

Hardware-Accelerated Video Decode in Unity* 3D

By Bryan Mackenzie

As it stands, Unity* does not provide hardware-accelerated decode for video playback. Therefore, playing video on a low-end device could suffer dropped frames, low frame rates, and poor quality. The provided project illustrates how to merge the hardware decode path within Unity. The main components within this solution are the creation of an external video texture mapped to Unity, the creation of the media player, and the calls exposed to Unity.

Video Texture Creation

To leverage the media player component, an external texture is created and shared with the Unity rendering component. To gain access to the Unity rendering component we use the `IUnityInterface` to retrieve the `IUnityGraphicsD3D11` interface, which provides access to the Unity rendering component used to call `CreateTexture2D`, creating a staged texture on the Unity device. `CreateTexture2D` then receives the `ID3D11Texture2D` interface.

The D3D device is used to call `CreateShaderResourceView`, passing-in the `ID3D11Texture2D` that will serve as the input to the shader. The `CreateShaderResourceView` also receives the `ID3D11ShaderResourceView`, which provides access to the shader-resource-view interface, used to access data of the passed-in resource; in this case, the `ID3D11Texture2D` texture.

At this point, a shared texture is created and a handle to the shared texture is returned. The handle is then used to open the shared resource (`ID3D11Texture2D`), where the `IDXGISurface` surface of the texture is retrieved. `CreateDirect3D11SurfaceFromDXGISurface` is then called to create an instance of `IDirect3DSurface` from an `IDXGISurface`, whereupon a video frame is available. The frame is then copied to the `IDirect3DSurface` video surface which, as stated, is shared with the Unity rendering pipeline.

Media Player

To begin, we first create a new instance of the Windows Media* playback media player interface, which provides access to media playback functionality such as play, pause, seek, and so on. Once we have the interface, we load content by calling `CreateFromUri`, which creates a `MediaSource*` from the passed-in Uri, where `MediaSource` provides a means of accessing media data.

We then associate the `MediaSource` to a `MediaPlaybackItem`, which acts as a wrapper around a `MediaSource`, exposing audio and video tracks within the `MediaSource`.

Unity* Integration

The purpose of this project is to detail the integration of hardware-accelerated video in Unity, how it is achieved, and how you can leverage the code to integrate accelerated video into your project. A wrapper is created to expose the relevant calls to create, load, and interact with the media. While not within this

article's scope, more information on creating and exposing native dynamic libraries to Unity can be found here. The project does not expose all available features of the media player, but does expose core functionality to provide a jump-off point to further expand upon with new features. The following functionality is currently exposed and available for integration:

CreateMediaPlayback: Create media player instance

CreatePlaybackTexture: Return native texture to a pointer

LoadContent: Load from Uri

SetPosition: Set current playback position (seek)

GetPosition: Get current playback position

GetDuration: Retrieve the video duration

GetPlaybackRate: Retrieve current playback speed

StateChangedCallback: Media playback change event callback

Play: Play video

Stop: Stop video

Pause: Pause video
