows
   memptr := base + start * stride
   write_row_and_zero(dst, start, read_memory(memptr, nbytes), nbytes)
start := start + 1

OD

zero_upper_rows(dst, dst.rows)
zero_tileconfig_start()

### _tile_release

**Synopsis**

```c
void _tile_release ()
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Tile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header file</td>
<td>#include &lt;immintrin.h&gt;</td>
</tr>
<tr>
<td>Instruction</td>
<td>TILERELEASE</td>
</tr>
<tr>
<td>CPUID flags</td>
<td>AMXTILE</td>
</tr>
</tbody>
</table>

**Description**

Release the tile configuration to return to the init state, which releases all storage it currently holds.

**Technology**

AMX

**Category**

Application-Targeted

### _tile_storeconfig

**Synopsis**

```c
void _tile_storeconfig (void * mem_addr)
```

<table>
<thead>
<tr>
<th>Type</th>
<th>Tile</th>
</tr>
</thead>
<tbody>
<tr>
<td>Header file</td>
<td>#include &lt;immintrin.h&gt;</td>
</tr>
<tr>
<td>Instruction</td>
<td>STTILECFG m512</td>
</tr>
<tr>
<td>CPUID flags</td>
<td>AMXTILE</td>
</tr>
</tbody>
</table>

**Description**

Stores the current tile configuration to a 64-byte memory location specified by "mem_addr". The tile configuration format is specified below, and includes the tile type palette, the number of bytes per row, and the number of rows. If tiles are not configured, all zeroes will be stored to memory.

**Technology**

AMX

**Category**

Application-Targeted
Operation

```c
// format of memory payload. each field is a byte.
// 0: palette_id
// 1: startRow (8b)
// 2-15: reserved (must be zero)
// 16-17: tile0.colsb -- bytes_per_row
// 18-19: tile1.colsb

</tr>
<tr>
<td>Instruction</td>
<td>TILELOADDT1 tmm, sibmem</td>
</tr>
<tr>
<td>CPUID flags</td>
<td>AMXTILE</td>
</tr>
</tbody>
</table>

Description

Load tile rows from memory specified by "base" address and "stride" into destination tile "dst" using the tile configuration previously configured via "_tile_loadconfig". This intrinsic provides a hint to the implementation that the data will likely not be reused in the near future and the data caching can be optimized accordingly.

Technology

AMX

Category

Application-Targeted

Operation

```
start := tileconfig.startRow
IF start == 0 // not restarting, zero incoming state
   tilezero(dst)
FI

nbytes := dst.colsb
DO WHILE start < dst.rows
   memptr := base + start * stride
   write_row_and_zero(dst, start, read_memory(memptr, nbytes), nbytes)
   start := start + 1
OD

zero_upper_rows(dst, dst.rows)
zero_tileconfig_start()
```

_tile_zero

Synopsis

void _tile_zero (__tile tdest)

<table>
<thead>
<tr>
<th>Type</th>

</tbody>
</table>
**Description**
Zero the tile specified by "tdest".

**Technology**
AMX

**Category**
Application-Targeted

**Operation**

```c
nbytes := palette_table[tileconfig.palette_id].bytes_per_row
FOR i := 0 TO palette_table[tileconfig.palette_id].max_rows-1
    FOR j := 0 TO nbytes-1
        tdest.row[i].byte[j] := 0
    ENDFOR
ENDFOR
```

**Intrinsics for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) BF16 Instructions**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) BF16 instruction intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>a source vector element</td>
</tr>
<tr>
<td>b</td>
<td>a second source vector element</td>
</tr>
<tr>
<td>k</td>
<td>mask used as a selector; depending on the intrinsic, it may be a writemask or a zeromask</td>
</tr>
</tbody>
</table>

**_mm_cvtne2ps_pbh**

```c
__m128bh _mm_cvtne2ps_pbh (__m128 a, __m128 b)
```

Instructions: vcvtnes2psbf16 xmm, xmm, xmm

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in two vectors `a` and `b` to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector `dst`.

**_mm_mask_cvtne2ps_pbh**

```c
__m128bh _mm_mask_cvtne2ps_pbh (__m128h src, __mmask8 k, __m128 a, __m128 b)
```

Instructions: vcvtnes2psbf16 xmm {k}, xmm, xmm

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in two vectors `a` and `b` to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector `dst` using writemask `k`. Elements are copied from `src` when the corresponding mask bit is not set.
_mm_maskz_cvtne2ps_pbh

__m128bh _mm_maskz_cvtne2ps_pbh (__mmask8 k, __m128 a, __m128 b)

Instructions: vcvtne2ps2bf16 xmm {k}{z}, xmm, xmm
CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in two vectors a and b to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector dst using zeromask k. Elements are zeroed out when the corresponding mask bit is not set.

_mm256_cvtne2ps_pbh

__m256bh _mm256_cvtne2ps_pbh (__m256 a, __m256 b)

Instructions: vcvtne2ps2bf16 ymm, ymm, ymm
CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in two vectors a and b to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector dst.

_mm256_mask_cvtne2ps_pbh

__m256bh _mm256_mask_cvtne2ps_pbh (__m256bh src, __mmask16 k, __m256 a, __m256 b)

Instructions: vcvtne2ps2bf16 ymm {k}, ymm, ymm
CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in two vectors a and b to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector dst using writemask k. Elements are copied from src when the corresponding mask bit is not set.

_mm256_maskz_cvtne2ps_pbh

__m256bh _mm256_maskz_cvtne2ps_pbh (__mmask16 k, __m256 a, __m256 b)

Instructions: vcvtne2ps2bf16 ymm {k}{z}, ymm, ymm
CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in two vectors a and b to packed BF16 (16-bit) floating-point elements, and stores the results in single vector dst using zeromask k. Elements are zeroed out when the corresponding mask bit is not set.

_mm512_cvtne2ps_pbh

__m512bh _mm512_cvtne2ps_pbh (__m512 a, __m512 b)

Instructions: vcvtne2ps2bf16 zmm, zmm, zmm
CPUID Flags: AVX512_BF16 + AVX512F

Converts packed single-precision (32-bit) floating-point elements in two vectors a and b to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector dst.

_mm512_mask_cvtne2ps_pbh

__m512bh _mm512_mask_cvtne2ps_pbh (__m512bh src, __mmask32 k, __m512 a, __m512 b)

Instructions: vcvtne2ps2bf16 zmm {k}, zmm, zmm
CPUID Flags: AVX512_BF16 + AVX512F
Converts packed single-precision (32-bit) floating-point elements in two vectors \(a\) and \(b\) to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector \(dst\) using writemask \(k\). Elements are copied from \(src\) when the corresponding mask bit is not set.

**_mm512_maskz_cvtne2ps_pbh_**

\[
\texttt{__m512bh _mm512_maskz_cvtne2ps_pbh (__mmask32 k, __m512 a, __m512 b)}
\]

Instructions: \texttt{vcvtne2ps2bf16 zmm \{k\}{z}, zmm, zmm}

CPUID Flags: AVX512_BF16 + AVX512F

Converts packed single-precision (32-bit) floating-point elements in two vectors \(a\) and \(b\) to packed BF16 (16-bit) floating-point elements, and stores the results in a single vector \(dst\) using zeromask \(k\). Elements are zeroed out when the corresponding mask bit is not set.

**_mm_cvtneps_pbh_**

\[
\texttt{__m128bh _mm_cvtneps_pbh (__m128 a)}
\]

Instructions: \texttt{vcvtneps2bf16 xmm, xmm}

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in \(a\) to packed BF16 (16-bit) floating-point elements, and stores the results in \(dst\).

**_mm_mask_cvtneps_pbh_**

\[
\texttt{__m128bh _mm_mask_cvtneps_pbh (__m128bh src, __mmask8 k, __m128 a)}
\]

Instructions: \texttt{vcvtneps2bf16 xmm \{k\}, xmm}

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in \(a\) to packed BF16 (16-bit) floating-point elements, and stores the results in \(dst\) using writemask \(k\). Elements are copied from \(src\) when the corresponding mask bit is not set.

**_mm_maskz_cvtneps_pbh_**

\[
\texttt{__m128bh _mm_maskz_cvtneps_pbh (__mmask8 k, __m128 a)}
\]

Instructions: \texttt{vcvtneps2bf16 xmm \{k\}{z}, xmm}

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in \(a\) to packed BF16 (16-bit) floating-point elements, and stores the results in \(dst\) using zeromask \(k\). Elements are zeroed out when the corresponding mask bit is not set.

**_mm256_cvtneps_pbh_**

\[
\texttt{__m128bh _mm256_cvtneps_pbh (__m256 a)}
\]

Instructions: \texttt{vcvtneps2bf16 xmm, ymm}

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in \(a\) to packed BF16 (16-bit) floating-point elements, and stores the results in \(dst\).
_mm256_mask_cvtneps_pbh

__m128bh _mm256_mask_cvtneps_pbh (__m128bh src, __mmask8 k, __m256 a)

Instructions: vcvtneps2bf16 xmm {k}, ymm

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in a to packed BF16 (16-bit) floating-point elements, and stores the results in dst using writemask k. Elements are copied from src when the corresponding mask bit is not set.

_mm256_maskz_cvtneps_pbh

Instructions: vcvtneps2bf16 xmm {k}{z}, ymm

CPUID Flags: AVX512_BF16 + AVX512VL

Converts packed single-precision (32-bit) floating-point elements in a to packed BF16 (16-bit) floating-point elements, and stores the results in dst using zeromask k. Elements are zeroed out when the corresponding mask bit is not set.

_mm512_cvtneps_pbh

__m256bh _mm512_cvtneps_pbh (__m512 a)

Instructions: vcvtneps2bf16 ymm, zmm

CPUID Flags: AVX512_BF16 + AVX512F

Converts packed single-precision (32-bit) floating-point elements in a to packed BF16 (16-bit) floating-point elements, and stores the results in dst.

_mm512_mask_cvtneps_pbh

__m256bh _mm512_mask_cvtneps_pbh (__m256bh src, __mmask16 k, __m512 a)

Instructions: vcvtneps2bf16 ymm {k}, zmm

CPUID Flags: AVX512_BF16 + AVX512F

Converts packed single-precision (32-bit) floating-point elements in a to packed BF16 (16-bit) floating-point elements, and stores the results in dst using writemask k. Elements are copied from src when the corresponding mask bit is not set.

_mm512_maskz_cvtneps_pbh

__m256bh _mm512_maskz_cvtneps_pbh (__mmask16 k, __m512 a)

Instructions: vcvtneps2bf16 ymm {k}{z}, zmm

CPUID Flags: AVX512_BF16 + AVX512F

Converts packed single-precision (32-bit) floating-point elements in a to packed BF16 (16-bit) floating-point elements, and stores the results in dst using zeromask k. Elements are zeroed out when the corresponding mask bit is not set.

_mm_dpbf16_ps

__m128 _mm_dpbf16_ps (__m128 src, __m128bh a, __m128bh b)

Instructions: vdpbf16ps xmm, xmm, xmm
Computes the dot-product of BF16 (16-bit) floating-point pairs in \( a \) and \( b \), accumulating the intermediate single-precision (32-bit) floating-point elements with elements in \( src \), and stores the results in \( dst \).

### \_mm\_mask\_dpbf16\_ps

Intrinsics for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Additional Instructions

Additional Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Instructions

The additional instructions documented in this section enrich the operations available as part of Intel® AVX-512 Foundation instructions. A large portion of these instructions can be divided into two groups: Byte and Word Instructions, and Doubleword and Quadword Instructions. The group of byte and word (8 and 16-bit) operations, indicated by the AVX512BW and AVX512VBMI CPUID flags, enhance small integer operations. The group of doubleword and quadword (32 and 64-bit) operations indicated by the AVX512DQ and AVX512IFMA52 CPUID flags, enhance integer and floating-point operations.

An additional orthogonal capability known as Vector Length Extensions provide for most AVX-512 instructions to operate on 128 or 256 bits, instead of only 512. Vector Length Extensions can currently be applied to most Foundation Instructions, the Conflict Detection Instructions as well as the new byte, word, doubleword and quadword instructions. These AVX-512 Vector Length Extensions are indicated by the AVX512VL CPUID flag.

The use of Vector Length Extensions extends most AVX-512 operations to also operate on XMM (128-bit, SSE) registers and YMM (256-bit, AVX) registers. The use of Vector Length Extensions allows the capabilities of EVEX encodings, including the use of mask registers and access to registers 16..31, to be applied to XMM and YMM registers instead of only to ZMM registers.

Byte and Word Instructions

The byte and word instructions, indicated by the AVX512BW CPUID flag, extend write-masking and zero-masking to support smaller element sizes. The original AVX-512 Foundation instructions supported such masking with vector element sizes of 32 or 64 bits. As a 512-bit vector register could hold at most 16 32-bit elements, a write-mask size of 16 bits was sufficient.

With an instruction indicated by an AVX512BW CPUID flag, a 512-bit vector can hold 64 8-bit elements or 32 16-bit elements, so write masks must be able to hold 64 bits. To support this, two new mask types, __mmask32 and __mmask64 have been introduced, along with additional maskable intrinsics that operate on vectors of 8 and 16-bit elements. For example,

```
__m512i _mm512_mask_abs_epi8(__m512i src, __mmask64 k, __m512i a);
```

will compute the absolute value of 8-bit elements in a corresponding to the set bits of write mask k. Elements corresponding to a zero bit in k are blended in from src.

Doubleword and Quadword Instructions

The doubleword and quadword instructions, indicated by the AVX512DQ CPUID flag, consist of additional instructions along the lines of the Foundation instructions indicated by the AVX512F CPUID flag in that they operate on 512-bit vectors whose elements are 16 32-bit elements or 8 64-bit elements. Some of these instructions provide new functionality such as the conversion of floating point numbers to 64-bit integers. Other instructions promote existing instructions (e.g., vxorps) to use 512-bit registers.

Vector Length Extensions

The vector length extensions indicated by CPUID flag AVX512VL add write-masking, zero-masking, and embedded broadcast features to 128- and 256-bit vector lengths. So for example,

```
__m256 _mm256_maskz_add_ps(__mmask8 k, __m256 a, __m256 b);
```

will add corresponding float32 elements of a and b where the mask bit from k is set, and will produce zero in the elements where the bit from k is clear.
**Intrinsics for Arithmetic Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `immintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>k</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>a</td>
<td>first source vector element</td>
</tr>
<tr>
<td>b</td>
<td>second source vector element</td>
</tr>
<tr>
<td>c</td>
<td>third source vector element</td>
</tr>
</tbody>
</table>

**_mm_mask_add_pd**

```c
__m128d _mm_mask_add_pd(__m128d src, __mmask8 k, __m128d a, __m128d b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vaddpd

Add packed double-precision (64-bit) floating-point elements in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_add_pd**

```c
__m128d _mm_maskz_add_pd(__mmask8 k, __m128d a, __m128d b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vaddpd

Add packed double-precision (64-bit) floating-point elements in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_add_pd**

```c
__m256d _mm256_mask_add_pd(__m256d src, __mmask8 k, __m256d a, __m256d b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vaddpd

Add packed double-precision (64-bit) floating-point elements in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_add_pd**

```c
__m256d _mm256_maskz_add_pd(__mmask8 k, __m256d a, __m256d b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vaddpd

Add packed double-precision (64-bit) floating-point elements in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
Add packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_\text{mm}\_\text{mask}\_\text{add}\_\text{pd}
\]
\[
\_m128 \_\text{mm}\_\text{mask}\_\text{add}\_\text{pd}(\_m128 \text{src}, \_\text{mmask}8 \text{k}, \_m128 \text{a}, \_m128 \text{b})
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vaddps

Add packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(\text{src}\) when the corresponding mask bit is not set).

\[
\_\text{mm}\_\text{maskz}\_\text{add}\_\text{ps}
\]
\[
\_m128 \_\text{mm}\_\text{maskz}\_\text{add}\_\text{ps}(\_\text{mmask}8 \text{k}, \_m128 \text{a}, \_m128 \text{b})
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vaddps

Add packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_\text{mm}_256\_\text{mask}\_\text{add}\_\text{ps}
\]
\[
\_m256 \_\text{mm}_256\_\text{mask}\_\text{add}\_\text{ps}(\_m256 \text{src}, \_\text{mmask}8 \text{k}, \_m256 \text{a}, \_m256 \text{b})
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vaddps

Add packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(\text{src}\) when the corresponding mask bit is not set).

\[
\_\text{mm}_256\_\text{maskz}\_\text{add}\_\text{ps}
\]
\[
\_m256 \_\text{mm}_256\_\text{maskz}\_\text{add}\_\text{ps}(\_\text{mmask}8 \text{k}, \_m256 \text{a}, \_m256 \text{b})
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vaddps

Add packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_\text{mm}\_\text{mask}\_\text{div}\_\text{pd}
\]
\[
\_m128d \_\text{mm}\_\text{mask}\_\text{div}\_\text{pd}(\_m128d \text{src}, \_\text{mmask}8 \text{k}, \_m128d \text{a}, \_m128d \text{b})
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vdivpd

Divide packed double-precision (64-bit) floating-point elements in \(a\) by packed elements in \(b\), and return the results using writemask \(k\) (elements are copied from \(\text{src}\) when the corresponding mask bit is not set).

\[
\_\text{mm}\_\text{maskz}\_\text{div}\_\text{pd}
\]
\[
\_m128d \_\text{mm}\_\text{maskz}\_\text{div}\_\text{pd}(\_\text{mmask}8 \text{k}, \_m128d \text{a}, \_m128d \text{b})
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vdivpd
Divide packed double-precision (64-bit) floating-point elements in \(a\) by packed elements in \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{__mm256\_mask\_div\_pd}
\]
\[
\_m256d \text{__mm256\_mask\_div\_pd}(\_m256d \text{src}, \_mmask8 \text{k}, \_m256d \text{a}, \_m256d \text{b})
\]
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vdivpd
Divide packed double-precision (64-bit) floating-point elements in \(a\) by packed elements in \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{__mm256\_maskz\_div\_pd}
\]
\[
\_m256d \text{__mm256\_maskz\_div\_pd}(\_mmask8 \text{k}, \_m256d \text{a}, \_m256d \text{b})
\]
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vdivps
Divide packed single-precision (32-bit) floating-point elements in \(a\) by packed elements in \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{__mm\_mask\_div\_ps}
\]
\[
\_m128 \text{__mm\_mask\_div\_ps}(\_m128 \text{src}, \_mmask8 \text{k}, \_m128 \text{a}, \_m128 \text{b})
\]
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vdivps
Divide packed single-precision (32-bit) floating-point elements in \(a\) by packed elements in \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{__mm\_maskz\_div\_ps}
\]
\[
\_m128 \text{__mm\_maskz\_div\_ps}(\_mmask8 \text{k}, \_m128 \text{a}, \_m128 \text{b})
\]
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vdivps
Divide packed single-precision (32-bit) floating-point elements in \(a\) by packed elements in \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{__mm256\_mask\_div\_ps}
\]
\[
\_m256 \text{__mm256\_mask\_div\_ps}(\_m256 \text{src}, \_mmask8 \text{k}, \_m256 \text{a}, \_m256 \text{b})
\]
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vdivps
Divide packed single-precision (32-bit) floating-point elements in \(a\) by packed elements in \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vdivps
Divide packed single-precision (32-bit) floating-point elements in a by packed elements in b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_fmadd_pd

__m128d _mm_mask_fmadd_pd(__m128d a, __mmask8 k, __m128d b, __m128d c)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmadd132pd, vfmadd213pd, vfmadd231pd
Multiply packed double-precision (64-bit) floating-point elements in a and b, add the intermediate result to packed elements in c, and return the results using writemask k (elements are copied from a when the corresponding mask bit is not set).

__m_mask3_fmadd_pd

__m128d __m128d a, __m128d b, __m128d c, __mmask8 k)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmadd132pd, vfmadd213pd, vfmadd231pd
Multiply packed double-precision (64-bit) floating-point elements in a and b, add the intermediate result to packed elements in c, and return the results using writemask k (elements are copied from c when the corresponding mask bit is not set).

_mm_maskz_fmadd_pd

__m128d __m128d a, __m128d b, __m128d c, __mmask8 k)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmadd132pd, vfmadd213pd, vfmadd231pd
Multiply packed double-precision (64-bit) floating-point elements in a and b, add the intermediate result to packed elements in c, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_fmadd_pd

__m256d __m256d a, __m256d b, __m256d c, __mmask8 k)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmadd132pd, vfmadd213pd, vfmadd231pd
Multiply packed double-precision (64-bit) floating-point elements in a and b, add the intermediate result to packed elements in c, and return the results using writemask k (elements are copied from a when the corresponding mask bit is not set).

_mm256_mask3_fmadd_pd

__m256d __m256d a, __m256d b, __m256d c, __mmask8 k)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmadd132pd, vfmadd213pd, vfmadd231pd
Multiply packed double-precision (64-bit) floating-point elements in a and b, add the intermediate result to packed elements in c, and return the results using writemask k (elements are copied from c when the corresponding mask bit is not set).
Multiply packed double-precision (64-bit) floating-point elements in \( a \) and \( b \), add the intermediate result to packed elements in \( c \), and return the results using writemask \( k \) (elements are copied from \( c \) when the corresponding mask bit is not set).

\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \text{vfmadd132ps}, \text{vfmadd213ps}, \text{vfmadd231ps}

Multiply packed single-precision (32-bit) floating-point elements in \( a \) and \( b \), add the intermediate result to packed elements in \( c \), and return the results using writemask \( k \) (elements are copied from \( a \) when the corresponding mask bit is not set).
_mm256_mask3_fmadd_ps

__m256 __m256_mask3_fmadd_ps(__m256 a, __m256 b, __m256 c, __mmask8 k)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmadd132ps, vfmadd213ps, vfmadd231ps

Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), add the intermediate result to packed elements in \(c\), and return the results using writemask \(k\) (elements are copied from \(c\) when the corresponding mask bit is not set).

_mm256_maskz_fmadd_ps

__m256 __m256_maskz_fmadd_ps(__mmask8 k, __m256 a, __m256 b, __m256 c)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmadd132ps, vfmadd213ps, vfmadd231ps

Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), add the intermediate result to packed elements in \(c\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_fmaddsub_pd

__m128d __m128d_mm_fmaddsub_pd(__m128d a, __mmask8 k, __m128d b, __m128d c)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmaddsub132pd, vfmaddsub213pd, vfmaddsub231pd

Multiply packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and return the results using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

_mm_mask3_fmaddsub_pd

__m128d __m128d_mm_mask3_fmaddsub_pd(__m128d a, __m128d b, __m128d c, __mmask8 k)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmaddsub132pd, vfmaddsub213pd, vfmaddsub231pd

Multiply packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and return the results using writemask \(k\) (elements are copied from \(c\) when the corresponding mask bit is not set).

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmaddsub132ps, vfmaddsub213ps, vfmaddsub231ps
Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm256}} \_\text{mask}_f_{\text{maddsub}}_{\text{ps}}(\_\text{m256} \ a, \_\text{mmask8} \ k, \_\text{m256} \ b, \_\text{m256} \ c)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmaddsub132ps, vfmaddsub213ps, vfmaddsub231ps

Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and return the results using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

\[
_{\text{mm256}} \_\text{mask3}_f_{\text{maddsub}}_{\text{ps}}(\_\text{m256} \ a, \_\text{m256} \ b, \_\text{m256} \ c, \_\text{mmask8} \ k)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmaddsub132ps, vfmaddsub213ps, vfmaddsub231ps

Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), alternatively add and subtract packed elements in \(c\) to/from the intermediate result, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm256}} \_\text{maskz}_f_{\text{maddsub}}_{\text{ps}}(\_\text{mmask8} \ k, \_\text{m256} \ a, \_\text{m256} \ b, \_\text{m256} \ c)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmaddsub132ps, vfmaddsub213ps, vfmaddsub231ps

Multiply packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), subtract packed elements in \(c\) from the intermediate result, and return the results using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

\[
_{\text{mm}} \_\text{mask}_{f_{\text{msub}}}_{\text{pd}}(\_\text{m128d} \ a, \_\text{mmask8} \ k, \_\text{m128d} \ b, \_\text{m128d} \ c)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmsub132pd, vfmsub213pd, vfmsub231pd

Multiply packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), subtract packed elements in \(c\) from the intermediate result, and return the results using writemask \(k\) (elements are copied from \(c\) when the corresponding mask bit is not set).

\[
_{\text{mm}} \_\text{mask3}_{f_{\text{msub}}}_{\text{pd}}(\_\text{m128d} \ a, \_\text{m128d} \ b, \_\text{m128d} \ c, \_\text{mmask8} \ k)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vfmsub132pd, vfmsub213pd, vfmsub231pd

\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vfnmsub132ps, vfnmsub213ps, vfnmsub231ps

Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), subtract packed elements in \(c\) from the negated intermediate result, and return the results using writemask \(k\) (elements are copied from \(a\) when the corresponding mask bit is not set).

\[
\text{_mm256_mask3_fnmsub_ps}
\]

\[
\text{_mm256_mask3_fnmsub_ps}(\text{m256 } a, \text{m256 } b, \text{m256 } c, \text{__mmask8 } k)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vfnmsub132ps, vfnmsub213ps, vfnmsub231ps

Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), subtract packed elements in \(c\) from the negated intermediate result, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{_mm256_maskz_fnmsub_ps}
\]

\[
\text{_mm256_maskz_fnmsub_ps}(\text{__mmask8 } k, \text{m256 } a, \text{m256 } b, \text{m256 } c)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vfnmsub132ps, vfnmsub213ps, vfnmsub231ps

Multiply packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), subtract packed elements in \(c\) from the negated intermediate result, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{_mm_mask_max_pd}
\]

\[
\text{_mm_mask_max_pd}(\text{m128d } src, \text{__mmask8 } k, \text{m128d } a, \text{m128d } b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmaxpd

Compare packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and store packed maximum values in the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{_mm_maskz_max_pd}
\]

\[
\text{_mm_maskz_max_pd}(\text{__mmask8 } k, \text{m128d } a, \text{m128d } b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmaxpd

Compare packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and store packed maximum values in the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).
```c
__mm256_mask_max_pd

\[
\_m128d \_\text{mm\_mask\_mul\_pd}(\_\text{m128d } src, \_\text{mmask8 } k, \_\text{m128d } a, \_\text{m128d } b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmulpd

Multiply packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set). RM.

\[
\_\text{mm\_maskz\_mul\_pd}
\]

\[
\_m128d \_\text{mm\_maskz\_mul\_pd}(\_\text{mmask8 } k, \_\text{m128d } a, \_\text{m128d } b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmulpd

Multiply packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).
**_mm256_mask_mul_pd_**

```c
_mm256_mask_mul_pd(_m256d src, __mmask8 k, __m256d a, __m256d b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vmulpd`

Multiply packed double-precision (64-bit) floating-point elements in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_mul_pd_**

```c
_mm256_maskz_mul_pd(__mmask8 k, __m256d a, __m256d b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vmulpd`

Multiply packed double-precision (64-bit) floating-point elements in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_mul_ps_**

```c
_mm_mask_mul_ps(__m128 src, __mmask8 k, __m128 a, __m128 b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vmulps`

Multiply packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set). RM.

**_mm_maskz_mul_ps_**

```c
_mm_maskz_mul_ps(__mmask8 k, __m128 a, __m128 b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vmulps`

Multiply packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_mul_ps_**

```c
_mm256_mask_mul_ps(__m256 src, __mmask8 k, __m256 a, __m256 b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vmulps`

Multiply packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set). RM.

**_mm256_maskz_mul_ps_**

```c
_mm256_maskz_mul_ps(__mmask8 k, __m256 a, __m256 b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vmulps`

Multiply packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
_mm_mask_rcp14_pd

_mm256_mask_rcp14_pd

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrcp14pd

Compute the approximate reciprocal of packed double-precision (64-bit) floating-point elements in \(a\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set). The maximum relative error for this approximation is less than 2^-14.

_mm_maskz_rcp14_pd

_mm256_maskz_rcp14_pd

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrcp14pd

Compute the approximate reciprocal of packed double-precision (64-bit) floating-point elements in \(a\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set). The maximum relative error for this approximation is less than 2^-14.

_mm_rcp14_pd

_mm256_rcp14_pd

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrcp14pd

Compute the approximate reciprocal of packed double-precision (64-bit) floating-point elements in \(a\), and return the results. The maximum relative error for this approximation is less than 2^-14.

_mm256_mask_rcp14_pd

_mm256_maskz_rcp14_pd

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrcp14pd

Compute the approximate reciprocal of packed double-precision (64-bit) floating-point elements in \(a\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set). The maximum relative error for this approximation is less than 2^-14.

_mm256_rcp14_pd

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrcp14pd

Compute the approximate reciprocal of packed double-precision (64-bit) floating-point elements in \(a\), and return the results. The maximum relative error for this approximation is less than \(2^{-14}\).

\[ \text{__m128 \_mm_mask_rcp14_ps(__m128 src, __mmask8 k, __m128 a)} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vrcp14ps

Compute the approximate reciprocal of packed single-precision (32-bit) floating-point elements in \(a\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set). The maximum relative error for this approximation is less than \(2^{-14}\).

\[ \text{__m128 \_mm_maskz_rcp14_ps(__mmask8 k, __m128 a)} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vrcp14ps

Compute the approximate reciprocal of packed single-precision (32-bit) floating-point elements in \(a\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set). The maximum relative error for this approximation is less than \(2^{-14}\).

\[ \text{__m128 \_mm_rcp14_ps(__m128 a)} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vrcp14ps

Compute the approximate reciprocal of packed single-precision (32-bit) floating-point elements in \(a\), and return the results. The maximum relative error for this approximation is less than \(2^{-14}\).

\[ \text{__m256 \_mm256_mask_rcp14_ps(__m256 src, __mmask8 k, __m256 a)} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vrcp14ps

Compute the approximate reciprocal of packed single-precision (32-bit) floating-point elements in \(a\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set). The maximum relative error for this approximation is less than \(2^{-14}\).

\[ \text{__m256 \_mm256_maskz_rcp14_ps(__mmask8 k, __m256 a)} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vrcp14ps

Compute the approximate reciprocal of packed single-precision (32-bit) floating-point elements in \(a\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set). The maximum relative error for this approximation is less than \(2^{-14}\).
_mm256_rcp14_ps

__m256 _mm256_rcp14_ps(__m256 a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrcp14ps

Compute the approximate reciprocal of packed single-precision (32-bit) floating-point elements in a, and return the results. The maximum relative error for this approximation is less than 2^-14.

_mm_mask_rsqrt14_pd

__m128d _mm_mask_rsqrt14_pd(__m128d src, __mmask8 k, __m128d a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrsqrt14pd

Compute the approximate reciprocal square root of packed double-precision (64-bit) floating-point elements in a, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set). The maximum relative error for this approximation is less than 2^-14.

_mm_maskz_rsqrt14_pd

__m128d _mm_maskz_rsqrt14_pd(__mmask8 k, __m128d a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrsqrt14pd

Compute the approximate reciprocal square root of packed double-precision (64-bit) floating-point elements in a, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set). The maximum relative error for this approximation is less than 2^-14.

__m256i _mm256_mask_adds_epu8(__m256i src, __mmask32 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpaddusb
Add packed unsigned 8-bit integers in a and b using saturation, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
_mm256_maskz_adds_epu8
__m256i _mm256_maskz_adds_epu8(__mmask32 k, __m256i a, __m256i b)
```
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpaddusb
Add packed unsigned 8-bit integers in \( a \) and \( b \) using saturation, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[ \_mm512\_adds\_epu8 \]
\[
\_m512i \_mm512\_adds\_epu8(\_m512i \ a, \_m512i \ b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpaddusb
Add packed unsigned 8-bit integers in \( a \) and \( b \) using saturation, and return the results.

\[ \_mm512\_mask\_adds\_epu8 \]
\[
\_m512i \_mm512\_mask\_adds\_epu8(\_m512i \ src, \_mmask64 \ k, \_m512i \ a, \_m512i \ b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpaddusb
Add packed unsigned 8-bit integers in \( a \) and \( b \) using saturation, and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[ \_mm512\_maskz\_adds\_epu8 \]
\[
\_m512i \_mm512\_maskz\_adds\_epu8(\_mmask64 \ k, \_m512i \ a, \_m512i \ b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpaddusb
Add packed unsigned 8-bit integers in \( a \) and \( b \) using saturation, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[ \_mm\_mask\_adds\_epu16 \]
\[

_m256i _mm256_maskz_add_epi16(__mmask16 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpaddw
Add packed 16-bit integers in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_add_epi16

_m512i _mm512_add_epi16(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpaddw
Add packed 16-bit integers in a and b, and return the results.

_mm512_mask_add_epi16

_m512i _mm512_mask_add_epi16(__m512i src, __mmask32 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpaddw
Add packed 16-bit integers in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_add_epi16

_m512i _mm512_maskz_add_epi16(__mmask32 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpaddw
Add packed 16-bit integers in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_avg_epu8

_m128i _mm_mask_avg_epu8(__m128i src, __mmask16 k, __m128i a, __m128i b)
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgb
Average packed unsigned 8-bit integers in $a$ and $b$, and return the results using writemask $k$ (elements are copied from src when the corresponding mask bit is not set).

```cpp
__m128i __m_maskz_avg_epu8(__mmask16 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgb
Average packed unsigned 8-bit integers in $a$ and $b$, and return the results using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```cpp
__m256i __m256_mask_avg_epu8(__m256i src, __mmask32 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgb
Average packed unsigned 8-bit integers in $a$ and $b$, and return the results using writemask $k$ (elements are copied from src when the corresponding mask bit is not set).

```cpp
__m256i __m256_maskz_avg_epu8(__mmask32 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgb
Average packed unsigned 8-bit integers in $a$ and $b$, and return the results using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```cpp
__m512i __m512_avg_epu8(__m512i a, __m512i b)
```

CPUID Flags: AVX512BW
Instruction(s): vpavgb
Average packed unsigned 8-bit integers in $a$ and $b$, and return the results.

```cpp
__m512i __m512_mask_avg_epu8(__m512i src, __mmask64 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW
Instruction(s): vpavgb
Average packed unsigned 8-bit integers in $a$ and $b$, and return the results using writemask $k$ (elements are copied from src when the corresponding mask bit is not set).

```cpp
__m512i __m512_maskz_avg_epu8(__mmask64 k, __m512i a, __m512i b)
```
CPUID Flags: AVX512BW
Instruction(s): vpavgb
Average packed unsigned 8-bit integers in \( a \) and \( b \), and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[ _\text{mm} \_\text{mask} \_\text{avg} \_\text{epu16} \]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgw
Average packed unsigned 16-bit integers in \( a \) and \( b \), and return the results using writemask \( k \) (elements are copied from \( \text{src} \) when the corresponding mask bit is not set).

\[ _\text{mm} \_\text{mask}z \_\text{avg} \_\text{epu16} \]
\[ _{\text{m}128i} \_\text{mm} \_\text{mask}z \_\text{avg} \_\text{epu16}(\_\text{mmask}8 \text{ k}, _\text{m}128i \text{ a}, _\text{m}128i \text{ b}) \]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgw
Average packed unsigned 16-bit integers in \( a \) and \( b \), and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[ _\text{mm}256 \_\text{mask} \_\text{avg} \_\text{epu16} \]
\[ _{\text{m}256i} \_\text{mm}256 \_\text{mask} \_\text{avg} \_\text{epu16}(\_\text{mmask}16 \text{ k}, _\text{m}256i \text{ a}, _\text{m}256i \text{ b}) \]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgw
Average packed unsigned 16-bit integers in \( a \) and \( b \), and return the results using writemask \( k \) (elements are copied from \( \text{src} \) when the corresponding mask bit is not set).

\[ _\text{mm}256 \_\text{mask}z \_\text{avg} \_\text{epu16} \]
\[ _{\text{m}256i} \_\text{mm}256 \_\text{mask}z \_\text{avg} \_\text{epu16}(\_\text{mmask}16 \text{ k}, _\text{m}256i \text{ a}, _\text{m}256i \text{ b}) \]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpavgw
Average packed unsigned 16-bit integers in \( a \) and \( b \), and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[ _\text{mm}512 \_\text{avg} \_\text{epu16} \]
\[ _{\text{m}512i} \_\text{mm}512 \_\text{avg} \_\text{epu16}(\_\text{m}512i \text{ a}, _\text{m}512i \text{ b}) \]

CPUID Flags: AVX512BW
Instruction(s): vpavgw
Average packed unsigned 16-bit integers in \( a \) and \( b \), and return the results.

\[ _\text{mm}512 \_\text{mask} \_\text{avg} \_\text{epu16} \]
\[ _{\text{m}512i} \_\text{mm}512 \_\text{mask} \_\text{avg} \_\text{epu16}(\_\text{m}512i \text{ src}, _\text{mmask}32 \text{ k}, _\text{m}512i \text{ a}, _\text{m}512i \text{ b}) \]
CPUID Flags: AVX512BW
Instruction(s): vpavgw
Average packed unsigned 16-bit integers in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{\_mm512\_maskz\_avg\_epu16}
\]

\[
\text{\_mm512\_maskz\_avg\_epu16}(\text{\_mmask32 } k, \text{\_m512i } a, \text{\_m512i } b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpavgw
Average packed unsigned 16-bit integers in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm\_mask\_maddubs\_epi16}
\]

\[
\text{\_mm\_mask\_maddubs\_epi16}(\text{\_m128i } \text{\_mmask8 } k, \text{\_m128i } a, \text{\_m128i } b)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddubsw
Multiply packed unsigned 8-bit integers in \(a\) by packed signed 8-bit integers in \(b\), producing intermediate signed 16-bit integers. Horizontally add adjacent pairs of intermediate signed 16-bit integers, and pack the saturated results in the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{\_mm\_maskz\_maddubs\_epi16}
\]

\[
\text{\_mm\_maskz\_maddubs\_epi16}(\text{\_mmask8 } k, \text{\_m128i } a, \text{\_m128i } b)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddubsw
Multiply packed unsigned 8-bit integers in \(a\) by packed signed 8-bit integers in \(b\), producing intermediate signed 16-bit integers. Horizontally add adjacent pairs of intermediate signed 16-bit integers, and pack the saturated results in the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm256\_mask\_maddubs\_epi16}
\]

\[
\text{\_mm256\_mask\_maddubs\_epi16}(\text{\_m256i } \text{\_mmask16 } k, \text{\_m256i } a, \text{\_m256i } b)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddubsw
Multiply packed unsigned 8-bit integers in \(a\) by packed signed 8-bit integers in \(b\), producing intermediate signed 16-bit integers. Horizontally add adjacent pairs of intermediate signed 16-bit integers, and pack the saturated results in the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{\_mm256\_maskz\_maddubs\_epi16}
\]

\[
\text{\_mm256\_maskz\_maddubs\_epi16}(\text{\_mmask16 } k, \text{\_m256i } a, \text{\_m256i } b)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddubsw
Multiply packed unsigned 8-bit integers in a by packed signed 8-bit integers in b, producing intermediate signed 16-bit integers. Horizontally add adjacent pairs of intermediate signed 16-bit integers, and pack the saturated results in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maddubs_epi16

__m512i _mm512_maddubs_epi16(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaddubsw

Vertically multiply each unsigned 8-bit integer from a with the corresponding signed 8-bit integer from b, producing intermediate signed 16-bit integers. Horizontally add adjacent pairs of intermediate signed 16-bit integers, and pack the saturated results in the return value.

_mm512_mask_maddubs_epi16

__m512i _mm512_mask_maddubs_epi16(__m512i src, __mmask32 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaddubsw

Multiply packed unsigned 8-bit integers in a by packed signed 8-bit integers in b, producing intermediate signed 16-bit integers. Horizontally add adjacent pairs of intermediate signed 16-bit integers, and pack the saturated results in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_maddubs_epi16

__m512i _mm512_maskz_maddubs_epi16(__mmask32 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaddubsw

Multiply packed unsigned 8-bit integers in a by packed signed 8-bit integers in b, producing intermediate signed 16-bit integers. Horizontally add adjacent pairs of intermediate signed 16-bit integers, and pack the saturated results in the return value using zeronmask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_madd_epi16

__m128i _mm_mask_madd_epi16(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddwd

Multiply packed 16-bit integers in a and b, producing intermediate 32-bit integers. Horizontally add adjacent pairs of intermediate 32-bit integers, and pack the saturated results in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_madd_epi16

__m128i _mm_maskz_madd_epi16(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddwd
Multiply packed 16-bit integers in a and b, producing intermediate 32-bit integers. Horizontally add adjacent pairs of intermediate 32-bit integers, and pack the saturated results in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddwd

Multiply packed 16-bit integers in a and b, producing intermediate 32-bit integers. Horizontally add adjacent pairs of intermediate 32-bit integers, and pack the saturated results in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_madd_epi16

_m256i _mm256_maskz_madd_epi16(__mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaddwd

Multiply packed 16-bit integers in a and b, producing intermediate 32-bit integers. Horizontally add adjacent pairs of intermediate 32-bit integers, and pack the saturated results in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_madd_epi16

_m512i _mm512_madd_epi16(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaddwd

Multiply packed 16-bit integers in a and b, producing intermediate 32-bit integers. Horizontally add adjacent pairs of intermediate 32-bit integers, and pack the saturated results in the return value.

_mm512_mask_madd_epi16

_m512i _mm512_mask_madd_epi16(__m512i src, __mmask16 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaddwd

Multiply packed 16-bit integers in a and b, producing intermediate 32-bit integers. Horizontally add adjacent pairs of intermediate 32-bit integers, and pack the saturated results in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_madd_epi16

_m512i _mm512_maskz_madd_epi16(__mmask16 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaddwd

Multiply packed 16-bit integers in a and b, producing intermediate 32-bit integers. Horizontally add adjacent pairs of intermediate 32-bit integers, and pack the saturated results in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
__mm_mask_max_epi8

__m128i __mm_mask_max_epi8(__m128i src, __mmask16 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaxsb
Compare packed 8-bit integers in a and b, and store packed maximum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_max_epi8

__m128i __mm_maskz_max_epi8(__mmask16 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaxsb
Compare packed 8-bit integers in a and b, and store packed maximum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_max_epi8

__m256i __mm256_mask_max_epi8(__m256i src, __mmask32 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaxsb
Compare packed 8-bit integers in a and b, and store packed maximum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_max_epi8

__m256i __mm256_maskz_max_epi8(__mmask32 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmaxsb
Compare packed 8-bit integers in a and b, and store packed maximum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm512_mask_max_epi8

__m512i __mm512_mask_max_epi8(__m512i src, __mmask64 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaxsb
Compare packed 8-bit integers in a and b, and store packed maximum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m512i __mm512_maskz_max_epi8(__mmask64 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmaxsb
Compare packed 8-bit integers in a and b, and store packed maximum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
__mm512_max_epi8

__m512 __m512_max_epi8(__m512 a, __m512 b)

CPUID Flags: AVX512BW
Instruction(s): vpmaxsb
Compare packed 8-bit integers in a and b, and store packed maximum values in the return value.

__mm_mask_max_epi32

__m128 __m_mask_max_epi32(__m128 src, __mmask8 k, __m128 a, __m128 b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmaxsd
Compare packed 32-bit integers in a and b, and store packed maximum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_max_epi32

__m128 __m_maskz_max_epi32(__mmask8 k, __m128 a, __m128 b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmaxsd
Compare packed 32-bit integers in a and b, and store packed maximum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_max_epi32

__m256 __m256_mask_max_epi32(__m256 src, __mmask8 k, __m256 a, __m256 b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmaxsd
Compare packed 32-bit integers in a and b, and store packed maximum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_max_epi32

__m256 __m256_maskz_max_epi32(__mmask8 k, __m256 a, __m256 b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmaxsd
Compare packed 32-bit integers in a and b, and store packed maximum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_max_epi64

__m128 __m_mask_max_epi64(__m128 src, __mmask8 k, __m128 a, __m128 b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmaxsd
Compare packed 64-bit integers in a and b, and store packed maximum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm_maskz_max_epi64

__m128i _mm_maskz_max_epi64(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmaxsq

Compare packed 64-bit integers in \( a \) and \( b \), and store packed maximum values in the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm_max_epi64

__m128i _mm_max_epi64(__m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmaxsq

Compare packed 64-bit integers in \( a \) and \( b \), and store packed maximum values in the return value.

_mm256_mask_max_epi64

__m256i _mm256_mask_max_epi64(__m256i src, __mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmaxsq

Compare packed 64-bit integers in \( a \) and \( b \), and store packed maximum values in the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

_mm256_maskz_max_epi64

__m256i _mm256_maskz_max_epi64(__mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmaxsq

Compare packed 64-bit integers in \( a \) and \( b \), and store packed maximum values in the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

_mm256_max_epi64

__m256i _mm256_max_epi64(__m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmaxsq

Compare packed 64-bit integers in \( a \) and \( b \), and store packed maximum values in the return value.

_mm_mask_max_epi16

__m128i _mm_mask_max_epi16(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmaxsw

Compare packed 16-bit integers in \( a \) and \( b \), and store packed maximum values in the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).
__mm_maskz_max_epi16

__m128i _mm_maskz_max_epi16(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmaxsw

Compare packed 16-bit integers in a and b, and store packed maximum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_max_epi16

__m256i _mm256_mask_max_epi16(__m256i src, __mmask16 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmaxsw

Compare packed 16-bit integers in a and b, and store packed maximum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminub

Compare packed unsigned 8-bit integers in `a` and `b`, and store packed minimum values in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_min_epu8**

```c
__m128i __mm_maskz_min_epu8(__mmask16 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminub

Compare packed unsigned 8-bit integers in `a` and `b`, and store packed minimum values in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_min_epu8**

```c
__m256i __mm256_mask_min_epu8(__m256i src, __mmask32 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminub

Compare packed unsigned 8-bit integers in `a` and `b`, and store packed minimum values in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_min_epu8**

```c
__m256i __mm256_maskz_min_epu8(__mmask32 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminub

Compare packed unsigned 8-bit integers in `a` and `b`, and store packed minimum values in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_mask_min_epu8**

```c
__m512i __mm512_mask_min_epu8(__m512i src, __mmask64 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpminub

Compare packed unsigned 8-bit integers in `a` and `b`, and store packed minimum values in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_maskz_min_epu8**

```c
__m512i __mm512_maskz_min_epu8(__mmask64 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpminub

Compare packed unsigned 8-bit integers in `a` and `b`, and store packed minimum values in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
__mm512_min_epu8

__m512i __mm512_min_epu8(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpminub

Compare packed unsigned 8-bit integers in a and b, and store packed minimum values in the return value.

__mm_mask_min_epu32

__m128i __mm_mask_min_epu32(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpminud

Compare packed unsigned 32-bit integers in a and b, and store packed minimum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_min_epu32

__m128i __mm_maskz_min_epu32(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpminud

Compare packed unsigned 32-bit integers in a and b, and store packed minimum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_min_epu32

__m256i __mm256_mask_min_epu32(__m256i src, __mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpminud

Compare packed unsigned 32-bit integers in a and b, and store packed minimum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_min_epu32

__m256i __mm256_maskz_min_epu32(__mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpminud

Compare packed unsigned 32-bit integers in a and b, and store packed minimum values in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_min_epu64

__m128i __mm_mask_min_epu64(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpminuq

Compare packed unsigned 64-bit integers in a and b, and store packed minimum values in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).
**_mm_maskz_min_epu64_**

\[
\text{\_m128i \_mm_maskz\_min\_epu64(\_mmask8 k, \_m128i a, \_m128i b)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpminuq

Compare packed unsigned 64-bit integers in \(a\) and \(b\), and store packed minimum values in the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm_min_epu64_**

\[
\text{\_m128i \_mm\_min\_epu64(\_m128i a, \_m128i b)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpminuq

Compare packed unsigned 64-bit integers in \(a\) and \(b\), and store packed minimum values in the return value.

**_mm256_mask_min_epu64_**

\[
\text{\_m256i \_mm256\_mask\_min\_epu64(\_m256i src, \_mmask8 k, \_m256i a, \_m256i b)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpminuq

Compare packed unsigned 64-bit integers in \(a\) and \(b\), and store packed minimum values in the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

**_mm256_maskz_min_epu64_**

\[
\text{\_m256i \_mm256\_maskz\_min\_epu64(\_mmask8 k, \_m256i a, \_m256i b)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpminuq

Compare packed unsigned 64-bit integers in \(a\) and \(b\), and store packed minimum values in the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_min_epu64_**

\[
\text{\_m256i \_mm256\_min\_epu64(\_m256i a, \_m256i b)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpminuq

Compare packed unsigned 64-bit integers in \(a\) and \(b\), and store packed minimum values in the return value.

**_mm_mask_min_epu16_**

\[
\text{\_m128i \_mm\_mask\_min\_epu16(\_m128i src, \_mmask8 k, \_m128i a, \_m128i b)}
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminuw

Compare packed unsigned 16-bit integers in \(a\) and \(b\), and store packed minimum values in the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).
### _mm_maskz_min_epu16_

```c
__m128i _mm_maskz_min_epu16(__mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminuw

Compare packed unsigned 16-bit integers in `a` and `b`, and store packed minimum values in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

### _mm256_mask_min_epu16_

```c
__m256i _mm256_mask_min_epu16(__m256i src, __mmask16 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminuw

Compare packed unsigned 16-bit integers in `a` and `b`, and store packed minimum values in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

### _mm256_maskz_min_epu16_

```c
__m256i _mm256_maskz_min_epu16(__mmask16 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpminuw

Compare packed unsigned 16-bit integers in `a` and `b`, and store packed minimum values in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

### _mm512_mask_min_epu16_

```c
__m512i _mm512_mask_min_epu16(__m512i src, __mmask32 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpminuw

Compare packed unsigned 16-bit integers in `a` and `b`, and store packed minimum values in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

### _mm512_maskz_min_epu16_

```c
__m512i _mm512_maskz_min_epu16(__mmask32 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpminuw

Compare packed unsigned 16-bit integers in `a` and `b`, and store packed minimum values in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

### _mm512_min_epu16_

```c
__m512i _mm512_min_epu16(__m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpminuw

Compare packed unsigned 16-bit integers in `a` and `b`, and store packed minimum values in the return value.
**_mm_mask_mul_epi32_**

```c
__m128i _mm_mask_mul_epi32(__m128i src, __mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmuldq

Multiply the low 32-bit integers from each packed 64-bit element in `a` and `b`, and store the signed 64-bit results in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_mul_epi32_**

```c
__m128i _mm_maskz_mul_epi32(__mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmuldq

Multiply the low 32-bit integers from each packed 64-bit element in `a` and `b`, and store the signed 64-bit results in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_mul_epi32_**

```c
__m256i _mm256_mask_mul_epi32(__m256i src, __mmask8 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmuldq

Multiply the low 32-bit integers from each packed 64-bit element in `a` and `b`, and store the signed 64-bit results in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_mul_epi32_**

```c
__m256i _mm256_maskz_mul_epi32(__mmask8 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmuldq

Multiply the low 32-bit integers from each packed 64-bit element in `a` and `b`, and store the signed 64-bit results in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_mulhrs_epi16_**

```c
__m128i _mm_mask_mulhrs_epi16(__m128i src, __mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmulhrsw

Multiply packed 16-bit integers in `a` and `b`, producing intermediate signed 32-bit integers. Truncate each intermediate integer to the 18 most significant bits, round by adding 1, and store bits [16:1] to the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_mulhrs_epi16_**

```c
__m128i _mm_maskz_mulhrs_epi16(__mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmulhrsw

Multiply packed 16-bit integers in `a` and `b`, producing intermediate signed 32-bit integers. Truncate each intermediate integer to the 18 most significant bits, round by adding 1, and store bits [16:1] to the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmlhrsw

Multiply packed 16-bit integers in \(a\) and \(b\), producing intermediate signed 32-bit integers. Truncate each intermediate integer to the 18 most significant bits, round by adding 1, and store bits \([16:1]\) to the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_\text{mm256\_mask\_mulhrs\_epi16}
\]

\[

\]

CPUID Flags: AVX512BW  
Instruction(s): vpmulhuw

Multiply the packed unsigned 16-bit integers in \(a\) and \(b\), producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using writemask \(k\) (elements are copied from \(\text{src}\) when the corresponding mask bit is not set).
_mm512_maskz_mulhi_epu16

__m512i _mm512_maskz_mulhi_epu16(__mmask32 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmulhuw

Multiply the packed unsigned 16-bit integers in a and b, producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mulhi_epu16

__m512i _mm512_mulhi_epu16(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpmulhuw

Multiply the packed unsigned 16-bit integers in a and b, producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value.

_mm_mask_mulhi_epi16

__m128i _mm_mask_mulhi_epi16(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmulhw

Multiply the packed 16-bit integers in a and b, producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_mulhi_epi16

__m128i _mm_maskz_mulhi_epi16(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmulhw

Multiply the packed 16-bit integers in a and b, producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_mulhi_epi16

__m256i _mm256_mask_mulhi_epi16(__m256i src, __mmask16 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmulhw

Multiply the packed 16-bit integers in a and b, producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_mulhi_epi16

__m256i _mm256_maskz_mulhi_epi16(__mmask16 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmulhw
Multiply the packed 16-bit integers in \( a \) and \( b \), producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

`_mm512_mask_mulhi_epi16`

```c
__m512i _mm512_mask_mulhi_epi16(__m512i src, __mmask32 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpmulhw
Multiply the packed 16-bit integers in \( a \) and \( b \), producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

`_mm512_maskz_mulhi_epi16`

```c
__m512i _mm512_maskz_mulhi_epi16(__mmask32 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpmulhw
Multiply the packed 16-bit integers in \( a \) and \( b \), producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

`_mm512_mulhi_epi16`

```c
__m512i _mm512_mulhi_epi16(__m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpmulhw
Multiply the packed 16-bit integers in \( a \) and \( b \), producing intermediate 32-bit integers, and store the high 16 bits of the intermediate integers in the return value.

`_mm_mask_mullo_epi32`

```c
__m128i _mm_mask_mullo_epi32(__m128i src, __mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmulld
Multiply the packed 32-bit integers in \( a \) and \( b \), producing intermediate 64-bit integers, and store the low 32 bits of the intermediate integers in the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

`_mm_maskz_mullo_epi32`

```c
__m128i _mm_maskz_mullo_epi32(__mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmulld
Multiply the packed 32-bit integers in \( a \) and \( b \), producing intermediate 64-bit integers, and store the low 32 bits of the intermediate integers in the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\]

CPUID Flags: AVX512IFMA52
Instruction(s): vpmadd52luq
Multiply packed unsigned 52-bit integers in each 64-bit element of \( b \) and \( c \) to form a 104-bit intermediate result. Add the low 52-bit unsigned integer from the intermediate result with the corresponding unsigned 64-bit integer in \( a \), and return the result using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Bit Manipulation Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the \( \text{zmmintrin.h} \) header file. To use these intrinsics, include the \( \text{immintrin.h} \) file as follows:

\[
#include \ <\text{immintrin.h}>
\]

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>( src )</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>( k )</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>( a )</td>
<td>first source vector element</td>
</tr>
</tbody>
</table>

\[
\_mm\_lzcnt\_epi32
\]

\[
\_m128i\_mm\_lzcnt\_epi32(\_m128i\ a)
\]

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vplzcntd
Counts the number of leading zero bits in each packed 32-bit integer in \( a \), and return the results.

\[
\_mm\_mask\_lzcnt\_epi32
\]

\[
\_m128i\_mm\_mask\_lzcnt\_epi32(\_m128i\ src,\ _mmask8\ k,\ _m128i\ a)
\]

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vplzcntd
Counts the number of leading zero bits in each packed 32-bit integer in \( a \), and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).
**_mm_maskz_lzcnt_epi32_**

```

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vplzcntd

Counts the number of leading zero bits in each packed 32-bit integer in `a`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_lzcnt_epi64_**

```
__m128i _mm_lzcnt_epi64(__m128i a)
```

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vplzcntq

Counts the number of leading zero bits in each packed 64-bit integer in `a`, and return the results.

**_mm_mask_lzcnt_epi64_**

```
__m128i _mm_mask_lzcnt_epi64(__m128i src, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vplzcntq

Counts the number of leading zero bits in each packed 64-bit integer in `a`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
__mm_maskz_lzcnt_epi64

__m128i __mm_maskz_lzcnt_epi64(__mmask8 k, __m128i a)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vplzcntq
Counts the number of leading zero bits in each packed 64-bit integer in \( a \), and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

__mm256_lzcnt_epi64

__m256i __mm256_lzcnt_epi64(__m256i a)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vplzcntq
Counts the number of leading zero bits in each packed 64-bit integer in \( a \), and return the results.

__mm256_mask_lzcnt_epi64

__m256i __mm256_mask_lzcnt_epi64(__m256i src, __mmask8 k, __m256i a)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vplzcntq
Counts the number of leading zero bits in each packed 64-bit integer in \( a \), and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

__mm256_maskz_lzcnt_epi64

__m256i __mm256_maskz_lzcnt_epi64(__mmask8 k, __m256i a)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vplzcntq
Counts the number of leading zero bits in each packed 64-bit integer in \( a \), and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

__mm_multishift_epi64_epi8

__m128i __mm_multishift_epi64_epi8(__m128i a, __m128i b)
CPUID Flags: AVX512VBMI, AVX512VL
Instruction(s): vpmultishiftq
For each 64-bit element in \( b \), select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of \( a \), and store the 8 assembled bytes to the corresponding 64-bit element of the return value.

__mm_mask_multishift_epi64_epi8

__m128i __mm_mask_multishift_epi64_epi8(__m128i src, __mmask16 k, __m128i a, __m128i b)
CPUID Flags: AVX512VBMI, AVX512VL
Instruction(s): vpmultishiftq
For each 64-bit element in $b$, select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of $a$, and store the 8 assembled bytes to the corresponding 64-bit element of the return value using writemask $k$ (elements are copied from src when the corresponding mask bit is not set).

```
_mm_maskz_multishift_epi64_epi8
__m128i _mm_maskz_multishift_epi64_epi8(__mmask16 k, __m128i a, __m128i b)
```
CPUID Flags: AVX512VBMI, AVX512VL
Instruction(s): vpmultishiftqb

For each 64-bit element in $b$, select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of $a$, and store the 8 assembled bytes to the corresponding 64-bit element of the return value using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```
_mm256_multishift_epi64_epi8
__m256i _mm256_multishift_epi64_epi8(__m256i a, __m256i b)
```
CPUID Flags: AVX512VBMI, AVX512VL
Instruction(s): vpmultishiftqb

For each 64-bit element in $b$, select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of $a$, and store the 8 assembled bytes to the corresponding 64-bit element of the return value.

```
_mm256_mask_multishift_epi64_epi8
__m256i _mm256_mask_multishift_epi64_epi8(__m256i src, __mmask32 k, __m256i a, __m256i b)
```
CPUID Flags: AVX512VBMI, AVX512VL
Instruction(s): vpmultishiftqb

For each 64-bit element in $b$, select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of $a$, and store the 8 assembled bytes to the corresponding 64-bit element of the return value using writemask $k$ (elements are copied from src when the corresponding mask bit is not set).

```
_mm256_maskz_multishift_epi64_epi8
__m256i _mm256_maskz_multishift_epi64_epi8(__mmask32 k, __m256i a, __m256i b)
```
CPUID Flags: AVX512VBMI, AVX512VL
Instruction(s): vpmultishiftqb

For each 64-bit element in $b$, select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of $a$, and store the 8 assembled bytes to the corresponding 64-bit element of the return value using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```
_mm512_multishift_epi64_epi8
__m512i _mm512_multishift_epi64_epi8(__m512i a, __m512i b)
```
CPUID Flags: AVX512VBMI
Instruction(s): vpmultishiftqb
For each 64-bit element in \( b \), select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of \( a \), and store the 8 assembled bytes to the corresponding 64-bit element of the return value.

\[
\_\text{mm512\_mask\_multishift\_epi64\_epi8}
\]

\[
\_\text{m512i \_mm512\_mask\_multishift\_epi64\_epi8(_\text{mm512i \_mm512\_mask\_multishift\_epi64\_epi8(_\text{mm512i \_mm512\_mask\_multishift\_epi64\_epi8(_\_m512i \_mm512\_mask\_multishift\_epi64\_epi8(_\text{mm512i \src, \_mmask64 \_k, \_m512i \_a, \_m512i \_b}))})}}
\]

CPUID Flags: AVX512VBMI

Instruction(s): vpmultishiftqb

For each 64-bit element in \( b \), select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of \( a \), and store the 8 assembled bytes to the corresponding 64-bit element of the return value using writemask \( k \) (elements are copied from \( \src \) when the corresponding mask bit is not set).

\[
\_\text{mm512\_maskz\_multishift\_epi64\_epi8}
\]

\[
\_\text{m512i \_mm512\_maskz\_multishift\_epi64\_epi8(_\text{mmask64 \_k, \_m512i \_a, \_m512i \_b})}
\]

CPUID Flags: AVX512VBMI

Instruction(s): vpmultishiftqb

For each 64-bit element in \( b \), select 8 unaligned bytes using a byte-granular shift control within the corresponding 64-bit element of \( a \), and store the 8 assembled bytes to the corresponding 64-bit element of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

### Intrinsics for Comparison Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \src )</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>( k )</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>( a )</td>
<td>first source vector element</td>
</tr>
<tr>
<td>( b )</td>
<td>second source vector element</td>
</tr>
<tr>
<td>( \text{imm} )</td>
<td>comparison predicate, which can be any of the following values:</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_EQ - Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_LT - Less than</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_LE - Less than or Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_NE - Not Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_NLT - Not Less than</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_GE - Greater than or Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_NLE - Not Less than or Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_GT - Greater than</td>
</tr>
</tbody>
</table>
_mm_conflict_epi32

_mm128i _mm_conflict_epi32(mm128i a)

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpconflictd

Test each 32-bit element of a for equality with all other elements in a closer to the least significant element. Each element's comparison forms a zero extended bit vector in the return value.

_mm_mask_conflict_epi32

_mm128i _mm_mask_conflict_epi32(mm128i src, mmask8 k, mm128i a)

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpconflictd

Test each 32-bit element of a for equality with all other elements in a closer to the least significant element using writemask k (elements are copied from src when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.

_mm_maskz_conflict_epi32

_mm128i _mm_maskz_conflict_epi32(mmask8 k, mm128i a)

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpconflictd

Test each 32-bit element of a for equality with all other elements in a closer to the least significant element using zeromask k (elements are zeroed out when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.

_mm256_conflict_epi32

_mm256i _mm256_conflict_epi32(mm256i a)

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpconflictd

Test each 32-bit element of a for equality with all other elements in a closer to the least significant element. Each element's comparison forms a zero extended bit vector in the return value.

_mm256_mask_conflict_epi32

_mm256i _mm256_mask_conflict_epi32(mm256i src, mmask8 k, mm256i a)

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpconflictd

Test each 32-bit element of a for equality with all other elements in a closer to the least significant element using writemask k (elements are copied from src when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.

_mm256_maskz_conflict_epi32

_mm256i _mm256_maskz_conflict_epi32(mmask8 k, mm256i a)

CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpconflictd
Test each 32-bit element of a for equality with all other elements in a closer to the least significant element using zeromask k (elements are zeroed out when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.

_mm_conflict_epi64

__m128i _mm_conflict_epi64(__m128i a)

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vpconflictq
Test each 64-bit element of a for equality with all other elements in a closer to the least significant element. Each element's comparison forms a zero extended bit vector in the return value.

_mm_mask_conflict_epi64

__m128i _mm_mask_conflict_epi64(__m128i src, __mmask8 k, __m128i a)

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vpconflictq
Test each 64-bit element of a for equality with all other elements in a closer to the least significant element using writemask k (elements are copied from src when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.

_mm_maskz_conflict_epi64

__m128i _mm_maskz_conflict_epi64(__mmask8 k, __m128i a)

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vpconflictq
Test each 64-bit element of a for equality with all other elements in a closer to the least significant element using zeromask k (elements are zeroed out when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.

_mm256_conflict_epi64

__m256i _mm256_conflict_epi64(__m256i a)

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vpconflictq
Test each 64-bit element of a for equality with all other elements in a closer to the least significant element. Each element's comparison forms a zero extended bit vector in the return value.

_mm256_mask_conflict_epi64

__m256i _mm256_mask_conflict_epi64(__m256i src, __mmask8 k, __m256i a)

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vpconflictq
Test each 64-bit element of a for equality with all other elements in a closer to the least significant element using writemask k (elements are copied from src when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.
__mm256_maskz_conflict_epi64

__m256i __mm256_maskz_conflict_epi64(__mmask8 k, __m256i a)

CPUID Flags: AVX512CD, AVX512VL

Instruction(s): vpconflictq

Test each 64-bit element of a for equality with all other elements in a closer to the least significant element using zeromask k (elements are zeroed out when the corresponding mask bit is not set). Each element's comparison forms a zero extended bit vector in the return value.

__mm_cmp_pd_mask

__mmask8 __mm_cmp_pd_mask(__m128d a, __m128d b, const int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcmppd

Compare packed double-precision (64-bit) floating-point elements in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value.

__mm_mask_cmp_pd_mask

__mmask8 __mm_mask_cmp_pd_mask(__mmask8 k1, __m128d a, __m128d b, const int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcmppd

Compare packed double-precision (64-bit) floating-point elements in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value using zeromask k1 (elements are zeroed out when the corresponding mask bit is not set).

__mm256_cmp_pd_mask

__mmask8 __mm256_cmp_pd_mask(__m256d a, __m256d b, const int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcmppd

Compare packed double-precision (64-bit) floating-point elements in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value.

__mm256_mask_cmp_pd_mask

__mmask8 __mm256_mask_cmp_pd_mask(__mmask8 k1, __m256d a, __m256d b, const int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcmppd

Compare packed double-precision (64-bit) floating-point elements in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value using zeromask k1 (elements are zeroed out when the corresponding mask bit is not set).

__mm_cmp_ps_mask

__mmask8 __mm_cmp_ps_mask(__m128 a, __m128 b, const int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcmpps
Compare packed single-precision (32-bit) floating-point elements in \( a \) and \( b \) based on the comparison operand specified by \( \text{imm} \), and put each result in the corresponding bit of the returned mask value.

\[
\texttt{__mm_mask_cmp_ps_mask}
\]
\[
\texttt{__mmask8 \_mm_mask_cmp_ps_mask(__mmask8 k1, \_m128 a, \_m128 b, const int imm)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \texttt{vcmpps}

Compare packed single-precision (32-bit) floating-point elements in \( a \) and \( b \) based on the comparison operand specified by \( \text{imm} \), and put each result in the corresponding bit of the returned mask value using zeromask \( k1 \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\texttt{__mm256_mask_cmp_ps_mask}
\]
\[
\texttt{__mmask8 \_mm256_mask_cmp_ps_mask(__mmask8 k1, \_m256 a, \_m256 b, const int imm)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \texttt{vcmpps}

Compare packed single-precision (32-bit) floating-point elements in \( a \) and \( b \) based on the comparison operand specified by \( \text{imm} \), and and put each result in the corresponding bit of the returned mask value.

\[
\texttt{__mm256_cmp_ps}
\]
\[
\texttt{__mmask8 \_mm256_cmp_ps(__m256 a, \_m256 b, const int imm)}
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \texttt{vcmpps}

Compare packed single-precision (32-bit) floating-point elements in \( a \) and \( b \) based on the comparison operand specified by \( \text{imm} \), and and put each result in the corresponding bit of the returned mask value using zeromask \( k1 \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\texttt{__mm_cmp_epi8_mask}
\]
\[
\texttt{__mmask16 \_mm_cmp_epi8_mask(__m128i a, \_m128i b, const int imm)}
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \texttt{vpcmpb}

Compare packed 8-bit integers in \( a \) and \( b \) based on the comparison operand specified by \( \text{imm} \), and and put each result in the corresponding bit of the returned mask value.

\[
\texttt{__mm_cmpeq_epi8_mask}
\]
\[
\texttt{__mmask16 \_mm_cmpeq_epi8_mask(__m128i a, \_m128i b)}
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \texttt{vpcmpb}

Compare packed 8-bit integers in \( a \) and \( b \) for equality, and and put each result in the corresponding bit of the returned mask value.

\[
\texttt{__mm_cmpge_epi8_mask}
\]
\[
\texttt{__mmask16 \_mm_cmpge_epi8_mask(__m128i a, \_m128i b)}
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \texttt{vpcmpb}

Compare packed 8-bit integers in \( a \) and \( b \) for equality, and and put each result in the corresponding bit of the returned mask value.
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in $a$ and $b$ for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

```
__mm_cmpgt_epi8_mask
__m128i __mm_cmpgt_epi8_mask(__m128i a, __m128i b)
```
**_mm_mask_cmpeq_epi8_mask_**

```c
__mmask16 _mm_mask_cmpeq_epi8_mask(__mmask16 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL  
Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for equality, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmpge_epi8_mask_**

```c
__mmask16 _mm_mask_cmpge_epi8_mask(__mmask16 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL  
Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmpgt_epi8_mask_**

```c
__mmask16 _mm_mask_cmpgt_epi8_mask(__mmask16 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL  
Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmple_epi8_mask_**

```c
__mmask16 _mm_mask_cmple_epi8_mask(__mmask16 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL  
Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmplt_epi8_mask_**

```c
__mmask16 _mm_mask_cmplt_epi8_mask(__mmask16 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL  
Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for less-than, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmpneq_epi8_mask_**

```c
__mmask16 _mm_mask_cmpneq_epi8_mask(__mmask16 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL  
Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for not-equal, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in \(a\) and \(b\) for not-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_\text{mm256\_cmp\_epi8\_mask}
\]

\[
\_\text{mmask32 \_mm256\_cmp\_epi8\_mask(_\text{m256i a, m256i b, const int imm})}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in \(a\) and \(b\) based on the comparison operand specified by \(imm\), and and put each result in the corresponding bit of the returned mask value.

\[
\_\text{mm256\_cmpeq\_epi8\_mask}
\]

\[
\_\text{mmask32 \_mm256\_cmpeq\_epi8\_mask(_\text{m256i a, m256i b})}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in \(a\) and \(b\) for equality, and and put each result in the corresponding bit of the returned mask value.

\[
\_\text{mm256\_cmpge\_epi8\_mask}
\]

\[
\_\text{mmask32 \_mm256\_cmpge\_epi8\_mask(_\text{m256i a, m256i b})}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in \(a\) and \(b\) for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

\[
\_\text{mm256\_cmpgt\_epi8\_mask}
\]

\[
\_\text{mmask32 \_mm256\_cmpgt\_epi8\_mask(_\text{m256i a, m256i b})}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in \(a\) and \(b\) for greater-than, and and put each result in the corresponding bit of the returned mask value.

\[
\_\text{mm256\_cmple\_epi8\_mask}
\]

\[
\_\text{mmask32 \_mm256\_cmple\_epi8\_mask(_\text{m256i a, m256i b})}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in \(a\) and \(b\) for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value.
**_mm256_cmplt_epi8_mask_**

```
__mmask32 _mm256_cmplt_epi8_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for less-than, and and put each result in the corresponding bit of the returned mask value.

**_mm256_cmpneq_epi8_mask_**

```
__mmask32 _mm256_cmpneq_epi8_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for not-equal, and and put each result in the corresponding bit of the returned mask value.

**_mm256_mask_cmp_epi8_mask_**

```
__mmask32 _mm256_mask_cmp_epi8_mask(__mmask32 k1, __m256i a, __m256i b, const int imm)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` based on the comparison operand specified by `imm`, and and put each result in the corresponding bit of the returned mask value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cmpeq_epi8_mask_**

```
__mmask32 _mm256_mask_cmpeq_epi8_mask(__mmask32 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for equality, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cmpge_epi8_mask_**

```
__mmask32 _mm256_mask_cmpge_epi8_mask(__mmask32 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cmpgt_epi8_mask_**

```
__mmask32 _mm256_mask_cmpgt_epi8_mask(__mmask32 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpb

Compare packed 8-bit integers in `a` and `b` for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).
Compare packed 8-bit integers in $a$ and $b$ for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask $k1$ (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm256_mask_cmple_epi8_mask
__mmask32 __mm256_mask_cmple_epi8_mask(__mmask32 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in $a$ and $b$ for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask $k1$ (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm256_mask_cmplt_epi8_mask
__mmask32 __mm256_mask_cmplt_epi8_mask(__mmask32 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in $a$ and $b$ for less-than, and and put each result in the corresponding bit of the returned mask value using zeromask $k1$ (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm256_mask_cmpneq_epi8_mask
__mmask32 __mm256_mask_cmpneq_epi8_mask(__mmask32 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpb

Compare packed 8-bit integers in $a$ and $b$ based on the comparison operand specified by $imm$, and and put each result in the corresponding bit of the returned mask value.

```c
__mm512_cmp_epi8_mask
__mmask64 __mm512_cmp_epi8_mask(__m512i a, __m512i b, const int imm)
```

CPUID Flags: AVX512BW
Instruction(s): vpcmpb

Compare packed 8-bit integers in $a$ and $b$ for equality, and and put each result in the corresponding bit of the returned mask value.

```c
__mm512_cmpeq_epi8_mask
__mmask64 __mm512_cmpeq_epi8_mask(__m512i a, __m512i b)
```

CPUID Flags: AVX512BW
Instruction(s): vpcmpb
_mm512_cmpge_epi8_mask

__mmask64 __mm512_cmpge_epi8_mask(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpcmpb

Compare packed 8-bit integers in a and b for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

_mm512_cmpgt_epi8_mask

__mmask64 __mm512_cmpgt_epi8_mask(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpcmpb

Compare packed 8-bit integers in a and b for greater-than, and and put each result in the corresponding bit of the returned mask value.

_mm512_cmple_epi8_mask

__mmask64 __mm512_cmple_epi8_mask(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpcmpb

Compare packed 8-bit integers in a and b for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

_mm512_cmplt_epi8_mask

__mmask64 __mm512_cmplt_epi8_mask(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpcmpb

Compare packed 8-bit integers in a and b for less-than, and and put each result in the corresponding bit of the returned mask value.

_mm512_cmpneq_epi8_mask

__mmask64 __mm512_cmpneq_epi8_mask(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpcmpb

Compare packed 8-bit integers in a and b for not-equal, and and put each result in the corresponding bit of the returned mask value.

_mm512_mask_cmp_epi8_mask

__mmask64 __mm512_mask_cmp_epi8_mask(__mmask64 k1, __m512i a, __m512i b, const int imm)

CPUID Flags: AVX512BW
Instruction(s): vpcmpb
Compare packed 8-bit integers in $a$ and $b$ based on the comparison operand specified by $imm$, and and put each result in the corresponding bit of the returned mask value using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm512_mask_cmpeq_epi8_mask

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpq

Compare packed 64-bit integers in \( a \) and \( b \) for greater-than-or-equal, and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
__mm_mask_cmpgt_epi64_mask

__mmask8 __mm_mask_cmpgt_epi64_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq

Compare packed 64-bit integers in a and b for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_cmple_epi64_mask

__mmask8 __mm_mask_cmple_epi64_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq

Compare packed 64-bit integers in a and b for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_cmplt_epi64_mask

__mmask8 __mm_mask_cmplt_epi64_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq

Compare packed 64-bit integers in a and b for less-than, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_cmpneq_epi64_mask

__mmask8 __mm_mask_cmpneq_epi64_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq

Compare packed 64-bit integers in a and b for not-equal, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_cmp_epi64_mask

__mmask8 __mm256_cmp_epi64_mask(__m256i a, __m256i b, const _MM_CMPINT_ENUM imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq

Compare packed 64-bit integers in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value.

__mm256_cmpeq_epi64_mask

__mmask8 __mm256_cmpeq_epi64_mask(__m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq
Compare packed 64-bit integers in $a$ and $b$ for equality, and and put each result in the corresponding bit of the returned mask value.

```c
_mm256_cmpge_epi64_mask
__mmask8 _mm256_cmpge_epi64_mask(__m256i a, __m256i b)
```
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpq
Compare packed 64-bit integers in $a$ and $b$ for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

```c
_mm256_cmpgt_epi64_mask
__mmask8 _mm256_cmpgt_epi64_mask(__m256i a, __m256i b)
```
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpq
Compare packed 64-bit integers in $a$ and $b$ for greater-than, and and put each result in the corresponding bit of the returned mask value.

```c
_mm256_cmple_epi64_mask
__mmask8 _mm256_cmple_epi64_mask(__m256i a, __m256i b)
```
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpq
Compare packed 64-bit integers in $a$ and $b$ for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

```c
_mm256_cmplt_epi64_mask
__mmask8 _mm256_cmplt_epi64_mask(__m256i a, __m256i b)
```
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpq
Compare packed 64-bit integers in $a$ and $b$ for less-than, and and put each result in the corresponding bit of the returned mask value.

```c
_mm256_cmpneq_epi64_mask
__mmask8 _mm256_cmpneq_epi64_mask(__m256i a, __m256i b)
```
CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpq
Compare packed 64-bit integers in $a$ and $b$ for not-equal, and and put each result in the corresponding bit of the returned mask value.

```c
_mm256_mask_cmp_epi64_mask
__mmask8 _mm256_mask_cmp_epi64_mask(__mmask8 kl, __m256i a, __m256i b, const _MM_CMPINT_ENUM imm)
```
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq
Compare packed 64-bit integers in a and b based on the comparison operand specified by \textit{imm}, and and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm256\_mask\_cmpeq\_epi64\_mask

\[ \text{\_mmask8 } \_\_mm256\_mask\_cmpeq\_epi64\_mask(\_\_mmask8 \ k1, \_\_m256i \ a, \_\_m256i \ b) \]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq
Compare packed 64-bit integers in a and b for equality, and and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm256\_mask\_cmpge\_epi64\_mask

\[ \text{\_mmask8 } \_\_mm256\_mask\_cmpge\_epi64\_mask(\_\_mmask8 \ k1, \_\_m256i \ a, \_\_m256i \ b) \]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq
Compare packed 64-bit integers in a and b for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm256\_mask\_cmpgt\_epi64\_mask

\[ \text{\_mmask8 } \_\_mm256\_mask\_cmpgt\_epi64\_mask(\_\_mmask8 \ k1, \_\_m256i \ a, \_\_m256i \ b) \]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq
Compare packed 64-bit integers in a and b for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm256\_mask\_cmple\_epi64\_mask

\[ \text{\_mmask8 } \_\_mm256\_mask\_cmple\_epi64\_mask(\_\_mmask8 \ k1, \_\_m256i \ a, \_\_m256i \ b) \]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq
Compare packed 64-bit integers in a and b for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_\_mm256\_mask\_cmplt\_epi64\_mask

\[ \text{\_mmask8 } \_\_mm256\_mask\_cmplt\_epi64\_mask(\_\_mmask8 \ k1, \_\_m256i \ a, \_\_m256i \ b) \]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpq
Compare packed 64-bit integers in \( a \) and \( b \) for less-than, and and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_mm256_mask_cmpneq_epi64_mask
\]
\[
__mmask8 _mm256_mask_cmpneq_epi64_mask(__mmask8 k1, __m256i a, __m256i b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \( \text{vpcmpq} \)

Compare packed 64-bit integers in \( a \) and \( b \) for not-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_mm_cmpeq_epi8_mask
\]
\[
__mmask16 _mm_cmpeq_epi8_mask(__m128i a, __m128i b, const int imm)
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \( \text{vpcmpub} \)

Compare packed unsigned 8-bit integers in \( a \) and \( b \) based on the comparison operand specified by \( \text{imm} \), and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmpeq_epi8_mask
\]
\[
__mmask16 _mm_cmpeq_epi8_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \( \text{vpcmpub} \)

Compare packed unsigned 8-bit integers in \( a \) and \( b \) for equality, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmpge_epi8_mask
\]
\[
__mmask16 _mm_cmpge_epi8_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \( \text{vpcmpub} \)

Compare packed unsigned 8-bit integers in \( a \) and \( b \) for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmpgt_epi8_mask
\]
\[
__mmask16 _mm_cmpgt_epi8_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \( \text{vpcmpub} \)

Compare packed unsigned 8-bit integers in \( a \) and \( b \) for greater-than, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmple_epi8_mask
\]
\[
__mmask16 _mm_cmple_epi8_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \( \text{vpcmpub} \)

Compare packed unsigned 8-bit integers in \( a \) and \( b \) for greater-than, and and put each result in the corresponding bit of the returned mask value.
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpub
Compare packed unsigned 8-bit integers in a and b for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

```c
__mm_cmplt_epu8_mask
__mmask16 _mm_cmplt_epu8_mask(__m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpub
Compare packed unsigned 8-bit integers in a and b for less-than, and and put each result in the corresponding bit of the returned mask value.

```c
__mm_cmpneq_epu8_mask
__mmask16 _mm_cmpneq_epu8_mask(__m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpub
Compare packed unsigned 8-bit integers in a and b for not-equal, and and put each result in the corresponding bit of the returned mask value.

```c
__mm_mask_cmp_epu8_mask
__mmask16 _mm_mask_cmp_epu8_mask(__mmask16 k1, __m128i a, __m128i b, const int imm)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpub
Compare packed unsigned 8-bit integers in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value using zeromask k1 (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm_mask_cmpge_epu8_mask
__mmask16 _mm_mask_cmpge_epu8_mask(__mmask16 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpub
Compare packed unsigned 8-bit integers in a and b for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask k1 (elements are zeroed out when the corresponding mask bit is not set).
__mm_mask_cmpgt_epu8_mask

CPUID Flags: AVX512BW
Instruction(s): vpcmpub
Compare packed unsigned 8-bit integers in $a$ and $b$ for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask $k1$ (elements are zeroed out when the corresponding mask bit is not set).
**_mm512_mask_cmpgt_epu8_mask_**

\[
\text{__mmask64 } \text{_mm512_mask_cmpgt_epu8_mask)(__mmask64 k1, \text{__m512i } a, \text{__m512i } b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpcmpub

Compare packed unsigned 8-bit integers in \(a\) and \(b\) for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_mask_cmple_epu8_mask_**

\[
\text{__mmask64 } \text{_mm512_mask_cmple_epu8_mask)(__mmask64 k1, \text{__m512i } a, \text{__m512i } b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpcmpub

Compare packed unsigned 8-bit integers in \(a\) and \(b\) for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_mask_cmplt_epu8_mask_**

\[
\text{__mmask64 } \text{_mm512_mask_cmplt_epu8_mask)(__mmask64 k1, \text{__m512i } a, \text{__m512i } b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpcmpub

Compare packed unsigned 8-bit integers in \(a\) and \(b\) for less-than, and and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_mask_cmpneq_epu8_mask_**

\[
\text{__mmask64 } \text{_mm512_mask_cmpneq_epu8_mask)(__mmask64 k1, \text{__m512i } a, \text{__m512i } b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpcmpub

Compare packed unsigned 8-bit integers in \(a\) and \(b\) for not-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm_cmp_epu32_mask_**

\[
\text{__mmask8 } \text{_mm_cmp_epu32_mask(__m128i } a, \text{__m128i } b, \text{const } \text{MM_CMPINT_ENUM } \text{imm})
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpud

Compare packed unsigned 32-bit integers in \(a\) and \(b\) based on the comparison operand specified by \(\text{imm}\), and and put each result in the corresponding bit of the returned mask value.

**_mm_cmpeq_epu32_mask_**

\[
\text{__mmask8 } \text{_mm_cmpeq_epu32_mask(__m128i } a, \text{__m128i } b)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpud
Compare packed unsigned 32-bit integers in \(a\) and \(b\) for equality, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmpge_epu32_mask
\]

\[
\_mmask8 \_mm_cmpge_epu32_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpud
Compare packed unsigned 32-bit integers in \(a\) and \(b\) for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmpgt_epu32_mask
\]

\[
\_mmask8 \_mm_cmpgt_epu32_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpud
Compare packed unsigned 32-bit integers in \(a\) and \(b\) for greater-than, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmple_epu32_mask
\]

\[
\_mmask8 \_mm_cmple_epu32_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpud
Compare packed unsigned 32-bit integers in \(a\) and \(b\) for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmplt_epu32_mask
\]

\[
\_mmask8 \_mm_cmplt_epu32_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpud
Compare packed unsigned 32-bit integers in \(a\) and \(b\) for less-than, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_cmpneq_epu32_mask
\]

\[
\_mmask8 \_mm_cmpneq_epu32_mask(__m128i a, __m128i b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpud
Compare packed unsigned 32-bit integers in \(a\) and \(b\) for not-equal, and and put each result in the corresponding bit of the returned mask value.

\[
_mm_mask_cmp_epu32_mask
\]

\[
\_mmask8 \_mm_mask_cmp_epu32_mask(_mmask8 k1, __m128i a, __m128i b, const _MM_CMPINT_ENUM imm)
\]
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpud

Compare packed unsigned 32-bit integers in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_cmpeq_epu32_mask

__m128i _mm_mask_cmpeq_epu32_mask(__m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpud

Compare packed unsigned 32-bit integers in a and b for equality, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_cmpge_epu32_mask

__m128i _mm_mask_cmpge_epu32_mask(__m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpud

Compare packed unsigned 32-bit integers in a and b for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_cmpgt_epu32_mask

__m128i _mm_mask_cmpgt_epu32_mask(__m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpud

Compare packed unsigned 32-bit integers in a and b for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_cmple_epu32_mask

__m128i _mm_mask_cmple_epu32_mask(__m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpud

Compare packed unsigned 32-bit integers in a and b for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_cmplt_epu32_mask

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpuq

Compare packed unsigned 64-bit integers in `a` and `b` for equality, and and put each result in the corresponding bit of the returned mask value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```
_mm256_mask_cmpge_epu64_mask
__m8 mm256_mask_cmpge_epu64_mask(__m8 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcmpuq

Compare packed unsigned 64-bit integers in `a` and `b` for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
**_mm256_mask_cmpgt_epu64_mask_**

```
__m256i __mm256_mask_cmpgt_epu64_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpuq

Compare packed unsigned 64-bit integers in `a` and `b` for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cmple_epu64_mask_**

```
__m256i __mm256_mask_cmple_epu64_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpuq

Compare packed unsigned 64-bit integers in `a` and `b` for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cmplt_epu64_mask_**

```
__m256i __mm256_mask_cmplt_epu64_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpuq

Compare packed unsigned 64-bit integers in `a` and `b` for less-than, and and put each result in the corresponding bit of the returned mask value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cmpneq_epu64_mask_**

```
__m256i __mm256_mask_cmpneq_epu64_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcmpuq

Compare packed unsigned 64-bit integers in `a` and `b` for not-equal, and and put each result in the corresponding bit of the returned mask value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_cmp_epu16_mask_**

```
__m128i __mm_cmp_epu16_mask(__m128i a, __m128i b, const int imm)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpuw

Compare packed unsigned 16-bit integers in `a` and `b` based on the comparison operand specified by `imm`, and and put each result in the corresponding bit of the returned mask value.

**_mm_cmpeq_epu16_mask_**

```
__m128i __mm_cmpeq_epu16_mask(__m128i a, __m128i b)
```

CPUID Flags: AVX512BW, AVX512VL

Compare packed unsigned 16-bit integers in `a` and `b` based on the comparison operand specified by `imm`, and and put each result in the corresponding bit of the returned mask value.
Instruction(s): vpcmpuw
Compare packed unsigned 16-bit integers in \(a\) and \(b\) for equality, and and put each result in the corresponding bit of the returned mask value.

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw
Compare packed 16-bit integers in a and b based on the comparison operand specified by imm, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_cmpeq_epi16_mask

__m128i __mm_mask_cmpeq_epi16_mask(__m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw
Compare packed 16-bit integers in a and b for equality, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_cmpge_epi16_mask

__m128i __mm_mask_cmpge_epi16_mask(__m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw
Compare packed 16-bit integers in a and b for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
**_mm_mask_cmpgt_epi16_mask_**

__mmask8 _mm_mask_cmpgt_epi16_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw

Compare packed 16-bit integers in \(a\) and \(b\) for greater-than, and and put each result in the corresponding bit of the returned mask value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmple_epi16_mask_**

__mmask8 _mm_mask_cmple_epi16_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw

Compare packed 16-bit integers in \(a\) and \(b\) for less-than-or-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmplt_epi16_mask_**

__mmask8 _mm_mask_cmplt_epi16_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw

Compare packed 16-bit integers in \(a\) and \(b\) for less-than, and and put each result in the corresponding bit of the returned mask value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cmpneq_epi16_mask_**

__mmask8 _mm_mask_cmpneq_epi16_mask(__mmask8 k1, __m128i a, __m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw

Compare packed 16-bit integers in \(a\) and \(b\) for not-equal, and and put each result in the corresponding bit of the returned mask value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_cmp_epi16_mask_**

__mmask16 _mm256_cmp_epi16_mask(__m256i a, __m256i b, const int imm)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw

Compare packed 16-bit integers in \(a\) and \(b\) based on the comparison operand specified by \(imm\), and and put each result in the corresponding bit of the returned mask value.

**_mm256_cmpeq_epi16_mask_**

__mmask16 _mm256_cmpeq_epi16_mask(__m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpcmpw

Compare packed 16-bit integers in \( a \) and \( b \) for equality, and and put each result in the corresponding bit of the returned mask value.

\[
\text{\_mm256\_cmpge\_epi16\_mask}
\]

\[
\text{\_mmask16 \_mm256\_cmpge\_epi16\_mask(\_m256i a, \_m256i b)}
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpcmpw

Compare packed 16-bit integers in \( a \) and \( b \) for greater-than-or-equal, and and put each result in the corresponding bit of the returned mask value.

\[
\text{\_mm256\_cmpgt\_epi16\_mask}

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vptestnmb

Compute the bitwise AND of packed 8-bit integers in a and b, producing intermediate 8-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

__mm256_mask_testn_epi8_mask

__mmask32 _mm256_mask_testn_epi8_mask(__mmask32 k1, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vptestnmb

Compute the bitwise AND of packed 8-bit integers in a and b, producing intermediate 8-bit values, and set the corresponding bit in the returned mask value (subject to writemask k) if the intermediate value is zero.

__mm256_testn_epi8_mask

__mmask32 _mm256_testn_epi8_mask(__m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vptestnmb

856
Compute the bitwise AND of packed 8-bit integers in $a$ and $b$, producing intermediate 8-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

```c
_mm512_mask_testn_epi8_mask
__mmask64 _mm512_mask_testn_epi8_mask(__mmask64 k1, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vptestnmb

Compute the bitwise AND of packed 8-bit integers in $a$ and $b$, producing intermediate 8-bit values, and set the corresponding bit in the returned mask value (subject to writemask $k$) if the intermediate value is zero.

```c
_mm512_testn_epi8_mask
__mmask64 _mm512_testn_epi8_mask(__m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vptestnmb

Compute the bitwise AND of packed 8-bit integers in $a$ and $b$, producing intermediate 8-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

```c
_mm_mask_testn_epi32_mask
__mmask8 _mm_mask_testn_epi32_mask(__mmask8 k1, __m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vptestnmd

Compute the bitwise AND of packed 32-bit integers in $a$ and $b$, producing intermediate 32-bit values, and set the corresponding bit in the returned mask value (subject to writemask $k$) if the intermediate value is zero.

```c
_mm_testn_epi32_mask
__mmask8 _mm_testn_epi32_mask(__m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vptestnmd

Compute the bitwise AND of packed 32-bit integers in $a$ and $b$, producing intermediate 32-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

```c
_mm256_mask_testn_epi32_mask
__mmask8 _mm256_mask_testn_epi32_mask(__mmask8 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vptestnmd

Compute the bitwise AND of packed 32-bit integers in $a$ and $b$, producing intermediate 32-bit values, and set the corresponding bit in the returned mask value (subject to writemask $k$) if the intermediate value is zero.

```c
_mm256_testn_epi32_mask
__mmask8 _mm256_testn_epi32_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vptestnmd
Compute the bitwise AND of packed 32-bit integers in \(a\) and \(b\), producing intermediate 32-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

\[
_mm\_mask\_testn\_epi64\_mask
\]

\[
_mm\_mask\_testn\_epi64\_mask(\_mmask8 \_k1, \_m128i \_a, \_m128i \_b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vptestnmg
Compute the bitwise AND of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and set the corresponding bit in the returned mask value (subject to writemask \(k\)) if the intermediate value is zero.

\[
_mm\_testn\_epi64\_mask
\]

\[
_mm\_testn\_epi64\_mask(\_m128i \_a, \_m128i \_b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vptestnmg
Compute the bitwise AND of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

\[
_mm256\_mask\_testn\_epi64\_mask
\]

\[
_mm256\_mask\_testn\_epi64\_mask(\_mmask8 \_k1, \_m256i \_a, \_m256i \_b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vptestnmg
Compute the bitwise AND of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

\[
_mm256\_testn\_epi64\_mask
\]

\[
_mm256\_testn\_epi64\_mask(\_m256i \_a, \_m256i \_b)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vptestnmg
Compute the bitwise AND of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

\[
_mm\_mask\_testn\_epi16\_mask
\]

\[
_mm\_mask\_testn\_epi16\_mask(\_mmask8 \_k1, \_m128i \_a, \_m128i \_b)
\]

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vptestnmg
Compute the bitwise AND of packed 64-bit integers in \(a\) and \(b\), producing intermediate 64-bit values, and set the corresponding bit in the returned mask value (subject to writemask \(k\)) if the intermediate value is zero.

\[
_mm\_testn\_epi16\_mask
\]

\[
_mm\_testn\_epi16\_mask(\_m128i \_a, \_m128i \_b)
\]
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vptestnwmw

Compute the bitwise AND of packed 16-bit integers in \( a \) and \( b \), producing intermediate 16-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

**_mm256_mask_testn_epi16_mask_**

```c
_mm256_mask_testn_epi16_mask(__mmask16 k1, __m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vptestnwmw

Compute the bitwise AND of packed 16-bit integers in \( a \) and \( b \), producing intermediate 16-bit values, and set the corresponding bit in the returned mask value (subject to writemask \( k \)) if the intermediate value is zero.

**_mm256_testn_epi16_mask_**

```c
_mm256_testn_epi16_mask(__m256i a, __m256i b)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vptestnwmw

Compute the bitwise AND of packed 16-bit integers in \( a \) and \( b \), producing intermediate 16-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

**_mm512_mask_testn_epi16_mask_**

```c
_mm512_mask_testn_epi16_mask(__mmask32 k1, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW
Instruction(s): vptestnwmw

Compute the bitwise AND of packed 16-bit integers in \( a \) and \( b \), producing intermediate 16-bit values, and set the corresponding bit in the returned mask value (subject to writemask \( k \)) if the intermediate value is zero.

**_mm512_testn_epi16_mask_**

```c
_mm512_testn_epi16_mask(__m512i a, __m512i b)
```

CPUID Flags: AVX512BW
Instruction(s): vptestnwmw

Compute the bitwise AND of packed 16-bit integers in \( a \) and \( b \), producing intermediate 16-bit values, and set the corresponding bit in the returned mask value if the intermediate value is zero.

**Intrinsics for Conversion Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```
<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>k</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>a</td>
<td>first source vector element</td>
</tr>
<tr>
<td>rounding</td>
<td>Rounding control values; these can be one of the following (along with the <code>sae</code> suppress all exceptions flag):</td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_FROUND_TO_NEAREST_INT</code> - rounds to nearest even</td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_FROUND_TO_NEG_INF</code> - rounds to negative infinity</td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_FROUND_TO_POS_INF</code> - rounds to positive infinity</td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_FROUND_TO_ZERO</code> - rounds to zero</td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_FROUND_CUR_DIRECTION</code> - rounds using default from MXCSR register</td>
</tr>
</tbody>
</table>

**_mm_mask_cvtpd_ps**

```c
__m128 _mm_mask_cvtpd_ps(__m128 src, __mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtpd2ps

Convert packed double-precision (64-bit) floating-point elements in `a` to packed single-precision (32-bit) floating-point elements, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_cvtpd_ps**

```c
__m128 _mm_maskz_cvtpd_ps(__mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtpd2ps

Convert packed double-precision (64-bit) floating-point elements in `a` to packed single-precision (32-bit) floating-point elements, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cvtpd_ps**

```c
__m128 _mm256_mask_cvtpd_ps(__m128 src, __mmask8 k, __m256d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtpd2ps

Convert packed double-precision (64-bit) floating-point elements in `a` to packed single-precision (32-bit) floating-point elements, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_cvtpd_ps**

```c
__m128 _mm256_maskz_cvtpd_ps(__mmask8 k, __m256d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtpd2ps
Convert packed double-precision (64-bit) floating-point elements in a to packed single-precision (32-bit) floating-point elements, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_cvtph_ps

__m128 __m128_mm_mask_cvtph_ps(__m128 src, __mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtph2ps

Convert packed half-precision (16-bit) floating-point elements in a to packed single-precision (32-bit) floating-point elements, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_cvtph_ps

__m128 __m128_mm_maskz_cvtph_ps(__mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtph2ps

Convert packed half-precision (16-bit) floating-point elements in a to packed single-precision (32-bit) floating-point elements, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_cvtph_ps

__m256 __m256_mm_mask_cvtph_ps(__m256 src, __mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtph2ps

Convert packed half-precision (16-bit) floating-point elements in a to packed single-precision (32-bit) floating-point elements, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_cvtph_ps

__m256 __m256_mm_maskz_cvtph_ps(__mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtph2ps

Convert packed half-precision (16-bit) floating-point elements in a to packed single-precision (32-bit) floating-point elements, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_cvt_roundps_ph

```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtps2ph

Convert packed single-precision (32-bit) floating-point elements in `a` to packed half-precision (16-bit) floating-point elements, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_mask_cvtps_ph_**

```markdown
_m128i _mm256_mask_cvtps_ph(_m128i src, __mmask8 k, __m256 a, int rounding)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtps2ph

Convert packed single-precision (32-bit) floating-point elements in `a` to packed half-precision (16-bit) floating-point elements, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_cvt_roundps_ph_**

```markdown
__m128i _mm256_maskz_cvt_roundps_ph(__mmask8 k, __m256 a, int rounding)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtps2ph

Convert packed single-precision (32-bit) floating-point elements in `a` to packed half-precision (16-bit) floating-point elements, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtps2ph

Convert packed single-precision (32-bit) floating-point elements in \(a\) to packed half-precision (16-bit) floating-point elements, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm256\_maskz\_cvtps\_ph

\_m256i \_mm256\_maskz\_cvtps\_ph(\_mmask8 k, \_m256 a, int rounding)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtps2ph

Convert packed single-precision (32-bit) floating-point elements in \(a\) to packed half-precision (16-bit) floating-point elements, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm\_mask\_cvtepi32\_pd

\_m128d \_mm\_mask\_cvtepi32\_pd(\_m128d src, \_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtdq2pd

Convert packed 32-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm\_maskz\_cvtepi32\_pd

\_m128d \_mm\_maskz\_cvtepi32\_pd(\_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtdq2pd

Convert packed 32-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm256\_mask\_cvtepi32\_pd

\_m256d \_mm256\_mask\_cvtepi32\_pd(\_m256d src, \_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtdq2pd

Convert packed 32-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm256\_maskz\_cvtepi32\_pd

\_m256d \_mm256\_maskz\_cvtepi32\_pd(\_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vcvtdq2pd

Convert packed 32-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).
**_mm_mask_cvt_epi32_ps_**

```c
__m128 _mm_mask_cvt_epi32_ps(__m128 src, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtdq2ps

Convert packed 32-bit integers in `a` to packed single-precision (32-bit) floating-point elements, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_cvt_epi32_ps_**

```c
__m128 _mm_maskz_cvt_epi32_ps(__mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtdq2ps

Convert packed 32-bit integers in `a` to packed single-precision (32-bit) floating-point elements, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_cvt_epi32_ps_**

```c
__m256 _mm256_mask_cvt_epi32_ps(__m256 src, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtdq2ps

Convert packed 32-bit integers in `a` to packed single-precision (32-bit) floating-point elements, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_cvt_epi32_ps_**

```c
__m256 _mm256_maskz_cvt_epi32_ps(__mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtdq2ps

Convert packed 32-bit integers in `a` to packed single-precision (32-bit) floating-point elements, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_cvt_pd_epi32_**

```c
__m128i _mm_mask_cvt_pd_epi32(__m128i src, __mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtpd2dq

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 32-bit integers, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_cvt_pd_epi32_**

```c
__m128i _mm_maskz_cvt_pd_epi32(__mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vcvtpd2dq

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 32-bit integers, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
Convert packed double-precision (64-bit) floating-point elements in `a` to packed 32-bit integers, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 32-bit integers, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results.
**_mm256_mask_cvtpd_epi64_**

```c
__m256i __mm256_mask_cvtpd_epi64(__m256i src, __mmask8 k, __m256d a)
```

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vcvtpd2qq

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_cvtpd_epi64_**

```c
__m256i __mm256_maskz_cvtpd_epi64(__mmask8 k, __m256d a)
```

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vcvtpd2qq

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_cvt_roundpd_epi64_**

```c
__m512i __mm512_cvt_roundpd_epi64(__m512d a, int rounding)
```

CPUID Flags: AVX512DQ

Instruction(s): vcvtpd2qq

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results.

**_mm512_cvtpd_epi64_**

```c
__m512i __mm512_cvtpd_epi64(__m512d a)
```

CPUID Flags: AVX512DQ

Instruction(s): vcvtpd2qq

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results.

**_mm512_mask_cvt_roundpd_epi64_**

```c
__m512i __mm512_mask_cvt_roundpd_epi64(__m512i src, __mmask8 k, __m512d a, int rounding)
```

CPUID Flags: AVX512DQ

Instruction(s): vcvtpd2qq

Convert packed double-precision (64-bit) floating-point elements in `a` to packed 64-bit integers, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm512_mask_cvtpd_epi64_**

```c
__m512i __mm512_mask_cvtpd_epi64(__m512i src, __mmask8 k, __m512d a)

Instruction(s): vcvtqq2pd

Convert packed 64-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{__mm256\_cvtepi64\_pd}
\]

\[
\_m256d\ _\text{mm256\_cvtepi64\_pd}(\_\text{m256i}\ a)
\]

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vcvtqq2pd

Convert packed 64-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results.

\[
\text{__mm256\_mask\_cvtepi64\_pd}
\]

\[
\_m256d\ _\text{mm256\_mask\_cvtepi64\_pd}(\_\text{m256d}\ src,\ _\text{mmask8}\ k,\ _\text{m256i}\ a)
\]

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vcvtqq2pd

Convert packed 64-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\text{__mm256\_maskz\_cvtepi64\_pd}
\]

\[
\_m256d\ _\text{mm256\_maskz\_cvtepi64\_pd}(\_\text{mmask8}\ k,\ _\text{m256i}\ a)
\]

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vcvtqq2pd

Convert packed 64-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{__mm512\_cvtepi64\_pd}
\]

\[
\_m512d\ _\text{mm512\_cvtepi64\_pd}(\_\text{m512i}\ a)
\]

CPUID Flags: AVX512DQ
Instruction(s): vcvtqq2pd

Convert packed 64-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results.

\[
\text{__mm512\_cvt\_roundepi64\_pd}
\]

\[
\_m512d\ _\text{mm512\_cvt\_roundepi64\_pd}(\_\text{m512i}\ a,\ \text{int}\ \text{rounding})
\]

CPUID Flags: AVX512DQ
Instruction(s): vcvtqq2pd

Convert packed 64-bit integers in \(a\) to packed double-precision (64-bit) floating-point elements, and return the results.
Instruction(s): vcvtqq2pd
Convert packed 64-bit integers in a to packed double-precision (64-bit) floating-point elements, and return the results.

__mm512_mask_cvt_roundepi64_pd

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdb
Convert packed 32-bit integers in a to packed 8-bit integers with truncation, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_cvtepi32_epi8

__m128i_mm256_cvtepi32_epi8(__m256i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdb
Convert packed 32-bit integers in a to packed 8-bit integers with truncation, and return the results.

_mm256_mask_cvtepi32_epi8

__m128i_mm256_mask_cvtepi32_epi8(__m128i src, __mmask8 k, __m256i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdb
Convert packed 32-bit integers in a to packed 8-bit integers with truncation, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_cvtepi32_epi8

__m128i_mm256_maskz_cvtepi32_epi8(__mmask8 k, __m256i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdb
Convert packed 32-bit integers in a to packed 8-bit integers with truncation, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_cvtepi32_epi16

__m128i_mm_cvtepi32_epi16(__m128i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdw
Convert packed 32-bit integers in a to packed 16-bit integers with truncation, and return the results.

_mm_mask_cvtepi32_epi16

__m128i_mm_mask_cvtepi32_epi16(__m128i src, __mmask8 k, __m128i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdw
Convert packed 32-bit integers in a to packed 16-bit integers with truncation, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
__mm_maskz_cvtepi32_epi16

```
__m128i __mm_maskz_cvtepi32_epi16(__mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovd

Convert packed 32-bit integers in a to packed 16-bit integers with truncation, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_cvtepi32_epi16

```
__m128i __mm256_cvtepi32_epi16(__m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovd

Convert packed 32-bit integers in a to packed 16-bit integers with truncation, and return the results.

__mm256_mask_cvtepi32_epi16

```
__m128i __mm256_mask_cvtepi32_epi16(__m256i src, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovd

Convert packed 32-bit integers in a to packed 16-bit integers with truncation, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_cvtepi32_epi16

```
__m128i __mm256_maskz_cvtepi32_epi16(__mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovd

Convert packed 32-bit integers in a to packed 16-bit integers with truncation, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_cvtepi64_epi8

```
__m128i __mm_cvtepi64_epi8(__m128i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovqb

Convert packed 64-bit integers in a to packed 8-bit integers with truncation, and return the results.

__mm_mask_cvtepi64_epi8

```
__m128i __mm_mask_cvtepi64_epi8(__m128i src, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovqb

Convert packed 64-bit integers in a to packed 8-bit integers with truncation, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm_maskz_cvtepi64_epi8

__m128i _mm_maskz_cvtepi64_epi8(__mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL

\[
\quad \_m128i \_mm\_cvtusepi64\_epi16(\_m128i \ a)
\]

CPUID Flags: AVX512F, AVX512VL  
Instruction(s): vpmovusqw

Convert packed unsigned 64-bit integers in \( a \) to packed unsigned 16-bit integers with unsigned saturation, and return the results.

\[
\_mm\_mask\_cvtusepi64\_epi16
\]

\[
\quad \_m128i \_mm\_mask\_cvtusepi64\_epi16(\_m128i \ src, \_mmask8 \ k, \_m128i \ a)
\]

CPUID Flags: AVX512F, AVX512VL  
Instruction(s): vpmovusqw

Convert packed unsigned 64-bit integers in \( a \) to packed unsigned 16-bit integers with unsigned saturation, and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
\_mm\_maskz\_cvtusepi64\_epi16
\]

\[
\quad \_m128i \_mm\_maskz\_cvtusepi64\_epi16(\_mmask8 \ k, \_m128i \ a)
\]

CPUID Flags: AVX512F, AVX512VL  
Instruction(s): vpmovusqw

Convert packed unsigned 64-bit integers in \( a \) to packed unsigned 16-bit integers with unsigned saturation, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_mm256\_cvtusepi64\_epi16
\]

\[
\quad \_m128i \_mm256\_cvtusepi64\_epi16(\_m256i \ a)
\]

CPUID Flags: AVX512F, AVX512VL  
Instruction(s): vpmovusqw

Convert packed unsigned 64-bit integers in \( a \) to packed unsigned 16-bit integers with unsigned saturation, and return the results.

\[
\_mm256\_mask\_cvtusepi64\_epi16
\]

\[
\quad \_m128i \_mm256\_mask\_cvtusepi64\_epi16(\_m128i \ src, \_mmask8 \ k, \_m256i \ a)
\]

CPUID Flags: AVX512F, AVX512VL  
Instruction(s): vpmovusqw

Convert packed unsigned 64-bit integers in \( a \) to packed unsigned 16-bit integers with unsigned saturation, and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).
**_mm256_maskz_cvtusepi64_epi16_**

```c
__m256i _mm256_maskz_cvtusepi64_epi16(__mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovusqw

Convert packed unsigned 64-bit integers in `a` to packed unsigned 16-bit integers with unsigned saturation, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm_cvtusepi16_epi8_**

```c
__m128i _mm_cvtusepi16_epi8(__m128i a)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results.

**_mm_mask_cvtusepi16_epi8_**

```c
__m128i _mm_mask_cvtusepi16_epi8(__m128i src, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_cvtusepi16_epi8_**

```c

```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results.

**_mm256_mask_cvtusepi16_epi8_**

```c
__m256i _mm256_mask_cvtusepi16_epi8(__m128i src, __mmask16 k, __m256i a)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results.
Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

`_mm256_maskz_cvtusepi16_epi8`

\[
\text{__m128i } \_\text{mm256}_{\text{maskz}}\_\text{cvtusepi16}_{\text{_epi8}}(\_\text{mmask16 } k, \_\text{m256i } a)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

`_mm512_cvtusepi16_epi8`

\[
\text{__m256i } \_\text{mm512}_{\text{cvtusepi16}}\_\text{_epi8}(\_\text{m512i } a)
\]

CPUID Flags: AVX512BW
Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

`_mm512_mask_cvtusepi16_epi8`

\[
\text{__m256i } \_\text{mm512}_{\text{mask}}\_\text{cvtusepi16}_{\text{_epi8}}(\_\text{mmask32 } k, \_\text{m512i } a)
\]

CPUID Flags: AVX512BW
Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

`_mm512_maskz_cvtusepi16_epi8`

\[
\text{__m256i } \_\text{mm512}_{\text{maskz}}\_\text{cvtusepi16}_{\text{_epi8}}(\_\text{mmask32 } k, \_\text{m512i } a)
\]

CPUID Flags: AVX512BW
Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in `a` to packed unsigned 8-bit integers with unsigned saturation, and return the results.

`_mm_cvtepi16_epi8`

\[
\text{__m128i } \_\text{mm}_{\text{cvtepi16}}\_\text{epi8}(\_\text{m128i } a)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovwb

Convert packed 16-bit integers in `a` to packed 8-bit integers with truncation, and return the results.

`_mm_mask_cvtepi16_epi8`

\[
\text{__m128i } \_\text{mm}_{\text{mask}}\_\text{cvtepi16}_{\text{_epi8}}(\_\text{m128i } src, \_\text{mmask8 } k, \_\text{m128i } a)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovwb
Convert packed 16-bit integers in a to packed 8-bit integers with truncation, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_cvtepi16_epi8

__m128i _mm_maskz_cvtepi16_epi8(__mmask8 k, __m128i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovwb
Convert packed 16-bit integers in a to packed 8-bit integers with truncation, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_cvtepi16_epi8

__m128i _mm256_cvtepi16_epi8(__m256i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovwb
Convert packed 16-bit integers in a to packed 8-bit integers with truncation, and return the results.

_mm256_mask_cvtepi16_epi8

__m128i _mm256_mask_cvtepi16_epi8(__m256i src, __mmask16 k, __m256i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovwb
Convert packed 16-bit integers in a to packed 8-bit integers with truncation, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_cvtepi16_epi8

__m128i _mm256_maskz_cvtepi16_epi8(__mmask16 k, __m256i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpmovwb
Convert packed 16-bit integers in a to packed 8-bit integers with truncation, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtepi16_epi8

__m256i _mm512_cvtepi16_epi8(__m512i a)

CPUID Flags: AVX512BW

Instruction(s): vpmovwb
Convert packed 16-bit integers in a to packed 8-bit integers with truncation, and return the results.

_mm512_mask_cvtepi16_epi8

__m256i _mm512_mask_cvtepi16_epi8(__m512i src, __mmask32 k, __m512i a)

CPUID Flags: AVX512BW

Instruction(s): vpmovwb
Convert packed 16-bit integers in `a` to packed 8-bit integers with truncation, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m512__m512_maskz_cvtepi16_epi8
    __m512i __m512_maskz_cvtepi16_epi8(__mmask32 k, __m512i a)
CPUID Flags: AVX512BW
Instruction(s): vpmovwb
```

Convert packed 16-bit integers in `a` to packed 8-bit integers with truncation, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
__m_mask_cvtepu8_epi32
    __m128i __m_mask_cvtepu8_epi32(__m128i src, __mmask8 k, __m128i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovzxbd
```

Zero extend packed unsigned 8-bit integers in the low 4 bytes of `a` to packed 32-bit integers, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m_maskz_cvtepu8_epi32
    __m128i __m_maskz_cvtepu8_epi32(__mmask8 k, __m128i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovzxbd
```

Zero extend packed unsigned 8-bit integers in the low 8 bytes of `a` to packed 32-bit integers, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m256__m256_mask_cvtepu8_epi32
    __m256i __m256_mask_cvtepu8_epi32(__m256i src, __mmask8 k, __m256i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovzxbd
```

Zero extend packed unsigned 8-bit integers in the low 8 bytes of `a` to packed 32-bit integers, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
__m256__m256_maskz_cvtepu8_epi32
    __m256i __m256_maskz_cvtepu8_epi32(__mmask8 k, __m256i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovzxbd
```

Zero extend packed unsigned 8-bit integers in the low 8 bytes of `a` to packed 32-bit integers, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
__m_mask_cvtepu8_epi64

__m512i _mm512_packus_epi16(__m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpackuswb
Convert packed 16-bit integers from a and b to packed 8-bit integers using unsigned saturation, and return the results.

_mm_mask_cvtepi32_storeu_epi8

void _mm_mask_cvtepi32_storeu_epi8(void* base_addr, __mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdb
Convert packed 32-bit integers in a to packed 8-bit integers with truncation, and store the active results (those with their respective bit set in writemask k) to unaligned memory at base_addr.

_mm256_mask_cvtepi32_storeu_epi8

void _mm256_mask_cvtepi32_storeu_epi8(void* base_addr, __mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpmovdb
Convert packed 32-bit integers in a to packed 8-bit integers with truncation, and store the active results (those with their respective bit set in writemask k) to unaligned memory at base_addr.
**_mm_mask_cvtepi32_storeu_epi16_**

```c
void _mm_mask_cvtepi32_storeu_epi16(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovdw

Convert packed 32-bit integers in `a` to packed 16-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

**_mm256_mask_cvtepi32_storeu_epi16_**

```c
void _mm256_mask_cvtepi32_storeu_epi16(void* base_addr, __mmask8 k, _m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovdw

Convert packed 32-bit integers in `a` to packed 16-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

**_mm_mask_cvtepi64_storeu_epi8_**

```c
void _mm_mask_cvtepi64_storeu_epi8(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovqb

Convert packed 64-bit integers in `a` to packed 8-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

**_mm256_mask_cvtepi64_storeu_epi8_**

```c
void _mm256_mask_cvtepi64_storeu_epi8(void* base_addr, __mmask8 k, _m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovqb

Convert packed 64-bit integers in `a` to packed 8-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

**_mm_mask_cvtepi64_storeu_epi32_**

```c
void _mm_mask_cvtepi64_storeu_epi32(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovqd

Convert packed 64-bit integers in `a` to packed 32-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

**_mm256_mask_cvtepi64_storeu_epi32_**

```c
void _mm256_mask_cvtepi64_storeu_epi32(void* base_addr, __mmask8 k, _m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovqd

Convert packed 64-bit integers in `a` to packed 32-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.
_mm_mask_cvtepi64_storeu_epi16

```c
void _mm_mask_cvtepi64_storeu_epi16(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovqvw

Convert packed 64-bit integers in `a` to packed 16-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm256_mask_cvtepi64_storeu_epi16

```c
void _mm256_mask_cvtepi64_storeu_epi16(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovqvw

Convert packed 64-bit integers in `a` to packed 16-bit integers with truncation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm_mask_cvtsepi32_storeu_epi8

```c
void _mm_mask_cvtsepi32_storeu_epi8(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsdb

Convert packed 32-bit integers in `a` to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm256_mask_cvtsepi32_storeu_epi8

```c
void _mm256_mask_cvtsepi32_storeu_epi8(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsdb

Convert packed 32-bit integers in `a` to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm_mask_cvtsepi32_storeu_epi16

```c
void _mm_mask_cvtsepi32_storeu_epi16(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsdw

Convert packed 32-bit integers in `a` to packed 16-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

_mm256_mask_cvtsepi32_storeu_epi16

```c
void _mm256_mask_cvtsepi32_storeu_epi16(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsdw

Convert packed 32-bit integers in `a` to packed 16-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base addr`.
_mm_mask_cvtsepi64_storeu_epi8

```c
void _mm_mask_cvtsepi64_storeu_epi8(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsqb

Convert packed 64-bit integers in `a` to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

__mm256_mask_cvtsepi64_storeu_epi8

```c
void __mm256_mask_cvtsepi64_storeu_epi8(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsqb

Convert packed 64-bit integers in `a` to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

__mm_mask_cvtsepi64_storeu_epi32

```c
void __mm_mask_cvtsepi64_storeu_epi32(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsqd

Convert packed 64-bit integers in `a` to packed 32-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

__mm256_mask_cvtsepi64_storeu_epi32

```c
void __mm256_mask_cvtsepi64_storeu_epi32(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsqd

Convert packed 64-bit integers in `a` to packed 32-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

__mm_mask_cvtsepi64_storeu_epi16

```c
void __mm_mask_cvtsepi64_storeu_epi16(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsqw

Convert packed 64-bit integers in `a` to packed 16-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`.

__mm256_mask_cvtsepi64_storeu_epi16

```c
void __mm256_mask_cvtsepi64_storeu_epi16(void* base_addr, __mmask8 k, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpmovsqw

Convert packed 64-bit integers in `a` to packed 16-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask `k`) to unaligned memory at `base_addr`. 
Convert packed 64-bit integers in \( a \) to packed 16-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask \( k \)) to unaligned memory at \( base \_ addr \).

\[
\text{\_mm\_mask\_cvtsepi16\_storeu\_epi8}
\]
\[
\text{void _mm_mask_cvtsepi16_storeu_epi8(\*base_addr, __mmask8 k, __m128i a)}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovswb

Convert packed 16-bit integers in \( a \) to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask \( k \)) to unaligned memory at \( base \_ addr \).

\[
\text{\_mm256\_mask\_cvtsepi16\_storeu\_epi8}

\]

CPUID Flags: AVX512BW
Instruction(s): vpmovuswb

Convert packed unsigned 16-bit integers in \( a \) to packed unsigned 8-bit integers with unsigned saturation, and store the active results (those with their respective bit set in writemask \( k \)) to unaligned memory at \( base_{addr} \).
_mm_mask_cvtepi16_storeu_epi8

```c
void _mm_mask_cvtepi16_storeu_epi8(void* base_addr, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovwb

Convert packed 16-bit integers in \( a \) to packed 8-bit integers with truncation, and store the active results (those with their respective bit set in writemask \( k \)) to unaligned memory at \( base\_addr \).

__mm256_mask_cvtepi16_storeu_epi8

```c
void __mm256_mask_cvtepi16_storeu_epi8(void* base_addr, __mmask16 k, __m256i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovwb

Convert packed 16-bit integers in \( a \) to packed 8-bit integers with truncation, and store the active results (those with their respective bit set in writemask \( k \)) to unaligned memory at \( base\_addr \).

__mm512_mask_cvtepi16_storeu_epi8

```c
void __mm512_mask_cvtepi16_storeu_epi8(void* base_addr, __mmask32 k, __m512i a)
```

CPUID Flags: AVX512BW
Instruction(s): vpmovwb

Convert packed 16-bit integers in \( a \) to packed 8-bit integers with truncation, and store the active results (those with their respective bit set in writemask \( k \)) to unaligned memory at \( base\_addr \).

**Intrinsics for Load Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>k</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>mem_addr</td>
<td>pointer to base address in memory</td>
</tr>
<tr>
<td>base_addr</td>
<td>pointer to base address in memory to begin load or store operation</td>
</tr>
</tbody>
</table>

__mm_mask_expandloadu_pd

```c
__m128d __mm_mask_expandloadu_pd(__m128d src, __mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vexpandpd
Load as many contiguous double-precision (64-bit) floating-point elements from unaligned memory at `mem_addr` as there are ones in the low 2 bits of mask `k`, and place them in the result element positions corresponding to the positions of the ones in the mask (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_expandloadu_pd**

```c
_m128d _mm_maskz_expandloadu_pd(__mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vexpandpd

Load as many contiguous double-precision (64-bit) floating-point elements from unaligned memory at `mem_addr` as there are ones in the low 2 bits of mask `k`, and place them in the result element positions corresponding to the positions of the ones in the mask (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_expandloadu_pd**

```c
_m256d _mm256_mask_expandloadu_pd(__m256d src, __mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vexpandpd

Load as many contiguous double-precision (64-bit) floating-point elements from unaligned memory at `mem_addr` as there are ones in the low 4 bits of mask `k`, and place them in the result element positions corresponding to the positions of the ones in the mask (elements are copied from `src` when the corresponding mask bit is not set).

**_mm256_maskz_expandloadu_pd**

```c
_m256d _mm256_maskz_expandloadu_pd(__mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vexpandpd

Load as many contiguous double-precision (64-bit) floating-point elements from unaligned memory at `mem_addr` as there are ones in the low 4 bits of mask `k`, and place them in the result element positions corresponding to the positions of the ones in the mask (elements are zeroed out when the corresponding mask bit is not set).

**_mm_mask_expandloadu_ps**

```c
_m128 _mm_mask_expandloadu_ps(__m128 src, __mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vexpandps

Load as many contiguous single-precision (32-bit) floating-point elements from unaligned memory at `mem_addr` as there are ones in the low 4 bits of mask `k`, and place them in the result element positions corresponding to the positions of the ones in the mask (elements are copied from `src` when the corresponding mask bit is not set).

**_mm_maskz_expandloadu_ps**

```c
_m128 _mm_maskz_expandloadu_ps(__mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Load as many contiguous single-precision (32-bit) floating-point elements from unaligned memory at `mem_addr` as there are ones in the low 4 bits of mask `k`, and place them in the result element positions corresponding to the positions of the ones in the mask (elements are zeroed out when the corresponding mask bit is not set).
Instruction(s): vexpandps
Load as many contiguous single-precision (32-bit) floating-point elements from unaligned memory at
\textit{mem\_addr} as there are ones in the low 4 bits of mask \textit{k}, and place them in the result element positions
 corresponding to the positions of the ones in the mask (elements are zeroed out when the corresponding
 mask bit is not set).

\_mm256\_mask\_expandloadu\_ps
\begin{verbatim}
\_m256 \_mm256\_mask\_expandloadu\_ps(\_m256 src, \_mmask8 k, void const* mem\_addr)
\end{verbatim}
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vexpandps
Load as many contiguous single-precision (32-bit) floating-point elements from unaligned memory at
\textit{mem\_addr} as there are ones in the low 8 bits of mask \textit{k}, and place them in the result element positions
 corresponding to the positions of the ones in the mask (elements are copied from \textit{src} when the
 corresponding mask bit is not set).

\_mm256\_maskz\_expandloadu\_ps
\begin{verbatim}
\_m256 \_mm256\_maskz\_expandloadu\_ps(\_mmask8 k, void const* mem\_addr)
\end{verbatim}
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vexpandps
Load as many contiguous single-precision (32-bit) floating-point elements from unaligned memory at
\textit{mem\_addr} as there are ones in the low 8 bits of mask \textit{k}, and place them in the result element positions
 corresponding to the positions of the ones in the mask (elements are zeroed out when the corresponding
 mask bit is not set).

\_mm\_mmask\_i32gather\_pd
\begin{verbatim}
\_m128d \_mm\_mmask\_i32gather\_pd(\_m128d src, \_mmask8 k, \_m128i vindex, void const* base\_addr,
const int scale)
\end{verbatim}
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vgatherdpd
Gather double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements
 are loaded from addresses starting at \textit{base\_addr} and offset by each 32-bit element in \textit{vindex} (each index is
 scaled by the factor in \textit{scale}). Gathered elements are merged into the return value using writemask \textit{k}
 (elements are copied from \textit{src} when the corresponding mask bit is not set). \textit{scale} should be 1, 2, 4 or 8.

\_mm256\_mmask\_i32gather\_pd
\begin{verbatim}
\_m256d \_mm256\_mmask\_i32gather\_pd(\_m256d src, \_mmask8 k, \_m128i vindex, void const* base\_addr, 
const int scale)
\end{verbatim}
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vgatherdpd
Gather double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements
 are loaded from addresses starting at \textit{base\_addr} and offset by each 32-bit element in \textit{vindex} (each index is
 scaled by the factor in \textit{scale}). Gathered elements are merged into the return value using writemask \textit{k}
 (elements are copied from \textit{src} when the corresponding mask bit is not set). \textit{scale} should be 1, 2, 4 or 8.
_mm_mask_i32gather_ps

_mm_mask_i32gather_ps(__m128 src, __mmask8 k, __m128i vindex, void const* base_addr, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vgatherdps

Gather single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_mm256_mask_i32gather_ps

_mm256_mask_i32gather_ps(__m256 src, __mmask8 k, __m256i vindex, void const* base_addr, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vgatherdps

Gather single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at base_addr and offset by each 32-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_mm_mask_i64gather_pd

_mm_mask_i64gather_pd(__m128d src, __mmask8 k, __m128i vindex, void const* base_addr, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vgatherqpd

Gather double-precision (64-bit) floating-point elements from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_mm256_mask_i64gather_pd

_mm256_mask_i64gather_pd(__m256d src, __mmask8 k, __m256i vindex, void const* base_addr, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vgatherqpd

Gather double-precision (64-bit) floating-point elements from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.

_mm_mask_i64gather_ps

_mm_mask_i64gather_ps(__m128 src, __mmask8 k, __m128i vindex, void const* base_addr, const int scale)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vgatherqpd

Gather double-precision (64-bit) floating-point elements from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at base_addr and offset by each 64-bit element in vindex (each index is scaled by the factor in scale). Gathered elements are merged into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set). scale should be 1, 2, 4 or 8.
Instruction(s): vgatherqps
Gather single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`). Gathered elements are merged into the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

```c
__m256_mm_mask_i64gather_ps
    __m128d __m256_mm_mask_i64gather_ps(__m128 src, __mmask8 k, __m256i vindex, void const* base_addr,
    const int scale)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vgatherqps
Gather single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`). Gathered elements are merged into the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

```c
__mm_mask_load_pd
    __m128d __mm_mask_load_pd(__m128d src, __mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmmovapd
Load packed double-precision (64-bit) floating-point elements from memory into the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set). `mem_addr` must be aligned on a 16-byte boundary or a general-protection exception may be generated.

```c
__mm_maskz_load_pd
    __m128d __mm_maskz_load_pd(__mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmmovapd
Load packed double-precision (64-bit) floating-point elements from memory into the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set). `mem_addr` must be aligned on a 16-byte boundary or a general-protection exception may be generated.

```c
__m256_mask_load_pd
    __m256d __m256_mask_load_pd(__m256d src, __mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmmovapd
Load packed double-precision (64-bit) floating-point elements from memory into the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set). `mem_addr` must be aligned on a 32-byte boundary or a general-protection exception may be generated.

```c
__m256_maskz_load_pd
    __m256d __m256_maskz_load_pd(__mmask8 k, void const* mem_addr)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovapd
Load packed double-precision (64-bit) floating-point elements from memory into the return value using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set). $\text{mem\_addr}$ must be aligned on a 32-byte boundary or a general-protection exception may be generated.

```
__mm_mask_load_ps

```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpgatherqq

Gather 64-bit integers from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at `base_addr` and offset by each 64-bit element in `vindex` (each index is scaled by the factor in `scale`). Gathered elements are merged into the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set). `scale` should be 1, 2, 4 or 8.

**Intrinsics for Logical Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>k</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>a</td>
<td>first source vector element</td>
</tr>
<tr>
<td>b</td>
<td>second source vector element</td>
</tr>
<tr>
<td>c</td>
<td>third source vector element</td>
</tr>
<tr>
<td>imm</td>
<td>comparison predicate, which can be any of the following values:</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_EQ - Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_LT - Less than</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_LE - Less than or Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_NE - Not Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_NLT - Not Less than</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_GE - Greater than or Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_NLE - Not Less than or Equal</td>
</tr>
<tr>
<td></td>
<td>• _MM_CMPINT_GT - Greater than</td>
</tr>
</tbody>
</table>

**_mm_mask_andnot_pd**

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vandpd

Compute the bitwise AND of packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[\text{_mm256\_maskz\_and\_pd}\]
\[
\text{_m256d \_mm256\_maskz\_and\_pd(\_mmask8 k, \_m256d a, \_m256d b)}
\]

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vandpd

Compute the bitwise AND of packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[\text{_mm512\_and\_pd}\]
\[
\text{_m512d \_mm512\_and\_pd(\_m512d a, \_m512d b)}
\]

CPUID Flags: AVX512DQ

Instruction(s): vandpd

Compute the bitwise AND of packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results.

\[\text{_mm512\_mask\_and\_pd}\]
\[
\text{_m512d \_mm512\_mask\_and\_pd(\_m512d src, \_mmask8 k, \_m512d a, \_m512d b)}
\]

CPUID Flags: AVX512DQ
Instruction(s): vandpd

Compute the bitwise AND of packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\_mm512\_maskz\_and\_pd
\]

\[
_m512d\ _mm512\_maskz\_and\_pd(_mmask8\ k,\ _m512d\ a,\ _m512d\ b)
\]

CPUID Flags: AVX512DQ

Instruction(s): vandpd

Compute the bitwise AND of packed double-precision (64-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_mm\_mask\_and\_ps
\]

\[
_ml28\ _mm\_mask\_and\_ps(_ml28\ src,\ _mmask8\ k,\ _ml28\ a,\ _ml28\ b)
\]

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vandps

Compute the bitwise AND of packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\_mm\_maskz\_and\_ps
\]

\[
_ml28\ _mm\_maskz\_and\_ps(_mmask8\ k,\ _ml28\ a,\ _ml28\ b)
\]

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vandps

Compute the bitwise AND of packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_mm256\_mask\_and\_ps
\]

\[
_m256\ _mm256\_mask\_and\_ps(_m256\ src,\ _mmask8\ k,\ _m256\ a,\ _m256\ b)
\]

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vandps

Compute the bitwise AND of packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
\_mm256\_maskz\_and\_ps
\]

\[
_m256\ _mm256\_maskz\_and\_ps(_mmask8\ k,\ _m256\ a,\ _m256\ b)
\]

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vandps

Compute the bitwise AND of packed single-precision (32-bit) floating-point elements in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\_mm512\_and\_ps
\]

\[
_m512\ _mm512\_and\_ps(_m512\ a,\ _m512\ b)
\]
CPUID Flags: AVX512DQ
Instruction(s): vandps
Compute the bitwise AND of packed single-precision (32-bit) floating-point elements in a and b, and return the results.

_mm512_mask_and_ps

_mm512_mm512_mask_and_ps(__m512 src, __mmask16 k, __m512 a, __m512 b)

CPUID Flags: AVX512DQ
Instruction(s): vandps
Compute the bitwise AND of packed single-precision (32-bit) floating-point elements in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_and_ps

_mm512_mm512_maskz_and_ps(__mmask16 k, __m512 a, __m512 b)

CPUID Flags: AVX512DQ
Instruction(s): vandps
Compute the bitwise AND of packed single-precision (32-bit) floating-point elements in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_or_pd

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpord

Compute the bitwise OR of packed 32-bit integers in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

__mm256_maskz_or_epi32

__m256i __mm256_maskz_or_epi32(__mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpord

Compute the bitwise OR of packed 32-bit integers in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_or_epi64

__m128i __mm_mask_or_epi64(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vporq

Compute the bitwise OR of packed 64-bit integers in \(a\) and \(b\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

__mm_maskz_or_epi64

__m128i __mm_maskz_or_epi64(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vporq

Compute the bitwise OR of packed 64-bit integers in \(a\) and \(b\), and return the results using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).
_mm256_mask_or_epi64

```c
__m256i _mm256_mask_or_epi64(__m256i src, __mmask8 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vporq

Compute the bitwise OR of packed 64-bit integers in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm256_maskz_or_epi64

```c
__m256i _mm256_maskz_or_epi64(__mmask8 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vporq

Compute the bitwise OR of packed 64-bit integers in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_ternarylogic_epi32

```c
__m128i _mm_mask_ternarylogic_epi32(__m128i src, __mmask8 k, __m128i a, __m128i b, int imm8)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogd

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 32-bit integer, the corresponding bit from `src`, `a`, and `b` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value using writemask `k` at 32-bit granularity (32-bit elements are copied from `src` when the corresponding mask bit is not set).

_mm_maskz_ternarylogic_epi32

```c
__m128i _mm_maskz_ternarylogic_epi32(__mmask8 k, __m128i a, __m128i b, __m128i c, int imm8)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogd

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 32-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value using zeromask `k` at 32-bit granularity (32-bit elements are zeroed out when the corresponding mask bit is not set).

_mm_ternarylogic_epi32

```c
__m128i _mm_ternarylogic_epi32(__m128i a, __m128i b, __m128i c, int imm8)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogd

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 32-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value.
__m256_mask_ternarylogic_epi32

__m256i __m256_mask_ternarylogic_epi32(__m256i src, __mmask8 k, __m256i a, __m256i b, int imm8)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogd

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in imm8. For each bit in each packed 32-bit integer, the corresponding bit from src, a, and b are used to form a 3 bit index into imm8, and the value at that bit in imm8 is written to the corresponding bit in the return value using writemask k at 32-bit granularity (32-bit elements are copied from src when the corresponding mask bit is not set).

__m256_maskz_ternarylogic_epi32

__m256i __m256_maskz_ternarylogic_epi32(__mmask8 k, __m256i a, __m256i b, __m256i c, int imm8)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogd

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in imm8. For each bit in each packed 32-bit integer, the corresponding bit from a, b, and c are used to form a 3 bit index into imm8, and the value at that bit in imm8 is written to the corresponding bit in the return value using zeromask k at 32-bit granularity (32-bit elements are zeroed out when the corresponding mask bit is not set).

__m256_ternarylogic_epi32

__m256i __m256_ternarylogic_epi32(__m256i a, __m256i b, __m256i c, int imm8)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogd

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in imm8. For each bit in each packed 32-bit integer, the corresponding bit from a, b, and c are used to form a 3 bit index into imm8, and the value at that bit in imm8 is written to the corresponding bit in the return value.

__m128i_mask_ternarylogic_epi64

__m128i __m128i_mask_ternarylogic_epi64(__m128i src, __mmask8 k, __m128i a, __m128i b, int imm8)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogq

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in imm8. For each bit in each packed 64-bit integer, the corresponding bit from src, a, and b are used to form a 3 bit index into imm8, and the value at that bit in imm8 is written to the corresponding bit in the return value using writemask k at 64-bit granularity (64-bit elements are copied from src when the corresponding mask bit is not set).

__m128i_maskz_ternarylogic_epi64

__m128i __m128i_maskz_ternarylogic_epi64(__mmask8 k, __m128i a, __m128i b, __m128i c, int imm8)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogq

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in imm8. For each bit in each packed 64-bit integer, the corresponding bit from a, b, and c are used to form a 3 bit index into imm8, and the value at that bit in imm8 is written to the corresponding bit in the return value using zeromask k at 64-bit granularity (64-bit elements are zeroed out when the corresponding mask bit is not set).
Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 64-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value using zeromask `k` at 64-bit granularity (64-bit elements are zeroed out when the corresponding mask bit is not set).

```c
_mm_ternarylogic_epi64
__m128i _mm_ternarylogic_epi64(__m128i a, __m128i b, __m128i c, int imm8)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogq

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 64-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value.

```c
_mm256_mask_ternarylogic_epi64
__m256i _mm256_mask_ternarylogic_epi64(__m256i src, __mmask8 k, __m256i a, __m256i b, int imm8)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogq

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 64-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value using writemask `k` at 64-bit granularity (64-bit elements are copied from `src` when the corresponding mask bit is not set).

```c
_mm256_maskz_ternarylogic_epi64
__m256i _mm256_maskz_ternarylogic_epi64(__mmask8 k, __m256i a, __m256i b, __m256i c, int imm8)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogq

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 64-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value using zeromask `k` at 64-bit granularity (64-bit elements are zeroed out when the corresponding mask bit is not set).

```c
_mm256_ternarylogic_epi64
__m256i _mm256_ternarylogic_epi64(__m256i a, __m256i b, __m256i c, int imm8)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpternlogq

Bitwise ternary logic that provides the capability to implement any three-operand binary function; the specific binary function is specified by value in `imm8`. For each bit in each packed 64-bit integer, the corresponding bit from `a`, `b`, and `c` are used to form a 3 bit index into `imm8`, and the value at that bit in `imm8` is written to the corresponding bit in the return value.
_mm_mask_xor_epi32

__m128i _mm_mask_xor_epi32(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpxord

Compute the bitwise XOR of packed 32-bit integers in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_xor_epi32

__m128i _mm_maskz_xor_epi32(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpxord

Compute the bitwise XOR of packed 32-bit integers in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_xor_epi32

__m256i _mm256_mask_xor_epi32(__m256i src, __mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpxord

Compute the bitwise XOR of packed 32-bit integers in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_xor_epi32

__m256i _mm256_maskz_xor_epi32(__mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpxord

Compute the bitwise XOR of packed 32-bit integers in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_xor_epi64

__m128i _mm_mask_xor_epi64(__m128i src, __mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpxorq

Compute the bitwise XOR of packed 64-bit integers in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_xor_epi64

__m128i _mm_maskz_xor_epi64(__mmask8 k, __m128i a, __m128i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpxorq

Compute the bitwise XOR of packed 64-bit integers in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
**_mm256_mask_xor_epi64**

```c
__m256i _mm256_mask_xor_epi64(__m256i src, __mmask8 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpxorq

Compute the bitwise XOR of packed 64-bit integers in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

**_mm256_maskz_xor_epi64**

```c
__m256i _mm256_maskz_xor_epi64(__mmask8 k, __m256i a, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpxorq

Compute the bitwise XOR of packed 64-bit integers in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

**Intrinsics for Miscellaneous Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>k</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>a</td>
<td>first source vector element</td>
</tr>
<tr>
<td>b</td>
<td>second source vector element</td>
</tr>
<tr>
<td>c</td>
<td>third source vector element</td>
</tr>
</tbody>
</table>

**rounding**

Rounding control values; these can be one of the following (along with the sae suppress all exceptions flag):

- `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even
- `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity
- `_MM_FROUND_TO_POS_INF` - rounds to positive infinity
- `_MM_FROUND_TO_ZERO` - rounds to zero
- `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

**interv**

Where `_MM_MANTISSA_NORM_ENUM` can be one of the following:

- `_MM_MANT_NORM_1_2` - interval [1, 2)
- `_MM_MANT_NORM_p5_2` - interval [1.5, 2)
- `_MM_MANT_NORM_p5_1` - interval [1.5, 1)
- `_MM_MANT_NORM_p75_1p5` - interval [0.75, 1.5)
<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>sc</td>
<td>Where <code>_MM_MANTISSA_SIGN_ENUM</code> can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_MANT_SIGN_src</code> - <code>sign = sign(SRC)</code></td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_MANT_SIGN_zero</code> - <code>sign = 0</code></td>
</tr>
<tr>
<td></td>
<td>• <code>_MM_MANT_SIGN_nan</code> - <code>DEST = NaN</code> if <code>sign(SRC) = 1</code></td>
</tr>
</tbody>
</table>

```c
__m128i _mm_broadcast_i32x2(__m128i a)
```

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from `a` to all elements of "dst."

```c
__m128i _mm_mask_broadcast_i32x2(__m128i src, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from `a` to all elements of the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m128i _mm_maskz_broadcast_i32x2(__mmask8 k, __m128i a)
```

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from `a` to all elements of the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
__m256i _mm256_broadcast_i32x2(__m128i a)
```

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from `a` to all elements of "dst."

```c
__m256i _mm256_mask_broadcast_i32x2(__m256i src, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from `a` to all elements of the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
__mm256_maskz_broadcast_i32x2

__m256i __mm256_maskz_broadcast_i32x2(__m512i k, __m128i a)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm512_broadcast_i32x2

__m512i __mm512_broadcast_i32x2(__m128i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from a to all elements of "dst.

__mm512_mask_broadcast_i32x2

__m512i __mm512_mask_broadcast_i32x2(__m512i src, __mmask16 k, __m128i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm512_maskz_broadcast_i32x2

__m512i __mm512_maskz_broadcast_i32x2(__mmask16 k, __m128i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti32x2

Broadcast the lower 2 packed 32-bit integers from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_broadcast_i32x4

__m256i __mm256_broadcast_i32x4(__m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vbroadcasti32x4

Broadcast the 4 packed 32-bit integers from a to all elements of the return value.

__mm256_mask_broadcast_i32x4

__m256i __mm256_mask_broadcast_i32x4(__m256i src, __mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vbroadcasti32x4

Broadcast the 4 packed 32-bit integers from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm256_maskz_broadcast_i32x4

__m256i _mm256_maskz_broadcast_i32x4(__mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vbroadcasti32x4

Broadcast the 4 packed 32-bit integers from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcast_i32x8

__m512i _mm512_broadcast_i32x8(__m256i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti32x8

Broadcast the 8 packed 32-bit integers from a to all elements of the return value.

_mm512_mask_broadcast_i32x8

__m512i _mm512_mask_broadcast_i32x8(__m512i src, __mmask16 k, __m256i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti32x8

Broadcast the 8 packed 32-bit integers from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_broadcast_i32x8

__m512i _mm512_maskz_broadcast_i32x8(__mmask16 k, __m256i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti32x8

Broadcast the 8 packed 32-bit integers from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_broadcast_i64x2

__m256i _mm256_broadcast_i64x2(__m128i a)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti64x2

Broadcast the 2 packed 64-bit integers from a to all elements of the return value.

_mm256_mask_broadcast_i64x2

__m256i _mm256_mask_broadcast_i64x2(__m256i src, __mmask8 k, __m128i a)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti64x2

Broadcast the 2 packed 64-bit integers from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm256_maskz_broadcast_i64x2

_m256i _mm256_maskz_broadcast_i64x2(__mmask8 k, __m128i a)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vbroadcasti64x2
Broadcast the 2 packed 64-bit integers from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcast_i64x2

_m512i _mm512_broadcast_i64x2(__m128i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti64x2
Broadcast the 2 packed 64-bit integers from a to all elements of the return value.

_mm512_mask_broadcast_i64x2

_m512i _mm512_mask_broadcast_i64x2(__m512i src, __mmask8 k, __m128i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti64x2
Broadcast the 2 packed 64-bit integers from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_broadcast_i64x2

_m512i _mm512_maskz_broadcast_i64x2(__mmask8 k, __m128i a)

CPUID Flags: AVX512DQ
Instruction(s): vbroadcasti64x2
Broadcast the 2 packed 64-bit integers from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_inserti32x4

_m256i _mm256_inserti32x4(__m256i a, __m128i b, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vininserti32x4
Copy a to the return value, then insert 128 bits (composed of 4 packed 32-bit integers) from b into dst at the location specified by imm.

_mm256_mask_inserti32x4

_m256i _mm256_mask_inserti32x4(__m256i src, __mmask8 k, __m256i a, __m128i b, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vininserti32x4
Copy a to tmp, then insert 128 bits (composed of 4 packed 32-bit integers) from b into tmp at the location specified by imm. Store tmp to the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vinserti64x2
Copy a to tmp, then insert 128 bits (composed of 2 packed 64-bit integers) from b into tmp at the location specified by imm. Store tmp to the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
_mm256_mask_inserti64x2

__m256i _mm256_mask_inserti64x2(__mmask8 k, __m256i a, __m128i b, int imm)
```
CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vinserti64x2
Copy a to tmp, then insert 128 bits (composed of 2 packed 64-bit integers) from b into tmp at the location specified by imm. Store tmp to the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm512_inserti64x2

__m512i _mm512_inserti64x2(__m512i a, __m128i b, int imm)
```
CPUID Flags: AVX512DQ
Instruction(s): vinserti64x2
Copy a to the return value, then insert 128 bits (composed of 2 packed 64-bit integers) from b into dst at the location specified by imm.

```c
_mm512_mask_inserti64x2

__m512i _mm512_mask_inserti64x2(__m512i src, __mmask8 k, __m512i a, __m128i b, int imm)
```
CPUID Flags: AVX512DQ
Instruction(s): vinserti64x2
Copy a to tmp, then insert 128 bits (composed of 2 packed 64-bit integers) from b into tmp at the location specified by imm. Store tmp to the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
_mm512_maskz_inserti64x2

__m512i _mm512_maskz_inserti64x2(__mmask8 k, __m512i a, __m128i b, int imm)
```
CPUID Flags: AVX512DQ
Instruction(s): vinserti64x2
Copy a to tmp, then insert 128 bits (composed of 2 packed 64-bit integers) from b into tmp at the location specified by imm. Store tmp to the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm256_mask_shuffle_i32x4

__m256i _mm256_mask_shuffle_i32x4(__m256i src, __mmask8 k, __m256i a, __m256i b, const int imm)
```
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vshufi32x4
Shuffle 128-bits (composed of 4 32-bit integers) selected by imm from a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm256_maskz_shuffle_i32x4

__m256i _mm256_maskz_shuffle_i32x4(__mmask8 k, __m256i a, __m256i b, const int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vshufi32x4

Shuffle 128-bits (composed of 4 32-bit integers) selected by imm from a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__m256_shuffle_i32x4

__m256i _mm256_shuffle_i32x4(__m256i a, __m256i b, const int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vshufi32x4

Shuffle 128-bits (composed of 4 32-bit integers) selected by imm from a and b, and return the results.

__m256_mask_shuffle_i64x2

__m256i _mm256_mask_shuffle_i64x2(__m256i src, __mmask8 k, __m256i a, __m256i b, const int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vshufi64x2

Shuffle 128-bits (composed of 2 64-bit integers) selected by imm from a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m256_maskz_shuffle_i64x2

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vinsertf32x4
Copy \(a\) to \(tmp\), then insert 128 bits (composed of 4 packed single-precision (32-bit) floating-point elements) from \(b\) into \(tmp\) at the location specified by \(imm\). Store \(tmp\) to the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

```plaintext
_mm512_insertf32x8

__m512 __m512_insertf32x8(__m512 a, __m256 b, int imm)
```

CPUID Flags: AVX512DQ
Instruction(s): vinsertf32x8
Copy \(a\) to the return value, then insert 256 bits (composed of 8 packed single-precision (32-bit) floating-point elements) from \(b\) into \(dst\) at the location specified by \(imm\).

```plaintext
_mm512_mask_insertf32x8

__m512 __m512_mask_insertf32x8(__m512 src, __mmask16 k, __m512 a, __m256 b, int imm)
```

CPUID Flags: AVX512DQ
Instruction(s): vinsertf32x8
Copy \(a\) to \(tmp\), then insert 256 bits (composed of 8 packed single-precision (32-bit) floating-point elements) from \(b\) into \(tmp\) at the location specified by \(imm\). Store \(tmp\) to the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

```plaintext
_mm512_maskz_insertf32x8

__m512 __m512_maskz_insertf32x8(__mmask16 k, __m512 a, __m256 b, int imm)
```

CPUID Flags: AVX512DQ
Instruction(s): vinsertf32x8
Copy \( a \) to \( tmp \), then insert 256 bits (composed of 8 packed single-precision (32-bit) floating-point elements) from \( b \) into \( tmp \) at the location specified by \( imm \). Store \( tmp \) to the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in \textit{imm}) for packed double-precision (64-bit) floating-point elements in $a$ and $b$, and return the results using writemask $k$ (elements are copied from \textit{src} when the corresponding mask bit is not set).

\textbf{\underline{\text{_mm_maskz_range_pd}}}
\[
\text{\_m128d } \text{\_mm_maskz_range\_pd}(\text{\_mmask8 } k, \text{\_m128d } a, \text{\_m128d } b, \text{\int imm})
\]

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in \textit{imm}) for packed double-precision (64-bit) floating-point elements in $a$ and $b$, and return the results using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).
__mm_range_pd

__m128d __mm_range_pd(__m128d a, __m128d b, int imm)

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results.

__mm256_mask_range_pd

__m256d __mm256_mask_range_pd(__m256d src, __mmask8 k, __m256d a, __m256d b, int imm)

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_range_pd

__m256d __mm256_maskz_range_pd(__mmask8 k, __m256d a, __m256d b, int imm)

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_range_pd

__m256d __mm256_range_pd(__m256d a, __m256d b, int imm)

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results.

__mm512_mask_range_pd

__m512d __mm512_mask_range_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, int imm)

CPUID Flags: AVX512DQ

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm512_mask_range_round_pd

__m512d __mm512_mask_range_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b, int imm, int rounding)

CPUID Flags: AVX512DQ
Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_range_pd

_m512d _mm512_maskz_range_pd(__mmask8 k, __m512d a, __m512d b, int imm)

CPUID Flags: AVX512DQ

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_range_round_pd

_m512d _mm512_maskz_range_round_pd(__mmask8 k, __m512d a, __m512d b, int imm, int rounding)

CPUID Flags: AVX512DQ

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_range_pd

_m512d _mm512_range_pd(__m512d a, __m512d b, int imm)

CPUID Flags: AVX512DQ

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results.

_mm512_range_round_pd

_m512d _mm512_range_round_pd(__m512d a, __m512d b, int imm, int rounding)

CPUID Flags: AVX512DQ

Instruction(s): vrangepd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed double-precision (64-bit) floating-point elements in a and b, and return the results.

_mm_mask_range_ps

_m128 _mm_mask_range_ps(__m128 src, __mmask8 k, __m128 a, __m128 b, int imm)

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed single-precision (32-bit) floating-point elements in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
__mm_maskz_range_ps

__m128 __mm_maskz_range_ps(__mmask8 k, __m128 a, __m128 b, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed single-precision (32-bit) floating-point elements in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_range_ps

__m128 __mm_range_ps(__m128 a, __m128 b, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed single-precision (32-bit) floating-point elements in a and b, and return the results.

__mm256_mask_range_ps

__m256 __mm256_mask_range_ps(__m256 src, __mmask8 k, __m256 a, __m256 b, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed single-precision (32-bit) floating-point elements in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_range_ps

__m256 __mm256_maskz_range_ps(__mmask8 k, __m256 a, __m256 b, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed single-precision (32-bit) floating-point elements in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_range_ps

__m256 __mm256_range_ps(__m256 a, __m256 b, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for packed single-precision (32-bit) floating-point elements in a and b, and return the results.

__mm512_mask_range_ps

__m512 __mm512_mask_range_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vrangeps
Calculate the max, min, absolute max, or absolute min (depending on control in `imm`) for packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m512_mm512_mask_range_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int imm, int rounding)
```

CPUID Flags: AVX512DQ
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in `imm`) for packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m512_mm512_maskz_range_ps(__mmask16 k, __m512 a, __m512 b, int imm)
```

CPUID Flags: AVX512DQ
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in `imm`) for packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
__m512_mm512_maskz_range_round_ps(__mmask16 k, __m512 a, __m512 b, int imm, int rounding)
```

CPUID Flags: AVX512DQ
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in `imm`) for packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results.

```c
__m512_mm512_range_ps(__m512 a, __m512 b, int imm)
```

CPUID Flags: AVX512DQ
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in `imm`) for packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results.

```c
__m512_mm512_range_round_ps(__m512 a, __m512 b, int imm, int rounding)
```

CPUID Flags: AVX512DQ
Instruction(s): vrangeps

Calculate the max, min, absolute max, or absolute min (depending on control in `imm`) for packed single-precision (32-bit) floating-point elements in `a` and `b`, and return the results.
_mm_mask_range_round_sd

__m128d _mm_mask_range_round_sd(__m128 src, __mmask8 k, __m128d a, __m128d b, int imm, int rounding)

CPUID Flags: AVX512DQ
Instruction(s): vrangesd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower double-precision (64-bit) floating-point element in a and b, store the result in the lower element of the return value using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper element from a to the upper element of dst.

_mm_mask_range_sd

__m128d _mm_mask_range_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vrangesd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower double-precision (64-bit) floating-point element in a and b, store the result in the lower element of the return value using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper element from a to the upper element of dst.

_mm_maskz_range_round_sd

__m128d _mm_maskz_range_round_sd(__mmask8 k, __m128d a, __m128d b, int imm, int rounding)

CPUID Flags: AVX512DQ
Instruction(s): vrangesd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower double-precision (64-bit) floating-point element in a and b, store the result in the lower element of the return value using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper element from a to the upper element of dst.

_mm_maskz_range_sd

__m128d _mm_maskz_range_sd(__mmask8 k, __m128d a, __m128d b, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vrangesd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower double-precision (64-bit) floating-point element in a and b, store the result in the lower element of the return value using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper element from a to the upper element of dst.

_mm_range_round_sd

__m128d _mm_range_round_sd(__m128d a, __m128d b, int imm, int rounding)

CPUID Flags: AVX512DQ
Instruction(s): vrangesd

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower double-precision (64-bit) floating-point element in a and b, store the result in the lower element of the return value, and copy the upper element from a to the upper element of dst.
Compiler Reference

__mm_mask_range_round_ss

__m128 __mm_mask_range_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int imm, int rounding)

CPUID Flags: AVX512DQ
Instruction(s): vrangess

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower single-precision (32-bit) floating-point element in a and b, store the result in the lower element of the return value using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper 3 packed elements from a to the upper elements of dst.

__mm_mask_range_ss

__m128 __mm_mask_range_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vrangess

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower single-precision (32-bit) floating-point element in a and b, store the result in the lower element of the return value using writemask k (the element is copied from src when mask bit 0 is not set), and copy the upper 3 packed elements from a to the upper elements of dst.

__mm_maskz_range_round_ss

__m128 __mm_maskz_range_round_ss(__mmask8 k, __m128 a, __m128 b, int imm, int rounding)

CPUID Flags: AVX512DQ
Instruction(s): vrangess

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower single-precision (32-bit) floating-point element in a and b, store the result in the lower element of the return value using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper 3 packed elements from a to the upper elements of dst.

__mm_maskz_range_ss

__m128 __mm_maskz_range_ss(__mmask8 k, __m128 a, __m128 b, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vrangess

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower single-precision (32-bit) floating-point element in a and b, store the result in the lower element of the return value using zeromask k (the element is zeroed out when mask bit 0 is not set), and copy the upper 3 packed elements from a to the upper elements of dst.

__mm_range_round_ss

__m128 __mm_range_round_ss(__m128 a, __m128 b, int imm, int rounding)

CPUID Flags: AVX512DQ
Instruction(s): vrangess

Calculate the max, min, absolute max, or absolute min (depending on control in imm) for the lower single-precision (32-bit) floating-point element in a and b, store the result in the lower element of the return value, and copy the upper 3 packed elements from a to the upper elements of dst.
_mm_mask_reduce_pd

__m128d __mm_mask_reduce_pd(__m128d src, __mmask8 k, __m128d a, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vreducepd

Extract the reduced argument of packed double-precision (64-bit) floating-point elements in a by the number of bits specified by imm, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_reduce_pd

__m128d __mm_maskz_reduce_pd(__mmask8 k, __m128d a, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vreducepd

Extract the reduced argument of packed double-precision (64-bit) floating-point elements in a by the number of bits specified by imm, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_reduce_pd

__m128d __mm_reduce_pd(__m128d a, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vreducepd

Extract the reduced argument of packed double-precision (64-bit) floating-point elements in a by the number of bits specified by imm, and return the results.

</table>

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vrndscalepd`

Round packed double-precision (64-bit) floating-point elements in `a` to the number of fraction bits specified by `imm`, and return the results.
_mm_mask_roundscale_ps

_mm128_mm_mask_roundscale_ps(__m128 src, __mmask8 k, __m128 a, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrndscaleps
Round packed single-precision (32-bit) floating-point elements in a to the number of fraction bits specified by imm, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_roundscale_ps

_mm128_mm_maskz_roundscale_ps(__mmask8 k, __m128 a, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrndscaleps
Round packed single-precision (32-bit) floating-point elements in a to the number of fraction bits specified by imm, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_roundscale_ps

_mm128_mm_roundscale_ps(__m128 a, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrndscaleps
Round packed single-precision (32-bit) floating-point elements in a to the number of fraction bits specified by imm, and return the results.

_mm256_mask_roundscale_ps

_mm256_mm_mask_roundscale_ps(__m256 src, __mmask8 k, __m256 a, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrndscaleps
Round packed single-precision (32-bit) floating-point elements in a to the number of fraction bits specified by imm, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_roundscale_ps

_mm256_mm_maskz_roundscale_ps(__mmask8 k, __m256 a, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrndscaleps
Round packed single-precision (32-bit) floating-point elements in a to the number of fraction bits specified by imm, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_roundscale_ps

_mm256_mm256_roundscale_ps(__m256 a, int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vrndscalesps
Round packed single-precision (32-bit) floating-point elements in \( a \) to the number of fraction bits specified by \( imm \), and return the results.

```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): valignq

Concatenate `a` and `b` into a 32-byte immediate result, shift the result right by `count` 64-bit elements, and store the low 16 bytes (2 elements) in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**__mm256_alignr_epi64**

```c
__m256i __mm256_alignr_epi64(__m256i a, __m256i b, const int count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): valignq

Concatenate `a` and `b` into a 64-byte immediate result, shift the result right by `count` 64-bit elements, and store the low 32 bytes (4 elements) in the return value.

**__mm256_mask_alignr_epi64**

```c
__m256i __mm256_mask_alignr_epi64(__m256i src, __mmask8 k, __m256i a, __m256i b, const int count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): valignq

Concatenate `a` and `b` into a 64-byte immediate result, shift the result right by `count` 64-bit elements, and store the low 32 bytes (4 elements) in the return value using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

**__mm256_maskz_alignr_epi64**

```c
__m256i __mm256_maskz_alignr_epi64(__mmask8 k, __m256i a, __m256i b, const int count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): valignq

Concatenate `a` and `b` into a 64-byte immediate result, shift the result right by `count` 64-bit elements, and store the low 32 bytes (4 elements) in the return value using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**__mm_dbsad_epu8**

```c
__m128i __mm_dbsad_epu8(__m128i a, __m128i b, int imm)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vdbpsadbw

Compute the sum of absolute differences (SADs) of quadruplets of unsigned 8-bit integers in `a` compared to those in `b`, and store the 16-bit results in the return value.

**__mm_mask_dbsad_epu8**

```c
__m128i __mm_mask_dbsad_epu8(__m128i src, __mmask8 k, __m128i a, __m128i b, int imm)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vdbpsadbw
Compute the sum of absolute differences (SADs) of quadruplets of unsigned 8-bit integers in a compared to those in b, and store the 16-bit results in the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_dbsad_epu8

```c

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpblendmb

Blend packed 8-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

__mm256_mask_blend_epi8

__m256i __mm256_mask_blend_epi8(__mmask32 k, __m256i a, __m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpblendmb
Blend packed 8-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

\[
\_\text{mm512\_mask\_blend\_epi8}
\]

\[
\_m512i \_\text{mm512\_mask\_blend\_epi8}(\_\text{mmask64}\ k, \_m512i\ a, \_m512i\ b)
\]

CPUID Flags: AVX512BW
Instruction(s): vpblendmb

Blend packed 8-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

\[
\_\text{mm\_mask\_blend\_epi32}
\]

\[
\_m128i \_\text{mm\_mask\_blend\_epi32}(\_\text{mmask8}\ k, \_m128i\ a, \_m128i\ b)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpblendmd

Blend packed 32-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

\[
\_\text{mm256\_mask\_blend\_epi32}
\]

\[
\_m256i \_\text{mm256\_mask\_blend\_epi32}(\_\text{mmask8}\ k, \_m256i\ a, \_m256i\ b)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpblendmd

Blend packed 32-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

\[
\_\text{mm\_mask\_blend\_epi64}
\]

\[
\_m128i \_\text{mm\_mask\_blend\_epi64}(\_\text{mmask8}\ k, \_m128i\ a, \_m128i\ b)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpblendmq

Blend packed 64-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

\[
\_\text{mm256\_mask\_blend\_epi64}
\]

\[
\_m256i \_\text{mm256\_mask\_blend\_epi64}(\_\text{mmask8}\ k, \_m256i\ a, \_m256i\ b)
\]

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpblendmq

Blend packed 64-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

\[
\_\text{mm\_mask\_blend\_epi16}
\]

\[
\_m128i \_\text{mm\_mask\_blend\_epi16}(\_\text{mmask8}\ k, \_m128i\ a, \_m128i\ b)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpblendmw

Blend packed 16-bit integers from \( a \) and \( b \) using control mask \( k \), and return the results.

\[
\_\text{mm256\_mask\_blend\_epi16}
\]

\[
\_m256i \_\text{mm256\_mask\_blend\_epi16}(\_\text{mmask16}\ k, \_m256i\ a, \_m256i\ b)
\]
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpblandmw
Blend packed 16-bit integers from a and b using control mask k, and return the results.

```c
_mm512_mask_blend_epi16
__m512i _mm512_mask_blend_epi16(__mmask32 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW
Instruction(s): vpblandmw
Blend packed 16-bit integers from a and b using control mask k, and return the results.

```c
_mm_mask_broadcastb_epi8
__m128i _mm_mask_broadcastb_epi8(__m128i src, __mmask16 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb
Broadcast the low packed 8-bit integer from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
_mm_maskz_broadcastb_epi8
__m128i _mm_maskz_broadcastb_epi8(__mmask16 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb
Broadcast the low packed 8-bit integer from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm256_mask_broadcastb_epi8
__m256i _mm256_mask_broadcastb_epi8(__m256i src, __mmask32 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb
Broadcast the low packed 8-bit integer from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
_mm256_maskz_broadcastb_epi8
__m256i _mm256_maskz_broadcastb_epi8(__mmask32 k, __m128i a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb
Broadcast the low packed 8-bit integer from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm512_broadcastb_epi8
__m512i _mm512_broadcastb_epi8(__m128i a)
```

CPUID Flags: AVX512BW
Instruction(s): vpbroadcastb
Broadcast the low packed 8-bit integer from \( a \) to all elements of the return value.

\_mm512\_mask\_broadcastb\_epi8

\_m512i \_mm512\_mask\_broadcastb\_epi8(\_m512i src, \_mmask64 k, \_m128i a)

CPUID Flags: AVX512BW

Instruction(s): vpbroadcastb
Broadcast the low packed 8-bit integer from \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\_mm512\_maskz\_broadcastb\_epi8

\_m512i \_mm512\_maskz\_broadcastb\_epi8(\_mmask64 k, \_m128i a)

CPUID Flags: AVX512BW

Instruction(s): vpbroadcastb
Broadcast the low packed 8-bit integer from \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_mm\_mask\_broadcastd\_epi32

\_m128i \_mm\_mask\_broadcastd\_epi32(\_m128i src, \_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastd
Broadcast the low packed 32-bit integer from \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\_mm\_maskz\_broadcastd\_epi32

\_m128i \_mm\_maskz\_broadcastd\_epi32(\_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastd
Broadcast the low packed 32-bit integer from \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_mm256\_mask\_broadcastd\_epi32

\_m256i \_mm256\_mask\_broadcastd\_epi32(\_m256i src, \_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastd
Broadcast the low packed 32-bit integer from \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\_mm256\_maskz\_broadcastd\_epi32

\_m256i \_mm256\_maskz\_broadcastd\_epi32(\_mmask8 k, \_m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpbroadcastd
Broadcast the low packed 32-bit integer from a to all elements of the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_broadcastmb_epi64

__m128i __mm_broadcastmb_epi64(__mmask8 k)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpbroadcastmb2q
Broadcast the low 8-bits from input mask k to all 64-bit elements of the return value.

__m256i __mm256_broadcastmb_epi64(__mmask8 k)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpbroadcastmb2q
Broadcast the low 8-bits from input mask k to all 64-bit elements of the return value.

_mm_broadcastmw_epi32

__m128i __mm_broadcastmw_epi32(__mmask16 k)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpbroadcastmw2d
Broadcast the low 16-bits from input mask k to all 32-bit elements of the return value.

__m256i __mm256_broadcastmw_epi32(__mmask16 k)
CPUID Flags: AVX512CD, AVX512VL
Instruction(s): vpbroadcastmw2d
Broadcast the low 16-bits from input mask k to all 32-bit elements of the return value.

_mm_mask_broadcastq_epi64

__m128i __mm_mask_broadcastq_epi64(__m128i src, __mmask8 k, __m128i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpbroadcastq
Broadcast the low packed 64-bit integer from a to all elements of the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__m128i __mm_maskz_broadcastq_epi64(__mmask8 k, __m128i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpbroadcastq
Broadcast the low packed 64-bit integer from \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\_mm256\_mask\_broadcastq\_epi64}

\[
\text{\_m256i } \text{\_mm256\_mask\_broadcastw\_epi16}(\text{\_m256i } \text{src}, \text{\_mmask16 } \text{k}, \text{\_m128i } \text{a})
\]
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastw

Broadcast the low packed 16-bit integer from \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( \text{src} \) when the corresponding mask bit is not set).

\[
\text{\_mm256\_maskz\_broadcastw\_epi16}
\]
\[
\text{\_m256i } \text{\_mm256\_maskz\_broadcastw\_epi16}(\text{\_mmask16 } \text{k}, \text{\_m128i } \text{a})
\]
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \textit{a} to all elements of the return value using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\_\_\_mm512\_broadcastw\_epi16
\_\_\_m512i \_\_\_mm512\_broadcastw\_epi16(\_\_\_m128i \textit{a})
CPUID Flags: AVX512BW
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \textit{a} to all elements of the return value.

\_\_\_mm512\_mask\_broadcastw\_epi16
\_\_\_m512i \_\_\_mm512\_mask\_broadcastw\_epi16(\_\_\_m128i \textit{src}, \_\_\_mmask32 \textit{k}, \_\_\_m128i \textit{a})
CPUID Flags: AVX512BW
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \textit{a} to all elements of the return value using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\_\_\_mm512\_maskz\_broadcastw\_epi16
\_\_\_m512i \_\_\_mm512\_maskz\_broadcastw\_epi16(\_\_\_mmask32 \textit{k}, \_\_\_m128i \textit{a})
CPUID Flags: AVX512BW
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \textit{a} to all elements of the return value using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\_\_\_mm\_mask\_compress\_epi32
\_\_\_m128i \_\_\_mm\_mask\_compress\_epi32(\_\_\_m128i \textit{src}, \_\_\_mmask8 \textit{k}, \_\_\_m128i \textit{a})
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcompressd
Contiguously store the active 32-bit integers in \textit{a} (those with their respective bit set in writemask \textit{k}) to the return value, and pass through the remaining elements from \textit{src}.

\_\_\_mm\_maskz\_compress\_epi32
\_\_\_m128i \_\_\_mm\_maskz\_compress\_epi32(\_\_\_mmask8 \textit{k}, \_\_\_m128i \textit{a})
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcompressd
Contiguously store the active 32-bit integers in \textit{a} (those with their respective bit set in zeromask \textit{k}) to the return value, and set the remaining elements to zero.

\_\_\_mm256\_mask\_compress\_epi32
\_\_\_m256i \_\_\_mm256\_mask\_compress\_epi32(\_\_\_m256i \textit{src}, \_\_\_mmask8 \textit{k}, \_\_\_m256i \textit{a})
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpcompressd
Contiguously store the active 32-bit integers in a (those with their respective bit set in writemask k) to the return value, and pass through the remaining elements from src.

__mm256_maskz_compress_epi32

__m256i __mm256_maskz_compress_epi32(__mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcompressd
Contiguously store the active 32-bit integers in a (those with their respective bit set in zeromask k) to the return value, and set the remaining elements to zero.

__mm_mask_compress_epi64

__m128i __mm_mask_compress_epi64(__m128i src, __mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcompressq
Contiguously store the active 64-bit integers in a (those with their respective bit set in writemask k) to the return value, and pass through the remaining elements from src.

__mm_maskz_compress_epi64

__m128i __mm_maskz_compress_epi64(__mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcompressq
Contiguously store the active 64-bit integers in a (those with their respective bit set in zeromask k) to the return value, and set the remaining elements to zero.

__mm256_mask_compress_epi64

__m256i __mm256_mask_compress_epi64(__m256i src, __mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcompressq
Contiguously store the active 64-bit integers in a (those with their respective bit set in writemask k) to the return value, and pass through the remaining elements from src.

__mm256_maskz_compress_epi64

__m256i __mm256_maskz_compress_epi64(__mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpcompressq
Contiguously store the active 64-bit integers in a (those with their respective bit set in zeromask k) to the return value, and set the remaining elements to zero.

__mm256_mask_permutexvar_epi32

__m256i __mm256_mask_permutexvar_epi32(__m256i src, __mmask8 k, __m256i idx, __m256i a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpermd
Shuffle 32-bit integers in a across lanes using the corresponding index in idx, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
__m256i __m256_maskz_permutexvar_epi32(__m256i a, __m256i idx, __mmask8 k)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpermd
Shuffle 32-bit integers in a across lanes using the corresponding index in idx, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
__m256i __m256_permutexvar_epi32(__m256i idx, __m256i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpermd
Shuffle 32-bit integers in a across lanes using the corresponding index in idx, and return the results.

```c
__m128i __m128_mask2_permutex2var_epi32(__m128i a, __m128i idx, __mmask8 k, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpermi2d
Shuffle 32-bit integers in a and b across lanes using the corresponding selector and index in idx, and return the results using writemask k (elements are copied from idx when the corresponding mask bit is not set).

```c
__m256i __m256_mask2_permutex2var_epi32(__m256i a, __m256i idx, __mmask8 k, __m256i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpermi2d
Shuffle 32-bit integers in a and b across lanes using the corresponding selector and index in idx, and return the results using writemask k (elements are copied from idx when the corresponding mask bit is not set).

```c

Set each packed 16-bit integer in the return value to all ones or all zeros based on the value of the corresponding bit in k.

_mm512_movm_epi16

__m512i _mm512_movm_epi16(__mmask32 k)

CPUID Flags: AVX512BW
Instruction(s): vpmovm2w
Set each packed 16-bit integer in the return value to all ones or all zeros based on the value of the corresponding bit in \( k \).

\_mm512\_sad\_epu8

\_m512i \_mm512\_sad\_epu8(\_m512i a, \_m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpsadbw

Compute the absolute differences of packed unsigned 8-bit integers in \( a \) and \( b \), then horizontally sum each consecutive 8 differences to produce four unsigned 16-bit integers, and pack these unsigned 16-bit integers in the low 16 bits of 64-bit elements in the return value.

\_mm\_mask\_shuffle\_epi8

\_m128i \_mm\_mask\_shuffle\_epi8(\_m128i src, \_mmask16 k, \_m128i a, \_m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpshufb

Shuffle packed 8-bit integers in \( a \) according to shuffle control mask in the corresponding 8-bit element of \( b \), and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\_mm\_maskz\_shuffle\_epi8

\_m128i \_mm\_maskz\_shuffle\_epi8(\_mmask16 k, \_m128i a, \_m128i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpshufb

Shuffle packed 8-bit integers in \( a \) according to shuffle control mask in the corresponding 8-bit element of \( b \), and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\_mm256\_mask\_shuffle\_epi8

\_m256i \_mm256\_mask\_shuffle\_epi8(\_m256i src, \_mmask32 k, \_m256i a, \_m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpshufb

Shuffle packed 8-bit integers in \( a \) according to shuffle control mask in the corresponding 8-bit element of \( b \), and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\_mm256\_maskz\_shuffle\_epi8

\_m256i \_mm256\_maskz\_shuffle\_epi8(\_mmask32 k, \_m256i a, \_m256i b)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpshufb

Shuffle packed 8-bit integers in \( a \) according to shuffle control mask in the corresponding 8-bit element of \( b \), and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
_mm512_mask_shuffle_epi8
__m512i _mm512_mask_shuffle_epi8(__m512i src, __mmask64 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpshufb
Shuffle 8-bit integers in a within 128-bit lanes using the control in the corresponding 8-bit element of b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_shuffle_epi8

Unpack and interleave 16-bit integers from the low half of each 128-bit lane in a and b, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm512_mask_unpacklo_epi16

__m512i __m512_mask_unpacklo_epi16(__m512i src, __mmask32 k, __m512i a, __m512i b)

CPUID Flags: AVX512BW
Instruction(s): vpunpcklwd
Unpack and interleave 16-bit integers from the low half of each 128-bit lane in a and b, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
**_mm512_maskz_unpacklo_epi16_**

```
_mm512_maskz_unpacklo_epi16(__mmask32 k, __m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpunpcklwd

Unpack and interleave 16-bit integers from the low half of each 128-bit lane in `a` and `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_unpacklo_epi16_**

```
_mm512_unpacklo_epi16(__m512i a, __m512i b)
```

CPUID Flags: AVX512BW

Instruction(s): vpunpcklwd

Unpack and interleave 16-bit integers from the low half of each 128-bit lane in `a` and `b`, and return the results.

**_mm512_kunpackd_**

```
__mmask64 _mm512_kunpackd(__mmask64 a, __mmask64 b)
```

CPUID Flags: AVX512BW

Instruction(s): kunpckdq

Unpack and interleave 32 bits from masks `a` and `b`, and return the 64-bit result.

**_mm512_kunpackw_**

```
__mmask32 _mm512_kunpackw(__mmask32 a, __mmask32 b)
```

CPUID Flags: AVX512BW

Instruction(s): kunpckwd

Unpack and interleave 16 bits from masks `a` and `b`, and store the 32-bit result in `k`.

**_mm_fpclass_pd_mask_**

```
__mmask8 _mm_fpclass_pd_mask(__m128d a, int imm)
```

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vfpclasspd

Test packed double-precision (64-bit) floating-point elements in `a` for special categories specified by `imm`, and put each result in the corresponding bit of the returned mask value.

**_mm_mask_fpclass_pd_mask_**

```
__mmask8 _mm_mask_fpclass_pd_mask(__mmask8 k1, __m128d a, int imm)
```

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vfpclasspd

Test packed double-precision (64-bit) floating-point elements in `a` for special categories specified by `imm`, and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).
_mm256_fpclass_pd_mask

__mmask8 _mm256_fpclass_pd_mask(__m256d a, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vfpclasspd
Test packed double-precision (64-bit) floating-point elements in `a` for special categories specified by `imm`, and and put each result in the corresponding bit of the returned mask value.

_mm256_mask_fpclass_pd_mask

__mmask8 _mm256_mask_fpclass_pd_mask(__mmask8 k1, __m256d a, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vfpclasspd
Test packed double-precision (64-bit) floating-point elements in `a` for special categories specified by `imm`, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

_mm512_fpclass_pd_mask

__mmask8 _mm512_fpclass_pd_mask(__m512d a, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vfpclasspd
Test packed double-precision (64-bit) floating-point elements in `a` for special categories specified by `imm`, and and put each result in the corresponding bit of the returned mask value.

_mm512_mask_fpclass_pd_mask

__mmask8 _mm512_mask_fpclass_pd_mask(__mmask8 k1, __m512d a, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vfpclasspd
Test packed double-precision (64-bit) floating-point elements in `a` for special categories specified by `imm`, and and put each result in the corresponding bit of the returned mask value using zeromask `k1` (elements are zeroed out when the corresponding mask bit is not set).

_mm_fpclass_ps_mask

__mmask8 _mm_fpclass_ps_mask(__m128 a, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vfpclassps
Test packed single-precision (32-bit) floating-point elements in `a` for special categories specified by `imm`, and and put each result in the corresponding bit of the returned mask value.

_mm_mask_fpclass_ps_mask

__mmask8 _mm_mask_fpclass_ps_mask(__mmask8 k1, __m128 a, int imm)

CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vfpclassps
Test packed single-precision (32-bit) floating-point elements in \(a\) for special categories specified by \(imm\), and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\texttt{\_mm256\_fpclass\_ps\_mask}}
\]
\[
\text{\texttt{\_mm256\_mask\_fpclass\_ps\_mask}}
\]
CPUID Flags: AVX512DQ, AVX512VL
Instruction(s): vfpclassps
Test packed single-precision (32-bit) floating-point elements in \(a\) for special categories specified by \(imm\), and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\texttt{\_mm512\_fpclass\_ps\_mask}}
\]
\[
\text{\texttt{\_mm512\_mask\_fpclass\_ps\_mask}}
\]
CPUID Flags: AVX512DQ
Instruction(s): vfpclassps
Test packed single-precision (32-bit) floating-point elements in \(a\) for special categories specified by \(imm\), and put each result in the corresponding bit of the returned mask value using zeromask \(k1\) (elements are zeroed out when the corresponding mask bit is not set).

\[
\text{\texttt{\_mm\_fpclass\_sd\_mask}}
\]
CPUID Flags: AVX512DQ
Instruction(s): vfpclasssd
Test the lower double-precision (64-bit) floating-point element in \(a\) for special categories specified by \(imm\), and put the result in the returned mask value.
_mm_mask_fpclass_sd_mask

__mmask8 _mm_mask_fpclass_sd_mask(__mmask8 k1, __m128d a, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vfpclasssd
Test the lower double-precision (64-bit) floating-point element in \( a \) for special categories specified by \( imm \), and put the result in the returned mask value using zeromask \( k1 \) (the element is zeroed out when mask bit 0 is not set).

_mm_fpclass_ss_mask

__mmask8 _mm_fpclass_ss_mask(__m128 a, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vfpclassss
Test the lower single-precision (32-bit) floating-point element in \( a \) for special categories specified by \( imm \), and store the result in mask vector "k.

_mm_mask_fpclass_ss_mask

__mmask8 _mm_mask_fpclass_ss_mask(__mmask8 k1, __m128 a, int imm)

CPUID Flags: AVX512DQ
Instruction(s): vfpclassss
Test the lower single-precision (32-bit) floating-point element in \( a \) for special categories specified by \( imm \), and and put the result in the returned mask value using zeromask \( k1 \) (the element is zeroed out when mask bit 0 is not set).

_mm_movepi8_mask

__mmask16 _mm_movepi8_mask(__m128i a)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovb2m
Set each bit of the returned mask value based on the most significant bit of the corresponding packed 8-bit integer in \( a \).

_mm256_movepi8_mask

__mmask32 _mm256_movepi8_mask(__m256i a)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpmovb2m
Set each bit of the returned mask value based on the most significant bit of the corresponding packed 8-bit integer in \( a \).

_mm512_movepi8_mask

__mmask64 _mm512_movepi8_mask(__m512i a)

CPUID Flags: AVX512BW
Instruction(s): vpmovb2m
Set each bit of the returned mask value based on the most significant bit of the corresponding packed 8-bit integer in \( a \).

\texttt{\_mm\_movepi32\_mask} \\
\texttt{__mmask8 \_mm\_movepi32\_mask(__m128i a)}

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vpmovd2m

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 32-bit integer in \( a \).

\texttt{\_mm256\_movepi32\_mask} \\
\texttt{__mmask8 \_mm256\_movepi32\_mask(__m256i a)}

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vpmovd2m

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 32-bit integer in \( a \).

\texttt{\_mm512\_movepi32\_mask} \\
\texttt{__mmask16 \_mm512\_movepi32\_mask(__m512i a)}

CPUID Flags: AVX512DQ

Instruction(s): vpmovd2m

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 32-bit integer in \( a \).

\texttt{\_mm\_movepi64\_mask} \\
\texttt{__mmask8 \_mm\_movepi64\_mask(__m128i a)}

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vpmovq2m

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 64-bit integer in \( a \).

\texttt{\_mm256\_movepi64\_mask} \\
\texttt{__mmask8 \_mm256\_movepi64\_mask(__m256i a)}

CPUID Flags: AVX512DQ, AVX512VL

Instruction(s): vpmovq2m

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 64-bit integer in \( a \).

\texttt{\_mm512\_movepi64\_mask} \\
\texttt{__mmask8 \_mm512\_movepi64\_mask(__m512i a)}

CPUID Flags: AVX512DQ
Instruction(s): \texttt{vpmovq2m}

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 64-bit integer in \textit{a}.

\begin{verbatim}
\_mm\_movepi16\_mask
_\_mmask8 _\_mm\_movepi16\_mask(_\_m128i a)
\end{verbatim}

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \texttt{vpmovw2m}

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 16-bit integer in \textit{a}.

\begin{verbatim}
\_mm256\_movepi16\_mask
_\_mmask16 _\_mm256\_movepi16\_mask(_\_m256i a)
\end{verbatim}

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): \texttt{vpmovw2m}

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 16-bit integer in \textit{a}.

\begin{verbatim}
\_mm512\_movepi16\_mask
_\_mmask32 _\_mm512\_movepi16\_mask(_\_m512i a)
\end{verbatim}

CPUID Flags: AVX512BW

Instruction(s): \texttt{vpmovw2m}

Set each bit of the returned mask value based on the most significant bit of the corresponding packed 16-bit integer in \textit{a}.

\begin{verbatim}
\_mm\_permutexvar\_epi8
_\_m128i _\_mm\_permutexvar\_epi8(_\_m128i idx, _\_m128i a)
\end{verbatim}

CPUID Flags: AVX512VBMI, AVX512VL

Instruction(s): \texttt{vpermb}

Shuffle 8-bit integers in \textit{a} across lanes using the corresponding index in \textit{idx}, and return the result.

\begin{verbatim}
\_mm\_mask\_permutexvar\_epi8
_\_m128i _\_mm\_mask\_permutexvar\_epi8(_\_m128i src, _\_mmask16 k, _\_m128i idx, _\_m128i a)
\end{verbatim}

CPUID Flags: AVX512VBMI, AVX512VL

Instruction(s): \texttt{vpermb}

Shuffle 8-bit integers in \textit{a} across lanes using the corresponding index in \textit{idx}, and return the result using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\begin{verbatim}

\[
_{\text{m512i}} \_{\text{mm512}}_{\text{maskz}}_{\text{permutex2var}}_{\text{epi8}}(_{\text{mmask64}} \ k, \_{\text{m512i}} \ a, \_{\text{m512i}} \ idx, \_{\text{m512i}} \ b)
\]

CPUID Flags: AVX512VBMI

Instruction(s): vpermi2b, vpermt2b
Shuffle 8-bit integers in $a$ and $b$ across lanes using the corresponding index in $idx$, and return the result using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

**Intrinsics for Move Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>src</td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td>$k$</td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td>$a$</td>
<td>first source vector element</td>
</tr>
</tbody>
</table>

**_mm_mask_mov_pd**

```c
__m128d _mm_mask_mov_pd(__m128d src, __mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovapd

Move packed double-precision (64-bit) floating-point elements from $a$ to the return value using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

**_mm_maskz_mov_pd**

```c
__m128d _mm_maskz_mov_pd(__mmask8 k, __m128d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovapd

Move packed double-precision (64-bit) floating-point elements from $a$ into the return value using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_mov_pd**

```c
__m256d _mm256_mask_mov_pd(__m256d src, __mmask8 k, __m256d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovapd

Move packed double-precision (64-bit) floating-point elements from $a$ to the return value using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

**_mm256_maskz_mov_pd**

```c
__m256d _mm256_maskz_mov_pd(__mmask8 k, __m256d a)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovapd

Move packed double-precision (64-bit) floating-point elements from $a$ into the return value using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).
Move packed double-precision (64-bit) floating-point elements from \(a\) into the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm\_mask\_mov\_ps

\_m128 \_mm\_mask\_mov\_ps(\_m128 src, \_mmask8 k, \_m128 a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovaps

Move packed single-precision (32-bit) floating-point elements from \(a\) to the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm\_maskz\_mov\_ps

\_m128 \_mm\_maskz\_mov\_ps(\_mmask8 k, \_m128 a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovaps

Move packed single-precision (32-bit) floating-point elements from \(a\) into the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm256\_mask\_mov\_ps

\_m256 \_mm256\_mask\_mov\_ps(\_m256 src, \_mmask8 k, \_m256 a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovaps

Move packed single-precision (32-bit) floating-point elements from \(a\) to the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm256\_maskz\_mov\_ps

\_m256 \_mm256\_maskz\_mov\_ps(\_mmask8 k, \_m256 a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovaps

Move packed single-precision (32-bit) floating-point elements from \(a\) into the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\_mm\_mask\_movedup\_pd

\_m128d \_mm\_mask\_movedup\_pd(\_m128d src, \_mmask8 k, \_m128d a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovddup

Duplicate even-indexed double-precision (64-bit) floating-point elements from \(a\), and return the results using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\_mm\_maskz\_movedup\_pd

\_m128d \_mm\_maskz\_movedup\_pd(\_mmask8 k, \_m128d a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmmovddup
Duplicate even-indexed double-precision (64-bit) floating-point elements from a, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_movedup_pd

_m256d_mm256_mask_movedup_pd(__m256d src, __mmask8 k, __m256d a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmmovddup
Duplicate even-indexed double-precision (64-bit) floating-point elements from a, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_movedup_pd

_m256d_mm256_maskz_movedup_pd(__mmask8 k, __m256d a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmmovddup
Duplicate even-indexed double-precision (64-bit) floating-point elements from a, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_movehdup_ps

_m128_mm_mask_movehdup_ps(__m128 src, __mmask8 k, __m128 a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovshdup
Duplicate odd-indexed single-precision (32-bit) floating-point elements from a, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_movehdup_ps

_m128_mm_maskz_movehdup_ps(__mmask8 k, __m128 a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovshdup
Duplicate odd-indexed single-precision (32-bit) floating-point elements from a, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_movehdup_ps

_m256_mm256_mask_movehdup_ps(__m256 src, __mmask8 k, __m256 a)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vmovshdup
Duplicate odd-indexed single-precision (32-bit) floating-point elements from a, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_movehdup_ps

_m256_mm256_maskz_movehdup_ps(__mmask8 k, __m256 a)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): v movshdup
Duplicate odd-indexed single-precision (32-bit) floating-point elements from $a$, and return the results using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```c
__m128 __m_mask_moveldup_ps(__m128 src, __mmask8 k, __m128 a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): v movsl dup
Duplicate even-indexed single-precision (32-bit) floating-point elements from $a$, and return the results using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```c
__m128 __m_maskz_moveldup_ps(__mmask8 k, __m128 a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): v movsl dup
Duplicate even-indexed single-precision (32-bit) floating-point elements from $a$, and return the results using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```c
__m256 __mm256_mask_moveldup_ps(__m256 src, __mmask8 k, __m256 a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): v movsl dup
Duplicate even-indexed single-precision (32-bit) floating-point elements from $a$, and return the results using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).

```c
__m256 __mm256_maskz_moveldup_ps(__mmask8 k, __m256 a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): v movsl dup
Duplicate even-indexed single-precision (32-bit) floating-point elements from $a$, and return the results using zeromask $k$ (elements are zeroed out when the corresponding mask bit is not set).

```c
__m128i __m_mask_mov_epi32(__m128i src, __mmask8 k, __m128i a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): v movd qa32
Move packed 32-bit integers from $a$ to the return value using writemask $k$ (elements are copied from $src$ when the corresponding mask bit is not set).
__mm_maskz_mov_epi32

__m128i __mm_maskz_mov_epi32(__mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqa32
Move packed 32-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_mov_epi32

__m256i __mm256_mask_mov_epi32(__m256i src, __mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqa32
Move packed 32-bit integers from a to the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_mov_epi32

__m256i __mm256_maskz_mov_epi32(__mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqa32
Move packed 32-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_mov_epi64

__m128i __mm_mask_mov_epi64(__m128i src, __mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqa64
Move packed 64-bit integers from a to the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_mov_epi64

__m128i __mm_maskz_mov_epi64(__mmask8 k, __m128i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqa64
Move packed 64-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_mov_epi64

__m256i __mm256_mask_mov_epi64(__m256i src, __mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqa64
Move packed 64-bit integers from a to the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm256_maskz_mov_epi64

__m256i _mm256_maskz_mov_epi64(__mmask8 k, __m256i a)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vmovdqa64
Move packed 64-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_mov_epi16

__m128i _mm_mask_mov_epi16(__m128i src, __mmask8 k, __m128i a)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vmovdqu16
Move packed 16-bit integers from a into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_mov_epi16

__m128i _mm_maskz_mov_epi16(__mmask8 k, __m128i a)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vmovdqu16
Move packed 16-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_mov_epi16

__m256i _mm256_mask_mov_epi16(__m256i src, __mmask16 k, __m256i a)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vmovdqu16
Move packed 16-bit integers from a into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_mov_epi16

__m256i _mm256_maskz_mov_epi16(__mmask16 k, __m256i a)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vmovdqu16
Move packed 16-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_mov_epi16

__m512i _mm512_mask_mov_epi16(__m512i src, __mmask32 k, __m512i a)

CPUID Flags: AVX512BW
Instruction(s): vmovdqu16
Move packed 16-bit integers from a into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm512_maskz_mov_epi16

__m512i _mm512_maskz_mov_epi16(__mmask32 k, __m512i a)

CPUID Flags: AVX512BW

Instruction(s): vmovdqu16

Move packed 16-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_mov_epi8

__m128i _mm_mask_mov_epi8(__m128i src, __mmask16 k, __m128i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vmovdqu8

Move packed 8-bit integers from a into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_mov_epi8

__m128i _mm_maskz_mov_epi8(__mmask16 k, __m128i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vmovdqu8

Move packed 8-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_mask_mov_epi8

__m256i _mm256_mask_mov_epi8(__m256i src, __mmask32 k, __m256i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vmovdqu8

Move packed 8-bit integers from a into the return value using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_mov_epi8

__m256i _mm256_maskz_mov_epi8(__mmask32 k, __m256i a)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vmovdqu8

Move packed 8-bit integers from a into the return value using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_mov_epi8

__m512i _mm512_mask_mov_epi8(__mmask64 k, __m512i a)

CPUID Flags: AVX512BW

Instruction(s): vmovdqu8
Move packed 8-bit integers from \( a \) into the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

**_mm512_maskz_mov_epi8**

\[
\_m512i \_mm512\_maskz\_mov\_epi8(\_mmask64 k, \_m512i a)
\]

CPUID Flags: AVX512BW
Instruction(s): vmovdqu8

Move packed 8-bit integers from \( a \) into the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

**Intrinsics for Set Operations**

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.

To use these intrinsics, include the immintrin.h file as follows:

```c
#include <immintrin.h>
```

<table>
<thead>
<tr>
<th>variable</th>
<th>definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>src</strong></td>
<td>source element to use based on writemask result</td>
</tr>
<tr>
<td><strong>k</strong></td>
<td>writemask used as a selector</td>
</tr>
<tr>
<td><strong>a</strong></td>
<td>first source vector element</td>
</tr>
</tbody>
</table>

**_mm_mask_set1_epi8**

\[
\_m128i \_mm\_mask\_set1\_epi8(\_m128i src, \_mmask16 k, char a)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb

Broadcast 8-bit integer \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

**_mm_maskz_set1_epi8**

\[
\_m128i \_mm\_maskz\_set1\_epi8(\_mmask16 k, char a)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb

Broadcast 8-bit integer \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_mask_set1_epi8**

\[
\_m256i \_mm256\_mask\_set1\_epi8(\_m256i src, \_mmask32 k, char a)
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb

Broadcast 8-bit integer \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
Broadcast 8-bit integer \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
__m256i __mm256_maskz_set1_epi8(__mmask32 k, char a)
```

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastb

Broadcast 8-bit integer \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

```c
__m512i __mm512_maskz_set1_epi8(__mmask64 k, char a)
```

CPUID Flags: AVX512BW
Instruction(s): vpbroadcastb

Broadcast 8-bit integer \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
__m512i __mm512_mask_set1_epi8(__m512i src, __mmask64 k, char a)
```

CPUID Flags: AVX512BW
Instruction(s): vpbroadcastb

Broadcast 8-bit integer \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

```c
__m128i __mm_mask_set1_epi32(__m128i src, __mmask8 k, int a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpbroadcastd

Broadcast 32-bit integer \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

```c
__m128i __mm_maskz_set1_epi32(__mmask8 k, int a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpbroadcastd

Broadcast 32-bit integer \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

```c
__m256i __mm256_mask_set1_epi32(__m256i src, __mmask8 k, int a)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpbroadcastd
Broadcast 32-bit integer \(a\) to all elements of the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
_{\text{mm256}} \_\text{maskz\_set1\_epi32}
\]

\[
_{\text{m256i \_mm256\_maskz\_set1\_epi32}}(_{\text{mmask8}} k, \text{int} a)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastd
Broadcast 32-bit integer \(a\) to all elements of the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm\_mask\_set1\_epi64}}
\]

\[
_{\text{m128i \_mm\_mask\_set1\_epi64}}(_{\text{ml28i}} src, _{\text{mmask8}} k, _{\text{int64}} a)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastq
Broadcast 64-bit integer \(a\) to all elements of the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
_{\text{mm\_maskz\_set1\_epi64}}
\]

\[
_{\text{m128i \_mm\_maskz\_set1\_epi64}}(_{\text{mmask8}} k, _{\text{int64}} a)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastq
Broadcast 64-bit integer \(a\) to all elements of the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm256}} \_\text{mask\_set1\_epi64}
\]

\[
_{\text{m256i \_mm256\_mask\_set1\_epi64}}(_{\text{m256i}} src, _{\text{mmask8}} k, _{\text{int64}} a)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastq
Broadcast 64-bit integer \(a\) to all elements of the return value using writemask \(k\) (elements are copied from \(src\) when the corresponding mask bit is not set).

\[
_{\text{mm256}} \_\text{maskz\_set1\_epi64}
\]

\[
_{\text{m256i \_mm256\_maskz\_set1\_epi64}}(_{\text{mmask8}} k, _{\text{int64}} a)
\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpbroadcastq
Broadcast 64-bit integer \(a\) to all elements of the return value using zeromask \(k\) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm\_mask\_set1\_epi16}}
\]

\[
_{\text{m128i \_mm\_mask\_set1\_epi16}}(_{\text{ml28i}} src, _{\text{mmask8}} k, \text{short} a)
\]
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
_{\text{mm\_maskz\_set1\_epi16}}
\]
\[
_{\text{m128i \_mm\_maskz\_set1\_epi16}(\_mm\_mask8 \ k, \ short \ a)}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm256\_mask\_set1\_epi16}}
\]
\[
_{\text{m256i \_mm256\_mask\_set1\_epi16}(\_m256i \ src, \ _mm\_mask16 \ k, \ short \ a)}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
_{\text{mm256\_maskz\_set1\_epi16}}
\]
\[
_{\text{m256i \_mm256\_maskz\_set1\_epi16}(\_mm\_mask16 \ k, \ short \ a)}
\]

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

\[
_{\text{mm512\_mask\_set1\_epi16}}
\]
\[
_{\text{m512i \_mm512\_mask\_set1\_epi16}(\_m512i \ src, \ _mm\_mask32 \ k, \ short \ a)}
\]

CPUID Flags: AVX512BW
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \( a \) to all elements of the return value using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\[
_{\text{mm512\_maskz\_set1\_epi16}}
\]
\[
_{\text{m512i \_mm512\_maskz\_set1\_epi16}(\_mm\_mask32 \ k, \ short \ a)}
\]

CPUID Flags: AVX512BW
Instruction(s): vpbroadcastw
Broadcast the low packed 16-bit integer from \( a \) to all elements of the return value using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
Intrinsics for Shift Operations

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \textit{vprold}

Rotate the bits in each packed 32-bit integer in \textit{a} to the left by the number of bits specified in \textit{imm}, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\textbf{\_mm256\_rol\_epi32}

\begin{verbatim}
\_m256i \_mm256\_rol\_epi32(const int imm)
\end{verbatim}

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \textit{vprold}

Rotate the bits in each packed 32-bit integer in \textit{a} to the left by the number of bits specified in \textit{imm}, and return the results.

\textbf{\_mm\_mask\_rol\_epi64}

\begin{verbatim}
\_m128i \_mm\_mask\_rol\_epi64(const\_mmask8 k, \_m128i a, const int imm)
\end{verbatim}

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \textit{vprolq}

Rotate the bits in each packed 64-bit integer in \textit{a} to the left by the number of bits specified in \textit{imm}, and return the results using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

\textbf{\_mm\_maskz\_rol\_epi64}

\begin{verbatim}
\_m128i \_mm\_maskz\_rol\_epi64(const\_mmask8 k, \_m128i a, const int imm)
\end{verbatim}

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \textit{vprolq}

Rotate the bits in each packed 64-bit integer in \textit{a} to the left by the number of bits specified in \textit{imm}, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

\textbf{\_mm\_rol\_epi64}

\begin{verbatim}
\_m128i \_mm\_rol\_epi64(const int imm)
\end{verbatim}

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \textit{vprolq}

Rotate the bits in each packed 64-bit integer in \textit{a} to the left by the number of bits specified in \textit{imm}, and return the results.

\textbf{\_mm256\_mask\_rol\_epi64}

\begin{verbatim}
\_m256i \_mm256\_mask\_rol\_epi64(const\_mmask8 k, \_m256i a, const int imm)
\end{verbatim}
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vprolq
Rotate the bits in each packed 64-bit integer in `a` to the left by the number of bits specified in `imm`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
_mm256_maskz_rol_epi64
__m256i _mm256_maskz_rol_epi64(__mmask8 k, __m256i a, const int imm)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vprolq
Rotate the bits in each packed 64-bit integer in `a` to the left by the number of bits specified in `imm`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm256_rol_epi64
__m256i _mm256_rol_epi64(__m256i a, const int imm)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vprolvd
Rotate the bits in each packed 32-bit integer in `a` to the left by the number of bits specified in the corresponding element of `b`, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
_mm_mask_rolv_epi32
__m128i _mm_mask_rolv_epi32(__m128i src, __mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vprolvd
Rotate the bits in each packed 32-bit integer in `a` to the left by the number of bits specified in the corresponding element of `b`, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
_mm_maskz_rolv_epi32
__m128i _mm_maskz_rolv_epi32(__mmask8 k, __m128i a, __m128i b)
```

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vprolvd
Rotate the bits in each packed 32-bit integer in `a` to the left by the number of bits specified in the corresponding element of `b`, and return the results.

```c
_mm_rolv_epi32
__m128i _mm_rolv_epi32(__m128i a, __m128i b)
```
_mm256_mask_rolv_epi32

__m256i _mm256_mask_rolv_epi32(__m256i src, __mmask8 k, __m256i a, __m256i b)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vprolvd

Rotate the bits in each packed 32-bit integer in \( a \) to the left by the number of bits specified in the corresponding element of \( b \), and return the results using writemask \( k \) (elements are copied from \( src \) when the corresponding mask bit is not set).

\]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): \text{vprorvq}

Rotate the bits in each packed 64-bit integer in \(a\) to the right by the number of bits specified in the corresponding element of \(b\), and return the results.
__mm_mask_sll_epi32

__m128i __mm_mask_sll_epi32(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in a left by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_mask_slli_epi32

__m128i __mm_mask_slli_epi32(__m128i src, __mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in a left by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_sll_epi32

__m128i __mm_maskz_sll_epi32(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in a left by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_maskz_slli_epi32

__m128i __mm_maskz_slli_epi32(__mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in a left by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_sll_epi32

__m256i __mm256_mask_sll_epi32(__m256i src, __mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in a left by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_mask_slli_epi32

__m256i __mm256_mask_slli_epi32(__m256i src, __mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in a left by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
**_mm256_maskz_sll_epi32_**

\[ \texttt{m256i \_mm256\_maskz\_sll\_epi32(__mmask8 k, \texttt{m256i a, m128i count})} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in \( a \) left by \( \text{count} \) while shifting in zeros, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

**_mm256_maskz_slli_epi32_**

\[ \texttt{m256i \_mm256\_maskz\_slli\_epi32(__mmask8 k, \texttt{m256i a, unsigned int imm})} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpslld

Shift packed 32-bit integers in \( a \) left by \( \text{imm} \) while shifting in zeros, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).

**_mm512_bslle_epi128_**

\[ \texttt{m512i \_mm512\_bsl\_epi128(__m512i a, int imm)} \]

CPUID Flags: AVX512BW

Instruction(s): vpslldq

Shift 128-bit lanes in \( a \) left by \( \text{imm} \) bytes while shifting in zeros, and return the results.

**_mm_mask_sll_epi64_**

\[ \texttt{m128i \_mm\_mask\_sll\_epi64(__m128i src, __mmask8 k, \texttt{m128i a, m128i count})} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in \( a \) left by \( \text{count} \) while shifting in zeros, and return the results using writemask \( k \) (elements are copied from \( \text{src} \) when the corresponding mask bit is not set).

**_mm_mask_slli_epi64_**

\[ \texttt{m128i \_mm\_mask\_slli\_epi64(__m128i src, __mmask8 k, \texttt{m128i a, unsigned int imm})} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in \( a \) left by \( \text{imm} \) while shifting in zeros, and return the results using writemask \( k \) (elements are copied from \( \text{src} \) when the corresponding mask bit is not set).

**_mm_maskz_sll_epi64_**

\[ \texttt{m128i \_mm\_maskz\_sll\_epi64(__mmask8 k, \texttt{m128i a, m128i count})} \]

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in \( a \) left by \( \text{count} \) while shifting in zeros, and return the results using zeromask \( k \) (elements are zeroed out when the corresponding mask bit is not set).
_mm_maskz_slli_epi64

__m128i __m128i_mm_maskz_slli_epi64(__mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in a left by \textit{imm} while shifting in zeros, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_sll_epi64

__m256i __m256i_mm256_mask_sll_epi64(__m256i src, __mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in a left by \textit{count} while shifting in zeros, and return the results using writemask \textit{k} (elements are copied from \textit{src} when the corresponding mask bit is not set).

__mm256_maskz_sll_epi64

__m256i __m256i_mm256_maskz_sll_epi64(__mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in a left by \textit{count} while shifting in zeros, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

__mm256_maskz_slli_epi64

__m256i __m256i_mm256_maskz_slli_epi64(__mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in a left by \textit{imm} while shifting in zeros, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

__mm256_maskz_sll_epi64

__m256i __m256i_mm256_maskz_sll_epi64(__mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllq

Shift packed 64-bit integers in a left by \textit{count} while shifting in zeros, and return the results using zeromask \textit{k} (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_sllv_epi32

__m128i __m128i_mm_mask_sllv_epi32(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsllvd
Shift packed 32-bit integers in a left by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```cpp
__m128i _mm_maskz_sllv_epi32(__mmask8 k, __m128i a, __m128i count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vpsllvd`

Shift packed 32-bit integers in a left by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```cpp
__m256i _mm256_mask_sllv_epi32(__m128i src, __mmask8 k, __m256i a, __m256i count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vpsllvd`

Shift packed 32-bit integers in a left by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```cpp
__m256i _mm256_maskz_sllv_epi32(__mmask8 k, __m256i a, __m256i count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vpsllvd`

Shift packed 32-bit integers in a left by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```cpp
__m128i _mm_mask_sllv_epi64(__m128i src, __mmask8 k, __m128i a, __m128i count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vpsllvq`

Shift packed 64-bit integers in a left by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```cpp
__m128i _mm_maskz_sllv_epi64(__mmask8 k, __m128i a, __m128i count)
```

CPUID Flags: AVX512F, AVX512VL

Instruction(s): `vpsllvq`

Shift packed 64-bit integers in a left by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
_mm256_mask_sllv_epi64

__m256i _mm256_mask_sllv_epi64(__m256i src, __mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsllvq
Shift packed 64-bit integers in a left by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_sllv_epi64

__m256i _mm256_maskz_sllv_epi64(__mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsllvq
Shift packed 64-bit integers in a left by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_sllv_epi16

__m512i mm512_sll_epi16(__m512i a, __m128i count)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by count while shifting in zeros, and return the results.

__mm512_slli_epi16

__m512i mm512_slli_epi16(__m512i a, unsigned int imm)

CPUID Flags: AVX512BW
Instruction(s): vpsllw
Shift packed 16-bit integers in a left by imm while shifting in zeros, and return the results.

__mm_mask_sra_epi32

__m128i mm_mask_sra_epi32(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in a right by count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_mask_srai_epi32

__m128i mm_mask_srai_epi32(__m128i src, __mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in a right by imm while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_sra_epi32

__m128i mm_maskz_sra_epi32(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in a right by count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_maskz_srai_epi32

__m128i mm_maskz_srai_epi32(__mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsrad
Shift packed 32-bit integers in a right by imm while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
_mm256_mask_sra_epi32

_mm256_mask_sra_epi32(__m256i src, __mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrad

Shift packed 32-bit integers in `a` right by `count` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm256_mask_srai_epi32

_mm256_mask_srai_epi32(__m256i src, __mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrad

Shift packed 32-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm256_maskz_sra_epi32

_mm256_maskz_sra_epi32(__mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrad

Shift packed 32-bit integers in `a` right by `count` while shifting in sign bits, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm256_maskz_srai_epi32

_mm256_maskz_srai_epi32(__mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsrad

Shift packed 32-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_sra_epi64

_mm_mask_sra_epi64(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `count` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

_mm_mask_srai_epi64

_mm_mask_srai_epi64(__m128i src, __mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in `a` right by `imm` while shifting in sign bits, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).
__mm_maskz_sra_epi64

__m128i __mm_maskz_sra_epi64(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in a right by count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_maskz_srai_epi64

__m128i __mm_maskz_srai_epi64(__mmask8 k, __m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in a right by imm while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_sra_epi64

__m128i __mm_sra_epi64(__m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in a right by count while shifting in sign bits, and return the results.

__mm_srai_epi64

__m128i __mm_srai_epi64(__m128i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in a right by imm while shifting in sign bits, and return the results.

__mm256_mask_sra_epi64

__m256i __mm256_mask_sra_epi64(__m256i src, __mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in a right by count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_mask_srai_epi64

__m256i __mm256_mask_srai_epi64(__m256i src, __mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsraq

Shift packed 64-bit integers in a right by imm while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).
_mm256_maskz_sra_epi64

__m256i _mm256_maskz_sra_epi64(__mmask8 k, __m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsraq

Shift packed 64-bit integers in a right by count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_maskz_srai_epi64

__m256i _mm256_maskz_srai_epi64(__mmask8 k, __m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsraq

Shift packed 64-bit integers in a right by imm while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm256_sra_epi64

__m256i _mm256_sra_epi64(__m256i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsraq

Shift packed 64-bit integers in a right by count while shifting in sign bits, and return the results.

_mm256_srai_epi64

__m256i _mm256_srai_epi64(__m256i a, unsigned int imm)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsraq

Shift packed 64-bit integers in a right by imm while shifting in sign bits, and return the results.

_mm_mask_srav_epi32

__m128i _mm_mask_srav_epi32(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsravd

Shift packed 32-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_srav_epi32

__m128i _mm_maskz_srav_epi32(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsravd

Shift packed 32-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).
_mm256_mask_srav_epi32

__m256i _mm256_mask_srav_epi32(__m256i src, __mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsravd

Shift packed 32-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm256_maskz_srav_epi32

__m256i _mm256_maskz_srav_epi32(__mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsravd

Shift packed 32-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_srav_epi64

__m128i _mm_mask_srav_epi64(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsravq

Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_srav_epi64

__m128i _mm_maskz_srav_epi64(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsravq

Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm_srav_epi64

__m128i _mm_srav_epi64(__m128i a, __m128i count)

CPUID Flags: AVX512F, AVX512VL

Instruction(s): vpsravq

Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results.

_mm256_mask_srav_epi64

__m256i _mm256_mask_srav_epi64(__m256i src, __mmask8 k, __m256i a, __m256i count)

CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsravq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_srav_epi64

__m256i __m256_maskz_srav_epi64(__mmask8 k, __m256i a, __m256i count)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsravq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_srav_epi64

__m256i __m256_srav_epi64(__m256i a, __m256i count)
CPUID Flags: AVX512F, AVX512VL
Instruction(s): vpsravq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results.

__mm_mask_srav_epi16

__m128i __mm_mask_srav_epi16(__m128i src, __mmask8 k, __m128i a, __m128i count)
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsravw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm_maskz_srav_epi16

__m128i __mm_maskz_srav_epi16(__mmask8 k, __m128i a, __m128i count)
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsravw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_srrav_epi16

__m128i __mm_srrav_epi16(__m128i a, __m128i count)
CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsravw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results.
__mm256_mask_srav_epi16

__m256i __mm256_mask_srav_epi16(__m256i src, __mmask16 k, __m256i a, __m256i count)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsravw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_srav_epi16

__m256i __mm256_maskz_srav_epi16(__mmask16 k, __m256i a, __m256i count)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsravw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_srav_epi16

__m256i __mm256_srav_epi16(__m256i a, __m256i count)

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsravw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results.

__mm512_mask_srav_epi16

__m512i __mm512_mask_srav_epi16(__m512i src, __mmask32 k, __m512i a, __m512i count)

CPUID Flags: AVX512BW

Instruction(s): vpsravw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm512_maskz_srav_epi16

__m512i __mm512_maskz_srav_epi16(__mmask32 k, __m512i a, __m512i count)

CPUID Flags: AVX512BW

Instruction(s): vpsravw

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm512_srav_epi16

__m512i __mm512_srav_epi16(__m512i a, __m512i count)

CPUID Flags: AVX512BW
Instruction(s): vpsraw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in sign bits, and return the results.

```c
__mm_mask_sra_epi16
__m128i __mm_mask_sra_epi16(__m128i src, __mmask8 k, __m128i a, __m128i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsraw
Shift packed 16-bit integers in a right by count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
__mm_mask_srai_epi16
__m128i __mm_mask_srai_epi16(__m128i src, __mmask8 k, __m128i a, unsigned int imm)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsraw
Shift packed 16-bit integers in a right by imm while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
__mm_maskz_sra_epi16
__m128i __mm_maskz_sra_epi16(__mmask8 k, __m128i a, __m128i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsraw
Shift packed 16-bit integers in a right by count while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm_maskz_srai_epi16
__m128i __mm_maskz_srai_epi16(__mmask8 k, __m128i a, unsigned int imm)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsraw
Shift packed 16-bit integers in a right by imm while shifting in sign bits, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

```c
__mm256_mask_sra_epi16
__m256i __mm256_mask_sra_epi16(__m256i src, __mmask16 k, __m256i a, __m128i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsraw
Shift packed 16-bit integers in a right by count while shifting in sign bits, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

```c
__mm256_mask_srai_epi16

Instruction(s): vpsrlvq
Shift packed 64-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_mask_srlv_epi16

__m128i __mm_mask_srlv_epi16(__m128i src, __mmask8 k, __m128i a, __m128i count)
CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlvw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m256i __m256_maskz_srlv_epi16(__mmask16 k, __m256i a, __m256i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlv

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).

```c
__m256i __m256_srlv_epi16(__m256i a, __m256i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlv

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using writemask `k` (elements are copied from `src` when the corresponding mask bit is not set).

```c
__m256i __m256_maskz_srlv_epi16(__mmask16 k, __m256i a, __m256i count)
```

CPUID Flags: AVX512BW, AVX512VL

Instruction(s): vpsrlv

Shift packed 16-bit integers in a right by the amount specified by the corresponding element in `count` while shifting in zeros, and return the results using zeromask `k` (elements are zeroed out when the corresponding mask bit is not set).
_mm512_mask_srlv_epi16

__m512i _mm512_mask_srlv_epi16(__m512i src, __mmask32 k, __m512i a, __m512i count)

CPUID Flags: AVX512BW
Instruction(s): vpsrlwv
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_srlv_epi16

__m512i _mm512_maskz_srlv_epi16(__mmask32 k, __m512i a, __m512i count)

CPUID Flags: AVX512BW
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srlv_epi16

__m512i _mm512_srlv_epi16(__m512i a, __m512i count)

CPUID Flags: AVX512BW
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by the amount specified by the corresponding element in count while shifting in zeros, and return the results.

_mm_mask_srl_epi16

__m128i _mm_mask_srl_epi16(__m128i src, __mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_mask_srli_epi16

__m128i _mm_mask_srli_epi16(__m128i src, __mmask8 k, __m128i a, int imm)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm_maskz_srl_epi16

__m128i _mm_maskz_srl_epi16(__mmask8 k, __m128i a, __m128i count)

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm_maskz_srli_epi16

_mm256_maskz_srli_epi16

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm256_mask_srli_epi16

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_mask_srl_epi16

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

__mm256_maskz_srl_epi16

CPUID Flags: AVX512BW, AVX512VL
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm512_maskz_srli_epi16

CPUID Flags: AVX512BW
Instruction(s): vpsrlw

Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

__mm512_mask_srl_epi16

CPUID Flags: AVX512BW
Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_mask_srl_epi16

_m512i _mm512_mask_srl_epi16(__m512i src, __mmask32 k, __m512i a, unsigned int imm)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using writemask k (elements are copied from src when the corresponding mask bit is not set).

_mm512_maskz_srl_epi16

_m512i _mm512_maskz_srl_epi16(__mmask32 k, __m512i a, __m128i count)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_srl_epi16

_m512i _mm512_maskz_srl_epi16(__mmask32 k, __m512i a, int imm)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by imm while shifting in zeros, and return the results using zeromask k (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srl_epi16

_m512i _mm512_srl_epi16(__m512i a, __m128i count)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results.

_mm512_srl_epi16

_m512i _mm512_srl_epi16(__m512i a, __m128i count)

CPUID Flags: AVX512BW

Instruction(s): vpsrlw
Shift packed 16-bit integers in a right by count while shifting in zeros, and return the results.
