If the keyword NML is omitted, the namelist specifier must be the second specifier in the control list; the io-
unit specifier must be first.
If a namelist specifier appears in a control list, a format specifier must not appear.

Rules for Namelist Sequential WRITE Statements for details on namelist output
READ
WRITE

Record Specifier (REC=)
The record specifier identifies the number of the record for data transfer in a file connected for direct access.
It takes the following form:
REC=r

  r  Is a scalar numeric expression indicating the record number. The
  value of the expression must be greater than or equal to 1, and less
  than or equal to the maximum number of records allowed in the file.

If necessary, the value is converted to integer data type before use.
If REC is present, no END specifier, * format specifier, or namelist group name can appear in the same
control list.
See Also
Alternative Syntax for a RecordSpecifier

I/O Status Specifier (IOSTAT=)
The I/O status specifier designates a variable to store a value indicating the status of a data transfer operation. It takes the following form:

IOSTAT=ivar

ivar Is a scalar integer variable. When a data transfer statement is executed, ivar is set to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Positive integer</td>
<td>Indicating an error condition occurred.</td>
</tr>
<tr>
<td>Negative integer</td>
<td>Indicating an end-of-file or end-of-record condition occurred. The negative integers differ depending on which condition occurred.</td>
</tr>
<tr>
<td>Zero</td>
<td>Indicating no error, end-of-file, or end-of-record condition occurred.</td>
</tr>
</tbody>
</table>

Execution continues with the statement following the data transfer statement, or the statement identified by a branch specifier (if any).

An end-of-file condition occurs only during execution of a sequential READ statement; an end-of-record condition occurs only during execution of a nonadvancing READ statement.

List of Run-Time Error Messages
CLOSE
READ
WRITE

Branch Specifiers (END=, EOR=, ERR=)
A branch specifier identifies a branch target statement that receives control if an error, end-of-file, or end-of-record condition occurs. There are three branch specifiers, taking the following forms:

ERR=label
END=label
EOR=label

label Is the label of the branch target statement that receives control when the specified condition occurs.

The branch target statement must be in the same scoping unit as the data transfer statement.

The following rules apply to these specifiers:

- **ERR**
  - The error specifier can appear in a sequential access READ or WRITE statement, a direct-access READ statement, or a REWRITE statement.
  - If an error condition occurs, the position of the file is indeterminate, and execution of the statement terminates.
If IOSTAT was specified, the IOSTAT variable becomes defined as a positive integer value. If SIZE was specified (in a nonadvancing READ statement), the SIZE variable becomes defined as an integer value. If a label was specified, execution continues with the labeled statement.

• END

The end-of-file specifier can appear only in a sequential access READ statement.

An end-of-file condition occurs when no more records exist in a file during a sequential read, or when an end-of-file record produced by the ENDFILE statement is encountered. End-of-file conditions do not occur in direct-access READ statements.

If an end-of-file condition occurs, the file is positioned after the end-of-file record, and execution of the statement terminates.

If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value. If a label was specified, execution continues with the labeled statement.

• EOR

The end-of-record specifier can appear only in a formatted, sequential access READ statement that has the specifier ADVANCE='NO' (nonadvancing input).

An end-of-record condition occurs when a nonadvancing READ statement tries to transfer data from a position after the end of a record.

If an end-of-record condition occurs, the file is positioned after the current record, and execution of the statement terminates.

If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value. If PAD='YES' was specified for file connection, the record is padded with blanks (as necessary) to satisfy the input item list and the corresponding data edit descriptor. If SIZE was specified, the SIZE variable becomes defined as an integer value. If a label was specified, execution continues with the labeled statement.

If one of the conditions occurs, no branch specifier appears in the control list, but an IOSTAT specifier appears, execution continues with the statement following the I/O statement. If neither a branch specifier nor an IOSTAT specifier appears, the program terminates.

I/O Status Specifier
Branch Statements

Compiler Reference section: Error Handling for details on error processing

Advance Specifier (ADVANCE=)

The advance specifier determines whether nonadvancing I/O occurs for a data transfer statement. It takes the following form:

ADVANCE=c-expr

c-expr

Is a scalar character expression that evaluates to 'YES' for advancing I/O or 'NO' for nonadvancing I/O. The default value is 'YES'.

Trailing blanks in the expression are ignored. The values specified are without regard to case.

The ADVANCE specifier can appear only in a formatted, sequential data transfer statement that specifies an external unit. It must not be specified for list-directed or namelist data transfer, for a data transfer statement within a DO CONCURRENT block, nor for a data transfer statement within a DO CONCURRENT block.

Advancing I/O always positions a file at the end of a record, unless an error condition occurs. Nonadvancing I/O can position a file at a character position within the current record.

See Also

Compiler Reference: Data and I/O: Fortran I/O: Advancing and Nonadvancing Record I/O
Asynchronous Specifier (ASYNCHRONOUS=)
The asynchronous specifier determines whether asynchronous I/O occurs for a data transfer statement. It takes the following form:

ASYNCHRONOUS=i-expr

i-expr

Is a scalar character constant expression that evaluates to 'YES' for asynchronous I/O or 'NO' for synchronous I/O. The value 'YES' should not appear unless the data transfer statement specifies a file unit number for io-unit. The default value is 'NO'.

Trailing blanks in the expression are ignored. The values specified are without regard to case.

Asynchronous I/O is permitted only for external files opened with an OPEN statement that specifies ASYNCHRONOUS='YES'.

When an asynchronous I/O statement is executed, the pending I/O storage sequence for the data transfer operation is defined to be:

- The set of storage units specified by the I/O item list or by the NML= specifier
- The storage units specified by the SIZE= specifier

Character Count Specifier (SIZE=)
The character count specifier defines a variable to contain the count of the characters transferred by data edit descriptors during execution of the current input statement. It takes the following form:

SIZE=i-var

i-var

Is a scalar integer variable.

If PAD='YES' was specified for file connection, blanks inserted as padding are not counted.

For input statements, the SIZE= specifier can appear only in a formatted, sequential READ statement that has the specifier ADVANCE='NO' (nonadvancing input). It must not be specified for list-directed or namelist data transfer.

For asynchronous nonadvancing input, the storage units specified in the SIZE= specifier become defined with the count of the characters transferred when the corresponding wait operation is executed.

ID Specifier (ID=)
The ID specifier identifies a pending data transfer operation for a specified unit. It takes the following form:

ID=id-var

id-var

Is a scalar integer variable to be used as an identifier.

This specifier can only be used if the value of ASYNCHRONOUS=i-expr is 'YES'.

If an ID specifier is used in a data transfer statement, a wait operation is performed for the operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.

If an error occurs during the execution of a data transfer statement containing an ID specifier, the variable specified becomes undefined.

In an INQUIRE statement, the ID= specifier identifies a pending asynchronous data transfer. It is used with the PENDING specifier to determine whether a specific asynchronous pending data transfer is completed.

POS Specifier (POS=)
The POS specifier identifies the file position in file storage units in a stream file (ACCESS='STREAM'). It takes the following form:

POS=p
\( p \)

Is a scalar integer expression that specifies the file position. It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

Each file storage unit has a unique file position, represented by a positive integer. The first file storage unit is a file at file position 1. The position of each subsequent file storage unit is one greater than that of its preceding file storage unit.

For a formatted file, the file storage unit is an eight-bit byte. For an unformatted file, the file storage unit is an eight-bit byte (if option assume byterecl is specified) or a 32-bit word (if option assume nobyterecl, the default, is specified).

**I/O Message Specifier (IOMSG=)**

The I/O message specifier designates a variable to contain the message to be returned when an I/O error occurs. It takes the following form:

\[ \text{IOMSG}= \text{msg-var} \]

\( \text{msg-var} \)

Is a scalar default character variable.

If an error (ERR=), end-of-file (END=), or end-of-record (EOR=) condition occurs during execution of an I/O statement, \( \text{msg-var} \) is assigned an explanatory message.

If no error occurs, the value of the variable remains unchanged.

**I/O Lists**

In a data transfer statement, the I/O list specifies the entities whose values will be transferred. An input list is made up of implied-do lists and simple lists of variables (except for assumed-size arrays). An output list is made up of implied-do lists, expressions, and simple lists of variables (except for assumed-size arrays).

In input statements, the I/O list cannot contain constants and expressions because these do not specify named memory locations that can be referenced later in the program.

However, constants and expressions can appear in the I/O lists for output statements because the compiler can use temporary memory locations to hold these values during the execution of the I/O statement.

If an input item is a pointer, it must be currently associated with a definable target; data is transferred from the file to the associated target. If an output item is a pointer, it must be currently associated with a target; data is transferred from the target to the file.

If an input or output item is an array, it is treated as if the elements (if any) were specified in array element order. For example, if \( \text{ARRAY}_A \) is an array of shape \((2,1)\), the following input statements are equivalent:

\[
\begin{align*}
\text{READ } *, \text{ ARRAY}_A \\
\text{READ } *, \text{ ARRAY}_A(1,1), \text{ ARRAY}_A(2,1)
\end{align*}
\]

However, no element of that array can affect the value of any expression in the input list, nor can any element appear more than once in an input list. For example, the following input statements are invalid:

\[
\begin{align*}
\text{INTEGER } \text{B}(50) \\
\text{...} \\
\text{READ } *, \text{ B(B)} \\
\text{READ } *, \text{ B(B(1):B(10))}
\end{align*}
\]

If an input or output item is an allocatable array, it must be currently allocated.

If an input or output item is a derived type, the following rules apply:

- Any derived-type component must be in the scoping unit containing the I/O statement.
- The derived type must not have a pointer component.
- In a formatted I/O statement, a derived type is treated as if all of the components of the structure were specified in the same order as in the derived-type definition.
- In an unformatted I/O statement, a derived type is treated as a single object.

Simple List Items in I/O Lists
Implied-DO Lists in I/O Lists

Simple List Items in I/O Lists
In a data transfer statement, a simple list of items takes the following form:

\[ \text{item} \ [\text{, item}] \ldots \]

\text{item} \hspace{1cm} \text{Is one of the following:}

- For input statements: a variable name
  The variable must not be an assumed-size array, unless one of the following appears in the last dimension: a subscript, a vector subscript, or a section subscript specifying an upper bound.
- For output statements: a variable name, expression, or constant
  Any expression must not attempt further I/O operations on the same logical unit. For example, it must not refer to a function subprogram that performs I/O on the same logical unit.

The data transfer statement assigns values to (or transfers values from) the list items in the order in which the items appear, from left to right.

When multiple array names are used in the I/O list of an unformatted input or output statement, only one record is read or written, regardless of how many array name references appear in the list.

Examples
The following example shows a simple I/O list:

\[
\text{WRITE (6,10) J, K(3), 4, (L+4)/2, N}
\]

When you use an array name reference in an I/O list, an input statement reads enough data to fill every item of the array. An output statement writes all of the values in the array.

Data transfer begins with the initial item of the array and proceeds in the order of subscript progression, with the leftmost subscript varying most rapidly. The following statement defines a two-dimensional array:

\[
\text{DIMENSION ARRAY(3,3)}
\]

If the name ARRAY appears with no subscripts in a READ statement, that statement assigns values from the input record(s) to ARRAY(1,1), ARRAY(2,1), ARRAY(3,1), ARRAY(1,2), and so on through ARRAY(3,3).

An input record contains the following values:

\[
1,3,721.73
\]

The following example shows how variables in the I/O list can be used in array subscripts later in the list:

\[
\text{DIMENSION ARRAY(3,3)}
\]

\[
\text{READ (1,30) J, K, ARRAY(J,K)}
\]

When the READ statement is executed, the first input value is assigned to J and the second to K, establishing the subscript values for ARRAY(J,K). The value 721.73 is then assigned to ARRAY(1,3). Note that the variables must appear before their use as array subscripts.

Consider the following derived-type definition and structure declaration:

\[
\text{TYPE EMPLOYEE}
\]

\[
\text{INTEGER ID}
\]

\[
\text{CHARACTER(LEN=40) NAME}
\]
END TYPE EMPLOYEE

TYPE(EMPLOYEE) :: CONTRACT  ! A structure of type EMPLOYEE

The following statements are equivalent:

READ *, CONTRACT
READ *, CONTRACT%ID, CONTRACT%NAME

The following shows more examples:

! A variable and array element in iolist:
REAL b(99)
READ (*, 300) n, b(n)  ! n and b(n) are the iolist
300  FORMAT (I2, F10.5) ! FORMAT statement telling what form the input data has

! A derived type and type element in iolist:
TYPE YOUR_DATA
  REAL a
  CHARACTER(30) info
  COMPLEX cx
END TYPE YOUR_DATA
TYPE (YOUR_DATA) yd1, yd2
  yd1.a = 2.3
  yd1.info = "This is a type demo."
  yd1.cx = (3.0, 4.0)
  yd2.cx = (4.5, 6.7)
! The iolist follows the WRITE (*,500).
  WRITE (*, 500) yd1, yd2.cx
! The format statement tells how the iolist will be output.
500  FORMAT (F5.3, A21, F5.2, ',', F5.2, ' yd2.cx = (', F5.2,
          ',',F5.2, ' )')
! The output looks like:
!  2.300This is a type demo 3.00, 4.00 yd2.cx = ( 4.50, 6.70 )

The following example uses an array and an array section:

! An array in the iolist:
INTEGER handle(5)
DATA handle / 5*0 /
WRITE (*, 99) handle
99  FORMAT (5I5)
! An array section in the iolist.
WRITE (*, 100) handle(2:3)
100  FORMAT (2I5)

The following shows another example:

PRINT *,'(I5)', 2*3  ! The iolist is the expression 2*3.

The following example uses a namelist:

! Namelist I/O:
  INTEGER int1
  LOGICAL log1
  REAL r1
  CHARACTER (20) char20
NAMELIST /mylist/ int1, log1, r1, char20
int1 = 1
log1 = .TRUE.
r1 = 1.0
char20 = 'NAMELIST demo'
OPEN (UNIT = 4, FILE = 'MYFILE.DAT', DELIM = 'APOSTROPHE')
WRITE (UNIT = 4, NML = mylist)
! Writes the following:
! &MYLIST
! ! INT1 = 1,
! ! LOG1 = T,
! ! R1 = 1.000000,
! ! CHAR20 = 'NAMELIST demo '
! /
REWIND(4)
READ (4, mylist)

I/O Lists for details on the general rules for I/O lists

Implied-DO Lists in I/O Lists
In a data transfer statement, an implied-DO list acts as though it were a part of an I/O statement within a DO loop. It takes the following form:

( list, do-var = expr 1, expr 2 [, expr 3] )

list Is a list of variables, expressions, or constants (see Simple List Items in I/O Lists).

do-var Is the name of a scalar integer or real variable. The variable must not be one of the input items in list.

expr Are scalar numeric expressions of type integer or real. They do not all have to be the same type, or the same type as the DO variable.

The implied-DO loop is initiated, executed, and terminated in the same way as a DO construct.
The list is the range of the implied-DO loop. Items in that list can refer to do-var, but they must not change the value of do-var.
Two nested implied-DO lists must not have the same (or an associated) DO variable.
Use an implied-DO list to do the following:
- Specify iteration of part of an I/O list
- Transfer part of an array
- Transfer array items in a sequence different from the order of subscript progression
If the I/O statement containing an implied-DO list terminates abnormally (with an END, EOR, or ERR branch or with an IOSTAT value other than zero), the DO variable becomes undefined.

Examples
The following two output statements are equivalent:

```
WRITE (3,200) (A,B,C, I=1,3) ! An implied-DO list
```

The following example shows nested implied-DO lists. Execution of the innermost list is repeated most often:

```
WRITE (6,150) ((FORM(K,L), I=1,10), K=1,10,2)
```
The inner DO loop is executed 10 times for each iteration of the outer loop; the second subscript (L) advances from 1 through 10 for each increment of the first subscript (K). This is the reverse of the normal array element order. Note that K is incremented by 2, so only the odd-numbered rows of the array are output.

In the following example, the entire list of the implied-DO list \((P(1), Q(1,1), Q(1,2)\ldots,Q(1,10))\) are read before I is incremented to 2:

```fortran
READ (5,999) (P(I), (Q(I,J), J=1,10), I=1,5)
```

The following example uses fixed subscripts and subscripts that vary according to the implied-DO list:

```fortran
READ (3,5555) (BOX(1,J), J=1,10)
```

Input values are assigned to BOX(1,1) through BOX(1,10), but other elements of the array are not affected.

The following example shows how a DO variable can be output directly:

```fortran
WRITE (6,1111) (I, I=1,20)
```

Integers 1 through 20 are written.

Consider the following:

```fortran
INTEGER mydata(25)
READ (10, 9000) (mydata(I), I=6,10,1)
9000  FORMAT (5I3)
```

In this example, the `iolist` specifies to put the input data into elements 6 through 10 of the array called `mydata`. The third value in the implied-DO loop, the increment, is optional. If you leave it out, the increment value defaults to 1.

I/O Lists for details on the general rules for I/O lists

### Forms for READ Statements

This section discusses the various forms you can specify for READ statements.

#### Forms for Sequential READ Statements

Sequential READ statements transfer input data from external sequential-access records. The statements can be formatted with format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential READ statement takes one of the following forms:

**Formatted:**

```fortran
```

```fortran
READ form [, io-list]
```

**Formatted - List-Directed:**

```fortran
```

```fortran
READ * [, io-list]
```
**Formatted - Namelist:**

```
```

**Unformatted:**

```
```

**See Also**

READ

I/O control-list specifiers

I/O lists

**Rules for Formatted Sequential READ Statements**

Formatted, sequential READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.

If the number of I/O list items is *less* than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is *greater* than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

**Examples**

The following example shows formatted, sequential READ statements:

```
READ (*, '(B)', ADVANCE='NO') C

READ (FMT="(E2.4)", UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

**See Also**

READ statement

Forms for Sequential READ Statements

**Rules for List-Directed Sequential READ Statements**

List-directed, sequential READ statements translate data from character to binary form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then assigned to the entities in the I/O list in the order in which they appear, from left to right.

If a slash ( / ) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.
List-Directed Records

A list-directed external record consists of a sequence of values and value separators. A value can be any of the following:

- A constant

Each constant must be a literal constant of type integer, real, complex, logical, or character; or a nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.

In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:

- A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements). Conversion is not performed between numeric and logical types unless compiler option `assume old logical ldio` is in effect. The decimal point in a numeric constant can either be a period if `DECIMAL='POINT'` or a comma if `DECIMAL='COMMA'`.
- A complex constant has the form of a pair of real or integer constants separated by a comma if `DECIMAL='POINT'` or a semicolon if `DECIMAL='COMMA'` and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, and after the separating comma or semicolon, and between the second constant and the closing parenthesis.
- A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

A character string does not need delimiting apostrophes or quotation marks if the corresponding I/O list item is of type default character, and the following is true:

- The character string does not contain a blank, comma (,), or slash (/).
- The character string is not continued across a record boundary.
- The first nonblank character in the string is not an apostrophe or a quotation mark.
- The leading character is not a string of digits followed by an asterisk.

A nondelimited character string is terminated by the first blank, comma, slash, or end-of-record encountered. Apostrophes and quotation marks within nondelimited character strings are transferred as is.

- A null value

A null value is specified by two consecutive value separators (such as,,) or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.

- A repetition of a null value (r*) or a constant (r*constant), where r is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.

A value separator is any number of blanks, a slash, or a comma if `DECIMAL='POINT'` or a semicolon if `DECIMAL='COMMA'`, preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the character constant, not value separators.

The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.
Examples

Suppose the following statements are specified:

```fortran
CHARACTER*14 C
DOUBLE PRECISION T
COMPLEX D,E
LOGICAL L,M
READ (1,*) I,R,D,E,L,M,J,S,T,C,A,B
```

Then suppose the following external record is read:

```
4 6.3 (3.4,4.2), (3, 2 ), T,F,,3*14.6,'ABC,DEF/GHI''JK'/
```

The following values are assigned to the I/O list items when DECIMAL='POINT':

<table>
<thead>
<tr>
<th>I/O List Item</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>4</td>
</tr>
<tr>
<td>R</td>
<td>6.3</td>
</tr>
<tr>
<td>D</td>
<td>(3.4,4.2)</td>
</tr>
<tr>
<td>E</td>
<td>(3.0,2.0)</td>
</tr>
<tr>
<td>L</td>
<td>.TRUE.</td>
</tr>
<tr>
<td>M</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>J</td>
<td>Unchanged</td>
</tr>
<tr>
<td>K</td>
<td>14</td>
</tr>
<tr>
<td>S</td>
<td>14.6</td>
</tr>
<tr>
<td>T</td>
<td>14.6D0</td>
</tr>
<tr>
<td>C</td>
<td>ABC,DEF/GHI' JK</td>
</tr>
<tr>
<td>A</td>
<td>Unchanged</td>
</tr>
<tr>
<td>B</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>

With DECIMAL='COMMA', the following external record produces the same values as in the table above:

```
4 6,3 (3,4;4,2), (3; 2 ); T,F;,3*14,6,'ABC;DEF/GHI''JK'/
```

The following example shows list-directed input and output:

```fortran
REAL    a
INTEGER i
COMPLEX c
LOGICAL up, down
DATA a /2358.2E-8/, i /91585/, c /(705.60,819.60)/
DATA up / .TRUE. /, down / .FALSE. /
OPEN (UNIT = 9, FILE = 'listout', STATUS = 'NEW')
WRITE  (9, *) a, i
WRITE  (9, *) c, up, down
REWIND (9)
READ   (9, *) a, i
READ   (9, *) c, up, down
```
WRITE  (*, *) a, i
WRITE  (*, *) c, up, down
END

The preceding program produces the following output:

```
   2.3582001E-05     91585
   (705.6000,819.6000) T F
```

READ

*Forms for Sequential READ Statements*

*Intrinsic Data Types* for details on the literal constant forms of intrinsic data types

*Rules for List-Directed Sequential WRITE Statements* for details on list-directed output

**Rules for Namelist Sequential READ Statements**

Namelist, sequential READ statements translate data from external to internal form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is assigned to objects in the namelist group by specifying the name of the object to which the data is to be assigned.

The order of the object name and data pairs in the input records need not match the order of the objects in the namelist var-list. The input need not specify all objects in the namelist var-list. They may specify a part of an object more than once. Namelist group names and object names are case insensitive.

If a slash (/) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged. An ampersand (&) encountered during input is treated the same as a slash (/).

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

**Namelist Records**

A namelist external record takes the following form:

```
&group-nameobject = value [{, | ;} object = value] .../
```

- **group-name**
  - Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit. The name cannot contain embedded blanks and must be contained within a single record.

- **object**
  - Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks except within the parentheses of a subscript or substring specifier. Each object must be contained in a single record.

- **value**
  - Is any of the following:
    - A constant
      - Each constant must be a literal constant of type integer, real, complex, logical, or character; or a delimited or nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.
      - In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:
• A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements). Logical list items and logical constants are not considered numeric, unless the compiler option `assume old logical ldio` is specified. The decimal point in a numeric constant can either be a period if DECIMAL='POINT' or a comma if DECIMAL='COMMA'.

• A complex constant has the form of a pair of real or integer constants separated by a comma if DECIMAL='POINT' or a semicolon if DECIMAL='COMMA' and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, before and after the separating comma or semicolon, and between the second constant and the closing parenthesis.

• A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

Normally, a character string in a NAMELIST statement must be delimited to be read. A delimited string is denoted by apostrophes (DELM=APPOSTROPHE), or quotes (DELM=QUOTE).

Intel® Fortran also allows setting DELM=NONE, which is the default for both input and output. In this case, non-delimited strings are allowed under certain circumstances.

A character string does not need delimiting apostrophes or quotation marks if the corresponding NAMELIST item is of type default character and it complies with the following rules:

• The character string cannot contain a blank, tab, equal sign (=), dollar sign ($), slash (/), new line, ampersand (&), or exclamation point(!). A nondelimited character string is terminated if one of these is encountered.

• Normally, a comma will also cause termination of the nondelimited character string. However, if DECIMAL=COMMA is specified, then the character string cannot contain semicolons but it can contain commas. In this case, if a semicolon is encountered the nondelimited character string is terminated.

• A null value
A null value is specified by two consecutive value separators (such as two adjacent commas ",,") or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.

• A repetition of a null value (r*) or a constant (r*constant), where r is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.
Blanks can precede or follow the beginning ampersand (&), follow the group name, precede or follow the equal sign, or precede the terminating slash.

Comments (beginning with ! only) can appear anywhere in namelist input. The comment extends to the end of the source line.

If an entity appears more than once within the input record for a namelist data transfer, the last value is the one that is used.

If there is more than one object = value pair, they must be separated by value separators.

A value separator is any number of blanks, a slash, or a comma if DECIMAL='POINT' or a semicolon if DECIMAL='COMMA', preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the character constant, not value separators.

The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.

When the name in the input record is an array variable or a variable of derived type, the effect is as if the variable represented were expanded into a sequence of scalar list items of intrinsic data types. Each input value following the equal sign must comply with format specifications for the intrinsic type of the list item in the corresponding position in the expanded sequence.

The number of values following the equal sign must be equal to or less than the number of list items in the expanded sequence. In the latter case (less than), the effect is as if null values have been added to match any remaining list items in the expanded sequence.

The string length in the NAMELIST statement is not checked against the size of the CHARACTER variable to which it will be assigned. This means that an array of $n$ elements written in a NAMELIST statement with DELIM=NONE may not be read back as $n$ values. For example, consider a three-element array ARR of three-character elements with values "ABC","DEF","GHI". In DELIM=NONE form, it prints to the data file as follows:

```plaintext
ARR = ABCDEFGHI
```

If your program reads that data file, the value will be interpreted as one non-delimited string with the value "ABCDEFGH" because termination is caused by the trailing blank, tab, or new line.

In some cases, values can be read as more than one string; for example, if the values themselves have final or internal blanks, tabs, or new lines. Consider that ARR contains strings "WX ","Y\tR", "S\nQ", where "\t" is a tab character and "\n" is a newline character. In this case, the data file contains:

```plaintext
ARR = WX Y\tRS\nQ
```

The NAMELIST processing will interpret this as four non-delimited strings: "WX", "Y", "RS" and "Q".

**NOTE**

In NAMELIST declarations, you may get unexpected results if all of the following are true:

1. DELIM=NONE is in effect on input.
2. A character variable is followed by another variable.
3. The other variable is either an array variable that is subscripted or a string variable that is a substring.
4. That subscript or substring expression contains blanks.
In Intel® Fortran, a list of values may follow the equal sign when the object is a single array element. In this case, values are assigned to the specified array element and subsequent elements, in element sequence order. For example, suppose the following input is read:

```
&ELEM
ARRAY_A(3)=34.54, 45.34, 87.63, 3*20.00
/
```

New values are assigned only to array `ARRAY_A` elements 3 through 8. The other element values are unchanged.

**Prompting for Namelist Group Information**

During execution of a program containing a namelist READ statement, you can specify a question mark character (?) or a question mark character preceded by an equal sign (=?) to get information about the namelist group. The ? or =? must follow one or more blanks.

If specified for a unit capable of both input and output, the ? causes display of the group name and the objects in that group. The =? causes display of the group name, objects within that group, and the current values for those objects (in namelist output form). If specified for another type of unit, the symbols are ignored.

For example, consider the following statements:

```
NAMELIST /NLIST/ A,B,C
REAL A /1.5/
INTEGER B /2/
CHARACTER*5 C /'ABCDE'/
READ (5,NML=NLIST)
WRITE (6,NML=NLIST)
END
```

During execution, if a blank followed by ? is entered on a terminal device, the following values are displayed:

```
&NLIST
A
B
C
/
```

If a blank followed by =? is entered, the following values are displayed:

```
&NLIST
A  =  1.500000,
B  =            2,
C  = ABCDE
/
```

**Examples**

Suppose the following statements are specified:

```
NAMELIST /CONTROL/ TITLE, RESET, START, STOP, INTERVAL
CHARACTER*10 TITLE
REAL(KIND=8) START, STOP
LOGICAL(KIND=4) RESET
INTEGER(KIND=4) INTERVAL
READ (UNIT=1, NML=CONTROL)
```
The NAMELIST statement associates the group name CONTROL with a list of five objects. The corresponding READ statement reads the following input data from unit 1:

```plaintext
&CONTROL
   TITLE='TESTT002AA',
   INTERVAL=1,
   RESET=.TRUE.,
   START=10.2,
   STOP =14.5
/
```

The following values are assigned to objects in group CONTROL:

<table>
<thead>
<tr>
<th>Namelist Object</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>TITLE</td>
<td>TESTT002AA</td>
</tr>
<tr>
<td>RESET</td>
<td>T</td>
</tr>
<tr>
<td>START</td>
<td>10.2</td>
</tr>
<tr>
<td>STOP</td>
<td>14.5</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>1</td>
</tr>
</tbody>
</table>

It is not necessary to assign values to all of the objects declared in the corresponding NAMELIST group. If a namelist object does not appear in the input statement, its value (if any) is unchanged.

Similarly, when character substrings and array elements are specified, only the values of the specified variable substrings and array elements are changed. For example, suppose the following input is read:

```plaintext
&CONTROL TITLE(9:10)='BB' /
```

The new value for TITLE is TESTT002BB; only the last two characters in the variable change.

The following example shows an array as an object:

```plaintext
DIMENSION ARRAY_A(20)
NAMELIST /ELEM/ ARRAY_A
READ (UNIT=1,NML=ELEM)
```

Suppose the following input is read:

```plaintext
&ELEM
ARRAY_A=1.1, 1.2,, 1.4
/
```

The following values are assigned to the ARRAY_A elements:

<table>
<thead>
<tr>
<th>Array Element</th>
<th>Value Assigned</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARRAY_A(1)</td>
<td>1.1</td>
</tr>
<tr>
<td>ARRAY_A(2)</td>
<td>1.2</td>
</tr>
<tr>
<td>ARRAY_A(3)</td>
<td>Unchanged</td>
</tr>
<tr>
<td>ARRAY_A(4)</td>
<td>1.4</td>
</tr>
<tr>
<td>ARRAY_A(5)...ARRAY(20)</td>
<td>Unchanged</td>
</tr>
</tbody>
</table>
Nondelimited character strings that are written out by using a NAMELIST write may not be read in as expected by a corresponding NAMELIST read. Consider the following:

```
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/ 'AAA', 'BBB', 'CCC', 'DDD'/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
WRITE (1, NML=TEST)
END
```

The output file NMLTEST.DAT will contain:

```
&TEST CHARR   = AAABBBCCCDDD/
```

If an attempt is then made to read the data in NMLTEST.DAT with a NAMELIST read using nondelimited character strings, as follows:

```
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/ 4*'   '/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
READ (1, NML=TEST)
PRINT *, 'CHARR read in >', CHARR(1), '<  >', CHARR(2), '<  >',
          1       CHARR(3), '<  >', CHARR(4), '<'
END
```

The result is the following:

```
CHARR read in >AAA<  >  >  >  >
```

The 12 characters of input were read, truncated to 3 characters, and stored in CHARR(1). The other 3 elements of CHARR were unchanged.

Rules for Unformatted Sequential READ Statements

Unformatted, sequential READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. The value transferred from the file is called a field. Only one record is read.

Objects of intrinsic or derived types can be transferred.

For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, sequential READ statement reads a single record. Each field value in the record must be of the same type as the corresponding entity in the input list, unless the field value is real or complex.

If the field value is real or complex, one complex field value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.

If the number of I/O list items is less than or equal to the number of fields in an input record, the READ statement ignores the excess fields. If the number of I/O list items is greater than the number of fields in an input record, an error occurs.

If a READ statement contains no I/O list, it skips over one full record, positioning the file to read the following record on the next execution of a READ statement.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.
You have previously been able to buffer the output (WRITEs) of variable length, unformatted, sequential files, by specifying certain values for an OPEN statement, environment variable, or compiler option. You can now do the same buffering for input (READs) of records. To enable buffering for the input of records, you can specify any of the following:

- BUFFERED=YES in the file's OPEN statement
- Value YES (Y or y), or TRUE (T or t), or a number > 0 for the environment variable FORT_BUFFERED
- Setting buffered_io for the assume option

When any of the above are specified, the Fortran Runtime Library buffers all input records from variable length, unformatted, sequential files, regardless of the size of the records in the file. In addition, if the environment variable FORT_BUFFERING_THRESHOLD has a positive value $n$, the following occurs:

- I/O list items with a size $\leq n$ are buffered and are moved one at a time from the runtime buffer to the I/O list item
- I/O list items with a size $> n$ are not buffered and are moved one at a time from the file to the I/O list item

**Determining the Size of I/O Buffers**

If both the block size and the buffer count have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. If neither is specified, the default size of the buffer is 8KB (8192 bytes). This is the initial size of the I/O buffer; the buffer may be expanded to hold a larger record.

If block size is not specified, the following occurs:

- The block size defaults to 128KB
- If the buffer count is not specified, it defaults to 1
- The initial default buffer size is 8KB
- If buffer count is specified, then the initial default buffer size is (8KB * buffercount)

If a block size is specified, the following occurs:

- The block size is the specified value, rounded up to 512-byte boundary
- If the buffer count is not specified, it defaults to 1
- The initial default buffer size is the block size, rounded up to 512-byte boundary
- If buffer count is specified, then the initial default buffer size is (block size * buffer count)

**Optimizing for Time or Space**

When reading variable length, unformatted sequential records, the runtime system may optimize for time or for space.

This optimization decision is made during runtime on a record-by-record basis using specifications made by the program and the length of a given record. That is, one record may be optimized for time while another record from the same file may be optimized for space.

The default behavior when reading records of this type whose length exceeds the specified block size, is to not buffer the input records. You can override this default behavior by requesting that the input be buffered.

The following table shows the relationship between a file's specified block size and the length of its variable length records. Note that the length of the individual record is the key:

<table>
<thead>
<tr>
<th>Buffering</th>
<th>Record Length $\geq$ Block Size</th>
<th>Record Length $&lt;\text{ block size}$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buffering unspecified</td>
<td>Optimizes for space</td>
<td>Optimizes for time</td>
</tr>
<tr>
<td>OPEN (BUFFERED='YES')</td>
<td>Optimizes for time</td>
<td>Optimizes for time</td>
</tr>
<tr>
<td>OPEN (BUFFERED='NO')</td>
<td>Optimizes for space</td>
<td>Optimizes for time</td>
</tr>
</tbody>
</table>

If an input record's length is less than or equal to the specified block size, then by default, the runtime system always optimizes for time rather than for space and the input is buffered.
If an input record’s length is greater than the specified block size, then the following occurs:

- By default, the runtime system always optimizes for space rather than time and the input is not buffered.
- If you request buffering of input, then the runtime system optimizes for time and the input is buffered.
- If you request no buffering of input, then the runtime system optimizes for space rather than time and the input is not buffered.
- If you request dynamic buffering of input, the runtime system optimizes based on the size of the I/O list item and some items are buffered and some are not.

**Optimizing for time:**

Traditionally, optimizing for time comes at the expense of using more memory.

When the runtime system optimizes for time, it buffers input. It reads as much data as possible during one disk access into the runtime’s internal buffer, extending it if necessary to hold the file’s largest record. Fields within the record are then moved to the user space in response to READs from the file. Typically, minimizing file accesses is faster.

However, there are circumstances when optimizing for space can actually be faster than optimizing for time. For example, consider you are reading records whose length exceeds the block size and the data is being read into a contiguous array. Reading this huge array directly into a user's space is going to be faster than reading it first into the runtime system's internal buffer, then moving the data to the user's space. In this case, it is better to optimize for space; that is, you should not buffer the input record.

On the other hand, if the READ is being done into non-contiguous elements of an array, the traditional method of optimizing for time becomes a huge win. Data being read into non-contiguous array elements must be moved, or read, into the user's space one element at a time. In this case, you always want to optimize for time; that is, you should buffer the input data.

If you are reading large, variable length, unformatted records, you should try both buffered and unbuffered I/O to determine which delivers the better performance.

**Optimizing for space:**

Traditionally, optimizing for space comes at the expense of time.

When the runtime system optimizes for space, it wants to avoid creating a huge internal buffer in order to hold a "very large" record. The size of a "very large" record is clearly subjective, but the rule of thumb here is whether or not a record's size is greater than the specified block size.

If this is the case, the runtime system will read one field at a time from the record, directly into the I/O list items. The optimal record for this optimization is one whose record length exceeds the default block size of 128 KB (or a user-specified block size) and contains "very large" fields.

Note that because fields are read one at a time from the file to the user space, very large records that contain very small fields may see a serious performance issue. In these cases, it may be better to buffer the input. If you are reading large, variable length, unformatted records, you should try both buffered and unbuffered I/O to determine which delivers the better performance.

**Optimizing unformatted sequential input based on field size - dynamic buffering:**

Dynamic buffering is a hybrid solution that chooses the time/space trade-off on a per field basis. The decision is based on a "field size threshold" supplied by the user, deciding, for every field in every record in the file, regardless of the record length, whether or not to buffer a field from the file to the I/O list item. The runtime system can do this because it knows the size of a field that is being requested before actually attempting to read the field.

When a READ statement is first executed, a read from the file is issued to fill the buffer, regardless of its size. This is necessary so that the runtime system can extract the record size from the first length control field. (Each unformatted sequential record has 4-byte leading and trailing record lengths to facilitate reading both
forwards and backwards in the file.) From that point on, dynamic buffering decides whether or not to buffer a field or to read it directly from the file to the I/O list item. If the buffer holds the beginning portion of a large field, it will be moved to the start of the I/O list item and the remainder will be read directly from the file.

The following table shows the various buffering options for unformatted, sequential input:

<table>
<thead>
<tr>
<th>Buffering Option</th>
<th>How do I get this?</th>
<th>What happens?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-buffered</td>
<td>You get this kind of buffering by default, or by specifying:</td>
<td>When non-buffered is in effect:</td>
</tr>
<tr>
<td></td>
<td>• OPEN (BUFFERED=NO)</td>
<td>• The runtime system does not re-allocate its buffer to accommodate large records.</td>
</tr>
<tr>
<td></td>
<td>- or -</td>
<td>• Records with lengths &gt; the block size:</td>
</tr>
<tr>
<td></td>
<td>- FORT_BUFFERED=NO</td>
<td>• Are not buffered.</td>
</tr>
<tr>
<td></td>
<td>- or -</td>
<td>• All fields are moved one at a time from the file to the I/O list item.</td>
</tr>
<tr>
<td></td>
<td>• assume nobuffered_io</td>
<td>• Records with lengths &lt;= the block size:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Are buffered.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• All fields are moved one at a time from the buffer to the I/O list item.</td>
</tr>
<tr>
<td>Buffered</td>
<td>You get this kind of buffering by specifying:</td>
<td>When buffered is in effect:</td>
</tr>
<tr>
<td></td>
<td>• OPEN (BUFFERED=YES)</td>
<td>• The runtime system re-allocates its buffer to accommodate the largest record read.</td>
</tr>
<tr>
<td></td>
<td>- or -</td>
<td>• All input records are buffered.</td>
</tr>
<tr>
<td></td>
<td>- FORT_BUFFERED=YES</td>
<td>• All fields are moved one at a time from the buffer to the I/O list item.</td>
</tr>
<tr>
<td></td>
<td>- or -</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• assume buffered_io</td>
<td></td>
</tr>
<tr>
<td>Dynamic buffering</td>
<td>You get this kind of buffering by specifying:</td>
<td>When dynamic buffering is in effect:</td>
</tr>
<tr>
<td></td>
<td>• FORT_BUFFERING_THRESHOLD D=n</td>
<td>• The runtime system does not re-allocate its buffer to accommodate large records.</td>
</tr>
<tr>
<td></td>
<td>- and one of -</td>
<td>• All fields with a size &lt;= n are buffered and are moved one at a time from the buffer to the I/O list item.</td>
</tr>
<tr>
<td></td>
<td>• OPEN (BUFFERED=YES)</td>
<td>• Fields with a size &gt; n are not buffered and are moved one at a time from the file to the I/O list item.</td>
</tr>
<tr>
<td></td>
<td>- or -</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• FORT_BUFFERED=YES</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- or -</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• assume buffered_io</td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

The following example shows an unformatted, sequential READ statement:

```
READ (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

READ statement
Forms for Sequential READ Statements
Record Types

Forms for Direct-Access READ Statements
Direct-access READ statements transfer input data from external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)
A direct-access READ statement can be formatted or unformatted, and takes one of the following forms:

**Formatted:**

**Unformatted:**

See Also
READ
I/O control-list specifiers
I/O lists

Rules for Formatted Direct-Access READ Statements
Formatted, direct-access READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.
Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.
For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.
If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.
If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.
If the format specification specifies another record, the record number is increased by one as each subsequent record is read by that input statement.

Examples
The following example shows a formatted, direct-access READ statement:

```
READ (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

Rules for Unformatted Direct-Access READ Statements
Unformatted, direct-access READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. Only one record is read.
Objects of intrinsic or derived types can be transferred.
For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, direct-access READ statement reads a single record. Each value in the record must be of the same type as the corresponding entity in the input list, unless the value is real or complex.

If the value is real or complex, one complex value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields. If the number of I/O list items is greater than the number of fields in an input record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

**Examples**

The following example shows unformatted, direct-access READ statements:

```plaintext
READ (1, REC=10) LIST(1), LIST(8)
READ (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

**Forms for Stream READ Statements**

The forms for stream READ statements take the same forms as sequential READ statements. A POS specifier may be present to specify at what file position the READ will start.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

**Examples**

The following example shows stream READ statements:

```plaintext
READ (12 ) I       !stream reading without POS= specifier
READ (12,POS=10) J !stream reading with POS= specifier
```

**See Also**

NEW_LINE

**Forms and Rules for Internal READ Statements**

Internal READ statements transfer input data from an internal file.

An internal READ statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is also permitted.

An internal READ statement takes one of the following forms:

```plaintext
READ (iunit, format [, nml-group] [, iostat] [, err] [, end] [, iomsg]) [io-list]
READ (iunit, nml-group [, iostat] [, err] [, end] [, iomsg]) [io-list]
```

For more information on syntax, see READ.

Formatted, internal READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

This form of READ statement behaves as if the format begins with a BN edit descriptor. (You can override this behavior by explicitly specifying the BZ edit descriptor.)
Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

Before data transfer occurs, the file is positioned at the beginning of the first record. This record becomes the current record.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is greater than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains.

In list-directed and namelist formatting, character strings have no delimiters.

**Examples**

The following program segment reads a record and examines the first character to determine whether the remaining data should be interpreted as decimal, octal, or hexadecimal. It then uses internal READ statements to make appropriate conversions from character string representations to binary.

```fortran
INTEGER IVAL
CHARACTER TYPE, RECORD*80
CHARACTER(*) AFMT, IFMT, OFMT, ZFMT
PARAMETER (AFMT='(Q,A)', IFMT= '(I10)', OFMT= '(O11)', & ZFMT= '(Z8)')
ACCEPT AFMT, ILEN, RECORD
TYPE = RECORD(1:1)
IF (TYPE .EQ. 'D') THEN
   READ (RECORD(2:MIN(ILEN, 11)), IFMT) IVAL
ELSE IF (TYPE .EQ. 'O') THEN
   READ (RECORD(2:MIN(ILEN, 12)), OFMT) IVAL
ELSE IF (TYPE .EQ. 'X') THEN
   READ (RECORD(2:MIN(ILEN, 9)),ZFMT) IVAL
ELSE
   PRINT *, 'ERROR'
END IF
END
```

Rules for List-Directed Sequential READ Statements for details on list-directed input

Rules for Namelist Sequential READ Statement for details on namelist input

**Forms for WRITE Statements**

This section discusses the various forms you can specify for WRITE statements.

**Forms for Sequential WRITE Statements**

Sequential WRITE statements transfer output data to external sequential access records. The statements can be formatted by using format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential WRITE statement takes one of the following forms:

**Formatted:**

Formatted - List-Directed:

I/O lists

Rules for Formatted Sequential WRITE Statements
Formatted, sequential WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for sequential access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

The output list and format specification must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

Examples
The following example shows formatted, sequential WRITE statements:

```
WRITE (UNIT=8, FMT='(B)', ADVANCE='NO') C
WRITE (*, "(F6.5)", ERR=25, IOSTAT=IO_STATUS) A, B, C
```

WRITE statement
Forms for Sequential WRITE Statements

Rules for List-Directed Sequential WRITE Statements
List-directed, sequential WRITE statements transfer data from binary to character form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

The following table shows the default output formats for each intrinsic data type:
Default Formats for List-Directed Output

¹ Where w is the length of the character expression.

² If option assume noold ldout_format is in effect, the compiler uses Fortran 2018 standard semantics for output of integer and real values in list-directed and namelist-directed output. This means that for real and complex values, the output is in E or F format depending on the magnitude of the value. For more information, see the description of option assume.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

If DECIMAL='POINT', the decimal point in a numeric value is displayed as a period, values are separated by commas, and the separator between the real and imaginary parts of a complex value is a comma. If DECIMAL='COMMA', the decimal point is displayed as a comma, values are separated by semicolons, and the separator between the real and imaginary parts of a complex value is a semicolon.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma or semicolon and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control.

Slashes, octal values, null values, and repeated forms of values are not output.
If the file is connected for unformatted I/O, list-directed data transfer is prohibited.

**Examples**

Suppose the following statements are specified:

```plaintext
DIMENSION A(4)
DATA A/4*3.4/
WRITE (1,*) 'ARRAY VALUES FOLLOW'
WRITE (1,*) A,4
```

The following records are then written to external unit 1:

```
ARRAY VALUES FOLLOW
3.400000  3.400000  3.400000  3.400000  4
```

The following shows another example:

```plaintext
INTEGER i, j
REAL a, b
LOGICAL on, off
CHARACTER(20) c
DATA i /123456/, j /500/, a /28.22/, b /.0015555/
DATA on /'.TRUE./, off/.FALSE./
DATA c '/Here''s a string'/
WRITE (*, *) i, j
WRITE (*, *) a, b, on, off
WRITE (*, *) c
END
```

The preceding example produces the following output:

```
123456   500
28.22000 1.555500E-03  T  F
Here's a string
```

**See Also**

Rules for Formatted Sequential WRITE Statements
Rules for List-Directed Sequential READ Statements for details on list-directed input

**Rules for Namelist Sequential WRITE Statements**

Namelist, sequential WRITE statements translate data from internal to external form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.
If DECIMAL='POINT', the decimal point in a numeric value is displayed as a period, values are separated by commas, and the separator between the real and imaginary parts of a complex value is a comma. If DECIMAL='COMMA', the decimal point is displayed as a comma, values are separated by semicolons, and the separator between the real and imaginary parts of a complex value is a semicolon.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma or semicolon and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control, except for literal character constants that are continued from the previous record.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

**Examples**

Consider the following statements:

```
CHARACTER*19 NAME(2)/2*' '/
REAL PITCH, ROLL, YAW, POSITION(3)
LOGICAL DIAGNOSTICS
INTEGER ITERATIONS
TYPE MYTYPE
   INTEGER X
   REAL Y
   CHARACTER(5)Z
END TYPE MYTYPE
TYPE(MYTYPE) :: TYPEVAR = MYTYPE(1,2.0,'ABCDE')
NAMELIST /PARAM/ NAME, PITCH, ROLL, TYPEVAR, YAW, POSITION, &
   DIAGNOSTICS, ITERATIONS
...
READ (UNIT=1,NML=PARAM)
WRITE (UNIT=2,NML=PARAM)
```

Suppose the following input is read:
```
&PARAM
   NAME(2)(10:)= 'HEISENBERG',
   PITCH=5.0, YAW=0.0, ROLL=5.0,
   DIAGNOSTICS=.TRUE.,
   ITERATIONS=10
/
```

The following is then written to the file connected to unit 2:
```
&PARAM
   NAME     =                          ', ',' HEISENBERG',,
   PITCH    = 5.0000000,
   ROLL     = 5.0000000,
   TYPEVAR  = 1, 2.0, 'ABCDE'
   YAW      = 0.0000000E+00,
   POSITION = 3*0.0000000E+00,
   DIAGNOSTICS = T,
   ITERATIONS = 10
/
```

Note that character values are not enclosed in apostrophes unless the output file is opened with DELIM='APOSTROPHE'. The value of POSITION is not defined in the namelist input, so the current value of POSITION is written.
The following example declares a number of variables, which are placed in a namelist, initialized, and then written to the screen with namelist I/O:

```fortran
INTEGER(1) int1
INTEGER int2, int3, array(3)
LOGICAL(1) log1
LOGICAL log2, log3
REAL real1
REAL(8) real2
COMPLEX z1, z2
CHARACTER(1) char1
CHARACTER(10) char2

NAMELIST /example/ int1, int2, int3, log1, log2, log3, &
&       real1, real2, z1, z2, char1, char2, array

int1 = 11
int2 = 12
int3 = 14
log1 = .TRUE.
log2 = .TRUE.
log3 = .TRUE.
real1 = 24.0
real2 = 28.0d0
z1 = (38.0,0.0)
z2 = (316.0d0,0.0d0)
char1 = 'A'
char2 = '0123456789'
array(1) = 41
array(2) = 42
array(3) = 43
WRITE (*, example)
```

The preceding example produces the following output:

```fortran
&EXAMPLE
INT1 = 11,
INT2 = 12,
INT3 = 14,
LOG1 = T,
LOG2 = T,
LOG3 = T,
REAL1 = 24.00000,
REAL2 = 28.0000000000000,
Z1 = (38.00000,0.0000000E+00),
Z2 = (316.0000,0.0000000E+00),
CHAR1 = A,
CHAR2 = 0123456789,
ARRAY = 41, 42, 43
/```

NAMELIST
Rules for Formatted Sequential WRITE Statements
Rules for Namelist Sequential READ Statements
Rules for Unformatted Sequential WRITE Statements

Unformatted, sequential WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.

This form of WRITE statement writes exactly one record. If there is no I/O item list, the statement writes one null record.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

For a discussion of I/O buffering, see Rules for Unformatted Sequential READ Statements.

Examples

The following example shows an unformatted, sequential WRITE statement:

```
WRITE (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

Forms for Direct-Access WRITE Statements

Direct-access WRITE statements transfer output data to external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)

A direct-access WRITE statement can be formatted or unformatted, and takes one of the following forms:

Formatted:

```
```

Unformatted:

```
```

See Also

WRITE
I/O control-list specifiers
I/O lists

Rules for Formatted Direct-Access WRITE Statements

Formatted, direct-access WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for direct access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the format specification specifies another record, the record number is increased by one as each subsequent record is written by that output statement.

Examples

The following example shows a formatted, direct-access WRITE statement:

```
WRITE (2, REC=35, FMT=10) (NUM(K), K=1,10)
```
Rules for Unformatted Direct-Access WRITE Statements

Unformatted, direct-access WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

Examples

The following example shows unformatted, direct-access WRITE statements:

```
WRITE (1, REC=10) LIST(1), LIST(8)
WRITE (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

Forms for Stream WRITE Statements

The forms for stream WRITE statements take the same forms as sequential WRITE statements. A POS specifier may be present to specify at what file position the WRITE will start.

After a formatted stream WRITE where no error occurred, the output file is truncated after the byte with the largest POS value. An unformatted stream WRITE does not truncate the output file.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

See Also
NEW_LINE

Forms and Rules for Internal WRITE Statements

Internal WRITE statements transfer output data to an internal file.

An internal WRITE statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is also permitted.

An internal WRITE statement takes one of the following forms:

```
WRITE (iunit, format [, iostat] [, err] [, iomsg]) [io-list]
WRITE (iunit, nml-group [, iostat] [, err] [, iomsg]) [io-list]
```

For more information on syntax, see WRITE.

Formatted, internal WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an internal file.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the number of characters written in a record is less than the length of the record, the rest of the record is filled with blanks. The number of characters to be written must not exceed the length of the record.

Character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.
Examples
The following example shows an internal WRITE statement:

```fortran
INTEGER J, K, STAT_VALUE
CHARACTER*50 CHAR_50
...
WRITE (FMT=*, UNIT=CHAR_50, IOSTAT=STAT_VALUE) J, K
```

User-Defined Derived-Type I/O

By default, when a derived-type object is in a formatted I/O statement, it is treated as if all of its components were specified in the component order. The components must be accessible in the scope of the I/O statement and they cannot be pointers or allocatables. In an unformatted I/O statement, a derived-type object is treated as a single value in a processor-dependent form.

User-defined derived-type I/O lets you replace the default I/O processing for a derived-type object. For both unformatted and formatted I/O, a procedures can be invoked that will handle the I/O of the derived type. This is similar to defined operators and defined assignment.

For formatted I/O, the replacement occurs for list-directed formatting, namelist formatting, and for an explicit format with the DT edit descriptor. Other edit descriptors in the explicit format do not have any effect on user-defined I/O.

A procedure can be associated with defined I/O through generic bindings or generic interface blocks. The procedure must conform to the interface that specifies its characteristics. It cannot directly or indirectly use OpenMP constructs. A defined I/O procedure can also call itself recursively.

An I/O statement that includes a derived-type object and causes a defined I/O procedure to be invoked is called a parent I/O statement. An I/O statement that is executed while a parent statement is being processed, and specifies the unit passed to a defined I/O procedure, is called a child I/O statement.

A defined I/O procedure can be invoked as a parent I/O statement for an external or internal file opened for sequential, direct, or stream access.

This section also has information about how to resolve user-defined I/O procedure references.

Specifying the User-Defined Derived Type

This section discusses various aspects of user-defined I/O, such as characteristics of defined I/O procedures and resolving defined I/O procedure references.

DT Edit Descriptor in User-Defined I/O

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

```
DT [string] [(v-list)]
```

The `string` is a default character literal constant delimited by single quotes (‘‘) or double quotes ("’’); no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character. If `string` is not specified, a character string of length zero is passed.

The `v-list` is a list of one or more signed or unsigned integer literal constants; no kind parameter can be specified. If `v-list` is not specified, an integer array of length zero is passed.
A DT edit descriptor must correspond to a list item of a derived type. Also, there should be an accessible interface to a corresponding defined FORMATTED I/O procedure for that derived type.

In a format statement, if the last closing parenthesis of the format string is reached and there are no effective items left, then format processing terminates. But, if there are more items to be processed, then format control reverts to the beginning of the format item which was terminated by the next-to-last right parenthesis.

If there is no such preceding right parenthesis, it reverts to the first left parenthesis of the format specification. During this format reversion, the right parenthesis that is part of a DT edit descriptor is not considered as the next-to-last parenthesis. For example, consider the following:

```
write (10, '(F10.3, I5, DT "sample" (1, 2) )' ) 10.1, 3, obj1, 4.7, 1, obj2
```

In the above case, format control reverts to the left parenthesis before F10.3 and not to DT.

**Examples**

The following are valid ways to specify the DT edit descriptor:

- `DT`
- `DT "z8, i4, e10.2"`
- `DT (1, -1, +1000)`
- `DT 'spec1 type' (0)`

**Associating a Procedure with Defined I/O**

This section discusses defined I/O procedures, generic bindings, and generic interface blocks.

**Defined I/O Procedures**

For a particular derived type and a particular set of kind-type parameter values, there are four possible sets of characteristics for defined I/O procedures: formatted input, formatted output, unformatted input, and unformatted output.

To specify that an I/O procedure should be used for derived-type I/O, specify one of the following with a defined-io-generic-spec:

- A generic binding
- An interface block

A defined-io-generic-spec is one of the following statements:

- `READ (FORMATTED)`
- `READ (UNFORMATTED)`
- `WRITE (FORMATTED)`
- `WRITE (UNFORMATTED)`

**Generic Bindings**

User-defined I/O procedures can be type-bound procedures that use a defined-io-generic-spec (see Defined I/O Procedures).

Consider the following:

```
TYPE LIST
  TYPE(NODE), POINTER :: FIRST
CONTAINS
  PROCEDURE :: FMTREAD => LIST_FMTREAD
  PROCEDURE :: FMTWRITE => LIST_FMTWRITE
  GENERIC,PUBLIC :: READ(FORMATTED) => FMTREAD
  GENERIC,PUBLIC :: WRITE(FORMATTED) => FMTWRITE
END TYPE LIST
```

In the above example, LIST_FMTREAD and LIST_FMTWRITE are the type-bound defined I/O procedures. If an object of type LIST is an effective item in a formatted READ statement, LIST_FMTREAD will be called to perform the read operation.
See Also
Type-Bound Procedures
Resolving Defined I/O Procedure References

Generic Interface Block
A generic interface block can be used to associate procedures with defined I/O. The generic identifier should be the \texttt{defined-io-generic-spec} (see Defined I/O Procedures). This is the only option for sequence or BIND(C) types.

Consider the following:

```fortran
MODULE EXAMPLE

TYPE LIST
 INTEGER :: X
END TYPE

INTERFACE READ (FORMATTED)
 MODULE PROCEDURE R1
END INTERFACE

CONTAINS

SUBROUTINE R1 (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
 CLASS(LIST), INTENT(INOUT) :: DTV
 INTEGER, INTENT(IN) :: UNIT
 CHARACTER(*), INTENT(IN) :: IOTYPE
 INTEGER, INTENT(IN) :: V_LIST(:)
 INTEGER, INTENT(OUT) :: IOSTAT
 CHARACTER(*), INTENT(INOUT) :: IOMSG
 READ (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%X
END SUBROUTINE R1

END MODULE EXAMPLE
```

In the above example, \texttt{R1} is the \texttt{READ (FORMATTED)} defined I/O procedure.

If an object of type \texttt{LIST} is an effective item in a formatted \texttt{READ} statement, \texttt{R1} will be called.

See Also
TYPE Statement (Derived Types)
Defining Generic Names for Procedures

Characteristics of Defined I/O Procedures
Shown below are the four interfaces that specify the characteristics of the user-defined I/O procedures. The actual specific procedure names and the names of the dummy arguments in these interfaces are arbitrary.

The following names are used in the interfaces:

\texttt{dtv-type-spec} is one of the following:

- \texttt{TYPE(d-name)} for a sequence or BIND(C) type
- \texttt{CLASS(d-name)} for an extensible type

\texttt{d-name} is the name of the derived type. It cannot be an abstract type. All length type parameters of the derived type must be assumed.
var
Is a scalar of the derived type. For output, it holds the value to be written. For input, it will be altered in accordance with the values read.

unit
Is the scalar integer value of the I/O unit on which input or output is taking place. It is a negative number for an internal file or for an external unit that is a NEWUNIT value. It is a processor-dependent number (which may be negative) for the '*' unit.

iotype
Is the value 'LISTDIRECTED', 'NAMELIST', or 'DT'//string, where string is the character string from the DT edit descriptor.

vlist
Is a rank-one assumed-shape integer array whose value comes from the parenthetical list of integers from the DT edit descriptor. For list-directed formatting and namelist formatting, vlist is a zero-sized integer array.

iostat
Is a scalar integer variable that must be given a positive value if an error condition occurs. If an end-of-file or end-of-record condition occurs, it must be given the value IOSTAT_END or IOSTAT_EOR (from the intrinsic module ISO_FORTRAN_ENV). In all other cases, it must be given the value zero.

iomsg
Is an assumed-length scalar character variable that must be set to an explanatory message if iostat is given a nonzero value. Otherwise, it must not be altered.

The following interfaces specify the characteristics of the user-defined I/O procedures:

```
SUBROUTINE my_readFormatted (var, unit, iotype, vlist, iostat, iomsg)
dtv-type-spec, INTENT(INOUT) :: var
INTEGER, INTENT(IN) :: unit
CHARACTER(*), INTENT(IN) :: iotype
INTEGER, INTENT(IN) :: vlist(:)
INTEGER, INTENT(OUT) :: iostat
CHARACTER(*), INTENT(INOUT) :: iomsg
END

SUBROUTINE my_readUnformatted (var, unit, iostat, iomsg)
dtv-type-spec, INTENT(INOUT) :: var
INTEGER, INTENT(IN) :: unit
INTEGER, INTENT(OUT) :: iostat
CHARACTER(*), INTENT(INOUT) :: iomsg
END

SUBROUTINE my_writeFormatted (var, unit, iotype, vlist, iostat, iomsg)
dtv-type-spec, INTENT(IN) :: var
INTEGER, INTENT(IN) :: unit
CHARACTER(*), INTENT(IN) :: iotype
INTEGER, INTENT(IN) :: vlist(:)
INTEGER, INTENT(OUT) :: iostat
CHARACTER(*), INTENT(INOUT) :: iomsg
END

SUBROUTINE my_writeUnformatted (var, unit, iostat, iomsg)
dtv-type-spec, INTENT(IN) :: var
INTEGER, INTENT(IN) :: unit
```
INTEGER, INTENT(OUT) :: iostat
CHARACTER(*), INTENT(INOUT) :: iomsg
END

See Also
ISO_FORTRAN_ENV Module

Defined I/O Data Transfers
The following rules apply to defined I/O data transfers:

- During execution of a defined I/O procedure, there must be no I/O for an external unit except for the unit argument. However, I/O is permitted for internal files.
- You cannot use user-defined I/O in combination with asynchronous I/O.
- No file-positioning commands are permitted in the defined I/O procedure. OPEN, CLOSE, BACKSPACE, ENDFILE, and REWIND statements will not be executed. Any ADVANCE= specifier in a child statement is ignored.
- A record positioning edit descriptor, such as TL and TR, used on the unit by a child data transfer statement will not cause the record position to be positioned before the record position at the time the defined I/O procedure was invoked.
- A child data transfer statement must not specify the ID=, POS=, or REC= specifier in an I/O control list.
- The file position on entry is treated as a left tab limit and there is no record termination on return. However, a child statement with slash (/) edit descriptor, or explicit record termination by a list-directed child I/O, is allowed.
- If the unit is associated with an external file (for example, non-negative, or equal to one of the constants ERROR_UNIT, INPUT_UNIT, or OUTPUT_UNIT from the intrinsic module ISO_FORTRAN_ENV), the current settings for the pad mode, sign mode, etc., can be discovered by using INQUIRE with PAD=, SIGN=, etc. on the unit argument.

Note that INQUIRE must not be used if the unit is an internal unit passed to a user-defined derived-type I/O procedure from a parent I/O statement. When an internal unit is used with the INQUIRE statement, an error condition will occur, and the variable specified in an IOSTAT= specifier in the INQUIRE statement will be assigned the value IOSTAT_INQUIRE_INTERNAL_UNIT from the intrinsic module ISO_FORTRAN_ENV.

ISO_FORTRAN_ENV Module
User-Defined Derived-Type I/O

Resolving Defined I/O Procedure References
A generic interface for defined I/O of a derived-type object is one that has both of the following:

- A defined-io-generic-spec that is appropriate to the READ or WRITE direction and the form (formatted or unformatted) of the data transfer (see Defined IO Procedures, Generic Bindings, and Generic Interface Block).
- A specific interface whose var argument is compatible with the derived-type item.

Within the scope of a defined-io-generic-spec, if two procedures have that generic identifier, they must be distinguishable.

For defined I/O procedures, only the var argument corresponds to something explicitly written in the program, so it is the var that must be distinguishable.

Because var arguments are required to be scalar, they cannot differ in rank. So, the var must be distinguishable in the type and kind type parameters.

You cannot have two procedures with the same defined-io-generic-spec.

See Also
Characteristics of Defined I/O Procedures
Recursive Defined I/O

A defined I/O procedure can invoke itself indirectly. It can have an I/O statement that includes a derived-type object that results in the invocation of the same procedure. In this case, the defined I/O procedure must be declared RECURSIVE.

Consider the following:

```fortran
MODULE LIST_MODULE
IMPLICIT NONE
TYPE NODE
! This type declaration represents a singly-linked list that also
! contains a user-defined i/o procedure. The name of the procedure
! is arbitrary, but the order of arguments must conform to the
! standard definition.
    INTEGER :: VALUE = -1
    TYPE(NODE), POINTER :: NEXT_NODE => NULL()
CONTAINS
    PROCEDURE :: PWF
    GENERIC :: WRITE(FORMATTED) => PWF ! <=== GENERIC BINDING.
END TYPE NODE
CONTAINS
RECURSIVE SUBROUTINE PWF( DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG )
! These arguments are defined in the standard.
    CLASS(NODE), INTENT(IN) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(LEN=*), INTENT(IN) :: IOTYPE
    INTEGER, DIMENSION(:), INTENT(IN) :: V_LIST
    INTEGER :: IOSTAT
    CHARACTER(LEN=*), INTENT(INOUT) :: IOMSG

Examples of User-Defined Derived-Type I/O

Example 1
The following example shows formatted defined I/O using the DT edit descriptor and both generic type-bound and explicit interface procedures:

MODULE TYPES
  TYPE T
    INTEGER :: K(10)
  CONTAINS

! a generic type-bound procedure
  PROCEDURE :: UDIO_READ_ARRAY
    GENERIC :: READ (FORMATTED) => UDIO_READ_ARRAY
  END TYPE T

! an explicit interface
  INTERFACE WRITE(FORMATTED)
    MODULE PROCEDURE UDIO_WRITE_ARRAY
  END INTERFACE
  CONTAINS
  SUBROUTINE UDIO_READ_ARRAY (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(T), INTENT(INOUT) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(*), INTENT(IN) :: IOTYPE
    INTEGER, INTENT(IN) :: V_LIST (:)
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER(*), INTENT(INOUT) :: IOMSG

    ! This is the child I/O that gets performed when the procedure
    ! is called from a parent I/O – it uses list-directed input to read
    ! the array K
Consider that procedure UDIO_READ_ARRAY reads an input file named TEST.INPUT that contains the following:

```
1, 3, 5, 7, 9, 2, 4, 6, 8, 10
```

In this case, the program TEST1 in procedure UDIO_WRITE_ARRAY prints:

```
 1   3   5   7   9   2
 4   6   8  10
```

**Example 2**

The following example shows list-directed formatted output and user-defined I/O:

```fortran
MODUKE M
  TYPE T
    REAL, POINTER :: R (:)
  CONTAINS
    PROCEDURE :: UDIO_WRITE_LD
    GENERIC :: WRITE(FORMATTED) => UDIO_WRITE_LD
  END TYPE T
  CONTAINS
    SUBROUTINE UDIO_WRITE_LD (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
      CLASS(T), INTENT(IN) :: DTV
      INTEGER, INTENT(IN) :: UNIT
      CHARACTER(*), INTENT(IN) :: IOTYPE
      INTEGER, INTENT(IN) :: V_LIST (:)
      INTEGER, INTENT(OUT) :: IOSTAT
      CHARACTER(*), INTENT(INOUT) :: IOMSG
      WRITE (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%K
    END SUBROUTINE UDIO_WRITE_LD
  END CONTAINS
END MODULE M
```
Example 3

The following example shows user-defined derived-type NAMELIST input/output:

```fortran
! PROGRAM: uio_nml_read_write.f90
!
! This program tests NAMELIST READ and WRITE. In the WRITE subroutine, there
! are FORMATTED WRITES as well as NAMELIST WRITES.
!
MODULE UDIO

TYPE MYDT
  INTEGER F1
  INTEGER F2
CONTAINS
  PROCEDURE :: MYSUBROUTINE
  GENERIC :: READ (FORMATTED) => MYSUBROUTINE
END TYPE MYDT

INTERFACE WRITE (FORMATTED)
  MODULE PROCEDURE :: WRITESUBROUTINE
END INTERFACE

CONTAINS

SUBROUTINE WRITESUBROUTINE (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
  CLASS (MYDT), INTENT(IN) :: DTV
  INTEGER*4, INTENT(IN) :: UNIT
  CHARACTER (LEN=*) , INTENT(IN) :: IOTYPE
  INTEGER, INTENT(IN) :: V_LIST (:)
  INTEGER, INTENT(OUT) :: IOSTAT
  CHARACTER (LEN=*) , INTENT(INOUT) :: IOMSG
  IOSTAT = 0
  PRINT *, SIZE (DTV%R)
  WRITE (UNIT, *) DTV%R
END SUBROUTINE UDIO_WRITE_LD

END MODULE M
```

TEST2 should print "3 0.8414710 0.5403023 1.557408".

```fortran
PROGRAM TEST2
  USE M
  TYPE (T) :: X
  REAL, TARGET :: V (3)
  V = [ SIN (1.0), COS (1.0), TAN (1.0) ]
  X = T (R=V)
  PRINT *, X
END PROGRAM TEST2
```

Example 3

The following example shows user-defined derived-type NAMELIST input/output:
I=DTV%F1
J=DTV%F2

WRITE (UNIT, '(A,2I5.2)', IOSTAT=IOSTAT) IOTYPE, DTV%F1, DTV%F2
WRITE (UNIT, NML=SUBRT_NML)
END SUBROUTINE WRITESUBROUTINE

SUBROUTINE MYSUBROUTINE (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
CLASS (MYDT),    INTENT(INOUT)    :: DTV
INTEGER*4,        INTENT(IN)    :: UNIT
CHARACTER (LEN=*) ,     INTENT(IN)    :: IOTYPE
INTEGER,             INTENT(IN)    :: V_LIST(:)
INTEGER*4,        INTENT(OUT)    :: IOSTAT
CHARACTER (LEN=*) ,    INTENT(INOUT)    :: IOMSG

! X and Y are aliases for DTV%F1 and DTV%F2 since field references
! cannot be referenced in a NAMELIST statement

INTEGER X, Y
NAMELIST /SUBRT_NML/ X, Y

READ (UNIT, *) DTV%F1, DTV%F2
X = DTV%F1
Y = DTV%F2

READ (UNIT, NML=SUBRT_NML, IOSTAT=IOSTAT)
END SUBROUTINE MYSUBROUTINE

END MODULE UDIO

PROGRAM UDIO_PROGRAM
  USE UDIO
  TYPE (MYDT) :: MYDTV
  INTEGER :: A, B
  NAMELIST /MAIN_NML/ A, MYDTV, B

  OPEN (10, FILE='udio_nml_read_write.in')
  READ (10, NML=MAIN_NML)
  WRITE (6, NML=MAIN_NML)
  CLOSE (10)
END PROGRAM UDIO_PROGRAM

The following shows input file 'udio_nml_read_write.in' on unit 10 read by MYSUBROUTINE:

&MAIN_NML
A=100
MYDTV=20 30
&SUBRT_NML
X=20
Y=30
/B=200
/
The following shows output to unit 6 by WRITESUBROUTINE:

```fortran
&MAIN_NML
  A = 100,
  MYDTV=NAMELIST 20 30
&SUBRT_NML
  I = 20,
  J = 30
/B = 200
/
```

Example 4
The following example shows user-defined derived-type UNFORMATTED input/output:

```fortran
! PROGRAM: udio_unformatted_1.f90
!
! This test first writes unformatted data to a file via user-defined derived type output
! and then reads the data from the file via user-defined derived type input.
!
MODULE UNFORMATTED
  TYPE UNFORMATTED_TYPE
    INTEGER :: I
    CHARACTER*25 :: CHAR
  CONTAINS
    PROCEDURE :: MY_UNFMT_WRITE
    GENERIC :: WRITE (UNFORMATTED) => MY_UNFMT_WRITE
  END TYPE UNFORMATTED_TYPE

  INTERFACE READ (UNFORMATTED)
    MODULE PROCEDURE :: MY_UNFMT_READ
  END INTERFACE

  CONTAINS
    SUBROUTINE MY_UNFMT_WRITE (DTV, UNIT, IOSTAT, IOMSG)
      CLASS (UNFORMATTED_TYPE), INTENT(IN) :: DTV
      INTEGER, INTENT(IN) :: UNIT
      INTEGER, INTENT(OUT) :: IOSTAT
      CHARACTER(LEN=*) , INTENT(INOUT) :: IOMSG
      WRITE (UNIT=UNIT, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%I+1, DTV%CHAR
    END SUBROUTINE MY_UNFMT_WRITE

    SUBROUTINE MY_UNFMT_READ (DTV, UNIT, IOSTAT, IOMSG)
      CLASS (UNFORMATTED_TYPE), INTENT(INOUT) :: DTV
      INTEGER, INTENT(IN) :: UNIT
      INTEGER, INTENT(OUT) :: IOSTAT
      CHARACTER (LEN=*) , INTENT(INOUT) :: IOMSG
      READ (UNIT=UNIT, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%I, DTV%CHAR
      DTV%I = 1-DTV%I
    END SUBROUTINE MY_UNFMT_READ

END MODULE UNFORMATTED

PROGRAM UNFORMATTED_WRITE_PROGRAM
  USE UNFORMATTED
```

1000
TYPE (UNFORMATTED_TYPE) :: READ_UNFORMATTED (1,2), UNFORMATTED_OBJECT (3:3,0:1)
INTEGER :: IOSTAT
CHARACTER(LEN=100) :: IOMSG

UNFORMATTED_OBJECT (3, 1) = UNFORMATTED_TYPE (I=71, CHAR='HELLO WORLD.')</n>UNFORMATTED_OBJECT (3, 0) = UNFORMATTED_TYPE (I=72, CHAR='WORLD HELLO.')</n>

OPEN (UNIT=71, FILE='MYUNFORMATTED_DATA.DAT', FORM='UNFORMATTED')
WRITE (UNIT=71) UNFORMATTED_OBJECT
CLOSE (UNIT=71)

OPEN (UNIT=77, FILE='MYUNFORMATTED_DATA.DAT', FORM='UNFORMATTED')
READ (UNIT=77) READ_UNFORMATTED
CLOSE (UNIT=77)

PRINT *, -READ_UNFORMATTED (:,1:2)%I .EQ. UNFORMATTED_OBJECT%I
PRINT *, READ_UNFORMATTED%CHAR .EQ. UNFORMATTED_OBJECT%CHAR

END PROGRAM UNFORMATTED_WRITE_PROGRAM

The following shows output to unit * from program UNFORMATTED_WRITE_PROGRAM:

T T
T T

I/O Formatting

A format appearing in an input or output (I/O) statement specifies the form of data being transferred and the
data conversion (editing) required to achieve that form. The format specified can be explicit or implicit.

Explicit format is indicated in a format specification that appears in a FORMAT statement or a character
expression (the expression must evaluate to a valid format specification).

The format specification contains edit descriptors, which can be data edit descriptors, control edit descriptors,
or string edit descriptors.

Implicit format is determined by the processor and is specified using list-directed or namelist formatting.

List-directed formatting is specified with an asterisk (*); namelist formatting is specified with a namelist
group name.

List-directed formatting can be specified for advancing sequential files and internal files. Namelist formatting
can be specified only for advancing sequential files.

Rules for Namelist Sequential READ Statements for details on namelist input
Rules for Namelist Sequential WRITE Statements for details on namelist output

Format Specifications

A format specification can appear in a FORMAT statement or a character expression. In a FORMAT statement,
it is preceded by the keyword FORMAT. A format specification takes one of the following forms:

( [format-items])
( [format-items, ] unlimited-format-item)
format-items

Is format-items [[,] format-item]...

where format-item is one of the following:

[r] data-edit-desc
control-edit-desc
char-string-edit-desc
[r] (format-items)

r

(Optional) Is an integer literal constant. This is called a repeat specification. The range of r is 1 through 2147483647 (2**31-1). If r is omitted, it is assumed to be 1.

data-edit-desc

Is one of the data edit descriptors: I, B, O, Z, F, E, EN, ES, EX, D, DT, G, L, or A.

A repeat specification can precede any data edit descriptor.

control-edit-desc

Is one of the control edit descriptors: T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q.

A repeat specification can precede the slash (/) edit descriptor.

char-string-edit-desc

Is one of the string edit descriptors: H, 'c', and "c", where c is a character constant.

unlimited-format-item

Is * (format-items). The * indicates an unlimited repeat count.

If more than one edit descriptor is specified, they must be separated by commas or slashes (/).

A comma can be omitted in the following cases:

• Between a P edit descriptor and an immediately following F, E, EN, ES, EX, D, or G edit descriptor
• Before a slash (/) edit descriptor when the optional repeat specification is not present
• After a slash (/) edit descriptor
• Before or after a colon (:) edit descriptor

Description

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see BLANK Specifier in OPEN statements.)

For formatted input, you can use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.

The following table summarizes the edit descriptors that can be used in format specifications.

<table>
<thead>
<tr>
<th>Code</th>
<th>Form</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A[w]</td>
<td>Transfers character or Hollerith values.</td>

<td>\</td>
<td>\</td>
<td>Continues the same record; same as $.</td>
</tr>
<tr>
<td>'c'</td>
<td>'c'</td>
<td>Transfers the character literal constant (between the delimiters) to an output record.</td>
</tr>
</tbody>
</table>

**Character Format Specifications**

In data transfer I/O statements, a format specifier ([FMT=]format) can be a character expression that is a character array, character array element, or character constant. This type of format is also called a run-time format because it can be constructed or altered during program execution.

The expression must evaluate to a character string whose leading part is a valid format specification (including the enclosing parentheses).

If the expression is a character array element, the format specification must be contained entirely within that element.

If the expression is a character array, the format specification can continue past the first element into subsequent consecutive elements.

If the expression is a character constant delimited by apostrophes, use two consecutive apostrophes ('' ) to represent an apostrophe character in the format specification; for example:

```
PRINT ''("NUM can't be a real number")''
```

Similarly, if the expression is a character constant delimited by quotation marks, use two consecutive quotation marks (""") to represent a quotation mark character in the format specification.
To avoid using consecutive apostrophes or quotation marks, you can put the character constant in an I/O list instead of a format specification, as follows:

```fortran
PRINT "(A)", "NUM can't be a real number"
```

The following shows another character format specification:

```fortran
WRITE (6, '(I12, I4, I12)') I, J, K
```

In the following example, the format specification changes with each iteration of the DO loop:

```fortran
SUBROUTINE PRINT(TABLE)
REAL TABLE(10,5)
CHARACTER*5 FORCHR(0:5), RPAR*1, FBIG, FMED, FSML
DATA FORCHR(0), RPAR /'(',')'/
DATA FBIG, FMED, FSML /'F8.2,','F9.4,','F9.6,'/
DO I=1,10
  DO J=1,5
    IF (TABLE(I,J) .GE. 100.) THEN
      FORCHR(J) = FBIG
    ELSE IF (TABLE(I,J) .GT. 0.1) THEN
      FORCHR(J) = FMED
    ELSE
      FORCHR(J) = FSML
    END IF
  END DO
  FORCHR(5)(5:5) = RPAR
  WRITE (6,FORCHR) (TABLE(I,J), J=1,5)
END DO
END
```

The DATA statement assigns a left parenthesis to character array element FORCHR(0), and (for later use) a right parenthesis and three F edit descriptors to character variables.

Next, the proper F edit descriptors are selected for inclusion in the format specification. The selection is based on the magnitude of the individual elements of array TABLE.

A right parenthesis is added to the format specification just before the WRITE statement uses it.

**NOTE**
Format specifications stored in arrays are recompiled at run time each time they are used. If a Hollerith or character run-time format is used in a READ statement to read data into the format itself, that data is not copied back into the original array, and the array is unavailable for subsequent use as a run-time format specification.

**Examples**

The following example shows a format specification:

```fortran
WRITE (*, 9000) int1, real1(3), char1
9000 FORMAT (I5, 3F4.5, A16)
! I5, 3F5.2, A16 is the format list.
```

The following shows a format example using a character expression:

```fortran
WRITE (*, '(I5, 3F5.2, A16)') iolist
! I5, 3F4.5, A16 is the format list.
```
In the following example, the format list is put into an 80-character variable called MYLIST:

```fortran
CHARACTER(80) MYLIST
MYLIST = '(I5, 3F5.2, A16)'
WRITE (*, MYLIST) iolist
```

Consider the following two-dimensional array:

```
  1  2  3
  4  5  6
```

In this case, the elements are stored in memory in the order: 1, 4, 2, 5, 3, 6 as follows:

```fortran
CHARACTER(6) array(3)
DATA array / '(I5', ',3F5.2', ',A16)' /
WRITE (*, array) iolist
```

In the following example, the WRITE statement uses the character array element array(2) as the format specifier for data transfer:

```fortran
CHARACTER(80) array(5)
array(2) = '(I5, 3F5.2, A16)'
WRITE (*, array(2)) iolist
```

Data Edit Descriptors

A data edit descriptor causes the transfer or conversion of data to or from its internal representation. The part of a record that is input or output and formatted with data edit descriptors (or character string edit descriptors) is called a field.

Forms for Data Edit Descriptors

A data edit descriptor takes one of the following forms:

- `[r]c`
- `[r]cw`
- `[r]cw.m`
- `[r]cw.d`
- `[r]cw.d[Ee]`

- `r` is a repeat specification. The range of `r` is 1 through 2147483647 (2**31-1). If `r` is omitted, it is assumed to be 1.
- `c` is one of the following format codes: I, B, O, Z, F, E, EN, ES, EX, D, G, L, or A.
- `w` is the total number of digits in the field (the field width). If omitted, the system applies default values (see Default Widths for Data Edit Descriptors). The range of `w` is 1 through 2147483647 (2**31-1) on
Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. For I, B, O, Z, D, E, EN, ES, EX, F, and G, the range can start at zero.

$m$

Is the minimum number of digits that must be in the field (including leading zeros). The range of $m$ is 0 through 32767 (2**15-1) on Intel® 64 architecture; 0 through 255 (2**8-1) on IA-32 architecture. $w.m$ applies to I, B, O, and Z format edit descriptors.

$d$

Is the number of digits to the right of the decimal point (the significant digits). The range of $d$ is 0 through 255. If $d$ exceeds 255 at compile time, a warning is issued and the value 255 is used. If $d$ exceeds 255 in a run-time format, no warning or error is issued and the value 255 is used.

The number of significant digits is affected if a scale factor is specified for the data edit descriptor. For the G edit descriptor, $d$ must be specified if $w$ is not zero. $w.d$ applies to F, E, EN, ES, EX, G, and D format edit descriptors.

$E$

Identifies an exponent field.

$e$

Is the number of digits in the exponent. The range of $e$ is 0 through 255. If $e$ exceeds 255 at compile time, a warning is issued and the value 255 is used. If $e$ exceeds 255 in a run-time format, no warning or error is issued and the value 255 is used. For the G edit descriptor, if $w$ is zero, $e$ must not be specified.

**Description**

Standard Fortran allows the field width to be omitted only for the A descriptor. However, Intel® Fortran allows the field width to be omitted for any data edit descriptor.

The $r$, $w$, $m$, $d$, and $e$ must all be positive, unsigned, integer literal constants, or the digit 0 where allowed, or variable format expressions -- no kind parameter can be specified. They must not be named constants.

Actual useful ranges for $r$, $w$, $m$, $d$, and $e$ may be constrained by record sizes (RECL) and the file system.

The data edit descriptors have the following specific forms:

- **Integer:** $Iw[m]$, $Bw[m]$, $Ow[m]$, and $Zw[m]$
- **Logical:** $Lw$
- **Character:** $A[w]$

The $d$ must be specified with F, E, EN, ES, EX, D, and G field descriptors even if $d$ is zero. The decimal point is also required. You must specify both $w$ and $d$.

A repeat specification can simplify formatting. For example, the following two statements are equivalent:

```
20  FORMAT (E12.4,E12.4,E12.4,I5,I5,I5,I5)
20  FORMAT (3E12.4,4I5)
```

**Examples**

```fortran
! This WRITE outputs three integers, each in a five-space field
! and four reals in pairs of F7.2 and F5.2 values.
INTEGER(2) int1, int2, int3
```

1007
REAL(4) r1, r2, r3, r4
DATA int1, int2, int3 /143, 62, 999/
DATA r1, r2, r3, r4 /2458.32, 43.78, 664.55, 73.8/
WRITE (*,9000) int1, int2, int3, r1, r2, r3, r4
9000 FORMAT (3I5, 2(1X, F7.2, 1X, F5.2))

The following output is produced from the above code:

143  62  999 2458.32 43.78  664.55 73.80

General rules for numeric editing
Nested and group repeats

General Rules for Numeric Editing

The following rules apply to input and output data for numeric editing (data edit descriptors I, B, O, Z, F, E, EN, ES, EX, D, and G).

Rules for Input Processing

Leading blanks in the external field are ignored. If the input field is not a hexadecimal-significand number or an IEEE exceptional value, the interpretation of embedded and trailing blanks is determined by the blank interpretation mode. If BLANK='NULL' is in effect (or the BN edit descriptor has been specified) embedded and trailing blanks are ignored; otherwise, they are treated as zeros. An all-blank field is treated as a value of zero.

The following table shows how blanks are interpreted by default:

<table>
<thead>
<tr>
<th>Type of Unit or File</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>An explicitly OPENed unit</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>An internal file</td>
<td>BLANK='NULL'</td>
</tr>
<tr>
<td>A preconnected file¹</td>
<td>BLANK='NULL'</td>
</tr>
</tbody>
</table>

¹ For interactive input from preconnected files, you should explicitly specify the BN or BZ edit descriptor to ensure desired behavior.

A minus sign must precede a negative value in an external field; a plus sign is optional before a positive value.

In input records, constants can include any valid kind parameter. Named constants are not permitted.

If the data field in a record contains fewer than \( w \) characters, an input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data. The comma terminates the data field, and can also be used to designate null (zero-length) fields. For more information, see Terminating Short Fields of Input Data.

Rules for Output Processing

The field width \( w \) must be large enough to include any leading plus or minus sign, and any decimal point or exponent. For example, the field width for an E data edit descriptor must be large enough to contain the following:

- For positive numbers: \( d + 5 \) or \( d + e + 3 \) characters
- For negative numbers: \( d + 6 \) or \( d + e + 4 \) characters

For D, E, EN, ES, EX, F, and I edit descriptors, a non-negative value can have a plus sign, depending on which sign edit descriptor is in effect. If a value is negative, the leftmost nonblank character is a minus sign.
If the value is smaller than the field width specified, leading blanks are inserted (the value is right-justified).
If the value is too large for the field width specified, the entire output field is filled with asterisks (*).

When the value of the field width is zero, the compiler selects the smallest possible positive actual field width that does not result in the field being filled with asterisks.

Forms for data edit descriptors
Format Specifications

Integer Editing
Integer editing is controlled by the I (decimal), B (binary), O (octal), and Z (hexadecimal) data edit descriptors.

I Editing
The I edit descriptor transfers decimal integer values. It takes the following form:

$Iw[.m]$

The value of $m$ (the minimum number of digits in the constant) must not exceed the value of $w$ (the field width), unless $w$ is zero. The $m$ has no effect on input, only output.

The specified I/O list item must be of type integer; logical and real items are also allowed if the compiler option check format is not specified.

The G edit descriptor can be used to edit integer data; it follows the same rules as $Iw$.

Rules for Input Processing
On input, the I data edit descriptor transfers $w$ characters from an external field and assigns their integer value to the corresponding I/O list item. The external field data must be an integer constant. $w$ must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>14</td>
<td>2788</td>
<td>2788</td>
</tr>
<tr>
<td>13</td>
<td>-26</td>
<td>-26</td>
</tr>
<tr>
<td>19</td>
<td>^^^^^^312</td>
<td>312</td>
</tr>
</tbody>
</table>

Rules for Output Processing
On output, the I data edit descriptor transfers the value of the corresponding I/O list item, right-justified, to an external field that is $w$ characters long.

The field consists of zero or more blanks, followed by a sign (a plus sign is optional for positive values, a minus sign is required for negative values), followed by an unsigned integer constant with no leading zeros.

If $m$ is specified, the unsigned integer constant will have at least $m$ digits, padded with leading zeros if necessary.

If the output list item has the value zero, and $m$ is zero, the external field is filled with blanks; if $w$ is also zero, the external field is one blank.

If $w$ is zero, the external field has the minimum number of characters necessary to represent the value, left justifying the value with no leading blanks. If both $w$ and $m$ are zero and the internal value is zero, the external field is one blank.
The following shows output using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

B Editing
The B data edit descriptor transfers binary (base 2) values. It takes the following form:

\[ B^w[m] \]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

Rules for Input Processing
On input, the B data edit descriptor transfers \( w \) characters from an external field and assigns their binary value to the corresponding I/O list item. The external field must contain only binary digits (0 or 1) or blanks.

\( w \) must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the B edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>1001</td>
<td>9</td>
</tr>
<tr>
<td>B1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>B2</td>
<td>^0</td>
<td>0</td>
</tr>
<tr>
<td>B6</td>
<td>^^122</td>
<td>An error; the 2 is invalid in binary notation</td>
</tr>
</tbody>
</table>

Rules for Output Processing
On output, the B data edit descriptor transfers the binary value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of binary digits) with no leading zeros. A negative value is transferred in internal form.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.
The following shows output using the B edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>B4</td>
<td>9</td>
<td>1001</td>
</tr>
<tr>
<td>B2.2</td>
<td>1</td>
<td>01</td>
</tr>
<tr>
<td>B0</td>
<td>42</td>
<td>101010</td>
</tr>
</tbody>
</table>

See Also
Forms for data edit descriptors
General rules for numeric editing

O Editing
The O data edit descriptor transfers octal (base 8) values. It takes the following form:

O\[ .m\]

The value of \( m \) (the minimum number of digits in the constant) must not exceed the value of \( w \) (the field width), unless \( w \) is zero. The \( m \) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

Rules for Input Processing
On input, the O data edit descriptor transfers \( w \) characters from an external field and assigns their octal value to the corresponding I/O list item. The external field must contain only octal digits (0 through 7) or blanks. \( w \) must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>O5</td>
<td>77777</td>
<td>32767</td>
</tr>
<tr>
<td>O4</td>
<td>77777</td>
<td>4095</td>
</tr>
<tr>
<td>O3</td>
<td>97^</td>
<td>An error; the 9 is invalid in octal notation</td>
</tr>
</tbody>
</table>

Rules for Output Processing
On output, the O data edit descriptor transfers the octal value of the corresponding I/O list item, right-justified, to an external field that is \( w \) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of octal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If \( w \) is zero, the external field has the minimum number of characters necessary to represent the value. If both \( w \) and \( m \) are zero and the internal value is zero, the external field is one blank.

If \( m \) is specified, the unsigned integer constant must have at least \( m \) digits. If necessary, it is padded with leading zeros.

If \( m \) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>O6</td>
<td>32767</td>
<td>^77777</td>
</tr>
<tr>
<td>012</td>
<td>-32767</td>
<td>^37777700001</td>
</tr>
<tr>
<td>02</td>
<td>14261</td>
<td>**</td>
</tr>
<tr>
<td>04</td>
<td>27</td>
<td>^^33</td>
</tr>
<tr>
<td>05</td>
<td>10.5</td>
<td>41050</td>
</tr>
</tbody>
</table>
The Z data edit descriptor transfers hexadecimal (base 16) values. It takes the following form:

\[
Zw[m]
\]

The value of \(m\) (the minimum number of digits in the constant) must not exceed the value of \(w\) (the field width), unless \(w\) is zero. The \(m\) has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

### Rules for Input Processing

On input, the Z data edit descriptor transfers \(w\) characters from an external field and assigns their hexadecimal value to the corresponding I/O list item. The external field must contain only hexadecimal digits (0 through 9 and A (a) through F(f)) or blanks. \(w\) must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the Z edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Z3</td>
<td>A94</td>
<td>2708</td>

<td>A23DEF</td>
<td>664542</td>
</tr>
<tr>
<td>5</td>
<td>95.AF2</td>
<td>An error; the decimal point is invalid</td>
</tr>
</tbody>
</table>

### Rules for Output Processing

On output, the Z data edit descriptor transfers the hexadecimal value of the corresponding I/O list item, right-justified, to an external field that is \(w\) characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of hexadecimal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If \(w\) is zero, the external field has the minimum number of characters necessary to represent the value. If both \(w\) and \(m\) are zero and the internal value is zero, the external field is one blank.

If \(m\) is specified, the unsigned integer constant must have at least \(m\) digits. If necessary, it is padded with leading zeros.

If \(m\) is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the Z edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>

</tbody>
</table>
Real and Complex Editing

Real and complex editing is controlled by the F, E, D, EN, ES, and EX data edit descriptors. The G, B, O, and Z edit descriptors can also be used to edit real and complex data.

If no field width \( w \) is specified for a real data edit descriptor, the system supplies default values.

Real data edit descriptors can be affected by specified scale factors.

**Note**

Do not use the real data edit descriptors when attempting to parse textual input. These descriptors accept some forms that are purely textual as valid numeric input values. For example, input values T and F are treated as values \(-1.0\) and \(0.0\), respectively, for .TRUE. and .FALSE.

See Also

Forms for data edit descriptors
General rules for numeric editing

Scale Factor Editing (P)

Default Widths for Data Edit Descriptors for details on system default values for data edit descriptors

**F Editing**

The F data edit descriptor transfers real values. It takes the following form:

\[
F_{w.d}
\]

The value of \( d \) (the number of places after the decimal point) must not exceed the value of \( w \) (the field width) unless \( w \) is zero. When \( w \) is zero, the processor selects the field width. On input, \( w \) must not be zero. The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the F data edit descriptor transfers \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The external field data must be an integer or real constant.

An input field is one of the following:

- An IEEE exception specification
- An hexadecimal-significand number
- An optional sign, followed by a string of one or more digits optionally containing a decimal symbol; any blanks are interpreted as zeros.

The basic form can be followed by an exponent in one of the following forms:

- A sign followed by one or more digits
- An E or D followed by zero or more blanks, followed by an optional sign and one or more digits

An exponent containing a D is processed in the same way as an exponent containing an E.

If the input field contains only an exponent letter or decimal point, it is treated as a zero value.

If the input field does not contain a decimal point or an exponent, it is treated as a real number of \( w \) digits, with \( d \) digits to the right of the decimal point. (Leading zeros are added, if necessary.)

If the input field contains a decimal point, the location of that decimal point overrides the location specified by the F descriptor.
If the field contains an exponent, that exponent is used to establish the magnitude of the value before it is assigned to the list element.

An input field that is an IEEE exception specification consists of optional blanks, followed by either of the following:

- An optional sign, followed by the string 'INF' or the string 'INFINITY'; this is an IEEE infinity
  This form can not be used if the processor does not support IEEE infinities for the input variable.
- An optional sign, followed by the string 'NAN', optionally followed by zero or more alphanumeric characters enclosed in parentheses, optionally followed by blanks; this is an IEEE Nan
  This form can not be used if the processor does not support IEEE Nans for the input variable.

The NaN value is a quiet NaN if the only nonblank characters in the field are 'NAN' or 'NAN(').

An input field that is a hexadecimal-significand number contains an optional sign, followed by the digit 0, followed immediately by the letter X, followed by the hexadecimal significand followed by a hexadecimal exponent. A hexadecimal significand is a string of one or more hexadecimal characters, optionally containing a decimal symbol. The position of the hexadecimal point is indicated by the decimal symbol. The hexadecimal point implicitly follows the last hexadecimal character if decimal symbol appears in the string. A hexadecimal exponent is the letter P followed by a signed decimal digit string. Embedded blanks are not allowed; trailing blanks are ignored. The value is equal to the significand multiplied by two raised to the power of the exponent. If the optional sign is a minus, the value is negated.

The following shows input using the F edit descriptor:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>123456789</td>
<td>123.45678</td>
</tr>
<tr>
<td>F8.5</td>
<td>-1234.567</td>
<td>-1234.56</td>
</tr>
<tr>
<td>F8.5</td>
<td>24.77E+2</td>
<td>2477.0</td>
</tr>
<tr>
<td>F5.2</td>
<td>1234567.89</td>
<td>123.45</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the F data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \(d\) decimal positions, to an external field that is \(w\) characters long.

For an internal value that is an IEEE infinity, the output field consists of blanks, if needed, followed by a sign (optional if the value is positive and descriptor SP is not in effect), followed by the letters 'Inf' or 'Infinity', right justified within the field.

If \(w\) is less than 3, the field is filled with asterisks; otherwise, if \(w\) is less than 8, 'Inf' is produced.

For an internal value that is an IEEE NaN, the output field consists of blanks, if necessary, followed by the letters 'NaN' and optionally followed by one to \(w - 5\) alphanumeric characters enclosed in parentheses, right justified within the field.

If \(w\) is less than 3, the field is filled with asterisks.

For an internal value that is neither an IEEE infinity nor an IEEE NaN, the \(w\) must be greater than or equal to \(d+3\) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- At least one digit to the left of the decimal point
- The decimal point
- The \(d\) digits to the right of the decimal point

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.00000001 in F5.1 format will be displayed as -0.0 rather than as 0.0. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.
The following shows output using the F edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5</td>
<td>2.3547188</td>

Forms for data edit descriptors

General rules for numeric editing

assume compiler option

E and D Editing

The E and D data edit descriptors transfer real values in exponential form. They take the following form:

Ew.d[Ee]

Dw.d

where \( w \) is the total field width, \( d \) is the number of places after the decimal point, and \( e \) is the number of digits in the exponent.

For the E edit descriptor, if \( w \) is zero, the processor selects the field width. If \( e \) is zero, the exponent part contains the minimum number of digits needed to represent the value of the exponent.

For the D edit descriptor, if the value of \( w \) is zero, the processor selects the field width.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the E and D data edit descriptors transfer \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The E and D descriptors interpret and assign input data in the same way as the F data edit descriptor. On input, \( w \) cannot be zero. The \( e \), if present, has no effect on input.

The following shows input using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>E9.3</td>
<td>734.432E3</td>
<td>734432.0</td>
</tr>
<tr>
<td>E12.4</td>
<td>^^1022.43E</td>
<td>1022.43E-6</td>
</tr>
<tr>
<td>E15.3</td>
<td>52.3759663^^^^^</td>
<td>52.3759663</td>
</tr>
<tr>
<td>E12.5</td>
<td>210.5271D+10</td>
<td>210.5271E10</td>
</tr>
<tr>
<td>BZ,D10.2</td>
<td>12345^^^^^</td>
<td>12345000.0D0</td>
</tr>
<tr>
<td>D10.2</td>
<td>^^123.45^^</td>
<td>123.45D0</td>
</tr>
<tr>
<td>D15.3</td>
<td>367.4981763D+04</td>
<td>3.674981763D+06</td>
</tr>
</tbody>
</table>

If the I/O list item is single-precision real, the E edit descriptor treats the D exponent indicator as an E indicator.

Rules for Output Processing

On output, the E and D data edit descriptors transfer the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long.

If \( w \) is greater than zero, it should be greater than or equal to \( d+7 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- An optional zero to the left of the decimal point
• The decimal point
• The \( d \) digits to the right of the decimal point
• The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>( Ew.d )</td>
<td>(</td>
<td>exp</td>
<td>99)</td>
</tr>
<tr>
<td></td>
<td>( 99 &lt;</td>
<td>exp</td>
<td>999 )</td>
</tr>
<tr>
<td>( Ew.dEe )</td>
<td>(</td>
<td>exp</td>
<td>10^e - 1)</td>
</tr>
<tr>
<td>( Dw.d )</td>
<td>(</td>
<td>exp</td>
<td>99)</td>
</tr>
<tr>
<td></td>
<td>( 99 &lt;</td>
<td>exp</td>
<td>999 )</td>
</tr>
</tbody>
</table>

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \( w \) is filled with asterisks.

The exponent field width (\( e \)) is optional for the \( E \) edit descriptor; if omitted, the default value is 2. If \( e \) is specified, \( w \) should be greater than or equal to \( d + e + 5 \), or zero.

**NOTE**
If \( w \) is greater than zero, it can be as small as \( d + 5 \) or \( d + e + 3 \), if the optional fields for the sign and the zero are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for \( Fw.d \).

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.01 in "-5P,E20.5" format will be displayed as -0.00 rather than as 0.00. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.

The following shows output using the \( E \) and \( D \) edit descriptors (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>

1016
**EN Editing**

The EN data edit descriptor transfers values by using engineering notation. It takes the following form:

\[ \text{ENw.d}[\text{Ee}] \]

where \( w \) is the total field width, \( d \) is the number of places after the decimal point, and \( e \) is the number of digits in the exponent.

If \( w \) is zero, the processor chooses the field width. If \( e \) is present and zero, the exponent part contains the minimal number of digits needed to represent the exponent.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

**Rules for Input Processing**

On input, the EN data edit descriptor transfers \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The EN descriptor interprets and assigns input data in the same way as the F data edit descriptor. \( w \) cannot be zero on input. \( e \), if present, has no effect on input.

The following shows input using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.3</td>
<td>^^5.321E+00</td>
<td>5.32100</td>
</tr>
<tr>
<td>EN11.3</td>
<td>-600.00E-03</td>
<td>-.60000</td>

<td>.00315</td>
</tr>
<tr>
<td>EN12.3</td>
<td>^^^3.829E+03</td>
<td>3829.0</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the EN data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long if \( w \) is positive. The real value is output in engineering notation, where the decimal exponent is divisible by 3 and the absolute value of the significand is greater than or equal to 1 and less than 1000 (unless the output value is zero).

If \( w \) is greater than zero, it should be greater than or equal to \( d+9 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One to three digits to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENw.d</td>
<td>(</td>
<td>\exp</td>
<td>99)</td>
</tr>
<tr>
<td></td>
<td>99 &lt; (</td>
<td>\exp</td>
<td>999)</td>
</tr>
<tr>
<td>ENw.dEe</td>
<td>(</td>
<td>\exp</td>
<td>10^e - 1)</td>
</tr>
</tbody>
</table>

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \( w \) is filled with asterisks.

The exponent field width (\( e \)) is optional; if omitted, the default value is 2. If \( e \) is specified, \( w \) should be greater than or equal to \( d + e + 5 \), or zero.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.
The following shows output using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>EN11.2</td>
<td>475867.222</td>
<td>^475.87E+03</td>
</tr>
<tr>
<td>EN11.5</td>
<td>475867.222</td>
<td>**************</td>
</tr>
<tr>

<td>**************</td>
</tr>
<tr>
<td>EN11.2</td>
<td>0.0</td>
<td>^000.00E-03</td>
</tr>
</tbody>
</table>

**See Also**

Forms for data edit descriptors

General rules for numeric editing

**ES Editing**

The ES data edit descriptor transfers values by using scientific notation. It takes the following form:

\[ ESw.d[Ee] \]

where \( w \) is the total field width, \( d \) is the number of places after the decimal point, and \( e \) is the number of digits in the exponent.

If \( w \) is zero, the processor selects the field width. If \( e \) is present and zero, the exponent part contains the minimal number of digits needed to represent the exponent.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

**Rules for Input Processing**

On input, the ES data edit descriptor transfers \( w \) characters from an external field and assigns their real value to the corresponding I/O list item. The ES descriptor interprets and assigns input data in the same way as the F data edit descriptor. \( w \) cannot be zero for input. If \( e \) is present, it has no effect on input.

The following shows input using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ES11.3</td>
<td>^^5.321E+00</td>
<td>5.32100</td>
</tr>
<tr>
<td>ES11.3</td>
<td>-6.000E-03</td>
<td>-.60000</td>
</tr>
<tr>
<td>ES12.3</td>
<td>^^^3.150E-03</td>
<td>.00315</td>
</tr>
<tr>
<td>ES12.3</td>
<td>^^^3.829E+03</td>
<td>3829.0</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the ES data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to \( d \) decimal positions, to an external field that is \( w \) characters long if \( w \) is positive. The real value is output in scientific notation, where the absolute value of the significand is greater than or equal to 1 and less than 10 (unless the output value is zero).

If \( w \) is greater than zero, it should be greater than or equal to \( d+7 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:
<table>
<thead>
<tr>
<th>Edit Descriptor</th>
<th>Absolute Value of Exponent</th>
<th>Positive Form of Exponent</th>
<th>Negative Form of Exponent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESw.d</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>[exp] 99</td>
<td>E+nn</td>
</tr>
<tr>
<td></td>
<td>99 &lt; [exp] 999</td>
<td>E+nn</td>
<td>E-nn</td>
</tr>
<tr>
<td>ESw.dEe</td>
<td></td>
<td>[exp] 10^n - 1</td>
<td>E+n_1n_2…n_e</td>
</tr>
</tbody>
</table>

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \(w\) is filled with asterisks.

The exponent field width \(e\) is optional; if omitted, the default value is 2. If \(e\) is specified, the \(w\) should be greater than or equal to \(d + e + 5\).

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>ES11.2</td>
<td>473214.356</td>
<td>^^^4.73E+05</td>
</tr>
<tr>
<td>ES11.5</td>
<td>473214.356</td>
<td>4.73214E+05</td>
</tr>
<tr>
<td>ES12.3</td>
<td>0.00069</td>
<td>^^6.900E-04</td>
</tr>
<tr>
<td>ES10.3</td>
<td>-0.5555</td>
<td>-5.555E-01</td>
</tr>
<tr>
<td>ES11.2</td>
<td>0.0</td>
<td>^0.000E+00</td>
</tr>
</tbody>
</table>

**See Also**

Forms for data edit descriptors  
General rules for numeric editing  

**EX Editing**

The EX data edit descriptor transfers real values represented as hexadecimal-significand numbers. It takes the following form:

\[ \text{EX}w.d[Ee] \]

\(w\) is the external field width, unless it is zero. \(d\) is the width of the fractional part of the number, unless it is 0.

If \(w\) or \(d\) are zero, the processor picks the external field width or the width of the fractional part, respectively. \(d\) cannot be zero if the radix of the internal value is not a power of two. The hexadecimal point appears after the first hexadecimal digit and it is represented by the decimal symbol.

\(e\), if present and nonzero, is the number of digits in the exponent. If Ee is not present, or \(e\) is zero, the exponent contains the minimum number of digits needed to represent the exponent. \(e\) is ignored on input.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

**Rules for Input Processing**

The form and interpretation is the same as that for Fw.d editing.

**Rules for Output Processing**

The form of the external field for an internal value that is an IEEE infinity or NaN is the same as for Fw.d. Otherwise, it takes the form:

\([\pm]0X_{x0.x1x2…}e\exp\]

where the plus or minus sign is optional, the period signifies the decimal signal, \(x0x1x2\) are the most significant hexadecimal digits after rounding if \(d\) is nonzero, and \(\exp\) is the exponent.
For EXw.dEe with e greater than zero, the form is P[+|]-z1z2...ze. For EXw.d and EXw.dE0, the form of the exponent is P[+|]-z1z2...zn where n is the minimum number of digits required to represent the exponent. The exponent sign is always produced and is plus if the exponent is zero. The choice of the binary exponent is processor dependent.

The following shows possible output using the EX edit descriptor if SS is in effect:

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>EX10.2</td>
<td>42.5</td>
<td>0XA.A0P+2</td>

<td>6502.0</td>
<td>0XC.B3P+9</td>
</tr>
<tr>
<td>EX9.0E2</td>
<td>-0.0</td>
<td>-0X0.P+00</td>
</tr>
</tbody>
</table>

See Also
F Editing
General rules for numeric editing

G Editing
The G data edit descriptor for generalized editing can be used for input or output with any intrinsic type. It takes the following forms:

Gw
Gw.d
Gw.dEe

where w is the total field width, d is the number of places after the decimal point, and e is the number of digits in the exponent.

If w is 0, the field width is selected by the processor. If w is zero, you can only specify forms G0 or G0.d.

If w is nonzero, d must be specified.

If e is present and zero, the exponent part contains the minimal number of digits needed to represent the exponent. For integer, character, and logical data types d and e are ignored.

When used to specify I/O for integer data, the Gw, Gw.d and Gw.dEe edit descriptors follow the rules for Iw editing.

When used to specify I/O for logical data, the Gw.d and Gw.dEe edit descriptors with nonzero w follow the rules for Lw editing. On output, if w is 0, the Gw and Gw.d edit descriptors follow the rules for L1 editing.

When used to specify I/O for character data, the Gw.d and Gw.d.Ee edit descriptors with nonzero w follow the same rules as Aw editing. For output, when w is zero, the Gw and Gw.d edit descriptors follow the rules for Aw editing when no w is specified.

Rules for Real Input Processing
On input, the G data edit descriptor transfers w characters from an external field and assigns their real value to the corresponding I/O list item. The G descriptor interprets and assigns input data in the same way as the F data edit descriptor. w cannot be zero on input. If e is present, it has no effect on input.

Rules for Real Output Processing
The form in which the value is written depends on the magnitude of the internal value being edited. N is the magnitude of the internal value and r is the rounding mode value defined in the table below. If 0 < N < 0.1 - r x 10^-d-1 or N >= 10^d - r, or N is identically 0, w is nonzero, and d is 0, Gw.d output editing is the same as k PEw.d output editing and Gw.d Ee output editing is the same as k PEw.d Ee output editing, where k is the scale factor. If 0.1 - r x 10^-d-1 <= N < 10^d - r or N is identically 0 and d is not zero, the scale factor has no effect, and the value of N determines the editing as follows:
Effect of Data Magnitude on G Format Conversions

<table>
<thead>
<tr>
<th>Data Magnitude</th>
<th>Effective Conversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>( N = 0 )</td>
<td>( F(w - n).(d -1), n('b') )</td>
</tr>
<tr>
<td>( 0.1 - r \times 10^{-d-1} \leq N &lt; 1 - r \times 10^{-d} )</td>
<td>( F(w - n).d, n('b') )</td>
</tr>
<tr>
<td>( 1 - r \times 10^{-d} \leq N &lt; 10 - r \times 10^{-d+1} )</td>
<td>( F(w - n).(d -1), n('b') )</td>
</tr>
<tr>
<td>( 10 - r \times 10^{-d+1} \leq N &lt; 100 - r \times 10^{-d+2} )</td>
<td>( F(w - n).(d -2), n('b') )</td>
</tr>
<tr>
<td>( \ldots )</td>
<td>( \ldots )</td>
</tr>
<tr>
<td>( 10^d - r \times 10^{-2} \leq N &lt; 10^{d-1} - r \times 10^{-1} )</td>
<td>( F(w - n).1, n('b') )</td>
</tr>
<tr>
<td>( 10^{d-1} - r \times 10^{-1} \leq N &lt; 10^d - r )</td>
<td>( (w - n).0, n('b') )</td>
</tr>
</tbody>
</table>

The 'b' is a blank following the numeric data representation. For \( Gw.d, n('b') \) is 4 blanks. For \( Gw.dEe, n('b') \) is \( e+2 \) blanks.

The \( r \) is defined for each I/O rounding mode as follows:

<table>
<thead>
<tr>
<th>Rounding Mode</th>
<th>( r )</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMPATIBLE</td>
<td>0.5</td>
</tr>
</tbody>
</table>
| NEAREST       | 0.5 if the higher value is even  
               | -0.5 if the lower value is even |
| UP            | 1      |
| DOWN          | 0      |
| ZERO          | 1 if the internal value is negative  
               | 0 if the internal value is positive |

Note that the scale factor has no effect on output unless the magnitude of the datum to be edited is outside the range that permits effective use of F editing.

If \( w \) is greater than zero, it should be greater than or equal to \( d+7 \) to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The \( d \) digits to the right of the decimal point
- The 4-digit or \( e+2 \)-digit exponent

If \( e \) is specified and positive, \( w \) should be greater than or equal to \( d + e + 5 \) if \( w \) is positive.

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width \( w \) is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for \( Fw.d \).
The following shows output using the G edit descriptor and compares it to output using equivalent F editing (the symbol ^ represents a nonprinting blank character):

<table>
<thead>

I data edit descriptor
L data edit descriptor
A data edit descriptor
Scale Factor Editing (P)

Complex Editing

A complex value is an ordered pair of real values. Complex editing is specified by a pair of real edit descriptors, using any combination of the forms: \( Fw.d, Ew.d[Ee], Dw.d, ENw.d[Ee], ESw.d[Ee] \), or \( Gw.d[Ee] \).

Rules for Input Processing

On input, the two successive fields are read and assigned to the corresponding complex I/O list item as its real and imaginary part, respectively.

The following shows input using complex editing:

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>F8.5,F8.5</td>
<td>1234567012345.67</td>
<td>123.45678, 12345.67</td>
</tr>
<tr>
<td>E9.1,F9.3</td>
<td>734.432E8123456789</td>
<td>734.432E8, 123456.789</td>
</tr>
</tbody>
</table>

Rules for Output Processing

On output, the two parts of the complex value are transferred under the control of repeated or successive real edit descriptors. The two parts are transferred consecutively without punctuation or blanks, unless control or character string edit descriptors are specified between the pair of real edit descriptors.

The following shows output using complex editing (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>2F8.5</td>
<td>2.3547188, 3.456732</td>
<td>^2.35472 ^3.45673</td>
</tr>
<tr>
<td>E9.2,'^','^',E5.3</td>
<td>47587.222, 56.123</td>
<td>^0.48E+06^,^*****</td>
</tr>
</tbody>
</table>

See Also

Forms for data edit descriptors
General rules for numeric editing
General Rules for Complex Constants for details on complex constants
**Logical Editing (L)**

The L data edit descriptor transfers logical values. It takes the following form:

\[ Lw \]

The specified I/O list item must be of type logical or integer.

The G edit descriptor can be used to edit logical data; it follows the same rules as \( Lw \).

**Rules for Input Processing**

On input, the L data edit descriptor transfers \( w \) characters from an external field and assigns their logical value to the corresponding I/O list item. The value assigned depends on the external field data, as follows:

- \(.\text{TRUE.}\) is assigned if the first nonblank character is \( .T, T, .t, \) or \( t \). The logical constant \(.\text{TRUE.}\) is an acceptable input form.
- \(.\text{FALSE.}\) is assigned if the first nonblank character is \( .F, F, .f, \) or \( f \), or the entire field is filled with blanks. The logical constant \(.\text{FALSE.}\) is an acceptable input form.

If an other value appears in the external field, an error occurs.

**Rules for Output Processing**

On output, the L data edit descriptor transfers the following to an external field that is \( w \) characters long: \( w - 1 \) blanks, followed by a T or F (if the value is \(.\text{TRUE.}\) or \(.\text{FALSE.}\), respectively).

The following shows output using the L edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>L5</td>
<td>.TRUE.</td>
<td>^^^^T</td>
</tr>
<tr>
<td>L1</td>
<td>.FALSE.</td>
<td>F</td>
</tr>
</tbody>
</table>

**See Also**

Forms for data edit descriptors

**Character Editing (A)**

The A data edit descriptor transfers character or Hollerith values. It takes the following form:

\[ A[w] \]

If the corresponding I/O list item is of type character, character data is transferred. If the list item is of any other type, Hollerith data is transferred.

The G edit descriptor can be used to edit character data; it follows the same rules as \( Aw \).

**Rules for Input Processing**

On input, the A data edit descriptor transfers \( w \) characters from an external field and assigns them to the corresponding I/O list item.

The maximum number of characters that can be stored depends on the size of the I/O list item, as follows:

- For character data, the maximum size is the length of the corresponding I/O list item.
- For noncharacter data, the maximum size depends on the data type, as shown in the following table:

**Size Limits for Noncharacter Data Using A Editing**

<table>
<thead>
<tr>
<th>I/O List Element</th>
<th>Maximum Number of Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>1</td>
</tr>
</tbody>
</table>

1023
<table>
<thead>
<tr>
<th>I/O List Element</th>
<th>Maximum Number of Characters</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL(1) or LOGICAL*1</td>
<td>1</td>
</tr>
<tr>
<td>LOGICAL(2) or LOGICAL*2</td>
<td>2</td>
</tr>
<tr>
<td>LOGICAL(4) or LOGICAL*4</td>
<td>4</td>
</tr>
<tr>
<td>LOGICAL(8) or LOGICAL*8</td>
<td>8</td>
</tr>
<tr>
<td>INTEGER(1) or INTEGER*1</td>
<td>1</td>
</tr>
<tr>
<td>INTEGER(2) or INTEGER*2</td>
<td>2</td>
</tr>
<tr>
<td>INTEGER(4) or INTEGER*4</td>
<td>4</td>
</tr>
<tr>
<td>INTEGER(8) or INTEGER*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(4) or REAL*4</td>
<td>4</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>8</td>
</tr>
<tr>
<td>REAL(8) or REAL*8</td>
<td>8</td>
</tr>
<tr>
<td>REAL(16) or REAL*16</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(4) or COMPLEX*8</td>
<td>8</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(8) or COMPLEX*16</td>
<td>16</td>
</tr>
<tr>
<td>COMPLEX(16) or COMPLEX*32</td>
<td>32</td>
</tr>
</tbody>
</table>

1 Complex values are treated as pairs of real numbers, so complex editing requires a pair of edit descriptors. (See Complex Editing.)

If \( w \) is equal to or greater than the length (\( len \)) of the input item, the rightmost characters are assigned to that item. The leftmost excess characters are ignored.

If \( w \) is less than \( len \), or less than the number of characters that can be stored, \( w \) characters are assigned to the list item, left-justified, and followed by trailing blanks.

The following shows input using the A edit descriptor (the symbol \( ^ \) represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>A6</td>
<td>PAGE^#</td>
<td>#</td>
<td>CHARACTER (LEN=1)</td>

<td>GE^#</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>A6</td>
<td>PAGE^#</td>
<td>PAGE^#</td>
<td>^</td>
</tr>
</tbody>
</table>

**Rules for Output Processing**

On output, the A data edit descriptor transfers the contents of the corresponding I/O list item to an external field that is \( w \) characters long.
If \( w \) is greater than the size of the list item, the data is transferred to the output field, right-justified, with leading blanks. If \( w \) is less than or equal to the size of the list item, the leftmost \( w \) characters are transferred.

The following shows output using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>A5</td>
<td>OHMS</td>
<td>^OHMS</td>

Forms for data edit descriptors

Defined I/O Editing (DT)

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

\[
\text{DT [string] [(v-list)]}
\]

For more information on this edit descriptor, see DT Edit Descriptor in User-Defined I/O.

Default Widths for Data Edit Descriptors

If \( w \) (the field width) is omitted for the data edit descriptors, the system applies default values. For the real data edit descriptors, the system also applies default values for \( d \) (the number of characters to the right of the decimal point), and \( e \) (the number of characters in the exponent).

These defaults are based on the data type of the I/O list item, and are listed in the following table:

<table>
<thead>
<tr>
<th>Default Widths for Data Edit Descriptors</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Edit Descriptor</strong></td>
</tr>
<tr>
<td>I, B, O, Z, G</td>
</tr>
<tr>
<td></td>

</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

1 The default is the actual length of the corresponding I/O list item.

Terminating Short Fields of Input Data

On input, an edit descriptor such as Fw.d specifies that w characters (the field width) are to be read from the external field.

If the field contains fewer than w characters, the input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data.

Padding Short Fields

You can use the OPEN statement specifier PAD='YES' to indicate blank padding for short fields of input data. However, blanks can be interpreted as blanks or zeros, depending on which default behavior is in effect at the time. Consider the following:

```fortran
READ (2, *(I5)') J
```

If 3 is input for J, the value of J will be 30000 or 3 depending on which default behavior is in effect (BLANK='NULL' or BLANK='ZERO'). This can give unexpected results.

To ensure that the desired behavior is in effect, explicitly specify the BN or BZ edit descriptor. For example, the following ensures that blanks are interpreted as blanks (and not as zeros):

```fortran
READ (2, *(BN, I5)') J
```

Using Commas to Separate Input Data

You can use a comma to terminate a short data field. The comma has no effect on the d part (the number of characters to the right of the decimal point) of the specification.

The comma overrides the w specified for the I, B, O, Z, F, E, D, EN, ES, G, and L edit descriptors. For example, suppose the following statements are executed:

```fortran
READ (5,100) I,J,A,B
100 FORMAT (2I6,2F10.2)
```

Suppose a record containing the following values is read:

1, -2, 1.0, 35
The following assignments occur:

\[ \begin{align*}
  I &= 1 \\
  J &= -2 \\
  A &= 1.0 \\
  B &= 0.35 
\end{align*} \]

A comma can only terminate fields less than \( w \) characters long. If a comma follows a field of \( w \) or more characters, the comma is considered part of the next field.

A null (zero-length) field is designated by two successive commas, or by a comma after a field of \( w \) characters. Depending on the field descriptor specified, the resulting value assigned is 0, 0.0, 0.0D0, 0.0Q0, or .FALSE..

See Also
General Rules for Numeric Editing

Control Edit Descriptors

A control edit descriptor either directly determines how text is displayed or affects the conversions performed by subsequent data edit descriptors.

Forms for Control Edit Descriptors

A control edit descriptor takes one of the following forms:

\[ c \]

\[ c_n \]

\[ n_c \]

\( c \)

\( n \)

Is one of the following format codes: T, TL, TR, X, S, SP, SS, BN, BZ, P, RU, RD, RZ, RN, RC, RP, DC, DP, ;, \(/
\), \( \backslash \), $, and Q.

Is a number of character positions. It must be a positive integer literal constant or a variable format expression. No kind parameter can be specified. It cannot be a named constant.

The range of \( n \) is 1 through 2,147,483,647 (2**31-1) on Intel® 64 architecture; 1 through 32,767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

Description

In general, control edit descriptors are nonrepeatable. The only exception is the slash (/) edit descriptor, which can be preceded by a repeat specification or a * indicating an unlimited repeat count.

The control edit descriptors have the following specific forms:

<table>
<thead>
<tr>
<th>Positional:</th>
<th>Tn, TLn, TRn, and nX</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sign:</td>
<td>S, SP, and SS</td>
</tr>
<tr>
<td>Blank interpretation:</td>
<td>BN and BZ</td>
</tr>
<tr>
<td>Rounding mode:</td>
<td>RU, RD, RZ, RN, RC, and RP</td>
</tr>
<tr>
<td>Decimal mode:</td>
<td>DC and DP</td>
</tr>
<tr>
<td>Scale factor:</td>
<td>kP</td>
</tr>
</tbody>
</table>
The P edit descriptor is an exception to the general control edit descriptor syntax. It is preceded by a scale factor, rather than a character position specifier.

Control edit descriptors can be grouped in parentheses and preceded by a group repeat specification.

**See Also**
- Group repeat specifications
- Format Specifications

**Positional Editing**

The T, TL, TR, and X edit descriptors specify the position where the next character is transferred to or from a record.

On output, these descriptors do not themselves cause characters to be transferred and do not affect the length of the record. If characters are transferred to positions at or after the position specified by one of these descriptors, positions skipped and not previously filled are filled with blanks. The result is as if the entire record was initially filled with blanks.

The TR and X edit descriptors produce the same results.

**See Also**
- Forms for Control Edit Descriptors

**T Editing**

The T edit descriptor specifies a character position in an I/O record. It takes the following form:

\[ Tn \]

The \( n \) is a positive integer literal constant (with no kind parameter) indicating the character position of the record, relative to the left tab limit.

On input, the T descriptor positions the external record at the character position specified by \( n \). On output, the T descriptor indicates that data transfer begins at the \( n \)th character position of the external record.

**Examples**

In the following examples, the symbol \(^\) represents a nonprinting blank character.

Suppose a file has a record containing the value `ABC^^^XYZ`, and the following statements are executed:

```
READ (11,10) VALUE1, VALUE2
10   FORMAT (T7,A3,T1,A3)
```

The values read first are XYZ, then ABC.

Suppose the following statements are executed:

```
PRINT 25
25   FORMAT (T51,'COLUMN 2',T21,'COLUMN 1')
```

The following line is printed at the positions indicated:

```
Position 20                Position 50
|                             |
COLUMN 1                     COLUMN 2
```

Note that the first character of the record printed was reserved as a control character.

**See Also**
- Printing of Formatted Records
TL Editing
The TL edit descriptor specifies a character position to the left of the current position in an I/O record. It takes the following form:
TLn
The \( n \) is a positive integer literal constant (with no kind parameter) indicating the \( n \)th character position to the left of the current character.
If \( n \) is greater than or equal to the current position, the next character accessed is the first character of the record.

TR Editing
The TR edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:
TRn
The \( n \) is a positive integer literal constant (with no kind parameter) indicating the \( n \)th character position to the right of the current character.

X Editing
The X edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:
nX
The \( n \) is a positive integer literal constant (with no kind parameter) indicating the \( n \)th character position to the right of the current character.
On output, the X edit descriptor does not output any characters when it appears at the end of a format specification; for example:

```
WRITE (6,99) K
99   FORMAT ('^K=',I6,5X)
```
Note that the symbol ^ represents a nonprinting blank character. This example writes a record of only 9 characters. To cause \( n \) trailing blanks to be output at the end of a record, specify a format of \( n('\^') \).

Sign Editing
The SP, SS and S edit descriptors control the output of the optional plus (+) sign within numeric output fields. These descriptors have no effect during execution of input statements.
These specifiers correspond to the SIGN= specifier values PLUS, SUPPRESS, and PROCESSOR_DEFINED, respectively.
Within a format specification, a sign editing descriptor affects all subsequent I, F, E, EN, ES, EX, D, and G descriptors until another sign editing descriptor occurs.

Examples
Consider the following:

```fortran
INTEGER i
REAL r
!
! The following statements write:
! 251 +251 251 +251 251
i = 251
WRITE (*, 100) i, i, i, i, i
100   FORMAT (IS, SP, IS, SS, IS, SP, IS, S, IS)
```
! The following statements write:
! 0.673E+4 +.673E+40.673E+4 +.673E+40.673E+4
  r = 67.3E2
  WRITE (*, 200) r, r, r, r, r
  200 FORMAT (E8.3E1, 1X, SP, E8.3E1, SS, E8.3E1, 1X, SP, &
    & E8.3E1, S, E8.3E1)

See Also
Forms for Control Edit Descriptors

SP Editing
The SP edit descriptor causes the processor to produce a plus sign in any subsequent position where it would
be otherwise optional. It takes the following form:

SP

SS Editing
The SS edit descriptor causes the processor to suppress a plus sign in any subsequent position where it
would be otherwise optional. It takes the following form:

SS

S Editing
The S edit descriptor restores the plus sign as optional for all subsequent positive numeric fields. It takes the
following form:

S

The S edit descriptor restores to the processor the discretion of producing plus characters on an optional
basis.

Blank Editing
The BN and BZ descriptors control the interpretation of embedded and trailing blanks within numeric input
fields. These descriptors have no effect during execution of output statements.

Within a format specification, a blank editing descriptor affects all subsequent I, B, O, Z, F, E, EN, ES, D, and
G descriptors until another blank editing descriptor occurs.

The blank editing descriptors override the effect of the BLANK specifier during execution of a particular input
data transfer statement. (For more information, see the BLANK specifier in OPEN statements.)

See Also
Forms for Control Edit Descriptors

BN Editing
The BN edit descriptor causes the processor to ignore all embedded and trailing blanks in numeric input
fields. It takes the following form:

BN

The input field is treated as if all blanks have been removed and the remainder of the field is right-justified.
An all-blank field is treated as zero.

Examples
If an input field formatted as a six-digit integer (I6) contains '2 3 4', it is interpreted as '234'.

Consider the following code:

READ (*, 100) n
100 FORMAT (BN, I6)
If you enter any one of the following three records and terminate by pressing Enter, the READ statement interprets that record as the value 123:

```
  123
123
123   456
```

Because the repeatable edit descriptor associated with the I/O list item n is I6, only the first six characters of each record are read (three blanks followed by 123 for the first record, and 123 followed by three blanks for the last two records). Because blanks are ignored, all three records are interpreted as 123.

The following example shows the effect of BN editing with an input record that has fewer characters than the number of characters specified by the edit descriptors and ioist. Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. With BN editing in effect, the nonblank characters (123) are right-aligned, so the record is equal to 123.

**BZ Editing**

The BZ edit descriptor causes the processor to interpret all embedded and trailing blanks in numeric input fields as zeros. It takes the following form:

```
BZ
```

**Examples**

The input field ' 23 4 ' is interpreted as ' 23040'. If ' 23 4 ' is entered, the formatter adds one blank to pad the input to the six-digit integer format (I6), but this extra space is ignored, and the input is interpreted as ' 2304 '. The blanks following the E or D in real-number input are ignored, regardless of the form of blank interpretation in effect.

Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. If BZ editing is in effect, those three blanks are interpreted as zeros, and the record is equal to 123000.

**Round Editing**

The RU, RD, RZ, RN, RC, and RP edit descriptors temporarily change the I/O rounding mode for a connection. These forms of rounding correspond to the ROUND= specifier values UP, DOWN, ZERO, NEAREST, COMPATIBLE, and PROCESSOR DEFINED, respectively. Rounding conforms to the ISO/IEC/IEEE 60559:2011 standard.

The I/O rounding mode affects the conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, EX, F, and G editing.

Each descriptor continues to be in effect until a different round editing descriptor is encountered or until the end of the current I/O statement.

**See Also**

Forms for Control Edit Descriptors

**RU Editing**

The RU edit descriptor causes rounding to the smallest value that is greater than or equal to the original value. It takes the following form:
RU

**RD Editing**
The RD edit descriptor causes rounding to the largest representable value that is less than or equal to the original value. It takes the following form:

RD

**RZ Editing**
The RZ edit descriptor causes rounding to the value closest to the original value, but not greater in magnitude. It takes the following form:

RZ

**RN Editing**
The RN edit descriptor selects NEAREST rounding as specified by the ISO/IEC/IEEE 60559:2011 standard. It takes the following form:

RN

**RC Editing**
The RC edit descriptor causes rounding to the closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero. It takes the following form:

RC

**RP Editing**
The RP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

RP

**Decimal Editing**
The DC and DP edit descriptors temporarily change the decimal edit mode for a connection. These specifiers correspond to the DECIMAL= specifier values COMMA and POINT, respectively. The decimal editing mode controls the representation of the decimal symbol during conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, F, and G editing.

Each descriptor continues to be in effect until a different decimal editing descriptor is encountered or until the end of the current I/O statement.

**See Also**
Forms for Control Edit Descriptors

**DC Editing**
The DC edit descriptor changes the decimal editing mode for a connection to a decimal comma. It takes the following form:

DC

Note that during list-directed I/O, a semicolon is used as a value separator in place of a comma.

**DP Editing**
The DP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

DP
Scale-Factor Editing (P)

The P edit descriptor specifies a scale factor, which moves the location of the decimal point in real values and the two real parts of complex values. It takes the following form:

\[ kP \]

The \( k \) is a signed (sign is optional if positive), integer literal constant specifying the number of positions, to the left or right, that the decimal point is to move (the scale factor). The range of \( k \) is \(-128\) to \(127\).

At the beginning of a formatted I/O statement, the value of the scale factor is zero. If a scale editing descriptor is specified, the scale factor is set to the new value, which affects all subsequent real edit descriptors until another scale editing descriptor occurs.

To reinstate a scale factor of zero, you must explicitly specify \(0P\).

Format reversion does not affect the scale factor. (For more information on format reversion, see Interaction Between Format Specifications and I/O Lists.)

Rules for Input Processing

On input, a positive scale factor moves the decimal point to the left, and a negative scale factor moves the decimal point to the right. (On output, the effect is the reverse.)

On input, when an input field using an F, E, D, EN, ES, EX, or G real edit descriptor contains an explicit exponent, the scale factor has no effect. Otherwise, the internal value of the corresponding I/O list item is equal to the external field data multiplied by \(10^{-k}\). For example, a 2P scale factor multiplies an input value by .01, moving the decimal point two places to the left. A -2P scale factor multiplies an input value by 100, moving the decimal point two places to the right.

The scale factor applies to decimal numbers without an exponent. For hexadecimal-significand numbers, the exponent is mandatory so the scale factor has no effect.

The following shows input using the P edit descriptor (the symbol \(^\) represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Input</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>3PE10.5</td>
<td>^^^37.614^</td>
<td>.037614</td>
</tr>
<tr>
<td>3PE10.5</td>
<td>^^37.614E2</td>
<td>3761.4</td>
</tr>
<tr>
<td>~3PE10.5</td>
<td>^^^^37.614</td>
<td>37614.0</td>
</tr>
</tbody>
</table>

The scale factor must precede the first real edit descriptor associated with it, but it need not immediately precede the descriptor. For example, the following all have the same effect:

- \((3P, I6, F6.3, E8.1)\)
- \((I6, 3P, F6.3, E8.1)\)
- \((I6, 3PF6.3, E8.1)\)

Note that if the scale factor immediately precedes the associated real edit descriptor, the comma separator is optional.

Rules for Output Processing

On output, a positive scale factor moves the decimal point to the right, and a negative scale factor moves the decimal point to the left. (On input, the effect is the reverse.)

On output, the effect of the scale factor depends on which kind of real editing is associated with it, as follows:

- For F editing, the external value equals the internal value of the I/O list item multiplied by \(10^k\). This changes the magnitude of the data.
- For E and D editing, the external decimal field of the I/O list item is multiplied by \(10^k\), and \(k\) is subtracted from the exponent. This changes the form of the data.
A positive scale factor decreases the exponent; a negative scale factor increases the exponent.

For a positive scale factor, \( k \) must be less than \( d + 2 \) or an output conversion error occurs.

- For G editing, the scale factor has no effect if the magnitude of the data to be output is within the effective range of the descriptor (the G descriptor supplies its own scaling).

  If the magnitude of the data field is outside G descriptor range, E editing is used, and the scale factor has the same effect as E output editing.

- For EN, ES, and EX editing, the scale factor has no effect.

The following shows output using the P edit descriptor (the symbol ^ represents a nonprinting blank character):

<table>
<thead>
<tr>
<th>Format</th>
<th>Value</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td>1PE12.3</td>
<td>-270.139</td>
<td>^^-2.701E+02</td>
</tr>
<tr>
<td>1P,E12.2</td>
<td>-270.139</td>
<td>^^-2.70E+02</td>
</tr>
<tr>
<td>-1PE12.2</td>
<td>-270.139</td>
<td>^^-0.03E+04</td>
</tr>
</tbody>
</table>

**Examples**

The following shows a FORMAT statement containing a scale factor:

```fortran
DIMENSION A(6)
DO 10 I=1,6
   A(I) = 25.
   WRITE (6, 100) A
100 FORMAT(' ', F8.2, 2PF8.2, F8.2)
```

The preceding statements produce the following results:

```
  25.00  2500.00  2500.00
2500.00  2500.00  2500.00
```

The following code uses scale-factor editing when reading:

```fortran
READ (*, 100) a, b, c, d
100 FORMAT (F10.6, 1P, F10.6, F10.6, -2P, F10.6)
```

The program's output is:

```
  12.340      1.234      1.234   1234.000
12.340      1.234      1.234   1234.000
```

The next code shows scale-factor editing when writing:

```fortran
a = 12.34

WRITE (*, 100) a, a, a, a, a
100 FORMAT (1X, F9.4, E11.4E2, 1P, F9.4, E11.4E2, &
          & -2P, F9.4, E11.4E2)
```
This program's output is:

\[
\begin{array}{cccccccc}
12.3400 & 0.1234E+02 & 123.4000 & 1.2340E+01 & 0.1234 & 0.0012E+04 \\
\end{array}
\]

**See Also**

Forms for Control Edit Descriptors

---

**Slash Editing ( / )**

The slash edit descriptor terminates data transfer for the current record and starts data transfer for a new record. It takes the following form:

\[ [r]/ \]

The \( r \) is a repeat specification. It must be a positive default integer literal constant; no kind parameter can be specified.

The range of \( r \) is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. If \( r \) is omitted, it is assumed to be 1.

Multiple slashes cause the system to skip input records or to output blank records, as follows:

- When \( n \) consecutive slashes appear between two edit descriptors, \( n - 1 \) records are skipped on input, or \( n - 1 \) blank records are output. The first slash terminates the current record. The second slash terminates the first skipped or blank record, and so on.
- When \( n \) consecutive slashes appear at the beginning or end of a format specification, \( n \) records are skipped or \( n \) blank records are output, because the opening and closing parentheses of the format specification are themselves a record initiator and terminator, respectively. For example, suppose the following statements are specified:

```plaintext
WRITE (6,99)
99   FORMAT ('1',T51,'HEADING LINE'//T51,'SUBHEADING LINE'//)
```

The following lines are written:

<table>
<thead>
<tr>
<th>Column 50, top of page</th>
<th>HEADING LINE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>SUBHEADING LINE</td>
</tr>
<tr>
<td>blank line</td>
<td></td>
</tr>
<tr>
<td>blank line</td>
<td></td>
</tr>
<tr>
<td>blank line</td>
<td></td>
</tr>
</tbody>
</table>

Note that the first character of the record printed was reserved as a control character (see Printing of Formatted Records).

**Examples**

```plaintext
! The following statements write spreadsheet column and row labels:
WRITE (*, 100)
100   FORMAT ('   A     B     C     D     E'                             &
              /,' 1',/,' 2',/,' 3',/,' 4',/,' 5')
```

The above example generates the following output:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
</tbody>
</table>

**See Also**

Forms for Control Edit Descriptors
Colon Editing (:)

The colon edit descriptor terminates format control if there are no more items in the I/O list.

Examples

Suppose the following statements are specified:

```
PRINT 1,3
PRINT 2,13
  1 FORMAT (' I=',I2,' J=',I2)
  2 FORMAT (' K=',I2,:, ' L=',I2)
```

The above code causes the following lines to be written (the symbol ^ represents a nonprinting blank character):

```
I=^3^J=
K=13
```

The following shows another example:

```
!     The following example writes a= 3.20 b= .99
REAL a, b, c, d
DATA a /3.2/, b /.9871515/
WRITE (*, 100) a, b
100   FORMAT (' a=', F5.2, :, ' b=', F5.2, :, &
            ' c=', F5.2, :, ' d=', F5.2)
END
```

See Also

Forms for Control Edit Descriptors

Dollar-Sign ($) and Backslash ( \ ) Editing

The dollar sign and backslash edit descriptors modify the output of carriage control specified by the first character of the record. They only affect carriage control for formatted files, and have no effect on input.

If the first character of the record is a blank or a plus sign (+), the dollar sign and backslash descriptors suppress carriage return (after printing the record).

For terminal device I/O, when this trailing carriage return is suppressed, a response follows output on the same line. For example, suppose the following statements are specified:

```
TYPE 100
100 FORMAT (' ENTER RADIUS VALUE ',$)
ACCEPT 200, RADIUS
200 FORMAT (F6.2)
```

The following prompt is displayed:

```
 ENTER RADIUS VALUE
```

Any response (for example, "12.") is then displayed on the same line:

```
 ENTER RADIUS VALUE 12.
```

If the first character of the record is 0, 1, or ASCII NUL, the dollar sign and backslash descriptors have no effect.

Consider the following:

```
CHARACTER(20) MYNAME
WRITE (*,9000)
9000 FORMAT ('Please type your name:',\)
```
This example advances two lines, prompts for input, awaits input on the same line as the prompt, and prints the input.

The following shows the same example using Fortran standard constructs:

```
CHARACTER(20) MYNAME
WRITE (*,9000, ADVANCE='NO')
9000 FORMAT ('Please type your name:')
READ  (*,9001) MYNAME
9001 FORMAT (A20)
WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

See Also
Forms for Control Edit Descriptors

Character Count Editing (Q)
The character count edit descriptor returns the remaining number of characters in the current input record. The corresponding I/O list item must be of type integer or logical. For example, suppose the following statements are specified:

```
READ (4,1000) XRAY, KK, NCHRS, (ICHR(I), I=1,NCHRS)
1000  FORMAT (E15.7,I4,Q,(80A1))
```

Two fields are read into variables XRAY and KK. The number of characters remaining in the record is stored in NCHRS, and exactly that many characters are read into the array ICHR. (This instruction can fail if the record is longer than 80 characters.)

If you place the character count descriptor first in a format specification, you can determine the length of an input record.

On output, the character count edit descriptor causes the corresponding I/O list item to be skipped.

Examples
Consider the following:

```
CHARACTER ICHAR(80)
READ (4, 1000) XRAY, K, NCHAR, (ICHAR(I), I= 1, NCHAR)
1000  FORMAT (E15.7, I4, Q, (80A1))
```

The preceding input statement reads the variables XRAY and K. The number of characters remaining in the record is NCHAR, specified by the Q edit descriptor. The array ICHAR is then filled by reading exactly the number of characters left in the record. (Note that this instruction will fail if NCHAR is greater than 80, the length of the array ICHAR.) By placing Q in the format specification, you can determine the actual length of an input record.

Note that the length returned by Q is the number of characters left in the record, not the number of reals or integers or other data types. The length returned by Q can be used immediately after it is read and can be used later in the same format statement or in a variable format expression. (See Variable Format Expressions.)

Assume the file Q.DAT contains:

```
1234.567Hello, Q Edit
```
The following program reads in the number REAL1, determines the characters left in the record, and reads those into STR:

```
CHARACTER STR(80)
INTEGER LENGTH
REAL REAL1
OPEN (UNIT = 10, FILE = 'Q.DAT')
100   FORMAT (F8.3, Q, 80A1)
READ (10, 100) REAL1, LENGTH, (STR(I), I=1, LENGTH)
WRITE(*,'(F8.3,2X,I2,2X,<LENGTH>A1)') REAL1, LENGTH, (STR(I), &
 & I= 1, LENGTH)
END
```

The output on the screen is:

```
1234.567  13  Hello, Q Edit
```

A READ statement that contains only a Q edit descriptor advances the file to the next record. For example, consider that Q.DAT contains the following data:

```
abcdefg
abcd
```

Consider it is then READ with the following statements:

```
OPEN (10, FILE = "Q.DAT")
READ(10, 100) LENGTH
100   FORMAT(Q)
WRITE(*,'(I2)') LENGTH
READ(10, 100) LENGTH
WRITE(*,'(I2)') LENGTH
END
```

The output to the screen would be:

```
7
4
```

Forms for Control Edit Descriptors

**Character String Edit Descriptors**

Character string edit descriptors control the output of character strings. The character string edit descriptors are the character constant and H edit descriptor.

Although no string edit descriptor can be preceded by a repeat specification, a parenthesized group of string edit descriptors can be preceded by a repeat specification or a * indicating an unlimited repeat count.

**See Also**

Nested and Group Repeat Specifications

**Character Constant Editing**

The character constant edit descriptor causes a character string to be output to an external record. It takes one of the following forms:

'"string"

The string is a character literal constant; no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character.
To include an apostrophe in a character constant that is enclosed by apostrophes, place two consecutive apostrophes ("'") in the format specification; for example:

```fortran
50 FORMAT ('TODAY''S^DATE^IS:','/I2,'/','/I2')
```

Note that the symbol ^ represents a nonprinting blank character.

Similarly, to include a quotation mark in a character constant that is enclosed by quotation marks, place two consecutive quotation marks (""") in the format specification.

On input, the character constant edit descriptor transfers length of string characters to the edit descriptor.

### Examples

Consider the following '(3I5)' format in the WRITE statement:

```fortran
WRITE (10, '(3I5)') I1, I2, I3
```

This is equivalent to:

```fortran
WRITE (10, 100) I1, I2, I3
100 FORMAT( 3I5)
```

The following shows another example:

```fortran
! These WRITE statements both output ABC'DEF
! (The leading blank is a carriage-control character).
WRITE (*, 970)
970 FORMAT (' ABC''DEF')
WRITE (*, ' ('' ABC'''''DEF'' )')
! The following WRITE also outputs ABC'DEF. No carriage-
! control character is necessary for list-directed I/O.
WRITE (*,*) 'ABC''DEF'
```

Alternatively, if the delimiter is quotation marks, the apostrophe in the character constant ABC'DEF requires no special treatment:

```fortran
WRITE (*,*) "ABC'DEF"
```

### H Editing

The H edit descriptor transfers data between the external record and the H edit descriptor itself. The H edit descriptor is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

An H edit descriptor has the form of a Hollerith constant, as follows:

```
H
string
```

- `n` is an unsigned, positive default integer literal constant (with no kind parameter) indicating the number of characters in `string` (including blanks and tabs).

  The range of `n` is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

- `string` is a string of printable ASCII characters.
On input, the H edit descriptor transfers \( n \) characters from the external field to the edit descriptor. The first character appears immediately after the letter H. Any characters in the edit descriptor before input are replaced by the input characters. If the edit descriptor appears in a FORMAT statement, the replaced characters are preserved for future uses of that FORMAT statement; otherwise, the replacement is discarded.

On output, the H edit descriptor causes \( n \) characters following the letter H to be output to an external record.

**Examples**

```fortran
! These WRITE statements both print "Don't misspell 'Hollerith'"
!
WRITE (*, 960)
960 FORMAT (27H Don't misspell 'Hollerith')
WRITE (*, 961)
961 FORMAT (' Don''t misspell ''Hollerith''')
```

**See Also**

- Deleted and Obsolescent Language Features
- Format Specifications

**Nested and Group Repeat Specifications**

Format specifications can include nested format specifications enclosed in parentheses; for example:

```
15 FORMAT (E7.2,I8,I2,(A5,I6))
35 FORMAT (A6,(L8(3I2)),A)
```

A group repeat specification can precede a nested group of edit descriptors; it can be an unsigned integer literal constant, a variable format expression, or * to indicate an unlimited repeat count. For example, the following statements are equivalent, and the second statement shows a group repeat specification:

```
50 FORMAT (I8,I8,F8.3,E15.7,F8.3,E15.7,I5,I5)
50 FORMAT (2I8,3(F8.3,E15.7),2I5)
```

If a nested group does not show a repeat count, a default count of 1 is assumed.

Normally, the string edit descriptors and control edit descriptors cannot be repeated (except for slash), but any of these descriptors can be enclosed in parentheses and preceded by a group repeat specification. For example, the following statements are valid:

```
76 FORMAT ('MONTHLY',3('TOTAL'))
100 FORMAT (I8,(4(T7),A4)
```

Each of the following can be used to read data at the end of an input record into \( N \) elements of array \( A \):

```
read (10,'(<N>F8.2)') A(1:N)  ! Variable format expression
read(10,'(*(F8.2))') A(1:N)   ! Unlimited repeat count
```

Variable Format Expressions

A variable format expression is a numeric expression enclosed in angle brackets (< >) that can be used in a FORMAT statement or in a character format specification.

The numeric expression can be any valid Fortran expression, including function calls and references to dummy arguments.

If the expression is not of type integer, it is converted to integer type before being used.

If the value of a variable format expression does not obey the restrictions on magnitude applying to its use in the format, an error occurs.

Variable format expressions cannot be used with the H edit descriptor, and they are not allowed in character format specifications that are not character constant expressions.

Variable format expressions are evaluated each time they are encountered in the scan of the format. If the value of the variable used in the expression changes during the execution of the I/O statement, the new value is used the next time the format item containing the expression is processed.

Examples

Consider the following statement:

```
FORMAT (I<J+1>)
```

When the format is scanned, the preceding statement performs an I (integer) data transfer with a field width of J+1. The expression is reevaluated each time it is encountered in the normal format scan.

Consider the following statements:

```fortran
DIMENSION A(5)
DATA A/1.,2.,3.,4.,5./

DO 10 I=1,10
WRITE (6,100) I
100   FORMAT (I<MAX(I,5)>)
10    CONTINUE

DO 20 I=1,5
WRITE (6,101) (A(I), J=1,I)
101   FORMAT (<I>F10.<I-1>)
20    CONTINUE
END
```

On execution, these statements produce the following output:

```
1
2
3
4
5
6
7
8
9
10
2.0  2.0
3.00 3.00 3.00
4.000 4.000 4.000 4.000
5.0000 5.0000 5.0000 5.0000 5.0000
```
The following shows another example:

```fortran
WRITE(6,20) INT1
20     FORMAT(I<MAX(20,5)>)
WRITE(6,FMT=30) REAL2(10), REAL3
30     FORMAT(<J+K>X, <2*M>F8.3)
```

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement. For example:

```fortran
INTEGER width, value
width=2
READ (*,10) width, value
10     FORMAT(I1, I <width>)
PRINT *, value
END
```

When given input 3123, the program will print 123 and not 12.

**See Also**

*Interaction Between Format Specifications and I/O Lists* for details on the synchronization of I/O lists with formats

**Printing of Formatted Records**

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but used to control vertical spacing.

Printing control characters are a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following table lists the valid control characters for printing:

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>Overprinting</td>
<td>Outputs the record (at the current position in the current line) and a carriage return.</td>
</tr>
<tr>
<td>-</td>
<td>One line feed</td>
<td>Outputs the record (at the beginning of the following line) and a carriage return.</td>
</tr>
<tr>
<td>0</td>
<td>Two line feeds</td>
<td>Outputs the record (after skipping a line) and a carriage return.</td>
</tr>
<tr>
<td>1</td>
<td>Next page</td>
<td>Outputs the record (at the beginning of a new page) and a carriage return.</td>
</tr>
<tr>
<td>$</td>
<td>Prompting</td>
<td>Outputs the record (at the beginning of the following line), but no carriage return.</td>
</tr>
<tr>
<td>ASCII NUL</td>
<td>Overprinting with no advance</td>
<td>Outputs the record (at the current position in the current line), but no carriage return.</td>
</tr>
</tbody>
</table>
Any other character is interpreted as a blank and is deleted from the print line. If you do not specify a control character for printing, the first character of the record is not printed.

Interaction Between Format Specifications and I/O Lists

Format control begins with the execution of a formatted I/O statement. Each action of format control depends on information provided jointly by the next item in the I/O list (if one exists) and the next edit descriptor in the format specification.

Both the I/O list and the format specification are interpreted from left to right, unless repeat specifications or implied-DO lists appear.

If an I/O list specifies at least one list item, at least one data edit descriptor (I, B, O, Z, F, E, EN, ES, EX, D, G, L, or A) or the Q edit descriptor must appear in the format specification; otherwise, an error occurs.

Each data edit descriptor (or Q edit descriptor) corresponds to one item in the I/O list, except that an I/O list item of type complex requires the interpretation of two F, E, EN, ES, EX, D, or G edit descriptors. No I/O list item corresponds to a control edit descriptor (X, P, T, TL, TR, SP, SS, S, BN, BZ, $, or :), or a character string edit descriptor (H and character constants). For character string edit descriptors, data transfer occurs directly between the external record and the format specification.

When format control encounters a data edit descriptor in a format specification, it determines whether there is a corresponding I/O list item specified. If there is such an item, it is transferred under control of the edit descriptor, and then format control proceeds. If there is no corresponding I/O list item, format control terminates.

If there are no other I/O list items to be processed, format control also terminates when the following occurs:

- A colon edit descriptor is encountered.
- The end of the format specification is reached.

If additional I/O list items remain, part or all of the format specification is reused in format reversion.

In format reversion, the current record is terminated and a new one is initiated. Format control then reverts to one of the following (in order) and continues from that point:

1. The group repeat specification whose opening parenthesis matches the next-to-last closing parenthesis of the format specification
2. The initial opening parenthesis of the format specification

Format reversion has no effect on the scale factor (P), the sign control edit descriptors (S, SP, or SS), or the blank interpretation edit descriptors (BN or BZ).

Examples

The data in file FOR002.DAT is to be processed 2 records at a time. Each record starts with a number to be put into an element of a vector B, followed by 5 numbers to be put in a row in matrix A.

FOR002.DAT contains the following data:

<table>
<thead>
<tr>
<th>001</th>
<th>0101</th>
<th>0102</th>
<th>0103</th>
<th>0104</th>
<th>0105</th>
</tr>
</thead>
<tbody>
<tr>
<td>002</td>
<td>0201</td>
<td>0202</td>
<td>0203</td>
<td>0204</td>
<td>0205</td>
</tr>
<tr>
<td>003</td>
<td>0301</td>
<td>0302</td>
<td>0303</td>
<td>0304</td>
<td>0305</td>
</tr>
<tr>
<td>004</td>
<td>0401</td>
<td>0402</td>
<td>0403</td>
<td>0404</td>
<td>0405</td>
</tr>
<tr>
<td>005</td>
<td>0501</td>
<td>0502</td>
<td>0503</td>
<td>0504</td>
<td>0505</td>
</tr>
<tr>
<td>006</td>
<td>0601</td>
<td>0602</td>
<td>0603</td>
<td>0604</td>
<td>0605</td>
</tr>
<tr>
<td>007</td>
<td>0701</td>
<td>0702</td>
<td>0703</td>
<td>0704</td>
<td>0705</td>
</tr>
<tr>
<td>008</td>
<td>0801</td>
<td>0802</td>
<td>0803</td>
<td>0804</td>
<td>0805</td>
</tr>
<tr>
<td>009</td>
<td>0901</td>
<td>0902</td>
<td>0903</td>
<td>0904</td>
<td>0905</td>
</tr>
<tr>
<td>010</td>
<td>1001</td>
<td>1002</td>
<td>1003</td>
<td>1004</td>
<td>1005</td>
</tr>
</tbody>
</table>
The following example shows how several different format specifications interact with I/O lists to process data in file FOR002.DAT:

```fortran
  INTEGER I, J, A(2,5), B(2)
  OPEN (unit=2, access='sequential', file='FOR002.DAT')

  READ (2,100) (B(I), (A(I,J), J=1,5), I=1,2) 1

  100 FORMAT (2(I3, X, 5(I4,X), /)) 2

  WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 3

  999 FORMAT (' B is ', 2(I3, X), ';  A is', / 1 (' ', 5(I4, X)))

  READ (2,200) (B(I), (A(I,J), J=1,5), I=1,2) 4

  200 FORMAT (2(I3, X, 5(I4,X), :/)) 5

  WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 6

  READ (2,300) (B(I), (A(I,J), J=1,5), I=1,2) 7

  300 FORMAT ( (I3, X, 5(I4,X)) )

  WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 8

  READ (2,400) (B(I), (A(I,J), J=1,5), I=1,2) 9

  400 FORMAT (I3, X, 5(I4,X) )

  WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 9

END
```

1 This statement reads B(1); then A(1,1) through A(1,5); then B(2) and A(2,1) through A(2,5).
The first record read (starting with 001) starts the processing of the I/O list.

2 There are two records, each in the format I3, X, 5(I4, X). The slash (/) forces the reading of the second record after A(1,5) is processed. It also forces the reading of the third record after A(2,5) is processed; no data is taken from that record.

3 This statement produces the following output:

   B is 1 2 ; A is 101 102 103 104 105 201 202 203 204 205

4 This statement reads the record starting with 004. The slash (/) forces the reading of the next record after A(1,5) is processed. The colon (:) stops the reading after A(2,5) is processed, but before the slash (/) forces another read.

5 This statement produces the following output:

   B is 4 5 ; A is 401 402 403 404 405 501 502 503 504 505
This statement reads the record starting with 006. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I3.

This statement produces the following output:

\[
\begin{array}{cccccccccccc}
B & is & 6 & 7 ; & A & is & 601 & 602 & 603 & 604 & 605 & 701 & 702 & 703 & 704 & 705 \\
\end{array}
\]

This statement reads the record starting with 008. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I4.

This statement produces the following output:

\[
\begin{array}{cccccccccccc}
B & is & 8 & 90 ; & A & is & 801 & 802 & 803 & 804 & 805 & 9010 & 9020 & 9030 & 9040 & 100 \\
\end{array}
\]

The record 009 0901 0902 0903 0904 0905 is processed with I4 as "009 " for B(2), which is 90. X skips the next "0". Then "901 " is processed for A(2,1), which is 9010, "902 " for A(2,2), "903 " for A(2,3), and "904 " for A(2,4). The repeat specification of 5 is now exhausted and the format ends. Format reversion causes another record to be read and starts format processing at the left parenthesis before the I4, so "010 " is read for A(2,5), which is 100.

File Operation I/O Statements

The following are file connection, inquiry, and positioning I/O statements:

- **BACKSPACE**
  Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing.

- **CLOSE**
  Terminates the connection between a logical unit and a file or device.

- **DELETE**
  Deletes a record from a relative file.

- **ENDFILE**
  Writes an end-of-file record to a sequential file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.

- **FLUSH**
  Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.

- **INQUIRE**
  Requests information on the status of specified properties of a file or logical unit. For more information on specifiers you can use in INQUIRE statements, see INQUIRE Statement Specifiers.

- **OPEN**
  Connects a Fortran logical unit to a file or device; declares attributes for read and write operations. For more information on specifiers you can use in OPEN statements, see OPEN Statement Specifiers.

- **REWIND**
  Positions a sequential or direct access file at the beginning of the file (the initial point).
• **WAIT**

Performs a wait operation for a specified pending asynchronous data transfer operation.

The following table summarizes I/O statement specifiers:

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS=access</td>
<td>'SEQUENTIAL', 'DIRECT', 'STREAM', or 'APPEND'</td>
<td>Specifies the method of file access.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>ACTION=permission</td>
<td>'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')</td>
<td>Specifies file I/O mode.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>ADVANCE=c-expr</td>
<td>'NO' or 'YES' (default is 'YES')</td>
<td>Specifies formatted sequential data input as advancing, or non-advancing.</td>
<td>READ</td>
</tr>
<tr>
<td>ASSOCIATEVARIABLE=v</td>
<td>Integer variable</td>
<td>Specifies a variable to be updated to reflect the record number of the next sequential record in the file.</td>
<td>OPEN</td>
</tr>
<tr>
<td>ASYNCHRONOUS=async</td>
<td>'YES' or 'NO' (default is 'NO')</td>
<td>Specifies whether or not the I/O is done asynchronously</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BINARY=bin</td>
<td>'NO' or 'YES'</td>
<td>Returns whether file format is binary.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>BLANK=blank_control</td>
<td>'NULL' or 'ZERO' (default is 'NULL')</td>
<td>Specifies whether blanks are ignored in numeric fields or interpreted as zeros.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BLOCKSIZE=blocksize</td>
<td>Positive integer variable or expression</td>
<td>Specifies or returns the internal buffer size used in I/O.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>BUFFERCOUNT=bc</td>
<td>Numeric expression</td>
<td>Specifies the number of buffers to be associated with the unit for multibuffered I/O.</td>
<td>OPEN</td>
</tr>
<tr>
<td>BUFFERED=bf</td>
<td>'YES' or 'NO' (default is 'NO')</td>
<td>Specifies run-time library behavior following WRITE operations.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>CARRIAGECONTROL=control</td>
<td>'FORTRAN', 'LIST', or 'NONE'</td>
<td>Specifies carriage control processing.</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>CONVERT=form</td>
<td>'LITTLE_ENDIAN', 'BIG_ENDIAN', 'CRAY', 'FDX', 'FGX', 'IBM', 'VAXD', 'VAXG', or 'NATIVE' (default is 'NATIVE')</td>
<td>Specifies a numeric format for unformatted data.</td>
<td>INQUIRE, OPEN</td>
</tr>
</tbody>
</table>
## I/O Specifiers

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Values</th>
<th>Description</th>
<th>Used with:</th>
</tr>

<tr>
<td>DISPOSE=dis</td>
<td>'KEEP', 'SAVE', 'DELETE', 'PRINT', 'PRINT/DELETE', 'SUBMIT', or 'SUBMIT/DELETE' (default is 'DELETE' for scratch files; 'KEEP' for all other files)</td>
<td>Specifies the status of a file after the unit is closed.</td>
<td>OPEN, CLOSE</td>
</tr>
<tr>
<td>formatlist</td>
<td>Character variable or expression</td>
<td>Lists edit descriptors. Used in FORMAT statements and format specifiers (the FMT=formatspec option) to describe the format of data.</td>
<td>FORMAT, PRINT, READ, WRITE</td>
</tr>
<tr>
<td>END=endlabel</td>
<td>Integer between 1 and 99999</td>
<td>When an end of file is encountered, transfers control to the statement whose label is specified.</td>
<td>READ</td>
</tr>
<tr>
<td>EOR=eorlabel</td>
<td>Integer between 1 and 99999</td>
<td>When an end of record is encountered, transfers to the statement whose label is specified.</td>
<td>READ</td>
</tr>
<tr>
<td>ERR=errlabel</td>
<td>Integer between 1 and 99999</td>
<td>Specifies the label of an executable statement where execution is transferred after an I/O error.</td>
<td>All except PRINT</td>
</tr>
<tr>
<td>EXIST=ex</td>
<td>.TRUE. or .FALSE.</td>
<td>Returns whether a file exists and can be opened.</td>
<td>INQUIRE</td>
</tr>
<tr>
<td>FILE=file</td>
<td>Character variable or expression. Length and format of the name are determined by the operating system</td>
<td>Specifies the name of a file</td>
<td>INQUIRE, OPEN</td>
</tr>
<tr>
<td>NAME=name</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>[FMT=]formatspec</td>
<td>Character variable or expression</td>
<td>Specifies an editlist to use to format data.</td>
<td>PRINT, READ, WRITE</td>
</tr>

### INQUIRE Statement Specifiers

The INQUIRE statement returns information on the status of specified properties of a file or logical unit. For more information, see [INQUIRE](#).

The following table lists the INQUIRE statement specifiers and contains links to their descriptions:

<table>
<thead>
<tr>

INQUIRE: ACCESS Specifier

The ACCESS specifier asks how a file is connected. It takes the following form:

ACCESS = acc

<table>
<thead>
<tr>
<th>acc</th>
<th>Is a scalar default character variable that is assigned one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SEQUENTIAL'</td>
<td>If the file is connected for sequential access</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>If the file is connected for stream access</td>
</tr>
<tr>
<td>'DIRECT'</td>
<td>If the file is connected for direct access</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>

INQUIRE: ACTION Specifier

The ACTION specifier asks which I/O operations are allowed for a file. It takes the following form:

ACTION = act

<table>
<thead>
<tr>
<th>act</th>
<th>Is a scalar default character variable that is assigned one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'READ'</td>
<td>If the file is connected for input only</td>
</tr>
<tr>
<td>'WRITE'</td>
<td>If the file is connected for output only</td>
</tr>
<tr>
<td>'READWRITE'</td>
<td>If the file is connected for both input and output</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>
INQUIRE: ASYNCHRONOUS Specifier

The ASYNCHRONOUS specifier asks whether asynchronous I/O is in effect. It takes the following form:

\[
\text{ASYNCHRONOUS} = \text{asyn}
\]

\textit{asyn} is a scalar default character variable that is assigned one of the following values:

- 'NO': If the file or unit is connected and asynchronous input/output is not in effect.
- 'YES': If the file or unit is connected and asynchronous input/output is in effect.
- 'UNKNOWN': If the file or unit is not connected.

INQUIRE: BINARY Specifier (W*S)

The BINARY specifier asks whether a file is connected to a binary file. It takes the following form:

\[
\text{BINARY} = \text{bin}
\]

\textit{bin} is a scalar default character variable that is assigned one of the following values:

- 'YES': If the file is connected to a binary file.
- 'NO': If the file is connected to a nonbinary file.
- 'UNKNOWN': If the file is not connected.

INQUIRE: BLANK Specifier

The BLANK specifier asks what type of blank control is in effect for a file. It takes the following form:

\[
\text{BLANK} = \text{blnk}
\]

\textit{blnk} is a scalar default character variable that is assigned one of the following values:

- 'NULL': If null blank control is in effect for the file.
- 'ZERO': If zero blank control is in effect for the file.
- 'UNDEFINED': If the file is not connected, or it is not connected for formatted data transfer.

INQUIRE: BLOCKSIZE Specifier

The BLOCKSIZE specifier asks about the physical I/O transfer size. It takes the following form:
BLOCKSIZE = bks

*bks* is a scalar integer variable. The *bks* is assigned the current size of the physical I/O transfer. If the unit or file is not connected, the value assigned is zero.

**INQUIRE: BUFFERED Specifier**

The BUFFERED specifier asks whether run-time buffering is in effect. It takes the following form:

BUFFERED = *bf*

*bf* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>If the file or unit is connected and buffering is not in effect.</td>
</tr>
<tr>
<td>'YES'</td>
<td>If the file or unit is connected and buffering is in effect.</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected.</td>
</tr>
</tbody>
</table>

**INQUIRE: CARRIAGECONTROL Specifier**

The CARRIAGECONTROL specifier asks what type of carriage control is in effect for a file. It takes the following form:

CARRIAGECONTROL = *cc*

*cc* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FORTRAN'</td>
<td>If the file is connected with Fortran carriage control in effect</td>
</tr>
<tr>
<td>'LIST'</td>
<td>If the file is connected with implied carriage control in effect</td>
</tr>
<tr>
<td>'NONE'</td>
<td>If the file is connected with no carriage control in effect</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected.</td>
</tr>
</tbody>
</table>

**INQUIRE: CONVERT Specifier**

The CONVERT specifier asks what type of data conversion is in effect for a file. It takes the following form:

CONVERT = *fm*

*fm* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'LITTLE_ENDIAN'</td>
<td>If the file is connected with little endian integer and IEEE* floating-point data conversion in effect</td>
</tr>
<tr>
<td>Specification</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td>'BIG_ENDIAN'</td>
<td>If the file is connected with big endian integer and IEEE floating-point data conversion in effect</td>
</tr>
<tr>
<td>'CRAY'</td>
<td>If the file is connected with big endian integer and CRAY* floating-point data conversion in effect</td>
</tr>
<tr>
<td>'FDX'</td>
<td>If the file is connected with little endian integer and VAX* processor F_floating, D_floating, and IEEE binary128 data conversion in effect</td>
</tr>
<tr>
<td>'FGX'</td>
<td>If the file is connected with little endian integer and VAX processor F_floating, G_floating, and IEEE binary128 data conversion in effect</td>
</tr>
<tr>
<td>'IBM'</td>
<td>If the file is connected with big endian integer and IBM* System/370 floating-point data conversion in effect</td>
</tr>
<tr>
<td>'VAXD'</td>
<td>If the file is connected with little endian integer and VAX processor F_floating, D_floating, and H_floating in effect</td>
</tr>
<tr>
<td>'VAXG'</td>
<td>If the file is connected with little endian integer and VAX processor F_floating, G_floating, and H_floating in effect</td>
</tr>
<tr>
<td>'NATIVE'</td>
<td>If the file is connected with no data conversion in effect</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected for unformatted data transfer</td>
</tr>
</tbody>
</table>

**INQUIRE: DECIMAL Specifier**

The DECIMAL specifier asks which decimal editing mode is in effect for a file connection. It takes the following form:

```fortran
DECIMAL = dmode
```

Where `dmode` is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Specification</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'COMMA'</td>
<td>If a decimal comma is used during decimal editing mode.</td>
</tr>
<tr>
<td>'POINT'</td>
<td>If a decimal point is used during decimal editing mode.</td>
</tr>
</tbody>
</table>
**INQUIRE: DELIM Specifier**

The DELIM specifier asks how character constants are delimited in list-directed and namelist output. It takes the following form:

```
DELIM = del
```

*del* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'APOSTROPHE'</td>
<td>If apostrophes are used to delimit character constants in list-directed and namelist output</td>
</tr>
<tr>
<td>'QUOTE'</td>
<td>If quotation marks are used to delimit character constants in list-directed and namelist output</td>
</tr>
<tr>
<td>'NONE'</td>
<td>If no delimiters are used</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If the file is not connected, or is not connected for formatted data transfer</td>
</tr>
</tbody>
</table>

**INQUIRE: DIRECT Specifier**

The DIRECT specifier asks whether a file is connected for direct access. It takes the following form:

```
DIRECT = dir
```

*dir* is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected for direct access</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is not connected for direct access</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>

**INQUIRE: ENCODING Specifier**

The ENCODING specifier asks what type of encoding is in effect for a file. It takes the following form:

```
ENCODING = enc
```

*enc* is a scalar default character expression that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UTF-8'</td>
<td>If the file is connected with UTF-8 encoding in effect.</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If the file is connected for unformatted I/O.</td>
</tr>
</tbody>
</table>
'UNKNOWN'
If the processor is unable to determine the encoding form of the file.

**INQUIRE: EXIST Specifier**

The EXIST specifier asks whether a file exists and can be opened. It takes the following form:

\[
\text{EXIST} = \text{ex}
\]

\[
ex
\]
Is a scalar default logical variable that is assigned one of the following values:

\[
\text{.TRUE.} \quad \text{If the specified file exists and can be opened, or if the specified unit exists}
\]

\[
\text{.FALSE.} \quad \text{If the specified file or unit does not exist or if the file exists but cannot be opened}
\]

The unit exists if it is a number in the range allowed by the processor.

**INQUIRE: FORM Specifier**

The FORM specifier asks whether a file is connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

\[
\text{FORM} = \text{fm}
\]

\[
\text{fm}
\]
Is a scalar default character variable that is assigned one of the following values:

\[
'\text{FORMATTED}' \quad \text{If the file is connected for formatted data transfer}
\]

\[
'\text{UNFORMATTED}' \quad \text{If the file is connected for unformatted data transfer}
\]

\[
'\text{BINARY}' \quad \text{If the file is connected for binary data transfer}
\]

\[
'\text{UNDEFINED}' \quad \text{If the file is not connected}
\]

**INQUIRE: FORMATTED Specifier**

The FORMATTED specifier asks whether a file is connected for formatted data transfer. It takes the following form:

\[
\text{FORMATTED} = \text{fmt}
\]

\[
\text{fmt}
\]
Is a scalar default character variable that is assigned one of the following values:

\[
'\text{YES}' \quad \text{If the file is connected for formatted data transfer}
\]

\[
'\text{NO}' \quad \text{If the file is not connected for formatted data transfer}
\]
'UNKNOWN'  

If the processor cannot determine whether the file is connected for formatted data transfer

INQUIRE: IOFOCUS Specifier (W*S)

The IOFOCUS specifier asks if the indicated unit is the active window in a QuickWin application. It takes the following form:

IOFOCUS = iof

iof  

Is a scalar default logical variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>.TRUE.</th>
<th>If the specified unit is the active window in a QuickWin application</th>
</tr>
</thead>
<tbody>
<tr>
<td>.FALSE.</td>
<td>If the specified unit is not the active window in a QuickWin application</td>
</tr>
</tbody>
</table>

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window.

If you use this specifier with a non-Windows application, an error occurs.

INQUIRE: MODE Specifier

MODE is a nonstandard synonym for ACTION.

INQUIRE: NAME Specifier

The NAME specifier returns the name of a file. It takes the following form:

NAME = nme

nme  

Is a scalar default character variable that is assigned the name of the file to which the unit is connected. If the file does not have a name, nme is undefined.

The value assigned to nme is not necessarily the same as the value given in the FILE specifier. However, the value that is assigned is always valid for use with the FILE specifier in an OPEN statement, unless the value has been truncated in a way that makes it unacceptable. (Values are truncated if the declaration of nme is too small to contain the entire value.)

NOTE

The FILE and NAME specifiers are synonyms when used with the OPEN statement, but not when used with the INQUIRE statement.

See Also

*The appropriate manual in your operating system documentation set for details on the maximum size of file pathnames*
INQUIRE: NAMED Specifier
The NAMED specifier asks whether a file is named. It takes the following form:
NAMED = nmd

\( nmd \)

Is a scalar default logical variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.TRUE.</td>
<td>If the file has a name</td>
</tr>
<tr>
<td>.FALSE.</td>
<td>If the file does not have a name</td>
</tr>
</tbody>
</table>

INQUIRE: NEXTREC Specifier
The NEXTREC specifier asks where the next record can be read or written in a file connected for direct access. It takes the following form:
NEXTREC = nr

\( nr \)

Is a scalar integer variable that is assigned a value as follows:

- If the file is connected for direct access and a record \( r \) was previously read or written, the value assigned is \( r + 1 \).
- If no record has been read or written, the value assigned is 1.
- If there are pending asynchronous data transfer operations for the specified file, the value assigned is computed as if all pending data transfers have already completed.
- If the file is not connected for direct access, or if the file position cannot be determined because of an error condition, the value assigned is zero.
- If the file is connected for direct access and a REWIND has been performed on the file, the value assigned is 1.

INQUIRE: NUMBER Specifier
The NUMBER specifier asks the number of the unit connected to a file. It takes the following form:
NUMBER = num

\( num \)

Is a scalar integer variable. The \( num \) is assigned the number of the unit currently connected to the specified file. If there is no unit connected to the file, the value assigned is -1.

INQUIRE: OPENED Specifier
The OPENED specifier asks whether a file is connected. It takes the following form:
OPENED = od

\( od \)

Is a scalar default logical variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.TRUE.</td>
<td>If the specified file or unit is connected</td>
</tr>
<tr>
<td>.FALSE.</td>
<td>If the specified file or unit is not connected</td>
</tr>
</tbody>
</table>
INQUIRE: ORGANIZATION Specifier

The ORGANIZATION specifier asks how the file is organized. It takes the following form:

**ORGANIZATION = org**

<table>
<thead>
<tr>
<th>org</th>
<th>Is a scalar default character variable that is assigned one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'SEQUENTIAL'</td>
<td>If the file is a sequential file</td>
</tr>
<tr>
<td>'RELATIVE'</td>
<td>If the file is a relative file</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine the file's organization</td>
</tr>
</tbody>
</table>

INQUIRE: PAD Specifier

The PAD specifier asks whether blank padding was specified for the file. It takes the following form:

**PAD = pd**

<table>
<thead>
<tr>
<th>pd</th>
<th>Is a scalar default character variable that is assigned one of the following values:</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>If the file or unit was connected with PAD='NO'</td>
</tr>
<tr>
<td>'YES'</td>
<td>If the file or unit is not connected, or it was connected with PAD='YES'</td>
</tr>
</tbody>
</table>

INQUIRE: PENDING Specifier

The PENDING specifier asks whether previously pending asynchronous data transfers are complete. A data transfer is previously pending if it is not complete at the beginning of execution of the INQUIRE statement. It takes the following form:

**PENDING = pnd**

<table>
<thead>
<tr>
<th>pnd</th>
<th>Is a scalar default logical variable that is assigned the value .TRUE. or .FALSE.</th>
</tr>
</thead>
</table>

The value is assigned as follows:

- If an ID specifier appears in the INQUIRE statement, the following occurs:
  - If the data transfer specified by ID is complete, then variable pnd is set to .FALSE. and INQUIRE performs the WAIT operation for the specified data transfer.
  - If the data transfer specified by ID is not complete, then variable pnd is set to .TRUE. and no WAIT operation is performed. The previously pending data transfer remains pending after the execution of the INQUIRE statement.
- If an ID specifier does not appear in the INQUIRE statement, the following occurs:
  - If all previously pending data transfers for the specified unit are complete, then variable pnd is set to .FALSE. and the INQUIRE statement performs WAIT operations for all previously pending data transfers for the specified unit.
  - If there are data transfers for the specified unit that are not complete, then variable pnd is set to .TRUE. and no WAIT operations are performed. The previously pending data transfers remain pending after the execution of the INQUIRE statement.
See Also
ID Specifier

Example in INQUIRE Statement

INQUIRE: POS Specifier
The POS specifier identifies the file position in file storage units in a stream file. It takes the following form:
POS = p

p

Is a scalar integer variable that is assigned the number of the file storage unit immediately following the current position of a file connected for stream access (ACCESS='STREAM').

If the file is positioned at its terminal position, p is assigned a value one greater than the number of the highest-numbered file storage unit in the file.

If the file is not connected for stream access or if the position of the file is indeterminate because of previous error conditions, p is assigned the value one.

If there are pending asynchronous data operations for the specified file, the value assigned to the POS= specifier is computed as if all pending data transfers have already completed.

INQUIRE: POSITION Specifier
The POSITION specifier asks the position of the file. It takes the following form:
POSITION = pos

pos

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'REWIND'</td>
<td>If the file is connected with its position at its initial point</td>
</tr>
<tr>
<td>'APPEND'</td>
<td>If the file is connected with its position at its terminal point (or before its end-of-file record, if any)</td>
</tr>
<tr>
<td>'ASIS'</td>
<td>If the file is connected without changing its position</td>
</tr>
<tr>
<td>'UNDEFINED'</td>
<td>If the file is not connected, or is connected for direct access data transfer and a REWIND statement has not been performed on the unit</td>
</tr>
</tbody>
</table>

INQUIRE: READ Specifier
The READ specifier asks whether a file can be read. It takes the following form:
READ = rd

rd

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file can be read</td>
</tr>
</tbody>
</table>
INQUIRE: READWRITE Specifier

The READWRITE specifier asks whether a file can be both read and written to. It takes the following form:

\[ \text{READWRITE} = \text{rdwr} \]

\text{rdwr}

Is a scalar default character variable that is assigned one of the following values:

- 'YES': If the file can be both read and written to
- 'NO': If the file cannot be both read and written to
- 'UNKNOWN': If the processor cannot determine whether the file can be both read and written to

INQUIRE: RECL Specifier

The RECL specifier asks the maximum record length for a file. It takes the following form:

\[ \text{RECL} = \text{rcl} \]

\text{rcl}

Is a scalar integer variable that is assigned a value as follows:

- If the file or unit is connected, the value assigned is the maximum record length allowed.
- If the file does not exist, or it is not connected, the value assigned is zero.
- Fortran 2018 standardizes the value assigned to be -1 when the file does not exist, or it is not connected. To get the Fortran 2018 behavior, specify compiler option `assume -noold_inquire_recl`.
- If the file is connected for stream access, the value is undefined. Fortran 2018 standardizes this value to be -2. To get the Fortran 2018 behavior, specify compiler option `assume -noold_inquire_recl`.

The assigned value is expressed in 4-byte units if the file is currently (or was previously) connected for unformatted data transfer and the `assume byterecl` compiler option is not in effect; otherwise, the value is expressed in bytes.

INQUIRE: RECORDTYPE Specifier

The RECORDTYPE specifier asks which type of records are in a file. It takes the following form:

\[ \text{RECORDTYPE} = \text{rtype} \]

\text{rtype}

Is a scalar default character variable that is assigned one of the following values:

- 'FIXED': If the file is connected for fixed-length records
<table>
<thead>
<tr>
<th>Specifiers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'VARIABLE'</td>
<td>If the file is connected for variable-length records</td>
</tr>
<tr>
<td>'SEGMENTED'</td>
<td>If the file is connected for unformatted sequential data transfer using segmented records</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>If the file's records are not terminated</td>
</tr>
<tr>
<td>'STREAM_CR'</td>
<td>If the file's records are terminated with a carriage return</td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td>If the file's records are terminated with a line feed</td>
</tr>
<tr>
<td>'STREAM_CRLF'</td>
<td>If the file's records are terminated with a carriage return/line feed pair</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the file is not connected</td>
</tr>
</tbody>
</table>

**INQUIRE: ROUND Specifier**

The ROUND specifier asks which rounding mode is in effect for a file connection. It takes the following form:

\[
\text{ROUND} = \text{rmode}
\]

*rmode* is a scalar default character expression that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Specifiers</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UP'</td>
<td>If the I/O rounding is set to the smallest representable value that is greater than or equal to the original value.</td>
</tr>
<tr>
<td>'DOWN'</td>
<td>If the I/O rounding is set to the largest representable value that is less than or equal to the original value.</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>If the I/O rounding is set to the value closest to the original value, but no greater in magnitude than the original value.</td>
</tr>
<tr>
<td>'COMPATIBLE'</td>
<td>If the I/O rounding is set to the closer of the two nearest representable values, or the value farther from zero if halfway between them.</td>
</tr>
</tbody>
</table>
'PROCESSOR_DEFINED' If the I/O rounding mode behaves differently than the UP, DOWN, ZERO, NEAREST, and COMPATIBLE modes.

'UNDEFINED' If there is no connection or if the connection is not for formatted I/O.

**INQUIRE: SEQUENTIAL Specifier**

The SEQUENTIAL specifier asks whether a file is connected for sequential access. It takes the following form:

```
SEQUENTIAL = seq
```

`seq` is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected for sequential access</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is not connected for sequential access</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file is connected for sequential access</td>
</tr>
</tbody>
</table>

**INQUIRE: SHARE Specifier**

The SHARE specifier asks the current share status of a file or unit. It takes the following form:

```
SHARE = shr
```

`shr` is a scalar default character variable.

On Windows* systems, this variable is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>If the file is connected for deny-read/write mode</td>

<tr>
<td>'UNKNOWN'</td>
<td>If the file or unit is not connected</td>
</tr>
</tbody>
</table>

On Linux* and macOS* systems, this variable is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>If the file is connected for exclusive access</td>
</tr>
</tbody>
</table>
INQUIRE: SIGN Specifier

The SIGN specifier asks what treatment for plus signs is in effect during a connection. It takes the following form:

\[
\text{SIGN} = sn
\]

\(sn\)

Is a scalar default character expression that is assigned one of the following values:

- `'PLUS'` If the file is connected with addition of plus signs in effect.
- `'SUPPRESS'` If the file is connected with suppression of plus signs in effect.
- `'PROCESSOR_DEFINED'` If the file is connected with plus signs added at the discretion of the processor.
- `'UNDEFINED'` If there is no connection, or if the connection is not for formatted input/output.

INQUIRE: SIZE Specifier

The SIZE specifier asks the size of a file in file storage units. It takes the following form:

\[
\text{SIZE} = sz
\]

\(sz\)

Is a scalar integer variable.

The \(sz\) variable is assigned the size of the file in file storage units. If the file size cannot be determined, the variable is assigned the value -1.

For a file that is connected for stream access, the file size is the number of the highest-numbered file storage unit in the file.

For a file that is connected for sequential or direct access, the file size may be different from the number of storage units implied by the data in the records; the exact relationship is processor-dependent.

If there are pending asynchronous data transfer operations for the specified file, the value assigned to the SIZE= specifier is computed as if the pending data transfers have already completed.

INQUIRE: UNFORMATTED Specifier

The UNFORMATTED specifier asks whether a file is connected for unformatted data transfer. It takes the following form:

\[
\text{UNFORMATTED} = unf
\]
**unf**

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file is connected for unformatted data transfer</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file is not connected for unformatted data transfer</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file is connected for unformatted data transfer</td>
</tr>
</tbody>
</table>

**INQUIRE: WRITE Specifier**

The WRITE specifier asks whether a file can be written to. It takes the following form:

\[
\text{WRITE} = \text{wr}
\]

**wr**

Is a scalar default character variable that is assigned one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>If the file can be written to</td>
</tr>
<tr>
<td>'NO'</td>
<td>If the file cannot be written to</td>
</tr>
<tr>
<td>'UNKNOWN'</td>
<td>If the processor cannot determine whether the file can be written to</td>
</tr>
</tbody>
</table>

**OPEN Statement Specifiers**

The OPEN statement connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection. For more information, see OPEN.

The following table summarizes the OPEN statement specifiers and contains links to their descriptions:

</tbody>
</table>

1 The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.
2 If you use the compiler option specifying OpenVMS defaults, and the unit is connected to a terminal, the default is 'FORTRAN'.
3 n is the unit number.
4 If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..
5 On Linux* and macOS* systems, the default depends only on the FORM setting.
6 W*S
7 The default differs under certain conditions (see SHARE Specifier).
8 The default differs under certain conditions (see STATUS Specifier).

**Key to Values**

- c_expr: A scalar default character expression
- func: An external function
- label: A statement label
- n_expr: A scalar numeric expression
- var: A scalar integer variable

**See Also**

**INQUIRE Statement** for details on using the INQUIRE statement to get file attributes of existing files
OPEN: ACCESS Specifier

The ACCESS specifier indicates the access method for the connection of the file. It takes the following form:

```
ACCESS = acc
```

Is a scalar default character expression that evaluates to one of the following values:

- `'DIRECT'` Indicates direct access.
- `'SEQUENTIAL'` Indicates sequential access.
- `'STREAM'` Indicates stream access, where the file storage units of the file are accessible sequentially or by position.
- `'APPEND'` Indicates sequential access, but the file is positioned at the end-of-file record.

The default is 'SEQUENTIAL'.

There are limitations on record access by file organization and record type.

OPEN: ACTION Specifier

The ACTION specifier indicates the allowed I/O operations for the file connection. It takes the following form:

```
ACTION = act
```

Is a scalar default character expression that evaluates to one of the following values:

- `'READ'` Indicates that only READ statements can refer to this connection.
- `'WRITE'` Indicates that only WRITE, DELETE, and ENDFILE statements can refer to this connection.
- `'READWRITE'` Indicates that READ, WRITE, DELETE, and ENDFILE statements can refer to this connection.

The default is 'READWRITE'.

However, if compiler option fpscomp general is specified on the command line and `action` is omitted, the system first attempts to open the file with 'READWRITE'. If this fails, the system tries to open the file again, first using 'READ', then using 'WRITE'.

Note that in this case, omitting `action` is not the same as specifying ACTION='READWRITE'. If you specify ACTION='READWRITE' and the file cannot be opened for both read and write access, the attempt to open the file fails. You can use the INQUIRE statement to determine the actual access mode selected.

See Also

fpscomp compiler option
OPEN: ASSOCIATEVARIABLE Specifier

The ASSOCIATEVARIABLE specifier indicates a variable that is updated after each direct access I/O operation, to reflect the record number of the next sequential record in the file. It takes the following form:

ASSOCIATEVARIABLE = asv

asv

Is a scalar integer variable. It cannot be a dummy argument to the routine in which the OPEN statement appears.

Direct access READs, direct access WRITEs, and the FIND, DELETE, and REWRITE statements can affect the value of asv.

This specifier is valid only for direct access; it is ignored for other access modes.

OPEN: ASYNCHRONOUS Specifier

The ASYNCHRONOUS specifier indicates whether asynchronous I/O is allowed for a unit. It takes the following form:

ASYNCHRONOUS = asyn

asyn

Is a scalar expression of type default character that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'YES'</td>
<td>Indicates that asynchronous I/O is allowed for a unit.</td>
</tr>
<tr>
<td>'NO'</td>
<td>Indicates that asynchronous I/O is not allowed for a unit.</td>
</tr>
</tbody>
</table>

The default is 'NO'.

OPEN: BLANK Specifier

The BLANK specifier indicates how blanks are interpreted in a file. It takes the following form:

BLANK = blnk

blnk

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NULL'</td>
<td>Indicates all blanks are ignored, except for an all-blank field (which has a value of zero).</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>Indicates all blanks (other than leading blanks) are treated as zeros.</td>
</tr>
</tbody>
</table>

The default is 'NULL' (for explicitly OPENed files, preconnected files, and internal files). If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'ZERO'.

If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks.

This specifier is not allowed on unformatted input or output.

See Also
Blank Editing for details on the BN and BZ edit descriptors
f66
OPEN: BLOCKSIZE Specifier

The BLOCKSIZE specifier indicates the physical I/O transfer size in bytes for the file. It takes the following form:

\[
\text{BLOCKSIZE} = bks
\]

\(bks\) is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

If you specify a nonzero number for \(bks\), it is rounded up to a multiple of 512 byte blocks. The maximum valid value of BLOCKSIZE is 2,147,467,264.

If you do not specify BLOCKSIZE or you specify zero for \(bks\), the default value of 128 KB (131,072 bytes) is assumed. However, if you compile with the \texttt{assume buffered_stdout} option, the default blocksize for \texttt{stdout} is 8 KB.

The default BLOCKSIZE value can be changed by using the \texttt{FORT\_BLOCKSIZE} environment variable or by specifying the BLOCKSIZE parameter on the unit's OPEN. The BLOCKSIZE value can be changed for \texttt{stdout} by re-opening the unit corresponding to stdout with an explicit BLOCKSIZE parameter; for example:

```
OPEN(6, ACCESS='SEQUENTIAL', FORM='FORMATTED', BUFFERED='YES', BLOCKSIZE=1048576)
```

OPEN: BUFFERCOUNT Specifier

The BUFFERCOUNT specifier indicates the number of buffers to be associated with the unit for multibuffered I/O. It takes the following form:

\[
\text{BUFFERCOUNT} = bc
\]

\(bc\) is a scalar numeric expression in the range 1 through 127. If necessary, the value is converted to integer data type before use.

The BLOCKSIZE specifier determines the size of each buffer. For example, if BUFFERCOUNT=3 and BLOCKSIZE=2048, the total number of bytes allocated for buffers is 3*2048, or 6144 bytes.

If you do not specify BUFFERCOUNT or you specify zero for \(bc\), the default is 1.

See Also

BLOCKSIZE specifier

OPEN: BUFFERED Specifier

The BUFFERED specifier indicates run-time library behavior for READ and WRITE operations. Buffering of input records only applies to variable length, unformatted records. This specifier takes the following form:

\[
\text{BUFFERED} = bf
\]

\(bf\) is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'NO'</td>
<td>For WRITE operations: Requests that the run-time library send output data to the file system after each operation. For READ operations on variable length, unformatted files: Requests that the run-time library transfer input data directly from disk to user variables for each operation.</td>
</tr>
</tbody>
</table>
'YES' Requests that the run-time library accumulate data in its internal buffer, possibly across several READ or WRITE operations, before the data is transferred to, or from, the file system.

Buffering may improve run-time performance for output-intensive applications.

The default is 'NO' for buffering output. The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.

If BUFFERED='YES' is specified, the request may or may not be honored, depending on the device and other file or connection characteristics.

For direct access, you should specify BUFFERED='YES', although using direct-access I/O to a network file system may be much slower.

If both BLOCKSIZE and BUFFERCOUNT for OPEN have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. Otherwise, the default size of the internal buffer is 8 KB (8192 bytes).

**NOTE**
On Windows systems, the default size of the internal buffer is 1024 bytes if compiler option fpscomp general is used.

The internal buffer will grow to hold the largest single record but will never shrink.

**See Also**
Rules for Unformatted Sequential READ Statements

**OPEN: CARRIAGECONTROL Specifier**
The CARRIAGECONTROL specifier indicates the type of carriage control used when a file is displayed at a terminal. It takes the following form:

CARRIAGECONTROL = \[ \text{cc} \]

\[ \text{cc} \]

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FORTRAN'</td>
<td>Indicates normal Fortran interpretation of the first character.</td>
</tr>
<tr>
<td>'LIST'</td>
<td>Indicates one line feed between records.</td>
</tr>
<tr>
<td>'NONE'</td>
<td>Indicates no carriage control processing.</td>
</tr>
</tbody>
</table>

The default for binary (W*S) and unformatted files is 'NONE'. The default for formatted files is 'LIST'. However, if you specify compiler option vms or fpscomp general, and the unit is connected to a terminal, the default is 'FORTRAN'.

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file was processed by the *fortpr* format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but is used to control vertical spacing.
See Also
Printing of Formatted Records  for details on valid control characters for printing
vms  compiler option
fpscomp  compiler option

OPEN: CONVERT Specifier

The CONVERT specifier indicates a nonnative numeric format for unformatted data. It takes the following form:

CONVERT = *fm*

*fm* is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Specifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'LITTLE_ENDIAN'*1</td>
<td>Little endian integer data 2 and IEEE* floating-point data. 3</td>
</tr>
<tr>
<td>'BIG_ENDIAN'*1</td>
<td>Big endian integer data 2 and IEEE floating-point data. 3</td>
</tr>
<tr>
<td>'CRAY'</td>
<td>Big endian integer data 2 and CRAY* floating-point data of size REAL(8) or COMPLEX(8).</td>
</tr>
<tr>
<td>'FDX'</td>
<td>Little endian integer data 2 and VAX* processor floating-point data of format F_floating for REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'FGX'</td>
<td>Little endian integer data 2 and VAX processor floating-point data of format F_floating for REAL(4) or COMPLEX(4), G_floating for size REAL(8) or COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'IBM'</td>
<td>Big endian integer data 2 and IBM* System\370 floating-point data of size REAL(4) or COMPLEX(4) (IBM short 4), and size REAL(8) or COMPLEX(8) (IBM long 8).</td>
</tr>
<tr>
<td>'VAXD'</td>
<td>Little endian integer data 2 and VAX processor floating-point data of format F_floating for size REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and H_floating for REAL(16) or COMPLEX(16).</td>
</tr>
<tr>
<td>'VAXG'</td>
<td>Little endian integer data 2 and VAX processor floating-point data of format F_floating for size</td>
</tr>
</tbody>
</table>
REAL(4) or COMPLEX(4),
G_floating for size REAL(8) or
COMPLEX(8), and H_floating for
REAL(16) or COMPLEX(16).

'NATIVE'
No data conversion. This is the
default.

1 INTEGER(1) data is the same for little endian and big endian.
2 Of the appropriate size: INTEGER(1), INTEGER(2), INTEGER(4), or
   INTEGER(8)
3 Of the appropriate size and type: REAL(4), REAL(8), REAL(16),
   COMPLEX(4), COMPLEX(8), or COMPLEX(16)

You can use CONVERT to specify multiple formats in a single program, usually one format for each specified
unit number.

When reading a nonnative format, the nonnative format on disk is converted to native format in memory. If a
converted nonnative value is outside the range of the native data type, a run-time message appears.

There are other ways to specify numeric format for unformatted files: you can specify an environment
variable, compiler option convert, or OPTIONS/CONVERT. The following shows the order of precedence:

<table>
<thead>
<tr>
<th>Method Used</th>
<th>Precedence</th>
</tr>
</thead>
<tbody>
<tr>
<td>An environment variable</td>
<td>Highest</td>
</tr>
<tr>
<td>OPEN (CONVERT=)</td>
<td></td>
</tr>
<tr>
<td>OPTIONS/CONVERT</td>
<td></td>
</tr>
<tr>
<td>The convert compiler option</td>
<td>Lowest</td>
</tr>
</tbody>
</table>

Compiler option convert and OPTIONS/CONVERT affect all unit numbers used by the program, while
environment variables and OPEN (CONVERT=) affect specific unit numbers.

The following example shows how to code the OPEN statement to read unformatted CRAY* numeric data
from unit 15, which might be processed and possibly written in native little endian format to unit 20:

OPEN (CONVERT='CRAY', FILE='graph3.dat', FORM='UNFORMATTED',
1      UNIT=15)
...
OPEN (FILE='graph3_native.dat', FORM='UNFORMATTED', UNIT=20)

See Also
Data Types, Constants, and Variables for details on supported ranges for data types
convert compiler option

OPEN: DECIMAL Specifier

The DECIMAL specifier controls the representation of the decimal symbol for a connection. It takes the
following form:

DECIMAL = dmode

Is a scalar default character expression that evaluates to one of the following values:

| 'COMMA' | Indicates that a decimal comma should be used for decimal editing mode. |

Intel® Fortran Compiler Classic and Intel® Fortran Compiler Developer Guide and Reference
The default decimal editing mode is 'POINT'.

You can only use this specifier for a formatted I/O connection.

When the mode is DECIMAL='POINT', the decimal point in a numeric input or output value is a period, values are separated by commas in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a comma.

When the mode is DECIMAL='COMMA', the decimal point in a numeric input or output value is a comma, values are separated by semicolons in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a semicolon.

The decimal editing mode can be temporarily changed within a READ or WRITE statement by the DECIMAL= specifier or by the corresponding DC and DP edit descriptors.

This specifier is not allowed on unformatted input or output.

**OPEN: DEFAULTFILE Specifier**

The DEFAULTFILE specifier indicates a default file pathname string. It takes the following form:

```
DEFAULTFILE = def
```

*def* is a character expression indicating a default file pathname string. The default file pathname string is used primarily when accepting file pathnames interactively. File pathnames known to a user program normally appear in the FILE specifier.

DEFAULTFILE supplies a value to the Fortran I/O system that is prefixed to the name that appears in FILE. If *def* does not end in a slash (/), a slash is added. If DEFAULTFILE is omitted, the Fortran I/O system uses the current working directory.

**OPEN: DELIM Specifier**

The DELIM specifier indicates what characters (if any) are used to delimit character constants in list-directed and namelist output. It takes the following form:

```
DELIM = del
```

*del* is a scalar default character expression that evaluates to one of the following values:

- **'APOSTROPHE'**
  - Indicates apostrophes delimit character constants. All internal apostrophes are doubled.

- **'QUOTE'**
  - Indicates quotation marks delimit character constants. All internal quotation marks are doubled.

- **'NONE'**
  - Indicates character constants have no delimiters. No internal apostrophes or quotation marks are doubled.

The default is 'NONE'.

---

1075
The DELIM specifier is only allowed for files connected for formatted data transfer; it is ignored during input. This specifier is not allowed on unformatted input or output.

**OPEN: DISPOSE Specifier**

The DISPOSE (or DISP) specifier indicates the status of the file after the unit is closed. It takes one of the following forms:

DISPOSE = dis
DISP = dis

dis

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'KEEP' or 'SAVE'</td>
<td>Retains the file after the unit closes.</td>
</tr>
<tr>
<td>'DELETE'</td>
<td>Deletes the file after the unit closes.</td>
</tr>
<tr>
<td>'PRINT'</td>
<td>Submits the file to the line printer spooler and retains it.</td>
</tr>
<tr>
<td>'PRINT/DELETE'</td>
<td>Submits the file to the line printer spooler and then deletes it.</td>
</tr>
<tr>
<td>'SUBMIT'</td>
<td>Forks a process to execute the file.</td>
</tr>
<tr>
<td>'SUBMIT/DELETE'</td>
<td>Forks a process to execute the file, and then deletes the file after the fork is completed.</td>
</tr>
</tbody>
</table>

The default is 'DELETE' for scratch files. For all other files, the default is 'KEEP'.

On Windows*, PRINT and the PRINT part of PRINT/DELETE do not use the system PRINT command. One of the following occurs:

- If you set the environment variable FOR_DEFAULT_PRINT_DEVICE to a print device, the Fortran run-time will copy the file to that device.
- Otherwise, the Fortran run-time will copy the file to a new file named "PRN-FILE". In this case, you will need to do the actual printing

**OPEN: ENCODING Specifier**

The ENCODING specifier indicates the encoding form for a file. It takes the following form:

ENCODING = enc

enc

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UTF-8'</td>
<td>Indicates that the encoding form of the file is UTF-8 (a unicode file). All characters therein are of ISO 10646 character type, as specified by ISO/IEC 10646-1:2000.</td>
</tr>
</tbody>
</table>
This value must not be specified if the processor does not support the ISO 10646 character type.

'DEFAULT'

Indicates that the encoding form of the file is determined by the processor.

The default is 'DEFAULT'.

You can only use this specifier for a formatted I/O connection.

**OPEN: FILE Specifier**

The FILE specifier indicates the name of the file to be connected to the unit. It takes the following form:

```
FILE = name
```

*name* is a character or numeric expression.

The *name* can be any pathname allowed by the operating system.

Any trailing blanks in the name are ignored.

If the following conditions occur:

- FILE is omitted
- The unit is not connected to a file
- STATUS='SCRATCH' is not specified
- The corresponding FORTn environment variable is not set for the unit number

then Intel® Fortran generates a file name in the form fort.*n*, where *n* is the logical unit number. On Windows systems, if compiler option fpscomp general is specified, omitting FILE implies STATUS='SCRATCH'.

If the file name is stored in a numeric scalar or array, the name must consist of ASCII characters terminated by an ASCII null character (zero byte). However, if it is stored in a character scalar or array, it must not contain a zero byte.

On Windows systems, if the filename is 'USER' or 'CON', input and output are directed to the console.

In a Windows® QuickWin application, you can specify FILE='USER' to open a child window. All subsequent I/O statements directed to that unit appear in the child window.

On Windows systems, the *name* can be blank (FILE=' ') if the compatibility compiler option fpscomp filesfromcmd is specified. If the *name* is blank, the following occurs:

1. The program reads a filename from the list of arguments (if any) in the command line that started the program. If the argument is a null or blank string (" "), you are prompted for the corresponding filename. Each successive OPEN statement that specifies a blank name reads the next following command-line argument.
2. If no command-line arguments are specified or there are no more arguments in the list, you are prompted for additional filenames.

Assume the following command line started the program MYPROG (note that quotation marks (" ) are used):

```
myprog first.fil " " third.txt
```

MYPROG contains four OPEN statements with blank filenames, in the following order:

```
OPEN (2, FILE = ' ')
OPEN (4, FILE = ' ')
OPEN (5, FILE = ' ')
OPEN (10, FILE = ' ')
```
Unit 2 is associated with the file FIRST.FIL. Because a blank argument was specified on the command line for the second filename, the OPEN statement for unit 4 produces the following prompt:

Filename missing or blank - Please enter name UNIT 4?

Unit 5 is associated with the file THIRD.TXT. Because no fourth file was specified on the command line, the OPEN statement for unit 10 produces the following prompt:

Filename missing or blank - Please enter name UNIT 10?

See Also
fpscomp compiler option

OPEN: FORM Specifier

The FORM specifier indicates whether the file is being connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

\[ \text{FORM} = fm \]

\( fm \) is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>fm</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FORMATTED'</td>
<td>Indicates formatted data transfer</td>
</tr>
<tr>
<td>'UNFORMATTED'</td>
<td>Indicates unformatted data transfer</td>
</tr>
<tr>
<td>'BINARY'</td>
<td>Indicates binary data transfer</td>
</tr>
</tbody>
</table>

The default is 'FORMATTED' for sequential access files, and 'UNFORMATTED' for direct access files.

The data is stored and retrieved in a file according to the file's access (set by the ACCESS specifier) and the form of the data the file contains.

A formatted file is a sequence of formatted records. Formatted records are a series of ASCII characters terminated by an end-of-record mark (a carriage return and line feed sequence). The records in a formatted direct-access file must all be the same length. The records in a formatted sequential file can have varying lengths. All internal files must be formatted.

An unformatted file is a sequence of unformatted records. An unformatted record is a sequence of values. Unformatted direct files contain only this data, and each record is padded to a fixed length with undefined bytes. Unformatted sequential files contain the data plus information that indicates the boundaries of each record.

Binary sequential files are sequences of bytes with no internal structure. There are no records. The file contains only the information specified as I/O list items in WRITE statements referring to the file.

Binary direct files have very little structure. A record length is assigned by the RECL specifier in an OPEN statement. This establishes record boundaries, which are used only for repositioning and padding before and after read and write operations and during BACKSPACE operations. Record boundaries do not restrict the number of bytes that can be transferred during a read or write operation. If an I/O operation attempts to read or write more values than are contained in a record, the read or write operation is continued on the next record.

Fortran standard stream access provides similar functionality to FORM='BINARY'. This is specified using ACCESS='STREAM'.

See Also
Record Access
**OPEN: IOFOCUS Specifier (W*S)**

The IOFOCUS specifier indicates whether a particular unit is the active window in a QuickWin application. It takes the following form:

\[ \text{IOFOCUS} = \text{iof} \]

\[ \text{iof} \]

Is a scalar default logical expression that evaluates to one of the following values:

- **.TRUE.**  
  Indicates the QuickWin child window is the active window
- **.FALSE.**  
  Indicates the QuickWin child window is not the active window

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window. OUTTEXT, OUTGTEXT, or any other graphics routine call does not cause the focus to shift.

**OPEN: MAXREC Specifier**

The MAXREC specifier indicates the maximum number of records that can be transferred from or to a direct access file while the file is connected. It takes the following form:

\[ \text{MAXREC} = \text{mr} \]

\[ \text{mr} \]

Is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

The default is an unlimited number of records.

**OPEN: MODE Specifier**

MODE is a nonstandard synonym for ACTION.

**OPEN: NAME Specifier**

NAME is a nonstandard synonym for FILE.

**OPEN: NEWUNIT Specifier**

The NEWUNIT specifier opens a file on an unused unit number that is automatically chosen. It also returns the unit number that was chosen. It takes the following form:

\[ \text{NEWUNIT} = \text{u-var} \]

\[ \text{u-var} \]

Is a scalar integer variable that is assigned the automatically chosen unit number. It is always a negative integer.

If the OPEN is successful, \text{u-var} can be used in subsequent I/O statements to access the connected file.

If an error occurs during execution of the OPEN statement containing the NEWUNIT= specifier, the processor does not change the value of the variable.

**OPEN: NOSHARED Specifier**

The NOSHARED specifier indicates that the file is connected for exclusive access by the program. It takes the following form:
OPEN: ORGANIZATION Specifier

The ORGANIZATION specifier indicates the internal organization of the file. It takes the following form:

\( \text{ORGANIZATION} = \text{org} \)

- \( \text{org} \) is a scalar default character expression that evaluates to one of the following values:
  - 'SEQUENTIAL' indicates a sequential file.
  - 'RELATIVE' indicates a relative file.

The default is 'SEQUENTIAL'.

OPEN: PAD Specifier

The PAD specifier indicates whether a formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.

The PAD specifier takes the following form:

\( \text{PAD} = \text{pd} \)

- \( \text{pd} \) is a scalar default character expression that evaluates to one of the following values:
  - 'YES' indicates the record will be padded with blanks when necessary.
  - 'NO' indicates the record will not be padded with blanks. The input record must contain the data required by the input list and format specification.

The default is 'YES'.

This behavior is different from FORTRAN 77, which never pads short records with blanks and doesn't support the PAD= qualifier. For example, consider the following:

\[
\text{READ (5,'(I5)')} J
\]

If you enter 123 followed by a carriage return, FORTRAN 77 will issue the ENDRECDUR error message. However, Intel® Fortran pads the 123 with 2 blanks unless you explicitly open the unit with PAD='NO'. You can override blank padding by explicitly specifying the BN edit descriptor. The PAD specifier is ignored during output. This specifier is not allowed on unformatted input or output.

OPEN: POSITION Specifier

The POSITION specifier indicates the position of a file connected for sequential access. It takes the following form:

\( \text{POSITION} = \text{pos} \)

- \( \text{pos} \) is a scalar default character expression that evaluates to one of the following values:
'ASIS' Indicates the file position is unchanged if the file exists and is already connected. The position is unspecified if the file exists but is not connected.

'REWIND' Indicates the file is positioned at its initial point.

'APPEND' Indicates the file is positioned at its terminal point (or before its end-of-file record, if any).

The default is 'ASIS'.

A new file (whether specified as new explicitly or by default) is always positioned at its initial point.

In addition to the POSITION specifier, you can use position statements. The BACKSPACE statement positions a file back one record. The REWIND statement positions a file at its initial point. The ENDFILE statement writes an end-of-file record at the current position and positions the file after it. Note that ENDFILE does not go the end of an existing file, but creates an end-of-file where it is.

**OPEN: READONLY Specifier**

The READONLY specifier indicates only READ statements can refer to this connection. It takes the following form:

READONLY

READONLY is similar to specifying ACTION='READ', but READONLY prevents deletion of the file if it is closed with STATUS='DELETE' in effect.

The Fortran I/O system's default privileges for file access are READWRITE. If access is denied, the I/O system automatically retries accessing the file for READ access.

However, if you use compiler option vms, the I/O system does not retry accessing for READ access. So, run-time I/O errors can occur if the file protection does not permit WRITE access. To prevent such errors, if you wish to read a file for which you do not have write access, specify READONLY.

**OPEN: RECL Specifier**

The RECL specifier indicates the length of each record in a file connected for direct access, or the maximum length of a record in a file connected for sequential access.

The RECL specifier takes the following form:

RECL = rl

\( rl \) is a positive numeric expression indicating the length of records in the file. If necessary, the value is converted to integer data type before use.

If the file is connected for formatted data transfer, the value must be expressed in bytes (characters). Otherwise, the value is expressed in 4-byte units (longwords). If the file is connected for unformatted data transfer, the value can be expressed in bytes if compiler option assume byterecl is specified.

Except for segmented records, the \( rl \) is the length for record data only, it does not include space for control information. If \( rl \) is too large, you can exhaust your program's virtual memory resources trying to create room for the record.

The length specified is interpreted depending on the type of records in the connected file, as follows:

- For segmented records, RECL indicates the maximum length for any segment (including the four bytes of control information).
• For fixed-length records, RECL indicates the size of each record; it must be specified. If the records are unformatted, the size must be expressed as an even multiple of four.

You can use the RECL specifier in an INQUIRE statement to get the record length before opening the file.

• For variable-length records, RECL indicates the maximum length for any record.

If you read a fixed-length file with a record length different from the one used to create the file, indeterminate results can occur.

The maximum length for r1 depends on the record type and the setting of the CARRIAGECONTROL specifier, as shown in the following table:

### Maximum Record Lengths (RECL)

<table>
<thead>
<tr>
<th>Record Type</th>
<th>CARRIAGECONTROL</th>
<th>Formatted (size in bytes)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-length</td>
<td>'NONE'</td>
<td>Unlimited</td>
</tr>
<tr>
<td>Variable-length</td>
<td>'NONE'</td>
<td>2147483640 (2**31-8)</td>
</tr>
<tr>
<td>Segmented</td>
<td>'NONE'</td>
<td>32764 (2**15-4)</td>
</tr>
<tr>
<td>Stream</td>
<td>'NONE'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td>Stream_CR</td>
<td>'LIST'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td></td>
<td>'FORTRAN'</td>
<td>2147483646 (2**31-2)</td>
</tr>
<tr>
<td>Stream_LF</td>
<td>'LIST'</td>
<td>2147483647 (2**31-1)</td>
</tr>
<tr>
<td></td>
<td>'FORTRAN'</td>
<td>2147483646 (2**31-2)</td>
</tr>
</tbody>
</table>

1 L*X only

The default value depends on the setting of the RECORDTYPE specifier, as shown in the following table:

### Default Record Lengths (RECL)

<table>
<thead>
<tr>
<th>RECORDTYPE</th>
<th>RECL value</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>None; value must be explicitly specified.</td>
</tr>
<tr>
<td>All other settings</td>
<td>132 bytes for formatted records; 510 longwords for unformatted records.</td>
</tr>
</tbody>
</table>

1To change the default record length values, you can use environment variable FORT_FMT_RECL or FORT_UFMT_RECL.

For formatted records with other than RECORDTYPE='FIXED', the default RECL is 132.

There is a property of list-directed sequential WRITE statements called the right margin. If you do not specify RECL as an OPEN statement specifier or in environmental variable FORT_FMT_RECL, the right margin value defaults to 80. When RECL is specified, the right margin is set to the value of RECL. If the length of a list-directed sequential WRITE exceeds the value of the right margin value, the remaining characters will wrap to the next line. Therefore, writing 100 characters will produce two lines of output, and writing 180 characters will produce three lines of output. You can turn off the right margin using the wrap-margin compiler option or the FORT_FMT_NO_WRAP_MARGIN environment variable.

vms compiler option  
Record Transfer

**OPEN: RECORDSIZE Specifier**

RECORDSIZE is a nonstandard synonym for RECL.
OPEN: RECORDTYPE Specifier

The RECORDTYPE specifier indicates the type of records in a file. It takes the following form:

```
RECORDTYPE = typ
```

typ

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>Indicates fixed-length records.</td>
</tr>
<tr>
<td>'VARIABLE'</td>
<td>Indicates variable-length records.</td>
</tr>
<tr>
<td>'SEGMENTED'</td>
<td>Indicates segmented records.</td>
</tr>
<tr>
<td>'STREAM'</td>
<td>Indicates stream-type variable length data with no record terminators.</td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td>Indicates stream-type variable length records, terminated with a line feed.</td>
</tr>
<tr>
<td>'STREAM_CR'</td>
<td>Indicates stream-type variable length records, terminated with a carriage return.</td>
</tr>
<tr>
<td>'STREAM_CRLF'</td>
<td>Indicates stream-type variable length records, terminated with a carriage return/line feed pair.</td>
</tr>
</tbody>
</table>

When you open a file, default record types are as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'FIXED'</td>
<td>For relative files</td>
</tr>
<tr>
<td>'FIXED'</td>
<td>For direct access sequential files</td>
</tr>
<tr>
<td>'STREAM_LF'</td>
<td>For formatted sequential access files on Linux* and macOS* systems</td>
</tr>
<tr>
<td>'STREAM_CRLF'</td>
<td>For formatted sequential access files on Windows systems</td>
</tr>
<tr>
<td>'VARIABLE'</td>
<td>For unformatted sequential access files</td>
</tr>
</tbody>
</table>

A segmented record is a logical record consisting of segments that are physical records. Since the length of a segmented record can be greater than 65,535 bytes, only use segmented records for unformatted sequential access to disk or raw magnetic tape files.

Files containing segmented records can be accessed only by unformatted sequential data transfer statements.

If an output statement does not specify a full record for a file containing fixed-length records, the following occurs:

- In formatted files, the record is filled with blanks
- In unformatted files, the record is filled with zeros

OPEN: ROUND Specifier

The ROUND specifier indicates the I/O rounding mode for the duration of a connection. It takes the following form:
ROUND = rmode

rmode is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'UP'</td>
<td>The smallest representable value that is greater than or equal to the original value.</td>
</tr>
<tr>
<td>'DOWN'</td>
<td>The largest representable value that is less than or equal to the original value.</td>
</tr>
<tr>
<td>'ZERO'</td>
<td>The value closest to the original value, but no greater in magnitude than the original value.</td>
</tr>
<tr>
<td>'COMPATIBLE'</td>
<td>The closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero.</td>
</tr>
<tr>
<td>'PROCESSOR_DEFINED'</td>
<td>The value is determined by the default settings in the processor, which may correspond to one of the other modes.</td>
</tr>
</tbody>
</table>

The default I/O rounding mode is 'PROCESSOR_DEFINED'. For ifort, this corresponds to 'NEAREST'.

You can only use this specifier for a formatted I/O connection.

The rounding mode can be temporarily changed within a READ or WRITE statement by the corresponding RU, RD, RZ, RN, RC, and RP edit descriptors.

This specifier is not allowed on unformatted input or output.

OPEN: SHARE Specifier

The SHARE specifier indicates whether file locking is implemented while the unit is open. It takes the following form:

SHARE = shr

shr is a scalar default character expression.

On Windows* systems, this expression evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'DENYRW'</td>
<td>Indicates deny-read/write mode. No other process can open the file.</td>
</tr>
</tbody>
</table>
'DENYWR' Indicates deny-write mode. No process can open the file with write access.

'DENYRD' Indicates deny-read mode. No process can open the file with read access.

'DENYNONE' Indicates deny-none mode. Any process can open the file in any mode.

On Linux* and macOS* systems, this expression evaluates to one of the following values:

'DENYRW' Indicates exclusive access for cooperating processes.

'DENYNONE' Indicates shared access for cooperating processes.

On Windows systems, the default is 'DENYWR'. However, if you specify compiler option fpscomp general or the SHARED specifier, the default is 'DENYNONE'.

On Linux and macOS* systems, no restrictions are applied to file opening if you do not use a locking mechanism.

'COMPAT' is accepted for compatibility with previous versions. It is equivalent to 'DENYNONE'.

Use the ACCESS specifier in an INQUIRE statement to determine the access permission for a file.

Be careful not to permit other users to perform operations that might cause problems. For example, if you open a file intending only to read from it, and want no other user to write to it while you have it open, you could open it with ACTION='READ' and SHARE='DENYRW'. Other users would not be able to open it with ACTION='WRITE' and change the file.

Suppose you want several users to read a file, and you want to make sure no user updates the file while anyone is reading it. First, determine what type of access to the file you want to allow the original user. Because you want the initial user to read the file only, that user should open the file with ACTION='READ'. Next, determine what type of access the initial user should allow other users; in this case, other users should be able only to read the file. The first user should open the file with SHARE='DENYWR'. Other users can also open the same file with ACTION='READ' and SHARE='DENYWR'.

See Also
fpscomp compiler option

OPEN: SHARED Specifier

The SHARED specifier indicates that the file is connected for shared access by more than one program executing simultaneously. It takes the following form:

SHARED

On Linux* and macOS* systems, shared access is the default for the Fortran I/O system. On Windows* systems, it is the default if SHARED or compiler option fpscomp general is specified.

See Also
fpscomp compiler option

OPEN: SIGN Specifier

The SIGN specifier controls the optional plus characters in formatted numeric output created during the connection. It takes the following form:
SIGN = \texttt{sn}

\texttt{sn}

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'PLUS'</td>
<td>Indicates that the processor should produce a plus sign in any subsequent position where it would be otherwise optional. This has the same effect as the SP edit descriptor.</td>
</tr>
<tr>
<td>'SUPPRESS'</td>
<td>Indicates that the processor should suppress a plus sign in any subsequent position where it would be otherwise optional. This has the same effect as the SS edit descriptor.</td>
</tr>
<tr>
<td>'PROCESSOR_DEFINED'</td>
<td>Indicates that the processor determines whether a plus sign is added in any subsequent position where it would be otherwise optional. This has the same effect as the S edit descriptor.</td>
</tr>
</tbody>
</table>

The default is 'PROCESSOR_DEFINED'.

The setting can be overwritten by a SIGN= specifier in a WRITE statement.

This specifier is not allowed on unformatted input or output.

**OPEN: STATUS Specifier**

The STATUS specifier indicates the status of a file when it is opened. It takes the following form:

\texttt{STATUS = sta}

\texttt{sta}

Is a scalar default character expression that evaluates to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'OLD'</td>
<td>Indicates an existing file.</td>
</tr>
<tr>
<td>'NEW'</td>
<td>Indicates a new file; if the file already exists, an error occurs. Once the file is created, its status changes to 'OLD'.</td>
</tr>
<tr>
<td>'SCRATCH'</td>
<td>Indicates a new file that is unnamed (called a scratch file). When the file is closed or the program terminates, the scratch file is deleted.</td>
</tr>
<tr>
<td>'REPLACE'</td>
<td>Indicates the file replaces another. If the file to be replaced exists, it is deleted and a new file is created with the same name. If the file to be replaced</td>
</tr>
</tbody>
</table>
Scratch files go into a temporary directory and are visible while they are open. Scratch files are deleted when
the unit is closed or when the program terminates normally, whichever occurs first.

To specify the path for scratch files, you can use one of the following environment variables:

- On Windows*: FORT_TMPDIR, TMP, or TEMP, searched in that order
- On Linux* and macOS*: FORT_TMPDIR or TMPDIR, searched in that order

If no environment variable is defined, the default is the current directory.

The default is 'UNKNOWN'. This is also the default if you implicitly open a file by using WRITE. However, if
you implicitly open a file using READ, the default is 'OLD'. If you specify compiler option f66 (or OPTIONS/
NOF77), the default is 'NEW'.

### NOTE
The STATUS specifier can also appear in CLOSE statements to indicate the file's status after it is
closed. However, in CLOSE statements the STATUS values are the same as those listed for the
DISPOSE specifier.

### See Also
f66 compiler option

### OPEN: TITLE Specifier (W*S)

The TITLE specifier indicates the name of a child window in a QuickWin application. It takes the following
form:

```
TITLE = name
```

*name* Is a character expression.

If TITLE is specified in a non-Quickwin application, a run-time error occurs.

### OPEN: TYPE Specifier

TYPE is a nonstandard synonym for STATUS.

### OPEN: USEROPEN Specifier

The USEROPEN specifier lets you pass control to a routine that directly opens a file. The file can use system
calls or library routines to establish a special context that changes the effect of subsequent Fortran I/O
statements.

The USEROPEN specifier takes the following form:

```
USEROPEN = function-name
```

*function-name* Is the name of an external function. The external function can be
written in Fortran, C, or other languages.
The return value is the file descriptor. On Linux and macOS*, the file descriptor is a 4-byte integer on both 32-bit and 64-bit systems. On Windows, the file descriptor is a 4-byte integer on 32-bit systems and an 8-byte integer on 64-bit systems.

If the function is written in Fortran, do not execute a Fortran OPEN statement to open the file named in USEROPEN.

The Intel® Fortran Run-time Library (RTL) I/O support routines call the function named in USEROPEN in place of the system calls normally used when the file is first opened for I/O.

On Windows* systems, the Fortran RTL normally calls CreateFile( ) to open a file. When USEROPEN is specified, the called function opens the file (or pipe, etc.) by using CreateFile( ) and returns the handle of the file (return value from CreateFile( )) when it returns control to the calling Fortran program.

On Linux* and macOS* systems, the Fortran RTL normally calls the open function to open a file. When USEROPEN is specified, the called function opens the file by calling open and returns the file descriptor of the file when it returns control to the calling Fortran program.

When opening the file, the called function usually specifies options different from those provided by a normal Fortran OPEN statement.

NOTE

You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the run-time library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function.

For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures/USEROPEN Specifier.

Compilation Control Lines and Statements

In addition to specifying options on the compiler command line, you can specify the following lines and statements in a program unit to influence compilation:

- The INCLUDE Line
  Incorporates external source code into programs.
- The OPTIONS Statement
  Sets options usually specified in the compiler command line. OPTIONS statement settings override command line options.

Directive Enhanced Compilation

Directive enhanced compilation is performed by using compiler directives. Compiler directives are special commands that let you perform various tasks during compilation. They are similar to compiler options, but can provide more control within your program.

Compiler directives are preceded by a special prefix that identifies them to the compiler.
Syntax Rules for Compiler Directives

The following syntax rules apply to all general and OpenMP* Fortran compiler directives. You must follow these rules precisely to compile your program properly and obtain meaningful results.

A directive prefix (tag) takes one of the following forms:

- **General compiler directives**: `!DIR$`
- **OpenMP Fortran compiler directives**: `!$OMP`

The following prefix forms can be used in place of `!DIR$`: `cDIR$`, `cDEC$`, or `!MS$`, where `c` is one of the following: C (or c), !, or *.

The following prefix forms can be used in place of `!$OMP`: `c$OMP`, where `c` is one of the following: C (or c), !, or *.

The following are source form rules for directive prefixes:

- In fixed and tab source forms, prefixes begin with !, C (or c), or *.
  - The prefix must appear in columns 1 through 5; column 6 must be a blank or a tab (except for prefix `!MS$`). From column 7 on, blanks are insignificant, so the directive can be positioned anywhere on the line after column 6.

- In free source form, prefixes begin with !.
  - The prefix can appear in any column, but it cannot be preceded by any nonblank, nontab characters on the same line.

- In all source forms, directives spelled with two keywords can be separated by an optional space; for example, "LOOP COUNT" and "LOOCP Count" are both valid spellings for the same directive. However, when a directive name is preceded by the prefix "NO", this is not considered to be two keywords. For example, "NO DECLARE" is not a valid spelling; the only valid spelling for this directive is "NODEDECLARE".

A compiler directive ends in column 72 (or column 132, if compiler option extend-source is specified).

General compiler directives and OpenMP Fortran directives can be continued in the same way as Fortran statements can be continued:

- In fixed form, the first line of the directive (initial line) has the directive prefix in columns 1 through 5 and has a blank, a tab, or a zero in column 6; each continued line of the directive has the directive prefix in columns 1 through 5 and has a character other than a blank, a tab, or a zero in column 6.

- In free form, the initial line of the directive ends with an ampersand followed by an optional comment beginning with an exclamation point. Each continued line of the directive has the directive prefix optionally preceded by blanks or tabs, followed by an ampersand optionally preceded by blanks or tabs.

A comment beginning with an ! can follow a compiler directive on the same line.

Additional Fortran statements (or directives) cannot appear on the same line as the compiler directive.

Compiler directives cannot appear within a continued Fortran statement.

Blank common used in a compiler directive is specified by two slashes (`/ /`).

If the source line starts with a valid directive prefix but the directive is not recognized, the compiler displays an informational message and ignores the line.

General Compiler Directives

Compiler directives are specially formatted comments in the source file which provide information to the compiler. Some directives, such as line length or conditional compilation directives provide the compiler information which is used in interpreting the source file. Other directives, such as optimization directives provide hints or suggestions to the compiler, which, in some cases, may be ignored or overridden by the compiler based on the heuristics of the optimizer and/or code generator. You do not need to specify a compiler option to enable general directives. If the directive is ignored by the compiler, no diagnostic message is issued.

The following general compiler directives are available:
• **ALIAS**
  Specifies an alternate external name to be used when referring to external subprograms.
• **ASSUME**
  Provides heuristic information to the compiler optimizer.
• **ASSUME_ALIGNED**
  Specifies that an entity in memory is aligned.
• **ATTRIBUTES**
  Specifies properties for data objects and procedures.
• **BLOCK_LOOP** and **NOBLOCK_LOOP**
  Enables or disables loop blocking for the immediately following nested DO loops.
• **DECLARE** and **NODECLARE**
  Generates or disables warnings for variables that have been used but not declared.
• **DEFINE** and **UNDEFINE**
  Defines (or undefines) a symbolic variable whose existence (or value) can be tested during conditional compilation.
• **DISTRIBUTE POINT**
  Suggests a location at which a DO loop may be split.
• **FIXEDFORMLINESIZE**
  Sets the line length for fixed-form source code.
• **FMA** and **NOFMA**
  Enables (or disables) the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.
• **FREEFORM** and **NOFREEFORM**
  Specifies free-format or fixed-format source code.
• **IDENT**
  Specifies an identifier for an object module.
• **IF** and **IF DEFINED**
  Specifies a conditional compilation construct.
• **INLINE**, **FORCEINLINE**, **NOINLINE**
  Tell the compiler to perform the specified inlining on routines within statements or DO loops.
• **INTEGER**
  Specifies the default integer kind.
• **IVDEP**
  Assists the compiler’s dependence analysis of iterative DO loops.
• **LOOP COUNT**
  Specifies the typical trip count for a DO loop; this assists the optimizer.
• **MESSAGE**
  Specifies a character string to be sent to the standard output device during the first compiler pass.
• **NOFUSION**
  Prevents a loop from fusing with adjacent loops.
• **OBJCOMMENT**
  Specifies a library search path in an object file.
• **OPTIMIZE** and **NOOPTIMIZE**
  Enables or disables optimizations for the program unit.
• **OPTIONS**
  Affects data alignment and warnings about data alignment.
• **PACK**
  Specifies the memory alignment of derived-type items.
• **PARALLEL** and **NOPARALLEL**
Facilitates or prevents auto-parallelization by assisting the compiler's dependence analysis of the immediately following DO loop.

- **PREFETCH and NOPREFETCH**
  Enables or disables hint to the compiler to prefetch data from memory.

- **PSECT**
  Modifies certain characteristics of a common block.

- **REAL**
  Specifies the default real kind.

- **SIMD**
  Requires and controls SIMD vectorization of loops.

- **STRICT and NOSTRICT**
  Disables or enables language features not found in the language standard specified on the command line.

- **UNROLL and NOUNROLL**
  Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop.

- **UNROLL_AND_JAM and NOUNROLL_AND_JAM**
  Enables or disables loop unrolling and jamming.

- **VECTOR and NOVECTOR**
  Overrides default heuristics for vectorization of DO loops.

Syntax Rules for Compiler Directives
Rules for General Directives that Affect DO Loops

**Rules for Placement of Directives**

Directives can have different effects depending on placement:

- Some directives affect the next statement only.
- Some directives can appear only at the beginning of a scope and affect the rest of that scope.
- Some directives affect the statements starting at that point in the source and continue until changed by another directive or until the end of the scope containing the directive.

The scope can be a contained procedure or a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. A directive does not affect modules invoked with the USE statement in the program unit that contains it, but it does affect INCLUDE statements that follow the directive.

Certain directives may appear before program units or between program units in a source file. These directives affect only the next program unit that lexically follows the directive. The effect of the directive ceases at the end of the affected program unit. For example:

```
!dir$ integer:2
program m
integer k
print *, kind(k), kind(42) ! this prints 2, 2 which means the directive took effect
call sub()
end

subroutine sub()
integer kk
```
print *, kind(kk), kind(-42) ! this prints 4, 4 because the INTEGER:2 directive has no effect here
end

The following directives have this behavior:

- ALIAS
- ATTRIBUTES
- DECLARE and NODEDECLARE
- DEFINE and UNDEFINE
- FIXEDFORMLINESIZE
- FREEFORM and NOFREEFORM
- IDENT
- INTEGER
- OPTIMIZE and NOOPTIMIZE
- PACK
- PREFETCH
- PSECT
- REAL
- STRICT and NOSTRICT

Other rules may apply to these directives. For more information, see the description of each directive.

## Rules for General Directives that Affect DO Loops

This table lists the general directives that affect DO loops:

<table>
<thead>
<tr>
<th>General Directive</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK_LOOP and NOBLOCK_LOOP</td>
<td>PARALLEL and NOPARALLEL</td>
</tr>
<tr>
<td>CODE_ALIGN</td>
<td>PREFETCH and NOPREFETCH</td>
</tr>
<tr>
<td>DISTRIBUTED POINT</td>
<td>SIMD</td>
</tr>
<tr>
<td>FORCEINLINE</td>
<td>UNROLL and NOUNROLL</td>
</tr>
<tr>
<td>INLINE and NOINLINE</td>
<td>UNROLL_AND_JAM</td>
</tr>
<tr>
<td>IVDEP</td>
<td>VECTOR and NOVECTOR</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td></td>
</tr>
<tr>
<td>NOFUSION</td>
<td></td>
</tr>
<tr>
<td>NOUNROLL_AND_JAM</td>
<td></td>
</tr>
</tbody>
</table>

The following rules apply to all of the general directives:

- The directive must precede the DO statement for each DO loop it affects. The DO statement can be any of the following:
  - A counted DO loop
  - A DO WHILE loop
  - A DO CONCURRENT loop
- No source code lines, other than the following, can be placed between the directive statement and the DO statement:
  - One of the other general directives that affect DO loops
  - An OpenMP* Fortran PARALLEL DO directive
  - Comment lines
  - Blank lines

Other rules may apply to these directives. For more information, see the description of each directive.
See Also
Rules for Loop Directives that Affect Array Assignment Statements

Rules for Loop Directives that Affect Array Assignment Statements

When certain loop directives precede an array assignment statement, they affect the implicit loops that are generated by the compiler.

The following loop directives can affect array assignment statements:

- BLOCK_LOOP and NOBLOCK_LOOP
- CODE_ALIGN
- DISTRIBUTION
- PARALLEL and NOPARALLEL
- CODE_ALIGN
- PREFETCH and NOPREFETCH
- FORCEINLINE
- SIMD
- INLINE and NOINLINE
- UNROLL and NOUNROLL
- IVDEP
- UNROLL_AND_JAM
- LOOP COUNT
- VECTOR
- NOFUSION
- NOUNROLL_AND_JAM

Usually only one of the general directives can precede the array assignment statement (one-dimensional-array = expression) to affect it. The BLOCK_LOOP and NOBLOCK_LOOP directives may precede array assignment statements with any rank variable on the left-hand-side of the assignment.

Other rules may apply to the general directives. For more information, see the description of each directive.

Examples

Consider the following:

```fortran
REAL A(10), B(10)
...
!DIR$ IVDEP
   A = B + 3
```

This has the same effect as writing the following explicit loop:

```fortran
!DIR$ IVDEP
   DO I = 1, 10
     A (I) = B (I) + 3
   END DO
```

Rules for General Directives that Affect DO Loops

OpenMP* Fortran Compiler Directives

Intel® Fortran supports OpenMP* Fortran compiler directives that comply with OpenMP Fortran Application Program Interface (API) specification 5.0 Version TR4, and some of the directives of the OpenMP Version 5.1 specification.

To use these directives, you must specify compiler option `-qopenmp` (Linux* and macOS*) or `/Qopenmp` (Windows*).
OpenMP directives are specially formatted Fortran comment lines embedded in the source file which provide the compiler with hints and suggestions for parallelization, optimization, vectorization, and offloading code to accelerator hardware. The compiler uses the information specified in the directives with compiler heuristic algorithms to generate more efficient code. At times, these heuristics may choose to ignore or override the information provided by a directive. If the directive is ignored by the compiler, no diagnostic message is issued.

Options that use OpenMP* are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

This section discusses clauses used in multiple OpenMP* Fortran directives, conditional compilation rules, nesting and binding rules, and the following directives:

- **ALLOCATE directive**
  Specifies memory allocators to use for object allocation and deallocation. This feature is only available for ifx.
- **ATOMIC construct**
  Specifies that a specific memory location is to be updated atomically.
- **BARRIER directive**
  Synchronizes all the threads in a team.
- **CANCEL directive**
  Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.
- **CANCELLATION POINT directive**
  Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.
- **CRITICAL construct**
  Restricts access for a block of code to only one thread at a time.
- **DECLARE MAPPER directive**
  Declares a user-defined data mapper for derived types and local variables that can subsequently be used in MAP clauses. This feature is only available for ifx.
- **DECLARE REDUCTION directive**
  Declares a user-defined reduction for one or more types.
- **DECLARE SIMD directive**
  Generates a SIMD procedure.
- **DECLARE TARGET directive**
  Causes the creation of a device-specific version of a named routine that can be called from a target region. This feature is only available for ifx.
- **DECLARE VARIANT directive**
  Identifies a variant of a base procedure and specifies the context in which this variant is used. This feature is only available for ifx.
- **DISPATCH directive**
  Determines if a variant of a base procedure is to be called for a given subroutine or function call. This feature is only available for ifx.
- **DISTRIBUTE construct**
  Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.
- **DISTRIBUTE PARALLEL DO construct**
  Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
• **DISTRIBUTE PARALLEL DO SIMD construct**
  Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.
• **DISTRIBUTE SIMD construct**
  Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.
• **DO construct**
  Specifies that the iterations of the immediately following DO loop must be executed in parallel.
• **DO SIMD construct**
  Specifies a loop that can be executed concurrently using SIMD instructions.
• **FLUSH directive**
  Specifies synchronization points where the threads in a team must have a consistent view of memory.
• **INTEROP directive**
  Identifies a foreign runtime context and identifies runtime characteristics of that context, enabling interoperability with it. This feature is only available for ifx.
• **LOOP construct**
  Specifies that the iterations of the associated loops can execute concurrently. This feature is only available for ifx.
• **MASKED construct**
  Specifies a block of code to be executed by the primary thread of the team. This feature is only available for ifx.
• **MASKED TASKLOOP construct**
  Provides an abbreviated way to specify a TASKLOOP construct inside a MASKED construct. This feature is only available for ifx.
• **MASKED TASKLOOP SIMD construct**
  Provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASKED construct. This feature is only available for ifx.
• **MASTER construct**
  Deprecated; see MASKED. Specifies a block of code to be executed by the master thread of the team.
• **MASTER TASKLOOP construct**
  Deprecated; provides an abbreviated way to specify a TASKLOOP construct inside a MASTER construct. This feature is only available for ifx.
• **MASTER TASKLOOP SIMD construct**
  Deprecated; provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASTER construct. This feature is only available for ifx.
• **ORDERED directive and construct**
  Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.
• **PARALLEL construct**
  Defines a parallel region.
• **PARALLEL DO construct**
  Defines a parallel region that contains a single DO directive.
• **PARALLEL DO SIMD construct**
  Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.
• **PARALLEL LOOP construct**
  Specifies a shortcut for indicating that a loop or loop nest can execute concurrently across multiple threads. This feature is only available for ifx.
• **PARALLEL MASKED construct**
  Provides an abbreviated way to specify a MASKED construct inside a PARALLEL construct. This feature is only available for ifx.
• **PARALLEL MASKED TASKLOOP construct**
  Provides an abbreviated way to specify a MASKED TASKLOOP construct inside a PARALLEL construct. This feature is only available for ifx.

• **PARALLEL MASKED TASKLOOP SIMD construct**
  Provides an abbreviated way to specify a MASKED TASKLOOP SIMD construct inside a PARALLEL construct. This feature is only available for ifx.

• **PARALLEL MASTER construct**
  Deprecated; provides an abbreviated way to specify a MASTER construct inside a PARALLEL construct. This feature is only available for ifx.

• **PARALLEL MASTER TASKLOOP construct**
  Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP construct inside a PARALLEL construct. This feature is only available for ifx.

• **PARALLEL MASTER TASKLOOP SIMD construct**
  Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP SIMD construct inside a PARALLEL construct. This feature is only available for ifx.

• **PARALLEL SECTIONS construct**
  Defines a parallel region that contains a single SECTIONS directive.

• **PARALLEL WORKSHARE construct**
  Defines a parallel region that contains a single WORKSHARE directive.

• **REQUIRES directive**
  Lists the features that an implementation must support so that the program compiles and runs correctly. This feature is only available for ifx.

• **SCAN directive**
  Specifies a scan computation that updates each list item in each iteration of the loop the directive appears in.

• **SECTIONS construct**
  Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team.

• **SIMD construct**
  Requires and controls SIMD vectorization of loops.

• **SINGLE construct**
  Specifies a block of code to be executed by only one thread in a team at a time.

• **TARGET construct**
  Creates a device data environment and executes the construct on the same device. This feature is only available for ifx.

• **TARGET DATA construct**
  Creates a device data environment for the extent of the region. This feature is only available for ifx.

• **TARGET ENTER DATA**
  Specifies that variables are mapped to a device data environment. This feature is only available for ifx.

• **TARGET EXIT DATA**
  Specifies that variables are unmapped from a device data environment. This feature is only available for ifx.

• **TARGET PARALLEL construct**
  Creates a device data environment in a parallel region and executes the construct on that device.

• **TARGET PARALLEL DO construct**
  Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.

• **TARGET PARALLEL DO SIMD construct**
  Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.

• **TARGET PARALLEL LOOP construct**
Specifies a shortcut for specifying a parallel loop inside a TARGET construct that contains no other statements than the parallel loop. This feature is only available for ifx.

- **TARGET SIMD construct**

  Specifies a TARGET construct that contains a SIMD construct and no other statement.

- **TARGET TEAMS construct**

  Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.

- **TARGET TEAMS DISTRIBUTE construct**

  Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a TEAMS construct.

- **TARGET TEAMS DISTRIBUTE PARALLEL DO construct**

  Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct.

- **TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD construct**

  Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions.

- **TARGET TEAMS DISTRIBUTE SIMD construct**

  Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the master threads of all thread teams in a league created by a TEAMS construct. It will be executed concurrently using SIMD instructions.

- **TARGET TEAMS LOOP construct**

  Specifies a shortcut for specifying a TEAMS LOOP construct inside a TEAMS construct that contains no other statements. This feature is only available for ifx.

- **TARGET UPDATE directive**

  Makes the list items in the device data environment consistent with their corresponding original list items.

- **TARGET VARIANT DISPATCH directive**

  Conditionally calls a procedure offload variant if the device is free; otherwise, executes the procedure on the host. This feature is only available for ifx.

- **TASK construct**

  Defines a task region.

- **TASKGROUP construct**

  Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.

- **TASKLOOP construct**

  Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.

- **TASKLOOP SIMD construct**

  Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.

- **TASKWAIT directive**

  Specifies a wait on the completion of child tasks generated since the beginning of the current task.

- **TASKYIELD directive**

  Specifies that the current task can be suspended at this point in favor of execution of a different task.

- **TEAMS construct**

  Creates a group of thread teams to be used in a parallel region.

- **TEAMS DISTRIBUTE construct**
The OpenMP parallel directives can be grouped into the categories. For more information about the categories for these directives, see OpenMP* Directives Summary.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DEFAULT</strong></td>
<td>Lets you specify a scope for all variables in the lexical extent of a parallel region.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FIRSTPRIVATE</td>
<td>Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.</td>
</tr>
<tr>
<td>IN_REDUCTION</td>
<td>Specifies that a task participates in a reduction.</td>
</tr>
<tr>
<td>LASTPRIVATE</td>
<td>Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.</td>
</tr>
<tr>
<td>LINEAR</td>
<td>Specifies that all variables in a list are private to a SIMD task and that they have a linear relationship within the iteration space of a loop.</td>
</tr>
<tr>
<td>PRIVATE</td>
<td>Declares one or more variables to be private to each thread in a team.</td>
</tr>
<tr>
<td>SHARED</td>
<td>Specifies variables that will be shared by all the threads in a team.</td>
</tr>
</tbody>
</table>

The data copying clauses let you copy data values from private or threadprivate variables in one implicit task or thread to the corresponding variables in other implicit tasks or threads in the team.

**Data Copying Clauses**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COPYIN</td>
<td>Specifies that the data in the primary thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.</td>
</tr>
<tr>
<td>COPYPRIVATE</td>
<td>Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.</td>
</tr>
</tbody>
</table>

The data motion clause MAP is used in OpenMP* Fortran TARGET directives. This data motion clause does not modify the values of any of the internal control variables (ICVs).

List items that appear in this data motion clause may have corresponding new list items created in the device data environment that is associated with the construct. If a new list item is created, a new list item of the same type, kind, and rank is allocated. The initial value of the new list item is undefined.

The original list items and new list items may share storage. This means that data races can occur. Data races are caused by unintended sharing of data; for example, when WRITEs to either item by one task or device are followed by a READ of the other item by another task or device without intervening synchronization.

**Data Allocation and Data Mapping Clauses**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE</td>
<td>Specifies the memory allocator to be used for one or more private variables or common blocks of a construct. This feature is only available for ifx.</td>
</tr>
</tbody>
</table>
### MAP
Maps a variable from the data environment of the current task to the data environment of the device associated with the construct.

The following are other clauses that can be used in more than one OpenMP* Fortran directive.

## Miscellaneous Clauses

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIGNED</td>
<td>Specifies that all variables in a list are aligned.</td>
</tr>
<tr>
<td>COLLAPSE</td>
<td>Specifies how many loops are associated with the loop construct.</td>
</tr>
<tr>
<td>DEPEND</td>
<td>Enforces additional constraints on the scheduling of a task by enabling dependences between sibling tasks in the task region.</td>
</tr>
<tr>
<td>DEVICE</td>
<td>Specifies the target device for certain TARGET directives.</td>
</tr>
<tr>
<td>FINAL</td>
<td>Specifies that the generated task will be a final task.</td>
</tr>
<tr>
<td>IF</td>
<td>Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.</td>
</tr>
<tr>
<td>MERGEABLE</td>
<td>Specifies that the implementation may generate a merged task.</td>
</tr>
<tr>
<td>NOWAIT</td>
<td>Specifies that threads may resume execution before the execution of the region completes.</td>
</tr>
<tr>
<td>ORDER (CONCURRENT)</td>
<td>Indicates that the iterations of the loop may execute in any order or simultaneously. For more information, see LOOP and DO Directive.</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>Specifies that the generated tasks have the indicated priority for execution.</td>
</tr>
<tr>
<td>REDUCTION</td>
<td>Performs a reduction operation on the specified variables.</td>
</tr>
<tr>
<td>SUBDEVICE</td>
<td>Specifies which tiles or compute slices (c-slices) of the offload device the offloaded code will run on. This feature is only available for ifx.</td>
</tr>
<tr>
<td>UNTIED</td>
<td>Specifies that the task is never tied to the thread that started its execution.</td>
</tr>
</tbody>
</table>

## Conditional Compilation Rules

The OpenMP* Fortran API lets you conditionally compile Intel® Fortran statements if you use the appropriate directive prefix.

The prefix depends on which source form you are using, although !$ is valid in all forms.

The prefix must be followed by a valid Intel Fortran statement on the same line.
Free Source Form
The free source form conditional compilation prefix is $!. This prefix can appear in any column as long as it is preceded only by white space. It must appear as a single word with no intervening white space. Free-form source rules apply to the directive line.

Initial lines must have a space after the prefix. Continued lines must have an ampersand as the last nonblank character on the line. Continuation lines can have an ampersand after the prefix with optional white space before and after the ampersand.

Fixed Source Form
For fixed source form programs, the conditional compilation prefix is one of the following: $!, C$ (or $c$), or $*!$.

The prefix must start in column one and appear as a single string with no intervening white space. Fixed-form source rules apply to the directive line.

After the prefix is replaced with two spaces, initial lines must have a space or zero in column six, and continuation lines must have a character other than a space or zero in column six. For example, the following forms for specifying conditional compilation are equivalent:

```
c23456789
!$ IAM = OMP_GET_THREAD_NUM( ) +
!$ * INDEX
$IFDEF _OPENMP
  IAM = OMP_GET_THREAD_NUM( ) +
  * INDEX
$ENDIF
```

Nesting and Binding Rules
This section describes the dynamic nesting and binding rules for OpenMP* Fortran API directives.

Binding Rules
The following rules apply to dynamic binding:

- The DO, SECTIONS, SINGLE, MASKED, MASTER, and BARRIER directives bind to the dynamically enclosing PARALLEL directive, if one exists.
- The ORDERED directive binds to the dynamically enclosing DO directive.
- The ATOMIC directive enforces exclusive access with respect to ATOMIC directives in all threads, not just the current team.
- The CRITICAL directive enforces exclusive access with respect to CRITICAL directives in all threads, not just the current team.
- A directive can never bind to any directive outside the closest enclosing PARALLEL directive.

Nesting Rules
The following rules apply to dynamic nesting:

- A PARALLEL directive dynamically inside another PARALLEL directive logically establishes a new team, which is composed of only the current thread unless nested parallelism is enabled.
- DO, SECTIONS, and SINGLE directives that bind to the same PARALLEL directive are not allowed to be nested one inside the other.
- DO, SECTIONS, and SINGLE directives are not permitted in the dynamic extent of CRITICAL, MASTER, and MASTER directives.
- BARRIER directives are not permitted in the dynamic extent of DO, SECTIONS, SINGLE, MASKED, MASTER, and CRITICAL directives.
• MASKED and MASTER directives are not permitted in the dynamic extent of DO, SECTIONS, and SINGLE directives.
• ORDERED sections are not allowed in the dynamic extent of CRITICAL sections.
• Any directive set that is legal when executed dynamically inside a PARALLEL region is also legal when executed outside a parallel region. When executed dynamically outside a user-specified parallel region, the directive is executed with respect to a team composed of only the primary thread.

Examples

The following example shows nested PARALLEL regions:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO
   DO I =1, N
   !$OMP PARALLEL SHARED(I,N)
   !$OMP DO
      DO J =1, N
      CALL WORK(I,J)
   END DO
   !$OMP END PARALLEL
END DO
!$OMP END PARALLEL
```

Note that the inner and outer DO directives bind to different PARALLEL regions.

The following shows a variation of the preceding example:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
!$OMP DO
   DO I =1, N
      CALL SOME_WORK(I,N)
   END DO
!$OMP END PARALLEL
...
SUBROUTINE SOME_WORK(I,N)
   !$OMP PARALLEL DEFAULT(SHARED)
   !$OMP DO
      DO J =1, N
      CALL WORK(I,J)
   END DO
   !$OMP END PARALLEL
   RETURN
END
```

Equivalent Compiler Options

Some compiler directives and compiler options have the same effect, as shown in the table below. However, compiler directives can be turned on and off throughout a program, while compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

The following table shows compiler directives and equivalent command-line compiler options:

<table>
<thead>
<tr>
<th>Compiler Directive</th>
<th>Equivalent Command-Line Compiler Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>DECLARE</td>
<td>-warn declarations (Linux* and macOS*)</td>
</tr>
<tr>

**Scope and Association**

Program entities are identified by names, labels, input/output unit numbers, operator symbols, or assignment symbols. For example, a variable, a derived type, or a subroutine is identified by its name.

**Scope** refers to the area in which a name is recognized. A scoping unit is the program or part of a program in which a name is defined or known. It can be any of the following:

- An entire executable program
- A single scoping unit
- A single statement (or part of a statement)

The region of the program in which a name is known and accessible is referred to as the scope of that name. These different scopes allow the same name to be used for different things in different regions of the program.
Association is the language concept that allows different names to refer to the same entity in a particular region of a program.

**Scope**

Program entities have the following kinds of scope (as shown in the table below):

- **Global**
  Entities that are accessible throughout an executable program. The name of a global entity must be unique. It cannot be used to identify any other global entity in the same executable program.

- **Scoping unit (Local scope)**
  Entities that are declared within a scoping unit. These entities are local to that scoping unit. The names of local entities are divided into classes (see the table below).
  
  A **scoping unit** is one of the following:
  
  - A derived-type definition
  - A procedure interface body (excluding any derived-type definitions and interface bodies contained within it)
  - A program unit or subprogram (excluding any derived-type definitions, interface bodies, and subprograms contained within it)

  A scoping unit that immediately surrounds another scoping unit is called the host scoping unit. Named entities within the host scoping unit are accessible to the nested scoping unit by host association, unless access is blocked by an IMPORT ONLY or IMPORT NONE statement. For information about host association, see Use and Host Association.

  Once an entity is declared in a scoping unit, its name can be used throughout that scoping unit. An entity declared in another scoping unit is a different entity even if it has the same name and properties.

  Within a scoping unit, a local entity name that is not generic or an OpenMP* reduction identifier must be unique within its class. However, the name of a local entity in one class can be used to identify a local entity of another class.

  Within a scoping unit, a generic name can be the same as any one of the procedure names in the interface block. A generic name can be the same as the name of a derived type.

  An OpenMP* reduction identifier can be the same as any local entity name.

  A component name has the same scope as the derived type of which it is a component. It can appear only within a component designator of a structure of that type.

  For information on interactions between local and global names, see the table below.

- **Statement**
  Entities that are accessible only within a statement or part of a statement; such entities cannot be referenced in subsequent statements.

  The name of a statement entity can also be the name of a common block, or a local or construct variable accessible in the same scoping unit or construct; in this case, the name is interpreted within the statement as that of the statement entity.

- **Construct**
  Construct entities are accessible during the execution of the construct in which they are declared. Entities declared in the specification part of a BLOCK construct, associate names in ASSOCIATE, SELECT RANK, and SELECT TYPE constructs, and index variables in FORALL statements or constructs, or DO CONCURRENT constructs are construct entities. An index name of an inner FORALL statement or construct, or of a DO CONCURRENT construct cannot be the same as that of an index variable of an outer (containing) FORALL or DO CONCURRENT construct.

  An associate name of a SELECT TYPE construct has a different scope for each block of the construct; the declared type, dynamic type, type parameters, rank or bounds may differ from block to block. An associate name for a SELECT RANK construct has a different scope for each block of the construct since the rank of the associate name is different in each block. An associate name for an ASSOCIATE construct has the scope of the ASSOCIATE construct.

<tr>
<td>Intrinsic assignment</td>
<td>Global(^4)</td>
</tr>
<tr>
<td>Defined assignment</td>
<td>Local or construct</td>
</tr>
</tbody>
</table>

\(^1\) Names of common blocks can also be used to identify local entities.
If an intrinsic procedure is not used in a scoping unit, its name can be used as a local entity within that scoping unit. For example, if intrinsic function COS is not used in a program unit, COS can be used as a local variable there.

The DO variable in an implied-DO list of an I/O list has local scope.

The scope of the assignment symbol (=) is global, but it can identify additional operations (see Defining Generic Assignment).

Scoping units can contain other scoping units. For example, the following shows six scoping units:

```
MODULE MOD_1                     ! Scoping unit 1
  ...
  ! Scoping unit 1
CONTAINS                       ! Scoping unit 1
  FUNCTION FIRST                !   Scoping unit 2
    TYPE NAME                  !     Scoping unit 3
      ...
      ! Scoping unit 3
    END TYPE NAME              !     Scoping unit 3
    ...
    ! Scoping unit 2
CONTAINS                       ! Scoping unit 2
  SUBROUTINE SUB_B              !   Scoping unit 4
    TYPE PROCESS               !     Scoping unit 5
      ...
      ! Scoping unit 5
    END TYPE PROCESS           !     Scoping unit 5
    INTERFACE                 !     Scoping unit 5
      SUBROUTINE SUB_A         !       Scoping unit 6
        ...
        ! Scoping unit 6
      BLOCK                    !       Scoping unit 7
        ...
        ! Scoping unit 7
      END BLOCK                !       Scoping unit 7
      END SUBROUTINE SUB_A     !       Scoping unit 6
    END INTERFACE              !     Scoping unit 5
    END SUBROUTINE SUB_B       !   Scoping unit 4
    END FUNCTION FIRST        !   Scoping unit 2
END MODULE                    ! Scoping unit 1
```

Unambiguous Generic Procedure References

When a generic procedure reference is made, a specific procedure is invoked. If the following rules are used, the generic reference will be unambiguous:
Two dummy arguments are said to be distinguishable if any of the following are true:

- One is a procedure and the other is a data object.
- One has the ALLOCATABLE attribute and the other has the POINTER attribute without INTENT (IN).
- They are both data objects or both known to be functions, and they have different type and kind parameters, or different rank.
- One is a function with nonzero rank and the other is not known to be a function.
- Within a scoping unit, two procedures that have the same generic name must both be subroutines or both be functions. One of the procedures must have a nonoptional dummy argument that is one of the following:
  - Not present by position or argument keyword in the other argument list
  - Is present, but is distinguishable from the dummy argument in the other argument list
- Within a scoping unit, two procedures that have the same generic operator must both have the same number of arguments or both define assignment.
  - One of the procedures must have a dummy argument that corresponds, by position in the argument list, to a dummy argument of the other procedure. The dummy arguments must be distinguishable from each other in each argument list.

When an interface block extends an intrinsic procedure, operator, or assignment, the rules apply as if the intrinsic consists of a collection of specific procedures, one for each allowed set of arguments.

When a generic procedure is accessed from a module, the rules apply to all the specific versions, even if some of them are inaccessible by their specific names.

Defining Generic Names for Procedures for details on generic procedure names

Resolving Procedure References

The procedure name in a procedure reference is either established to be generic or specific, or is not established. The rules for resolving a procedure reference differ depending on whether the procedure is established and how it is established.

This section discusses the following topics:

- References to Generic Names
- References to Specific Names
- References to Nonestablished Names

References to Generic Names

Within a scoping unit, a procedure name is established to be generic if any of the following is true:

- The scoping unit contains an interface block with that procedure name.
- The procedure name matches the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is established to be generic in a module, and the scoping unit contains a USE statement making that procedure name accessible.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be generic in a host scoping unit.

To resolve a reference to a procedure name established to be generic, the following rules are used in the order shown:

1. If an interface block with that procedure name appears in one of the following, the reference is to the specific procedure providing that interface:
   a. The scoping unit that contains the reference
   b. A module made accessible by a USE statement in the scoping unit

   The reference must be consistent with one of the specific interfaces of the interface block.

2. If the procedure name is specified with the INTRINSIC attribute in one of the following, the reference is to that intrinsic procedure:
a. The same scoping unit
b. A module made accessible by a USE statement in the scoping unit

The reference must be consistent with the interface of that intrinsic procedure.

3. If the following is true, the reference is resolved by applying rules 1 and 2 to the host scoping unit:
   a. The procedure name is established to be generic in the host scoping unit
   b. There is agreement between the scoping unit and the host scoping unit as to whether the procedure is a function or subroutine name.

4. If none of the preceding rules apply, the reference must be to the generic intrinsic procedure with that name. The reference must be consistent with the interface of that intrinsic procedure.

Examples

The following example shows how a module can define three separate procedures and give them a generic name DUP through an interface block. Although the main program calls all three by the generic name, there is no ambiguity since the arguments are of different data types, and DUP is a function rather than a subroutine. The module UN_MOD must give each procedure a different name.

```fortran
MODULE UN_MOD

    CONTAINS
      subroutine dup1(x,y)
        real x,y
        print *, ' Real arguments', x, y
      end subroutine dup1

      subroutine dup2(m,n)
        integer m,n
        print *, ' Integer arguments', m, n
      end subroutine dup2

      character function dup3 (z)
        character(len=2) z
        dup3 = 'String argument ' // z
      end function dup3

END MODULE

PROGRAM UNECLAIR

    ! shows how to use generic procedure references

    USE UN_MOD
    INTERFACE DUP
      MODULE PROCEDURE dup1, dup2, dup3
    END INTERFACE

    REAL a,b
    INTEGER c,d
    CHARACTER (LEN=2) state

    a = 1.5
    b = 2.32
    c = 5
    d = 47
    state = 'WA'
```

```
Note that the function DUP3 only prints one character, since module UN_MOD specifies no length parameter for the function result.

If the dummy arguments x and y for DUP were declared as integers instead of reals, then any calls to DUP would be ambiguous. If this is the case, a compile-time error results.

The subroutine definitions, DUP1, DUP2, and DUP3, must have different names. The generic name is specified in the first line of the interface block, and in the example is DUP.

References to Specific Names

In a scoping unit, a procedure name is established to be specific if it is not established to be generic and any of the following is true:

- The scoping unit contains an interface body with that procedure name.
- The scoping unit contains an internal procedure, module procedure, or statement function with that procedure name.
- The procedure name is the same as the name of a generic intrinsic procedure, and it is specified with the INTRINSIC attribute in that scoping unit.
- The procedure name is specified with the EXTERNAL attribute in that scoping unit.
- The procedure name is established to be specific in a module, and the scoping unit contains a USE statement making that procedure name accessible.
- The scoping unit contains no declarations for that procedure name, but the procedure name is established to be specific in a host scoping unit.

To resolve a reference to a procedure name established to be specific, the following rules are used in the order shown:

1. If either of the following is true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   - The scoping unit is a subprogram, and it contains an interface body with that procedure name.
   - The procedure name has been declared EXTERNAL, and the procedure name is a dummy argument of that subprogram.

   The procedure invoked by the reference is the one supplied as the corresponding actual argument.

2. If the scoping unit contains an interface body or the procedure name has been declared EXTERNAL, and Rule 1 does not apply, the reference is to an external procedure with that name.

3. If the scoping unit contains an internal procedure or statement function with that procedure name, the reference is to that entity.

4. If the procedure name has been declared INTRINSIC in the scoping unit, the reference is to the intrinsic procedure with that name.

5. If the scoping unit contains a USE statement that makes the name of a module procedure accessible, the reference is to that procedure. Since the USE statement allows renaming, the name referenced may differ from the name of the module procedure.

6. If none of the preceding rules apply, the reference is resolved by applying these rules to the host scoping unit.

References to Nonestablished Names

In a scoping unit, a procedure name is not established if it is not determined to be generic or specific.

To resolve a reference to a procedure name that is not established, the following rules are used in the order shown:

1. If both of the following are true, the dummy argument is a dummy procedure and the reference is to that dummy procedure:
   - The scoping unit is a subprogram.
b. The procedure name is a dummy argument of that subprogram.

The procedure invoked by the reference is the one supplied as the corresponding actual argument.

2. If both of the following are true, the procedure is an intrinsic procedure and the reference is to that intrinsic procedure:
   a. The procedure name matches the name of an intrinsic procedure.
   b. There is agreement between the intrinsic procedure definition and the reference of the name as a function or subroutine.

3. If neither of the preceding rules apply, the reference is to an external procedure with that name.

Association

Association allows different program units to access the same value through different names. Entities are associated when each is associated with the same storage location.

Association can occur in the following ways:

- Name association
- Pointer association
- Storage association
- Inheritance association

The following example shows name, pointer, and storage association between an external program unit and an external procedure.

Example of Name, Pointer, and Storage Association

```fortran
! Scoping Unit 1: An external program unit

REAL A, B(4)
REAL, POINTER :: M(:)
REAL, TARGET :: N(12)
COMMON /COM/...
EQUIVALENCE (A, B(1)) ! Storage association between A and B(1)
M => N ! Pointer association
CALL P (actual-arg,...)
...

! Scoping Unit 2: An external procedure

SUBROUTINE P (dummy-arg,...) ! Name and storage association between
! these arguments and the calling
! routine's arguments in scoping unit 1
COMMON /COM/... ! Storage association with common block COM
! in scoping unit 1

REAL Y
CALL Q (actual-arg,...)
CONTAINS
   SUBROUTINE Q (dummy-arg,...) ! Name and storage association
   between
   ! these arguments and the calling
   ! routine's arguments in host procedure
```
The following example shows inheritance association:

```fortran
TYPE POINT                  ! A base type
REAL :: X, Y
END TYPE POINT

TYPE, EXTENDS(POINT) :: COLOR_POINT   ! An extension of TYPE(POINT)
  ! Components X and Y, and component name POINT,
  ! are inherited from the parent type POINT
INTEGER :: COLOR
END TYPE COLOR_POINT
```

**Name Association**

Name association allows an entity to be accessed from different scoping units by the same name or by different names.

Name association can occur in the following ways:

- By argument association
- By use association
- By host association
- By linkage association
- By construct association

**Argument Association**

Arguments are the values passed to and from functions and subroutines through calling program argument lists.

Execution of a procedure reference establishes argument association between an actual argument and its corresponding dummy argument. The name of a dummy argument can be different from the name of its associated actual argument (if any).

When the procedure completes execution, the argument association is terminated. A dummy argument of that procedure can be associated with an entirely different actual argument in a subsequent invocation of the procedure.

**Association Between Actual Arguments and Dummy Data Objects**

A scalar dummy argument of a nonelemental procedure can be associated only with a scalar actual argument.

If the actual argument is scalar, the corresponding dummy argument must be scalar unless the actual argument is one of the following:

- Of type default character
- Of type character with the C character kind
- An element or substring of an element of an array that is not an assumed-shape or pointer array

If the procedure is nonelemental and is referenced by a generic name or as a defined operator or defined assignment, the ranks of the actual arguments and corresponding dummy arguments must agree.
If a scalar dummy argument is of type default character, the length of the dummy argument must be less than or equal to the length of the actual argument. The dummy argument becomes associated with the leftmost \textit{len} characters of the actual argument. If an array dummy argument is of type default character and is not assumed shape, it becomes associated with the leftmost characters of the actual argument element sequence and it must not extend beyond the end of that sequence.

If a dummy argument is not allocatable and is not a pointer, it must be type compatible with the associated actual argument. If a dummy argument is allocatable or a pointer, the associated actual argument must be polymorphic only if the dummy argument is polymorphic, and the declared type of the actual argument must be the same as the declared type of the dummy argument.

If the dummy argument is a pointer, the actual argument must be a pointer and the nondeferred type parameters and ranks must agree. If a dummy argument is allocatable, the actual argument must be allocatable and the nondeferred type parameters and ranks must agree. The actual argument can have an allocation status of unallocated.

At the invocation of the procedure, the pointer association status of an actual argument associated with a pointer dummy argument becomes undefined if the dummy argument has \texttt{INTENT(OUT)}.

The dynamic type of a polymorphic, allocatable, or pointer dummy argument can change as a result of execution of an allocate statement or pointer assignment in the subprogram. Because of this behavior, the corresponding actual argument needs to be polymorphic and have a declared type that is the same as the declared type of the dummy argument, or an extension of that type.

The values of assumed type parameters of a dummy argument are assumed from the corresponding type parameters of the associated actual argument.

Except in references to intrinsic inquiry functions, if the dummy argument is not a pointer and the corresponding actual argument is a pointer, the actual argument must be associated with a target and the dummy argument becomes the argument associated with that target.

Except in references to intrinsic inquiry functions, if the dummy argument is not allocatable and the actual argument is allocatable, the actual argument must be allocated.

If the dummy argument has the \texttt{VALUE} attribute, it becomes associated with a definable anonymous data object whose initial value is that of the actual argument. Subsequent changes to the value or definition status of the dummy argument do not affect the actual argument.

If the dummy argument does not have the \texttt{TARGET} or \texttt{POINTER} attribute, any pointers associated with the actual argument do not become associated with the corresponding dummy argument on invocation of the procedure.

If the dummy argument has the \texttt{TARGET} attribute, does not have the \texttt{VALUE} attribute, is either a scalar or an assumed-shape array, and the corresponding actual argument has the \texttt{TARGET} attribute but is not an array section with a vector subscript, then the following is true:

- Any pointers associated with the actual argument become associated with the corresponding dummy argument on invocation of the procedure.
- When execution of the procedure completes, any pointers that do not become undefined and are associated with the dummy argument remain associated with the actual argument.

Any pointers associated with the dummy argument become undefined when execution of the procedure completes in these cases:

- If the dummy argument has the \texttt{TARGET} attribute and the corresponding actual argument does not have the \texttt{TARGET} attribute, or is an array section with a vector subscript.
- If the dummy argument has the \texttt{TARGET} attribute and the \texttt{VALUE} attribute.

If a nonpointer dummy argument has \texttt{INTENT(OUT)} or \texttt{INTENT(INOUT)}, the actual argument must be definable. If a dummy argument has \texttt{INTENT(OUT)}, the corresponding actual argument becomes undefined at the time the association is established, except for components of an object of derived type for which
default initialization has been specified. If the dummy argument is not polymorphic and the type of the actual argument is an extension of the type of the dummy argument, only the part of the actual argument that is of the same type as the dummy argument becomes undefined.

**Association Between Actual Arguments and Dummy Procedure Entities**

If a dummy argument is a procedure pointer, the associated actual argument must be a procedure pointer, a reference to a function that returns a procedure pointer, or a reference to the NULL intrinsic function.

If a dummy argument is a dummy procedure without the POINTER attribute, the associated actual argument must be the specific name of an external, module, dummy, or intrinsic procedure, an associated procedure pointer, or a reference to a function that returns an associated procedure pointer. If the specific name is also a generic name, only the specific procedure is associated with the dummy argument.

For generic declarations, a dummy argument is type, kind, and rank compatible with another dummy argument if following is true:

- The first is type compatible with the second.
- The kind type parameters of the first have the same values as the corresponding kind type parameters of the second.
- Both have the same rank or either is assumed-rank.

If an external procedure name or a dummy procedure name is used as an actual argument, its interface must be explicit or it must be explicitly declared to have the EXTERNAL attribute.

If the interface of the dummy argument is explicit, the procedure characteristics must be the same for the associated actual argument and the corresponding dummy argument, except that a pure actual argument can be associated with a dummy argument that is not pure, and an elemental intrinsic actual procedure can be associated with a dummy procedure that is prohibited from being elemental.

If the interface of the dummy argument is implicit and either the name of the dummy argument is explicitly typed or it is referenced as a function, the dummy argument must not be referenced as a subroutine and the actual argument must be a function, function procedure pointer, or dummy procedure.

If the interface of the dummy argument is implicit and a reference to it appears as a subroutine reference, the actual argument must be a subroutine, subroutine procedure pointer, or dummy procedure.

An assumed-rank dummy argument can correspond to an actual argument of any rank. If the actual argument has rank zero (is a scalar), the dummy argument has rank zero; the shape is a zero-sized array and the LBOUND and UBOUND intrinsic functions, with no DIM argument, return zero-sized arrays. If the actual argument has rank greater than zero, the rank and extents of the dummy argument are assumed from the actual argument, including the lack of a final extent in the case of an assumed-size array. If the actual argument is an array and the dummy argument is allocatable or a pointer, the bounds of the dummy argument are assumed from the actual argument.

An assumed-type dummy argument must not correspond to an actual argument that is of a derived type that has type parameters, type-bound procedures, or final subroutines.

**Association For C Interoperability**

When a Fortran procedure that has an INTENT(OUT) allocatable dummy argument is invoked by a C function, and the actual argument in the C function is the address of a C descriptor that describes an allocated allocatable variable, the variable is deallocated upon entry to the Fortran procedure.

When a C function is invoked from a Fortran procedure by means of an interface with an INTENT(OUT) allocatable dummy argument, and the actual argument in the reference to the C function is an allocated allocatable variable, the variable is deallocated on invocation (before execution of the C function begins).

Argument Association in Procedures
Procedure Characteristics
Use and Host Association Overview

*Use association* allows the entities in a module to be accessible to other scoping units. *Host association* allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program.

Use association and host association remain in effect throughout the execution of the executable program.

An interface body does not access named entities by host association, but it can access entities by use association.

Examples

The following example shows host and use association:

```fortran
MODULE SHARE_DATA
  REAL Y, Z
END MODULE

PROGRAM DEMO
  USE SHARE_DATA ! All entities in SHARE_DATA are available
  REAL B, Q     ! through use association.
  ...
  CALL CONS (Y)
END PROGRAM DEMO

CONTAINS
  SUBROUTINE CONS (Y) ! Y is a local entity (dummy argument).
    REAL C, Y
    ...
    Y = B + C + Q + Z ! B and Q are available through host association.
    ...
    ! C is a local entity, explicitly declared.
  END SUBROUTINE CONS ! is available through use association.
```

*Use Association*  
*Host Association*  
*Scope*  for details on entities with local scope

Use Association

Use association allows the entities in a module to be accessible to other scoping units. This association remains in effect throughout the execution of the program. The mechanism for use association is the USE statement. The USE statement provides access to all public entities in the module, unless ONLY is specified. In this case, only the entities named in the ONLY list can be accessed.

If an entity that is accessed by use association has the same nongeneric name as a host entity, the host entity is inaccessible. A name that appears in the scoping unit as an external name in an EXTERNAL statement is a global name, and any entity of the host that has this as its nongeneric name is inaccessible.

For more information on rules that apply to use association, see the USE statement.

*Host Association*  
*Scope*  for details on entities with local scope

Host Association

Host association allows the entities in a host scoping unit to be accessible to an internal subprogram, a module subprogram, or submodule program. This association remains in effect throughout the execution of the program.
The following also have access to entities from its host:

- A module procedure interface body
- A derived-type definition
- An interface body that is not a separate interface body has access to the named entities from its host that are made accessible by IMPORT statements in the interface body.

The accessed entities are known by the same name and have the same attributes as in the host, except that a local entity can have the ASYNCHRONOUS attribute even if the host entity does not, and a noncoarray local entity can have the VOLATILE attribute even if the host entity does not. The accessed entities can be named data objects, derived types, abstract interfaces, procedures, generic identifiers, and namelist groups.

Entities that are local to a procedure are not accessible to their hosts.

The following are considered local identifiers within a scoping unit so they are not accessible to their hosts:

- A function name in a statement function, an entity declaration in a type declaration statement, or the name of an entity declared by an interface body, unless any of these are global identifiers.
- An object name in an entity declaration in a type declaration statement or a POINTER, SAVE, ALLOCATABLE, or TARGET statement.
- A type name in a derived type statement.
- A procedure pointer that has the EXTERNAL attribute.
- The name of a variable that is wholly or partially initialized in a DATA statement.
- The name of an object that is wholly or partially initialized in an EQUIVALENCE statement.
- A namelist group name in a NAMELIST statement.
- A generic name in a generic specification in an INTERFACE statement.
- The name of a named construct.
- The name of a dummy argument in a FUNCTION, SUBROUTINE, or ENTRY statement, or a statement function.
- A named constant defined in a PARAMETER statement.
- An array name in a DIMENSION statement.
- A variable name in a common block object in a COMMON statement.
- A result name in a FUNCTION or ENTRY statement.
- An intrinsic procedure name in an INTRINSIC statement.

A name that appears in an ASYNCHRONOUS or VOLATILE statement is not necessarily the name of a local variable. In an internal or module procedure, if a variable that is accessible via host association is specified in an ASYNCHRONOUS or VOLATILE statement, that host variable is given the ASYNCHRONOUS or VOLATILE attribute in the local scope.

If an intrinsic procedure is accessed by means of host association, it must be established to be intrinsic in the host scoping unit by one of the following methods:

- It must be explicitly given the INTRINSIC attribute.
- It must be invoked as an intrinsic procedure.
- It must be accessed from a module or from its host where it is established to be intrinsic.

If a procedure gains access to a pointer by host association, the association of the pointer with a target that is current at the time the procedure is invoked remains current within the procedure. This pointer association can be changed within the procedure. After execution of the procedure, the pointer association remains current, unless the execution caused the target to become undefined. If this occurs, the host associated pointer becomes undefined.

**NOTE**

Implicit declarations can cause problems for host association. It is recommended that you use IMPLICIT NONE in both the host and the contained procedure, and that you explicitly declare all entities.

When all entities are explicitly declared, local declarations override host declarations, and host declarations that are not overridden are available in the contained procedure.
Examples

The following example shows how a host and an internal procedure can use host-associated entities:

```fortran
program INTERNAL
! shows use of internal subroutine and CONTAINS statement
  real a,b,c
  call find
  print *, c
contains
  subroutine find
    read *, a,b
    c = sqrt(a**2 + b**2)
  end subroutine find
end
```

In this case, the variables `a`, `b`, and `c` are available to the internal subroutine `find` through host association. They do not have to be passed as arguments to the internal procedure. In fact, if they are, they become local variables to the subroutine and hide the variables declared in the host program.

Conversely, the host program knows the value of `c`, when it returns from the internal subroutine that has defined `c`.

*Use Association*

*Scope* for details on entities with local scope

**Linkage Association**

Linkage association occurs between the following:

- A module variable that has the BIND attribute and the C variable with which it interoperates
- A Fortran common block and the C variable with which it interoperates

This association remains in effect throughout the execution of the program.

**See Also**

*USE statement*

*Host Association*

*Scope* for details on entities with local scope

**Construct Association**

Construct association establishes an association between each selector and the corresponding associate name of an ASSOCIATE, CHANGE TEAM, SELECT RANK, or SELECT TYPE construct.

If the selector is allocatable, it must be allocated. The associate name is associated with the data object and does not have the ALLOCATABLE attribute.

If the selector has the POINTER attribute, it must be associated. The associate name is associated with the target of the pointer and does not have the POINTER attribute; it has the TARGET attribute if the selector is a variable that has the POINTER or TARGET attribute.

If the selector has the ASYNCHRONOUS or VOLATILE attribute, the entity associated with the corresponding associate name also has that attribute. If the selector is polymorphic, the associated entity has the same dynamic type and type parameters as the selector. If the selector has the OPTIONAL attribute, it must be present. If the selector is contiguous, the associated entity is also contiguous.

If the selector is a variable other than an array section having a vector subscript, the association is with the data object specified by the selector; otherwise, the association is with the value of the selector expression, which is evaluated before the execution of the block.
Each associate name remains associated with the corresponding selector throughout the execution of the executed block. Within the block, each selector is known by, and can be accessed by, the corresponding associate name. When the construct is terminated, the association is terminated.

Host Association
Additional Attributes Of Associate Names
Scope for details on entities with local scope

Additional Attributes Of Associate Names
In an ASSOCIATE, CHANGE TEAM, or SELECT TYPE construct, the rank of each entity identified by an associate name has the same rank as its corresponding selector. The lower bound of each dimension is the result of the intrinsic function LBOUND applied to the corresponding dimension of selector. The upper bound of each dimension is one less than the sum of the lower bound and the extent.

Each entity identified by an associate name in an ASSOCIATE, SELECT RANK, or SELECT TYPE construct has the same corank as the corresponding selector. The cobounds of each codimension of the entity are the same as those of the selector. In a CHANGE TEAM construct, the entity identified by an associate name is a coarray, with coshape and cobounds as specified in its codimension declaration.

The associated entity is a variable; it is not definable if the selector is not definable. An associate name or a subobject of the associate name is not allowed in a variable definition context or a pointer association context if the selector is not allowed in a variable definition context.

In a SELECT RANK construct, the selector has assumed rank, and assumed rank entities are not otherwise definable. However, in the block following a RANK(*) statement the associate name is the name of a one dimensional assumed-size array, and in the block following a RANK (scalar-int-const-expr), the variable has the specified rank. In these cases, if the selector is otherwise definable ignoring that it is assumed rank, the associated entity may be defined or undefined.

SELECT TYPE

Pointer Association
A pointer can be associated with a target. At different times during the execution of a program, a pointer can be undefined, associated with different targets, or be disassociated. The initial association status of a pointer is undefined. A pointer can become associated by the following:

- Pointer assignment (pointer => target)
  The target must be associated, or specified with the TARGET attribute. If the target is allocatable, it must be currently allocated.
- Allocation (successful execution of an ALLOCATE statement)
  The ALLOCATE statement must reference the pointer.

A pointer becomes disassociated if any of the following occur:

- The pointer is nullified by a NULLIFY statement.
- The pointer is deallocated by a DEALLOCATE statement.
- The pointer is assigned a disassociated pointer or the NULL intrinsic function.
- The pointer is an ultimate component of an object of a type for which default initialization is specified for the component and one of the following is true:
  - A procedure is invoked with this object as an actual argument corresponding to a nonpointer, nonallocatable, dummy argument with INTENT (OUT).
A procedure is invoked with this object as an unsaved, nonpointer, nonallocatable local object that is not accessed by use or host association.

This object is allocated.

When a pointer is associated with a target, the definition status of the pointer is defined or undefined, depending on the definition status of the target. A target is undefined in the following cases:

- If it was never allocated
- If it is not deallocated through the pointer
- If a RETURN or END statement causes it to become undefined

If a pointer is associated with a definable target, the definition status of the pointer can be defined or undefined, according to the rules for a variable.

The association status of a pointer becomes undefined when a DO CONCURRENT construct is terminated and the pointer’s association status was changed in more than one iteration of the construct.

If the association status of a pointer is disassociated or undefined, the pointer must not be referenced or deallocated.

Whatever its association status, a pointer can always be nullified, allocated, or associated with a target. When a pointer is nullified, it is disassociated. When a pointer is allocated, it becomes associated, but is undefined. When a pointer is associated with a target, its association and definition status are determined by its target.

**Storage Association**

*Storage association* describes the relationships that exist among data objects. It is the association of two or more data objects that occurs when two or more storage sequences share, or are aligned with, one or more *storage units*. Storage sequences are used to describe relationships among variables, common blocks, and result variables.

**See Also**
- Storage Units and Storage Sequence
- Array Association

**Storage Units and Storage Sequence**

A *storage unit* is a fixed unit of physical memory allocated to certain data. A *storage sequence* is a sequence of storage units. The size of a storage sequence is the number of storage units in the storage sequence. A storage unit can be numeric, character, or unspecified.

A nonpointer scalar of type default real, integer, or logical occupies one numeric storage unit. A nonpointer scalar of type double precision real or default complex occupies two contiguous numeric storage units. In Intel® Fortran, one numeric storage unit corresponds to 4 bytes of memory.

A nonpointer scalar of type default character with character length 1 occupies one character storage unit. A nonpointer scalar of type default character with character length `len` occupies `len` contiguous character storage units. In Intel® Fortran, one character storage unit corresponds to 1 byte of memory.

A nonpointer scalar of nondefault data type occupies a single unspecified storage unit. The number of bytes corresponding to the unspecified storage unit differs depending on the data type.

The following table lists the storage requirements (in bytes) for the intrinsic data types:
Data Type Storage Requirements

<table>
<thead>
<tr>

<tr>
<td>CHARACTER</td>
<td>1</td>
</tr>
<tr>
<td>CHARACTER*len</td>
<td>len</td>
</tr>
<tr>
<td>CHARACTER*(*)</td>
<td>assumed-length</td>
</tr>
</tbody>
</table>

1 Depending on default integer, LOGICAL and INTEGER can have 2, 4, or 8 bytes. The default allocation is four bytes.
2 Depending on default real, REAL can have 4, 8, or 16 bytes and COMPLEX can have 8, 16, or 32 bytes. The default allocations are four bytes for REAL and eight bytes for COMPLEX.
3 The value of len is the number of characters specified. The largest valid value is 2**31-1 on IA-32 architecture; 2**63-1 on Intel® 64 architecture. Negative values are treated as zero.
4 The assumed-length format *(*) applies to dummy arguments, PARAMETER statements, or character functions, and indicates that the length of the actual argument or function is used. (See Assumed-Length Character Arguments.)

A nonpointer scalar of sequence derived type occupies a sequence of storage sequences corresponding to the components of the structure, in the order they occur in the derived-type definition. Note that a sequence derived type has a SEQUENCE statement.
A pointer occupies a single unspecified storage unit that is different from that of any nonpointer object and is different for each combination of type, type parameters, and rank.

The definition status and value of a data object affects the definition status and value of any storage-associated entity.

When two objects occupy the same storage sequence, they are totally storage-associated. When two objects occupy parts of the same storage sequence, they are partially associated. An EQUIVALENCE statement, a COMMON statement, or an ENTRY statement can cause total or partial storage association of storage sequences.

Assumed-Length Character Arguments
COMMON
ENTRY
EQUIVALENCE

Array Association
A nonpointer array occupies a sequence of contiguous storage sequences, one for each array element, in array element order.

Two or more arrays are associated when each one is associated with the same storage location. They are partially associated when part of the storage associated with one array is the same as part or all of the storage associated with another array.

If arrays with different data types are associated, or partially associated, with the same storage location, and the value of one array is defined (for example, by assignment), the value of the other array becomes undefined. This happens because an element of an array is considered defined only if the storage associated with it contains data of the same type as the array name.

An array element, array section, or whole array is defined by a DATA statement before program execution. Note that the array properties must be declared in a previous specification statement. During program execution, array elements and sections are defined by an assignment or input statement, and entire arrays are defined by input statements.

Storage Association
Pointer Association
Deleted and Obsolescent Language Features

Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 deleted some Fortran 90 features, and identified some Fortran 90 language features to be obsolescent.

Fortran 90 identified some FORTRAN 77 features to be obsolescent. Fortran 95 deleted some Fortran 90 obsolescent features, and identified some Fortran 90 language features to become obsolescent. Subsequent standard revisions have continued to identify some features of previous standards as obsolescent and to delete selected features that were previously deemed obsolescent.

Fortran 2008 has also identified some earlier standard language features to be obsolescent. Features considered obsolescent may be removed from future revisions of the Fortran Standard.

Fortran 2018 identified the following language features as obsolescent: the COMMON and EQUIVALENCE statement, the FORALL statement and construct, BLOCK DATA subprograms, labeled DO loops, and specific names for intrinsic procedures. The arithmetic IF statement and the non-block form of DO constructs were deleted in Fortran 2018.

To have these features flagged, you can specify compiler option stand.

NOTE
Intel® Fortran fully supports features identified as deleted from or obsolescent in the Fortran Standard.

See Also
stand compiler option

Deleted Language Features in the Fortran Standard

Some language features, considered redundant in older versions of the Fortran Standard, are not included in the current Fortran Standard. However, they are still fully supported by Intel® Fortran.

In the examples below, both forms are supported by Intel® Fortran, but the Fortran 2018 Standard only supports the second form:

- ASSIGN and assigned GO TO statements

  The ASSIGN statement, when assigning a label for use with the assigned GO TO statement, can be replaced by assigning the integer value of the label to an integer variable; the assigned GO TO statement can then be replaced by an IF statement that tests the integer variable for various values and then goes to the label that represents that value. For example, replace:

```fortran
ASSIGN 10 TO J
...
ASSIGN 20 TO J
...
GO TO J
```

with:

```fortran
J = 10
...
J = 20
...
IF (J.EQ. 10) THEN
   GO TO 10
```

1121
ELSE IF (J .EQ. 20) THEN
    GO TO 20
END IF

• Arithmetic IF statement

The arithmetic IF statement can be replace by an IF-THEN-ELSE construct or a CASE SELECT construct.

For example, replace:

IF (expr) 10, 20, 30

with:

IF (expr .LT. 0) THEN
  GO TO 10
ELSE IF (expr .EQ. 0) THEN
  GO TO 20
ELSE
  GO TO 30
ENDIF

• Assigned FORMAT specifier

The assigned FORMAT specifier sets an integer variable to the label of a FORMAT statement and then the integer variable is used in an I/O statement instead of the FORMAT label. You can replace the integer variable with a character variable whose value is the contents of the FORMAT statement, and then use the character variable in the I/O statement as the format. For example, replace:

ASSIGN 1000 TO IFMT
...
WRITE (6, IFMT) X, Y
...
1000 FORMAT (2E10.2)

with:

CHARACTER(20) :: IFMT = "(2E10.2)"
...
WRITE (6, IFMT) X, Y

• The non-block form of a DO statement

The non-block form of a DO loop contains a statement label in the DO statement identifying the terminal statement of the DO. The terminal statement may be an executable statement and may be shared with another non-block DO statement. Use an END DO statement as the terminal statement for each DO loop.

You should not use statement labels on the terminating statement and in the DO statement, because labeled DO loops are now obsolescent.

For example, replace the following:

DO 10 I = 1, N
  DO 10 J = 1, M
10  A(I, J) = F_OF (I, J)

with this:

DO I = 1, N
  DO J = 1, M
    A(I, J) = F_OF (I, J)
END DO
END DO

• Branching to an END IF statement from outside its IF block
The END IF statement can no longer be a target of a GO TO statement that is outside the IF block that ends with that END IF statement. Use a CONTINUE statement after the END IF as the target of the GO TO statement. For example, replace:

```
IF ...  
   GO TO 100
ELSE IF ...  
100   END IF
```

with:

```
IF ...  
   GO TO 100
ELSE IF ...  
END IF
100   CONTINUE
```

- **H edit descriptor**

  Replace the H edit descriptor of the form \(nH\text{characters}\) with "\text{characters}". Remember to double any quotes or apostrophes in the string \text{characters}.

- **PAUSE statement**

  The PAUSE statement displays a character string on the standard output device and then suspends program execution until any character is typed on the standard input device. You can replace the PAUSE statement with a WRITE statement followed by a READ statement. For example, replace:

  ```
  PAUSE " don’t forget to buy milk"
  ```

  with:

  ```
  WRITE (6, ") " don’t forget to buy milk"
  READ (5, *)  ! no io-list is necessary, the input is ignored
  ```

- **Real and double precision DO control variables and DO loop control expressions**

  REAL variables of any KIND can no longer be used as DO loop control variables and expressions. You can replace such DO loops with the appropriate DO WHILE loop that explicitly initializes, increments, and tests the REAL variable. For example, replace:

  ```
  DO X = 0.1, 0.5, 0.01  
...  
END DO
  ```

  with:

  ```
  X = 0.1  
DO WHILE (X .LE. 0.5)  
...  
   X = X + 0.01  
END DO
  ```

- **Vertical format control**

  Formatted output to certain printing output units used to result in the first character of each record being interpreted as controlling vertical spacing on the unit. There is no standard way to detect whether output to such a unit should result in such vertical format control and no way to specify that it should be applied. The effect can be achieved by post-processing a formatted file after it is created to interpret the first character as some form of control character. This is left to the user.

Intel Fortran flags these features if you specify compiler option `stand`.

**See Also**

Obsolescent Language Features in the Fortran Standard

`stand` compiler option
Obsolescent Language Features in the Fortran Standard

Some language features, considered redundant in older versions of the Fortran Standard, are identified as obsolescent in the current Fortran Standard.

Intel® Fortran flags these features if you specify compiler option stand.

Other methods are suggested to achieve the functionality of the following obsolescent features:

- **Alternate returns (labels in an argument list)**
  To replace this functionality, it is recommended that you use an integer variable to return a value to the calling program, and let the calling program use a **CASE construct** to test the value and perform operations.

- **Assumed-length character functions**
  To replace this functionality, it is recommended that you use one of the following:
  - An automatic character-length function, where the length of the function result is declared in a specification expression
  - A subroutine whose arguments correspond to the function result and the function arguments

  Dummy arguments of a function can still have assumed character length; this feature is not obsolescent.

- **BLOCK DATA subprograms**
  BLOCK DATA was used to initialize COMMON block variables. This can be achieved with initialization of MODULE data when it is declared. MODULE data is the preferred method of sharing data between compilation units, and for replacing COMMON blocks.

- **CHARACTER*(*) form of CHARACTER declaration**
  To replace this functionality, it is recommended that you use the Fortran 90 forms of specifying a length selector in CHARACTER declarations (see Declaration Statements for Character Types).

- **COMMON blocks**
  To replace this functionality, it is recommended data specified in COMMON be declared in a MODULE which can be made available through USE association where the data is needed.

- **Computed GO TO statement**
  To replace this functionality, it is recommended that you use a **CASE construct**.

- **DATA statements among executable statements**
  This functionality has been included since FORTRAN 66, but is considered to be a potential source of errors.

- **ENTRY statement**
  To replace this functionality, it is recommended that you use multiple module procedures that can access shared data in the module.

- **EQUIVALENCE**
  The use of storage association thru EQUIVALENCE statements is not recommended.

- **Fixed source form**
  Newer methods of entering data have made this source form obsolescent and error-prone.

  The recommended method for coding is to use **free source form**.

- **FORALL statement and construct**
  These were added to the language with the expectation they would result in very efficient and possibly parallel code. The complexity and many restrictions prevented compilers from taking advantage of them.

  The DO CONCURRENT construct makes FORALL redundant. Data manipulations which can be done with FORALL can be done more effectively with pointers using rank remapping. Both the FORALL statement form and the construct became obsolescent in Fortran 2018.

- **Labeled DO loops**
  To replace this functionality, it is recommended that you use an END DO statements to terminate loops, and CYCLE statements to branch to the end of the loop to start the next iteration of the loop (or exit the loop, if the last iteration of the loop takes the branch).

- **Statement functions**
To replace this functionality, it is recommended that you use an internal function.

- Specific names of intrinsic functions that also have generic names
  To replace this functionality, it is recommended that you use the generic names.

# Additional Language Features

To facilitate compatibility with older versions of Fortran, Intel® Fortran provides the following additional language features:

- The DEFINE FILE statement
- The ENCODE and DECODE statements
- The FIND statement
- The INTERFACE TO statement
- FORTRAN 66 Interpretation of the EXTERNAL Statement
- An alternative syntax for the PARAMETER statement
- The VIRTUAL statement
- An alternative syntax for binary, octal, and hexadecimal constants
- An alternative syntax for a record specifier
- An alternate syntax for the DELETE statement
- An alternative form for namelist external records
- The integer POINTER statement
- Record structures

These language features are particularly useful in porting older Fortran programs to Standard Fortran. However, you should avoid using them in new programs on these systems, and in new programs for which portability to other Standard Fortran implementations is important.

## FORTRAN 66 Interpretation of the EXTERNAL Statement

If you specify compiler option f66, the EXTERNAL statement is interpreted in the way that was specified by the FORTRAN 66 (FORTRAN IV) standard. This interpretation became incompatible with FORTRAN 77 and later revisions of the Fortran standard.

The FORTRAN 66 interpretation of the EXTERNAL statement combines the functionalities of the INTRINSIC statement and the EXTERNAL statement.

This lets you use subprograms as arguments to other subprograms. The subprograms to be used as arguments can be either user-supplied procedures or Fortran intrinsic procedures.

The FORTRAN 66 EXTERNAL statement takes the following form:

**EXTERNAL [\*]v [, [\*]v] ...**

- \* Specifies that a user-supplied external procedure is to be used instead of a Fortran intrinsic procedure having the same name. This modifier is not standard FORTRAN 66, but was an extension in some FORTRAN 66 compilers, and provides the FORTRAN 77 meaning of EXTERNAL where required.

- v Is the name of a subprogram or the name of a dummy argument associated with the name of a subprogram.

**Description**

The FORTRAN 66 EXTERNAL statement declares that each name in its list is an external procedure name. Such a name can then be used as an actual argument to a subprogram, which then can use the corresponding dummy argument in a function reference or CALL statement.
However, when used as an argument, a complete function reference represents a value, not a subprogram name; for example, SQRT(B) in CALL SUBR(A, SQRT(B), C). Therefore, it does not need to be defined in an EXTERNAL statement. Note that the incomplete reference SQRT would need to be defined in an EXTERNAL statement.

**Examples**

The following example, when compiled with compiler option f66, shows the FORTRAN 66 EXTERNAL statement:

```
Main Program                        Subprograms
EXTERNAL SIN, COS, *TAN, SINDEG     SUBROUTINE TRIG(X,F,Y)
.                                    Y = F(X)
.                                    RETURN
.                                    END
CALL TRIG(ANGLE, SIN, SINE)
.                                    FUNCTION TAN(X)
.                                    TAN = SIN(X)/COS(X)
CALL TRIG(ANGLE, COS, COSINE)       RETURN
.                                    END
.                                    END
CALL TRIG(ANGLE, TAN, TANGNT)       FUNCTION SINDEG(X)/
.                                    SINDEG = SIN(X*3.1459/180)
.                                    RETURN
.                                    END
CALL TRIG(ANGLED, SINDEG, SINE)
```

The CALL statements pass the name of a function to the subroutine TRIG. The function reference F(X) subsequently invokes the function in the second statement of TRIG. Depending on which CALL statement invoked TRIG, the second statement is equivalent to one of the following:

- \( Y = \sin(X) \)
- \( Y = \cos(X) \)
- \( Y = \tan(X) \)
- \( Y = \text{SINDEG}(X) \)

The functions SIN and COS are examples of trigonometric functions supplied in the Fortran intrinsic procedure library. The function TAN is also supplied in the library, but the asterisk (*) in the EXTERNAL statement specifies that the user-supplied function be used, instead of the intrinsic function. The function SINDEG is also a user-supplied function. Because no library function has the same name, no asterisk is required.

**See Also**

f66 compiler option

**Alternative Syntax for the PARAMETER Statement**

The PARAMETER statement discussed here is similar to the one discussed in PARAMETER; they both assign a name to a constant. However, this PARAMETER statement differs from the other one in the following ways:

- Its list is not bounded with parentheses.
- The form of the constant, rather than implicit or explicit typing of the name, determines the data type of the variable.

This PARAMETER statement takes the following form:

```
PARAMETER  \( c = \text{expr} [, c = \text{expr}] \ldots \)```
**Description**

Each name `c` becomes a constant and is defined as the value of expression `expr`. Once a name is defined as a constant, it can appear in any position in which a constant is allowed. The effect is the same as if the constant were written there instead of the name.

The name of a constant cannot appear as part of another constant, except as the real or imaginary part of a complex constant. For example:

```fortran
PARAMETER I=3
PARAMETER M=I.25           ! Not allowed
PARAMETER N=(1.703, I)     ! Allowed
```

The name used in the `PARAMETER` statement identifies only the name's corresponding constant in that program unit. Such a name can be defined only once in `PARAMETER` statements within the same program unit.

The name of a constant assumes the data type of its corresponding constant expression. The data type of a parameter constant cannot be specified in a type declaration statement. Nor does the initial letter of the constant's name implicitly affect its data type.

**Examples**

The following are valid examples of this form of the `PARAMETER` statement:

```fortran
PARAMETER PI=3.1415927, DPI=3.141592653589793238D0
PARAMETER PIOV2=PI/2, DPIOV2=DPI/2
PARAMETER FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS'
```

---

**Alternative Syntax for Binary, Octal, and Hexadecimal Constants**

In Intel® Fortran, you can use an alternative syntax for binary, octal, and hexadecimal constants. The following table shows the alternative syntax and equivalents:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Alternative Syntax</th>
<th>Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>'0..1'B</td>
<td>B'0..1'</td>
</tr>
<tr>
<td>Octal</td>
<td>'0..7'O</td>
<td>0'0..7'</td>
</tr>
<tr>
<td>Hexadecimal</td>
<td>'0..F'X</td>
<td>Z'0..F'</td>
</tr>
<tr>
<td></td>
<td>X'0..F'</td>
<td></td>
</tr>
</tbody>
</table>

You can use a quotation mark ("') in place of an apostrophe in all the above syntax forms.

For information on the # syntax for integers not in base 10, see Integer Constants.

**See Also**

Binary constants
Octal constants
Hexadecimal constants
**Alternative Syntax for a Record Specifier**

In Intel® Fortran, you can specify the following form for a record specifier in an I/O control list:

```
r
```

Is a numeric expression with a value that represents the position of the record to be accessed using direct access I/O.

The value must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file. If necessary, a record number is converted to integer data type before being used.

If this nonkeyword form is used in an I/O control list, it must immediately follow the nonkeyword form of the io-unit specifier.

**Alternative Syntax for the DELETE Statement**

In Intel® Fortran, you can specify the following form of the DELETE statement when deleting records from a relative file:

```
DELETE ( io-unit 'r ', ERR=label [, IOSTAT=i-var] )
```

- **io-unit** Is the number of the logical unit containing the record to be deleted.
- **r** Is the positional number of the record to be deleted.
- **label** Is the label of an executable statement that receives control if an error condition occurs.
- **i-var** Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

This form deletes the direct access record specified by `r`.

**See Also**

DELETE statement

**Alternative Form for Namelist External Records**

In Intel® Fortran, you can use the following form for an external record:

```
$group-name object = value [object = value] ...[END]
```

- **group-name** Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit.
- **object** Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks, but it can be preceded or followed by blanks.
- **value** Is a null value, a constant (or list of constants), a repetition of constants in the form r*c, or a repetition of null values in the form r*.

If more than one `object=value` or more than one value is specified, they must be separated by value separators.

A value separator is any number of blanks, or a comma or slash, preceded or followed by any number of blanks.

**See Also**

NAMELIST statement
Record Structures

The record structure was defined in earlier versions of Intel® Fortran as a language extension. It is still supported, although its functionality has been replaced by Standard Fortran derived data types. Record structures in existing code can be easily converted to Standard Fortran derived type structures for portability, but can also be left in their old form. In most cases, an Intel Fortran record and a Standard Fortran derived type can be used interchangeably.

Intel Fortran record structures are similar to Standard Fortran derived types.

A record structure is an aggregate entity containing one or more elements. (Record elements are also called fields or components.) You can use records when you need to declare and operate on multi-field data structures in your programs.

Creating a record is a two-step process:

1. You must define the form of the record with a multistatement structure declaration.
2. You must use a RECORD statement to declare the record as an entity with a name. (More than one RECORD statement can refer to a given structure.)

Examples

Intel Fortran record structures, using only intrinsic types, easily convert to Standard Fortran derived types. The conversion can be as simple as replacing the keyword STRUCTURE with TYPE and removing slash ( / ) marks. The following shows an example conversion:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Standard Fortran Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_name/</td>
<td>TYPE employee_name</td>
</tr>
<tr>
<td>CHARACTER*25 last_name</td>
<td>CHARACTER*25 last_name</td>
</tr>
<tr>
<td>CHARACTER*15 first_name</td>
<td>CHARACTER*15 first_name</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
<tr>
<td>STRUCTURE /employee_addr/</td>
<td>TYPE employee_addr</td>
</tr>
<tr>
<td>CHARACTER*20 street_name</td>
<td>CHARACTER*20 street_name</td>
</tr>
<tr>
<td>INTEGER(2) street_number</td>
<td>INTEGER(2) street_number</td>
</tr>
<tr>
<td>INTEGER(2) apt_number</td>
<td>INTEGER(2) apt_number</td>
</tr>
<tr>
<td>CHARACTER*20 city</td>
<td>CHARACTER*20 city</td>
</tr>
<tr>
<td>CHARACTER*2 state</td>
<td>CHARACTER*2 state</td>
</tr>
<tr>
<td>INTEGER(4) zip</td>
<td>INTEGER(4) zip</td>
</tr>
<tr>
<td>END STRUCTURE</td>
<td>END TYPE</td>
</tr>
</tbody>
</table>

The record structures can be used as subordinate record variables within another record, such as the employee_data record. The equivalent Standard Fortran derived type would use the derived-type objects as components in a similar manner, as shown below:

<table>
<thead>
<tr>
<th>Record Structure</th>
<th>Standard Fortran Derived-Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>STRUCTURE /employee_data/</td>
<td>TYPE employee_data</td>
</tr>
<tr>
<td>RECORD /employee_name/name</td>
<td>TYPE (employee_name) name</td>
</tr>
<tr>
<td>RECORD /employee_addr/addr</td>
<td>TYPE (employee_addr) addr</td>
</tr>
<tr>
<td>INTEGER(4) telephone</td>
<td>INTEGER(4) telephone</td>
</tr>
<tr>
<td>INTEGER(2) date_of_birth</td>
<td>INTEGER(2) date_of_birth</td>
</tr>
<tr>
<td>INTEGER(2) date_of_hire</td>
<td>INTEGER(2) date_of_hire</td>
</tr>
<tr>
<td>INTEGER(2) social_security(3)</td>
<td>INTEGER(2) social_security(3)</td>
</tr>
</tbody>
</table>
Record Structure

<table>
<thead>
<tr>
<th>LOGICAL(2) married</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(2) dependents</td>
</tr>
<tr>
<td>END STRUCTURE</td>
</tr>
</tbody>
</table>

Standard Fortran Derived-Type

<table>
<thead>
<tr>
<th>LOGICAL(2) married</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER(2) dependents</td>
</tr>
<tr>
<td>END TYPE</td>
</tr>
</tbody>
</table>

RECORD Statement

Structure Declarations

A structure declaration defines the field names, types of data within fields, and order and alignment of fields within a record. Fields and structures can be initialized, but records cannot be initialized. For more information, see STRUCTURE.

Type Declarations
Substructure Declarations
Union Declarations

Type Declarations within Record Structures

The syntax of a type declaration within a record structure is identical to that of a normal Fortran type statement.

The following rules and behavior apply to type declarations in record structures:

- %FILL can be specified in place of a field name to leave space in a record for purposes such as alignment. This creates an unnamed field.

  %FILL can have an array specification; for example:

  INTEGER %FILL (2,2)

  Unnamed fields cannot be initialized. For example, the following statement is invalid and generates an error message:

  INTEGER %FILL /1980/

- Initial values can be supplied in field declaration statements. Unnamed fields cannot be initialized; they are always undefined.

- Field names must always be given explicit data types. The IMPLICIT statement does not affect field declarations.

- Any required array dimensions must be specified in the field declaration statements. DIMENSION statements cannot be used to define field names.

- Adjustable or assumed sized arrays and assumed-length CHARACTER declarations are not allowed in field declarations.

Substructure Declarations

A field within a structure can itself be a structured item composed of other fields, other structures, or both. You can declare a substructure in two ways:

- By nesting structure declarations within other structure or union declarations (with the limitation that you cannot refer to a structure inside itself at any level of nesting).

  One or more field names must be defined in the STRUCTURE statement for the substructure, because all fields in a structure must be named. In this case, the substructure is being used as a field within a structure or union.

  Field names within the same declaration nesting level must be unique, but an inner structure declaration can include field names used in an outer structure declaration without conflict.
By using a RECORD statement that specifies another previously defined record structure, thereby including it in the structure being declared.

See the example in STRUCTURE for a sample structure declaration containing both a nested structure declaration (TIME) and an included structure (DATE).

References to Record Fields

References to record fields must correspond to the kind of field being referenced. Aggregate field references refer to composite structures (and substructures). Scalar field references refer to singular data items, such as variables.

An operation on a record can involve one or more fields.

Record field references take one of the following forms:

**Aggregate Field Reference:**

\[
\text{record-name} [.\text{aggregate-field-name}] ...
\]

**Scalar Field Reference:**

\[
\text{record-name} [.\text{aggregate-field-name}] ... .\text{scalar-field-name}
\]

- `record-name` is the name used in a RECORD statement to identify a record.
- `aggregate-field-name` is the name of a field that is a substructure (a record or a nested structure declaration) within the record structure identified by the record name.
- `scalar-field-name` is the name of a data item (having a data type) defined within a structure declaration.

Description

Records and record fields cannot be used in DATA statements, but individual fields can be initialized in the STRUCTURE definition.

An automatic array cannot be a record field.

A scalar field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names followed by the name of a scalar field. A scalar field reference refers to a single data item (having a data type) and can be treated like a normal reference to a Fortran variable or array element.

You can use scalar field references in statement functions and in executable statements. However, they cannot be used in COMMON, SAVE, NAMELIST, or EQUIVALENCE statements, or as the control variable in an indexed DO-loop.

Type conversion rules for scalar field references are the same as those for variables and array elements.

An aggregate field reference consists of the name of a record (as specified in a RECORD statement) and zero or more levels of aggregate field names.

You can only assign an aggregate field to another aggregate field (record = record) if the records have the same structure. Intel Fortran supports no other operations (such as arithmetic or comparison) on aggregate fields.

Intel Fortran requires qualification on all levels. While some languages allow omission of aggregate field names when there is no ambiguity as to which field is intended, Intel Fortran requires all aggregate field names to be included in references.
You can use aggregate field references in unformatted I/O statements; one I/O record is written no matter how many aggregate and array name references appear in the I/O list. You cannot use aggregate field references in formatted, namelist, and list-directed I/O statements.

You can use aggregate field references as actual arguments and record dummy arguments. The declaration of the dummy record in the subprogram must match the form of the aggregate field reference passed by the calling program unit; each structure must have the same number and types of fields in the same order. The order of map fields within a union declaration is irrelevant.

Records are passed by reference. Aggregate field references are treated like normal variables. You can use adjustable arrays in RECORD statements that are used as dummy arguments.

**Examples**

The following examples show record and field references. Consider the following structure declarations:

**Structure DATE:**

```fortran
  STRUCTURE /DATE/
      INTEGER*1 DAY, MONTH
      INTEGER*2 YEAR
  STRUCTURE
```

**Structure APPOINTMENT:**

```fortran
  STRUCTURE /APPOINTMENT/
      RECORD /DATE/      APP_DATE
      STRUCTURE /TIME/   APP_TIME(2)
          INTEGER*1 HOUR, MINUTE
      END STRUCTURE
      CHARACTER*20 APP_MEMO(4)
      LOGICAL*1 APP_FLAG
  END STRUCTURE
```

The following RECORD statement creates a variable named NEXT_APP and a 10-element array named APP_LIST. Both the variable and each element of the array take the form of the structure APPOINTMENT.

```fortran
  RECORD /APPOINTMENT/    NEXT_APP,APP_LIST(10)
```

Each of the following examples of record and field references are derived from the previous structure declarations and RECORD statement:

**Aggregate Field References**

- The record NEXT_APP:

  ```fortran
  NEXT_APP
  ```

- The field APP_DATE, a 4-byte array field in the record array APP_LIST(3):

  ```fortran
  APP_LIST(3).APP_DATE
  ```

**Scalar Field References**

- The field APP_FLAG, a LOGICAL field of the record NEXT_APP:

  ```fortran
  NEXT_APP.APP_FLAG
  ```

- The first character of APP_MEMO(1), a CHARACTER*20 field of the record NEXT_APP:

  ```fortran
  NEXT_APP.APP_MEMO(1)(1:1)
  ```
NOTE
Because periods are used in record references to separate fields, you should avoid using relational
operators (.EQ., .XOR.), logical constants (.TRUE., .FALSE.), and logical expressions
(.AND., .NOT., .OR.) as field names in structure declarations. Dots can also be used instead of % to
separate fields of a derived type.

Consider the following example:

```fortran
module mod
  type T1_t
    integer :: i
  end type T1_t
  type T2_t
    type (T1_t) :: eq
    integer    :: i
  end type T2_t

  interface operator (.eq.)
    module procedure eq_func
  end interface operator (.eq.)

  contains
  function eq_func(t2, i) result (rslt)
    type(T2_t), intent (in) :: t2
    integer,   intent (in) :: i
    rslt = t2%eq%i + i
  end function eq_func
end module mod

use mod
  type(T2_t) :: t2
  integer    :: i
  t2%eq%i = 0
  t2%i    = -10
  i       = -10
  print *, t2.eq.i, (t2).eq.i
end
```

In this case, the reference "t2.eq.i" prints 0. The reference "(t2).eq.i" will invoke eq_func and will print -10.

Aggregate Assignment

For aggregate assignment statements, the variable and expression must have the same structure as the
aggregate they reference.

The aggregate assignment statement assigns the value of each field of the aggregate on the right of an equal
sign to the corresponding field of the aggregate on the left. Both aggregates must be declared with the same
structure.
Examples

The following example shows valid aggregate assignments:

```fortran
STRUCTURE /DATE/
   INTEGER*1 DAY, MONTH
   INTEGER*2 YEAR
END STRUCTURE

RECORD /DATE/ TODAY, THIS_WEEK(7)
STRUCTURE /APPOINTMENT/
   ...
   RECORD /DATE/ APP_DATE
END STRUCTURE

RECORD /APPOINTMENT/ MEETING

DO I = 1,7
   CALL GET_DATE (TODAY)
   THIS_WEEK(I) = TODAY
   THIS_WEEK(I).DAY = TODAY.DAY + 1
END DO
MEETING.APP_DATE = TODAY
```

Additional Character Sets

This topic contains information about the additional character sets you can use in your Fortran programs.

Character and Key Code Charts for Windows*

This topic contains the ASCII and ANSI character code charts, and the Key code charts that are available on Windows* OS.

ASCII Character Codes for Windows*

The ASCII character code charts contain the decimal and hexadecimal values of the extended ASCII (American Standards Committee for Information Interchange) character set. The extended character set includes the ASCII character set (Chart 1) and 128 other characters for graphics and line drawing (Chart 2), often called the "IBM* character set".

### ANSI Character Codes for Windows*

The ANSI character code chart lists the extended character set of most of the programs used by Windows* operating systems. The codes of the ANSI (American National Standards Institute) character set from 32 through 126 are displayable characters from the ASCII character set. The ANSI characters displayed as solid blocks are undefined characters and may appear differently on output devices.

### Key Codes for Windows*

Some keys, such as function keys, cursor keys, and ALT+KEY combinations, have no ASCII code. When a key is pressed, a microprocessor within the keyboard generates an "extended scan code" of two bytes.

The first (low-order) byte contains the ASCII code, if any. The second (high-order) byte has the scan code—a unique code generated by the keyboard when a key is either pressed or released. Because the extended scan code is more extensive than the standard ASCII code, programs can use it to identify keys which do not have an ASCII code.

For more details on key codes, see:
- Key Codes Chart 1
- Key Codes Chart 2

# ASCII Character Set for Linux* and macOS*

This topic describes the ASCII character set that is available on Linux* and macOS* operating systems.

The ASCII character set contains characters with decimal values 0 through 127. The first half of each of the numbered columns identifies the character as you would enter it on a terminal or as you would see it on a printer. Except for SP and HT, the characters with names are nonprintable. In the figure, the characters with names are defined as follows:

<table>
<thead>
<tr>
<th>Key</th>
<th>Scan Code</th>
<th>ASCII (Extended)</th>
<th>ASCII (Extended) with CTRL</th>
<th>ASCII (Extended) with ALT</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUL</td>
<td>00 00</td>
<td>Null</td>
<td>DC1</td>
<td>Device Control 1 (XON)</td>
</tr>
<tr>
<td>SOH</td>
<td>01 00</td>
<td>Start of Heading</td>
<td>DC2</td>
<td>Device Control 2</td>
</tr>
<tr>
<td>STX</td>
<td>02 00</td>
<td>Start of Text</td>
<td>DC3</td>
<td>Device Control 3</td>
</tr>
<tr>
<td>ETX</td>
<td>03 00</td>
<td>End of Text</td>
<td>DC4</td>
<td>Device Control 4</td>
</tr>
<tr>
<td>EOT</td>
<td>04 00</td>
<td>End of Transmission</td>
<td>NAK</td>
<td>Negative Acknowledge</td>
</tr>
</tbody>
</table>

† Extended codes return a "NUL" or a 01 hexadecimal character.
§ These key combinations are only available on extended keyboards.
$ These combinations are only available on extended keyboards. They are the only available on extended keyboards. They are not available on the VT100 or VT220 keyboards.

†† Under the X-POS, START, STOP, and CTRL-S commands, the scan codes are interpreted as escape codes. Under the X-POS, START, and CTRL-S commands, the scan codes are interpreted as escape codes.
The remaining half of each column identifies the character by the binary value of the byte; the value is stated in three radices—octal, decimal, and hexadecimal. For example, the uppercase letter A has, under ASCII conventions, a storage value of hexadecimal 41 (a bit configuration of 01000001), equivalent to 101 in octal notation and 65 in decimal notation.

ASCII Character Set (L*X, M*X)

Data Representation Models

Several of the numeric intrinsic functions are defined by a model set for integers (for each intrinsic kind used) and reals (for each real kind used). The bit functions are defined by a model set for bits (binary digits).

The following intrinsic functions provide information on the data representation models:

<table>
<thead>
<tr>
<th>Intrinsic function</th>
<th>Model</th>
<th>Value returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>Bit</td>
<td>The number of bits (s) in the bit model</td>
</tr>
<tr>
<td>DIGITS</td>
<td>Integer or Real</td>
<td>The number of significant digits in the model for the argument</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Real</td>
<td>The number that is almost negligible when compared to one</td>
</tr>
<tr>
<td>EXPONENT</td>
<td>Real</td>
<td>The value of the exponent part of a real argument</td>
</tr>
<tr>
<td>FRACTION</td>
<td>Real</td>
<td>The fractional part of a real argument</td>
</tr>
<tr>
<td>HUGE</td>
<td>Integer or Real</td>
<td>The largest number in the model for the argument</td>
</tr>
</tbody>
</table>
## Intrinsic function

<table>
<thead>
<tr>
<th>Intrinsic function</th>
<th>Model</th>
<th>Value returned</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAXEXPONENT</td>
<td>Real</td>
<td>The maximum exponent in the model for the argument</td>
</tr>
<tr>
<td>MINEXPONENT</td>
<td>Real</td>
<td>The minimum exponent in the model for the argument</td>
</tr>
<tr>
<td>NEAREST</td>
<td>Real</td>
<td>The nearest different machine-representable number in a given direction</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Real</td>
<td>The decimal precision (real or complex) of the argument</td>
</tr>
<tr>
<td>RADIX</td>
<td>Integer or Real</td>
<td>The base of the model for the argument</td>
</tr>
<tr>
<td>RANGE</td>
<td>Integer or Real</td>
<td>The decimal exponent range of the model for the argument</td>
</tr>
<tr>
<td>RRSPACING</td>
<td>Real</td>
<td>The reciprocal of the relative spacing near the argument</td>
</tr>
<tr>
<td>SCALE</td>
<td>Real</td>
<td>The value of the exponent part (of the model for the argument) changed by a specified value</td>
</tr>
<tr>
<td>SET_EXPONENT</td>
<td>Real</td>
<td>The value of the exponent part (of the model for the argument) set to a specified value</td>
</tr>
<tr>
<td>SPACING</td>
<td>Real</td>
<td>The value of the absolute spacing of model numbers near the argument</td>
</tr>
<tr>
<td>TINY</td>
<td>Real</td>
<td>The smallest positive number in the model for the argument</td>
</tr>
</tbody>
</table>

For more information on the range of values for each data type (and kind), see Data and I/O in the Compiler Reference.

## Model for Integer Data

In general, the model set for integers is defined as follows:

\[
i = s \times \sum_{k=1}^{q} w_k \times r^{k-1}
\]

The following values apply to this model set:
- \( i \) is the integer value.
- \( s \) is the sign (either +1 or -1).
- \( q \) is the number of digits (a positive integer).
- \( r \) is the radix (an integer greater than 1).
- \( w_k \) is a nonnegative number less than \( r \).

The model for INTEGER(4) follows:
The following example shows the general integer model for \( i = -20 \) using a base \((r)\) of 2:

\[
i = (-1) \times (0 \times 2^0 + 0 \times 2^1 + 1 \times 2^2 + 0 \times 2^3 + 1 \times 2^4)
\]

\[
i = (-1) \times (4 + 16)
\]

\[
i = -1 \times 20
\]

\[
i = -20
\]

**Model for Real Data**

The model set for reals, in general, is defined as one of the following:

\[ x = 0 \]

\[ x = s \times b^e \times \sum_{k=1}^{p} f_k \times b^{-k} \]

The following values apply to this model set:

- \( x \) is the real value.
- \( s \) is the sign (either +1 or -1).
- \( b \) is the base (real radix; an integer greater than 1; \( b = 2 \) in Intel\textsuperscript{®} Fortran).
- \( p \) is the number of mantissa digits (an integer greater than 1). The number of digits differs depending on the real format, as follows:

<table>
<thead>
<tr>
<th>Format</th>
<th>IEEE Format</th>
<th>Digits</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL(4)</td>
<td>IEEE binary32</td>
<td>24</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>IEEE binary64</td>
<td>53</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>IEEE binary128</td>
<td>113</td>
</tr>
</tbody>
</table>

- \( e \) is an integer in the range \( e_{\min} \) to \( e_{\max} \) inclusive. This range differs depending on the real format, as follows:

<table>
<thead>
<tr>
<th>Format</th>
<th>IEEE Format</th>
<th>( e_{\min} )</th>
<th>( e_{\max} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>REAL(4)</td>
<td>IEEE binary32</td>
<td>-125</td>
<td>128</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>IEEE binary64</td>
<td>-1021</td>
<td>1024</td>
</tr>
<tr>
<td>REAL(16)</td>
<td>IEEE binary128</td>
<td>-16381</td>
<td>16384</td>
</tr>
</tbody>
</table>

- \( f_k \) is a nonnegative number less than \( b \) (\( f_1 \) is also nonzero).

For \( x = 0 \), its exponent \( e \) and digits \( f_k \) are defined to be zero.

The model set for single-precision real (REAL(4)) is defined as one of the following:

\[ x = 0 \]
\[ x = s \times 2^e \times \left[ 1/2 + \sum_{k=2}^{24} f_k \times 2^{-k} \right], -125 \leq e \leq 128 \]

The following example shows the general real model for \( x = 20.0 \) using a base \((b)\) of 2:

\[ x = 1 \times 2^5 \times (1 \times 2^{-1} + 0 \times 2^{-2} + 1 \times 2^{-3}) \]
\[ x = 1 \times 32 \times (.5 + .125) \]
\[ x = 32 \times .625 \]
\[ x = 20.0 \]

**Model for Bit Data**

The model set for bits (binary digits) interprets a binary digit \( w \) located at position \( k \) of a nonnegative integer scalar object based on a model nonnegative integer defined by the following:

\[ j = \sum_{k=0}^{s-1} w_k \times 2^k \]

The following values apply to this model set:
- \( j \) is the integer value.
- \( s \) is the number of bits (the length of a sequence of bits).
- \( w_k \) is a bit value of 0 or 1. This defines a sequence of bits \( w_{s-1}...w_0 \) with \( w_{s-1} \) the leftmost bit and \( w_0 \) the rightmost bit. The positions of bits in the sequence are numbered from right to left, with the position of the rightmost bit being zero.

The interpretation of a negative integer as a sequence of bits is processor dependent.

The inquiry function \( \text{BIT\_SIZE} \) provides the value of the parameter \( s \) of the model.

The following example shows the bit model for \( j = 1001 \) (integer 9) using a bit number \((s)\) of 4:

\[
\begin{array}{cccc}
1 & 0 & 0 & 1 \\
\downarrow & \downarrow & \downarrow & \downarrow \\
\hat{w}_3 & \hat{w}_2 & \hat{w}_1 & \hat{w}_0 \\
\end{array}
\]

\[ j = (\hat{w}_0 \times 2^0) + (\hat{w}_1 \times 2^1) + (\hat{w}_2 \times 2^2) + (\hat{w}_3 \times 2^3) \]
\[ j = 1 + 0 + 0 + 8 \]
\[ j = 9 \]

**See Also**

\( \text{BIT\_SIZE} \)
Bit Sequence Comparisons

When bit sequences of unequal length are compared, the shorter sequence is padded with zero bits on the left, so that it is the same length as the longer sequence.

Bit sequences are compared from left to right, one bit at a time, until unequal bits are found, or until all bits have been compared and found to be equal.

If unequal bits are found, the sequence with zero in the unequal position is considered to be less than the sequence with one in the unequal position. Otherwise the sequences are considered to be equal.

Library Modules and Run-Time Library Routines

Intel® Fortran provides a library of modules that contain routines you can use in your programs:

<table>
<thead>
<tr>
<th>Module Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFAUTO</td>
<td>Interfaces to Automation library routines</td>
</tr>
<tr>
<td>IFCOM</td>
<td>Interfaces to COM library routines</td>
</tr>
<tr>
<td>IFCOMMONALLOC</td>
<td>Interface to a user-defined routine to dynamically allocate commons</td>
</tr>
<tr>
<td>IFCORE</td>
<td>Interfaces to miscellaneous run-time library routines</td>
</tr>
<tr>
<td>IFESTABLISH</td>
<td>Interface to a routine to handle Run-Time Library (RTL) errors</td>
</tr>
<tr>
<td>IFLOGM</td>
<td>Interfaces to routines from the dialog library</td>
</tr>
<tr>
<td>IFMT</td>
<td>Defines derived types for Thread/Process/Synchronization Win32 APIs</td>
</tr>
<tr>
<td>IFNLS</td>
<td>Interfaces to National Language Support routines</td>
</tr>
<tr>
<td>IFPORT</td>
<td>Interfaces to portability routines</td>
</tr>
<tr>
<td>IFPOSIX</td>
<td>Interfaces to Posix-compliant routines</td>
</tr>
<tr>
<td>IFQWIN</td>
<td>Interfaces to QuickWin and Graphics library routines</td>
</tr>
<tr>
<td>IFWINTY</td>
<td>Defines Fortran parameter constants and derived data types for use with Windows APIs</td>
</tr>
<tr>
<td>KERNEL32</td>
<td>Interfaces to the Windows APIs provided by kernel32.dll</td>
</tr>
</tbody>
</table>

NOTE
The same routine name may appear in different modules. These routines may have different semantics, so be careful you are using the module that contains the routine that will produce the results you want.

Run-Time Library Routines

Intel® Fortran provides library modules containing the following routines. Note that the links in this list go to the relevant language summary table:
• Routines that help you write programs for graphics, QuickWin, and other applications (in modules IFQWIN, IFLOGM, and IFCORE):
  - QuickWin routines (W*S)
  - Graphics routines (W*S)
  - Dialog routines (W*S)
  - Miscellaneous run-time routines
• Routines systems that help you write programs using Component Object Model (COM) and Automation servers (in modules IFCOM and IFAUTO):
  - COM routines (W*S)
  - AUTO routines (W*S)
• Portability routines that help you port your programs to or from other systems, or help you perform basic I/O to serial ports on Windows* systems (in module IFPORT).
• National Language Support routines that help you write foreign language programs for international markets (in module IFNLS). These routines are only available on Windows* systems.
• POSIX routines that help you write Fortran programs that comply with the POSIX* Standard (in module IFPOSIX).
  - ESTABLISHQQ lets you specify a routine to handle Run-Time Library (RTL) errors (in module IFESTABLISH).
  - FOR__SET_FTN_ALLOC lets you specify a user-defined routine to dynamically allocate commons. The caller of FOR__SET_FTN_ALLOC must include module IFCOMMONALLOC.

When you include the statement USE module-name in your program, these library routines are automatically linked to your program if called.

You can restrict what is accessed from a USE module by adding ONLY clauses to the USE statement.

**NOTE**
The same routine name may appear in different modules. These routines may have different semantics, so be careful you are using the module that contains the routine that will produce the results you want.

USE

**Overview of NLS and MCBS Routines (Windows*)**
The NLS and MCBS routines are only available on Windows* systems. These library routines for handling extended and multibyte character sets are divided into three categories:

• Locale Setting and Inquiry routines to set locales (local code sets) and inquire about their current settings
  - At program startup, the current language and country setting is retrieved from the operating system. The user can change this setting through the Control Panel Regional Settings icon. The current codepage is also retrieved from the system.
  - There is a system default console codepage and a system default Windows codepage. Console programs retrieve the system console codepage, while Windows programs (including QuickWin applications) retrieve the system Windows codepage.
  - The NLS Library provides routines to determine the current locale (local code set), to return parameters of the current locale, to provide a list of all the system supported locales, and to set the locale to another language, country and/or codepage. Note that the locales and codepages set with these routines affect only the program or console that calls the routine. They do not change the system defaults or affect other programs or consoles.
• NLS Formatting routines to format dates, currency, and numbers
  - You can set time, date, currency and number formats from the Control Panel, by clicking on the Regional Settings icon. The NLS Library also provides formatting routines for the current locale. These routines return strings in the current codepage, set by default at program start or by NLSSetLocale.
All the formatting routines return the number of bytes in the formatted string (not the number of characters, which can vary if multibyte characters are included). If the output string is longer than the formatted string, the output string is blank padded. If the output string is shorter than the formatted string, an error occurs, NLS$ErrorInsufficientBuffer is returned, and nothing is written to the output string.

- **Multibyte Character Set (MBCS) routines for using multi-byte characters**
  
  Examples of multibyte character sets are Japanese, Korean, and Chinese.
  
  - The MBCS inquiry routines provide information on the maximum length of multibyte characters, the length, number and position of multibyte characters in strings, and whether a multibyte character is a leading or trailing byte. The NLS library provides a parameter, MBLenMax, defined in the NLS module to be the longest length (in bytes) of any character, in any codepage. This parameter can be useful in comparisons and tests. To determine the maximum character length of the current codepage, use the MBCurMax function.
  - There are four MBCS conversion routines. Two convert Japan Industry Standard (JIS) characters to Microsoft Kanji characters or vice versa. Two convert between a codepage multibyte character string and a Unicode string.
  - There are several MBCS Fortran equivalent routines. They are the exact equivalents of Fortran intrinsic routines except that the MBCS equivalents allow character strings to contain multibyte characters.

**Examples**

The following example uses Locale Setting and Inquiry routines:

```fortran
USE IFNLS
INTEGER(4) strlen, status
CHARACTER(40) str

strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str  ! prints Monday
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str  ! prints Tuesday
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
print *, str  ! prints Wednesday

! Change locale to Spanish, Mexico
status = NLSSetLocale("Spanish", "Mexico")
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str  ! prints lunes
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str  ! prints martes
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME3, str)
print *, str  ! prints miércoles
END
```

The following example uses NLS Formatting routines:

```fortran
USE IFNLS
INTEGER(4) strlen, status
CHARACTER(40) str

strlen = NLSFormatTime(str)
print *, str  ! prints 11:42:24 AM
strlen = NLSFormatDate(str, flags= NLS$LongDate)
print *, str  ! prints Friday, July 14, 2000
status = NLSSetLocale ("Spanish", "Mexico")
strlen = NLSFormatTime(str)
print *, str  ! prints viernes 14 de julio de 2000
```
The following example uses Multibyte Character Set (MBCS) inquiry routines:

```fortran
USE IFNLS
CHARACTER(4) str
INTEGER status
status = NLSSetLocale ("Japan")
str = " ·, " ¿"
PRINT '(1X,"String by char = "",\')
DO i = 1, len(str)
   PRINT '(A2,",")',str(i:i)
END DO
PRINT '(/,1X,"MBLead = "")
DO i = 1, len(str)
   PRINT '(L2,",")',mblead(str(i:i))
END DO
PRINT '(/,1X,"String as whole = "",\')
PRINT '(/,1X,"MBStrLead = "")
DO i = 1, len(str)
   PRINT '(L1,",")',MBStrLead(str,i)
END DO
END
```

This code produces the following output for str = ·, " ¿

```
String by char = · · · ·
MBLead = TTTT
String as whole = 高德
MBStrLead = TFTF
```

The following example uses Multibyte Character Set (MBCS) Fortran equivalent routines:

```fortran
USE IFNLS
INTEGER(4) i, len(7), infotype(7)
CHARACTER(10) str(7)
LOGICAL(4) log4
data infotype / NLS$LI_SDAYNAME1, NLS$LI_SDAYNAME2, \\&
   NLS$LI_SDAYNAME3, NLS$LI_SDAYNAME4, \\&
   NLS$LI_SDAYNAME5, NLS$LI_SDAYNAME6, \\&
   NLS$LI_SDAYNAME7 /
WRITE(*,*) 'NLSGetLocaleInfo'
WRITE(*,*) '----------------'
WRITE(*,*) ' Getting the names of the days of the week...'
DO i = 1, 7
   len(i) = NLSGetLocaleInfo(infotype(i), str(i))
   WRITE(*, 11) 'len/str/hex = ', len(i), str(i), str(i)
END DO
11 FORMAT (1X, A, I2, 2X, A10, 2X, '[', Z20, ']')
WRITE(*,*) ' ' 
WRITE(*,*) 'Lexically comparing the names of the days...'
DO i = 1, 6
   log4 = MBLGE(str(i), str(i+1), NLS$IgnoreCase)
   WRITE(*, 12) 'Is day ', i, ' GT day ', i+1, '? Answer = ', log4
END DO
12 FORMAT (1X, A, I1, A, I1, A, L1)
```
This code produces the following output when the locale is Japan:

```
NLSGetLocaleInfo

Getting the names of the days of the week...
len/str/hex = 6 月曜日  [8C8E976A93FA20202020]
len/str/hex = 6 火曜日  [89CE976A93FA20202020]
len/str/hex = 6 水曜日  [9085976A93FA20202020]
len/str/hex = 6 木曜日  [96D8976A93FA20202020]
len/str/hex = 6 金曜日  [8BE0976A93FA20202020]
len/str/hex = 6 土曜日  [9379976A93FA20202020]
len/str/hex = 6 日曜日  [93FA976A93FA20202020]

Lexically comparing the names of the days...
Is day 1 GT day 2? Answer = T
Is day 2 GT day 3? Answer = F
Is day 3 GT day 4? Answer = F
Is day 4 GT day 5? Answer = T
Is day 5 GT day 6? Answer = F
Is day 6 GT day 7? Answer = F

Done.
```

Standard Fortran Routines That Handle MBCS Characters
USE

Standard Fortran Routines That Handle MBCS Characters (Windows*)

This section describes Fortran routines that work as usual even if MBCS characters are included in strings.

Because a space can never be a lead or tail byte, many routines that deal with spaces work as expected on strings containing MBCS characters. Such functions include:

- `ADJUSTL (string)`
- `ADJUSTR (string)`
- `TRIM (string)`

Some routines work with the computer collating sequence to return a character in a certain position in the sequence or the position in the sequence of a certain character. These functions are not dependent on a particular collating sequence. (You should note, however, that elsewhere in this manual the ASCII collating sequence is mentioned in reference to these functions.) Such functions use `position` and `c` values between 0 and 255 (inclusive) and include:

- `ACHAR (position)`
- `CHAR (position[,kind])`
- `IACHAR (c)`
- `ICHAR (c)`
Because Fortran uses character lengths instead of NULLs to indicate the length of a string, some functions work solely from the length of the string, and not with the contents of the string. This function works as usual on strings containing MBCS characters, and include:

**REPEAT** *(string, ncopies)*

**Overview of Portability Routines**

This section summarizes portability routines.

**Information Retrieval Routines**

Information retrieval routines return information about system commands, command-line arguments, environment variables, and process or user information.

Group, user, and process ID are INTEGER(4) variables. Login name and host name are character variables. The functions GETGID and GETUID are provided for portability, but always return 1.

**Process Control Routines**

Process control routines control the operation of a process or subprocess. You can wait for a subprocess to complete with either SLEEP or ALARM, monitor its progress and send signals via KILL, and stop its execution with ABORT.

In spite of its name, KILL does not necessarily stop execution of a program. Rather, the routine signaled could include a handler routine that examines the signal and takes appropriate action depending on the code passed.

Note that when you use SYSTEM, commands are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The portability library does not include the FORK routine. On Linux* and macOS* systems, FORK creates a duplicate image of the parent process. Child and parent processes each have their own copies of resources, and become independent from one another.

On Windows* systems, you can create a child process (called a thread), but both parent and child processes share the same address space and share system resources. If you need to create another process, use the CreateProcessWindows API routine.

**Numeric Values and Conversion Routines**

Numeric values and conversion routines are available for calculating Bessel functions, data type conversion, and generating random numbers. Some of these functions have equivalents in Standard Fortran, in which case the standard Fortran routines should be used.

Data object conversion can be accomplished by using the INT intrinsic function instead of LONG or SHORT. The intrinsic subroutines RANDOM_INIT, RANDOM_NUMBER, and RANDOM_SEED perform the same functions as some random number functions that are shown in table Numeric Values and Conversion, which appears in Portability Library Routines.

Other bit manipulation functions such as AND, XOR, OR, LSHIFT, and RSHIFT are intrinsic functions. You do not need the IFPORT module to access them. Standard Fortran includes many bit operation routines, which are listed in the Bit Operation and Representation Routines table.

**Input and Output Routines**

The portability library contains routines that change file properties, read and write characters and buffers, and change the offset position in a file. These input and output routines can be used with standard Fortran input or output statements such as READ or WRITE on the same files, provided that you take into account the following:
When used with direct files, after an FSEEK, GETC, or PUTC operation, the record number is the number of the next whole record. Any subsequent normal Fortran I/O to that unit occurs at the next whole record. For example, if you seek to absolute location 1 of a file whose record length is 10, the NEXTREC returned by an INQUIRE would be 2. If you seek to absolute location 10, NEXTREC would still return 2.

- On units with CARRIAGECONTROL='FORTRAN' (the default), PUTC and FPUTC characters are treated as carriage control characters if they appear in column 1.
- On sequentially formatted units, the C string "$\n"c, which represents the carriage return/line feed escape sequence, is written as CHAR(13) (carriage return) and CHAR(10) (line feed), instead of just line feed, or CHAR(10). On input, the sequence 13 followed by 10 is returned as just 10. (The length of character string "$\n"c is 1 character, whose ASCII value, indicated by ICHAR('$\n'c), is 10.)
- Reading and writing is in a raw form for direct files. Separators between records can be read and overwritten. Therefore, be careful if you continue using the file as a direct file.

I/O errors arising from the use of these routines result in an Intel® Fortran run-time error.

Some portability file I/O routines have equivalents in Standard Fortran. For example, you could use the ACCESS function to check a file specified by name for accessibility according to mode. It tests a file for read, write, or execute permission, as well as checking to see if the file exists. It works on the file attributes as they exist on disk, not as a program's OPEN statement specifies them.

Instead of ACCESS, you can use the INQUIRE statement with the ACTION specifier to check for similar information. (The ACCESS function always returns 0 for read permission on FAT files, meaning that all files have read permission.)

Date and Time Routines

Various date and time routines are available to determine system time, or convert it to local time, Greenwich Mean Time, arrays of date and time elements, or an ASCII character string.

DATE and TIME are available as either a function or subroutine. Because of the name duplication, if your programs do not include the USE IFPORT statement, each separately compiled program unit can use only one of these versions. For example, if a program calls the subroutine TIME once, it cannot also use TIME as a function.

Standard Fortran includes date and time intrinsic subroutines. For more information, see DATE_AND_TIME.

Error Handling Routines

Error handling routines detect and report errors.

IERRNO error codes are analogous to errno on Linux® and macOS® systems. The IFPORT module provides parameter definitions for many of UNIX's errno names, found typically in errno.h on UNIX systems.

IERRNO is updated only when an error occurs. For example, if a call to the GETC function results in an error, but two subsequent calls to PUTC succeed, a call to IERRNO returns the error for the GETC call. Examine IERRNO immediately after returning from one of the portability library routines. Other Standard Fortran routines might also change the value to an undefined value.

If your application uses multithreading, remember that IERRNO is set on a per-thread basis.

System, Drive, or Directory Control and Inquiry Routines

You can retrieve information about devices, directories, and files with the functions listed below. File names can be long file names or UNC file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications.

Standard Fortran provides the INQUIRE statement, which returns detailed file information either by file name or unit number. Use INQUIRE as an equivalent to FSTAT, LSTAT, or STAT. LSTAT and STAT return the same information; STAT is the preferred function.
Serial Port Routines (Windows* only)
The serial port I/O (SPORT_xxx) routines help you perform basic input and output to serial ports. These routines are available only on systems using IA-32 architecture.

Additional Routines
You can also use portability routines for program call and control, keyboards and speakers, file management, arrays, floating-point inquiry and control, IEEE* functionality, and other miscellaneous uses.

**NOTE**
On Windows* systems, all portability routines that take path names also accept long file names or UNC (Universal Naming Convention) file names. A forward slash in a path name is treated as a backslash. All path names can contain drive specifications as well as MBCS (multiple-byte character set) characters.

Portability Routines
Overview of Serial Port I/O Routines

Overview of Serial Port I/O Routines (Windows*)
The serial port I/O (SPORT_xxx) routines help you perform basic input and output to serial ports. These routines are available only on Windows* systems.

The programming model is much the same as a normal file except the user does a connect (SPORT_CONNECT, SPORT_CONNECT_EX) and release (SPORT_RELEASE) to the port instead of an open and close of a file.

Two types of read and write operations (as determined in a mode on the connect call) are provided:

- Read and write arbitrary data from/to the port using SPORT_READ_DATA and SPORT_WRITE_DATA.
- Read and writes line-terminated data using SPORT_READ_LINE and SPORT_WRITE_LINE.

Once any I/O operation has been requested on the port, an additional thread is started that keeps a read outstanding on the port so that data will not be missed.

The SPORT_SET_STATE, SPORT_SET_STATE_EX, and SPORT_SET_TIMEOUTS (W*32 W*64) routines allow you to set basic port parameters such as baud rate, stop bits, timeouts, and so on. Additionally, you can call SPORT_GET_HANDLE to return the Windows* handle to the port so that you can call Windows* Communication Functions to implement additional needs.

Calling the Serial Port I/O Routines
The SPORT_xxx routines are functions that return an error status:

- An error status of 0 (zero) indicates success
- Other values are Windows* error values that indicate an error

As described in the calling syntax, these routines require the following **USE** statement:

```fortran
USE IFPORT
```

The **USE IFPORT** statement includes the routine definitions in the compilation. You may also need to add a **USE IFWINNTY** statement to your program because some Windows* constants may be required that are typically defined in the IFWINNTY module.

Many arguments are optional. If a constant is used where an argument is both input and output, a probe for writeability is done before the output. Thus, in many cases, a constant may be used without creating a temporary variable. It should be noted, however, that doing so may not be compatible with all Fortran implementations.
Run-Time Behavior of the Serial Port I/O Routines

To help ensure that data overruns do not occur, the SPORT_xxx run-time support creates a separate thread that maintains an outstanding read to the connected port. This thread is started when any read or write operation is performed to the port using the affiliated read/write routine. As such, port parameters must not be changed after you have started reading or writing to the port. Instead, you should set up the port parameters after connecting to the port and then leave them unchanged until after the port has been released.

If the parameters of the port must be changed more dynamically, use the SPORT_CANCEL_IO routine to ensure that no I/O is in progress. Additionally, that call will kill the helper thread so that it will automatically pick up the new, correct, parameters when it restarts during the next I/O operation.

Serial Port Usage

Depending upon the application, serial port programming can be very simple or very complex. The SPORT_xxx routines are intended to provide a level of support that will help the user implement simple applications as well as providing a foundation that can be used for more complex applications. Users needing to implement full serial port protocols (such as a PPP/SLIP implementation or some other complex protocol) should use the Windows* Communication Functions directly to achieve the detailed level of control needed in those cases. Simple tasks, such as communicating with a terminal or some other data collection device are well suited for implementations using the SPORT_xxx routines.

You should first familiarize yourself with the hardware connection to the serial device. Typical connections used today involve either a 9 pin/wire connector or a 25 pin/wire connector. Many cables do not implement all 9 or 25 connections in order to save on costs. For certain applications these subset cables may work just fine but others may require the full 9 or 25 connections. All cables will implement the Receive/SendData signals as well as the SignalGround. Without these signals, there can be no data transfer. There are two other categories of important signals:

- Signals used for flow control
  
  Flow control signals tell the device/computer on the other end of the cable that data may be sent or that they should wait. Typically, the RequestToSend/ClearToSend signals are used for this purpose. Other signals such as DataSetReady or DataTerminalReady may also be used. Make sure that the cable used implements all the signals required by your hardware/software solution. Special characters (normally as XON/XOFF) may also be used to control the flow of data instead of or in addition to the hardware signals. Check your specific application to see what cabling is needed.

- Signals that indicate status or state of a modem or phone connection.
  
  These signals may not be required if the connection between the computer and the device is direct and not through a modem. This signals typically convey information such as the state of the carrier (CarrierDetect) or if the phone line is ringing (Ring). Again, make sure the cable used implements all the signals required for your application.

After the correct physical connection has been set up the programmer must become familiar with the data protocol used to communicate with the remote device/system.

Many simple devices terminate parcels of data with a "record terminator" (often a carriage return or line feed character). Other devices may simply send data in fixed length packets or packets containing some sort of count information. The two types of I/O routines provided by the SPORT_xxx support (line oriented using SPORT_READ_LINE and SPORT_WRITE_LINE or transfer raw data using SPORT_READ_DATA and SPORT_WRITE_DATA) can handle these two types of data transfer. The programmer must become familiar with the particular application to determine which type of I/O is more appropriate to use.

The SPORT_xxx routines call Windows* routines. For example, the SPORT_SET_STATE routine calls the routine SetCommState, which uses the DCB Communications Structure.

Summary of Language Extensions

This appendix summarizes the Intel® Fortran language extensions to the ANSI/ISO Fortran 2003 Standard. Most extensions are available on all supported operating systems. However, some extensions are limited to one or more platforms. If an extension is limited, it is labeled.

Language Extensions: Source Forms

The following are extensions to the methods and rules for source forms:

- Tab-formatting as a method to code lines
- The letter D as a debugging statement indicator in column 1 of fixed or tab source form
- An optional statement field width of 132 columns for fixed or tab source form
- An optional sequence number field for fixed source form
- Up to 511 continuation lines in a source program

Language Extensions: Names

As an extension, the dollar sign ($) is a valid character in names, and can be the first character.

Language Extensions: Character Sets

The following are extensions to the standard character set:

- The Tab (<Tab>) character (see Character Sets)
- ASCII Character Code Chart 2 -- IBM* Character Set
- ANSI Character Code Chart
- Key Code Charts

Language Extensions: Intrinsic Data Types

The following are data-type extensions:

<table>
<thead>
<tr>
<th>Type</th>
<th>INTEGER*1</th>
<th>REAL*16</th>
</tr>
</thead>
<tbody>
<tr>
<td>BYTE</td>
<td>INTEGER*1</td>
<td>REAL*16</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>INTEGER*2</td>
<td>COMPLEX*8</td>
</tr>
<tr>
<td>LOGICAL*1</td>
<td>INTEGER*4</td>
<td>COMPLEX*16</td>
</tr>
<tr>
<td>LOGICAL*2</td>
<td>INTEGER*8</td>
<td>COMPLEX*32</td>
</tr>
<tr>
<td>LOGICAL*4</td>
<td>REAL*4</td>
<td></td>
</tr>
<tr>
<td>LOGICAL*8</td>
<td>REAL*8</td>
<td></td>
</tr>
</tbody>
</table>

See Also

Intrinsic Data Types

Language Extensions: Constants

Hollerith constants are allowed as an extension.

C Strings are allowed as extensions in character constants.
Language Extensions: Expressions and Assignment

When operands of different intrinsic data types are combined in expressions, conversions are performed as necessary (see Data Type of Numeric Expressions).

Binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

The following are extensions allowed in logical expressions:

- `.XOR.` as a synonym for `.NEQV.`
- Integers as valid logical items
- Logical operators applied to integers bit-by-bit

Language Extensions: Specification Statements

The following specification attributes and statements are extensions:

- `AUTOMATIC` attribute and statement
- `STATIC` attribute and statement

Language Extensions: Execution Control

The following control statements are extensions:

- `ASSIGN`
- Assigned `GO TO`
- `IF` - Arithmetic
- Non-block form of a `DO` statement
- `PAUSE`

These are older Fortran features that have been deleted from the Fortran Standard. Intel® Fortran fully supports these features.

Language Extensions: Compilation Control Lines and Statements

The following line option and statement are extensions that can influence compilation:

- `[/[NO]LIST]`, which can be specified in an `INCLUDE` line
- The `OPTIONS` statement

Language Extensions: Built-In Functions

The following built-in functions are extensions:

- `%VAL`, `%REF`, and `%LOC`, which facilitate references to non-Fortran procedures
- `%FILL`, which can be used in record structure type definitions

Language Extensions: I/O Statements

The following I/O statements are extensions:

- The `ACCEPT` statement
- The `REWITE` statement
- The `TYPE` statement, which is a synonym for the `PRINT` statement

Language Extensions: I/O Formatting

The following are extensions allowed in I/O Formatting:
• The Q edit descriptor
• The dollar sign ($) edit descriptor and carriage-control character
• The backslash (\) edit descriptor
• The ASCII NUL carriage-control character
• Variable format expressions
• The H edit descriptor

This is an older Fortran feature that has been deleted in Fortran 95. Intel® Fortran fully supports this feature.

Language Extensions: File Operation Statements

The following statement specifiers and statements are extensions:

• CLOSE statement specifiers:
  • STATUS values: 'SAVE' (as a synonym for 'KEEP'), 'PRINT', 'PRINT/DELETE', 'SUBMIT', 'SUBMIT/DELETE'
  • DISPOSE (or DISP)
• DELETE statement
• INQUIRE statement specifiers:
  • BINARY (W*S)
  • BLOCKSIZE
  • BUFFERED
  • CARRIAGECONTROL
  • CONVERT
  • DEFAULTFILE
  • FORM values: 'UNKNOWN', 'BINARY' (W*S)
  • IOFOCUS (W*S)
  • MODE as a synonym for ACTION
  • ORGANIZATION
  • RECORDTYPE
  • SHARE (W*S)

See also INQUIRE Statement.

• OPEN statement specifiers:
  • ACCESS values: 'APPEND'
  • ASSOCIATEVARIABLE
  • BLOCKSIZE
  • BUFFERCOUNT
  • BUFFERED
  • CARRIAGECONTROL
  • CONVERT
  • DEFAULTFILE
  • DISPOSE (or DISP)
  • FORM value: 'BINARY' (W*S)
  • IOFOCUS (W*S)
  • MAXREC
  • MODE as a synonym for ACTION
  • NAME as a synonym for FILE
  • NOSHARED
  • ORGANIZATION
  • READONLY
  • RECORDSIZE as a synonym for RECL
  • RECORDTYPE
  • SHARE (W*S)
  • SHARED
  • TITLE (W*S)
  • TYPE as a synonym for STATUS
  • USEROPEN
See also OPEN Statement.

Language Extensions: Compiler Directives

The following General Directives are extensions:

- ALIAS
- ASSUME
- ASSUME_ALIGNED
- ATTRIBUTES
- BLOCK_LOOP and NOBLOCK_LOOP
- DECLARE and NODECLARE
- DEFINE and UNDEFINE
- DISTRIBUTE POINT
- FIXEDFORMLINESIZE
- FMA and NOFMA
- FORCEINLINE
- FREEFORM and NOFREEFORM
- IDENT
- IF and IF DEFINED
- INLINE and NOINLINE
- INTEGER
- IVDEP
- LOOP COUNT
- MESSAGE
- NOFUSION
- OBJCOMMENT
- OPTIMIZE and NOOPTIMIZE
- OPTIONS
- PACK
- PARALLEL and NOPARALLEL (loop)
- PREFETCH and NOPREFETCH
- PSECT
- REAL
- SIMD
- STRICT and NOSTRICT
- UNROLL and NOUNROLL
- UNROLL_AND_JAM and NOUNROLL_AND_JAM
- VECTOR and NOVECTOR

Language Extensions: Intrinsic Procedures

The following intrinsic procedures are extensions available on all platforms:

A to D

Language Extensions: Additional Language Features

The following are language extensions that facilitate compatibility with other versions of Fortran:

- DEFINE FILE statement
- ENCODE and DECODE statements
- FIND statement
- The INTERFACE TO statement
- FORTRAN 66 Interpretation of the EXTERNAL statement
- An alternative syntax for the PARAMETER statement
- VIRTUAL statement
- AND, OR, XOR, IMAG, LSHIFT, RSHIFT intrinsics (see the A to Z Reference)
- An alternative syntax for octal and hexadecimal constants
- An alternative syntax for an I/O record specifier
- An alternate syntax for the DELETE statement
- An alternative form for namelist external records
- The integer POINTER statement
- Record structures

Language Extensions: Run-Time Library Routines

The following run-time library routines are available as extensions:

- Run-Time Library Routines
- OpenMP® Run-time Library Routines for Fortran

A to Z Reference

This section contains the following:

- Language Summary Tables
  This section organizes the Fortran functions, subroutines, and statements by the operations they perform, and shows short descriptions of each routine. You can use the tables to locate a particular routine for a particular task.
- The descriptions of all Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.

Certain routine groups, such as POSIX* routines and NLS routines, are in separate sections.

NOTE
In the description of routines, pointers and handles are INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture.

ifx does not generate code to run on IA-32 architecture.

The Fortran compiler understands statements and intrinsic functions in your program without any additional information, such as that provided in modules.

However, modules must be included in programs that contain the following routines. Note that the links in this list go to the relevant language summary table:

- Quickwin routines and graphics routines
  These routines require a USE IFQWIN statement to include the library and graphics modules.
- Portability routines
  It is recommended that you specify USE IFPORT when accessing routines in the portability library.
- Serial port I/O routines
These routines require a USE IFPORT statement to access the portability library.

- **NLS routines**
  These routines require a USE IFNLS statement to access the NLS library.

- **POSIX* routines**
  These routines require a USE IFPOSIX statement to access the POSIX library.

- **Dialog routines**
  These routines require a USE IFLOGM statement to access the dialog library.

- **Component Object Module (COM) routines**
  These routines require a USE IFCOM statement to access the COM library.

- **Automation server routines**
  These routines require a USE IFAUTO statement to access the AUTO library.

- **Miscellaneous Run-Time Routines**
  Most of these routines require a USE IFCORE statement to obtain the proper interfaces.

Whenever required, these USE module statements are prominent in the *A to Z Reference*.

In addition to the appropriate USE statement, for some routines you must specify the types of libraries to be used when linking.

## Language Summary Tables

This section contains tables that summarize language features such as statements, directives, and routines.

### Statements for Program Unit Calls and Definitions

The following table lists statements used for program unit definition and procedure call and return.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BLOCK DATA</td>
<td>Identifies a block-data subprogram.</td>
</tr>
<tr>
<td>CALL</td>
<td>Executes a subroutine.</td>
</tr>
<tr>
<td>COMMON</td>
<td>Delineates variables shared between program units.</td>
</tr>
<tr>
<td>CONTAINS</td>
<td>Identifies the start of module procedures within a host module, contained procedures within a procedure, or bound procedures within a type.</td>
</tr>
<tr>
<td>ENTRY</td>
<td>Specifies a secondary entry point to a subroutine or external function.</td>
</tr>
<tr>
<td>EXTERNAL</td>
<td>Declares a name to be that of a user-defined subroutine or function, making it passable as an argument.</td>
</tr>
<tr>
<td>FUNCTION</td>
<td>Identifies a program unit as a function.</td>
</tr>
<tr>
<td>INCLUDE</td>
<td>Inserts the contents of a specified file into the source file.</td>
</tr>
<tr>
<td>INTERFACE</td>
<td>Specifies an explicit interface for external functions and subroutines.</td>
</tr>
<tr>
<td>INTRINSIC</td>
<td>Declares a predefined function.</td>
</tr>
<tr>
<td>MODULE</td>
<td>Identifies a module program unit.</td>
</tr>
<tr>
<td>PROGRAM</td>
<td>Identifies a program unit as a main program.</td>
</tr>
</tbody>
</table>
Statements Affecting Variables

The following table lists statements that affect variables.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATIC</td>
<td>Declares a variable on the stack, rather than at a static memory location.</td>
</tr>
<tr>
<td>BYTE</td>
<td>Specifies variables as the BYTE data type; BYTE is equivalent to INTEGER(1).</td>
</tr>
<tr>
<td>CHARACTER</td>
<td>Specifies variables as the CHARACTER data type.</td>
</tr>
<tr>
<td>CODIMENSION</td>
<td>Specifies that an entity is a coarray and specifies its corank and cobounds, if any.</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Specifies variables as the COMPLEX data type.</td>
</tr>
<tr>
<td>DATA</td>
<td>Assigns initial values to variables.</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>Specifies that an entity is an array and specifies its rank and bounds.</td>
</tr>
<tr>
<td>DOUBLE COMPLEX</td>
<td>Specifies variables as the DOUBLE COMPLEX data type, equivalent to COMPLEX(8).</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>Specifies variables as the DOUBLE-PRECISION real data type, equivalent to REAL(8).</td>
</tr>
<tr>
<td>EQUIVALENCE</td>
<td>Specifies that two or more variables or arrays share the same memory location.</td>
</tr>
<tr>
<td>IMPLICIT</td>
<td>Specifies the default types for variables and functions.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Specifies variables as the INTEGER data type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Specifies variables as the LOGICAL data type.</td>
</tr>
<tr>
<td>MAP</td>
<td>Within a UNION statement, delimits a group of variable type declarations that are to be ordered contiguously within memory.</td>
</tr>
<tr>
<td>NAMELIST</td>
<td>Declares a group name for a set of variables to be read or written in a single statement.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>Equates a constant expression with a name.</td>
</tr>
<tr>
<td>PROTECTED</td>
<td>Specifies limitations on the use of module entities.</td>
</tr>
<tr>
<td>REAL</td>
<td>Specifies variables as the REAL data type.</td>
</tr>
<tr>
<td>RECORD</td>
<td>Declares one or more variables of a user-defined structure type.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SAVE</td>
<td>Causes variables to retain their values between invocations of the procedure in which they are defined.</td>
</tr>
<tr>
<td>STATIC</td>
<td>Declares a variable is in a static memory location, rather than on the stack.</td>
</tr>
<tr>
<td>STRUCTURE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Defines a new variable type, composed of a collection of other variable types.</td>
</tr>
<tr>
<td>UNION</td>
<td>Within a structure, causes two or more maps to occupy the same memory locations.</td>
</tr>
<tr>
<td>VOLATILE</td>
<td>Specifies that the value of an object is totally unpredictable based on information available to the current program unit.</td>
</tr>
</tbody>
</table>

**Statements for Input and Output**

The following table lists statements used for input and output.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCEPT</td>
<td>Statement</td>
<td>Similar to a formatted, sequential READ statement.</td>
</tr>
<tr>
<td>BACKSPACE</td>
<td>Statement</td>
<td>Positions a file to the beginning of the previous record.</td>
</tr>
<tr>
<td>CLOSE</td>
<td>Statement</td>
<td>Disconnects the specified unit.</td>
</tr>
<tr>
<td>DELETE</td>
<td>Statement</td>
<td>Deletes a record from a relative file.</td>
</tr>
<tr>
<td>ENDFILE</td>
<td>Statement</td>
<td>Writes an end-of-file record or truncates a file.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Statement</td>
<td>Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.</td>
</tr>
<tr>
<td>INQUIRE</td>
<td>Statement</td>
<td>Returns the properties of a file or unit.</td>
</tr>
<tr>
<td>OPEN</td>
<td>Statement</td>
<td>Associates a unit number with an external device or file.</td>
</tr>
<tr>
<td>PRINT(or TYPE)</td>
<td>Statement</td>
<td>Displays data on the screen.</td>
</tr>
<tr>
<td>READ</td>
<td>Statement</td>
<td>Transfers data from a file to the items in an I/O list.</td>
</tr>
<tr>
<td>REWIND</td>
<td>Statement</td>
<td>Repositions a file to its first record.</td>
</tr>
<tr>
<td>REWRITE</td>
<td>Statement</td>
<td>Rewrites the current record.</td>
</tr>
</tbody>
</table>
**Compiler Directives**

The following tables list available compiler directives.

Each OpenMP Fortran directive name is preceded by the prefix c$OMP, where c is one of the following: !, C (or c), or *; for example, !$OMP ATOMIC.

Compiler directives are specially formatted comments in the source file that provide information to the compiler. Some directives, such as line length or conditional compilation directives, provide the compiler information that is used in interpreting the source file. Other directives, such as optimization directives, provide hints or suggestions to the compiler, which, in some cases, may be ignored or overridden by the compiler, based on the heuristics of the optimizer and/or code generator. If the directive is ignored by the compiler, no diagnostic message is issued.

You do not need to specify a compiler option to enable general directives.

Some directives may perform differently on Intel® microprocessors than on non-Intel microprocessors.

### General Directives

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALIAS</td>
<td>Specifies an alternate external name to be used when referring to an external subprogram.</td>
</tr>
<tr>
<td>ASSUME</td>
<td>Provides heuristic information to the compiler optimizer.</td>
</tr>
<tr>
<td>ASSUME_ALIGNED</td>
<td>Specifies that an entity in memory is aligned.</td>
</tr>
<tr>
<td>ATTRIBUTES</td>
<td>Applies attributes to variables and procedures.</td>
</tr>
<tr>
<td>BLOCK_LOOP</td>
<td>Enables loop blocking for the immediately following nested DO loops.</td>
</tr>
<tr>
<td>DECLARE</td>
<td>Generates warning messages for undeclared variables.</td>
</tr>
<tr>
<td>DEFINE</td>
<td>Creates a variable whose existence can be tested during conditional compilation.</td>
</tr>
<tr>
<td>DISTRIBUTE POINT</td>
<td>Suggests a location at which a DO loop may be split.</td>
</tr>
<tr>
<td>ELSE</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ELSEIF</td>
<td>Marks the beginning of an alternative conditional-compilation block to an IF directive construct.</td>
</tr>
<tr>
<td>ENDIF</td>
<td>Marks the end of a conditional-compilation block.</td>
</tr>
<tr>
<td>FIXEDFORMLINESIZE</td>
<td>Sets fixed-form line length. This directive has no effect on freeform code.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FMA</td>
<td>Tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions.</td>
</tr>
<tr>
<td>FORCEINLINE</td>
<td>Specifies that a routine should be inlined whenever the compiler can do so.</td>
</tr>
<tr>
<td>FREEFORM</td>
<td>Uses freeform format for source code.</td>
</tr>
<tr>
<td>IDENT</td>
<td>Specifies an identifier for an object module.</td>
</tr>
<tr>
<td>IF</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>IF DEFINED</td>
<td>Marks the beginning of a conditional-compilation block.</td>
</tr>
<tr>
<td>INLINE</td>
<td>Specifies that the routines can be inlined.</td>
</tr>
<tr>
<td>INTEGER</td>
<td>Selects default integer size.</td>
</tr>
<tr>
<td>IVDEP</td>
<td>Assists the compiler’s dependence analysis of iterative DO loops.</td>
</tr>
<tr>
<td>LOOP COUNT</td>
<td>Specifies the typical trip loop count for a DO loop; which assists the optimizer.</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>Sends a character string to the standard output device.</td>
</tr>
<tr>
<td>NOBLOCK_LOOP</td>
<td>Disables loop blocking for the immediately following nested DO loops.</td>
</tr>
<tr>
<td>NODEDECLARE</td>
<td>(Default) Turns off warning messages for undeclared variables.</td>
</tr>
<tr>
<td>NOFMA</td>
<td>Disables the generation of FMA instructions.</td>
</tr>
<tr>
<td>NOFREEFORM</td>
<td>(Default) Uses standard FORTRAN 77 code formatting column rules.</td>
</tr>
<tr>
<td>NOFUSION</td>
<td>Prevents a loop from fusing with adjacent loops.</td>
</tr>
<tr>
<td>NOINLINE</td>
<td>Specifies that a routine should not be inlined.</td>
</tr>
<tr>
<td>NOPARALLEL</td>
<td>Disables auto-parallelization for an immediately following DO loop.</td>
</tr>
<tr>
<td>NOOPTIMIZE</td>
<td>Disables optimizations for the program unit.</td>
</tr>
<tr>
<td>NOPREFETCH</td>
<td>Disables a data prefetch from memory.</td>
</tr>
<tr>
<td>NOSTRICT</td>
<td>(Default) Disables a previous STRICT directive.</td>
</tr>
<tr>
<td>NOUNROLL</td>
<td>Disables the unrolling of a DO loop.</td>
</tr>
<tr>
<td>NOUNROLL_AND_JAM</td>
<td>Disables loop unrolling and jamming.</td>
</tr>
<tr>
<td>NOVECTOR</td>
<td>Disables vectorization of a DO loop.</td>
</tr>
</tbody>
</table>
### OpenMP* Fortran Directives

OpenMP* directives are specially formatted Fortran comment lines embedded in the source file that provide the compiler with hints and suggestions for parallelization, optimization, vectorization, and offloading code to accelerator hardware. The compiler uses the information specified in the directives with compiler heuristic algorithms to generate more efficient code. At times, these heuristics may choose to ignore or override the information provided by a directive. If the directive is ignored by the compiler, no diagnostic message is issued.

To use the following directives, you must specify compiler option [q or Q]openmp. For more information, refer to the option description in the Compiler Options reference.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE</td>
<td>Specifies memory allocators to use for object allocation and deallocation. This feature is only available for ifx.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ATOMIC</td>
<td>Specifies that a specific memory location is to be updated atomically.</td>
</tr>
<tr>
<td>BARRIER</td>
<td>Synchronizes all the threads in a team.</td>
</tr>
<tr>
<td>CANCEL</td>
<td>Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.</td>
</tr>
<tr>
<td>CANCELLATION POINT</td>
<td>Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.</td>
</tr>
<tr>
<td>CRITICAL</td>
<td>Restricts access for a block of code to only one thread at a time.</td>
</tr>
<tr>
<td>DECLARE MAPPER</td>
<td>Declares a user defined data mapper for derived types and local variables that can subsequently be used in MAP clauses. This feature is only available for ifx.</td>
</tr>
<tr>
<td>DECLARE REDUCTION</td>
<td>Declares a user defined reduction for one or more types.</td>
</tr>
<tr>
<td>DECLARE SIMD</td>
<td>Generates a SIMD procedure.</td>
</tr>
<tr>
<td>DECLARE TARGET</td>
<td>Specifies that named variables, common blocks, functions, and subroutines are mapped to a device. This feature is only available for ifx.</td>
</tr>
<tr>
<td>DECLARE VARIANT</td>
<td>Identifies a variant of a base procedure and specifies the context in which this variant is used. This feature is only available for ifx.</td>
</tr>
<tr>
<td>DISPATCH</td>
<td>Determines if a variant of a procedure is called for a given function or subroutine call. This feature is only available for ifx.</td>
</tr>
<tr>
<td>DISTRIBUTE</td>
<td>Specifies that loop iterations will be executed by thread teams in the context of their implicit tasks.</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO</td>
<td>Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>DISTRIBUTE PARALLEL DO SIMD</td>
<td>Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>DISTRIBUTE SIMD</td>
<td>Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DO</td>
<td>Specifies that the iterations of the immediately following DO loop must be executed in parallel.</td>
</tr>
<tr>
<td>DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Specifies synchronization points where the implementation must have a consistent view of memory.</td>
</tr>
<tr>
<td>INTEROP</td>
<td>Identifies a foreign runtime context and identifies runtime characteristics of that context, enabling interoperability with it. This feature is only available for ifx.</td>
</tr>
<tr>
<td>LOOP</td>
<td>Specifies that all iterations of the associated DO loop(s) can execute in any order or concurrently. This feature is only available for ifx.</td>
</tr>
<tr>
<td>MASKED</td>
<td>Specifies a block of code to be executed by the primary thread of the team. This feature is only available for ifx.</td>
</tr>
<tr>
<td>MASKED TASKLOOP</td>
<td>Provides an abbreviated way to specify a TASKLOOP construct inside a MASKED construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>MASKED TASKLOOP SIMD</td>
<td>Provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASKED construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>MASTER</td>
<td>(Deprecated, see MASKED) Specifies a block of code to be executed by the master thread of the team.</td>
</tr>
<tr>
<td>MASTER TASKLOOP</td>
<td>Deprecated; provides an abbreviated way to specify a TASKLOOP construct inside a MASTER construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>MASTER TASKLOOP SIMD</td>
<td>Deprecated; provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASTER construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>ORDERED</td>
<td>Specifies a block of code to be executed sequentially.</td>
</tr>
<tr>
<td>PARALLEL</td>
<td>Defines a parallel region.</td>
</tr>
<tr>
<td>PARALLEL DO</td>
<td>Defines a parallel region that contains a single DO directive.</td>
</tr>
<tr>
<td>PARALLEL DO SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PARALLEL LOOP</td>
<td>Provides an abbreviated way to specify a PARALLEL region containing a single LOOP construct and no other statements. This feature is only available for ifx.</td>
</tr>
<tr>
<td>PARALLEL MASKED</td>
<td>Provides an abbreviated way to specify a MASKED construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>PARALLEL MASKED TASKLOOP</td>
<td>Provides an abbreviated way to specify a MASKED TASKLOOP construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>PARALLEL MASKED TASKLOOP SIMD</td>
<td>Provides an abbreviated way to specify a MASKED TASKLOOP SIMD construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>PARALLEL MASTER</td>
<td>Deprecated; provides an abbreviated way to specify a MASTER construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>PARALLEL MASTER TASKLOOP</td>
<td>Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>PARALLEL MASTER TASKLOOP SIMD</td>
<td>Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP SIMD construct inside a PARALLEL construct, with no other statements inside the PARALLEL construct. This feature is only available for ifx.</td>
</tr>
<tr>
<td>PARALLEL SECTIONS</td>
<td>Defines a parallel region that contains SECTIONS directives.</td>
</tr>
<tr>
<td>PARALLEL WORKSHARE</td>
<td>Defines a parallel region that contains a single WORKSHARE directive.</td>
</tr>
<tr>
<td>REQUIRES</td>
<td>Lists the features that an implementation must support so that the program compiles and runs correctly. This feature is only available for ifx.</td>
</tr>
<tr>
<td>SCAN</td>
<td>Specifies a scan computation that updates each list item in each iteration of the loop.</td>
</tr>
<tr>
<td>SECTION</td>
<td>Appears within a SECTIONS construct to indicate a block (section) of code. This directive is optional for the first block of code within the SECTIONS construct.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SECTIONS</td>
<td>Specifies a block of code to be divided among threads in a team (a worksharing area).</td>
</tr>
<tr>
<td>SIMD</td>
<td>Requires and controls SIMD vectorization of loops.</td>
</tr>
<tr>
<td>SINGLE</td>
<td>Specifies a block of code to be executed by only one thread in a team.</td>
</tr>
<tr>
<td>TARGET</td>
<td>Creates a device data environment and executes the construct on the same device. This feature is only available for ifx.</td>
</tr>
<tr>
<td>TARGET DATA</td>
<td>Creates a device data environment for the extent of the region. This feature is only available for ifx.</td>
</tr>
<tr>
<td>TARGET ENTER DATA</td>
<td>Specifies that variables are mapped to a device data environment. This feature is only available for ifx.</td>
</tr>
<tr>
<td>TARGET EXIT DATA</td>
<td>Specifies that variables are unmapped from a device data environment. This feature is only available for ifx.</td>
</tr>
<tr>
<td>TARGET PARALLEL</td>
<td>Creates a device data environment in a parallel region and executes the construct on that device.</td>
</tr>
<tr>
<td>TARGET PARALLEL DO</td>
<td>Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.</td>
</tr>
<tr>
<td>TARGET PARALLEL DO SIMD</td>
<td>Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.</td>
</tr>
<tr>
<td>TARGET PARALLEL LOOP</td>
<td>Provides an abbreviated way to specify a TARGET region containing a single PARALLEL LOOP construct and no other statements. This feature is only available for ifx.</td>
</tr>
<tr>
<td>TARGET SIMD</td>
<td>Specifies a TARGET construct that contains a SIMD construct and no other statement.</td>
</tr>
<tr>
<td>TARGET TEAMS</td>
<td>Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTED</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a TEAMS construct.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>-------------</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TARGET TEAMS DISTRIBUTE SIMD</td>
<td>Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TARGET TEAMS LOOP</td>
<td>Provides an abbreviated way to specify a TARGET region containing a single TEAMS LOOP construct and no other statements. This feature is only available for ifx.</td>
</tr>
<tr>
<td>TARGET UPDATE</td>
<td>Makes the list items in the device data environment consistent with their corresponding original list items.</td>
</tr>
<tr>
<td>TARGET VARIANT DISPATCH</td>
<td>Conditionally calls a procedure offload variant if the device is free; otherwise, executes the procedure on the host. This feature is only available for ifx.</td>
</tr>
<tr>
<td>TASK</td>
<td>Defines a task region.</td>
</tr>
<tr>
<td>TASKGROUP</td>
<td>Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.</td>
</tr>
<tr>
<td>TASKLOOP</td>
<td>Specifies that the iterations of one or more associated DO loops should be executed in parallel using OpenMP* tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed.</td>
</tr>
<tr>
<td>TASKLOOP SIMD</td>
<td>Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.</td>
</tr>
<tr>
<td>TASKWAIT</td>
<td>Specifies a wait on the completion of child tasks generated since the beginning of the current task.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TASKYIELD</td>
<td>Specifies that the current task can be suspended in favor of execution of a different task.</td>
</tr>
<tr>
<td>TEAMS</td>
<td>Creates a league of thread teams inside a target region to execute a structured block in the primary thread of each team.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE</td>
<td>Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies that loop iterations will be shared among the primary threads of all thread teams in a league created by a TEAMS construct.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO</td>
<td>Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE PARALLEL DO SIMD</td>
<td>Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the primary threads of the teams region, which will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TEAMS DISTRIBUTE SIMD</td>
<td>Creates a league of thread teams to execute the structured block in the primary thread of each team. It also specifies a loop that will be distributed across the primary threads of the teams region. The loop will be executed concurrently using SIMD instructions.</td>
</tr>
<tr>
<td>TEAMS LOOP</td>
<td>Provides an abbreviated way to specify a TEAMS region containing a single LOOP construct and no other statements. This feature is only available for ifx.</td>
</tr>
<tr>
<td>THREADPRIVATE</td>
<td>Makes named common blocks private to a thread but global within the thread.</td>
</tr>
<tr>
<td>WORKSHARE</td>
<td>Divides the work of executing a block of statements or constructs into separate units.</td>
</tr>
</tbody>
</table>

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

# Program Control Statements

The following table lists statements that affect program control.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL</td>
<td>Transfers control to a subroutine.</td>
</tr>
<tr>
<td>CASE</td>
<td>Within a SELECT CASE construct, marks a block of statements that are executed if an associated value matches the SELECT CASE expression.</td>
</tr>
<tr>
<td>CASE DEFAULT or CLASS DEFAULT</td>
<td>Identifies the block of statements to be executed in a SELECT CASE construct if the value of the expression does not match any of the CASE selectors, or in a SELECT TYPE construct if the dynamic type of the selector does not match the type of any of the TYPE IS or CLASS IS statements.</td>
</tr>
<tr>
<td>CLASS IS</td>
<td>Within a SELECT TYPE construct, marks a block of statements that are executed if the type or dynamic type of an expression matches the type of the CLASS IS expression.</td>
</tr>
<tr>
<td>CONTINUE</td>
<td>Often used as the target of GOTO or as the terminal statement in a DO loop; performs no operation.</td>
</tr>
<tr>
<td>CYCLE</td>
<td>Advances control to the end statement of a DO loop; the intervening loop statements are not executed.</td>
</tr>
<tr>
<td>DO</td>
<td>Marks the beginning of a loop construct. Statements through and including the ending statement may be executed repeatedly.</td>
</tr>
<tr>
<td>DO CONCURRENT</td>
<td>Marks the beginning of a DO CONCURRENT construct. The order of executions of iterations of a DO CONCURRENT construct are indeterminate.</td>
</tr>
<tr>
<td>DO WHILE</td>
<td>Evaluates statements in the DO WHILE loop, through and including the ending statement, until a logical condition becomes .FALSE..</td>
</tr>
<tr>
<td>ELSE</td>
<td>Marks an optional branch in an IF construct.</td>
</tr>
<tr>
<td>ELSE IF</td>
<td>Marks an optional branch in an IF construct.</td>
</tr>
<tr>
<td>ELSEWHERE</td>
<td>Marks an optional branch in a WHERE construct.</td>
</tr>
<tr>
<td>END</td>
<td>Marks the end of a program unit. Execution of the END [PROGRAM] statement of the main program initiates normal termination for the image that executes it.</td>
</tr>
<tr>
<td>END DO</td>
<td>Marks the end of a series of statements in a DO, DO CONCURRENT, or DO WHILE construct.</td>
</tr>
<tr>
<td>END FORALL</td>
<td>Marks the end of a series of statements following a block FORALL statement.</td>
</tr>
</tbody>
</table>
**Name** | **Description**
---|---
END IF | Marks the end of a series of statements following a block IF statement.
END SELECT | Marks the end of a SELECT CASE or SELECT TYPE statement.
END WHERE | Marks the end of a series of statements following a block WHERE statement.
ERROR STOP | Initiates error termination for all images.
EXIT | Terminates execution of a DO loop or other construct. Execution continues with the first statement that follows the construct.
FAIL_IMAGE | Causes the image that executes it to execute no more statements and stop participating in program execution.
FORALL | Indicates a loop construct where the output from one iteration cannot change the input to another.
GOTO | Transfers control to a specified part of the program.
IF | Controls conditional execution of other statements.
PAUSE | Suspends program execution and, optionally, executes operating-system commands.
SELECT CASE | Transfers program control to a block of statements, determined by the value of an expression.
SELECT TYPE | Transfers the program to a block of statements, determined by the dynamic type of an expression.
STOP | Initiates normal termination for the image that executes the statement.
TYPE IS | Within a SELECT TYPE construct, marks a block of statements that are executed if the type or dynamic type of an expression matches the type of the TYPE IS expression.
WHERE | Controls conditional execution of array assignments and elemental function calls.

### Inquiry Intrinsic Functions

The following table lists inquiry intrinsic functions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATED</td>
<td>Determines whether an allocatable variable is allocated.</td>
</tr>
<tr>
<td>ASSOCIATED</td>
<td>Determines if a pointer is associated or if two pointers are associated with the same target.</td>
</tr>
<tr>
<td>BIT_SIZE</td>
<td>Returns the number of bits in an integer type.</td>
</tr>
<tr>
<td>CACHESIZE</td>
<td>Returns the size of a level of the memory cache.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>COMMAND_ARGUMENT_COUNT</td>
<td>Returns the number of command-line arguments.</td>
</tr>
<tr>
<td>DIGITS</td>
<td>Returns number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>EOF</td>
<td>Determines whether a file is at or beyond the end-of-file record.</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.</td>
</tr>
<tr>
<td>HUGE</td>
<td>Returns the largest number that can be represented by numbers of the type of the argument.</td>
</tr>
<tr>
<td>IARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>INT_PTR_KIND</td>
<td>Returns the INTEGER KIND that will hold an address.</td>
</tr>
<tr>
<td>KIND</td>
<td>Returns the value of the kind parameter of the argument.</td>
</tr>
<tr>
<td>LBOUND</td>
<td>Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the length of a character expression.</td>
</tr>
<tr>
<td>LOC</td>
<td>Returns the address of the argument.</td>
</tr>
<tr>
<td>MAXEXponent</td>
<td>Returns the largest positive decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>MINEXponent</td>
<td>Returns the largest negative decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>NARGS</td>
<td>Returns the total number of command-line arguments, including the command.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Returns the number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>PRESENT</td>
<td>Determines whether an optional argument is present.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Returns the base for data of the same type as the argument.</td>
</tr>
<tr>
<td>RANGE</td>
<td>Returns the decimal exponent range for data of the same type as the argument.</td>
</tr>
<tr>
<td>SELECTED_INT_KIND</td>
<td>Returns the value of the kind parameter of integers in range $r$.</td>
</tr>
<tr>
<td>SELECTED_REAL_KIND</td>
<td>Returns the value of the kind parameter of reals with (optional) first argument digits and (optional) second argument exponent range. At least one optional argument is required.</td>
</tr>
<tr>
<td>SHAPE</td>
<td>Returns the shape of an array or scalar argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SIZEOF</td>
<td>Returns the number of bytes of storage used by the argument.</td>
</tr>
<tr>
<td>TINY</td>
<td>Returns the smallest positive number that can be represented by numbers of type the argument.</td>
</tr>
<tr>
<td>UBOUND</td>
<td>Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.</td>
</tr>
</tbody>
</table>

**Random Number Intrinsic Procedures**

The following table lists random number intrinsic procedures.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAN</td>
<td>Intrinsic function</td>
<td>Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1.</td>
</tr>
<tr>
<td>RANF</td>
<td>Intrinsic function</td>
<td>Generates a random number between 0.0 and RAND_MAX.</td>
</tr>
<tr>
<td>RANDOM_INIT</td>
<td>Intrinsic subroutine</td>
<td>Initializes the pseudorandom number generator used by RANDOM_NUMBER.</td>
</tr>
<tr>
<td>RANDOM_NUMBER</td>
<td>Intrinsic subroutine</td>
<td>Returns a pseudorandom real value greater than or equal to zero and less than one.</td>
</tr>
<tr>
<td>RANDOM_SEED</td>
<td>Intrinsic subroutine</td>
<td>Changes the starting point of RANDOM_NUMBER; takes one or no arguments.</td>
</tr>
<tr>
<td>RANDU</td>
<td>Intrinsic subroutine</td>
<td>Computes a pseudorandom number as a single-precision value.</td>
</tr>
</tbody>
</table>

The portability routines RANF, RANDOM, and SEED also supply this functionality.

**Atomic Intrinsic Subroutines**

The following table lists atomic intrinsic subroutines.

<table>
<thead>
<tr>
<th>Atomic Operation</th>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ATOMIC_ADD</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic addition.</td>
</tr>
<tr>
<td></td>
<td>ATOMIC_AND</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic bitwise AND.</td>
</tr>
<tr>
<td></td>
<td>ATOMIC_CAS</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic compare and swap.</td>
</tr>
<tr>
<td></td>
<td>ATOMIC_DEFINE</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomically defines a variable.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
<td></td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------</td>
<td>--------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>ATOMIC_FETCH_ADD</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic fetch and add.</td>
<td></td>
</tr>
<tr>
<td>ATOMIC_FETCH_AND</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic fetch and bitwise AND.</td>
<td></td>
</tr>
<tr>
<td>ATOMIC_FETCH_OR</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic fetch and bitwise OR.</td>
<td></td>
</tr>
<tr>
<td>ATOMIC_FETCH_XOR</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic fetch and bitwise exclusive OR.</td>
<td></td>
</tr>
<tr>
<td>ATOMIC_OR</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic bitwise OR.</td>
<td></td>
</tr>
<tr>
<td>ATOMIC_REF</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomically references a variable.</td>
<td></td>
</tr>
<tr>
<td>ATOMIC_XOR</td>
<td>Intrinsic Subroutine</td>
<td>Performs atomic bitwise exclusive OR.</td>
<td></td>
</tr>
</tbody>
</table>

**Collective Intrinsic Subroutines**

The following table lists collective intrinsic subroutines.

**Collective Operation**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CO_BROADCAST</td>
<td>Intrinsic Subroutine</td>
<td>Broadcasts a value to other images.</td>
</tr>
<tr>
<td>CO_MAX</td>
<td>Intrinsic Subroutine</td>
<td>Finds maximum value across images.</td>
</tr>
<tr>
<td>CO_MIN</td>
<td>Intrinsic Subroutine</td>
<td>Finds minimum value across images.</td>
</tr>
<tr>
<td>CO_REDUCE</td>
<td>Intrinsic Subroutine</td>
<td>Performs user-defined reduction across images.</td>
</tr>
<tr>
<td>CO_SUM</td>
<td>Intrinsic Subroutine</td>
<td>Performs sum reduction across images.</td>
</tr>
</tbody>
</table>

**Date and Time Intrinsic Subroutines**

The following table lists date and time intrinsic subroutines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPU_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the processor time in seconds.</td>
</tr>
<tr>
<td>DATE</td>
<td>Intrinsic subroutine</td>
<td>Returns the ASCII representation of the current date (in dd-mmm-yy form).</td>
</tr>
<tr>
<td>DATE_AND_TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the date and time. This is the preferred procedure for date and time.</td>
</tr>
</tbody>
</table>
### Language Reference

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDATE</td>
<td>Intrinsic subroutine</td>
<td>Returns three integer values representing the current month, day, and year.</td>
</tr>
<tr>
<td>SYSTEM_CLOCK</td>
<td>Intrinsic subroutine</td>
<td>Returns data from the system clock.</td>
</tr>
<tr>
<td>TIME</td>
<td>Intrinsic subroutine</td>
<td>Returns the ASCII representation of the current time (in hh:mm:ss form).</td>
</tr>
</tbody>
</table>

The portability routines GETDAT, GETTIM, SETDAT, and SETTIM also supply this functionality.

### Keyboard and Speaker Library Routines

The following table lists keyboard and speaker library routines.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETCHARQQ</td>
<td>Run-time Function</td>
<td>Returns the next keyboard keystroke.</td>
</tr>
<tr>
<td>BEEPQQ</td>
<td>Portability subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
<tr>
<td>GETSTRQQ</td>
<td>Run-time function</td>
<td>Reads a character string from the keyboard using buffered input.</td>
</tr>
<tr>
<td>PEEKCHARQQ</td>
<td>Run-time function</td>
<td>Checks the buffer to see if a keystroke is waiting.</td>
</tr>
</tbody>
</table>

### Statements and Intrinsic Procedures for Memory Allocation and Deallocation

The following table lists statements and intrinsic procedures that are used for memory allocation and deallocation.

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE</td>
<td>Statement</td>
<td>Dynamically establishes allocatable array dimensions.</td>
</tr>
<tr>
<td>ALLOCATED</td>
<td>Intrinsic Function</td>
<td>Determines whether an allocatable array is allocated.</td>
</tr>
<tr>
<td>DEALLOCATE</td>
<td>Statement</td>
<td>Frees the storage space previously reserved in an ALLOCATE statement.</td>
</tr>
<tr>
<td>FREE</td>
<td>Intrinsic Subroutine</td>
<td>Frees the memory block specified by the integer pointer argument.</td>
</tr>
<tr>
<td>MALLOC</td>
<td>Intrinsic Function</td>
<td>Allocates a memory block of size bytes and returns an integer pointer to the block.</td>
</tr>
<tr>
<td>MOVE_ALLOC</td>
<td>Intrinsic Subroutine</td>
<td>Moves an allocation from one allocatable object to another.</td>
</tr>
</tbody>
</table>
## Intrinsic Functions for Arrays

The following table lists intrinsic functions for arrays.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Determines whether all array values meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>ANY</td>
<td>Determines whether any array values meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>COSHAPE</td>
<td>Returns the sizes of codimensions of a coarray.</td>
</tr>
<tr>
<td>COUNT</td>
<td>Counts the number of array elements that meet the conditions in a mask along a (optional) dimension.</td>
</tr>
<tr>
<td>CSHIFT</td>
<td>Performs a circular shift along a (optional) dimension.</td>
</tr>
<tr>
<td>DIMENSION</td>
<td>Specifies that an entity is an array and specifies its rank and bounds.</td>
</tr>
<tr>
<td>DOT_PRODUCT</td>
<td>Performs dot-product multiplication on vectors (one-dimensional arrays).</td>
</tr>
<tr>
<td>EOSHIFT</td>
<td>Shifts elements off one end of array along a (optional) dimension and copies (optional) boundary values in other end.</td>
</tr>
<tr>
<td>LBOUND</td>
<td>Returns lower dimensional bounds of an array along a (optional) dimension.</td>
</tr>
<tr>
<td>LCOBOUND</td>
<td>Returns the lower cobounds of a coarray.</td>
</tr>
<tr>
<td>MATMUL</td>
<td>Performs matrix multiplication on matrices (two-dimensional arrays).</td>
</tr>
<tr>
<td>MAXLOC</td>
<td>Returns the location of the maximum value in an array meeting conditions in a (optional) mask along a (optional) dimension.</td>
</tr>
<tr>
<td>MAXVAL</td>
<td>Returns the maximum value in an array along a (optional) dimension that meets conditions in a (optional) mask.</td>
</tr>
<tr>
<td>MERGE</td>
<td>Merges two arrays according to conditions in a mask.</td>
</tr>
<tr>
<td>MINLOC</td>
<td>Returns the location of the minimum value in an array meeting conditions in a (optional) mask along a (optional) dimension.</td>
</tr>
<tr>
<td>MINVAL</td>
<td>Returns the minimum value in an array along a (optional) dimension that meets conditions in a (optional) mask.</td>
</tr>
<tr>
<td>PACK</td>
<td>Packs an array into a vector (one-dimensional array) of a (optional) size using a mask.</td>
</tr>
<tr>
<td>PRODUCT</td>
<td>Returns product of elements of an array along a (optional) dimension that meet conditions in a (optional) mask.</td>
</tr>
</tbody>
</table>
### Intrinsic Functions for Numeric and Type Conversion

The following table lists intrinsic functions for numeric and type conversion.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABS</td>
<td>Returns the absolute value of the argument.</td>
</tr>
<tr>
<td>AIMAG</td>
<td>Returns imaginary part of complex number ( z ).</td>
</tr>
<tr>
<td>AINT</td>
<td>Truncates the argument to a whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>AMAX0</td>
<td>Returns largest value among integer arguments as real.</td>
</tr>
<tr>
<td>AMIN0</td>
<td>Returns smallest value among integer arguments as real.</td>
</tr>
<tr>
<td>ANINT</td>
<td>Rounds to the nearest whole number of a specified (optional) kind.</td>
</tr>
<tr>
<td>CEILING</td>
<td>Returns smallest integer greater than the argument.</td>
</tr>
<tr>
<td>CMPLX</td>
<td>Converts the first argument and (optional) second argument to complex of a (optional) kind.</td>
</tr>
<tr>
<td>CONJG</td>
<td>Returns the conjugate of a complex number.</td>
</tr>
<tr>
<td>DBLE</td>
<td>Converts the argument to double precision type.</td>
</tr>
<tr>
<td>DCMPLX</td>
<td>Converts the argument to double complex type.</td>
</tr>
<tr>
<td>DFLOAT</td>
<td>Converts an integer to double precision type.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DIM</td>
<td>Returns the first argument minus the second argument if positive; else 0.</td>
</tr>
<tr>
<td>DPROD</td>
<td>Returns double-precision product of two single precision arguments.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>Converts the argument to REAL(4).</td>
</tr>
<tr>
<td>FLOOR</td>
<td>Returns the greatest integer less than or equal to the argument.</td>
</tr>
<tr>
<td>IFIX</td>
<td>Converts a single-precision real argument to an integer argument by truncating.</td>
</tr>
<tr>
<td>IMAG</td>
<td>Same as AIMAG.</td>
</tr>
<tr>
<td>INT</td>
<td>Converts a value to integer type.</td>
</tr>
<tr>
<td>LOGICAL</td>
<td>Converts between logical arguments of (optional) kind.</td>
</tr>
<tr>
<td>MAX</td>
<td>Returns largest value among arguments.</td>
</tr>
<tr>
<td>MAX1</td>
<td>Returns largest value among real arguments as integer.</td>
</tr>
<tr>
<td>MIN</td>
<td>Returns smallest value among arguments.</td>
</tr>
<tr>
<td>MIN1</td>
<td>Returns smallest value among real arguments as integer</td>
</tr>
<tr>
<td>MOD</td>
<td>Returns the remainder of the first argument divided by the second argument.</td>
</tr>
<tr>
<td>MODULO</td>
<td>Returns the first argument modulo the second argument.</td>
</tr>
<tr>
<td>NINT</td>
<td>Returns the nearest integer to the argument.</td>
</tr>
<tr>
<td>OUT_OF_RANGE</td>
<td>Indicates if a value can safely be converted to a specified type.</td>
</tr>
<tr>
<td>REAL</td>
<td>Converts a value to real type.</td>
</tr>
<tr>
<td>SIGN</td>
<td>Returns absolute value of the first argument times the sign of the second argument.</td>
</tr>
<tr>
<td>SNGL</td>
<td>Converts a double-precision argument to single-precision real type.</td>
</tr>
<tr>
<td>TRANSFER</td>
<td>Transforms first argument into type of second argument with (optional) size if an array.</td>
</tr>
<tr>
<td>ZEXT</td>
<td>Extends the argument with zeros.</td>
</tr>
</tbody>
</table>

**Trigonometric, Exponential, Root, and Logarithmic Intrinsic Procedures**

The following table lists intrinsic procedures for trigonometric, exponential, root, and logarithmic operations.
Many routines in the LIBM library (Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOS</td>
<td>Returns the arccosine of the argument, expressed in radians between 0 and pi.</td>
</tr>
<tr>
<td>ACOSD</td>
<td>Returns the arccosine of the argument, expressed in degrees between 0 and 180.</td>
</tr>
<tr>
<td>ALOG</td>
<td>Returns natural log of the argument.</td>
</tr>
<tr>
<td>ALOG10</td>
<td>Returns the common log (base 10) of the argument.</td>
</tr>
<tr>
<td>ASIN</td>
<td>Returns the arcsine of the argument, expressed in radians between ±pi/2.</td>
</tr>
<tr>
<td>ASIND</td>
<td>Returns the arcsine of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN</td>
<td>Returns the arctangent of the argument, expressed in radians between ±pi/2.</td>
</tr>
<tr>
<td>ATAND</td>
<td>Returns the arctangent of the argument, expressed in degrees between ±90°.</td>
</tr>
<tr>
<td>ATAN2</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in radians between ±pi.</td>
</tr>
<tr>
<td>ATAN2D</td>
<td>Returns the arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.</td>
</tr>
<tr>
<td>CCOS</td>
<td>Returns complex cosine of the argument.</td>
</tr>
<tr>
<td>CDCOS</td>
<td>Returns the double-precision complex cosine of the argument.</td>
</tr>
<tr>
<td>CDEXP</td>
<td>Returns double-precision complex exponential value of the argument.</td>
</tr>
<tr>
<td>CDLOG</td>
<td>Returns the double-precision complex natural log of the argument.</td>
</tr>
<tr>
<td>CDSIN</td>
<td>Returns the double-precision complex sine of the argument.</td>
</tr>
<tr>
<td>CDSQRT</td>
<td>Returns the double-precision complex square root of the argument.</td>
</tr>
<tr>
<td>CEXP</td>
<td>Returns the complex exponential value of the argument.</td>
</tr>
<tr>
<td>CLOG</td>
<td>Returns the complex natural log of the argument.</td>
</tr>
<tr>
<td>COS</td>
<td>Returns the cosine of the argument, which is in radians.</td>
</tr>
<tr>
<td>COSD</td>
<td>Returns the cosine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>COSH</td>
<td>Returns the hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>COTAN</td>
<td>Returns the cotangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>COTAND</td>
<td>Returns the cotangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>CSIN</td>
<td>Returns the complex sine of the argument.</td>
</tr>
<tr>
<td>CSQRT</td>
<td>Returns the complex square root of the argument.</td>
</tr>
<tr>
<td>DACOS</td>
<td>Returns the double-precision arccosine of the argument radians between 0 and pi.</td>
</tr>
<tr>
<td>DACOSD</td>
<td>Returns the arccosine of the argument in degrees between 0 and 180.</td>
</tr>
<tr>
<td>DASIN</td>
<td>Returns the double-precision arcsine of the argument in radians between ±pi/2.</td>
</tr>
<tr>
<td>DASIND</td>
<td>Returns the double-precision arcsine of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN</td>
<td>Returns the double-precision arctangent of the argument radians between ±pi/2.</td>
</tr>
<tr>
<td>DATAND</td>
<td>Returns the double-precision arctangent of the argument degrees between ±90°.</td>
</tr>
<tr>
<td>DATAN2</td>
<td>Returns the double-precision arctangent of the first argument divided by the second argument, expressed in radians between ±pi.</td>
</tr>
<tr>
<td>DATAN2D</td>
<td>Returns the double-precision arctangent of the first argument divided by the second argument, expressed in degrees between ±180°.</td>
</tr>
<tr>
<td>DCOS</td>
<td>Returns the double-precision cosine of the argument, which is in radians.</td>
</tr>
<tr>
<td>DCOSD</td>
<td>Returns the double-precision cosine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DCOSH</td>
<td>Returns the double-precision hyperbolic cosine of the argument.</td>
</tr>
<tr>
<td>DCOTAN</td>
<td>Returns the double-precision cotangent of the argument.</td>
</tr>
<tr>
<td>DEXP</td>
<td>Returns the double-precision exponential value of the argument.</td>
</tr>
<tr>
<td>DLOG</td>
<td>Returns the double-precision natural log of the argument.</td>
</tr>
<tr>
<td>DLOG10</td>
<td>Returns the double-precision common log (base 10) of the argument.</td>
</tr>
<tr>
<td>DSIN</td>
<td>Returns the double-precision sin of the argument, which is in radians.</td>
</tr>
</tbody>
</table>
### Intrinsic Functions for Floating-Point Inquiry and Control

The following table lists intrinsic functions for floating-point inquiry and control. Certain functions (EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT, and SPACING) return values related to components of the model set of real numbers. For a description of this model, see the [Model for Real Data](#).

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSIND</td>
<td>Returns the double-precision sin of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DSINH</td>
<td>Returns the double-precision hyperbolic sine of the argument.</td>
</tr>
<tr>
<td>DSQRT</td>
<td>Returns the double-precision square root of the argument.</td>
</tr>
<tr>
<td>DTAN</td>
<td>Returns the double-precision tangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>DTAND</td>
<td>Returns the double-precision tangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>DTANH</td>
<td>Returns the double-precision hyperbolic tangent of the argument.</td>
</tr>
<tr>
<td>EXP</td>
<td>Returns the exponential value of the argument.</td>
</tr>
<tr>
<td>EXP10</td>
<td>Returns the base 10 exponential value of the argument.</td>
</tr>
<tr>
<td>LOG</td>
<td>Returns the natural log of the argument.</td>
</tr>
<tr>
<td>LOG10</td>
<td>Returns the common log (base 10) of the argument.</td>
</tr>
<tr>
<td>SIN</td>
<td>Returns the sine of the argument, which is in radians.</td>
</tr>
<tr>
<td>SIND</td>
<td>Returns the sine of the argument, which is in degrees.</td>
</tr>
<tr>
<td>SINH</td>
<td>Returns the hyperbolic sine of the argument.</td>
</tr>
<tr>
<td>SQRT</td>
<td>Returns the square root of the argument.</td>
</tr>
<tr>
<td>TAN</td>
<td>Returns the tangent of the argument, which is in radians.</td>
</tr>
<tr>
<td>TAND</td>
<td>Returns the tangent of the argument, which is in degrees.</td>
</tr>
<tr>
<td>TANH</td>
<td>Returns the hyperbolic tangent of the argument.</td>
</tr>
<tr>
<td>DIGITS</td>
<td>Returns number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>EPSILON</td>
<td>Returns the smallest positive number that when added to one produces a number greater than one for data of the same type as the argument.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EXPONENT</td>
<td>Returns the exponent part of the representation of ( x ).</td>
</tr>
<tr>
<td>FRACTION</td>
<td>Returns the fractional part of the representation of the argument.</td>
</tr>
<tr>
<td>HUGE</td>
<td>Returns largest number that can be represented by data of type the argument.</td>
</tr>
<tr>
<td>MAXEXPONENT</td>
<td>Returns the largest positive decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>MINEXPONENT</td>
<td>Returns the largest negative decimal exponent for data of the same type as the argument.</td>
</tr>
<tr>
<td>NEAREST</td>
<td>Returns the nearest different machine representable number to the first argument in the direction of the sign of the second argument.</td>
</tr>
<tr>
<td>PRECISION</td>
<td>Returns the number of significant digits for data of the same type as the argument.</td>
</tr>
<tr>
<td>RADIX</td>
<td>Returns the base for data of the same type as the argument.</td>
</tr>
<tr>
<td>RANGE</td>
<td>Returns the decimal exponent range for data of the same type as the argument.</td>
</tr>
<tr>
<td>RRSPACING</td>
<td>Returns the reciprocal of the relative spacing of numbers near the argument.</td>
</tr>
<tr>
<td>SCALE</td>
<td>Multiplies the first argument by 2 raised to the power of the second argument.</td>
</tr>
<tr>
<td>SET_EXPONENT</td>
<td>Returns a number whose fractional part is the first argument and whose exponential part is the second argument.</td>
</tr>
<tr>
<td>SPACING</td>
<td>Returns the absolute spacing of numbers near the argument.</td>
</tr>
<tr>
<td>TINY</td>
<td>Returns smallest positive number that can be represented by data of type of the argument.</td>
</tr>
</tbody>
</table>

The portability routines GETCONTROLFPQQ, GETSTATUSFPQQ, LCWRQQ, SCWRQQ, SETCONTROLFPQQ, and SSWRQQ also supply this functionality.

**Character Intrinsic Functions**

The following table lists character intrinsic functions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACHAR</td>
<td>Returns character in a specified position in the ASCII character set.</td>
</tr>
<tr>
<td>ADJUSTL</td>
<td>Adjusts left, removing leading blanks and inserting trailing blanks.</td>
</tr>
<tr>
<td>ADJUSTR</td>
<td>Adjusts right, removing trailing blanks and inserting leading blanks.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CHAR</td>
<td>Returns character in a specified position in the processor's character set</td>
</tr>
<tr>
<td>IACHAR</td>
<td>Returns the position of the argument in the ASCII character set.</td>
</tr>
<tr>
<td>ICHAR</td>
<td>Returns the position of the argument in the processor's character set.</td>
</tr>
<tr>
<td>INDEX</td>
<td>Returns the starting position of a substring in a string, leftmost or (optional) rightmost occurrence.</td>
</tr>
<tr>
<td>LEN</td>
<td>Returns the size of the argument.</td>
</tr>
<tr>
<td>LEN_TRIM</td>
<td>Returns the number of characters in the argument, not counting trailing blanks.</td>
</tr>
<tr>
<td>LGE</td>
<td>Tests whether the first argument is greater than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LGT</td>
<td>Tests whether the first argument is greater than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLE</td>
<td>Tests whether the first argument is less than or equal to the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>LLT</td>
<td>Tests whether the first argument is less than the second argument, based on the ASCII collating sequence.</td>
</tr>
<tr>
<td>REPEAT</td>
<td>Concatenates multiple copies of a string.</td>
</tr>
<tr>
<td>SCAN</td>
<td>Scans a string for any characters in a set and returns leftmost or (optional) rightmost position where a match is found.</td>
</tr>
<tr>
<td>TRIM</td>
<td>Removes trailing blanks from a string.</td>
</tr>
<tr>
<td>VERIFY</td>
<td>Returns the position of the leftmost or (optional) rightmost character in the argument string not in a set, or zero if all characters in the set are present.</td>
</tr>
</tbody>
</table>

**Intrinsic Procedures for Bit Operation and Representation**

The following tables list intrinsic procedures for bit operation and representation.

**Bit Operation**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIT_SIZE</td>
<td>Intrinsic Function</td>
<td>Returns the number of bits in integers of the type the argument.</td>
</tr>
<tr>
<td>BTEST</td>
<td>Intrinsic Function</td>
<td>Tests a bit in a position of the argument; true if bit is 1.</td>
</tr>
<tr>
<td>IAND</td>
<td>Intrinsic Function</td>
<td>Performs a logical AND.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IBCHNG</td>
<td>Intrinsic Function</td>
<td>Reverses value of bit in a position of the argument.</td>
</tr>
<tr>
<td>IBCLR</td>
<td>Intrinsic Function</td>
<td>Clears the bit in a position of the argument to zero.</td>
</tr>
<tr>
<td>IBITS</td>
<td>Intrinsic Function</td>
<td>Extracts a sequence of bits of length from the argument starting in a position.</td>
</tr>
<tr>
<td>IBSET</td>
<td>Intrinsic Function</td>
<td>Sets the bit in a position of the argument to one.</td>
</tr>
<tr>
<td>IEOIR</td>
<td>Intrinsic Function</td>
<td>Performs an exclusive OR.</td>
</tr>
<tr>
<td>IOR</td>
<td>Intrinsic Function</td>
<td>Performs an inclusive OR.</td>
</tr>
<tr>
<td>ISHA</td>
<td>Intrinsic Function</td>
<td>Shifts the argument arithmetically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from the right, ones shifted in from the left.</td>
</tr>
<tr>
<td>ISHC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the argument left or right by shift bits; left if shift positive, right if shift negative. No bits lost.</td>
</tr>
<tr>
<td>ISHFT</td>
<td>Intrinsic Function</td>
<td>Shifts the argument logically left or right by shift bits; left if shift positive, right if shift negative. Zeros shifted in from opposite end.</td>
</tr>
<tr>
<td>ISHFTC</td>
<td>Intrinsic Function</td>
<td>Performs a circular shift of the rightmost bits of (optional) size by shift bits. No bits lost.</td>
</tr>
<tr>
<td>ISHL</td>
<td>Intrinsic Function</td>
<td>Shifts the argument logically left or right by shift bits. Zeros shifted in from opposite end.</td>
</tr>
<tr>
<td>MVBITS</td>
<td>Intrinsic Subroutine</td>
<td>Copies a sequence of bits from one integer to another.</td>
</tr>
<tr>
<td>NOT</td>
<td>Intrinsic Function</td>
<td>Performs a logical complement.</td>
</tr>
</tbody>
</table>
Bit Representation

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEADZ</td>
<td>Intrinsic Function</td>
<td>Returns leading zero bits in an integer.</td>
</tr>
<tr>
<td>POPCNT</td>
<td>Intrinsic Function</td>
<td>Returns number of 1 bits in an integer.</td>
</tr>
<tr>
<td>POPPAR</td>
<td>Intrinsic Function</td>
<td>Returns the parity of an integer.</td>
</tr>
<tr>
<td>TRAILZ</td>
<td>Intrinsic Function</td>
<td>Returns trailing zero bits in an integer.</td>
</tr>
</tbody>
</table>

QuickWin Library Routines Summary

The following table lists Quickwin library routines.
Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows* systems.

**NOTE**
QuickWin applications are only supported for ifort.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABOUTBOXQQ</td>
<td>Function</td>
<td>Adds an About Box with customized text.</td>
</tr>
<tr>
<td>APPENDMENUQQ</td>
<td>Function</td>
<td>Appends a menu item.</td>
</tr>
<tr>
<td>CLICKMENUQQ</td>
<td>Function</td>
<td>Sends menu click messages to the application window.</td>
</tr>
<tr>
<td>DELETEMENUQQ</td>
<td>Function</td>
<td>Deletes a menu item.</td>
</tr>
<tr>
<td>FOCUSQQ</td>
<td>Function</td>
<td>Makes a child window active, and gives focus to the child window.</td>
</tr>
<tr>
<td>GETACTIVEQQ</td>
<td>Function</td>
<td>Gets the unit number of the active child window.</td>
</tr>
<tr>
<td>GETEXITQQ</td>
<td>Function</td>
<td>Gets the setting for a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>GETHWNDQQ</td>
<td>Function</td>
<td>Gets the true windows handle from window with the specified unit number.</td>
</tr>
<tr>
<td>GETWINDOWCONFIG</td>
<td>Function</td>
<td>Returns the current window's properties.</td>
</tr>
<tr>
<td>GETWSIZEQQ</td>
<td>Function</td>
<td>Gets the size of the child or frame window.</td>
</tr>
<tr>
<td>GETUNITQQ</td>
<td>Function</td>
<td>Gets the unit number corresponding to the specified windows handle. Inverse of GETHWNDQQ.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INCHARQQ</td>
<td>Function</td>
<td>Reads a keyboard input and return its ASCII value.</td>
</tr>
<tr>
<td>INITIALSETTINGS</td>
<td>Function</td>
<td>Controls initial menu settings and initial frame window settings.</td>
</tr>
<tr>
<td>INQFOCUSQQ</td>
<td>Function</td>
<td>Determines which window is active and has the focus.</td>
</tr>
<tr>
<td>INSERTMENUQQ</td>
<td>Function</td>
<td>Inserts a menu item.</td>
</tr>
<tr>
<td>INTEGERTORGB</td>
<td>Subroutine</td>
<td>Converts a true color value into its red, green and blue components.</td>
</tr>
<tr>
<td>MESSAGEBOXQQ</td>
<td>Function</td>
<td>Displays a message box.</td>
</tr>
<tr>
<td>MODIFYMENUFLAGSQQ</td>
<td>Function</td>
<td>Modifies a menu item state.</td>
</tr>
<tr>
<td>MODIFYMENUROUTINEQQ</td>
<td>Function</td>
<td>Modifies a menu item's callback routine.</td>
</tr>
<tr>
<td>MODIFYMENUSTRINGQQ</td>
<td>Function</td>
<td>Changes a menu item's text string.</td>
</tr>
<tr>
<td>PASSDIRKEYSQQ</td>
<td>Function</td>
<td>Determines the behavior of direction and page keys.</td>
</tr>
<tr>
<td>REGISTERMOUSEEVENT</td>
<td>Function</td>
<td>Registers the application-defined routines to be called on mouse events.</td>
</tr>
<tr>
<td>RGBTOINTEGER</td>
<td>Function</td>
<td>Converts a trio of red, green and blue values to a true color value for use with RGB functions and subroutines.</td>
</tr>
<tr>
<td>SETACTIVEQQ</td>
<td>Function</td>
<td>Makes the specified window the current active window without giving it the focus.</td>
</tr>
<tr>
<td>SETEXITQQ</td>
<td>Function</td>
<td>Sets a QuickWin application's exit behavior.</td>
</tr>
<tr>
<td>SETMESSAGEQQ</td>
<td>Subroutine</td>
<td>Changes any QuickWin message, including status bar messages, state messages and dialog box messages.</td>
</tr>
<tr>
<td>SETMOUSECURSOR</td>
<td>Function</td>
<td>Sets the mouse cursor for the window in focus.</td>
</tr>
<tr>
<td>SETWINDOWCONFIG</td>
<td>Function</td>
<td>Configures the current window's properties.</td>
</tr>
<tr>
<td>SETWINDOWMENUQQ</td>
<td>Function</td>
<td>Sets the Window menu to which current child window names will be appended.</td>
</tr>
<tr>
<td>SETWSIZEQQ</td>
<td>Function</td>
<td>Sets the size of the child or frame window.</td>
</tr>
</tbody>
</table>
## Graphics Library Routines Summary

The following table lists library routines for graphics. Programs that use these routines must access the appropriate library with USE IFQWIN. These routines are restricted to Windows® systems.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNREGISTERMOUSEEVENT</td>
<td>Function</td>
<td>Removes the callback routine registered by REGISTERMOUSEEVENT.</td>
</tr>
<tr>
<td>WAITONMOUSEEVENT</td>
<td>Function</td>
<td>Blocks return until a mouse event occurs.</td>
</tr>
<tr>
<td>ARC, ARC_W</td>
<td>Functions</td>
<td>Draws an arc.</td>
</tr>
<tr>
<td>CLEARSCREEN</td>
<td>Subroutine</td>
<td>Clears the screen, viewport, or text window.</td>
</tr>
<tr>
<td>DISPLAYCURSOR</td>
<td>Function</td>
<td>Turns the cursor off and on.</td>
</tr>
<tr>
<td>ELLIPSE, ELLIPSE_W</td>
<td>Functions</td>
<td>Draws an ellipse or circle.</td>
</tr>
<tr>
<td>FLOODFILL, FLOODFILL_W</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current color index, using the current fill mask.</td>
</tr>
<tr>
<td>FLOODFILLRGB,</td>
<td>Functions</td>
<td>Fills an enclosed area of the screen with the current RGB color, using the current fill mask.</td>
</tr>
<tr>
<td>FLOODFILLRGB_W</td>
<td></td>
<td></td>
</tr>
<tr>
<td>GETARCINFO</td>
<td>Function</td>
<td>Determines the end points of the most recently drawn arc or pie.</td>
</tr>
<tr>
<td>GETBKCOLOR</td>
<td>Function</td>
<td>Returns the current background color index.</td>
</tr>
<tr>
<td>GETBKCOLORRGB</td>
<td>Function</td>
<td>Returns the current background RGB color.</td>
</tr>
<tr>
<td>GETCOLOR</td>
<td>Function</td>
<td>Returns the current color index.</td>
</tr>
<tr>
<td>GETCOLORRGB</td>
<td>Function</td>
<td>Returns the current RGB color.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION,</td>
<td>Subroutines</td>
<td>Returns the coordinates of the current graphics-output position.</td>
</tr>
<tr>
<td>GETCURRENTPOSITION_W</td>
<td></td>
<td></td>
</tr>
<tr>
<td>GETFILLMASK</td>
<td>Subroutine</td>
<td>Returns the current fill mask.</td>
</tr>
<tr>
<td>GETFONTFINFO</td>
<td>Function</td>
<td>Returns the current font characteristics.</td>
</tr>
<tr>
<td>GETGTEXTEXTENT</td>
<td>Function</td>
<td>Determines the width of the specified text in the current font.</td>
</tr>
<tr>
<td>GETGTEXTROTATION</td>
<td>Function</td>
<td>Get the current text rotation angle.</td>
</tr>
<tr>
<td>GETIMAGE, GETIMAGE_W</td>
<td>Subroutines</td>
<td>Stores a screen image in memory.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>GETLINESTYLE</td>
<td>Function</td>
<td>Returns the current line style.</td>
</tr>
<tr>
<td>GETLINEWIDTHQQ</td>
<td>Function</td>
<td>Returns the current line width or the line width set by the last call to SETLINEWIDTHQQ.</td>
</tr>
<tr>
<td>GETPHYSCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to physical coordinates.</td>
</tr>
<tr>
<td>GETPIXEL, GETPIXEL_W</td>
<td>Functions</td>
<td>Returns a pixel's color index.</td>
</tr>
<tr>
<td>GETPIXELRGB, GETPIXELRGB_W</td>
<td>Functions</td>
<td>Returns a pixel's RGB color.</td>
</tr>
<tr>
<td>GETPIXELS</td>
<td>Function</td>
<td>Returns the color indices of multiple pixels.</td>
</tr>
<tr>
<td>GETPIXELSRGB</td>
<td>Function</td>
<td>Returns the RGB colors of multiple pixels.</td>
</tr>
<tr>
<td>GETTEXTCOLOR</td>
<td>Function</td>
<td>Returns the current text color index.</td>
</tr>
<tr>
<td>GETTEXTCOLORRGB</td>
<td>Function</td>
<td>Returns the current text RGB color.</td>
</tr>
<tr>
<td>GETTEXTPOSITION</td>
<td>Subroutine</td>
<td>Returns the current text-output position.</td>
</tr>
<tr>
<td>GETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Returns the boundaries of the current text window.</td>
</tr>
<tr>
<td>GETVIEWCOORD, GETVIEWCOORD_W</td>
<td>Subroutines</td>
<td>Converts physical or window coordinates to viewport coordinates.</td>
</tr>
<tr>
<td>GETWINDOWCOORD</td>
<td>Subroutine</td>
<td>Converts viewport coordinates to window coordinates.</td>
</tr>
<tr>
<td>GETWRITEMODE</td>
<td>Function</td>
<td>Returns the logical write mode for lines.</td>
</tr>
<tr>
<td>GRSTATUS</td>
<td>Function</td>
<td>Returns the status (success or failure) of the most recently called graphics routine.</td>
</tr>
<tr>
<td>IMAGESIZE, IMAGESIZE_W</td>
<td>Functions</td>
<td>Returns image size in bytes.</td>
</tr>
<tr>
<td>INITIALIZEFONTS</td>
<td>Function</td>
<td>Initializes the font library.</td>
</tr>
<tr>
<td>LINETO, LINETO_W</td>
<td>Functions</td>
<td>Draws a line from the current position to a specified point.</td>
</tr>
<tr>
<td>LINETOAR</td>
<td>Function</td>
<td>Draws a line between points in one array and corresponding points in another array.</td>
</tr>
<tr>
<td>LINETOAREX</td>
<td>Function</td>
<td>Similar to LINETOAR, but also lets you specify color and line style.</td>
</tr>
<tr>
<td>LOADIMAGE, LOADIMAGE_W</td>
<td>Functions</td>
<td>Reads a Windows bitmap file (.BMP) and displays it at the specified location.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MOVETO, MOVETO_W</td>
<td>Subroutines</td>
<td>Moves the current position to the specified point.</td>
</tr>
<tr>
<td>OUTGTEXT</td>
<td>Subroutine</td>
<td>Sends text in the current font to the screen at the current position.</td>
</tr>
<tr>
<td>OUTTEXT</td>
<td>Subroutine</td>
<td>Sends text to the screen at the current position.</td>
</tr>
<tr>
<td>PIE, PIE_W</td>
<td>Functions</td>
<td>Draws a pie slice.</td>
</tr>
<tr>
<td>POLYBEZIER, POLYBEZIER_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYBEZIER, POLYBEZIER_W</td>
<td>Functions</td>
<td>Draws one or more Bezier curves.</td>
</tr>
<tr>
<td>POLYGON, POLYGON_W</td>
<td>Functions</td>
<td>Draws a polygon.</td>
</tr>
<tr>
<td>POLYLINEQQ</td>
<td>Function</td>
<td>Draws a line between successive points in an array.</td>
</tr>
<tr>
<td>PUTIMAGE, PUTIMAGE_W</td>
<td>Subroutines</td>
<td>Retrieves an image from memory and displays it.</td>
</tr>
<tr>
<td>RECTANGLE, RECTANGLE_W</td>
<td>Functions</td>
<td>Draws a rectangle.</td>
</tr>
<tr>
<td>REMAPALLPALETTERGB</td>
<td>Function</td>
<td>Remaps a set of RGB color values to indices recognized by the current video configuration.</td>
</tr>
<tr>
<td>REMAPPALETTERGB</td>
<td>Function</td>
<td>Remaps a single RGB color value to a color index.</td>
</tr>
<tr>
<td>SAVEIMAGE, SAVEIMAGE_W</td>
<td>Functions</td>
<td>Captures a screen image and saves it as a Windows bitmap file.</td>
</tr>
<tr>
<td>SCROLLTEXTWINDOW</td>
<td>Subroutine</td>
<td>Scrolls the contents of a text window.</td>
</tr>
<tr>
<td>SETBKCOLOR</td>
<td>Function</td>
<td>Sets the current background color.</td>
</tr>
<tr>
<td>SETBKCOLORRGB</td>
<td>Function</td>
<td>Sets the current background color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETCLIPRGN</td>
<td>Subroutine</td>
<td>Limits graphics output to a part of the screen.</td>
</tr>
<tr>
<td>SETCOLOR</td>
<td>Function</td>
<td>Sets the current color to a new color index.</td>
</tr>
<tr>
<td>SETCOLORRGB</td>
<td>Function</td>
<td>Sets the current color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETFILLMASK</td>
<td>Subroutine</td>
<td>Changes the current fill mask to a new pattern.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SETFONT</td>
<td>Function</td>
<td>Finds a single font matching the specified characteristics and assigns it to OUTGTEXT.</td>
</tr>
<tr>
<td>SETGTEXTROTATION</td>
<td>Subroutine</td>
<td>Sets the direction in which text is written to the specified angle.</td>
</tr>
<tr>
<td>SETLINESTYLE</td>
<td>Subroutine</td>
<td>Changes the current line style.</td>
</tr>
<tr>
<td>SETLINEWIDTHQQ</td>
<td>Subroutine</td>
<td>Sets the width of a solid line drawn using any of the supported graphics functions.</td>
</tr>
<tr>
<td>SETPIXEL, SETPIXEL_W</td>
<td>Functions</td>
<td>Sets color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELRGB, SETPIXELRGB_W</td>
<td>Functions</td>
<td>Sets RGB color of a pixel at a specified location.</td>
</tr>
<tr>
<td>SETPIXELS</td>
<td>Subroutine</td>
<td>Sets the color indices of multiple pixels.</td>
</tr>
<tr>
<td>SETPIXELSRGB</td>
<td>Subroutine</td>
<td>Sets the RGB color of multiple pixels.</td>
</tr>
<tr>
<td>SETTEXTCOLOR</td>
<td>Function</td>
<td>Sets the current text color to a new color index.</td>
</tr>
<tr>
<td>SETTEXTCOLORRRGB</td>
<td>Function</td>
<td>Sets the current text color to a direct color value rather than an index to a defined palette.</td>
</tr>
<tr>
<td>SETTEXTCURSOR</td>
<td>Function</td>
<td>Sets the height and width of the text cursor for the window in focus.</td>
</tr>
<tr>
<td>SETTEXTPosition</td>
<td>Subroutine</td>
<td>Changes the current text position.</td>
</tr>
<tr>
<td>SETTEXTWINDOW</td>
<td>Subroutine</td>
<td>Sets the current text display window.</td>
</tr>
<tr>
<td>SETVIEWORG</td>
<td>Subroutine</td>
<td>Positions the viewport coordinate origin.</td>
</tr>
<tr>
<td>SETVIEWPORT</td>
<td>Subroutine</td>
<td>Defines the size and screen position of the viewport.</td>
</tr>
<tr>
<td>SETWINDOW</td>
<td>Function</td>
<td>Defines the window coordinate system.</td>
</tr>
<tr>
<td>SETWRITEMODE</td>
<td>Function</td>
<td>Changes the current logical write mode for lines.</td>
</tr>
<tr>
<td>WRAPON</td>
<td>Function</td>
<td>Turns line wrapping on or off.</td>
</tr>
</tbody>
</table>

**Portability Library Routines**

The following tables list library routines for portability.

If you have programs that use these routines, it is recommended that they access the portability library with USE IFPORT.
Some routines in this library can be called with different sets of arguments, and some can be used as a function or a subroutine. In these cases, the arguments and calling mechanism determine the meaning of the routine. The IFPORT module contains generic interface blocks that give procedure definitions for these routines.

Fortran contains intrinsic procedures for many of the portability functions. The portability routines are extensions to the Fortran 2018 standard. For portability and performance, you should write code using Fortran standard intrinsic procedures whenever possible.

**Information Retrieval**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FOR_IFCORE_VERSION</td>
<td>Function</td>
<td>Returns the version of the Fortran run-time library (ifcore).</td>
</tr>
<tr>
<td>FOR_IFPORT_VERSION</td>
<td>Function</td>
<td>Returns the version of the Fortran portability library (ifport).</td>
</tr>
<tr>
<td>FSTAT</td>
<td>Function</td>
<td>Returns information about a logical file unit.</td>
</tr>
<tr>
<td>GETCWD</td>
<td>Function</td>
<td>Returns the pathname of the current working directory.</td>
</tr>
<tr>
<td>GETENV</td>
<td>Subroutine</td>
<td>Searches the environment for a given string and returns its value if found.</td>
</tr>
<tr>
<td>GETGID</td>
<td>Function</td>
<td>Returns the group ID of the user.</td>
</tr>
<tr>
<td>GETLOG</td>
<td>Subroutine</td>
<td>Returns the user's login name.</td>
</tr>
<tr>
<td>GETPID</td>
<td>Function</td>
<td>Returns the process ID of the process.</td>
</tr>
<tr>
<td>GETUID</td>
<td>Function</td>
<td>Returns the user ID of the user of the process.</td>
</tr>
<tr>
<td>HOSTNAM(^1)</td>
<td>Function</td>
<td>Returns the name of the user's host.</td>
</tr>
<tr>
<td>ISATTY</td>
<td>Function</td>
<td>Checks whether a logical unit number is a terminal.</td>
</tr>
<tr>
<td>STAT</td>
<td>Function</td>
<td>Returns information about a named file. STAT is the preferred form of this function.</td>
</tr>
<tr>
<td>RENAME</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>STAT</td>
<td>Function</td>
<td>Returns information about a named file.</td>
</tr>
<tr>
<td>UNLINK</td>
<td>Function</td>
<td>Deletes the file given by path.</td>
</tr>
</tbody>
</table>

**Process Control**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABORT</td>
<td>Subroutine</td>
<td>Stops execution of the current process, clears I/O buffers, and writes a string to external unit 0.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ALARM</td>
<td>Function</td>
<td>Executes an external subroutine after waiting a specified number of seconds.</td>
</tr>
<tr>
<td>KILL</td>
<td>Function</td>
<td>Sends a signal code to the process given by ID.</td>
</tr>
<tr>
<td>SIGNAL</td>
<td>Function</td>
<td>Changes the action for signal.</td>
</tr>
<tr>
<td>SLEEP</td>
<td>Subroutine</td>
<td>Suspends program execution for a specified number of seconds.</td>
</tr>
<tr>
<td>SYSTEM</td>
<td>Function</td>
<td>Executes a command in a separate shell.</td>
</tr>
</tbody>
</table>

### Numeric Values and Conversion

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN</td>
<td>Functions</td>
<td>Return single-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td>BIC, BIS</td>
<td>Subroutines</td>
<td>Perform bit level clear, set, and test for integers.</td>
</tr>
<tr>
<td>BIT</td>
<td>Function</td>
<td>Performs bit level clear, set, and test for integers.</td>
</tr>
<tr>
<td>CDFLOAT</td>
<td>Function</td>
<td>Converts a COMPLEX(4) argument to DOUBLE PRECISION type.</td>
</tr>
<tr>
<td>COMPLINT, COMPLREAL, COMPLLOG</td>
<td>Functions</td>
<td>Return a BIT-WISE complement or logical .NOT. of the argument.</td>
</tr>
<tr>
<td>CSMG</td>
<td>Function</td>
<td>Performs an effective BIT-WISE store under mask.</td>
</tr>
<tr>
<td>DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN</td>
<td>Functions</td>
<td>Return double-precision values of Bessel functions of the first and second kind of orders 1, 2, and n, respectively.</td>
</tr>
<tr>
<td>DFLOATI, DFLOATJ, DFLOATK</td>
<td>Functions</td>
<td>Convert an integer to double-precision real type.</td>
</tr>
<tr>
<td>DRAND, DRANDM</td>
<td>Functions</td>
<td>Return random numbers between 0.0 and 1.0.</td>
</tr>
<tr>
<td>DRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>IDFLOAT</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to double-precision real type.</td>
</tr>
<tr>
<td>IFLOATI, IFLOATJ</td>
<td>Functions</td>
<td>Convert an integer to single-precision real type.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INMAX</td>
<td>Function</td>
<td>Returns the maximum positive value for an integer.</td>
</tr>
<tr>
<td>INTC</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>IRAND, IRANDM</td>
<td>Functions</td>
<td>Return a positive integer in the range 0 through 2<strong>31-1 or 2</strong>15-1 if called without an argument.</td>
</tr>
<tr>
<td>IRANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>IRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>JABS</td>
<td>Function</td>
<td>Computes an absolute value.</td>
</tr>
<tr>
<td>LONG</td>
<td>Function</td>
<td>Converts an INTEGER(2) argument to INTEGER(4) type.</td>
</tr>
<tr>
<td>QRANSET</td>
<td>Subroutine</td>
<td>Sets the seed for a sequence of pseudo-random numbers.</td>
</tr>
<tr>
<td>RAND, RANDOM2</td>
<td>Functions</td>
<td>Return random values in the range 0 through 1.0.</td>
</tr>
<tr>
<td>RANF</td>
<td>Function</td>
<td>Generates a random number between 0.0 and RAND_MAX.</td>
</tr>
<tr>
<td>RANGET</td>
<td>Subroutine</td>
<td>Returns the current seed.</td>
</tr>
<tr>
<td>RANSET</td>
<td>Subroutine</td>
<td>Sets the seed for the random number generator.</td>
</tr>
<tr>
<td>SEED</td>
<td>Subroutine</td>
<td>Changes the starting point of RANDOM.</td>
</tr>
<tr>
<td>SHORT</td>
<td>Function</td>
<td>Converts an INTEGER(4) argument to INTEGER(2) type.</td>
</tr>
<tr>
<td>SRAND</td>
<td>Subroutine</td>
<td>Seeds the random number generator used with IRAND and RAND.</td>
</tr>
</tbody>
</table>

### Input and Output

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS</td>
<td>Function</td>
<td>Checks a file for accessibility according to mode.</td>
</tr>
<tr>
<td>CHMOD</td>
<td>Function</td>
<td>Changes file attributes.</td>
</tr>
<tr>
<td>FGETC</td>
<td>Function</td>
<td>Reads a character from an external unit.</td>
</tr>
<tr>
<td>FLUSH</td>
<td>Function</td>
<td>Flushes the buffer for an external unit to its associated file.</td>
</tr>
<tr>
<td>FPUTC</td>
<td>Function</td>
<td>Writes a character to an external unit.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>----------------</td>
<td>-------------------------------------------------------</td>
</tr>
<tr>
<td>FSEEK</td>
<td>Subroutine</td>
<td>Repositions a file on an external unit.</td>
</tr>
<tr>
<td>FTELL, FTELLI8</td>
<td>Function</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>GETC</td>
<td>Function</td>
<td>Reads a character from unit 5.</td>
</tr>
<tr>
<td>GETPOS, GETPOSI8</td>
<td>Functions</td>
<td>Return the offset, in bytes, from the beginning of the file.</td>
</tr>
<tr>
<td>PUTC</td>
<td>Function</td>
<td>Writes a character to unit 6.</td>
</tr>
</tbody>
</table>

### Date and Time

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLOCK</td>
<td>Function</td>
<td>Returns current time in HH:MM:SS format using a 24-hour clock.</td>
</tr>
<tr>
<td>CLOCKX</td>
<td>Subroutine</td>
<td>Returns the processor clock to the nearest microsecond.</td>
</tr>
<tr>
<td>CTIME</td>
<td>Function</td>
<td>Converts system time to a 24-character ASCII string.</td>
</tr>
<tr>
<td>DATE³</td>
<td>Subroutine or Function</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DATE4</td>
<td>Subroutine</td>
<td>Returns the current system date.</td>
</tr>
<tr>
<td>DCLOCK</td>
<td>Function</td>
<td>Returns the elapsed time in seconds since the start of the current process.</td>
</tr>
<tr>
<td>DTIME</td>
<td>Function</td>
<td>Returns CPU time since later of (1) start of program, or (2) most recent call to DTIME.</td>
</tr>
<tr>
<td>ETIME</td>
<td>Function</td>
<td>Returns elapsed CPU time since the start of program execution.</td>
</tr>
<tr>
<td>FDATE</td>
<td>Subroutine or Function</td>
<td>Returns the current date and time as an ASCII string.</td>
</tr>
<tr>
<td>GETDAT</td>
<td>Subroutine</td>
<td>Returns the date.</td>
</tr>
<tr>
<td>GETTIM</td>
<td>Subroutine</td>
<td>Returns the time.</td>
</tr>
<tr>
<td>GMTIME</td>
<td>Subroutine</td>
<td>Returns Greenwich Mean Time as a 9-element integer array.</td>
</tr>
<tr>
<td>IDATE³</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>IDATE4</td>
<td>Subroutine</td>
<td>Returns the date either as one 3-element array or three scalar parameters (month, day, year).</td>
</tr>
<tr>
<td>ITIME</td>
<td>Subroutine</td>
<td>Returns current time as a 3-element array (hour, minute, second).</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>JDATE</td>
<td>Function</td>
<td>Returns current date as an 8-character string with the Julian date.</td>
</tr>
<tr>
<td>JDATE4</td>
<td>Function</td>
<td>Returns current date as a 10-character string with the Julian date.</td>
</tr>
<tr>
<td>LTIME</td>
<td>Subroutine</td>
<td>Returns local time as a 9-element integer array.</td>
</tr>
<tr>
<td>RTC</td>
<td>Function</td>
<td>Returns number of seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>SECONDS</td>
<td>Function</td>
<td>Returns number of seconds since midnight, less the value of its argument.</td>
</tr>
<tr>
<td>SETDAT</td>
<td>Function</td>
<td>Sets the date.</td>
</tr>
<tr>
<td>SETTIM</td>
<td>Function</td>
<td>Sets the time.</td>
</tr>
<tr>
<td>TIME</td>
<td>Subroutine or Function</td>
<td>As a subroutine, returns time formatted as HH:MM:SS; as a function, returns time in seconds since 00:00:00 GMT, Jan 1, 1970.</td>
</tr>
<tr>
<td>TIMEF</td>
<td>Function</td>
<td>Returns the number of seconds since the first time this function was called (or zero).</td>
</tr>
</tbody>
</table>

**Error Handling**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GETLASTERROR</td>
<td>Function</td>
<td>Returns the last error set.</td>
</tr>
<tr>
<td>GETLASTERRORQQ</td>
<td>Function</td>
<td>Returns the last error set by a run-time function or subroutine.</td>
</tr>
<tr>
<td>IERRORNO</td>
<td>Function</td>
<td>Returns the last code error.</td>
</tr>
<tr>
<td>SETERRORMODEQQ</td>
<td>Subroutine</td>
<td>Sets the mode for handling critical errors.</td>
</tr>
</tbody>
</table>

**Program Control**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAISEQQ</td>
<td>Function</td>
<td>Sends an interrupt to the executing program, simulating an interrupt from the operating system.</td>
</tr>
<tr>
<td>RUNQQ</td>
<td>Function</td>
<td>Calls another program and waits for it to execute.</td>
</tr>
<tr>
<td>SIGNALQQ</td>
<td>Function</td>
<td>Controls signal handling.</td>
</tr>
<tr>
<td>SLEEPQQ</td>
<td>Subroutine</td>
<td>Delays execution of the program for the specified time.</td>
</tr>
</tbody>
</table>
### System, Drive, and Directory

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHDIR</td>
<td>Function</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>CHANGEDIRQQ</td>
<td>Function</td>
<td>Makes the specified directory the current (default) directory.</td>
</tr>
<tr>
<td>CHANGEDRIVEQQ</td>
<td>Function</td>
<td>Makes the specified drive the current drive.</td>
</tr>
<tr>
<td>DELDIRQQ</td>
<td>Function</td>
<td>Deletes a specified directory.</td>
</tr>
<tr>
<td>GETDRIVEDIRQQ</td>
<td>Function</td>
<td>Returns the current drive and directory path.</td>
</tr>
<tr>
<td>GETDRIVESIZEQQ</td>
<td>Function</td>
<td>Gets the size of the specified drive.</td>
</tr>
<tr>
<td>GETDRIVESQQ</td>
<td>Function</td>
<td>Reports the drives available to the system.</td>
</tr>
<tr>
<td>GETENVQQ</td>
<td>Function</td>
<td>Gets a value from the current environment.</td>
</tr>
<tr>
<td>MAKEDIRQQ</td>
<td>Function</td>
<td>Makes a directory with the specified directory name.</td>
</tr>
<tr>
<td>SETENVQQ</td>
<td>Function</td>
<td>Adds a new environment variable, or sets the value of an existing one.</td>
</tr>
<tr>
<td>SYSTEMQQ</td>
<td>Function</td>
<td>Executes a command by passing a command string to the operating system's command interpretor.</td>
</tr>
</tbody>
</table>

### Speaker

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEEPQQ</td>
<td>Subroutine</td>
<td>Sounds the speaker for a specified duration in milliseconds at a specified frequency in Hertz.</td>
</tr>
</tbody>
</table>

### File Management

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DELFILESQQ</td>
<td>Function</td>
<td>Deletes the specified files in a specified directory.</td>
</tr>
<tr>
<td>FINDFILEQQ</td>
<td>Function</td>
<td>Searches for a file in the directories specified in the PATH environment variable.</td>
</tr>
<tr>
<td>FULLPATHQQ</td>
<td>Function</td>
<td>Returns the full path for a specified file or directory.</td>
</tr>
<tr>
<td>GETFILEINFOQQ</td>
<td>Function</td>
<td>Returns information about files with names that match a request string.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------</td>
<td>-----------------------------------------------------------</td>
</tr>
<tr>
<td>PACKTIMEQQ</td>
<td>Subroutine</td>
<td>Packs time values for use by SETFILETIMEQQ.</td>
</tr>
<tr>
<td>RENAMEFILEQQ</td>
<td>Function</td>
<td>Renames a file.</td>
</tr>
<tr>
<td>SETFILEACCESSQQ</td>
<td>Function</td>
<td>Sets file-access mode for the specified file.</td>
</tr>
<tr>
<td>SETFILETIMEQQ</td>
<td>Function</td>
<td>Sets modification time for a given file.</td>
</tr>
<tr>
<td>SPLITPATHQQ</td>
<td>Function</td>
<td>Breaks a full path into four components.</td>
</tr>
<tr>
<td>UNPACKTIMEQQ</td>
<td>Subroutine</td>
<td>Unpacks a file's packed time and date value into its component parts.</td>
</tr>
</tbody>
</table>

**Arrays**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BSEARCHQQ</td>
<td>Function</td>
<td>Performs a binary search for a specified element on a sorted one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
<tr>
<td>SORTQQ</td>
<td>Subroutine</td>
<td>Sorts a one-dimensional array of non-structure data types (derived types are not allowed).</td>
</tr>
</tbody>
</table>

**Floating-Point Inquiry and Control**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLEARSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Clears the exception flags in the floating-point processor status word.</td>
</tr>
<tr>
<td>GETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>GETSTATUSFPQQ</td>
<td>Subroutine</td>
<td>Returns the value of the floating-point processor status word.</td>
</tr>
<tr>
<td>LCWRQQ</td>
<td>Subroutine</td>
<td>Same as SETCONTROLFPQQ.</td>
</tr>
<tr>
<td>SCWRQQ</td>
<td>Subroutine</td>
<td>Same as GETCONTROLFPQQ.</td>
</tr>
<tr>
<td>SETCONTROLFPQQ</td>
<td>Subroutine</td>
<td>Sets the value of the floating-point processor control word.</td>
</tr>
<tr>
<td>SSWRQQ</td>
<td>Subroutine</td>
<td>Same as GETSTATUSFPQQ.</td>
</tr>
</tbody>
</table>

**IEEE Functionality**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_FLAGS</td>
<td>Function</td>
<td>Sets, gets, or clears IEEE flags.</td>
</tr>
<tr>
<td>IEEE_HANDLER</td>
<td>Function</td>
<td>Establishes a handler for IEEE exceptions.</td>
</tr>
</tbody>
</table>
## Serial Port I/O

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SPORT_CANCEL_IO</td>
<td>Function</td>
<td>Cancels any I/O in progress to the specified port.</td>
</tr>
<tr>
<td>SPORT_CONNECT</td>
<td>Function</td>
<td>Establishes the connection to a serial port and defines certain usage parameters.</td>
</tr>
<tr>
<td>SPORT_CONNECT_EX</td>
<td>Function</td>
<td>Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception.</td>
</tr>
<tr>
<td>SPORT_GET_HANDLE</td>
<td>Function</td>
<td>Returns the Windows* handle associated with the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits, and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_STATE_EX</td>
<td>Function</td>
<td>Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_GET_TIMEOUTS</td>
<td>Function</td>
<td>Returns the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT.Peek_Data</td>
<td>Function</td>
<td>Returns information about the availability of input data.</td>
</tr>
<tr>
<td>SPORT.Peek_Line</td>
<td>Function</td>
<td>Returns information about the availability of input records.</td>
</tr>
<tr>
<td>SPORT.PURGE</td>
<td>Function</td>
<td>Executes a purge function on the specified port.</td>
</tr>
<tr>
<td>SPORT_READ_DATA</td>
<td>Function</td>
<td>Reads available data from the port specified.</td>
</tr>
<tr>
<td>SPORT_READ_LINE</td>
<td>Function</td>
<td>Reads a record from the port specified.</td>
</tr>
<tr>
<td>SPORT_RELEASE</td>
<td>Function</td>
<td>Releases a serial port that has previously been connected.</td>
</tr>
<tr>
<td>SPORT_SET_STATE</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits and stop bit settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_STATE_EX</td>
<td>Function</td>
<td>Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port.</td>
</tr>
<tr>
<td>SPORT_SET_TIMEOUTS</td>
<td>Function</td>
<td>Sets the user selectable timeouts for the serial port.</td>
</tr>
<tr>
<td>SPORT_SHOW_STATE</td>
<td>Function</td>
<td>Displays the state of a port.</td>
</tr>
<tr>
<td>Name</td>
<td>Procedure Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>----------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SPORT_SPECIAL_FUNC</td>
<td>Function</td>
<td>Executes a communications function on a specified port.</td>
</tr>
<tr>
<td>SPORT_WRITE_DATA</td>
<td>Function</td>
<td>Outputs data to a specified port.</td>
</tr>
<tr>
<td>SPORT_WRITE_LINE</td>
<td>Function</td>
<td>Outputs data to a specified port and follows it with a record terminator.</td>
</tr>
</tbody>
</table>

**Miscellaneous**

<table>
<thead>
<tr>
<th>Name</th>
<th>Procedure Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LNBLNK</td>
<td>Function</td>
<td>Returns the index of the last non-blank character in a string.</td>
</tr>
<tr>
<td>QSORT</td>
<td>Subroutine</td>
<td>Returns a sorted version of a one-dimensional array of a specified number of elements of a named size.</td>
</tr>
<tr>
<td>RINDEX</td>
<td>Function</td>
<td>Returns the index of the last occurrence of a substring in a string.</td>
</tr>
<tr>
<td>SCANENV</td>
<td>Subroutine</td>
<td>Scans the environment for the value of an environment variable.</td>
</tr>
<tr>
<td>TTYNAM</td>
<td>Subroutine</td>
<td>Checks whether a logical unit is a terminal.</td>
</tr>
</tbody>
</table>

1. This routine can also be specified as HOSTNM.
2. There is also a RANDOM subroutine in the portability library.
3. The two-digit year return value of DATE, IDATE, and JDATE may cause problems with the year 2000. Use the intrinsic subroutine DATE_AND_TIME instead.
4. W*S

**National Language Support Library Routines Summary**

The following table lists library routines for National Language Support (NLS).

Programs that use these routines must access the NLS library with USE IFNLS. These routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

<table>
<thead>
<tr>
<th>Name</th>
<th>Routine Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MBCharLen</td>
<td>Function</td>
<td>Returns the length of the first multibyte character in a string.</td>
</tr>
<tr>
<td>MBConvertMBToUnicode</td>
<td>Function</td>
<td>Converts a character string from a multibyte codepage to a Unicode string.</td>
</tr>
<tr>
<td>MBConvertUnicodeToMB</td>
<td>Function</td>
<td>Converts a Unicode string to a multibyte character string of the current codepage.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MBCurMax</td>
<td>Function</td>
<td>Returns the longest possible multibyte character for the current codepage.</td>
</tr>
<tr>
<td>MBINCHARQQ</td>
<td>Function</td>
<td>Same as INCHARQQ, but can read a single multibyte character at once.</td>
</tr>
<tr>
<td>MBINDEX</td>
<td>Function</td>
<td>Same as INDEX, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>MBJISToJMS</td>
<td>Function</td>
<td>Converts a Japan Industry Standard (JIS) character to a Kanji (Shift JIS or JMS) character.</td>
</tr>
<tr>
<td>MBJMSToJIS</td>
<td>Function</td>
<td>Converts a Kanji (Shift JIS or JMS) character to a Japan Industry Standard (JIS) character.</td>
</tr>
<tr>
<td>MBLead</td>
<td>Function</td>
<td>Determines whether a given character is the first byte of a multibyte character.</td>
</tr>
<tr>
<td>MBLen</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, including trailing spaces.</td>
</tr>
<tr>
<td>MBLen_Trim</td>
<td>Function</td>
<td>Returns the number of multibyte characters in a string, not including trailing spaces.</td>
</tr>
<tr>
<td>MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE</td>
<td>Function</td>
<td>Same as LGE, LGT, LLLE, and LLT, and the logical operators .EQ. and .NE., except that multibyte characters can be included in their arguments.</td>
</tr>
<tr>
<td>MBNext</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately after the given string position.</td>
</tr>
<tr>
<td>MBPrev</td>
<td>Function</td>
<td>Returns the string position of the first byte of the multibyte character immediately before the given string position.</td>
</tr>
<tr>
<td>MBSCAN</td>
<td>Function</td>
<td>Same as SCAN, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>MBStrLead</td>
<td>Function</td>
<td>Performs a context sensitive test to determine whether a given byte in a character string is a lead byte.</td>
</tr>
<tr>
<td>MBVERIFY</td>
<td>Function</td>
<td>Same as VERIFY, except that multibyte characters can be included in its arguments.</td>
</tr>
<tr>
<td>Name</td>
<td>Routine Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NLSEnumCodepages</td>
<td>Function</td>
<td>Returns an array of valid codepages for the current console.</td>
</tr>
<tr>
<td>NLSEnumLocales</td>
<td>Function</td>
<td>Returns an array of locales (language/country combinations) installed on the system.</td>
</tr>
<tr>
<td>NLSFormatCurrency</td>
<td>Function</td>
<td>Formats a currency number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatDate</td>
<td>Function</td>
<td>Formats a date according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatNumber</td>
<td>Function</td>
<td>Formats a number according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSFormatTime</td>
<td>Function</td>
<td>Formats a time according to conventions of the current locale (language/country).</td>
</tr>
<tr>
<td>NLSGetEnvironmentCodepage</td>
<td>Function</td>
<td>Returns the current codepage for the system Window or console.</td>
</tr>
<tr>
<td>NLSGetLocale</td>
<td>Subroutine</td>
<td>Returns the current language, country, and/or codepage.</td>
</tr>
<tr>
<td>NLSGetLocaleInfo</td>
<td>Function</td>
<td>Returns information about the current locale.</td>
</tr>
<tr>
<td>NLSSetEnvironmentCodepage</td>
<td>Function</td>
<td>Sets the codepage for the console.</td>
</tr>
<tr>
<td>NLSSetLocale</td>
<td>Function</td>
<td>Sets the current language, country, and codepage.</td>
</tr>
</tbody>
</table>

### POSIX* Library Procedures Summary

Programs that use POSIX procedures must access the appropriate libraries with USE IFPOSIX. The IPX *nnnn* routines are functions; the PXF *nnnn* routines are subroutines, except for the routines named PXFIS *nnnn* and PXFWIF *nnnn*.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPXFARGC</td>
<td>Returns the index of the last command-line argument.</td>
</tr>
<tr>
<td>IPXCONST</td>
<td>Returns the value associated with a constant defined in the C POSIX standard.</td>
</tr>
<tr>
<td>IPXFLENTRIM</td>
<td>Returns the index of the last non-blank character in an input string.</td>
</tr>
<tr>
<td>IPXFEXITSTATUS(^1)</td>
<td>Returns the exit code of a child process.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IPXFWSTOPSIG(^1)</td>
<td>Returns the number of the signal that caused a child process to stop.</td>
</tr>
<tr>
<td>IPXFWTERMSIG(^1)</td>
<td>Returns the number of the signal that caused a child process to terminate.</td>
</tr>
<tr>
<td>PXF(type)GET</td>
<td>Gets the value stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXF(type)SET</td>
<td>Sets the value of a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)GET</td>
<td>Gets the array values stored in a component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFA(type)SET</td>
<td>Sets the value of an array component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFACCESS</td>
<td>Determines the accessibility of a file.</td>
</tr>
<tr>
<td>PXFALARM</td>
<td>Schedules an alarm.</td>
</tr>
<tr>
<td>PXFCALLSUBHANDLE</td>
<td>Calls the associated subroutine.</td>
</tr>
<tr>
<td>PXFCFGETISPEED(^1)</td>
<td>Returns the input baud rate from a termios structure.</td>
</tr>
<tr>
<td>PXFCFGETOSPEED(^1)</td>
<td>Returns the output baud rate from a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETISPEED(^1)</td>
<td>Sets the input baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCFSETOSPEED(^1)</td>
<td>Sets the output baud rate in a termios structure.</td>
</tr>
<tr>
<td>PXFCHDIR</td>
<td>Changes the current working directory.</td>
</tr>
<tr>
<td>PXFCHMOD</td>
<td>Changes the ownership mode of the file.</td>
</tr>
<tr>
<td>PXFCHOWN(^1)</td>
<td>Changes the owner and group of a file.</td>
</tr>
<tr>
<td>PXFCLEARENV</td>
<td>Clears the process environment.</td>
</tr>
<tr>
<td>PXFCLOSE</td>
<td>Closes the file associated with the descriptor.</td>
</tr>
<tr>
<td>PXFCLOSEDIR</td>
<td>Closes the directory stream.</td>
</tr>
<tr>
<td>PXFCNTL(^1)</td>
<td>Manipulates an open file descriptor.</td>
</tr>
<tr>
<td>PXFCONST</td>
<td>Returns the value associated with a constant.</td>
</tr>
<tr>
<td>PXFCREAT</td>
<td>Creates a new file or rewrites an existing file.</td>
</tr>
<tr>
<td>PXFCTERMID(^1)</td>
<td>Generates a terminal pathname.</td>
</tr>
<tr>
<td>PXFDUP, PXFDUP2</td>
<td>Duplicates an existing file descriptor.</td>
</tr>
<tr>
<td>PXFE(type)GET</td>
<td>Gets the value stored in an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFE(type)SET</td>
<td>Sets the value of an array element component (or field) of a structure.</td>
</tr>
<tr>
<td>PXFEXECV, PXFEXECVE, PXFEXECVP</td>
<td>Executes a new process by passing command-line arguments.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFEXIT, PXFFASTEXIT</td>
<td>Exits from a process.</td>
</tr>
<tr>
<td>PXFFDOPEN</td>
<td>Opens an external unit.</td>
</tr>
<tr>
<td>PXFFFLUSH</td>
<td>Flushes a file directly to disk.</td>
</tr>
<tr>
<td>PXFFGETC</td>
<td>Reads a character from a file.</td>
</tr>
<tr>
<td>PXFFILENO</td>
<td>Returns the file descriptor associated with a specified unit.</td>
</tr>
<tr>
<td>PXFFORK¹</td>
<td>Creates a child process that differs from the parent process only in its PID.</td>
</tr>
<tr>
<td>PXFFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFFPUTC</td>
<td>Writes a character to a file.</td>
</tr>
<tr>
<td>PXFFSEEK</td>
<td>Modifies a file position.</td>
</tr>
<tr>
<td>PXFFSTAT</td>
<td>Gets a file's status information.</td>
</tr>
<tr>
<td>PXFTELL</td>
<td>Returns the relative position in bytes from the beginning of the file.</td>
</tr>
<tr>
<td>PXFGETARG</td>
<td>Gets the specified command-line argument.</td>
</tr>
<tr>
<td>PXFGETC</td>
<td>Reads a character from standard input unit 5.</td>
</tr>
<tr>
<td>PXFGETCWD</td>
<td>Returns the path of the current working directory.</td>
</tr>
<tr>
<td>PXFGETEGID¹</td>
<td>Gets the effective group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETENV</td>
<td>Gets the setting of an environment variable.</td>
</tr>
<tr>
<td>PXFGETEUID¹</td>
<td>Gets the effective user ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGID¹</td>
<td>Gets the real group ID of the current process.</td>
</tr>
<tr>
<td>PXFGETGRGID¹</td>
<td>Gets group information for the specified GID.</td>
</tr>
<tr>
<td>PXFGETGRNAM¹</td>
<td>Gets group information for the named group.</td>
</tr>
<tr>
<td>PXFGETGROUPS¹</td>
<td>Gets supplementary group IDs.</td>
</tr>
<tr>
<td>PXFGETLOGIN</td>
<td>Gets the name of the user.</td>
</tr>
<tr>
<td>PXFGETPGRP¹</td>
<td>Gets the process group ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPID</td>
<td>Gets the process ID of the calling process.</td>
</tr>
<tr>
<td>PXFGETPPID</td>
<td>Gets the process ID of the parent of the calling process.</td>
</tr>
<tr>
<td>PXFGETPWNAM¹</td>
<td>Gets password information for a specified name.</td>
</tr>
<tr>
<td>PXFGETPWUID¹</td>
<td>Gets password information for a specified UID.</td>
</tr>
<tr>
<td>PXFGETSUBHANDLE</td>
<td>Returns a subroutine handle for a subroutine.</td>
</tr>
<tr>
<td>PXFGETUID¹</td>
<td>Gets the real user ID of the current process.</td>
</tr>
<tr>
<td>PXFISATTY¹</td>
<td>Tests whether a file descriptor is connected to a terminal.</td>
</tr>
<tr>
<td>Name</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PXFISBLK</td>
<td>Tests for a block special file.</td>
</tr>
<tr>
<td>PXFISCHR</td>
<td>Tests for a character file.</td>
</tr>
<tr>
<td>PXFISCONST</td>
<td>Tests whether a string is a valid constant name.</td>
</tr>
<tr>
<td>PXFISDIR</td>
<td>Tests whether a file is a directory.</td>
</tr>
<tr>
<td>PXFISFIFO</td>
<td>Tests whether a file is a special FIFO file.</td>
</tr>
<tr>
<td>PXFISREG</td>
<td>Tests whether a file is a regular file.</td>
</tr>
<tr>
<td>PXFKILL</td>
<td>Sends a signal to a specified process.</td>
</tr>
<tr>
<td>PXFLINK</td>
<td>Creates a link to a file or directory.</td>
</tr>
<tr>
<td>PXFLOCALTIME</td>
<td>Converts a given elapsed time in seconds to local time.</td>
</tr>
<tr>
<td>PXFLSEEK</td>
<td>Positions a file a specified distance in bytes.</td>
</tr>
<tr>
<td>PXFMKDIR</td>
<td>Creates a new directory.</td>
</tr>
<tr>
<td>PXFMKFIFO</td>
<td>Creates a new FIFO.</td>
</tr>
<tr>
<td>PXFOPEN</td>
<td>Opens or creates a file.</td>
</tr>
<tr>
<td>PXFOPENDIR</td>
<td>Opens a directory and associates a stream with it.</td>
</tr>
<tr>
<td>PXFPATHCONF</td>
<td>Gets the value for a configuration option of an opened file.</td>
</tr>
<tr>
<td>PXFPAUSE</td>
<td>Suspends process execution.</td>
</tr>
<tr>
<td>PXFPIPE</td>
<td>Creates a communications pipe between two processes.</td>
</tr>
<tr>
<td>PXFPOSIXIO</td>
<td>Sets the current value of the POSIX I/O flag.</td>
</tr>
<tr>
<td>PXFPUTC</td>
<td>Outputs a character to logical unit 6 (stdout).</td>
</tr>
<tr>
<td>PXFREAD</td>
<td>Reads from a file.</td>
</tr>
<tr>
<td>PXFREaddir</td>
<td>Reads the current directory entry.</td>
</tr>
<tr>
<td>PXFRENAME</td>
<td>Changes the name of a file.</td>
</tr>
<tr>
<td>PXFREWINDDIR</td>
<td>Resets the position of the stream to the beginning of the directory.</td>
</tr>
<tr>
<td>PXFREMDIR</td>
<td>Removes a directory.</td>
</tr>
<tr>
<td>PXFSETENV</td>
<td>Adds a new environment variable or sets the value of an environment variable.</td>
</tr>
<tr>
<td>PXFSETGID</td>

### COM and Automation Library Routines (W*S)

The following tables list COM and Automation library routines.

Programs that use COM routines must access the appropriate libraries with USE IFCOM. Programs that use automation routines must access the appropriate libraries with USE IFAUTO. Some procedures also require the USE IFWINTY module.

The COM and Automation routines are restricted to Windows* systems.

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

#### Name                  | Routine Type | Description                                                  |

<td>Subroutine</td>
<td>Provides traceback information.</td>
</tr>
</tbody>
</table>

1. **W*S**
2. You do not need a USE IFCORE statement for this routine.

### A to B

This section describes language features that start with A or B.

#### ABORT

**Portability Subroutine:** Flushes and closes I/O buffers, and terminates program execution.

**Module**

USE IFPORT

**Syntax**

CALL ABORT[string]

*string* (Input; optional) Character*(*). Allows you to specify an abort message at program termination. When ABORT is called, "abort:" is written to external unit 0, followed by *string*. If omitted, the default message written to external unit 0 is "abort: Fortran Abort Called."

This subroutine causes the program to terminate and an exit code value of 134 is returned to the program that launched it.

**Example**

USE IFPORT

!The following prints "abort: Fortran Abort Called"
CALL ABORT
!The following prints "abort: Out of here!"
Call ABORT ("Out of here!")

**See Also**

EXIT
STOP

#### ABS

**Elemental Intrinsic Function (Generic):** Computes an absolute value.

**Syntax**

result=ABS(a)
(Input) Must be of type integer, real, or complex.

**Results**

The result has the same type and kind type parameter as \( a \) except if \( a \) is a complex value, the result type is real. If \( a \) is an integer or real value, the value of the result is \(| a |\); if \( a \) is a complex value \((X, Y)\), the result is the real value \(\sqrt{X^2 + Y^2}\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BABS</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIABS(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>IABS (^2)</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIABS</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
<tr>
<td>ABS</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DABS</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QABS</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>CABS (^3)</td>
<td>COMPLEX(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>CDABS(^4)</td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>CQABS</td>
<td>COMPLEX(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)Or HABS.

\(^2\)Or JIABS. For compatibility with older versions of Fortran, IABS can also be specified as a generic function, which allows integer arguments of any kind and produces a result of type default INTEGER.

\(^3\)The setting of compiler options specifying real size can affect CABS, making CABS generic, which allows a complex argument of any kind to produce a result of default REAL.

\(^4\)This function can also be specified as ZABS.

**Example**

ABS (-7.4) has the value 7.4.

ABS ((6.0, 8.0)) has the value 10.0.

The following ABS.F90 program calculates two square roots, retaining the sign:

```fortran
REAL mag(2), sgn(2), result(2)
WRITE (*, '(A)') ' Enter two signed magnitudes: '
READ (*, *) mag
sgn = SIGN((/1.0, 1.0/), mag) ! transfer the signs to 1.0s
result = SQRT (ABS (mag))
! Restore the sign by multiplying by -1 or +1:
result = result * sgn
WRITE (*, *) result
END
```

**ABSTRACT INTERFACE**

**Statement:** Defines an abstract interface.
Syntax

ABSTRACT INTERFACE

[interface-body]...

END INTERFACE

interface-body

Is one or more function or subroutine subprograms or a procedure pointer. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.

The subprogram must not contain a statement function or a DATA, ENTRY, or FORMAT statement; an entry name can be used as a procedure name.

The subprogram can contain a USE statement.

Description

An abstract interface block defines an interface whose name can be used in a PROCEDURE declaration statement to declare subprograms with identical arguments and characteristics.

An abstract interface block cannot contain a PROCEDURE statement or a MODULE PROCEDURE statement.

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host association.

The function or subroutine named in the interface-body cannot have the same name as a keyword that specifies an intrinsic type.

To make an interface block available to multiple program units (through a USE statement), place the interface block in a module.

Example

Previously, within an interface block, you needed to individually declare subroutines and functions that had the same argument keywords and characteristics. For example:

```fortran
INTERFACE
SUBROUTINE SUB_ONE (X)
   REAL, INTENT(IN) :: X
END SUBROUTINE SUB_ONE
SUBROUTINE SUB_TWO (X)
   REAL, INTENT(IN) :: X
END SUBROUTINE SUB_TWO
...
END INTERFACE
```

Now you can use an abstract interface to specify a subprogram name for these identical arguments and characteristics. For example:

```fortran
ABSTRACT INTERFACE
SUBROUTINE TEMPLATE (X)
   REAL, INTENT(IN) :: X
END SUBROUTINE TEMPLATE
END INTERFACE
```
You can then use the subprogram in the abstract interface as a template in a PROCEDURE statement to declare procedures. For example:

```fortran
PROCEDURE (TEMPLATE) :: SUB_ONE, SUB_TWO, ...
```

**See Also**

INTERFACE
PROCEDURE
FUNCTION
SUBROUTINE
Procedure Interfaces
Use and Host Association

**ACCEPT**

*Statement:* Transfers input data.

**Syntax**

**Formatted:**

`ACCEPT form[,io-list]`

**Formatted - List-Directed:**

`ACCEPT *[,io-list]`

**Formatted - Namelist:**

`ACCEPT nml`

- `form` is the nonkeyword form of a format specifier (no FMT=).
- `io-list` is an I/O list.
- `*` is the format specifier indicating list-directed formatting.
- `nml` is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.

The ACCEPT statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units. You can override this restriction by using environment variable FOR_ACCEPT.

**Example**

In the following example, character data is read from the implicit unit and binary values are assigned to each of the five elements of array CHARAR:

```fortran
CHARACTER*10 CHARAR(5)

ACCEPT 200, CHARAR
200 FORMAT (5A10)
```

**ACCESS Function**

*Portability Function:* Determines if a file exists and how it can be accessed.

**Module**

USE IFPORT
Syntax

\[
\text{result} = \text{ACCESS}(\text{name}, \text{mode})
\]

(name) Character*(*). Name of the file whose accessibility is to be determined.

(mode) Character*(*). Modes of accessibility to check for. Must be a character string of length one or greater containing only the characters "r", "w", "x", or "" (a blank). These characters are interpreted as follows.

<table>
<thead>
<tr>
<th>Character</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>r</td>
<td>Tests for read permission</td>
</tr>
<tr>
<td>w</td>
<td>Tests for write permission</td>
</tr>
<tr>
<td>x</td>
<td>Tests for execute permission. On Windows* systems, the extension of name must be .COM, .EXE, .BAT, .CMD, .PL, .KSH, or .CSH.</td>
</tr>
<tr>
<td>(blank)</td>
<td>Tests for existence</td>
</tr>
</tbody>
</table>

The characters within mode can appear in any order or combination. For example, wrx and r are legal forms of mode and represent the same set of inquiries.

Results

The value of the result is INTEGER(4). It is zero if all inquiries specified by mode are true. If either argument is invalid, or if the file cannot be accessed in all of the modes specified, one of the following error codes is returned:

- EACCESS: Access denied; the file's permission setting does not allow the specified access
- EINVAL: The mode argument is invalid
- ENOENT: File or path not found

For a list of error codes, see IERNO.

The name argument can contain either forward or backward slashes for path separators.

On Windows* systems, all files are readable. A test for read permission always returns 0.

Example

use ifport
! checks for read and write permission on the file "DATAFILE.TXT"
J = ACCESS ("DATAFILE.TXT", "rw")
PRINT *, J
! checks whether "DATAFILE.TXT" is executable. It is not, since
! it does not end in .COM, .EXE, .BAT, or .CMD
J = ACCESS ("DATAFILE.TXT","x")
PRINT *, J

INQUIRE
GETFILEINFOQQ
ACHAR

Elemental Intrinsic Function (Generic): Returns the character in a specified position of the ASCII character set, even if the processor’s default character set is different. It is the inverse of the IACHAR function. In Intel® Fortran, ACHAR is equivalent to the CHAR function.

**Syntax**

```
result = ACHAR (i [, kind])
```

- `i` (Input) Is of type integer.
- `kind` (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is character with length 1. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If `i` has a value within the range 0 to 127, the result is the character in position `i` of the ASCII character set; otherwise, it is processor defined. ACHAR (IACHAR(C)) has the value `C` for any character `C` capable of representation in the default character set. For a complete list of ASCII character codes, see Character and Key Code Charts.

**Example**

ACHAR (71) has the value 'G'.

ACHAR (63) has the value '?'.

**See Also**

CHAR
IACHAR
ICHAR

ACOS

Elemental Intrinsic Function (Generic): Produces the arccosine of `x`.

**Syntax**

```
result = ACOS (x)
```

- `x` (Input) Must be of type real, where |x| must be less than or equal to 1, or of type complex.

**Results**

The result type and kind are the same as `x` and is expressed in radians.

If the result is real, the value is expressed in radians and lies in the range 0 <= ACOS(X) <= pi.

If the result is complex, the real part is expressed in radians and lies in the range 0 <= REAL(ACOS (x)) <= pi.
ACOS  
**Elemental Intrinsic Function (Generic):** Produces the arccosine of x.

**Syntax**

\[
\text{result} = \text{ACOS} (x)
\]

\(x\) (Input) Must be of type real. The \(|x|\) must be less than or equal to 1.

**Results**

The result type and kind are the same as \(x\) and are expressed in degrees. The value lies in the range −90 to 90 degrees.

---

**Specific Name** | **Argument Type** | **Result Type**
---|---|---
ACOS ^1 | REAL(4) | REAL(4)
DACOS ^1 | REAL(8) | REAL(8)
QACOS ^2 | REAL(16) | REAL(16)

^1The setting of compiler options specifying real size can affect ACOS and DACOS.

^2Or QARCOS.

---

**Example**

ACOS (0.68032123) has the value .8225955.

ACOSH  
**Elemental Intrinsic Function (Generic):** Produces the hyperbolic arccosine of x.

**Syntax**

\[
\text{result} = \text{ACOSH} (x)
\]

\(x\) (Input) Must be of type real, where \(x\) must be greater than or equal to 1, or of type complex.

**Results**

The result type and kind are the same as \(x\).
If the result is complex, the real part is non-negative, and the imaginary part is expressed in radians and lies in the range \(-\pi \leq \text{AIMAG (ACOSH (x))} \leq \pi\).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACOSH (^1)</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DACOSH (^1)</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QACOSH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect ACOSH and DACOSH.

**Example**

ACOSH (1.0) has the value 0.0.
ACOSH (180.0) has the value 5.8861.

**ADJUSTL**

*Elemental Intrinsic Function (Generic):* Adjusts a character string to the left, removing leading blanks and inserting trailing blanks.

**Syntax**

\[
\text{result} = \text{ADJUSTL (string)}
\]

*string* (Input) Must be of type character.

**Results**

The result type is character with the same length and kind parameter as *string*. The value of the result is the same as *string*, except that any leading blanks have been removed and inserted as trailing blanks.

**Example**

```fortran
CHARACTER(16) STRING
STRING= ADJUSTL('   Fortran 90   ') ! returns 'Fortran 90      '
ADJUSTL ('    SUMMERTIME')     ! has the value 'SUMMERTIME    '
```

**See Also**

ADJUSTR

**ADJUSTR**

*Elemental Intrinsic Function (Generic):* Adjusts a character string to the right, removing trailing blanks and inserting leading blanks.

**Syntax**

\[
\text{result} = \text{ADJUSTR (string)}
\]

*string* (Input) Must be of type character.

**Results**

The result type is character with the same length and kind parameter as *string*. 

**Example**

```fortran
CHARACTER(16) STRING
STRING= ADJUSTR('   Fortran 90   ') ! returns '   Fortran 90   '
ADJUSTR ('   SUMMERTIME') ! has the value '   SUMMERTIME'
```
The value of the result is the same as string, except that any trailing blanks have been removed and inserted as leading blanks.

Example

```
CHARACTER(16) STRING
STRING = ADJUSTR('   Fortran 90   ') ! returns '     Fortran 90'
ADJUSTR('SUMMERTIME ') ! has the value ' SUMMERTIME'
```

See Also

ADJUSTL

**AIMAG**

*Elemental Intrinsic Function (Generic):* Returns the imaginary part of a complex number. *This function can also be specified as IMAG.*

**Syntax**

```
result = AIMAG (z)
```

*z*  
(Input) Must be of type complex.

**Results**

The result type is real with the same kind parameter as *z*. If *z* has the value (*x*, *y*), the result has the value *y*.

<table>
<thead>

<tr>
<td>AIMAG ¹</td>
<td>COMPLEX(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DIMAG</td>
<td>COMPLEX(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QIMAG</td>
<td>COMPLEX(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

¹The setting of compiler options specifying real size can affect AIMAG.

To return the real part of complex numbers, use REAL.

**Example**

AIMAG ((4.0, 5.0)) has the value 5.0.

If *C* is complex, *C%IM* is the same as AIMAG (*C*).

The program AIMAG.F90 applies the quadratic formula to a polynomial and allows for complex results:

```
REAL a, b, c
COMPLEX ans1, ans2, d
WRITE (*, 100)
100 FORMAT (' Enter A, b, and c of the ', &
  'polynomial ax**2 + bx + c: '
)
READ (*, *) a, b, c
d = CSQRT (CMPLX (b**2 - 4.0*a*c)) ! d is either:
  ! 0.0 + i root, or
  ! root + i 0.0
ans1 = (-b + d) / (2.0 * a)
ans2 = (-b - d) / (2.0 * a)
WRITE (*, 200)
200 FORMAT (/ ' The roots are:' /)
```
WRITE (*, 300) REAL(ans1), AIMAG(ans1), &
     REAL(ans2), AIMAG(ans2)
300 FORMAT (' X = ', F10.5, ' + i', F10.5)
END

DBLE

AINT

Elemental Intrinsic Function (Generic): Truncates a value to a whole number.

Syntax
result = AINT (a [,kind])

a
  (Input) Must be of type real.
kind
  (Input; optional) Must be a scalar integer constant expression.

Results
The result type is real. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter is that of a.

The result is defined as the largest integer whose magnitude does not exceed the magnitude of a and whose sign is the same as that of a. If |a| is less than 1, AINT(a) has the value zero.

Specific Name    Argument Type    Result Type
AINT 1            REAL(4)         REAL(4)
DINT 1            REAL(8)         REAL(8)
QINT             REAL(16)         REAL(16)

1The setting of compiler options specifying real size can affect AINT and DINT.

To round rather than truncate, use ANINT.

Example
AINT (3.678) has the value 3.0.
AINT (-1.375) has the value -1.0.

REAL r1, r2
REAL(8) r3(2)
r1 = AINT(2.6) ! returns the value 2.0
r2 = AINT(-2.6) ! returns the value -2.0
r3 = AINT((/1.3, 1.9/), KIND = 8) ! returns the values (1.0D0, 1.0D0)

See Also
ANINT
ALARM

**Portability Function:** Causes a subroutine to begin execution after a specified amount of time has elapsed.

**Module**
USE IFPORT

**Syntax**
result = ALARM (time, proc)

- **time** (Input) Integer. Specifies the time delay, in seconds, between the call to ALARM and the time when proc is to begin execution. If time is 0, the alarm is turned off and no routine is called.

- **proc** (Input) Name of the procedure to call. The procedure takes no arguments and must be declared EXTERNAL.

**Results**
The return value is INTEGER(4). It is zero if no alarm is pending. If an alarm is pending (has already been set by a previous call to ALARM), it returns the number of seconds remaining until the previously set alarm is to go off, rounded up to the nearest second.

After ALARM is called and the timer starts, the calling program continues for time seconds. The calling program then suspends and calls proc, which runs in another thread. When proc finishes, the alarm thread terminates, the original thread resumes, and the calling program resets the alarm. Once the alarm goes off, it is disabled until set again.

If proc performs I/O or otherwise uses the Fortran library, you need to compile it with one of the multithread libraries.

The thread that proc runs in has a higher priority than any other thread in the process. All other threads are essentially suspended until proc terminates, or is blocked on some other event, such as I/O.

No alarms can occur after the main process ends. If the main program finishes or any thread executes an EXIT call, than any pending alarm is deactivated before it has a chance to run.

**Example**
```fortran
USE IFPORT
INTEGER(4) numsec, istat
EXTERNAL subprog
numsec = 4
write *, "subprog will begin in ", numsec, " seconds"
ISTAT = ALARM (numsec, subprog)
```

**See Also**
RUNQQ

**ALIAS Directive**

**General Compiler Directive:** Declares alternate external names for external subprograms.

**Syntax**
!DIR$ ALIAS internal-name,external-name
internal-name

The name of the entity as used in the current program unit. It can be a procedure name, a COMMON block name, a module variable that is initialized, or a PARAMETER in a module. It may not be the name of an internal procedure.

external-name

A name or a character constant, delimited by apostrophes or quotation marks.

If a name is specified, the name (in uppercase) is used as the external name for the specified internal-name. If a character constant is specified, it is used as is; the string is not changed to uppercase, nor are blanks removed.

The ALIAS directive affects only the external name used for references to the specified internal-name.

Names that are not acceptable to the linker will cause link-time errors.

ATTRIBUTES ALIAS
ATTRIBUTES DECORATE
ATTRIBUTES DEFAULT
General Compiler Directives
Syntax Rules for Compiler Directives

ALIGNED Clause

Parallel Directive Clause: Specifies that all variables in a list are aligned.

Syntax

ALIGNED (list [:n])

list

Is the name of one or more variables. Each name must be separated by a comma. Any variable that appears in list cannot appear in more than one ALIGNED clause.

n

Must be a constant positive integer expression; it indicates the number of bytes for the alignment. If n is not specified, the compiler uses the default alignment specified for SIMD instructions on the target platform.

The ALIGNED clause declares that the location of each list item is aligned to the number of bytes expressed in the optional alignment parameter n of the ALIGNED clause. If a list item has the ALLOCATABLE attribute, its allocation status must be allocated. If it has the POINTER attribute, its association status must be associated. If the type of a list item is type(C_PTR) or a Cray pointer, the item must be defined.

NOTE

Be careful when using the ALIGNED clause. Instructing the compiler to implement all array references with aligned data movement instructions will cause a runtime exception if some of the access patterns are actually unaligned.

ALL

Transformational Intrinsic Function (Generic):
Determines if all values are true in an entire array or in a specified dimension of an array.
Syntax
result = ALL (mask)
result = ALL (mask, dim)

mask  (Input) Must be a logical array.
dim   (Input) Must be a scalar integer with a value in the range 1 to n, where n is the rank of mask.

Results
The result is an array or a scalar of type logical.
The result is a scalar if dim is not specified or mask has rank one. A scalar result is true only if all elements of mask are true, or mask has size zero. The result has the value false if any element of mask is false.
An array result has the same type and kind parameters as mask, and a rank that is one less than mask. Its shape is (d₁, d₂, ..., dₘ₋₁, dₘ₊₁, ..., dₙ), where (d₁, d₂,..., dₙ) is the shape of mask.
Each element in an array result is true only if all elements in the one dimensional array defined by mask(s₁, s₂, ..., sₘ₋₁, :, sₘ₊₁, ..., sₙ) are true.

Example

```fortran
LOGICAL mask( 2, 3), AR1(3), AR2(2)
mask = RESHAPE((/ .TRUE., .TRUE., .FALSE., .TRUE., .FALSE., &
              .FALSE./),(/2,3/))
! mask is true false false
! true true false
   AR1 = ALL(mask,DIM = 1) ! evaluates the elements column by column yielding [true false false]
   AR2 = ALL(mask,DIM = 2) ! evaluates the elements row by row yielding [false false].
```

ALL ((/ .TRUE., .FALSE., .TRUE./)) has the value false because some elements of MASK are not true. ALL ((/ .TRUE., .FALSE., .TRUE./)) has the value true because all elements of MASK are true.

A is the array

```
[ 1  5  7 ]
[ 3  6  8 ]
```

and B is the array

```
[ 0  5  7 ]
[ 2  6  9 ].
```

ALL (A .EQ. B, DIM=1) tests to see if all elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, false) because only the second column has elements that are all equal.

ALL (A .EQ. B, DIM=2) tests to see if all elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (false, false) because each row has some elements that are not equal.

ANY
COUNT
ALLOCATABLE

**Statement and Attribute:** Specifies that an object is allocatable. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array. A character object may have a deferred length that is determined when the object is allocated with an ALLOCATE statement. A allocatable scalar object of any type may be allocated with an ALLOCATE statement.

**Syntax**

The ALLOCATABLE attribute can be specified in a type declaration statement or an ALLOCATE statement, and takes one of the following forms:

**Type Declaration Statement:**

type, [att-ls,] ALLOCATABLE [, att-ls] :: a[(d-spec)] [[coarray-spec]][, a[(d-spec)] [[coarray-spec]]]...

**Statement:**

ALLOCATABLE [::] a[(d-spec)] [[coarray-spec]][, a[(d-spec)] [[coarray-spec]]]...

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `a` Is the name of the allocatable object.
- `d-spec` Is a deferred-shape specification (: [, :) ...), where each colon represents a dimension of the array or a deferred-coshape specification.
- `coarray-spec` Is a deferred-coshape specification. The left bracket and right bracket are required.

**Description**

A character object declaration uses LEN=:: to indicate it is deferred length.

If the array is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

When the allocatable object is no longer needed, it can be deallocated by execution of a DEALLOCATE statement.

An allocatable object cannot be specified in a COMMON, EQUIVALENCE, DATA, or NAMELIST statement. Allocatable objects are not saved by default. If you want to retain the values of an allocatable object across procedure calls, you must specify the SAVE attribute for the object.

**Example**

```fortran
! Method for declaring and allocating objects.
INTEGER, ALLOCATABLE :: matrix(:, :)      ! deferred shape
REAL, ALLOCATABLE    :: vector(:)          ! char scalar, len=1
INTEGER, ALLOCATABLE :: k                   ! numeric scalar
CHARACTER(LEN=::), ALLOCATABLE :: c2, c3(:)  ! deferred length, shape
```
ALLOCATE(matrix(3,5),vector(-2:N+2)) ! specifies shapes
ALLOCATE(c1) ! specifies scalar, len=1
ALLOCATE(k) ! specifies scalar
ALLOCATE(character(len=5) :: c2) ! specifies scalar, len=5
ALLOCATE(character(len=3) :: c3(2:4)) ! specifies length, shape

The following example shows a type declaration statement specifying the ALLOCATABLE attribute:

```
REAL, ALLOCATABLE :: Z(:, :, :)
```

The following is an example of the ALLOCATABLE statement:

```
REAL A, B(:)
ALLOCATE :: A(:,:), B
```

Allocation of Allocatable Arrays
SAVE

**ALLOCATE Clause**

**Directive Clause:** Specifies the memory allocator to be used for one or more private variables or common blocks of a construct. This feature is only available for ifx.

**Syntax**

```
ALLOCATE ([allocator :] list)
-or-
ALLOCATE (allocator-modifier [, allocator-modifier] : list)
```

- **allocator**
  - Is an integer expression with a kind type of omp_allocator_handle_kind.

- **list**
  - Is a comma-separated list of variables or named common blocks that have been specified in a data sharing clause on the same directive that makes the variable or common block private for the construct. A common block name must be enclosed in slashes (/ /).

- **allocate-modifier**
  - Is one of the following:
    - ALLOCATOR (allocator)
      - allocator is an integer expression with a kind type of omp_allocator_handle_kind.

      If allocator is not specified, the list items in the clause will be allocated using the allocator specified by the def-allocator-var internal control variable (ICV).
At most one ALLOCATOR allocate-modifier is permitted in the ALLOCATE clause.

- ALIGN (alignment)

  \textit{alignment} is a positive integer scalar expression with a value that is a positive power of two.

  Each list item is allocated with a byte alignment of at least the maximum of the following:
  
  \begin{enumerate}
    \item The required alignment specified by Fortran
    \item The alignment trait of the specified allocator
    \item \textit{alignment} value specified by the ALIGN allocate-modifier
  \end{enumerate}

  If \textit{alignment} is not specified, each list item is allocated with a byte alignment of at least the maximum of the following:
  
  \begin{enumerate}
    \item The required alignment specified by Fortran
    \item The alignment trait of the specified allocator
  \end{enumerate}

  At most one ALIGN allocate-modifier is permitted in the ALLOCATE clause.

  Each list item must appear in a data sharing clause that creates a private copy of the list item in the directive containing the ALLOCATE clause. The storage for the private copies of an object specified in the list are allocated using the specified memory allocator.

  An ALLOCATE clause in a TARGET directive or a directive within a TARGET region must specify an allocator expression unless a REQUIRES directive with the DYNAMIC_ALLOCATORS clause appears in the same compilation unit.

  The result of allocating private variables with a memory allocator whose access trait is set to THREAD by a TASK, TASKLOOP, or TARGET directive is undefined.

**See Also**

ALLOCATE Directive
OpenMP* Memory Spaces and Allocators

**ALLOCATE Directive**

\textit{OpenMP* Fortran Compiler Directive}: Specifies memory allocators to use for object allocation and deallocation. This feature is only available for ifx.

**Syntax**

\begin{verbatim}
!$OMP ALLOCATE (list) [clause [[,] clause]...]
-or-
!$OMP ALLOCATE [(list)] [clause [[,] clause]...]
[!$OMP ALLOCATE (list) [clause [[,] clause]...]
[...]]
ALLOCATE statement

list

clause
\end{verbatim}

\textit{list} is a comma separated list of variables or named common blocks. A common block name must be enclosed in slashes (/ /).

\textit{clause} is one of the following:
• ALLOCATOR (allocator)

  
  allocator is an integer expression with a kind type of omp_allocator_handle_kind.

  If the ALLOCATOR clause is not specified, the list items in that directive will be allocated using the allocator specified by the def-allocator-var internal control variable (ICV).

  At most one ALLOCATOR clause is permitted in the ALLOCATE directive.

• ALIGN (alignment)

  
  alignment is a positive integer scalar expression with a value that is a positive power of two.

  Each list item is allocated with a byte alignment of at least the maximum of the following:

  1. The required alignment specified by Fortran
  2. The alignment trait of the specified allocator
  3. The alignment value specified by the ALIGN clause

  If the ALIGN clause is not specified, each list item is allocated with a byte alignment of at least the maximum of the following:

  1. The required alignment specified by Fortran
  2. The alignment trait of the specified allocator

  At most one ALIGN clause is permitted in the ALLOCATE directive.

The first form of the directive is not associated with an ALLOCATE statement. It is a declarative directive and must appear in the specification part where the list items are declared, and after all declarations of the list items. The storage for each list item will be allocated by the specified memory allocator and deallocated by the same memory allocator when the list item goes out of scope.

The list items in a declarative ALLOCATE directive must not have the POINTER or ALLOCATABLE attribute. If a list item has the SAVE attribute (implicitly or explicitly), is a common block name, or is declared in the scope of a module or submodule, then the specified allocator must be one of the pre-defined memory allocators. The list items in a declarative ALLOCATE directive cannot be an array element, a structure component, or a variable in a common block. The declaration of all list items must be in the same scope as the declarative ALLOCATE directive and must precede the ALLOCATE directive.

A list item may appear once in a declarative ALLOCATE directive and it may appear in only one declarative ALLOCATE directive.

The second form of the ALLOCATE directive is associated with an ALLOCATE statement and can appear in the executable statement part of a subprogram after the first executable statement or OpenMP* construct. It associates an allocator with each allocate item in the associated ALLOCATE statement. If an ALLOCATE directive with no list items appears, all the allocate list objects in the ALLOCATE statement that are not listed in an ALLOCATE directive associated with the same ALLOCATE statement, are allocated by the allocator specified in the ALLOCATE directive with no list items specified. Multiple ALLOCATE directives with list items can be specified for an ALLOCATE statement.

A list item may not appear in more than one ALLOCATE directive associated with a given ALLOCATE statement, or appear more than once in the same directive. Each list item must have the ALLOCATABLE or POINTER attribute. A list item may be a POINTER or ALLOCATABLE component of a derived type. A list item may not be an associate name.
If an object appears as a list item of an ALLOCATE directive, it must also appear in the allocation list of the associated ALLOCATE statement. When an object is deallocated, it is deallocated using the same allocator used to allocate it. If an object is deallocated and reallocated during intrinsic assignment, the same allocator is used for the deallocation and reallocation, otherwise, the allocator specified for a list item is used to allocate the list item only in the ALLOCATE statement associated with the ALLOCATE directive.

If multiple ALLOCATE directives are associated with an ALLOCATE statement, only one ALLOCATE directive can appear with no list items.

An ALLOCATOR must be specified in ALLOCATE directives that appear in a TARGET region, unless a REQUIRES directive with the DYNAMIC_ALLOCATORS clause is specified in the same compilation unit.

When a list item goes out of scope, if it has not been deallocated, it is automatically deallocated with the same allocator that allocated it.

ALLOCATE Clause
OpenMP* Memory Spaces and Allocators

ALLOCATE Statement
Statement: Dynamically creates storage for allocatable variables and pointer targets.

Syntax
ALLOCATE ([type:] object[(s-spec[, s-spec]...)] [, object[(s-spec[, s-spec]...)]]... [[coarray-spec]...[, alloc-opt[, alloc-opt]...])

| type         | Is a data type specifier. If specified, the kind type parameters of each object must be the same as the corresponding type parameter values and each object must be type compatible with the specified type. The type must not have an ultimate subcomponent that is a coarray. You cannot specify type if you specify SOURCE= or MOLD=.
| object       | Is the object to be allocated. It is a variable name or structure component, and must be a pointer or an allocatable object. The object can be of type character with zero length. If the object is a coarray and type is specified, type may not be C_PTR, C_FUNPTR, or TEAM_TYPE. If the object is a coarray and SOURCE= is specified, the declared type of source-expr cannot be C_PTR, C_FUNPTR, or TEAM_TYPE. The object may not be coindexed.
| s-spec       | Is an array shape specification in the form [lower-bound:] upper-bound. Each bound must be a scalar integer expression. The number of shape specifications must be the same as the rank of the object. You can specify an s-spec list for each array object in an ALLOCATE statement.
| coarray-spec | Is a coarray shape specification in the form: [[lower-bound:] upper-bound, ] ... [lower-bound:] * The brackets around coarray-spec are required. A coarray shape specification can only appear if the object is a coarray. The number of coarray specifications must be one less than the corank of the coarray object. |
You can specify STAT=, ERRMSG=, and one of MOLD= or SOURCE= in the same ALLOCATE statement. The keywords can appear in any order.

**Description**

The storage space allocated is uninitialized unless SOURCE= is specified or the type of the object is default initialized.

A bound in *s-spec* must not be an expression containing an array inquiry function whose argument is any allocatable object in the same ALLOCATE statement; for example, the following is not permitted:

```fortran
INTEGER ERR
INTEGER, ALLOCATABLE :: A(:), B(:)
...
ALLOCATE(A(10:25), B(SIZE(A)), STAT=ERR)  ! A is invalid as an argument to function SIZE
```

If *object* is an array, *s-spec* must appear and the number of *s-specs* must equal the rank of *object*, or *source-expr* must appear and have the same rank as *object* and the shape of *object* is that of *source-expr*. If both *s-spec* and SOURCE=*source-expr* appear, *source-expr* must be scalar. If *object* is scalar, no *s-spec* should appear. If SOURCE=*source-expr* appears, *object* is initialized with the value of *source-expr*.

A type parameter value in *type* can be an asterisk if and only if each *object* is a dummy argument for which the corresponding type parameter is assumed.

If a STAT= variable, ERRMSG= variable, or *source-expr* is specified, it must not be allocated in the ALLOCATE statement in which it appears; nor can they depend on the value, bounds, length type parameters, allocation status, or association status of any object in the same ALLOCATE statement.
If the allocation is successful, the STAT= variable becomes defined with the value zero, and the definition status of the ERRMSG= variable remains unchanged. If the allocation is not successful, an error condition occurs, and the STAT= variable is set to a positive integer value (representing the run-time error); the ERRMSG= variable contains a descriptive message about the error condition.

If no STAT= variable is specified and an error condition occurs, the program initiates error termination.

If the allocation is successful and source-expr is specified, the dynamic type and value of the allocated object becomes that of the source expression. If the value of a non-deferred length type parameter of object is different from the value of the corresponding type parameter of source-expr, an error condition occurs.

If any object has a deferred type parameter, is unlimited polymorphic, or is of ABSTRACT type, either type or source-expr must appear.

If object is a coarray, source-expr must not have a dynamic type of C_PTR, C_FUNPTR, EVENT_TYPE, or LOCK_TYPE, or have a subcomponent whose dynamic type is EVENT_TYPE or LOCK_TYPE. The object cannot be a coindexed object.

When an ALLOCATE statement is executed for an object that is a coarray, there is an implicit synchronization of all images. On each image, execution of the segment following the statement is delayed until all other images have executed the same statement the same number of times.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images of the current team has initiated normal termination, the STAT= variable becomes defined with the processor-dependent positive integer value of the constant STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. Otherwise, if an allocatable object is a coarray and one or more images of the current team has failed, the STAT= variable becomes defined with the processor-dependent positive integer value of the constant STAT_FAILED_IMAGE from the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of the ALLOCATE or DEALLOCATE statement, the STAT= variable becomes defined with a processor-dependent positive integer value different from STAT_STOPPED_IMAGE or STAT_FAILED_IMAGE.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images of the current team has failed, each allocatable object is successfully allocated or deallocated on the active images of the current team. If any other error occurs, the allocation status of each allocatable object is processor dependent:

- Successfully allocated allocatable objects have the allocation status of allocated, or associated if the allocate object has the POINTER attribute.
- Successfully deallocated allocatable objects have the allocation status of deallocated, or disassociated if the allocatable object has the POINTER attribute.
- An allocatable object that was not successfully allocated or deallocated has its previous allocation status, or its previous association status if it has the POINTER attribute.

If MOLD= appears and source-expr is a variable, its value does not have to be defined.

To release the storage for an object, use DEALLOCATE.

To determine whether an allocatable object is currently allocated, use the ALLOCATED intrinsic function.

To determine whether a pointer is currently associated with a target, use the ASSOCIATED intrinsic function.

Example

```fortran
!Method for creating and allocating deferred shape arrays.
INTEGER,ALLOCATABLE::matrix(:,:)
REAL, ALLOCATABLE:: vector(:)
.
.
ALLOCATE (matrix(3,5),vector(-2:N+2))
.
.
```
The following shows another example of the ALLOCATE statement:

```
INTEGER J, N, ALLOC_ERR
REAL, ALLOCATABLE :: A(:), B(:,:)
...
ALLOCATE(A(0:80), B(-3:J+1, N), STAT = ALLOC_ERR)
```

The above example allocates the scalar objects \(s\) and \(t\) to be 15 by 25 matrices with the value of \(r\).

Consider the following:

```
REAL(KIND=8) :: r(15, 25)
REAL(KIND=8), ALLOCATABLE :: s(:,,:), t(:,:)
...
ALLOCATE(s,SOURCE=r)
ALLOCATE(t,SOURCE=r)
```

The above example allocates \(s\) and \(t\) to be 15 by 25 arrays with the values of \(r\).

Pointer Assignments
ISO_FORTRAN_ENV Module

**ALLOCATED**

*Inquiry Intrinsic Function (Generic):* Indicates whether an allocatable array or allocatable scalar is currently allocated.

**Syntax**

```
result = ALLOCATED ([ARRAY=]array)
result = ALLOCATED ([SCALAR=]scalar)
```

- **array** (Input) Must be an allocatable array.
- **scalar** (Input) Must be an allocatable scalar.

**Results**

The result is a scalar of type default logical.

The result has the value true if argument \(array\) or \(scalar\) is currently allocated; it has the value false if the argument is not currently allocated.

**NOTE**

When the argument keyword ARRAY is used, \(array\) must be an allocatable array. When the argument keyword SCALAR is used, \(scalar\) must be an allocatable scalar.
Example

```fortran
REAL, ALLOCATABLE :: A(:)
...
IF (.NOT. ALLOCATED(A)) ALLOCATE (A (5))
```

Consider the following:

```fortran
REAL, ALLOCATABLE, DIMENSION (:,:,:) :: E
PRINT *, ALLOCATED (E) ! Returns the value false
ALLOCATE (E (12, 15, 20))
PRINT *, ALLOCATED (E) ! Returns the value true
```

Arrays
Dynamic Allocation

**ANINT**

**Elemental Intrinsic Function (Generic):** Calculates the nearest whole number.

**Syntax**

```fortran
result = ANINT (a[,kind] )
```

- **a**
  - (Input) Must be of type real.

- **kind**
  - (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is real. If **kind** is present, the kind parameter is that specified by **kind**; otherwise, the kind parameter is that of **a**. If **a** is greater than zero, ANINT (**a**) has the value AINT (**a** + 0.5); if **a** is less than or equal to zero, ANINT (**a**) has the value AINT (**a** - 0.5).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANINT ¹</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DNINT ¹</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QNINT</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

¹The setting of compiler options specifying real size can affect ANINT and DNINT.

To truncate rather than round, use AINT.

**Example**

ANINT (3.456) has the value 3.0.
ANINT (-2.798) has the value -3.0.

Consider the following:

```fortran
REAL r1, r2
r1 = ANINT(2.6) ! returns the value 3.0
r2 = ANINT(-2.6) ! returns the value -3.0
```
! Calculates and adds tax to a purchase amount.
   REAL amount, taxrate, tax, total
   taxrate = 0.081
   amount = 12.99
   tax = ANINT (amount * taxrate * 100.0) / 100.0
   total = amount + tax
   WRITE (*, 100) amount, tax, total
100 FORMAT ( 1X, 'AMOUNT', F7.2 /
   + 1X, 'TAX ', F7.2 /
   + 1X, 'TOTAL ', F7.2)
END

See Also
NINT

ANY

Transformational Intrinsic Function (Generic):
Determine if any value is true in an entire array or in
a specified dimension of an array.

Syntax
result = ANY (mask)
result = ANY (mask, dim)

mask
   (Input) Must be a logical array.

dim
   (Input) Must be a scalar integer expression with a value in the range 1
   to n, where n is the rank of mask.

Results
The result is an array or a scalar of type logical.

The result is a scalar if dim is not specified or mask has rank one. A scalar result is true if any elements of
mask are true. The result has the value false if no element of mask is true, or mask has size zero.

An array result has the same type and kind parameters as mask, and a rank that is one less than mask. Its
shape is (d1, d2, ..., dim-1, dim+1, ..., dn), where (d1, d2, ..., dn) is the shape of mask.

Each element in an array result is true if any elements in the one dimensional array defined by mask(s1,
s2, ..., dim-1, :, dim+1, ..., sn) are true.

Example
   LOGICAL mask(2, 3), AR1(3), AR2(2)
   logical, parameter :: T = .true.
   logical, parameter :: F = .false.
   DATA mask /T, T, F, T, F, F/
   ! mask is  true false false
   !            true true false
   !
   AR1 = ANY(mask,DIM = 1) ! evaluates the elements column by
   !   column yielding [true true false]
   AR2 = ANY(mask,DIM = 2) ! evaluates the elements row by row
   !   yielding [true true]

ANY ((/ .FALSE., .FALSE., .TRUE./)) has the value true because one element is true.
A is the array

\[
\begin{bmatrix}
1 & 5 & 7 \\
3 & 6 & 8 \\
\end{bmatrix}
\]

and B is the array

\[
\begin{bmatrix}
0 & 5 & 7 \\
2 & 6 & 9 \\
\end{bmatrix}
\]

ANY (A .EQ. B, DIM=1) tests to see if any elements in each column of A are equal to the elements in the corresponding column of B. The result has the value (false, true, true) because the second and third columns have at least one element that is equal.

ANY (A .EQ. B, DIM=2) tests to see if any elements in each row of A are equal to the elements in the corresponding row of B. The result has the value (true, true) because each row has at least one element that is equal.

ASIN

**Elemental Intrinsic Function (Generic):** Produces the arcsine of an argument.

**Syntax**

\[
\text{result} = \text{ASIN} \ (x)
\]

\(x\) (Input) Must be of type real, where | \(x\) | must be less than or equal to 1, or of type complex.

**Results**

The result type and kind are the same as \(x\).

If the result is real, it is expressed in radians and lies in the range - \(\pi/2 \leq \text{ASIN} \ (x) \leq \pi/2\).

If the result is complex, the real part is expressed in radians and lies in the range \(\pi/2 \leq \text{REAL} \ (\text{ASIN} \ (x)) \leq \pi/2\).

<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

\(\text{ASIN} \ (0.79345021)\) has the value 0.9164571.

ASIND

**Elemental Intrinsic Function (Generic):** Produces the arcsine of \(x\).

**Syntax**

\[
\text{result} = \text{ASIND} \ (x)
\]
Must be of type real. The $|x|$ must be less than or equal to 1.

**Results**
The result type and kind are the same as $x$ and are expressed in degrees. The value lies in the range $-90$ to $90$ degrees.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<tr>
<td>DASIND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QASIND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**
ASIND (0.2467590) has the value 14.28581.

**ASINH**
*Elemental Intrinsic Function (Generic): Produces the hyperbolic arcsine of $x$.*

**Syntax**
```fortran
result = ASINH (x)
```

(Input) Must be of type real or complex.

**Results**
The result type and kind are the same as $x$.

If the result is complex, the imaginary part is expressed in radians and lies in the range $-\pi/2 \leq \text{AIMAG (ASINH (x))} \leq \pi / 2$.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**
ASINH (1.0) has the value -0.88137.
ASINH (180.0) has the value 5.88611.

**ASSIGN - Label Assignment**
*Statement: Assigns a statement label value to an integer variable. This feature has been deleted in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.*

**Syntax**
```fortran
ASSIGN label TO var
```
**label**

Is the label of a branch target or FORMAT statement in the same scoping unit as the ASSIGN statement.

**var**

Is a scalar integer variable.

When an ASSIGN statement is executed, the statement label is assigned to the integer variable. The variable is then undefined as an integer variable and can only be used as a label (unless it is later redefined with an integer value).

The ASSIGN statement must be executed before the statements in which the assigned variable is used. Indirect branching through integer variables makes program flow difficult to read, especially if the integer variable is also used in arithmetic operations. Using these statements permits inconsistent usage of the integer variable, and can be an obscure source of error. The ASSIGN statement was used to simulate internal procedures, which now can be coded directly.

**Example**

The value of a label is not the same as its number; instead, the label is identified by a number assigned by the compiler. In the following example, 400 is the label number (not the value) of IVBL:

```
ASSIGN 400 TO IVBL
```

Variables used in ASSIGN statements are not defined as integers. If you want to use a variable defined by an ASSIGN statement in an arithmetic expression, you must first define the variable by a computational assignment statement or by a READ statement, as in the following example:

```
IVBL = 400
```

The following example shows ASSIGN statements:

```
INTEGER ERROR
...
ASSIGN 10 TO NSTART
ASSIGN 99999 TO KSTOP
ASSIGN 250 TO ERROR
```

Note that NSTART and KSTOP are integer variables implicitly, but ERROR must be previously declared as an integer variable.

The following statement associates the variable NUMBER with the statement label 100:

```
ASSIGN 100 TO NUMBER
```

If an arithmetic operation is subsequently performed on variable NUMBER (such as follows), the run-time behavior is unpredictable:

```
NUMBER = NUMBER + 1
```

To return NUMBER to the status of an integer variable, you can use the following statement:

```
NUMBER = 10
```

This statement dissociates NUMBER from statement 100 and assigns it an integer value of 10. Once NUMBER is returned to its integer variable status, it can no longer be used in an assigned GO TO statement.

**See Also**

Assignment: intrinsic

Obsolescent Language Features in the Fortran Standard
**Assignment(=) - Defined Assignment**

**Statement:** An interface block that defines generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.

**Syntax**

The initial line for such an interface block takes the following form:

```
INTERFACE ASSIGNMENT (=)
```

**Description**

The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN and/or attribute VALUE.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment, enclosed in parentheses, corresponds to the second argument. A defined assignment procedure with an ALLOCATABLE or POINTER dummy argument cannot be directly invoked through defined assignment; the right-hand side of the assignment operator becomes an expression, and an expression cannot have the ALLOCATABLE, POINTER, or TARGET attribute.

The ASSIGNMENT keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

**Example**

The following is an example of a procedure interface block defining assignment:

```
INTERFACE ASSIGNMENT (=)
  SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
    INTEGER, INTENT(OUT) :: NUM
    LOGICAL, INTENT(IN)  :: BIT(:)
  END SUBROUTINE BIT_TO_NUMERIC
  SUBROUTINE CHAR_TO_STRING (STR, CHAR)
    USE STRING_MODULE                    ! Contains definition of type STRING
    TYPE(STRING), INTENT(OUT) :: STR     ! A variable-length string
    CHARACTER(*) , INTENT(IN)  :: CHAR
  END SUBROUTINE CHAR_TO_STRING
END INTERFACE
```

The following example shows two equivalent ways to reference subroutine BIT_TO_NUMERIC:

```
CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
X = NUM(I:J)
```

The following example shows two equivalent ways to reference subroutine CHAR_TO_STRING:

```
CALL CHAR_TO_STRING(CH, '432C')
CH = '432C'
```
The following is an example of a declaration and reference to a defined assignment:

```fortran
! Converting circle data to interval data.
module mod1
  TYPE CIRCLE
    REAL radius, center_point(2)
  END TYPE CIRCLE
  TYPE INTERVAL
    REAL lower_bound, upper_bound
  END TYPE INTERVAL
  CONTAINS
    SUBROUTINE circle_to_interval(I,C)
      type (interval), INTENT(OUT):: I
      type (circle), INTENT(IN):: C
      ! Project circle center onto the x=-axis
      ! Note: the length of the interval is the diameter of the circle
      I%lower_bound = C%center_point(1) - C%radius
      I%upper_bound = C%center_point(1) + C%radius
    END SUBROUTINE circle_to_interval
  end module mod1

PROGRAM assign
  use mod1
  TYPE(CIRCLE) circle1
  TYPE(INTERVAL) interval1
  INTERFACE ASSIGNMENT(=)
    module procedure circle_to_interval
  END INTERFACE
  ! Begin executable part of program
  circle1%radius = 2.5
  circle1%center_point = (/3.0,5.0/)
  interval1 = circle1
  . . .
END PROGRAM
```

See Also

INTERFACE
Assignment Statements

Assignment - Intrinsic Computational

**Statement:** Assigns a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.

**Syntax**

```
variable = expression
```

variable

Is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the PARAMETER or INTENT(IN) attribute.
expression Is of intrinsic type or the same derived type as variable. Its shape must conform with variable. If necessary, it is converted to the same type and kind as variable.

Description
Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.

NOTE
When the run-time system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the run-time system to pass incorrect information back to the program.

If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.

If the !DIR$ NOSTRICT compiler directive (the default) is in effect, then you can assign a character expression to a noncharacter variable, and a noncharacter variable or array element (but not an expression) to a character variable.

Example

```
REAL a, b, c
LOGICAL abigger
CHARACTER(16) assertion
  c = .01
  a = SQRT (c)
  b = c**2
  assertion = 'a > b'
  abigger = (a .GT. b)
WRITE (*, 100) a, b
100 FORMAT ('a =', F7.4, 'b =', F7.4)
  IF (abigger) THEN
    WRITE (*, *) assertion, ' is true.'
  ELSE
    WRITE (*, *) assertion, ' is false.'
  END IF
END
```

The program above has the following output:
```
a = .1000 b = .0001 a > b is true.
```

The following code shows legal and illegal assignment statements:

```
INTEGER i, j
REAL rone(4), rtwo(4), x, y
COMPLEX z
CHARACTER name6(6), name8(8)
i = 4
x = 2.0
z = (3.0, 4.0)
ronel = 4.0
ronetw = 3.0
```
rone(3) = 2.0
rone(4) = 1.0
name8  = 'Hello,,'

! The following assignment statements are legal:
i     = rone(2); j = rone(i); j = x
y     = x; y = z; y = rone(3); rtwo = rone; rtwo = 4.7
name6 = name8

! The following assignment statements are illegal:
name6 = x + 1.0; int = name8//'test'; y = rone

END

See Also
Assignment: defined
NOSTRICT directive

ASSOCIATE
Statement: Marks the beginning of an ASSOCIATE construct. The ASSOCIATE construct creates a temporary association between a named entity and a variable or the value of an expression. The association lasts for the duration of the block.

Syntax
[name:] ASSOCIATE (assoc-entity[, assoc-entity]...)

        block

END ASSOCIATE [name]

name

assoc-entity

(Optional) Is the name of the ASSOCIATE construct.

Is associate-name => selector

associate-name

Is an identifier that becomes associated with the selector. It becomes the associating entity. The identifier name must be unique within the construct.

selector

Is an expression or variable. It becomes the associated entity.

block

Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of an ASSOCIATE statement, the same name must appear in the corresponding END ASSOCIATE statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of an ASSOCIATE statement, you cannot specify one following the END ASSOCIATE statement.

During execution of the block within the construct, each associate-name identifies an entity, which is associated with the corresponding selector. The associating entity assumes the declared type and type parameters of the selector.

You can only branch to an END ASSOCIATE statement from within its ASSOCIATE construct.
This construct is useful when you want to simplify multiple accesses to a variable that has a lengthy description; for example, if the variable contains multiple subscripts and component names.

**Example**

The following shows an expression as a selector:

```fortran
ASSOCIATE (O => (A-F)**2 + (B+G)**2)
   PRINT *, SQRT (O)
END ASSOCIATE
```

The following shows association with an array section:

```fortran
ASSOCIATE (ARRAY => AB % D (I, :) % X)
   ARRAY (3) = ARRAY (1) + ARRAY (2)
END ASSOCIATE
```

Without the ASSOCIATE construct, this is what you would need to write:

```fortran
AB % D (I, 3) % X = AB % D (I, 1) % X + AB % D (I, 2) % X
```

**See Also**

- Construct Association
- Additional Attributes Of Associate Names

## ASSOCIATED

### Inquiry Intrinsic Function (Generic):

*Returns the association status of its pointer argument or indicates whether the pointer is associated with the target.*

### Syntax

```fortran
result = ASSOCIATED (pointer [, target])
```

- **pointer** *(Input)* Must be a pointer. It can be of any data type. The pointer association status must be defined.
- **target** *(Input; optional)* Must be a pointer or target. If it is a pointer, the pointer association status must be defined.

### Results

The result is a scalar of type default logical. *The setting of compiler options specifying integer size can affect this function.*

- If only `pointer` appears, the result is true if it is currently associated with a target; otherwise, the result is false.
- If `target` also appears and is a target, the result is true if `pointer` is currently associated with `target`; otherwise, the result is false.
- If `target` is a pointer, the result is true if both `pointer` and `target` are currently associated with the same target; otherwise, the result is false. *(If either `pointer` or `target` is disassociated, the result is false.)*

### Example

```fortran
REAL C (:), D(:,), E(5)
POINTER C, D
TARGET E
LOGICAL STATUS
C => E           ! pointer assignment
D => E           ! pointer assignment
```
STATUS = ASSOCIATED(C)       ! returns TRUE; C is associated
STATUS = ASSOCIATED(C, E)    ! returns TRUE; C is associated with E
STATUS = ASSOCIATED(C, D)   ! returns TRUE; C and D are associated
                            ! with the same target

Consider the following:

REAL, TARGET, DIMENSION (0:50) :: TAR
REAL, POINTER, DIMENSION (:) :: PTR
PTR => TAR
PRINT *, ASSOCIATED (PTR, TAR) ! Returns the value true

The subscript range for PTR is 0:50. Consider the following pointer assignment statements:

(1) PTR => TAR (:)
(2) PTR => TAR (0:50)
(3) PTR => TAR (0:49)

For statements 1 and 2, ASSOCIATED (PTR, TAR) is true because TAR has not changed (the subscript range for PTR in both cases is 1:51, following the rules for deferred-shape arrays). For statement 3, ASSOCIATED (PTR, TAR) is false because the upper bound of TAR has changed.

Consider the following:

REAL, POINTER, DIMENSION (:) :: PTR2, PTR3
ALLOCATE (PTR2 (0:15))
PTR3 => PTR2
PRINT *, ASSOCIATED (PTR2, PTR3) ! Returns the value true
...
NULLIFY (PTR2)
NULLIFY (PTR3)
PRINT *, ASSOCIATED (PTR2, PTR3) ! Returns the value false

POINTER
TARGET
Pointer Assignments

ASSUME

General Compiler Directive: Provides heuristic information to the compiler optimizer.

Syntax

!DIR$ ASSUME (scalar-Boolean-expression)

scalar-Boolean-expression    Is any expression that evaluates to .TRUE. or .FALSE. at run time.

The scalar-Boolean-expression is presumed to be true and may be used by the optimizer to generate better code.

If the check assume option is specified and scalar-Boolean-expression does not evaluate to .TRUE. at run time, an error message is displayed and execution is aborted.
Example

In the example below, the compiler is told that A is aligned on a 32-byte boundary using the ASSUME_ALIGNED directive. The ASSUME directive says that the length of the first dimension of A is a multiple of 8. Therefore the optimizer knows that A(I,J+1) and A(I,J-1) are 0 mod 64 bytes away from A(I,J) and are therefore also aligned on 32-byte boundaries. This information helps the optimizer in generating efficiently vectorized code for these loops.

SUBROUTINE F (A, NX,NY,I1,I2,J1,J2)
REAL (8) :: A (NX,NY)
!DIR$ ASSUME_ALIGNED A:32
!DIR$ ASSUME (MOD(NX,8) .EQ. 0)
! ensure that the first array access in the loop is aligned
!DIR$ ASSUME (MOD(I1,8) .EQ. 1)
DO J=J1,J2
   DO I=I1,I2
      A(I,J) = A(I,J) + A(I,J+1) + A(I,J-1)
   ENDDO
ENDDO
END SUBROUTINE F

See Also
General Compiler Directives

Syntax Rules for Compiler Directives
ASSUME_ALIGNED directive
check compiler option (setting assume)

ASSUME_ALIGNED
General Compiler Directive: Specifies that an entity in memory is aligned.

Syntax
!DIR$ ASSUME_ALIGNED address1:n1 [, address2:n2]...

address
An array variable. It can be of any data type, kind, or rank > 0. It can be an array component of a variable of derived type or a record field reference, host or use associated, or have the ALLOCATABLE or POINTER attribute.

It cannot be any of the following:
- An entity in COMMON (or an entity EQUIVALENCEd to something in COMMON)
- A component of a variable of derived type or a record field reference
- An entity accessed by use or host association

If it is a module variable, that address is silently ignored.

n
A positive integer constant expression. Its value must be a power of 2 between 1 and 256, that is, 1, 2, 4, 8, 16, 32, 64, 128, 256. It specifies the memory alignment in bytes of address.

The ASSUME_ALIGNED directive must appear after the specification statements section or inside the executable statements section.

If you specify more than one address:n item, they must be separated by a comma.
If *address* is a Cray POINTER or it has the POINTER attribute, it is the POINTER and not the pointee or the TARGET that is assumed aligned.

If the check assume option is specified and *address* is not aligned on an $n$-byte boundary at run time, an error message is displayed and execution is aborted.

For more information, see the example in the description of the ASSUME directive.

**Example**
The following example shows the correct placement and usage of the ASSUME_ALIGNED directive:

```fortran
SUBROUTINE F(A, N)
  TYPE NODE
    REAL(KIND=8), POINTER :: A(:, :)
  END TYPE NODE

  TYPE(NODE), POINTER :: NODES

  ALLOCATE(NODES)
  ALLOCATE(NODES%A(1000, 1000))

  !DIR$ ASSUME_ALIGNED NODES%A(1, 1) : 16
  DO I = 1, N
    NODES%A(1, I) = NODES%A(1, I) + 1
  ENDDO

END
```

It is illegal to place ASSUME_ALIGNED inside a type definition; for example:

```fortran
TYPE S
  !DIR$ ASSUME_ALIGNED T : 16 ! this is an error
  REAL(8), ALLOCATABLE :: T(:)
END TYPE S
```

ATTRIBUTES ALIGN
ASSUME directive
check compiler option

**ASYNCRONOUS**

**Statement and Attribute:** Specifies that a variable can be used for asynchronous input and output.

**Syntax**
The ASYNCRONOUS attribute can be specified in a type declaration statement or an ASYNCRONOUS statement, and takes one of the following forms:

**Type Declaration Statement:**
```fortran
  type, [att-ls,] ASYNCRONOUS [, att-ls] :: var [, var] ...
```

**Statement:**
```fortran
  ASYNCRONOUS [:] var [, var] ...
```
**Description**

Asynchronous I/O, or non-blocking I/O, allows a program to continue processing data while the I/O operation is performed in the background.

A variable can have the ASYNCHRONOUS attribute in a particular scoping unit without necessarily having it in other scoping units. If an object has the ASYNCHRONOUS attribute, then all of its subobjects also have the ASYNCHRONOUS attribute.

The ASYNCHRONOUS attribute can also be implied by use of a variable in an asynchronous READ or WRITE statement.

You can specify variables that are used for asynchronous communication, such as with Message Passing Interface Standard (MPI). Asynchronous communication has the following restrictions:

- For input, a pending communication affector must not be referenced, become defined, become undefined, become associated with a dummy argument that has the VALUE attribute, or have its pointer association status changed.
- For output, a pending communication affector must not be redefined, become undefined, or have its pointer association status changed.

**Examples**

The following example shows how the ASYNCHRONOUS attribute can be applied in an OPEN and READ statement.

```fortran
program test
  integer, asynchronous, dimension(100) :: array
  open (unit=1, file='asynch.dat', asynchronous='YES', &
       form='unformatted')
  write (1) (i, i=1, 100)
  rewind (1)
  read (1, asynchronous='YES') array
  wait(1)
  write (*, *) array(1:10)
end
```

**ATAN**

*Elemental Intrinsic Function (Generic): Produces the arctangent of an argument.*

**Syntax**

\[
\text{result} = \text{ATAN} \ (x) \\
\text{result} = \text{ATAN} \ (y, x) \\
\]

- \(y\) (Input) Must be of type real.
Results
The result type and kind are the same as \( x \).

If \( y \) appears, the result is the same as the result of ATAN2 \((y, x)\).

If \( y \) does not appear, the real part of the result is expressed in radians and lies in the range \(-\pi/2 \leq \text{ATAN2} \((x) \leq \pi/2\).
If $y$ is a negative real zero, the result is $-\pi/2$.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATAN2</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DATAN2</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QATAN2</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

ATAN2 (2.679676, 1.0) has the value 1.213623.

If $Y$ is an array that has the value

\[
\begin{bmatrix}
  1 & 1 \\
  -1 & -1 \\
\end{bmatrix}
\]

and $X$ is an array that has the value

\[
\begin{bmatrix}
  -1 & 1 \\
  -1 & 1 \\
\end{bmatrix}
\]

then ATAN2 ($Y, X$) is

\[
\begin{bmatrix}
\frac{3\pi}{4} & \pi/4 \\
-\frac{3\pi}{4} & -\pi/4 \\
\frac{3\pi}{4} & \pi/4 \\
\end{bmatrix}
\]

**ATAN2D**

*Elemental Intrinsic Function (Generic):* Produces an arctangent. The result is the principal value of the argument of the nonzero complex number $(x, y)$.

**Syntax**

\[
\text{result} = \text{ATAN2D} (y, x)
\]

*y*  
(Input) Must be of type real.

*x*  
(Input) Must have the same type and kind parameters as *y*. If *y* has the value zero, *x* cannot have the value zero.

**Results**

The result type and kind are the same as *x* and are expressed in degrees. The value lies in the range -180 degrees to 180 degrees. If $x$ zero, the result is approximately equal to the value of arctan ($y/x$).

If $y >$ zero, the result is positive.

If $y <$ zero, the result is negative.

If $y =$ zero, the result is zero (if $x >$ zero) or 180 degrees (if $x <$ zero).

If $x =$ zero, the absolute value of the result is 90 degrees.
### ATAN2D

**Elemental Intrinsic Function (Generic):** Returns the arcus tangens of x.

**Syntax**

\[
\text{result} = \text{ATAN2D} (x, y)
\]

\(x, y\) (Input) Must be of type real.

**Result Type**

The result type and kind are the same as the input arguments and are expressed in degrees between ±90°.

### DATAN2D

**Example**

ATAN2D (2.679676, 1.0) has the value 69.53546.

### ATAND

**Elemental Intrinsic Function (Generic):** Produces the arctangent of x.

**Syntax**

\[
\text{result} = \text{ATAND} (x)
\]

x (Input) Must be of type real.

**Results**

The result type and kind are the same as x and are expressed in degrees between ±90°.

### ATANH

**Elemental Intrinsic Function (Generic):** Produces the hyperbolic arctangent of x.

**Syntax**

\[
\text{result} = \text{ATANH} (x)
\]

x (Input) Must be of type real, where |x| is less than or equal to 1, or of type complex.

**Results**

The result type and kind are the same as x.

- If the result is real, it lies in the range -1.0 < ATANH (x) < 1.0.
- If the result is complex, the imaginary part is expressed in radians and lies in the range -\(\pi/2\) <= AIMAG (ATANH (x)) <= \(\pi/2\).

Example

ATANH (-0.77) has the value -1.02033.
ATANH (0.5) has the value 0.549306.

**ATOMIC**

*OpenMP* **Fortran Compiler Directive**: Ensures that a specific memory location is updated atomically. This prevents the possibility of multiple threads simultaneously reading and writing the specific memory location.

**Syntax**

```
!$OMP ATOMIC [clause[[[,] clause]...]]
  block
!$OMP END ATOMIC
```

`clause` (Optional) Is one of the following:

- An *atomic-clause*, which is one of the following:
  - READ
  - UPDATE
  - WRITE

  For details on the effects of these clauses, see the table in the Description section.

- A *memory-order-clause*, which is one of the following:
  - ACQ_REL
    Specifies both an ACQUIRE and a RELEASE flush.
  - ACQUIRE
    Forces consistency between views of memory of two synchronizing threads by discarding any value of a shared variable in its temporary view, which the thread has not written since last performing a RELEASE flush.
    It also will reload any value of a shared variable propagated by a RELEASE flush that synchronizes with it.
  - RELAXED
    Permits a thread’s local or temporary view of memory, which may be held in registers, cache, or other local memory, to be temporarily inconsistent with the memory, which may have been updated by another thread.
Note that a strong flush operation forces consistency between memory and a threads temporary view and memory, and it restricts reordering of memory operations that may otherwise be performed. RELAXED memory ordering has no implicit flushes.

- RELEASE

Forces consistency between views of memory of two synchronizing threads by guaranteeing that any prior READ or WRITE of a shared variable will appear complete before any READ or WRITE of the same shared variable that follows an ACQUIRE flush that is synchronized with a RELEASE flush.

The RELEASE flush propagates the values of all shared variables in its temporary view of memory prior to the thread performing a subsequent atomic operation that establishes a synchronization.

- SEQ_CST

Specifies that the construct is a sequentially consistent atomic construct. Unlike non-sequentially consistent atomic constructs, sequentially consistent atomic constructs preserve the interleaving (sequentially consistent) behavior of correct, data-race-free programs.

However, sequentially consistent atomic constructs are not designed to replace the FLUSH directive as a mechanism to enforce ordering for non-sequentially consistent atomic constructs. Attempts to do so require extreme caution.

For example, a sequentially consistent ATOMIC WRITE construct may appear to be reordered with a subsequent non-sequentially consistent ATOMIC WRITE construct because such reordering would not be observable by a correct program if the second WRITE was outside an ATOMIC construct.

If a memory-order-clause is present, or implicitly provided by a REQUIRES directive, it specifies the effective memory ordering; otherwise, the effective memory ordering is RELAXED.

- Or one of the following:

  - CAPTURE

    Causes an atomic update to \( x \) to occur using the specified operator or intrinsic. The original or final value of the location \( x \) is captured and written to the storage location \( v \).

    Only the READ and WRITE of the location specified by \( x \) are performed mutually atomically. The evaluation of expr or exprlist and the write to \( v \) need not be atomic with respect to the READ and WRITE of \( x \).

  - COMPARE

    Specifies that the atomic update is a conditional atomic update. If the equality operator is used, the operation is an atomic compare and swap.
The values of $x$ and $e$ are compared and if equal, the value of $d$ is written to $x$. The original or final value of $x$ is written to $v$, which may be the same as $e$.

Only the READ and WRITE of $x$ is performed atomically; neither the comparison nor the writes to $v$ need be atomic with respect to the READ or WRITE of $x$.

- **HINT ($hint$-expression)**
  
  Provides additional information about the expected properties of the atomic operation, which can be used for optimization purposes.

  This clause does not affect the semantics of the ATOMIC construct.

  $hint$-expression is an integer constant expression with kind omp_sync_hint, which has a value that is a valid synchronization hint.

- **FAIL (SEQ_CAT | ACQUIRE | RELAXED)**
  
  Specifies that its parameter overrides the effective memory ordering used when the comparison for a conditional update fails.

- **WEAK**
  
  Indicates that the comparison performed by an atomic compare and swap may falsely fail, evaluating to not equal even when the values are equal.

$block$ is one of the following:

- $statement$
- or if $CAPTURE$ is also specified, it can be the following:
  
  - $statement$
  - $capture$-statement

  The order is not important. $capture$-statement can appear before $statement$.

$statement$ is one of the following:

- $capture$-statement - if atomic-clause is READ, or atomic-clause is UPDATE with $CAPTURE$ also specified
- compare-statement - if the COMPARE clause is present
- update-statement - if atomic-clause is UPDATE
- write-statement - if atomic-clause is WRITE, or atomic-clause is UPDATE with $CAPTURE$ also specified

$capture$-statement is an expression in the form $v = x$.

$compare$-statement is as follows:

```plaintext
if (x == e) then
x = d
end
```

or:

```plaintext
if (x == e) x = d
```
or if CAPTURE also appears and block contains no capture-statement it can also be the following:

```fortran
if (x == e) then
  x = d
else
  v = x
end if
```

**update-statement**

Is an expression with one of the following forms:

```fortran
x = x operator expr
x = expr operator x
x = intrinsic (x, expr-list)
```

The following rules apply:

- Operators in `expr` must have precedence equal to or greater than the precedence of `operator`, and cannot be defined operators.
- `xoperatorexpr` must be mathematically equivalent to `xoperator (expr)`. This requirement is satisfied if the operators in `expr` have precedence greater than `operator`, or by using parentheses around `expr` or subexpressions of `expr`.
- `exproperatorx` must be mathematically equivalent to `(expr) operatorx`. This requirement is satisfied if the operators in `expr` have precedence equal to or greater than `operator`, or by using parentheses around `expr` or subexpressions of `expr`.
- All assignments must be intrinsic assignments.

**write-statement**

Is an expression in the form `x = expr`.

**d, e, x, v**

Are scalar variables of intrinsic type. During execution of an atomic region, all references to storage location `x` must specify the same storage location.

`v` must not access the same storage location as `x`.

**expr, expr-list**

`expr` is a scalar expression. `expr-list` is a comma-separated list of expressions. They must not access the same storage location as `x` or `v`.

If `intrinsic` is IAND, IOR, or IEOR, then `expr-list` can contain only one expression.

**operator**

Is one of the following intrinsic operators: `+`, `*`, `-`, `/`, `.AND.`, `.OR.`, `.EQV.`, or `.NEQV.`.

**intrinsic**

Is one of the following intrinsic procedures: MAX, MIN, IAND, IOR, or IEOR.

If `x` is of size 8, 16, 32, or 64 bits and `x` is aligned to a multiple of its size, the binding thread set is all threads on the device. Otherwise, the binding thread set is all threads in the contention group. Atomic regions enforce exclusive access with respect to other atomic regions that access the same storage location `x` among all the threads in the binding thread set without regard to the teams to which the threads belong.

If !$OMP ATOMIC is specified with no atomic-clause, it is the same as specifying !$OMP ATOMIC UPDATE.

If !$OMP ATOMIC CAPTURE is specified, you must include an !$OMP END ATOMIC directive following the block. Otherwise, the !$OMP END ATOMIC directive is optional.
Note that the following restriction applies to the ATOMIC directive:

- All atomic accesses to the storage locations designated by \( x \) throughout the program must have the same type and type parameters.

The following table describes what happens when you specify one of the values in the `atomic-clause` in an ATOMIC construct.

<table>
<thead>
<tr>
<th>Clause</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ</td>
<td>Causes an atomic read of the location designated by ( x ) regardless of the native machine word size.</td>
</tr>
</tbody>
</table>
| UPDATE     | Causes an atomic update of the location designated by \( x \) using the designated operator or intrinsic. The following rules also apply:  
  - The evaluation of `expr` or `expr-list` need not be atomic with respect to the READ or WRITE of the location designated by \( x \).  
  - No task scheduling points are allowed between the READ and the WRITE of the location designated by \( x \). |
| WRITE      | Causes an atomic write of the location designated by \( x \) regardless of the native machine word size. |

If all of the following conditions are true, the strong flush on entry to the atomic operation is also a RELEASE flush:

- The `atomic-clause` is WRITE or UPDATE.
- The atomic operation is not a conditional update for which the comparison fails.
- The effective memory ordering is RELEASE, ACQ_REL, or SEQ_CST.

If both of the following conditions are true, the strong flush on exit from the atomic operation is also an ACQUIRE flush:

- The `atomic-clause` is READ or UPDATE.
- The effective memory ordering is ACQUIRE, ACQ_REL, or SEQ_CST.

Therefore, as the above shows, the effective memory ordering is not RELAXED. RELEASE and ACQUIRE flushes can be implied and permit synchronization between threads without an explicit FLUSH directive.

Any combination of two or more of these atomic constructs enforces mutually exclusive access to the locations designated by \( x \).

A race condition exists when two unsynchronized threads access the same shared variable with at least one thread modifying the variable; this can cause unpredictable results. To avoid race conditions, all accesses of the locations designated by \( x \) that could potentially occur in parallel must be protected with an ATOMIC construct.

Atomic regions do not guarantee exclusive access with respect to any accesses outside of atomic regions to the same storage location \( x \) even if those accesses occur during a CRITICAL or ORDERED region, while an OpenMP* lock is owned by the executing task, or during the execution of a REDUCTION clause.

However, other OpenMP* synchronization can ensure the desired exclusive access. For example, a BARRIER directive following a series of atomic updates to \( x \) guarantees that subsequent accesses do not form a race condition with the atomic accesses.

**Example**

The following example shows a way to avoid race conditions by using ATOMIC to protect all simultaneous updates of the location by multiple threads.
Since the ATOMIC directive below applies only to the statement immediately following it, elements of \( Y \) are not updated atomically.

```fortran
REAL FUNCTION FOO1(I)
INTEGER I
FOO1 = 1.0 * I
RETURN
END FUNCTION FOO1

REAL FUNCTION FOO2(I)
INTEGER I
FOO2 = 2.0 * I
RETURN
END FUNCTION FOO2

SUBROUTINE SUB(X, Y, INDEX, N)
REAL X(*), Y(*)
INTEGER INDEX(*), N
INTEGER I
!$OMP PARALLEL DO SHARED(X, Y, INDEX, N)
DO I=1,N
!$OMP ATOMIC UPDATE
   X(INDEX(I)) = X(INDEX(I)) + FOO1(I)
   Y(I) = Y(I) + FOO2(I)
ENDDO
END SUBROUTINE SUB

PROGRAM ATOMIC_DEMO
REAL X(1000), Y(10000)
INTEGER INDEX(10000)
INTEGER I
DO I=1,10000
   INDEX(I) = MOD(I, 1000) + 1
   Y(I) = 0.0
ENDDO
DO I = 1,1000
   X(I) = 0.0
ENDDO
CALL SUB(X, Y, INDEX, 10000)
END PROGRAM ATOMIC_DEMO
```

The following non-conforming example demonstrates the restriction on the ATOMIC construct:

```fortran
SUBROUTINE ATOMIC_INCORRECT()
   INTEGER:: I
   REAL:: R
   EQUIVALENCE(I,R)
!$OMP PARALLEL
!$OMP ATOMIC UPDATE
   I = I + 1
!$OMP ATOMIC UPDATE
   R = R + 1.0
! The above is incorrect because I and R reference the same location
! but have different types
!$OMP END PARALLEL
END SUBROUTINE ATOMIC_INCORRECT
```

**ATOMIC_ADD**

*Atomic Intrinsic Subroutine (Generic): Performs atomic addition.*

**Syntax**

```fortran
CALL ATOMIC_ADD (atom, value [, stat])
```

- **atom** *(Input; output)* Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `atom + value` if no error occurs. Otherwise, it becomes undefined.

  ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

- **value** *(Input)* Must be a scalar integer. The value of `value` and `value + atom` must be representable as integers with kind ATOMIC_INT_KIND.

- **stat** *(Output; optional)* Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to `stat` is specified in *Overview of Atomic Subroutines*. If `stat` is not present and an error condition occurs, error termination is initiated.

**Example**

Consider the following:

```fortran
CALL ATOMIC_ADD (N[12], 7)
```

If N on image 12 is 4 when this operation is initiated, the value of N on image 12 is defined with the value 11 when the operation is complete and no error occurs during the subroutine reference.

**See Also**

ISO_FORTRAN_ENV Module

**ATOMIC_AND**

*Atomic Intrinsic Subroutine (Generic): Performs atomic bitwise AND.*

**Syntax**

```fortran
CALL ATOMIC_AND (atom, value [, stat])
```
**Example**

Consider the following:

```fortran
CALL ATOMIC_AND (N[4], 22)
```

If the value of N on image 4 is 29 when this operation is initiated, the value of N on image 4 is 20 when the operation is complete and no error condition occurs during the subroutine reference.

ISO_FORTRAN_ENV Module

**ATOMIC_CAS**

**Atomic Intrinsic Subroutine (Generic):** Performs atomic compare and swap.

**Syntax**

```fortran
CALL ATOMIC_CAS (atom, old, compare, new [, stat])
```

- `atom` (Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or type logical with kind ATOMIC_LOGICAL_KIND. `atom` becomes undefined if an error occurs. Otherwise, if `atom` is of type integer and equal to `compare`, or of type logical and equivalent to `compare`, it becomes defined with the value `new`. If `atom` is of type logical and has been assigned a value other than .true. or .false., the result is undefined.

- `old` (Output) Must be a scalar of the same type as `atom`. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value `atom` has at the beginning of the atomic operation.

- `compare` (Input) Must be scalar and the same type and kind as `atom`.

- `new` (Input) Must be scalar and the same type and kind as `atom`.
**Example**

Consider the following:

```fortran
CALL ATOMIC_CAS (N[4], I, 8, 10)
```

If the value of N on image 4 is 8 when the atomic operation is initiated, N on image 4 is defined with the value 10, and I is defined with the value 8 when the operation is complete and no error occurs during the subroutine reference. If the value N on image 4 is 13 when the atomic operation is initiated, the value of N is unchanged, and the value of I is 13 when the operation completes and no error condition occurs during the procedure reference.

---

**ATOMIC_DEFINE**

**Atomic Intrinsic Subroutine (Generic):** Defines a variable atomically.

**Syntax**

```fortran
CALL ATOMIC_DEFINE (atom, value [, stat])
```

- **atom**
  - (Output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND. If its kind is the same as that of value or its type is logical, it becomes defined with the value of `value`. Otherwise, it becomes defined with the value of INT (VALUE, ATOMIC_INT_KIND).

  ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.

- **value**
  - (Input) Must be a scalar and of the same type as `atom`.

- **stat**
  - (Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to `stat` is specified in *Overview of Atomic Subroutines*. If `stat` is not present and an error condition occurs, error termination is initiated.

**Example**

Consider the following:

```fortran
CALL ATOMIC_DEFINE (N[9], 7)
```

This causes N on image 9 to become defined with the value 7.

**See Also**

Overview of Atomic Subroutines
ISO_FORTRAN_ENV Module
**ATOMIC_FETCH_ADD**

*Atomic Intrinsic Subroutine (Generic): Performs atomic fetch and addition.*

**Syntax**

CALL ATOMIC_FETCH_ADD (atom, value, old [, stat])

- **atom** (Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of \( \text{atom} + \text{value} \) if no error occurs. Otherwise, it becomes undefined.

  ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

- **value** (Input) Must be a scalar integer. The value of \( \text{value} \) and \( \text{value} + \text{atom} \) must be representable as integers with kind ATOMIC_INT_KIND.

- **old** (Output) Must be a scalar of the same type as \( \text{atom} \). It becomes undefined if an error occurs. Otherwise, it becomes defined with the value \( \text{atom} \) has at the beginning of the atomic operation.

- **stat** (Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to \( \text{stat} \) is specified in *Overview of Atomic Subroutines*. If \( \text{stat} \) is not present and an error condition occurs, error termination is initiated.

**Example**

Consider the following:

```
CALL ATOMIC_FETCH_ADD (N[4], 8, M)
```

If the value of \( N \) on image 4 was 7 when the atomic operation is initiated, \( N \) on image 4 is defined with the value 15, and \( M \) becomes is defined with the value 7 when the operation completes and no error occurs during the subroutine reference.

**See Also**

*Overview of Atomic Subroutines*

ISO_FORTRAN_ENV Module

---

**ATOMIC_FETCH_AND**

*Atomic Intrinsic Subroutine (Generic): Performs atomic fetch and bitwise AND.*

**Syntax**

CALL ATOMIC_FETCH_AND (atom, value, old [, stat])

- **atom** (Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of \( \text{iand} (\text{atom}, \text{int} (\text{value}, \text{ATOMIC_INT_KIND})) \) if no error occurs. Otherwise, it becomes undefined.
ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

**value**
(Input) Must be a scalar integer. The value of value must be representable as an integer with kind ATOMIC_INT_KIND.

**old**
(Output) Must be a scalar of the same type as atom. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value atom has at the beginning of the atomic operation.

**stat**
(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to stat is specified in Overview of Atomic Subroutines. If stat is not present and an error condition occurs, error termination is initiated.

**Example**
Consider the following:

```fortran
CALL ATOMIC_FETCH_AND (N[4], 29, M)
```

If the value of N on image 4 was 23 when the atomic operation is initiated, N on image 4 is defined with the value 21, and M is defined with the value 23 when the operation completes and no error occurs during the subroutine reference.

**See Also**

ISO_FORTRAN_ENV Module

**ATOMICFETCHOR**

**Atomic Intrinsic Subroutine (Generic): Performs atomic fetch and bitwise OR.**

**Syntax**

```fortran
CALL ATOMIC_FETCH_OR (atom, value, old [, stat])
```

**atom**
(Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of ior (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined.

ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

**value**
(Input) Must be a scalar integer. The value of value must be representable as an integer with kind ATOMIC_INT_KIND.

**old**
(Output) Must be a scalar of the same type as atom. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value atom has at the beginning of the atomic operation.

**stat**
(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to stat is specified in Overview of Atomic Subroutines. If stat is not present and an error condition occurs, error termination is initiated.
Example

Consider the following:

```
ATOMIC_FETCH_OR (N[4], 9, M)
```

If the value of N on image 4 is 4 when the atomic operation is initiated, N on image 4 is defined with the value 13, and M is defined with the value 4 when the operation completes and no error occurs during the subroutine reference.

**ATOMIC_FETCH_XOR**

**Atomic Intrinsic Subroutine (Generic):** Performs atomic fetch and bitwise exclusive OR.

**Syntax**

```
CALL ATOMIC_FETCH_XOR (atom, value, old [, stat])
```

- **atom** (Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value \( \text{ieor}(\text{atom}, \text{int}(\text{value}, \text{ATOMIC_INT_KIND})) \) if no error occurs. Otherwise, it becomes undefined.

  ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

- **value** (Input) Must be a scalar integer. The value of `value` must be representable as an integer with kind ATOMIC_INT_KIND.

- **old** (Output) Must be a scalar of the same type as `atom`. It becomes undefined if an error occurs. Otherwise, it becomes defined with the value `atom` has at the beginning of the atomic operation.

- **stat** (Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to `stat` is specified in *Overview of Atomic Subroutines*. If `stat` is not present and an error condition occurs, error termination is initiated.

**Example**

Consider the following:

```
CALL ATOMIC_FETCH_XOR (N[4], 9, M)
```

If the value of N on image 4 was 10 when the atomic operation is initiated, N on image 4 is defined with the value 3, and M is defined with the value 10 when the operation completes and no error occurs during the subroutine reference.

See Also

**ATOMIC_OR**

**Atomic Intrinsic Subroutine (Generic):** Performs atomic bitwise OR.

**Syntax**

```fortran
CALL ATOMIC_OR (atom, value [, stat])
```

- **atom** (Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of `ior (atom, int (value, ATOMIC_INT_KIND))` if no error occurs. Otherwise, it becomes undefined.
  
  ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

- **value** (Input) Must be a scalar integer. The value of `value` must be representable as an integer with kind ATOMIC_INT_KIND.

- **stat** (Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to `stat` is specified in Overview of Atomic Subroutines. If `stat` is not present and an error condition occurs, error termination is initiated.

**Example**

Consider the following:

```fortran
CALL ATOMIC_OR (N[4], 10)
```

If the value of N on image 4 is 9 when the atomic operation is initiated, the value of N on image 4 is 11 when the operation completes and no error condition occurs during the subroutine reference.

**See Also**

ISO_FORTRAN_ENV Module

**ATOMIC_REF**

**Atomic Intrinsic Subroutine (Generic):** Lets you reference a variable atomically.

**Syntax**

```fortran
CALL ATOMIC_REF (value, atom [, stat])
```

- **value** (Output) Must be a scalar and of the same type as `atom`. If its kind is the same as that of `atom` or its type is logical, it becomes defined with the value of `atom`. Otherwise, it is defined with the value of `INT(ATOM, KIND (VALUE))`.

- **atom** (Input) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND or of type logical with kind ATOMIC_LOGICAL_KIND.

  ATOMIC_INT_KIND and ATOMIC_LOGICAL_KIND are named constants in the intrinsic module ISO_FORTRAN_ENV.
**stat**

(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

**Example**

Consider the following:

```fortran
CALL ATOMIC_REF (SOL, I [9])
```

This causes SOL to become defined with the value of I on image 9.

**See Also**

**ISO_FORTRAN_ENV Module**

**ATOMIC_XOR**

**Atomic Intrinsic Subroutine (Generic):** Performs atomic bitwise exclusive OR.

**Syntax**

```fortran
CALL ATOMIC_XOR (atom, value [, stat])
```

*atom* (Input; output) Must be a scalar coarray or coindexed object and of type integer with kind ATOMIC_INT_KIND. It becomes defined with the value of \( \text{ieor} \) (atom, int (value, ATOMIC_INT_KIND)) if no error occurs. Otherwise, it becomes undefined.

ATOMIC_INT_KIND is a named constant in the intrinsic module ISO_FORTRAN_ENV.

*value* (Input) Must be a scalar integer. The value of *value* must be representable as an integer with kind ATOMIC_INT_KIND.

*stat* (Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to *stat* is specified in *Overview of Atomic Subroutines*. If *stat* is not present and an error condition occurs, error termination is initiated.

**Example**

Consider the following:

```fortran
CALL ATOMIC_XOR (N[4], 10)
```

If the value of N on image 4 is 14 when the atomic operation is initiated, the value on N on image 4 is the value 4 when the operation is complete and no error condition occurred during the subroutine reference.

¹A common block name is specified as [/]common-block-name[/]
²This option can only be applied to arrays.
³Module-level variables and arrays only.
⁴This option can only be applied to INTERFACE blocks.
⁵This option cannot be applied to EXTERNAL statements.
⁶This option can be applied to named main programs.

These options can be used in function and subroutine definitions, in type declarations, and with the INTERFACE and ENTRY statements.

Options applied to entities available through use or host association are in effect during the association. For example, consider the following:

```fortran
MODULE MOD1
  INTERFACE
    SUBROUTINE NEW_SUB
      !DIR$ ATTRIBUTES C, ALIAS:'othername' :: NEW_SUB
      END SUBROUTINE
  END INTERFACE
END MODULE MOD1
```
CONTAINS
   SUBROUTINE SUB2
   CALL NEW_SUB
   END SUBROUTINE
END MODULE

In this case, the call to NEW_SUB within SUB2 uses the C and ALIAS options specified in the interface block.

Options C, STDCALL, REFERENCE, VALUE, and VARYING affect the calling conventions of routines:

- You can specify C, STDCALL, REFERENCE, and VARYING for an entire routine.
- You can specify VALUE and REFERENCE for individual arguments.

Examples

INTERFACE
   SUBROUTINE For_Sub (I)
      !DIR$ ATTRIBUTES C, ALIAS:'_For_Sub' :: For_Sub
      INTEGER I
   END SUBROUTINE For_Sub
END INTERFACE

You can assign more than one option to multiple variables with the same compiler directive. All assigned options apply to all specified variables. For example:

!DIR$ ATTRIBUTES reference, varying, C :: A, B, C

In this case, the variables A, B, and C are assigned the REFERENCE, VARYING, and C options. The only restriction on the number of options and variables is that the entire compiler directive must fit on one line.

The identifier of the variable or procedure that is assigned one or more options must be a simple name. It cannot include initialization or array dimensions. For example, the following is not allowed:

!DIR$ ATTRIBUTES C :: A(10)  ! This is illegal.

The following shows another example:

SUBROUTINE ARRAYTEST(arr)
!DIR$ ATTRIBUTES DLLEXPORT :: ARRAYTEST
   REAL(4) arr(3, 7)
   INTEGER i, j
   DO i = 1, 3
      DO j = 1, 7
         arr (i, j) = 11.0 * i + j
      END DO
   END DO
END SUBROUTINE

Syntax Rules for Compiler Directives
Programming with Mixed Languages Overview

ATTRIBUTES ALIAS
The ATTRIBUTES directive option ALIAS specifies an alternate external name to be used when referring to external subprograms.

Syntax

!DIR$ ATTRIBUTES ALIAS: external-name:: subprogram
Is a character constant delimited by apostrophes or quotation marks. The character constant is used as is; the string is not changed to uppercase, nor are blanks removed.

Is an external subprogram.

The ALIAS option overrides the C (and STDCALL) option. If both C and ALIAS are specified for a subprogram, the subprogram is given the C calling convention, but not the C naming convention. It instead receives the name given for ALIAS, with no modifications.

ALIAS cannot be used with internal procedures, and it cannot be applied to dummy arguments.

The following example gives the subroutine happy the name "_OtherName@4" outside this scoping unit:

```
INTERFACE
  SUBROUTINE happy(i)
    !DIR$ ATTRIBUTES STDCALL, DECORATE, ALIAS:'OtherName' :: happy
    INTEGER i
  END SUBROUTINE
END INTERFACE
```

!DIR$ ATTRIBUTES ALIAS has the same effect as the !DIR$ ALIAS directive.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES DECORATE

ATTRIBUTES ALIGN

The ATTRIBUTES directive option ALIGN specifies the byte alignment for variables and for allocatable or pointer components of derived types.

Syntax

```
!DIR$ ATTRIBUTES ALIGN: n:: object
```

Is the number of bytes for the minimum alignment boundary.

For allocatable objects, the boundary value must be a power of 2, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on. \(n\) must have a value between 1 and 2097152 == 2**21 == 2MB on Linux* and macOS* systems, and between 1 and 8192 == 2**13 == 8KB on Windows* systems.

For non-allocatable objects, the boundary value must be a power of 2 between 1 and 64 on Windows systems, between 1 and 65536 == 2**16 == 64KB on Linux systems, or between 1 and 4096 == 2**12 == 4KB on macOS* systems.

Is the variable or the allocatable or pointer component of a derived type to be aligned.

Objects that can be aligned by this directive include static local variables, automatic variables, module variables, dynamically allocated arrays, allocatable array components of derived types, and the start of common blocks. This directive cannot be used to align variables within common blocks.

If you specify directive !DIR$ ATTRIBUTES ALIGN on an object with the ALLOCATABLE or POINTER attribute, an ALLOCATE statement will attempt to use that alignment when the memory is allocated.
For allocatable or pointer components of derived types, the directive must appear within the derived-type TYPE…END TYPE block.

If the TYPE is an extended type, the directive cannot reference a component in the parent type.

**Example**

Consider the following:

```fortran
TYPE EXAMPLE
  !DIR$ ATTRIBUTES ALIGN : 64 :: R_alloc
  REAL, ALLOCATABLE :: R_alloc ( :: )
  REAL :: R_scalar
  INTEGER :: I_nonalloc(25)
END TYPE EXAMPLE

TYPE (EXAMPLE) :: MyVar

ALLOCATE (MyVar%R_alloc(1000))   ! Memory is allocated aligned at a 64-byte boundary
```

Note that it is valid to give the ALIGN:64 attribute to component R_alloc, but not to component R_scalar or to component I_nonalloc.

The following example shows that the name of a common block may optionally be enclosed in slashes:

```fortran
!DIR$ ATTRIBUTES ALIGN: n :: /common_name/
```

**See Also**

ATTRIBUTES
ASSUME_ALIGNED directive
align compiler option (see setting arraynbyte)
Syntax Rules for Compiler Directives

**ATTRIBUTES ALLOCATABLE**

The ATTRIBUTES directive option ALLOCATABLE is provided for compatibility with older programs. It lets you delay allocation of storage for a particular declared entity until some point at run time when you explicitly call a routine that dynamically allocates storage for the entity.

**Syntax**

```fortran
!DIR$ ATTRIBUTES ALLOCATABLE :: entity
```

`entity` Is the name of the entity that should have allocation delayed.

The recommended method for dynamically allocating storage is to use the ALLOCATABLE statement or attribute.

**See Also**

ATTRIBUTES
Syntax Rules for Compiler Directives

**ATTRIBUTES ALLOW_NULL**

The ATTRIBUTES directive option ALLOW_NULL enables a corresponding dummy argument to pass a NULL pointer (defined by a zero or the NULL intrinsic) by value for the argument.
Syntax

!DIR$ ATTRIBUTES ALLOW_NULL :: arg

arg

Is the name of the argument.

ALLOW_NULL is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES C and STDCALL

The ATTRIBUTES directive options C and STDCALL specify procedure calling, naming, and argument passing conventions.

Syntax

!DIR$ ATTRIBUTES C :: object[, object] ...

!DIR$ ATTRIBUTES STDCALL :: object[, object] ...

object

Is the name of a data object or procedure.

On Windows* systems on IA-32 architecture, C and STDCALL have slightly different meanings; on all other platforms, STDCALL is treated as C.

When applied to a subprogram, these options define the subprogram as having a specific set of calling conventions. The effects depend on whether or not the subprogram is interoperable (has the BIND attribute).

For interoperable subprograms with the BIND attribute, ATTRIBUTES STDCALL has the following effects for subprograms in applications targeting Windows systems on IA-32 architecture:

- The STDCALL calling convention is used where the called subprogram cleans up the stack at exit.
- The external name has @n appended, where n is the number of bytes of arguments pushed on the stack.

No other effects of ATTRIBUTES STDCALL are applied for interoperable subprograms. If pass-by-value is desired for a dummy argument to an interoperable subprogram, the Fortran standard VALUE attribute should be specified for that argument.

For platforms other than Windows systems on IA-32 architecture, ATTRIBUTES STDCALL has no effect on interoperable subprograms. You should not specify ATTRIBUTES C for interoperable subprograms.

The following table and subsequent text summarizes the differences between the calling conventions for subprograms that are not interoperable:

<table>
<thead>

</tr>
</tbody>
</table>

¹ STDCALL is treated as C on Linux*, macOS*, and on Windows* on Intel® 64 architecture.

² The Intel® Fortran calling convention

³ On Linux, if there are one or more underscores in the external name, two trailing underscores are added; if there are no underscores, one is added.

⁴ IA-32 architecture only

If C or STDCALL is specified for a subprogram, arguments (except for arrays and characters) are passed by value. Subprograms using standard Fortran conventions pass arguments by reference.

On IA-32 architecture, an underscore ( _ ) is placed at the beginning of the external name of a subprogram. If STDCALL is specified, an at sign (@) followed by the number of argument bytes being passed is placed at the end of the name. For example, a subprogram named SUB1 that has three INTEGER(4) arguments and is defined with STDCALL is assigned the external name _sub1@12.

Character arguments are passed as follows:

- By default, hidden lengths are put at the end of the argument list.
  - On Windows* systems using IA-32 architecture, you can get Compaq* Visual Fortran default behavior by specifying compiler option iface.
- If C or STDCALL (only) is specified:
  - On all systems, the first character of the string is passed (and padded with zeros out to INTEGER(4) length).
- If C or STDCALL is specified, and REFERENCE is specified for the argument:
  - On all systems, the string is passed with no length.
- If C or STDCALL is specified, and REFERENCE is specified for the routine (but REFERENCE is not specified for the argument, if any):
  - On all systems, the string is passed with the length.

ATTRIBUTES
REFERENCE
BIND
Syntax Rules for Compiler Directives
iface  compiler option

Compiler Reference section: *Mixed Language Programming*
The ATTRIBUTES directive option CODE_ALIGN specifies the byte alignment for a procedure.

Syntax

!DIR$ ATTRIBUTES CODE_ALIGN: n:: procedure-name

n
Is the number of bytes for the minimum alignment boundary. It must be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on.

If you specify 1 for n, no alignment is performed. If you do not specify n, the default alignment is 16 bytes.

procedure-name
Is the name of a procedure.

This directive can be affected by compiler option -falign-loops (Linux* and macOS*) or /Qalign-loops (Windows*), the CODE_ALIGN directive, and the CODE_ALIGN attribute.

If code is compiled with the -falign-loops=m (Linux and macOS*) or /Qalign-loops:m (Windows) option and a procedure has the CODE_ALIGN:k attribute, the procedure is aligned on a MAX (m, k) byte boundary.
If a procedure has the CODE_ALIGN:k attribute and a CODE_ALIGN:n directive precedes a loop, then both the procedure and the loop are aligned on a MAX (k, n) byte boundary.

Example

Consider the following code fragment in file test_align.f90:

FUNCTION F ()
  !DIR$ ATTRIBUTES CODE_ALIGN:32 :: F
  ...
  !DIR$ CODE_ALIGN:16
  DO J = 1, N
  ...
  END DO
  ...
  END FUNCTION F

Compiling test_align.f90 with option -falign-loops=64 (Linux and macOS*) or /Qalign-loops:64 (Windows) aligns the function F and the DO J loop on 64-byte boundaries.

ATTRIBUTES
CODE_ALIGN directive
falign-loops, Qalign-loops compiler option
Syntax Rules for Compiler Directives

ATTRIBUTES CONCURRENCY_SAFE

The ATTRIBUTES directive option
CONCURRENCY_SAFE specifies that there are no unacceptable side effects and no illegal (or improperly synchronized) memory access interferences among multiple invocations of a routine or between an invocation of the specified routine and other statements in the program if they were executed concurrently.
Syntax

!DIR$ ATTRIBUTES CONCURRENCY_SAFE [: clause] :: routine-name-list

clause Is one of the following:
  • profitable
  • cost (int-cycle-count)

int-cycle-count Is an integer scalar constant expression.

routine-name-list Is a comma-separated list of function and subroutine names.

When a CONCURRENCY_SAFE routine is called from parallelized code, you can ignore assumed cross-block or cross-iteration dependencies and side effects of calling the specified routine from parallelized code.

The profitable clause indicates that the loops or blocks that contain calls to the routine can be safely executed in parallel if the loop or blocks are legal to be parallelized; that is, if it is profitable to parallelize them.

The cost clause indicates the execution cycles of the routine where the compiler can perform parallelization profitability analysis while compiling its enclosing loops or blocks.

The attribute can appear in the declaration of the routine; for example:

```fortran
function f(x)
!DIR$ attributes concurrency_safe :: f
```

The attribute can also appear in the code of the caller; for example:

```fortran
main m
integer f
external f
!dir$ attributes concurrency_safe :: f   ! or it could be in an interface block describing f
...
Print *, f(x)
```

NOTE
For every routine named in routine-name-list, you should ensure that any possible side effects are acceptable or expected, and the memory access interferences are properly synchronized.

ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES CVF
The ATTRIBUTES direction option CVF tells the compiler to use calling conventions compatible with Compaq Visual Fortran* and Microsoft Fortran PowerStation.

Syntax

!DIR$ ATTRIBUTES CVF :: object[, object] ...

object Is the name of a data object or procedure.

The conventions that are used are as follows:
  • The calling mechanism: STDCALL on Windows* systems using IA-32 architecture
The argument passing mechanism: by reference
Character-length argument passing: following the argument address
The external name case: uppercase
The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture. On Windows* systems using IA-32 architecture, @n suffix where n is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.

See Also
ATTRIBUTES

Syntax Rules for Compiler Directives

ATTRIBUTES DECORATE
The ATTRIBUTES directive option DECORATE specifies that the external name used in !DIR$ ALIAS or !DIR$ ATTRIBUTES ALIAS should have the prefix and postfix decorations performed on it that are associated with the platform and calling mechanism that is in effect. These are the same decorations performed on the procedure name when ALIAS is not specified, except that, on Linux* and macOS* systems, DECORATE does not add a trailing underscore signifying a Fortran procedure.

Syntax
!DIR$ ATTRIBUTES DECORATE :: exname

exname Is an external name. It may not be the name of an internal procedure.

The case of the ALIAS external name is not modified.
If ALIAS is not specified, this option has no effect.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES ALIAS
The summary of prefix and postfix decorations in the description of the ATTRIBUTES options C and STDCALL

ATTRIBUTES DEFAULT
The ATTRIBUTES directive option DEFAULT overrides certain compiler options that can affect external routine and COMMON block declarations.

Syntax
c!DIR$ ATTRIBUTES DEFAULT :: entity

entity Is an external procedure, a COMMON block, a module variable that is initialized, or a PARAMETER in a module.

It specifies that the compiler should ignore compiler options that change the default conventions for external symbol naming and argument passing for routines and COMMON blocks (such as names, assume underscore, assume 2underscores on Linux systems, and iface on Windows* systems).
This option can be combined with other ATTRIBUTES options, such as STDCALL, C, REFERENCE, ALIAS, etc. to specify properties different from the compiler defaults.
This option is useful when declaring INTERFACE blocks for external routines, since it prevents compiler options from changing calling or naming conventions.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives
iface compiler option
names compiler option
assume compiler option

ATTRIBUTES DLLEXPORT and DLLIMPORT

The ATTRIBUTES directive options DLLEXPORT and DLLIMPORT define a dynamic-link library's interface for processes that use them. The options can be assigned to module variables, COMMON blocks, and procedures. These directive options are available on Windows* and macOS* systems.

Syntax

!DIR$ ATTRIBUTES DLLEXPORT :: object[, object] ...
!DIR$ ATTRIBUTES DLLIMPORT :: object[, object] ...

object Is the name of a module variable, COMMON block, or procedure. The name of a COMMON block must be enclosed in slashes.

DLLEXPORT and DLLIMPORT define the interface for the following dynamic-link libraries:

• DLL on Windows*
• DYLIB on macOS*

DLLEXPORT specifies that procedures or data are being exported to other applications or dynamic libraries. This causes the compiler to produce efficient code; for example, eliminating the need on Windows systems for a module definition (.def) file to export symbols.

DLLEXPORT should be specified in the routine to which it applies. If the routine's implementation is in a submodule, specify DLLEXPORT in the parent module's INTERFACE block for the routine. If MODULE PROCEDURE is used in the submodule, the DLLEXPORT attribute will be inherited; otherwise you must also specify DLLEXPORT in the submodule routine.

Symbols defined in a DLL are imported by programs that use them. On Windows*, the program must link with the DLL import library (.lib).

The DLLIMPORT option is used inside the program unit that imports the symbol. DLLIMPORT is specified in a declaration, not a definition, since you cannot define a symbol you are importing.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES EXTERN

The ATTRIBUTES directive option EXTERN specifies that a variable is allocated in another source file. EXTERN can be used in global variable declarations, but it must not be applied to dummy arguments.

Syntax

!DIR$ ATTRIBUTES EXTERN :: var
var

Is the variable to be allocated.

This option must be used when accessing variables declared in other languages.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES INLINE, NOINLINE, and FORCEINLINE
The ATTRIBUTES directive options INLINE, NOINLINE, and FORCEINLINE can be used to control inlining decisions made by the compiler. You should place the directive option in the procedure whose inlining you want to influence.

Syntax
The INLINE option specifies that a function or subroutine can be inlined. The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.

!DIR$ ATTRIBUTES INLINE :: procedure

procedure

Is the function or subroutine that can be inlined.

The NOINLINE option disables inlining of a function.

!DIR$ ATTRIBUTES NOINLINE :: procedure

procedure

Is the function or subroutine that must not be inlined.

The FORCEINLINE option specifies that a function or subroutine must be inlined unless it will cause errors.

!DIR$ ATTRIBUTES FORCEINLINE :: procedure

procedure

Is the function or subroutine that must be inlined.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives

ATTRIBUTES IGNORE_LOC
The ATTRIBUTES directive option IGNORE_LOC enables %LOC to be stripped from an argument.

Syntax
!DIR$ ATTRIBUTES IGNORE_LOC :: arg

arg

Is the name of an argument.

IGNORE_LOC is only valid if ATTRIBUTES REFERENCE is also specified; otherwise, it has no effect.

See Also
ATTRIBUTES
Syntax Rules for Compiler Directives
**ATTRIBUTES MIXED_STR_LEN_ARG and NOMIXED_STR_LEN_ARG**

These ATTRIBUTES directive options specify where hidden lengths for character arguments and character-valued functions should be placed. **MIXED_STR_LEN_ARG** specifies that hidden lengths for character arguments and character-valued functions should be placed immediately following the argument address in the argument list. **NOMIXED_STR_LEN_ARG** specifies that these hidden lengths should be placed in sequential order at the end of the argument list.

**Syntax**

```
!DIR$ ATTRIBUTES MIXED_STR_LEN_ARG :: procs

!DIR$ ATTRIBUTES NOMIXED_STR_LEN_ARG :: procs
```

*procs* is a list of procedures to be given the specified attribute.

The default is **NOMIXED_STR_LEN_ARG**. However, if you specify compiler option `/iface:CVF` or `/iface:mixed_str_len_arg` (Windows*), or compiler option `-mixed-str-len-arg` (Linux* and macOS*), the default is **MIXED_STR_LEN_ARG**.

**See Also**

- ATTRIBUTES directive
- Syntax Rules for Compiler Directives
- `iface` compiler option

**ATTRIBUTES NO_ARG_CHECK**

The **ATTRIBUTES** directive option **NO_ARG_CHECK** specifies that type and shape matching rules related to explicit interfaces are to be ignored. This permits the construction of an INTERFACE block for an external procedure or a module procedure that accepts an argument of any type or shape; for example, a memory copying routine.

**Syntax**

```
!DIR$ ATTRIBUTES NO_ARG_CHECK :: object
```

*object* is the name of an argument or procedure.

**NO_ARG_CHECK** can appear only in an INTERFACE block for a non-generic procedure or in a module procedure. It can be applied to an individual dummy argument name or to the routine name, in which case the option is applied to all dummy arguments in that interface.

**NO_ARG_CHECK** cannot be used for procedures with the PURE or ELEMENTAL prefix.

**See Also**

- ATTRIBUTES
- Syntax Rules for Compiler Directives
ATTRIBUTES NOCLONE

The ATTRIBUTES directive option NOCLONE can be used to prevent a procedure from being considered for cloning, which is a mechanism performed by interprocedural constant propagation that produces specialized copies of the procedure.

Syntax

```fortran
!DIR$ ATTRIBUTES NOCLONE :: procedure
```

procedure

Is a function or subroutine that can be inlined.

Note that if you specify ATTRIBUTES NOINLINE, it does not prevent this cloning.

See Also

ATTRIBUTES
Syntax Rules for Compiler Directives
ATTRIBUTES INLINE

ATTRIBUTES OPTIMIZATION_PARAMETER

The ATTRIBUTES directive option OPTIMIZATION_PARAMETER passes certain information about a procedure or main program to the optimizer.

Syntax

```fortran
!DIR$ ATTRIBUTES OPTIMIZATION_PARAMETER: string::{ procedure-name | named-main-program}
```

string

Is a character constant that is passed to the optimizer. The constant must be delimited by apostrophes or quotation marks, and it may have one of the following values:

- **TARGET_ARCH= cpu**
  
  Tells the compiler to generate code specialized for a particular processor. For the list of cpus you can specify, see option `[Q]x`.

- **G2S = {ON | OFF}**
  
  Disables or enables the use of gather/scatter instructions in the specified program unit.

  ON tells the optimizer to disable the generation of gather/scatter and to transform gather/scatter into unit-strided loads/stores plus a set of shuffles wherever possible.

  OFF tells the optimizer to enable the generation of gather/scatter instructions and not to transform gather/scatter into unit-strided loads/stores.

- **INLINE_MAX_PER_ROUTINE= n**
  
  Specifies the maximum number of times the inliner may inline into the procedure. The `n` is one of the following:

  - A non-negative scalar integer constant (>=0) that specifies the maximum number of times the the inliner may inline into the procedure. If you specify zero, no inlining is done into the routine.
• The keyword UNLIMITED, which means that there is no limit to the number of times the inliner may inline into the procedure.

For more information, see option \[Q\]inline-max-per-routine.

• \(\text{INLINE_MAX_TOTAL_SIZE} = n\)

Specifies how much larger a routine can normally grow when inline expansion is performed. The \(n\) is one of the following:

• A non-negative scalar integer constant (\(\geq 0\)) that specifies the permitted increase in the routine's size when inline expansion is performed. If you specify zero, no inlining is done into the routine.
• The keyword UNLIMITED, which means that there is no limit to the size a routine may grow when inline expansion is performed.

For more information, see option \[Q\]inline-max-total-size.

\textit{procedure-name}  

Is the name of a procedure.

\textit{named-main-program}  

Is the name of a main program

\textbf{Description}

The characters in string can appear in any combination of uppercase and lowercase. The following rules also apply to string:

• If string does not contain an equal sign (=), then the entire value of string is converted to lowercase before being passed to the optimizer.
• If string contains an equal sign, then all characters to the left of the equal sign are converted to lowercase before all of string is passed to the optimizer.

Characters to the right of the equal sign are not converted to lowercase since their value may be case sensitive to the optimizer, for example “target_arch=AVX”.

You can specify multiple \texttt{ATTRIBUTES OPTIMIZATION\_PARAMETER} directives for one procedure or one main program.

For the named procedure or main program, the values specified for \texttt{ATTRIBUTES OPTIMIZATION\_PARAMETER} override any settings specified for the following compiler options:

• \[Q\]x, -m, and /arch
• \[Q\]inline-max-per-routine
• \[Q\]inline-max-total-size

\textbf{Example}

Consider the two attributes optimization\_parameter directives in the following code:

```fortran
function f (x)
!dir$ attributes optimization_parameter: “inline_max_per_routine=10” :: f
!dir$ attributes optimization_parameter: “inline_max_total_size=2000” :: f
  real :: f, x
```

The two directives have the same effect as if the function F had been compiled with 
"/Qinline-max-per-routine:10 /Qinline-max-total-size:2000" on Windows* or with 
"-inline-max-per-routine=10 -inline-max-total-size=2000" on Linux* or macOS*, that is, inlining will not increase the size of F by more than 2000 and the inliner will not inline routines into F more than 10 times.

Syntax Rules for Compiler Directives
x, Qx compiler option
inline-max-per-routine, Qinline-max-per-routine compiler option
inline-max-total-size, Qinline-max-total-size compiler option

ATTRIBUTES REFERENCE and VALUE
The ATTRIBUTES directive options REFERENCE and VALUE specify how a dummy argument is to be passed.

Syntax

!DIR$ ATTRIBUTES REFERENCE :: arg
!DIR$ ATTRIBUTES VALUE :: arg

arg Is the name of a dummy argument.

REFERENCE specifies a dummy argument’s memory location is to be passed instead of the argument’s value.
VALUE specifies a dummy argument’s value is to be passed instead of the argument’s memory location.

When VALUE is specified for a dummy argument, the actual argument passed to it can be of a different type. If necessary, type conversion is performed before the subprogram is called.

When a complex (KIND=4 or KIND=8) argument is passed by value, two floating-point arguments (one containing the real part, the other containing the imaginary part) are passed by immediate value.
Character values, substrings, assumed-size arrays, and adjustable arrays cannot be passed by value.

If REFERENCE (only) is specified for a character argument, the string is passed with no length.
If REFERENCE is specified for a character argument, and C (or STDCALL) has been specified for the routine, the string is passed with no length. This is true even if REFERENCE is also specified for the routine.
If REFERENCE and C (or STDCALL) are specified for a routine, but REFERENCE has not been specified for the argument, the string is passed with the length.

VALUE is the default if the C or STDCALL option is specified in the subprogram definition.
In the following example integer x is passed by value:

SUBROUTINE Subr (x)
  INTEGER x
  !DIR$ ATTRIBUTES VALUE :: x

Mixed Language Programming: Adjusting Calling Conventions in Mixed-Language Programming Overview

ATTRIBUTES VARYING
The ATTRIBUTES directive option VARYING allows a Fortran routine to call a C/C++ routine with a variable number of arguments.

Syntax

!DIR$ ATTRIBUTES VARYING :: var[, var] ...
\textit{var} \hspace{2cm} \text{Is a variable representing a C/C++ routine that takes a variable number of arguments.}

This attribute can be used in an interface block to create an explicit interface for a C/C++ routine or it can be used on a variable declared EXTERN that represents a C/C++ routine. When the routine is called from the Fortran code, a variable number of arguments can be specified.

This attribute cannot be used with a Fortran routine declaration.

If \text{ATTRIBUTES VARYING} is specified, the C calling convention must also be used, either implicitly or explicitly.

All actual arguments in the routine call are passed to the called routine, regardless of the number of dummy arguments specified in the interface. If the called routine tries to access a dummy argument that has no matching actual argument, it causes a user error and the program may fail unpredictably.

\textbf{See Also}
\textit{ATTRIBUTES}
\textit{Syntax Rules for Compiler Directives}

\textbf{ATTRIBUTES VECTOR}
\textit{The \text{ATTRIBUTES} directive option \text{VECTOR} tells the compiler to vectorize the specified function or subroutine.}

\textbf{Syntax}
\begin{verbatim}
!DIR$ ATTRIBUTES [att,] VECTOR [:clause] [, att]... :: routine-name
!DIR$ ATTRIBUTES [att,] VECTOR :(clause [, clause]...) [, att] :: routine-name
\end{verbatim}

\textit{att} \hspace{2cm} \text{Is an \text{ATTRIBUTES} directive option. For a list of possible directive options, see the description of argument \text{att} in \text{ATTRIBUTES}.}

\textit{clause} \hspace{2cm} \text{Is one or more of the following optional clauses:}

\begin{itemize}
  \item \text{LINEAR} \hspace{1cm} \text{(}\textit{var1:step1} [, \textit{var2:step2}]... \text{)}
  \begin{itemize}
    \item \textit{var} \hspace{2cm} \text{Is a scalar variable that is a dummy argument in the specified routine.}
    \item \textit{step} \hspace{2cm} \text{Is a compile-time positive, integer constant expression.}
  \end{itemize}

  \text{Tells the compiler that for each consecutive invocation of the routine in a serial execution, the value of} \textit{var1} \text{is incremented by} \textit{step1}, \textit{var2} \text{is incremented by} \textit{step2}, \text{and so on.}

  \text{If more than one} \textit{step} \text{is specified for a particular} \textit{var}, \text{a compile-time error occurs.}

  \text{Multiple LINEAR clauses are merged as a union.}

  \item \text{[NO]MASK}

  \text{Determines whether the compiler generates a masked vector version of the routine.}

  \item \text{PROCESSOR (cpuid)}

  \item \text{UNIFORM (arg [, arg]...)}
  \begin{itemize}
    \item \textit{arg} \hspace{2cm} \text{Is a scalar variable that is a dummy argument in the specified routine.}
  \end{itemize}
\end{itemize}
Tells the compiler that the values of the specified arguments can be broadcasted to all iterations as a performance optimization.

Multiple UNIFORM clauses are merged as a union.

- **VECTORLENGTH** \((n[, n]...\)
  
  \(n\)  
  
  Is a vector length (VL). It must be an integer, scalar constant expression that is a power of 2; the value must be 2, 4, 8, or 16. If you specify more than one \(n\), the compiler will choose the VL from the values specified.

Tells the compiler that each routine invocation at the call site should execute the computation equivalent to \(n\) times the scalar function execution.

The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

Multiple VECTORLENGTH clauses cause a syntax error.

- **VECTORLENGTHFOR** \((data-type)\)

  \(data-type\)  
  
  Is one of the following intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Fortran Intrinsic Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Default INTEGER</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>INTEGER (KIND=1)</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>INTEGER (KIND=2)</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>INTEGER (KIND=4)</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>INTEGER (KIND=8)</td>
</tr>
<tr>
<td>REAL</td>
<td>Default REAL</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>REAL (KIND=4)</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>REAL (KIND=8)</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Default COMPLEX</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>COMPLEX (KIND=4)</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>COMPLEX (KIND=8)</td>
</tr>
</tbody>
</table>
Causes each iteration in the vector loop to execute the computation equivalent to \( n \) iterations of scalar loop execution where \( n \) is computed from \( \frac{\text{size of vector register}}{\text{sizeof(data type)}} \).

For example, \texttt{VECTORLENGTHFOR(REAL (KIND=4))} results in \( n=4 \) for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and \( n=8 \) for AVX target (packed float operations available on 256-bit YMM registers). \texttt{VECTORLENGTHFOR(INTEGER (KIND=4))} results in \( n=4 \) for SSE2 to AVX targets.

The \texttt{VECTORLENGTHFOR} and \texttt{VECTORLENGTH} clauses are mutually exclusive. You cannot use the \texttt{VECTORLENGTHFOR} clause with the \texttt{VECTORLENGTH} clause, and vice versa.

Multiple \texttt{VECTORLENGTHFOR} clauses cause a syntax error.

Without explicit \texttt{VECTORLENGTH} and \texttt{VECTORLENGTHFOR} clauses, the compiler will choose a \texttt{VECTORLENGTH} using its own cost model. Misclassification of variables into \texttt{PRIVATE}, \texttt{FIRSTPRIVATE}, \texttt{LASTPRIVATE}, \texttt{LINEAR}, and \texttt{REDUCTION}, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

\texttt{routine-name} is the name of a routine (a function or subroutine). It must be the enclosing routine or the routine immediately following the directive.

If you specify more than one clause, they must be separated by commas and enclosed in parentheses.

When you specify the \texttt{ATTRIBUTES VECTOR} directive, the compiler provides data parallel semantics by combining with the vectorized operations or loops at the call site. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced. If you specify one or more clauses, they affect the data parallel semantics provided by the compiler.

If you specify the \texttt{ATTRIBUTES VECTOR} directive with no \texttt{VECTORLENGTH} clause, a default \texttt{VECTORLENGTH} is computed based on efficiency heuristics of the vectorizer and the following:

- The return type of the function, if the function has a return type.
- The data type of the first non-scalar argument (that is, the first argument that is specified in the scalar clause), if any.
- Default integer type, if neither of the above is supplied.

If you do not explicitly specify a \texttt{VECTORLENGTH} clause, the compiler will choose a \texttt{VECTORLENGTH} using its own cost model.

If you specify the \texttt{ATTRIBUTES VECTOR} directive with no clause, the compiler will generate vector code based on compiler efficiency heuristics and whatever processor compiler options are specified.

The \texttt{VECTOR} attribute implies the C attribute, so that when you specify the \texttt{VECTOR} attribute on a routine, the C attribute is automatically also set on the same routine. This changes how the routine name is decorated and how arguments are passed.

\textbf{NOTE}

You should ensure that any possible side effects for the specified routine-name are acceptable or expected, and the memory access interferences are properly synchronized.
The Fortran Standard keyword ELEMENTAL specifies that a procedure written with scalar arguments can be extended to conforming array arguments by processing the array elements one at a time in any order. The ATTRIBUTES VECTOR directive tells the optimizer to produce versions of the procedure `routine-name` that execute with contiguous slices of the array arguments as defined by the VECTORLENGTH clause in an "elemental" fashion. `routine-name` does not need to be defined as ELEMENTAL to be given the VECTOR attribute.

The VECTOR attribute causes the compiler to generate a short vector form of the procedure, which can perform the procedure's operation on multiple elements of its array arguments in a single invocation. The short vector version may be able to perform multiple operations as fast as the regular implementation performs a single operation by using the vector instruction set in the CPU.

In addition, when invoked from an OMP construct, the compiler may assign different copies of the elemental procedures to different threads, executing them concurrently. The end result is that your data parallel operation executes on the CPU using both the parallelism available in the multiple cores and the parallelism available in the vector instruction set. If the short vector procedure is called inside a parallel loop or an auto-parallelized loop that is vectorized, you can achieve both vector-level and thread-level parallelism.

The INTENT(OUT) or INTENT(INOUT) attribute is not allowed for arguments of a procedure with the VECTOR attribute since the VECTOR attribute forces the procedure to receive its arguments by value.

The Intel C/C++ compiler built-in function `__intel_simd_lane()` may be helpful in removing certain performance penalties caused by non-unit stride vector access. Consider the following:

```fortran
interface
! returns a number between 0 and vectorlength - 1 that reflects the current "lane id" within the SIMD vector
! __intel_simd_lane() will return zero if the loop is not vectorized
    function for_simd_lane () bind (C, name = "__intel_simd_lane")
        integer (kind=4) :: for_simd_lane
    !DEC$ attributes known_intrinsic, default :: for_simd_lane
    end function for_simd_lane
end interface
```

For more details, see the Intel C++ documentation.

---

**Product and Performance Information**

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

---

**Example**

The ATTRIBUTES VECTOR directive must be accessible in the caller, either via an INTERFACE block or by USE association.

The following shows an example of an external function with an INTERFACE block:

```fortran
!... function definition

    function f(x)
        !dir$ attributes vector :: f
        real :: f, x

    ...! attribute vector explicit in calling procedure using an INTERFACE

interface

    function f(x)

end interface
```
The ATTRIBUTES VECTOR directive can be brought into the caller by USE association if the vector function is a module procedure; for example:

```fortran
module use_vect
contains
  function f(x)
    !dir$ attributes vector :: f
    real :: f, x
    ... 
  end function
end module use_vect

USE use_vect !brings in ATTRIBUTE VECTOR for f(x)
...

! now simply call f(x)

    do i=1,n
        z(i) = f( x(i) )
    end do
```

You can specify more than one SCALAR or LINEAR clause in an ATTRIBUTES VECTOR directive. For example, all of the following are valid:

```
!DIR$ ATTRIBUTES VECTOR:PROCESSOR(atom) :: f
!DIR$ ATTRIBUTES VECTOR:(SCALAR(a), SCALAR(b)) :: f
!DIR$ ATTRIBUTES VECTOR:(LINEAR(x:1), LINEAR(y:1)) :: f
```

The three directives above are equivalent to specifying a single, continued, directive in fixed-form source, as follows:

```
!DIR$ ATTRIBUTES VECTOR:( PROCESSOR(atom), 
!DIR$& SCALAR(a, b),
!DIR$& LINEAR(x:1, y:1) ) :: f
```

**See Also**

ATTRIBUTES

Syntax Rules for Compiler Directives
AUTOMATIC

Statement and Attribute: Controls the storage allocation of variables in subprograms (as does STATIC). Variables declared as AUTOMATIC and allocated in memory reside in the stack storage area, rather than at a static memory location.

Syntax

The AUTOMATIC attribute can be specified in a type declaration statement or an AUTOMATIC statement, and takes one of the following forms:

**Type Declaration Statement:**

type, [att-ls] AUTOMATIC [, att-ls] :: v[, v] ...

**Statement:**

AUTOMATIC :: v[, v] ...

type Is a data type specifier.

att-ls Is an optional list of attribute specifiers.

v Is the name of a variable or an array specification. It can be of any type.

AUTOMATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

Automatic variables can reduce memory use because only the variables currently being used are allocated to memory.

Automatic variables allow possible recursion. With recursion, a subprogram can call itself (directly or indirectly), and resulting values are available upon a subsequent call or return to the subprogram. For recursion to occur, RECURSIVE must be specified in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

By default, the compiler allocates local scalar variables on the stack. Other non-allocatable variables of non-recursive subprograms are allocated in static storage by default. This default can be changed through compiler options. Appropriate use of the SAVE attribute may be required if your program assumes that local variables retain their definition across subprogram calls.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE (in one of the ways mentioned above).

To override any compiler option that may affect variables, explicitly specify the variables as AUTOMATIC.

**NOTE**

Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as AUTOMATIC more than once in the same scoping unit.

If the variable is a pointer, AUTOMATIC applies only to the pointer itself, not to any associated target.

Some variables cannot be specified as AUTOMATIC. The following table shows these restrictions:
A variable is in a module's outer scope, it cannot be specified as AUTOMATIC.

Use the heap-arrays compiler option to avoid stack overflows at run time by placing large automatic arrays in the heap instead of on the stack.

Example

The following example shows a type declaration statement specifying the AUTOMATIC attribute:

```fortran
REAL, AUTOMATIC :: A, B, C
```

The following example uses an AUTOMATIC statement:

```fortran
... CONTAINS
  INTEGER FUNCTION REDO_FUNC
    INTEGER I, J(10), K
    REAL C, D, E(30)
    AUTOMATIC I, J, K(20)
    STATIC C, D, E
  ...
END FUNCTION
...
```

In this example, all variables within the program unit are saved, except for "var1" and "var3". These are explicitly declared in an AUTOMATIC statement, and thus have memory locations on the stack:

```fortran
SUBROUTINE DoIt (arg1, arg2)
  INTEGER(4) arg1, arg2
  INTEGER(4) vari, var2, var3, var4
SAVE
  AUTOMATIC vari, var3
C  var2 and var4 are saved
```

**BACKSPACE**

**Statement:** Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing. It takes one of the following forms:

**Syntax**

```fortran
BACKSPACE (UNIT=io-unit[, ERR=label] [, IOMSG=msg-var] [, IOSTAT=i-var])
```

**io-unit** (Input) Is an external unit specifier.

**label** Is the label of the branch target statement that receives control if an error occurs.

**msg-var** (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

**i-var** (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**

The I/O unit number must specify an open file on disk or magnetic tape.

Backspacing from the current record \( n \) is performed by rewinding to the start of the file and then performing \( n - 1 \) successive READs to reach the previous record.

A BACKSPACE statement must not be specified for a file that is open for direct or append access, because \( n \) is not available to the Fortran I/O system.

BACKSPACE cannot be used to skip over records that have been written using list-directed or namelist formatting.

If a file is already positioned at the beginning of a file, a BACKSPACE statement has no effect.

If the file is positioned between the last record and the end-of-file record, BACKSPACE positions the file at the start of the last record.

**Example**

```fortran
BACKSPACE 5
BACKSPACE (5)
BACKSPACE lunit
BACKSPACE (UNIT = lunit, ERR = 30, IOSTAT = ios)
```

The following statement repositions the file connected to I/O unit 4 back to the preceding record:

```fortran
BACKSPACE 4
```

Consider the following statement:

```fortran
BACKSPACE (UNIT=9, IOSTAT=IOS, ERR=10)
```

This statement positions the file connected to unit 9 back to the preceding record. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

**See Also**

REWIND
**BADDRESS**

*Inquiry Intrinsic Function (Generic):* Returns the address of an argument. This function cannot be passed as an actual argument. This function can also be specified as IADDR.

**Syntax**

```fortran
result = BADDRESS(x)
```

*x* is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

**Example**

```
PROGRAM batest
  INTEGER X(5), I
  DO I = 1, 5
    PRINT *, BADDRESS(X(I))
  END DO
END
```

**BARRIER**

*OpenMP* Fortran Compiler Directive: Synchronizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.

**Syntax**

```fortran
!$OMP BARRIER
```

The binding thread set for a BARRIER construct is the current team. A barrier region binds to the innermost enclosing parallel region.

Each barrier region must be encountered by all threads in a team or by none at all, unless cancellation has been requested for the innermost enclosing parallel region.

The barrier region must also be encountered in the same order by all threads in a team.

**Example**

```
INTEGER K
K = 17
```
!$OMP PARALLEL SHARED (K) NUM_THREADS (2)
IF (OMP_GET_THREAD_NUM() == 0) THEN
  X = 5
ELSE
  ! The following read access of K creates a race condition
  PRINT *, "1: THREAD# ", OMP_GET_THREAD_NUM (), " K = ", K
ENDIF

! This barrier contains implicit flushes on all threads, as well as a thread
! synchronization: this guarantees that the value 5 will be printed by
! both PRINT 2 and PRINT 3 below.

!$OMP BARRIER
IF (OMP_GET_THREAD_NUM() == 0) THEN
  PRINT *, "2: THREAD# ", OMP_GET_THREAD_NUM (), " K = ", K
ELSE
  PRINT *, "3: THREAD# ", OMP_GET_THREAD_NUM (), " K = ", K
ENDIF
!$OMP END PARALLEL

BEEPQQ

*Portability Subroutine*: Sounds the speaker at the specified frequency for the specified duration in milliseconds.

Module
USE IFPORT

Syntax
CALL BEEPQQ (frequency, duration)

frequency (Input) INTEGER(4). Frequency of the tone in Hz.
duration (Input) INTEGER(4). Length of the beep in milliseconds.

BEEPQQ does not return until the sound terminates.

Example

USE IFPORT
INTEGER(4) frequency, duration
frequency = 4000
duration = 1000
CALL BEEPQQ(frequency, duration)

See Also
SLEEPQQ
**BESJ0, BESJ1, BESJN, BESY0, BESY1, BESYN**

*Portability Functions:* Compute the single-precision values of Bessel functions of the first and second kinds.

**Module**

USE IFPORT

**Syntax**

result = BESJ0 (value)
result = BESJ1 (value)
result = BESJN (n, value)
result = BESY0 (posvalue)
result = BESY1 (posvalue)
result = BESYN (n, value)

value  
(\text{Input}) \text{REAL}(4). Independent variable for a Bessel function.

n  
(\text{Input}) \text{INTEGER}(4). Specifies the order of the selected Bessel function computation.

posvalue  
(\text{Input}) \text{REAL}(4). Independent variable for a Bessel function. Must be greater than or equal to zero.

**Results**

BESJ0, BESJ1, and BESJN return Bessel functions of the first kind, orders 0, 1, and \(n\), respectively, with the independent variable \(posvalue\).

BESY0, BESY1, and BESYN return Bessel functions of the second kind, orders 0, 1, and \(n\), respectively, with the independent variable \(posvalue\).

Negative arguments cause BESY0, BESY1, and BESYN to return QNAN.

Bessel functions are explained more fully in most mathematics reference books, such as the *Handbook of Mathematical Functions* (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the BESSEL_* functions, if you need to use quad-precision (REAL(16)).

**See Also**

DBESJ0, DBESJ1, DBESJN

**BESSEL_J0**

*Elemental Intrinsic Function (Generic):* Computes a Bessel function of the first kind, order 0.

**Syntax**

result = BESSEL_J0 (x)

\(x\)  
(\text{Input}) Must be of type real.
Results
The result type and kind are the same as \( x \).
The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order zero of \( x \).

Example
BESSEL_J0 (1.0) has the approximate value 0.765.

BESSEL_J1

*Elemental Intrinsic Function (Generic):* Computes a Bessel function of the first kind, order 1.

Syntax
\[
\text{result} = \text{BESSEL_J1} (x)
\]
\( x \)  
(Input) Must be of type real.

Results
The result type and kind are the same as \( x \).
The result has a value equal to a processor-dependent approximation to the Bessel function of the first kind and order 1 of \( x \).

Example
BESSEL_J1 (1.0) has the approximate value 0.440.

BESSEL_JN

*Elemental and Transformational Intrinsic Functions (Generic):* Compute Bessel functions of the first kind.

Syntax
Elemental function:  
\[
\text{result} = \text{BESSEL_JN} (n, x)
\]
Transformational function:  
\[
\text{result} = \text{BESSEL_JN} (n1, n2, x)
\]
\( n, n1, n2 \)  
(Input) Must be of type integer and nonnegative.
\( x \)  
(Input) Must be of type real.

Results
The result type and kind are the same as \( x \).
The result of BESSEL_JN \((n, x)\) is scalar. The result value of BESSEL_JN \((n, x)\) is a processor-dependent approximation to the Bessel function of the first kind and order \( n \) of \( x \).
The result of BESSEL_JN \((n1, n2, x)\) is a rank-one array with extent \( \text{MAX} (n2 - n1 + 1, 0) \). Element \( i \) of the result value of BESSEL_JN \((n1, n2, x)\) is a processor-dependent approximation to the Bessel function of the first kind and order \( n1 + i - 1 \) of \( x \).

Example
BESSEL_JN (2, 1.0) has the approximate value 0.115.
Consider the following program Bessel.90:

```fortran
real :: z (6) = [0:5]/5.          ! 0.0 through 1.0 by 0.2
print *, z
print *, bessel_jn (2, 1.0)      ! scalar argument, answer about 0.115
print *, bessel_jn (1, z)          ! elemental
print *, bessel_jn (1, 4, 1.0)  ! orders 1 thru 4 on a scalar
end
```

Compile bessel.f90 and execute the result:

```
> ifort Bessel.f90 -o Bessel
> bessel
```

The above commands produce the following result:

```
0.0000000E+00  0.2000000      0.4000000      0.6000000      0.8000000      1.000000
0.1149035
0.0000000E+00  9.9500835E-02  0.1960266      0.2867010      0.3688421      0.4400506
0.4400506      0.1149035      1.9563355E-02  2.4766389E-03
```

### BESSEL_Y0

**Elemental Intrinsic Function (Generic):** Computes a Bessel function of the second kind, order 0.

**Syntax**

```fortran
result = BESSEL_Y0 (x)
```

$x$  
(Input) Must be of type real with a value greater than zero.

**Results**

The result type and kind are the same as $x$.

The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order zero of $x$.

**Example**

BESSEL_Y0 (1.0) has the approximate value 0.088.

### BESSEL_Y1

**Elemental Intrinsic Function (Generic):** Computes a Bessel function of the second kind, order 1.

**Syntax**

```fortran
result = BESSEL_Y1 (x)
```

$x$  
(Input) Must be of type real with a value greater than zero.

**Results**

The result type and kind are the same as $x$.

The result has a value equal to a processor-dependent approximation to the Bessel function of the second kind and order 1 of $x$.

**Example**

BESSEL_Y1 (1.0) has the approximate value -0.781.
BESSEL_YN
Elemental and Transformational Intrinsic Functions (Generic): Compute Bessel functions of the second kind.

Syntax
Elemental function: result = BESSEL_YN (n, x)
Transformational function: result = BESSEL_YN (n1, n2, x)

n, n1, n2 (Input) Must be of type integer and nonnegative.
x (Input) Must be of type real with a value greater than zero.

Results
The result type and kind are the same as x.
The result of BESSEL_YN (n, x) is scalar. The result value of BESSEL_YN (n, x) is a processor-dependent approximation to the Bessel function of the second kind and order n of x.
The result of BESSEL_YN (n1, n2, x) is a rank-one array with extent MAX (n2 - n1 + 1, 0). Element i of the result value of BESSEL_YN (n1, n2, x) is a processor-dependent approximation to the Bessel function of the second kind and order n1 + i - 1 of x.

Example
BESSEL_YN (2, 1.0) has the approximate value -1.651.

BGE
Elemental Intrinsic Function (Generic): Performs a bitwise greater than or equal to on its arguments.

Syntax
result = BGE (i, j)
i (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
j (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of i and j do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

Results
The result is true if the sequence of bits represented by i is greater than or equal to the sequence of bits represented by j, according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.
The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.
The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.
Example
If BIT_SIZE (J) has the value 8, BGE (Z'FF', J) has the value true for any value of J. BGE (0, -1) has the value false.

See Also
BIT_SIZE

**BGT**

*Elemental Intrinsic Function (Generic): Performs a bitwise greater than on its arguments.*

**Syntax**

\[
\text{result} = \text{BGT} \ (i, j)
\]

- \(i\) (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
- \(j\) (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of \(i\) and \(j\) do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by \(i\) is greater than the sequence of bits represented by \(j\), according to the method of bit sequence comparison in *Bit Sequence Comparisons*; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in *Binary, Octal, Hexadecimal, and Hollerith Constants*.

The model for the interpretation of an integer value as a sequence of bits is shown in *Model for Bit Data*.

**Example**

BGT (Z'FF', Z'FC') has the value true. BGT (0, -2) has the value false.

**BIC, BIS**

*Portability Subroutines: Perform a bit-level set and clear for integers.*

**Module**

USE IFPORT

**Syntax**

CALL BIC (bitnum, target)
CALL BIS (bitnum, target)

- \(bitnum\) (Input) INTEGER(4). Bit number to set. Must be in the range 0 (least significant bit) to 31 (most significant bit) if \(target\) is INTEGER(4). If \(target\) is INTEGER(8), \(bitnum\) must be in range 0 to 63.
- \(target\) (Input) INTEGER(4) or INTEGER(8). Variable whose bit is to be set.

BIC sets bit \(bitnum\) of \(target\) to 0; BIS sets bit \(bitnum\) to 1.
Example
Consider the following:

```
USE IFPORT
  integer(4) bitnum, target_i4
  integer(8) target_i8
  target_i4 = Z'AAAA'
  bitnum = 1
  call BIC(bitnum, target_i4)
  target_i8 = Z'FFFFFFFF00000000'
  bitnum = 40
  call BIC(bitnum, target_i8)
  bitnum = 0
  call BIS(bitnum, target_i4)
  bitnum = 1
  call BIS(bitnum, target_i8)
  print '('" integer*4 result ",Z')', target_i4
  print '('" integer*8 result ",Z')', target_i8
end
```

BIT

BIND

**Statement and Attribute:** Specifies that an object is interoperable with C and has external linkage.

**Syntax**
The BIND attribute can be specified in a type declaration statement or a BIND statement, and takes one of the following forms:

**Type Declaration Statement:**
```
type, [att-ls, ] BIND (C [, NAME=ext-name]) [, att-ls] :: object
```

**Statement:**
```
BIND (C [, NAME=ext-name]) :: object
```

- **type**
  Is a data type specifier.
- **att-ls**
  Is an optional list of attribute specifiers.
- **ext-name**
  Is a character scalar constant expression that can be used to construct the external name.
- **object**
  Is the name of a variable or common block. It can also be the name of an internal procedure if NAME= is not specified.

**Description**
If a common block is specified in a BIND statement, it must be specified with the same binding label in each scoping unit in which it is declared.

For variables and common blocks, BIND also implies the SAVE attribute, which may be explicitly confirmed with SAVE.

A variable given the BIND attribute (or declared in a BIND statement) must appear in the specification part of a module. You cannot specify BIND for a subroutine local variable or a variable in a main program.

The BIND attribute is similar to directive !DIR$ ATTRIBUTES C as follows:
• The compiler applies the same naming rules, that is, names are lowercase (unless NAME= specifies otherwise).
• The compiler applies the appropriate platform decoration, such as a leading underscore.

However, procedure argument passing differs. When BIND is specified, procedure arguments are passed by reference unless the VALUE attribute is also specified.

The BIND attribute can optionally be used in a PROCEDURE, SUBROUTINE, or FUNCTION declaration. It must be used in an ENUM declaration.

**Example**
The following example shows the BIND attribute used in a type declaration statement, a statement, and a SUBROUTINE statement.

```plaintext
INTEGER, BIND(C) :: SOMEVAR
BIND(C,NAME='SharedCommon') :: /SHAREDCOMMON/

! you need empty parens after the subroutine name if BIND is present
SUBROUTINE FOOBAR() BIND(C, NAME='FooBar')
  ...
END SUBROUTINE
```

**BIT**

*Portability Function:* Performs a bit-level test for integers.

**Module**

USE IFPORT

**Syntax**

```
result = BIT (bitnum, source)
```
bitnum  
(Input) INTEGER(4). Bit number to test. Must be in the range 0 (least significant bit) to 31 (most significant bit).

source  
(Input) INTEGER(4) or INTEGER(8). Variable being tested.

Results  
The result type is logical. It is .TRUE. if bit bitnum of source is 1; otherwise, .FALSE..

See Also  
BIC, BIS

BIT_SIZE  
Inquiry Intrinsic Function (Generic): Returns the number of bits in an integer type.

Syntax  
result = BIT_SIZE (i)

i  
(Input) Must be of type integer or of type logical (which is treated as an integer).

Results  
The result is a scalar integer with the same kind parameter as i. The result value is the number of bits (s) defined by the bit model for integers with the kind parameter of the argument. For information on the bit model, see Model for Bit Data.

Example  
BIT_SIZE (1_2) has the value 16 because the KIND=2 integer type contains 16 bits.

See Also  
BTTEST
IBCLR
IBITS
IBSET

BLE  
Elemental Intrinsic Function (Generic): Performs a bitwise less than or equal to on its arguments.

Syntax  
result = BLE (i,j)

i  
(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

j  
(Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of i and j do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.
**Results**

The result is true if the sequence of bits represented by \( i \) is less than or equal to the sequence of bits represented by \( j \), according to the method of bit sequence comparison in Bit Sequence Comparisons; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in Binary, Octal, Hexadecimal, and Hollerith Constants.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

BLE (0, J) has the value true for any value of J. BLE (-2, 0) has the value false.

**BLOCK**

*Statement:* Marks the beginning of a BLOCK construct. The BLOCK construct executes a block of statements or constructs that can contain declarations.

**Syntax**

```
[name:] BLOCK
   [specification-part]
   block
END BLOCK [name]
```

- **name** (Optional) Is the name of the BLOCK construct.
- **specification-part** (Optional) Is one or more specification statements, except for the following:
  - COMMON
  - FUNCTION (outside of an INTERFACE block)
  - EQUIVALENCE
  - IMPLICIT
  - INTENT (or its equivalent attribute)
  - MODULE
  - NAMELIST
  - OPTIONAL (or its equivalent attribute)
  - SUBROUTINE (outside of an INTERFACE block)
  - VALUE (or its equivalent attribute)
  - Statement functions

- **block** Is a sequence of zero or more statements or constructs, except for the following:
  - CONTAINS (outside of a TYPE definition)
  - ENTRY
  - IMPORT (outside of a TYPE definition)
  - Statement functions
Description

A BLOCK construct is itself a scoping unit. Entities declared in a BLOCK construct are local to the BLOCK construct and are accessible only in that construct and in any contained constructs. A local entity in a block construct hides any entity with the same name in its host scope. No transfer of control into a block from outside the block is allowed, except for the return from a procedure call. Transfers within a block or out of the block are allowed.

If a construct name is specified at the beginning of a BLOCK statement, the same name must appear in the corresponding END BLOCK statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a BLOCK statement, you cannot specify one following the END BLOCK statement.

You can only branch to an END BLOCK statement from within its BLOCK construct.

The SAVE attribute specifies that a local variable of a BLOCK construct retains its association status, allocation status, definition status, and value after termination of the construct unless it is a pointer and its target becomes undefined. If the BLOCK construct contains a SAVE statement, the SAVE statement cannot specify the name of a common block. A SAVE statement outside a BLOCK construct does not affect variables local to the BLOCK construct, because a SAVE statement affects variables in its scoping unit which excludes nested scoping units in it.

The statements specified within the specification-part are evaluated in a processor-dependent order, followed by execution of block. When execution exits block, all non-SAVEd automatic and allocatable local variables are deallocated.

Example

The following shows a BLOCK construct:

```fortran
block
  integer :: i
  real :: a(n)
  do i = 1,n
    a(i) = i
  end do
  ...
end block
```

When control exits the bottom of the BLOCK, local variables `i` and `a` revert to their meaning outside the block.

The following example shows two nested BLOCK constructs where the inner BLOCK construct has the construct name INNER and the outer one does not have a name:

```fortran
BLOCK
  ...
  INNER: BLOCK
  ...
  END BLOCK INNER
  ...
END BLOCK
```

In the following example, the appearance and the reference of the FORMAT statement are legal:

```fortran
PROGRAM MAIN
  WRITE(6, FMT=10)
  ...
  BLOCK
    10 FORMAT("Hello")
END PROGRAM MAIN
```
Implicit typing is not affected by BLOCK constructs. In the following example, even if NSQP only appears in the two BLOCK constructs, the scope of NSQP is the whole subroutine S:

```fortran
SUBROUTINE S(N)
...
IF (N>0) THEN
    BLOCK
        NSQP = CEILING(SQRT(DBLE(N)))
    END BLOCK
END IF
...
IF (N>0) THEN
    BLOCK
        PRINT *,NSQP
    END BLOCK
END IF
END SUBROUTINE S
```

### BLOCK DATA

**Statement:** Identifies a block-data program unit, which provides initial values for variables in named common blocks. BLOCK DATA is an obsolescent language feature in Standard Fortran.

**Syntax**

```
BLOCK DATA [name]

    [specification-part]

END [BLOCK DATA [name]]
```

- `name` is the name of the block data program unit.
- `specification-part` is one or more of the following statements:

<table>
<thead>
<tr>
<th>Statement</th>
<th>Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON</td>
<td>INTRINSIC STATIC</td>
</tr>
<tr>
<td>DATA</td>
<td>PARAMETER TARGET</td>
</tr>
<tr>
<td>Derived-type</td>
<td>POINTER Type declaration</td>
</tr>
<tr>
<td>definition</td>
<td></td>
</tr>
<tr>
<td>DIMENSION</td>
<td>RECORD USE</td>
</tr>
<tr>
<td>EQUIVALENCE</td>
<td>Record structure declaration</td>
</tr>
<tr>
<td>IMPLICIT</td>
<td>SAVE</td>
</tr>
</tbody>
</table>

1 For more information, see RECORD statement and record structure declarations.
2 Can only contain attributes: DIMENSION, INTRINSIC, PARAMETER, POINTER, SAVE, STATIC, or TARGET.
Description

A block data program unit need not be named, but there can only be one unnamed block data program unit in an executable program.

If a name follows the END statement, it must be the same as the name specified in the BLOCK DATA statement.

An interface block must not appear in a block data program unit and a block data program unit must not contain any executable statements.

If a DATA statement initializes any variable in a named common block, the block data program unit must have a complete set of specification statements establishing the common block. However, all of the variables in the block do not have to be initialized.

A block data program unit can establish and define initial values for more than one common block, but a given common block can appear in only one block data program unit in an executable program.

The name of a block data program unit can appear in the EXTERNAL statement of a different program unit to force a search of object libraries for the block data program unit at link time.

Example

The following shows a block data program unit:

```
BLOCK DATA BLKDAT
  INTEGER S, X
  LOGICAL T, W
  DOUBLE PRECISION U
  DIMENSION R(3)
  COMMON /AREA1/R, S, U, T /AREA2/W, X, Y
  DATA R/1.0, 2*2.0/, T/.FALSE./, U/0.214537D-7/, W/.TRUE./, Y/3.5/
END
```

The following shows another example:

```
C      Main Program
CHARACTER(LEN=10) family
INTEGER a, b, c, d, e
REAL X(10), Y(4)
COMMON/Lakes/a,b,c,d,e,family/Blk2/x,y ...
C      The following block-data subprogram initializes
C      the named common block /Lakes/:
C
BLOCK DATA InitLakes
COMMON /Lakes/ erie, huron, michigan, ontario,
+        superior, fname
DATA erie, huron, michigan, ontario, superior /1, 2, 3, 4, 5/
CHARACTER(LEN=10) fname/'GreatLakes'/
INTEGER erie, huron, michigan, ontario, superior
END
```

**BLOCK LOOP and NOBLOCK LOOP**

**General Compiler Directives:** Enables or disables loop blocking for the immediately following nested DO loops. BLOCK LOOP enables loop blocking for the nested loops, NOBLOCK LOOP disables loop blocking for the nested loops.

**Syntax**

!DIR$ BLOCK_LOOP [clause[,...]]

!DIR$ NOBLOCK_LOOP

clause

Is one or more of the following:

- **FACTOR**(*expr*)
  
  *expr* is a positive scalar constant integer expression representing the blocking factor for the specified loops.

  This clause is optional. If the FACTOR clause is not present, the blocking factor will be determined based on processor type and memory access patterns and will be applied to the specified levels in the nested loop following the directive.

  At most only one FACTOR clause can appear in a BLOCK_LOOP directive.

- **LEVEL**(*level[,...]*)

  *level* is specified in the form:

  `const1` or `const1:const2`

  where `const1` is a positive integer constant `m <= 8` representing the loop at level `m`, where the immediate following loop is level 1.

  The `const2` is a positive integer constant `n <= 8` representing the loop at level `n`, where `n > m`: `const1:const2` represents the nested loops from level `const1` through `const2`.

  This clause is optional. If the LEVEL clause is not present, the specified blocking factor is applied to all levels of the immediately following nested loops.

  At most only one LEVEL clause can appear in a BLOCK_LOOP directive.

  The clauses can be specified in any order. If you do not specify any clause, the compiler chooses the best blocking factor to apply to all levels of the immediately following nested loop.

The BLOCK LOOP directive lets you exert greater control over optimizations on a specific DO loop inside a nested DO loop.
Using a technique called loop blocking, the BLOCK_LOOP directive separates large iteration counted DO loops into smaller iteration groups. Execution of these smaller groups can increase the efficiency of cache space use and augment performance.

If there is no LEVEL and FACTOR clause, the blocking factor will be determined based on the processor’s type and memory access patterns and it will apply to all the levels in the nested loops following this directive.

You can use the NOBLOCK_LOOP directive to tune the performance by disabling loop blocking for nested loops.

**NOTE**
The loop-carried dependence is ignored during the processing of BLOCK_LOOP directives.

### Example

```
!dir$ block_loop factor(256) level(1) ! applies blocking factor 256 to
!dir$ block_loop factor(512) level(2) ! the top level loop in the following
      ! nested loop and blocking factor 512 to
      ! the 2nd level (1st nested) loop

!dir$ block_loop factor(256) level(2)
!dir$ block_loop factor(512) level(1) ! levels can be specified in any order

!dir$ block_loop factor(256) level(1:2) ! adjacent loops can be specified as a range

!dir$ block_loop factor(256) ! the blocking factor applies to all levels of loop nest
!dir$ block_loop ! the blocking factor will be determined based on
      ! processor type and memory access patterns and will
      ! be applied to all the levels in the nested loop
      ! following the directive

!dir$ noblock_loop ! None of the levels in the nested loop following this
      ! directive will have a blocking factor applied
```

Consider the following:

```
!dir$ block_loop factor(256) level(1:2)
do j = 1,n
  f = 0
  do i = 1,n
    f = f + a(i) * b(i)
  enddo
  c(j) = c(j) + f
enddo
```

The above code produces the following result after loop blocking:

```
do jj=1,n/256+1
  do ii = 1,n/256+1
    do j = (jj-1)*256+1, min(jj*256, n)
      f = 0
      do i = (ii-1)*256+1, min(ii*256,n)
        f = f + a(i) * b(i)
      enddo
      c(j) = c(j) + f
  enddo
enddo
```

BLT

**Elemental Intrinsic Function (Generic):** Performs a bitwise less than on its arguments.

**Syntax**

```
result = BLT (i, j)
```

- `i` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.
- `j` (Input) Must be of type integer or a binary, octal, or hexadecimal literal constant.

If the kinds of `i` and `j` do not match, the value with the smaller kind is extended with zeros on the left and the larger kind is used for the operation and the result.

**Results**

The result is true if the sequence of bits represented by `i` is less than the sequence of bits represented by `j`, according to the method of bit sequence comparison in `Bit Sequence Comparisons`; otherwise, the result is false.

The interpretation of a binary, octal, or hexadecimal literal constant as a sequence of bits is described in `Binary, Octal, Hexadecimal, and Hollerith Constants`.

The model for the interpretation of an integer value as a sequence of bits is shown in `Model for Bit Data`.

**Example**

BLT (0, 2) has the value true. BLT (Z'FF', Z'FC') has the value false.

BSEARCHQQ

**Portability Function:** Performs a binary search of a sorted one-dimensional array for a specified element. The array elements cannot be derived types or structures.

**Module**

USE IFPORT

**Syntax**

```
result = BSEARCHQQ (adrkey, adrray, length, size)
```
adrkey  (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the variable containing the element to be found (returned by LOC).

adrarray  (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

length  (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in the array.

size  (Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in size is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with size characters per element.

**Results**
The result type is INTEGER(4). It is an array index of the matched entry, or 0 if the entry is not found.
The array must be sorted in ascending order before being searched.

**Caution**
The location of the array and the element to be found must both be passed by address using the LOC function. This defeats Fortran type checking, so you must make certain that the length and size arguments are correct, and that size is the same for the element to be found and the array searched.

If you pass invalid arguments, BSEARCHQQ attempts to search random parts of memory. If the memory it attempts to search is not allocated to the current process, the program is halted, and you receive a General Protection Violation message.

**Example**

```fortran
USE IFPORT
INTEGER(4) array(10), length
INTEGER(4) result, target
length = SIZE(array)
...
result = BSEARCHQQ(LOC(target),LOC(array),length,SRT$INTEGER4)
```
See Also
SORTQQ
LOC

BTEST
Elemental Intrinsic Function (Generic): Tests a bit of an integer argument.

Syntax
result = BTEST (i, pos)

i
(Input) Must be of type integer or of type logical (which is treated as an integer).

pos
(Input) Must be of type integer. It must not be negative and it must be less than BIT_SIZE(i).

The rightmost (least significant) bit of i is in position 0.

Results
The result type is default logical.

The result is true if bit pos of i has the value 1. The result is false if pos has the value zero. For more information, see Bit Functions.

For information on the model for the interpretation of an integer value as a sequence of bits, see Model for Bit Data.

The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BBTEST</td>
<td>INTEGER(1)</td>
<td>LOGICAL(1)</td>
</tr>
<tr>
<td>BITEST¹</td>
<td>INTEGER(2)</td>
<td>LOGICAL(2)</td>
</tr>
<tr>
<td>BTEST²</td>
<td>INTEGER(4)</td>
<td>LOGICAL(4)</td>
</tr>
<tr>
<td>BKTEST</td>
<td>INTEGER(8)</td>
<td>LOGICAL(8)</td>
</tr>
</tbody>
</table>

¹Or HTEST
²Or BJTEST

Example
BTEST (9, 3) has the value true.

If A has the value

```
[ 1  2 ]
[ 3  4 ],
```

the value of BTEST (A, 2) is

```
[ false  false ]
[ false   true ]
```
and the value of BTEST (2, A) is

```
[ true false ]
[ false false ].
```

The following shows more examples:

<table>
<thead>
<tr>
<th>Function reference</th>
<th>Value of i</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>BTEST ( i,2)</td>
<td>00011100 0111000</td>
<td>.FALSE.</td>
</tr>
<tr>
<td>BTEST ( i,3)</td>
<td>00011100 0111000</td>
<td>.TRUE.</td>
</tr>
</tbody>
</table>

The following shows another example:

```
INTEGER(1) i(2)
LOGICAL result(2)
i(1) = 2#10101010
i(2) = 2#01010101
result = BTEST(i, (/3,2/))  ! returns (.TRUE.,.TRUE.)
write(*,*) result
```

Integer Data Types

**C to D**

This section describes language features that start with C or D.
C to D

C_ASSOCIATED

Intrinsic Module Inquiry function (Generic):
Indicates the association status of one argument, or whether two arguments are associated with the same entity.

Module
USE, INTRINSIC :: ISO_C_BINDING

Syntax
result = C_ASSOCIATED(c_ptr_1[, c_ptr_2])

c_ptr_1 (Input) Is a scalar of derived type C_PTR or C_FUNPTR.
c_ptr_2 (Optional; input) Is a scalar of the same type as c_ptr_1.

Results
The result is a scalar of type default logical. The result value is one of the following:

- If only c_ptr_1 is specified, the result is false if c_ptr_1 is a C null pointer; otherwise, the result is true.
- If c_ptr_2 is specified, the result is false if c_ptr_1 is a C null pointer. The result is true if c_ptr_1 is equal to c_ptr_2; otherwise, the result is false.

See Also
Intrinsic Modules
ISO_C_BINDING Module

C_F_POINTER

Intrinsic Module Subroutine: Associates a data pointer with the target of a C pointer and specifies its shape.

Module
USE, INTRINSIC :: ISO_C_BINDING

Syntax
CALL C_F_POINTER(cptr, fptr [,shape])

cptr (Input) Is a scalar of derived type C_PTR. Its value is the C address of an interoperable data entity, or the result of a reference to function C_LOC with a noninteroperable argument. If the value of cptr is the C address of a Fortran variable, it must have the TARGET attribute.

fptr (Output) Is a data pointer. If it is an array, shape must be specified.

shape (Optional, input) Must be of type integer and rank one. Its size equals the rank of fptr.
If the value of `cptr` is the C address of an interoperable data entity, `fptr` must be a data pointer with type and type parameters interoperable with the type of the entity. In this case, `fptr` becomes pointer-associated with the target of `cptr`.

If `fptr` is an array, it has the shape specified by `shape` and each lower bound is 1.

If the value of `cptr` is the result of a reference to C_LOC with a noninteroperable argument `x`, the following rules apply:

- C_LOC argument `x` (or its target) must not have been deallocated or have become undefined due to the execution of a RETURN or END statement since the reference to C_LOC.
- `fptr` is a scalar pointer with the same type and type parameters as `x`. `fptr` becomes pointer-associated with `x`, or it becomes pointer-associated with its target if `x` is a pointer.

Since the resulting data pointer `fptr` could point to a target that was not allocated with an ALLOCATE statement, `fptr` cannot be freed with a DEALLOCATE statement.

**See Also**

Intrinsic Modules

ISO_C_BINDING Module

C_LOC

**C_F_PROCPOINTER**

**Intrinsic Module Subroutine:** Associates a Fortran procedure pointer with the target of a C function pointer.

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

```
CALL C_F_PROCPOINTER(cptr, fptr)
```

- `cptr` (Input) Is a scalar of derived type C_FUNPTR. Its value is the C address of a procedure.
- `fptr` (Output) Is a Fortran procedure pointer. It becomes pointer-associated with the target of `cptr`.

**Examples**

Example 1

The following Fortran subroutine can be called from a C program that passes a pointer to a C function to be called:

```
SUBROUTINE CallIt (cp) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
TYPE(C_FUNPTR), INTENT(IN) :: cp
ABSTRACT INTERFACE
  SUBROUTINE Add_Int (i) BIND(C)
  IMPORT
  INTEGER(C_INT), INTENT(INOUT) :: i
END SUBROUTINE Add_Int
END INTERFACE
PROCEDURE(Add_Int), POINTER :: fp
```
Example 2

In the following C code, a function pointer to the C function `foo` is passed to the Fortran subroutine `bar`. `bar` converts the function pointer to a procedure pointer, and calls `foo` through the converted procedure pointer.

```c
#include <stdio.h>

extern void bar_ (void (*)(int*));
extern void foo (int *a){
    printf ("The value is %d\n", *a);
}

int main () {
    void (*fun_b)(int*) = NULL;
    int *i;
    int j = 10;
    fun_b = foo;
    i = &j;
    printf ("Test in C\n");
    fun_b (i);
    printf ("Test in Fortran\n");
    bar_ (&fun_b);
}
```

```fortran
SUBROUTINE bar (c_fptr)
    USE ISO_C_BINDING
    TYPE(c_funptr) :: c_fptr
    PROCEDURE(),POINTER :: proc_ptr
    INTEGER(c_int) :: i = 20
    CALL c_f_procpointer (c_fptr, proc_ptr)
    CALL proc_ptr (i)
END SUBROUTINE bar
```

When these two files are compiled, linked, and executed, the output is:

Test in C
  The value is 10
Test in Fortran
  The value is 20

ISO_C_BINDING Module

Procedure Pointers
PROCEDURE

**C_FUNLOC**

*Intrinsic Module Inquiry function (Generic):*  
*Returns the C address of a function pointer.*

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

```fortran
result = C_FUNLOC(x)
```

*x*  
*(Input)* Is a procedure or a Fortran pointer of type INTEGER associated with a procedure. If *x* is a procedure pointer, it must be associated. *x* cannot be a coindexed object. If C_FUNLOC is called from a PURE procedure, *x* must be PURE.

**Results**

The result is a scalar of derived type C_FUNPTR. The result value represents the C address of the argument.

**See Also**

Intrinsic Modules

ISO_C_BINDING Module

**C_LOC**

*Intrinsic Module Inquiry function (Generic):*  
*Returns the C address of an argument.*

**Module**

USE, INTRINSIC :: ISO_C_BINDING

**Syntax**

```fortran
result = C_LOC(x)
```

*x*  
*(Input)* Is a non-coindexed variable with the TARGET attribute. It must have interoperable type and type parameters, and it must be a non-polymorphic variable with no length type parameters, or an assumed-type variable.

If it is an array, it must be contiguous with non-zero size. It cannot be a zero-length string. If it is a pointer, it must be associated. If it has the ALLOCATABLE attribute, it must be allocated.

**Results**

The result is a scalar of derived type C_PTR. The result value represents the C address of the argument.

The result is a value that can be used as an actual CPTR argument in a call to procedure C_F_POINTER where *fptr* has attributes that allow the pointer assignment *fptr*=>*x*. Such a call to C_F_POINTER has the effect of the pointer assignment *fptr*=>*x*.
If \( x \) is a scalar, the result is determined as if \( \text{C\_PTR} \) were a derived type containing a scalar pointer component \( \text{PX} \) of the type and type parameters of \( x \) and the pointer assignment \( \text{CPTR}\%\text{PX}=\Rightarrow x \) were executed.

If \( x \) is an array, the result is determined as if \( \text{C\_PTR} \) were a derived type containing a scalar pointer component \( \text{PX} \) of the type and type parameters of \( x \) and the pointer assignment \( \text{CPTR}\%\text{PX} \) to the first element of \( x \) were executed.

Intrinsic Modules

ISO\_C\_BINDING Module

C\_F\_POINTER

---

**C\_SIZEOF**

**Intrinsic Module Inquiry function (Generic):**

Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.

**Module**

USE, INTRINSIC :: ISO\_C\_BINDING

**Syntax**

\[
\text{result} = \text{C\_SIZEOF}(x)
\]

\( x \) (Input) Is an interoperable data entity of any type and any rank. It must not be an assumed-size array or an assumed-rank array associated with an assumed-size array.

**Results**

The result is a scalar of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. If \( x \) is scalar, the result value is the size of \( x \) in bytes. If \( x \) is an array, the result value is the size of a single element of \( x \) multiplied by the number of elements in \( x \).

**Example**

Consider the following:

\[
\begin{align*}
\text{INTEGER(4)} & :: \text{S} \\
\text{INTEGER(4)} & :: \text{T(3)} \\
\text{C\_SIZEOF(S)} & \text{ has the value 4} \\
\text{C\_SIZEOF(T)} & \text{ has the value 12}
\end{align*}
\]

**See Also**
Intrinsic Modules

ISO\_C\_BINDING Module

SIZEOF
CACHESIZE

Inquiry Intrinsic Function (Generic): Returns the size of a level of the memory cache.

Syntax

\[
\text{result} = \text{CACHESIZE} (n)
\]

\(n\) (Input) Must be scalar and of type integer.

Results

The result type and kind are the same as \(n\). The result value is the number of kilobytes in the level \(n\) memory cache.

\(n = 1\) specifies the first level cache; \(n = 2\) specifies the second level cache; etc. If cache level \(n\) does not exist, the result value is 0.

Example

CACHESIZE(1) returns 16 for a processor with a 16KB first level memory cache.

CALL

Statement: Transfers control to a subroutine subprogram.

Syntax

\[
\text{CALL} \ sub[((a-arg[,a-arg]...))] \\
\]

\(\text{sub}\) Is the name of the subroutine subprogram or other external procedure, or a dummy argument associated with a subroutine subprogram or other external procedure.

\(\text{a-arg}\) Is an actual argument optionally preceded by [keyword=], where \(\text{keyword}\) is the name of a dummy argument in the explicit interface for the subroutine. The keyword is assigned a value when the procedure is invoked.

Each actual argument must be a variable, an expression, the name of a procedure, or an alternate return specifier. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)

An alternate return specifier is an asterisk (*), or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement. (An alternate return is an obsolescent feature in Standard Fortran.)

Description

When the CALL statement is executed, any expressions in the actual argument list are evaluated, then control is passed to the first executable statement or construct in the subroutine. When the subroutine finishes executing, control returns to the next executable statement following the CALL statement, or to a statement identified by an alternate return label (if any).
If an argument list appears, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

An actual argument associated with a dummy procedure must be the specific name of a procedure, or be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures).

The procedure invoked by the CALL statement must be a subroutine subprogram and not a function. Calling a function as if it were a subroutine can cause unpredictable results.

Example
The following example shows valid CALL statements:

```plaintext
CALL CURVE(BASE,3.14159+X,Y,LIMIT,R(LT+2))
CALL PNTOUT(A,N,'ABCD')
CALL EXIT
CALL MULT(A,B,*10,*20,C)       ! The asterisks and ampersands denote
CALL SUBA(X,&30,&50,Y)         !     alternate returns
```

The following example shows a subroutine with argument keywords:

```plaintext
PROGRAM KEYWORD_EXAMPLE
INTERFACE
  SUBROUTINE TEST_C(I, L, J, KYWD2, D, F, KYWD1)
    INTEGER I, L(20), J, KYWD1
    REAL, OPTIONAL :: D, F
    COMPLEX KYWD2
  END SUBROUTINE TEST_C
END INTERFACE
INTEGER I, J, K
INTEGER L(20)
COMPLEX Z1
CALL TEST_C(I, L, J, KYWD1 = K, KYWD2 = Z1)
```

The first three actual arguments are associated with their corresponding dummy arguments by position. The argument keywords are associated by keyword name, so they can appear in any order.

Note that the interface to subroutine TEST has two optional arguments that have been omitted in the CALL statement.

The following shows another example of a subroutine call with argument keywords:

```plaintext
CALL TEST(X, Y, N, EQUALITIES = Q, XSTART = X0)
```

The first three arguments are associated by position.

The following shows another example:

```plaintext
!Variations on a subroutine call
REAL S,T,X
INTRINSIC NINT
S=1.5
T=2.5
X=14.7
!This calls SUB1 using keywords. NINT is an intrinsic function.
```
CALL SUB1(B=X,C=S*T,FUNC=NINT,A=4.0)
!Here is the same call using an implicit reference
CALL SUB1(4.0,X,S*T,NINT)

CONTAINS
  SUBROUTINE sub1(a,b,c,func)
  INTEGER func
  REAL a,b,c
  PRINT *, a,b,c, func(b)
  END SUBROUTINE
END

CANCEL
OpenMP* Fortran Compiler Directive: Requests cancellation of the innermost enclosing region of the construct specified, and causes the encountering implicit or explicit task to proceed to the end of the canceled construct.

Syntax
!$OMP CANCEL construct-clause [,] if-clause

construct-clause Is one of the following:
• DO
• PARALLEL
• SECTIONS
• TASKGROUP

if-clause (Optional) IF (scalar-logical-expression)

The binding thread set of a CANCEL construct is the current team. The cancel region binds to the innermost enclosing construct of the type corresponding to the construct-clause specified in the directive specifying the innermost DO, PARALLEL, SECTIONS, or TASKGROUP construct.

This is a stand-alone directive, so there are some restrictions on its placement within a program:
• It can only be placed at a point where a Fortran executable statement is allowed.
• It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.

If construct-clause is TASKGROUP, the CANCEL construct must be closely nested inside a TASK construct. Otherwise, the CANCEL construct must be closely nested inside an OpenMP construct that matches the type specified in construct-clause.

The CANCEL construct requests cancellation of the innermost enclosing region of the type specified. The request is checked at a cancellation point. When a cancellation is observed, execution jumps to the end of the canceled region.

Cancellation points are implied at certain locations, as follows:
• Implicit barriers
- BARRIER regions
- CANCEL regions
- CANCELLATION POINT regions

When cancellation of tasks occurs with a CANCEL TASKGROUP construct, the encountering task jumps to the end of its task region and is considered complete. Any task that belongs to the innermost enclosing taskgroup and has already begun execution, must run to completion or run until a cancellation point is reached. Any task that belongs to the innermost enclosing taskgroup and has not begun execution may be discarded and considered completed.

When cancellation occurs for a PARALLEL region, each thread of the binding thread set resumes execution at the end of the canceled region and any tasks that have been created by a TASK construct and their descendants are canceled according to the above taskgroup cancellation semantics.

When cancellation occurs for a DO or SECTIONS region, each thread of the binding thread set resumes execution at the end of the canceled region but no task cancellation occurs.

A DO construct that is being canceled must not have a NOWAIT or an ORDERED clause. A SECTIONS construct that is being canceled must not have a NOWAIT clause.

The behavior for concurrent cancellation of a region and a region nested within it is unspecified.

**NOTE**
You must release locks and similar data structures that can cause a deadlock when a CANCEL construct is encountered; blocked threads cannot be canceled.

If the canceled construct contains a REDUCTION or LASTPRIVATE clause, the final value of the REDUCTION or LASTPRIVATE variable is undefined.

All private objects or subobjects with the ALLOCATABLE attribute that are allocated inside the canceled construct are deallocated.

**See Also**
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
CANCELLATION POINT
Parallel Processing Model for information about Binding Sets

**CANCELLATION POINT**

*OpenMP Fortran Compiler Directive:* Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.

**Syntax**

```openmp
!$OMP CANCELLATION POINT construct-clause
```

`construct-clause` is one of the following:

- `DO`
- `PARALLEL`
- `SECTIONS`
- `TASKGROUP`

This is a stand-alone directive, so there are some restrictions on its placement within a program:
• It can only be placed at a point where a Fortran executable statement is allowed.
• It cannot be used as the action statement in an IF statement, or as the executable statement following a label, if the label is referenced in the program.

A CANCELLATION POINT region binds to the current task region.

If construct-clause is TASKGROUP, the CANCELLATION POINT construct must be closely nested inside a TASK construct. Otherwise, the CANCELLATION POINT construct must be closely nested inside an OpenMP construct that matches the type specified by the construct-clause.

When an implicit or explicit task reaches a user-defined cancellation point, the task immediately checks for cancellation of the region specified in the clause and performs cancellation of this region if cancellation is observed. If the clause specified is TASKGROUP then the current task region is canceled.

An OpenMP program with orphaned CANCELLATION POINT constructs is non-conforming.

Syntax Rules for Compiler Directives
CANCEL

CASE
Statement: Marks the beginning of a CASE construct. A CASE construct conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement.

Syntax
[name:] SELECT CASE (expr)

[CASE (case-value [, case-value] ...) [name] ]

  block]...

[CASE DEFAULT [name] ]

  block]

END SELECT [name]

name

expr

case-value

Is the name of the CASE construct.

Is a scalar expression of type integer, logical, or character (enclosed in parentheses). Evaluation of this expression results in a value called the case index.

Is one or more scalar integer, logical, or character initialization expressions enclosed in parentheses. Each case-value must be of the same type and kind parameter as expr. If the type is character, case-value and expr can be of different lengths, but their kind parameter must be the same.

Integer and character expressions can be expressed as a range of case values, taking one of the following forms:

```
low:high
low:
:high
```

Case values must not overlap.
**block**
Is a sequence of zero or more statements or constructs.

**Description**
If a construct name is specified in a SELECT CASE statement, the same name must appear in the corresponding END SELECT statement. The same construct name can optionally appear in any CASE statement in the construct. The same construct name must not be used for different named constructs in the same scoping unit.

The case expression (expr) is evaluated first. The resulting case index is compared to the case values to find a matching value (there can only be one). When a match occurs, the block following the matching case value is executed and the construct terminates.

The following rules determine whether a match occurs:
- When the case value is a single value (no colon appears), a match occurs as follows:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>A Match Occurs If:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logical</td>
<td>case-index .EQV. case-value</td>
</tr>
<tr>
<td>Integer or Character</td>
<td>case-index = = case-value</td>
</tr>
</tbody>
</table>

- When the case value is a range of values (a colon appears), a match depends on the range specified, as follows:

<table>
<thead>
<tr>
<th>Range</th>
<th>A Match Occurs If:</th>
</tr>
</thead>
<tbody>
<tr>
<td>low :</td>
<td>case-index &gt;= low</td>
</tr>
<tr>
<td>: high</td>
<td>case-index &lt;= high</td>
</tr>
<tr>
<td>low : high</td>
<td>low &lt;= case-index &lt;= high</td>
</tr>
</tbody>
</table>

The following are all valid case values:

| CASE (1, 4, 7, 11:14, 22) | Individual values as specified: |
| CASE (:-1)                 | All values less than zero       |
| CASE (0)                   | Only zero                      |
| CASE (1:)                  | All values above zero          |

If no match occurs but a CASE DEFAULT statement is present, the block following that statement is executed and the construct terminates.

If no match occurs and no CASE DEFAULT statement is present, no block is executed, the construct terminates, and control passes to the next executable statement or construct following the END SELECT statement.

The following figure shows the flow of control in a CASE construct:

**Flow of Control in CASE Constructs**

You cannot use branching statements to transfer control to a CASE statement. However, branching to a SELECT CASE statement is allowed. Branching to the END SELECT statement is allowed only from within the CASE construct.
Example

The following are examples of CASE constructs:

```fortran
INTEGER FUNCTION STATUS_CODE (I)
  INTEGER I
  CHECK_STATUS: SELECT CASE (I)
    CASE (:-1)
      STATUS_CODE = -1
    CASE (0)
      STATUS_CODE = 0
    CASE (1:)
      STATUS_CODE = 1
  END SELECT CHECK_STATUS
END FUNCTION STATUS_CODE

SELECT CASE (J)
  CASE (1, 3:7, 9) ! Values: 1, 3, 4, 5, 6, 7, 9
    CALL SUB_A
  CASE DEFAULT
    CALL SUB_B
END SELECT
```

The following three examples are equivalent:

1. ```fortran
   SELECT CASE (ITEST .EQ. 1)
     CASE (.TRUE.)
       CALL SUB1 ()
     CASE (.FALSE.)
       CALL SUB2 ()
   END SELECT
   ```
2. ```fortran
   SELECT CASE (ITEST)
     CASE DEFAULT
       CALL SUB2 ()
     CASE (1)
       CALL SUB1 ()
   END SELECT
   ```
3. ```fortran
   IF (ITEST .EQ. 1) THEN
     CALL SUB1 ()
   ELSE
     CALL SUB2 ()
   END IF
   ```

The following shows another example:

```fortran
CHARACTER*1 cmdchar
GET_ANSWER: SELECT CASE (cmdchar)
  CASE ('0')
    WRITE (*, *) "Must retrieve one to nine files"
  CASE ('1': '9')
    CALL RetrieveNumFiles (cmdchar)
  CASE ('A', 'a')
    CALL AddEntry
  CASE ('D', 'd')
    CALL DeleteEntry
  CASE ('H', 'h')
    CALL Help
```
CASE DEFAULT
   WRITE (*, *) "Command not recognized; please use H for help"
END SELECT GET_ANSWER

See Also
Execution Control

CDFLOAT
Portability Function: Converts a COMPLEX(4) argument to double-precision real type.

Module
USE IFPORT

Syntax
result = CDFLOAT (input)

input (Input) COMPLEX(4). The value to be converted.

Results
The result type is REAL(8).

CEILING
Elemental Intrinsic Function (Generic): Returns the smallest integer greater than or equal to its argument.

Syntax
result = CEILING (a[,kind])

a (Input) Must be of type real.

kind (Input; optional) Must be a scalar integer constant expression.

Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the smallest integer greater than or equal to a.

The setting of compiler options specifying integer size can affect this function.

Example
CEILING (4.8) has the value 5.

CEILING (-2.55) has the value -2.0.

The following shows another example:

    INTEGER I, IARRAY(2)
I = CEILING(8.01) ! returns 9
I = CEILING(-8.01) ! returns -8
IARRAY = CEILING((/8.01,-5.6/)) ! returns (9, -5)
See Also
FLOOR

CFI_address

C function prototype: Returns the C address of an object described by a C descriptor.

Syntax

```c
void *CFI_address (const CFI_cdesc_t *dv,
                   const CFI_index_t subscripts[]);
```

Formal Parameters:

- `dv`
  - The address of a C descriptor describing the object. The object must not be an unallocated allocatable variable or a pointer that is not associated.

- `subscripts`
  - A null pointer or the address of an array of type `CFI_index_t`. If the object is an array, subscripts must be the address of an array of type `CFI_index_t` with at least `n` elements, where `n` is the rank of the object. The value of `subscripts[i]` must be within the bounds of dimension `i` specified by the `dim` member of the C descriptor.

Result Value

If the object is an array of rank `n`, the result is the C address of the element of the object that the first `n` elements of the subscripts argument would specify if used as subscripts. If the object is scalar, the result is its C address.

Example

If `dv` is the address of a C descriptor for the Fortran array `A` declared as follows:

```fortran
REAL(C_FLOAT) :: A(100, 100)
```

then the following code calculates the C address of `A(5, 10)`:

```c
CFI_index_t subscripts[2];
float *address;
subscripts[0] = 4;
subscripts[1] = 9;
address = (float *) CFI_address(dv, subscripts);
```

See Also
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_allocate

C function prototype: Allocates memory for an object described by a C descriptor.
Syntax

```c
int CFIAllocate (CFI_cdesc_t *dv,
               const CFI_index_t lower_bounds[],
               const CFI_index_t upper_bounds[],
               size_t elem_len);
```

**Formal Parameters:**

*dv*  
The address of a C descriptor specifying the rank and type of the object. The `base_addr` member of the C descriptor is a null pointer. If the type is not a character type, the `elem_len` member must specify the element length. The attribute member must have a value of `CFI_attribute_allocatable` or `CFI_attribute_pointer`.

*lower_bounds*  
The address of an array with at least `dv->rank` elements. The first `dv->rank` elements of `lower_bounds` provide the lower Fortran bounds for each corresponding dimension of the object.

*upper_bounds*  
The address of an array with at least `dv->rank` elements. The first `dv->rank` elements of `upper_bounds` provide the upper Fortran bounds for each corresponding dimension of the object.

*elem_len*  
If the type specified in the C descriptor type is a Fortran character type, the value of `elem_len` is the storage size in bytes of an element of the object; otherwise, `elem_len` is ignored.

**Description**

Successful execution of `CFIAllocate` allocates memory for the object described by the C descriptor with the address `dv` using the same mechanism as the Fortran `ALLOCATE` statement, and assigns the address of that memory to `dv->base_addr`.

The first `dv->rank` elements of the `lower_bounds` and `upper_bounds` arguments provide the lower and upper Fortran bounds, respectively, for each corresponding dimension of the object. The supplied lower and upper bounds override any current dimension information in the C descriptor. If the rank is zero, the `lower_bounds` and `upper_bounds` arguments are ignored.

If the type specified in the C descriptor is a character type, the supplied element length overrides the current element-length information in the descriptor.

If an error is detected, the C descriptor is not modified.

**Result Value**

The result is an error indicator.

**Example**

If `dv` is the address of a C descriptor for the Fortran array `A` declared as follows:

```fortran
REAL, ALLOCATABLE :: A(:, :)
```

and the array is not allocated, the following code allocates it to be of shape `[100, 500]`:

```c
CFI_index_t lower[2], upper[2];
int ind;
lower[0] = 1; lower[1] = 1;
upper[0] = 100; upper[1] = 500;
ind = CFIAllocate(dv, lower, upper, 0);
```
See Also
ALLOCATE
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_deallocate
C function prototype: Deallocates memory for an object described by a C descriptor.

Syntax
int CFI_deallocate (CFI_cdesc_t *dv);

Formal Parameters:
\(dv\) The address of a C descriptor describing the object. It must have been allocated using the same mechanism as the Fortran ALLOCATE statement. If the object is a pointer, it must be associated with a target satisfying the conditions for successful deallocation by the Fortran DEALLOCATE statement.

Description
Successful execution of CFI_deallocate deallocates memory for the object using the same mechanism as the Fortran DEALLOCATE statement, and the base_addr member of the C descriptor becomes a null pointer.

If an error is detected, the C descriptor is not modified.

Result Value
The result is an error indicator.

Example
If \(dv\) is the address of a C descriptor for the Fortran array \(A\) declared as follows:

\[
\text{REAL, ALLOCATABLE :: } A(:, :)
\]

and the array is allocated, the following code deallocates it:

\[
\text{int } \text{ind};
\text{ind } = \text{ CFI_deallocate(dv)};
\]

See Also
ALLOCATE
DEALLOCATE
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_establish
C function prototype: Establishes a C descriptor.

Syntax
int CFI_establish(CFI_cdesc_t *dv, void *base_addr,
\[\text{CFI_attribute_t attribute,}\]
\[\text{\ldots}\]
\]
CFI_type_t type, size_t elem_len,
CFI_rank_t rank,
const CFI_index_t extents[]);

Formal Parameters:

dv
The address of a data object large enough to hold a C descriptor of the rank specified by rank. It must not have the same value as either a C formal parameter that corresponds to a Fortran actual argument or a C actual argument that corresponds to a Fortran dummy argument. It must not be the address of a C descriptor that describes an allocated allocatable object.

base_addr
A null pointer or the base address of the object to be described. If it is not a null pointer, it must be the address of a contiguous storage sequence that is appropriately aligned for an object of the type specified by type.

attribute
One of the attribute codes in Table "Macros for attribute codes" in C Typedefs and Macros for interoperability. If it is CFI_attribute_allocatable, base_addr must be a null pointer.

type
One of the type codes in Table "Macros for type codes" in C Typedefs and Macros for interoperability.

elem_len
If the type is CFI_type_struct, CFI_type_other, or a Fortran character type code, elem_len must be greater than zero and equal to the storage size in bytes of an element of the object. Otherwise, type is ignored.

rank
A value in the range $0 \leq \text{rank} \leq \text{CFI\_MAX\_RANK}$. It specifies the rank of the object.

extents
This is ignored if rank is equal to zero or if base_addr is a null pointer. Otherwise, it must be the address of an array with rank elements; the value of each element must be nonnegative, and extents[i] specifies the extent of dimension $i$ of the object.

Description
Successful execution of CFI_establish updates the object with the address dv to be an established C descriptor for a nonallocatable nonpointer data object of known shape, an unallocated allocatable object, or a data pointer.

If base_addr is not a null pointer, it is the address for a nonallocatable entity that is a scalar or a contiguous array. If the attribute argument has the value CFI_attribute_pointer, the lower bounds of the object described by dv are set to zero. If base_addr is a null pointer, the established C descriptor is for an unallocated allocatable, a disassociated pointer, or is a C descriptor that has the attribute CFI_attribute_other but does not describe a data object. If base_addr is the C address of a Fortran data object, the type and elem_len arguments must be consistent with the type and type parameters of the Fortran data object.

The remaining properties of the object are given by the other arguments.

CFI_establish is used to initialize a C descriptor declared in C with CFI_CDESC_T before passing it to any other functions as an actual argument, in order to set the rank, attribute, type and element length.
A C descriptor with attribute `CFI_attribute_other` and a `base_addr` that is a null pointer can be used as the argument result in calls to `CFI_section` or `CFI_select_part`, which will produce a C descriptor for a nonallocatable nonpointer data object.

If an error is detected, the object with the address `dv` is not modified.

**Result Value**
The result is an error indicator.

**Example**
The following code fragment establishes a C descriptor for an unallocated rank-one allocatable array that can be passed to Fortran for allocation there:

```c
CFI_rank_t rank;
CFI_CDESC_T(1) field;
int ind;
rank = 1;
ind = CFI_establish((CFI_cdesc_t *)&field, NULL,
CFI_attribute_allocatable,
CFI_type_double, 0, rank, NULL);
```

If the following Fortran type definition is specified:

```fortran
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE
```

and a Fortran subprogram that has an assumed-shape dummy argument of type T, the following code fragment creates a descriptor `a_fortran` for an array of size 100 that can be used as the actual argument in an invocation of the subprogram from C:

```c
typedef struct {double x; double _Complex y;} t;
t a_c[100];
CFI_CDESC_T(1) a_fortran;
int ind;
CFI_index_t extent[1];
extent[0] = 100;
ind = CFI_establish((CFI_cdesc_t *)&a_fortran, a_c,
CFI_attribute_other,
CFI_type_struct, sizeof(t), 1, extent);
```

**See Also**
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

**CFI_is_contiguous**

*C function prototype:* Tests contiguity of an array.

**Syntax**

```c
int CFI_is_contiguous(const CFI_cdesc_t *dv);
```

**Formal Parameters:**
The address of a C descriptor describing an array. The base_addr member of the C descriptor must not be a null pointer.

Result Value
The value of the result is 1 if the array described by \( dv \) is contiguous; otherwise, 0.

Since assumed-size and allocatable arrays are always contiguous, the result of CFI_is_contiguous on a C descriptor for such an array is 1.

See Also
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

**CFI_section**

C function prototype: Updates a C descriptor for an array section for which each element is an element of a given array.

**Syntax**

```c
int CFI_section(CFI_cdesc_t *result, const CFI_cdesc_t *source,
                 const CFI_index_t lower_bounds[],
                 const CFI_index_t upper_bounds[],
                 const CFI_index_t strides[]);
```

**Formal Parameters:**

- **result**
  - The address of a C descriptor with rank equal to the rank of `source` minus the number of zero `strides`. The attribute member must have the value `CFI_attribute_other` or `CFI_attribute_pointer`. If the value of result is the same as either a C formal parameter that corresponds to a Fortran actual argument or a C actual argument that corresponds to a Fortran dummy argument, the attribute member must have the value `CFI_attribute_pointer`.

  Successful execution of **CFI_section** updates the `base_addr` and `dim` members of the C descriptor with the address `result` to describe the array section determined by `source`, `lower_bounds`, `upper_bounds`, and `strides`, as follows:

  - The array section is equivalent to the Fortran array section `SOURCE(sectsub1, sectsub2, ... sectsubn)`, where `SOURCE` is the array described by `source`, \( n \) is the rank of that array, and `sectsubi` is the subscript `loweri` if `stridesi` is zero, and the section subscript `loweri : upperi : stridei` otherwise.
  
  - The value of `loweri` is the lower bound of dimension \( i \) of `SOURCE` if `lower_bounds` is a null pointer and `lower_bounds[i]` otherwise.
  
  - The value of `upperi` is the upper bound of dimension \( i \) of `SOURCE` if `upper_bounds` is a null pointer and `upper_bounds[i]` otherwise.
  
  - The value of `stridei` is 1 if `strides` is a null pointer and `strides[i]` otherwise. If `stridei` has the value zero, `loweri` must have the same value as `upperi`. 

---

Language Reference

1327
source

The address of a C descriptor that describes a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer. The `elem_len` and `type` members of `source` must have the same values as the corresponding members of `result`.

lower_bounds

A null pointer or the address of an array with at least source->rank elements. If it is not a null pointer, and `stridei` is zero or `(upperi - lower_bounds[i] + stridei)/stridei > 0`, the value of `lower_bounds[i]` must be within the bounds of dimension `i` of `SOURCE`.

upper_bounds

A null pointer or the address of an array with at least source->rank elements. If source describes an assumed-size array, `upper_bounds` must not be a null pointer. If it is not a null pointer and `stridei` is zero or `(upper_bounds[i] - loweri + stridei)/stridei > 0`, the value of `upper_bounds[i]` must be within the bounds of dimension `i` of `SOURCE`.

strides

A null pointer or the address of an array with at least source->rank elements.

If an error is detected, the C descriptor with the address `result` is not modified.

**Result Value**

The result is an error indicator.

**Example**

If `source` is already the address of a C descriptor for the rank-one Fortran array `A`, the lower bounds of `A` are equal to 1, and the lower bounds in the C descriptor are equal to 0, the following code fragment establishes a new C descriptor section and updates it to describe the array section `A(3::5):`

```c
CFI_index_t lower[1], strides[1];
CFI_CDESC_T(1) section;
int ind;
lower[0] = 2;
strides[0] = 5;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
CFI_type_float, 0, 1, NULL);
ind = CFI_section((CFI_cdesc_t *)&section, source,
lower, NULL, strides);
```

If `source` is already the address of a C descriptor for a rank-two Fortran assumed-shape array `A` with lower bounds equal to 1, the following code fragment establishes a C descriptor and updates it to describe the rank-one array section `A(:, 42):`

```c
CFI_index_t lower[2], upper[2], strides[2];
CFI_CDESC_T(1) section;
int ind;
lower[0] = source->dim[0].lower_bound;
upper[0] = source->dim[0].lower_bound + source->dim[0].extent - 1;
strides[0] = 1;
strides[1] = 0;
ind = CFI_establish((CFI_cdesc_t *)&section, NULL,
CFI_attribute_other,
```
See Also
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

**CFI_select_part**

*C function prototype:* Updates a C descriptor for an array section for which each element is a part of the corresponding element of an array.

**Syntax**

```c
int CFI_select_part(CFI_cdesc_t *result, const CFI_cdesc_t *source,
                    size_t displacement, size_t elem_len);
```

**Formal Parameters:**

- **result**
  - The address of a C descriptor; result->rank must have the same value as source->rank and result->attribute must have the value CFI_attribute_other or CFI_attribute_pointer. If the address specified by result is the value of a C formal parameter that corresponds to a Fortran actual argument or of a C actual argument that corresponds to a Fortran dummy argument, result->attribute must have the value CFI_attribute_pointer. The value of result->type specifies the type of the array section.

- **source**
  - The address of a C descriptor for a nonallocatable nonpointer array, an allocated allocatable array, or an associated array pointer.

- **displacement**
  - A value 0 ≤ displacement ≤ source->elem_len − 1, and the sum of the displacement and the size in bytes of an element of the array section must be less than or equal to source->elem_len. The address displacement bytes greater than the value of source->base_addr is the base of the array section and must be appropriately aligned for an object of the type of the array section.

- **elem_len**
  - A value equal to the storage size in bytes of an element of the array section if result->type specifies a Fortran character type; otherwise, elem_len is ignored.

**Description**

Successful execution of CFI_select_part updates the base_addr, dim, and elem_len members of the C descriptor with the address result for an array section for which each element is a part of the corresponding element of the array described by the C descriptor with the address source. The part must be a component of a structure, a substring, or the real or imaginary part of a complex value. If an error is detected, the C descriptor with the address result is not modified.

**Result Value**

The result is an error indicator.
Example

If source is already the address of a C descriptor for the Fortran array A declared as follows:

```fortran
TYPE, BIND(C) :: T
REAL(C_DOUBLE) :: X
COMPLEX(C_DOUBLE_COMPLEX) :: Y
END TYPE

TYPE(T) A(100)
```

then the following code fragment establishes a C descriptor for the array A%Y:

```c
typedef struct {
    double x; double _Complex y;
} t;

CFI_CDESC_T(1) component;
CFI_cdesc_t * comp_cdesc = (CFI_cdesc_t *)&component;
CFI_index_t extent[] = { 100 };
(void)CFI_establish(comp_cdesc, NULL, CFI_attribute_other,
    CFI_type_double_Complex,
    sizeof(double _Complex), 1, extent);
(void)CFI_select_part(comp_cdesc, source, offsetof(t,y), 0);
```

See Also
C Structures Typedefs and Macros for interoperability
Interoperating with arguments using C descriptors

CFI_setpointer

**C function prototype:** Updates a C descriptor for a Fortran pointer to be associated with the whole of a given object or to be disassociated.

**Syntax**

```c
int CFI_setpointer(CFI_cdesc_t *result, CFI_cdesc_t *source,
    const CFI_index_t lower_bounds[]);
```

**Formal Parameters:**

- `result`:
  The address of a C descriptor for a Fortran pointer. It is updated using information from the `source` and `lower_bounds` arguments.

- `source`:
  A null pointer or the address of a C descriptor for a nonallocatable nonpointer data object, an allocated allocatable object, or a data pointer object. If `source` is not a null pointer, the corresponding values of the `elem_len`, `rank`, and `type` members must be the same in the C descriptors with the addresses `source` and `result`.

- `lower_bounds`:
  If source is not a null pointer and `source->rank` is nonzero, `lower_bounds` must be a null pointer or the address of an array with at least `source->rank` elements.

**Description**

Successful execution of `CFI_setpointer` updates the `base_addr` and `dim` members of the C descriptor with the address result as follows:

- If `source` is a null pointer or the address of a C descriptor for a disassociated pointer, the updated C descriptor describes a disassociated pointer.
Otherwise, the C descriptor with the address result becomes a C descriptor for the object described by the
C descriptor with the address source, except that if source->rank is nonzero and lower_bounds is not a
null pointer, the lower bounds are replaced by the values of the first source->rank elements of the
lower_bounds array.

Result Value
The result is an error indicator.

Example
If ptr is already the address of a C descriptor for an array pointer of rank 1, the following code updates it to
be a C descriptor for a pointer to the same array with lower bound 0:

```c
CFI_index_t lower_bounds[1];
int ind;
lower_bounds[0] = 0;
ind = CFI_setpointer(ptr, ptr, lower_bounds);
```

Interoperating with arguments using C descriptors

CHANGEDIRQQ

**Portability Function:** Makes the specified directory
the current, default directory.

**Module**

USE IFPORT

**Syntax**

```
result = CHANGEDIRQQ (dir)
```

*dir*  
(Input) Character*(*). Directory to be made the current directory.

**Results**

The result type is LOGICAL(4). It is .TRUE. if successful; otherwise, .FALSE..

If you do not specify a drive in the *dir* string, the named directory on the current drive becomes the current
directory. If you specify a drive in *dir*, the named directory on the specified drive becomes the current
directory.

**Example**

```c
USE IFPORT
LOGICAL(4) status
status = CHANGEDIRQQ('d:\fps90\bin'))
! We are now CCed to 'd:\fps90\bin'
status = CHANGEDIRQQ('bessel')
! We are now CCed to 'd:\fps90\bin\bessel'
```

**See Also**

GETDRIVEDIRQQ
MAKEDIRQQ
DELDIRQQ
CHANGEDRIVEQQ
CHANGEDRIVEQQ

**Portability Function:** Makes the specified drive the current, default drive.

**Module**

USE IFPORT

**Syntax**

result = CHANGEDRIVEQQ (drive)

`drive` (Input) Character*(*) String beginning with the drive letter.

**Results**

The result type is LOGICAL(4). On Windows* systems, the result is .TRUE. if successful; otherwise, .FALSE. On Linux* and macOS* systems, the result is always .FALSE..

Because drives are identified by a single alphabetic character, CHANGEDRIVEQQ examines only the first character of `drive`. The drive letter can be uppercase or lowercase.

CHANGEDRIVEQQ changes only the current drive. The current directory on the specified drive becomes the new current directory. If no current directory has been established on that drive, the root directory of the specified drive becomes the new current directory.

**Example**

```
USE IFPORT
LOGICAL(4) status
status = CHANGEDRIVEQQ('d')
```

CHANGE TEAM and END TEAM

**Statement:** Changes the current team of each image that executes the statement.

**Syntax**

The CHANGE TEAM construct takes the following form:

```
[name:] CHANGE TEAM (team-variable [, coarray-association-list][, sync-stat-list])
   block
END TEAM [[([sync-stat-list])] [name]]
```

`name` (Optional) Is the name of the CHANGE TEAM construct.

`team-variable` Is a scalar variable of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV.

`coarray-association` (Optional) Is codimension-decl => selector
codimension-decl

Is coarray-name [coarray-spec]

selector

Is a named coarray.

sync-stat

(Optional) Is STAT= stat-var or ERRMSG = err-var

stat-var

Is a scalar integer variable in which the status of the FORM TEAM operation is stored.

err-var

Is a scalar default character variable in which explanatory text is stored if an error occurs.

block

Is a sequence of zero or more statements or constructs.

The sync-stat-list items can appear in any order, but each sync-stat specifier may appear at most once. A selector may appear only once in selector-list. stat-var and err-var cannot be coindexed variables. team-variable must have been previously defined by the execution of a FORM TEAM statement.

Description

A CHANGE TEAM statement begins the CHANGE TEAM construct. The current team of each image that executes a CHANGE team statement becomes the team specified by the team variable. This remains the current team of the image until another CHANGE TEAM construct is executed by the image, or until the corresponding END TEAM statement is executed. The current team of each image executing an END TEAM statement becomes the team that was current prior to execution of the corresponding CHANGE TEAM statement.

Branching into or out of a CHANGE TEAM construct is not permitted. A branch to an END TEAM statement is permitted only from within the corresponding CHANGE TEAM construct. An EXIT statement in a CHANGE TEAM construct is effectively the same as a branch to the END TEAM statement of the construct. Within a CHANGE TEAM construct, a CYCLE or EXIT statement is not allowed if it belongs to an outer construct. A RETURN statement may not appear in a CHANGE TEAM construct.

If a construct name appears on the CHANGE TEAM statement of the construct, the same name must also appear on the END TEAM construct. If a construct name appears on an END TEAM statement, the same construct name must appear on the corresponding CHANGE TEAM statement. The construct name must not be the same as any other construct name in the scoping unit.

The purpose of the coarray-association is to redefine the codimensions of a coarray during execution of the CHANGE TEAM construct. The associating entity is a coarray with the corank and cobounds specified in the codimension-decl. This means the coshape and cobounds of an associating entity can be different from that of the selector. When the CHANGE TEAM statement is executed, the selectors must all be established coarrays.

The coarray name in a coarray-association must not be the same as the name as the name of another coarray or of a selector in the CHANGE TEAM statement. The coarray names specified in the codimension-decl are associate names associated with their corresponding selectors. The type and type parameters of the associating entity is that of its selector. The associating entity is polymorphic if the selector is polymorphic, in which case the associating entity assumes the dynamic type and type parameters of the selector.

On each active image that executes the CHANGE TEAM statement, the team variables must have been defined by corresponding execution of the same FORM TEAM statement. The current team executing prior to the CHANGE TEAM statement must be the same team that executed the FORM TEAM statement that defined the team variables. On each image, the team variable specified in the CHANGE TEAM statement cannot become undefined or redefined during execution of the construct.

An allocatable coarray that has an allocation status of allocated when the CHANGE TEAM construct is entered cannot be deallocated during execution of the construct. Allocatable coarrays that are allocated during the CHANGE TEAM construct and remain allocated at the end of the construct are deallocated upon exit from the construct. This is true even if the allocatable coarray has the SAVE attribute.
Each image executing the CHANGE TEAM statement is implicitly synchronized with all the other active images that will be on the same team after execution of the CHANGE TEAM construct. Execution of the statements forming the block of the CHANGE TEAM construct are delayed until all images on the new team have entered the construct. The construct completes execution when the END TEAM statement is executed. The images of the team executing the construct are implicitly synchronized when the END TEAM statement is executed.

If STAT= is specified on a CHANGE TEAM or END TEAM statement, stat-var becomes defined with the value 0 if no error condition occurs. If the team executing the statement contains a stopped image, stat-var becomes defined with the value STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. If the team contains a failed image and no other error condition occurs, stat-var becomes defined with the value STAT_FAILED_IMAGE defined in the module ISO_FORTRAN_ENV. Otherwise, stat-var becomes defined with a positive integer value other than STAT_FAILED_IMAGE or STAT_STOPPED_IMAGE. If STAT= is not specified, and the team contains a stopped or failed image, or if any other error occurs, error termination is initiated.

If ERRMSG= is specified in a CHANGE TEAM or an END TEAM statement and an error condition occurs, err-var becomes defined with a character string containing an informative message about the error. The string is truncated or padded according to the rules of intrinsic assignment. If no error occurs, err-var is unchanged.

**Examples**

Example 1:

```fortran
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE) :: odd_even
FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
CHANGE TEAM (odd_even)
  ! Segment 1
  ...
END TEAM
  ! Segment 2
  ...
END PROGRAM
```

If a team with 8 images executes the above code, two teams are formed. Team number 1 contains the odd numbered images [1, 3, 5, 7] of the parent team with new image indices [1, 2, 3, 4], and team number 2 contains the even numbered images [2, 4, 6, 8] of the parent team with new image indices [1, 2, 3, 4]. Segment 1 can be executed by team number 1 once images 1, 3, 5, and 7 of the initial team have arrived at the CHANGE TEAM construct. Team number 1 can execute segment 2 once the same images have executed the END TEAM statement. Similarly, segment 1 can be executed by team 2 only after image 2, 4, 6, and 8 have all arrived at the CHANGE TEAM statement, and they can execute segment 2 after they have all reached the END TEAM statement.

Example 2:

```fortran
USE ISO_FORTRAN_ENV
INTEGER, PARAMETER :: n = 4
TYPE (TEAM_TYPE) :: column
REAL, CODIMENSION[n, *] :: co_array
INTEGER, DIMENSION(2) :: my_cosubscripts
my_cosubscripts(1) = THIS_IMAGE(co_array)
FORM TEAM (my_cosubscripts(2), column, NEW_INDEX = my_cosubscripts(1))
CHANGE TEAM (column, ca[*] => co_array)
...
END TEAM
```

If there are 16 images on the initial team, the scalar coarray co_array will be distributed across a 4 x 4 grid of processors. Execution of the FORM TEAM statement divides the initial team into four teams of four images. Each team contains the images of one column of the grid of processors. The team number of each team is the column number in the processor grid, and the image indices on each new team are the row indices of the processor grid. Inside the CHANGE TEAM construct, the image pattern is a 1 x 4 pattern.

cor_array's cosubscripts:

| 1,1 | 1,2 | 1,3 | 1,4 |
| 2,1 | 2,2 | 2,3 | 2,4 |
| 3,1 | 3,2 | 3,3 | 3,4 |
| 4,1 | 4,2 | 4,3 | 4,4 |

cia's cosubscripts on each team:

<table>
<thead>
<tr>
<th>Team Number</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1,1</td>
<td>1,2</td>
<td>1,3</td>
<td>1,4</td>
<td></td>
</tr>
<tr>
<td>2,1</td>
<td>2,2</td>
<td>2,3</td>
<td>2,4</td>
<td></td>
</tr>
<tr>
<td>3,1</td>
<td>3,2</td>
<td>3,3</td>
<td>3,4</td>
<td></td>
</tr>
<tr>
<td>4,1</td>
<td>4,2</td>
<td>4,3</td>
<td>4,4</td>
<td></td>
</tr>
</tbody>
</table>

Example 3:

```fortran
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)    :: one_or_two
IF (THIS_IMAGE() .LE. NUM_IMAGES() / 2) THEN
   new_team = 1
ELSE
   new_team = 2
END IF
FORM TEAM (new_team, one_or_two)
SYNC ALL
CHANGE TEAM (one_or_two)
   ! Segment 1
   . . .
END TEAM
SYNC ALL
   ! Segment 2
   . . .
END PROGRAM
```

In the above case, the FORM TEAM statement creates two teams, team 1 and team 2. The SYNC ALL statement before the CHANGE TEAM statement prevents either team from entering the CHANGE TEAM construct until all images of the other team are ready to enter it also. Similarly, the SYNC ALL after the END TEAM statement prevents either team from executing segment 2 until all images of the other team have exited the CHANGE TEAM construct.

Example 4:

This example divides a 4x4 grid of images into 4 2x2 grids of images. The image indices of the 4x4 grid are:

<table>
<thead>
<tr>
<th>1</th>
<th>5</th>
<th>9</th>
<th>13</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>6</td>
<td>10</td>
<td>14</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>11</td>
<td>15</td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td>12</td>
<td>16</td>
</tr>
</tbody>
</table>

The 2x2 grids are laid out and identified symbolically and with team numbers as:

<table>
<thead>
<tr>
<th>top_left</th>
<th>top_right</th>
</tr>
</thead>
<tbody>
<tr>
<td>t(1,1)</td>
<td>h(1,2)</td>
</tr>
</tbody>
</table>
The image numbers on each of the teams in the 2x2 grids become:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

Here the CHANGE TEAM statement remaps the coarray co_array1 to 2x2 grids within each team accessed by the associate name ca. The assignment statement in the CHANGE TEAM construct assigns the value of ca[3] on team number 21 to x on all images of the initial team, assuming all four subteams execute the CHANGE TEAM construct. ca[3, TEAM_NUMBER=top_left] is co_array[1, 4] of the initial team located on image 13 of the initial team.

**CHAR**

**Elemental Intrinsic Function (Generic):** Returns the character in the specified position of the processor's character set. It is the inverse of the function **ICHAR**.

**Syntax**

\[
\text{result} = \text{CHAR} \left( i[,\text{kind}] \right)
\]

*i* (Input) Must be of type integer with a value in the range 0 to \( n - 1 \), where \( n \) is the number of characters in the processor's character set.
kind

(Input; optional) Must be a scalar integer constant expression.

Results

The result is of type character with length 1. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default character. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is the character in position i of the processor's character set. ICHAR(CHAR ( i, kind ( c ))) has the value I for 0 to n - 1 and CHAR(ICHAR ( c, kind ( c ))) has the value c for any character c capable of representation in the processor.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>INTEGER(4)</td>
<td>CHARACTER</td>
<td></td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>CHARACTER</td>
<td></td>
</tr>
</tbody>
</table>

^1This specific function cannot be passed as an actual argument.

Example

CHAR (76) has the value 'L'.
CHAR (94) has the value '^'.

Character and Key Code Charts

CHARACTER

Statement: Specifies the CHARACTER data type.

Syntax

CHARACTER ([LEN=len [, [KIND=n]])
CHARACTER (KIND=n [, [LEN=len]])
CHARACTER* len

n

Is kind 1.

len

Is a string length (not a kind). For more information, see Declaration Statements for Character Types.

If no kind type parameter is specified, the kind of the constant is default character.

Example

C
C   Length of wt and vs is 10, city is 80, and ch is 1
C
CHARACTER wt*10, city*80, ch
CHARACTER (LEN = 10), PRIVATE :: vs
CHARACTER(*) arg ! declares a dummy argument
C name and plume are ten-element character arrays
C of length 20
   CHARACTER name(10)*20
   CHARACTER(len=20), dimension(10):: plume
C
C Length of susan, emily, and naomi are 2, karen is 12,
C olivia is a 79-member array of length 2
C
   CHARACTER(2) susan, emily, karen*12, naomi, olivia(79)

Declaration Statements for Character Types

CHDIR
Portability Function: Changes the default directory.

Module
USE IFPORT

Syntax
result = CHDIR(dir_name)

dir_name (Input) Character*(*). Name of a directory to become the default directory.

Results
The result type is INTEGER(4). It returns zero if the directory was changed successfully; otherwise, an error code. Possible error codes are:

• ENOENT: The named directory does not exist.
• ENOTDIR: The dir_name parameter is not a directory.

Example

use ifport
   integer(4) istatus, enoent, enotdir
   character(255)  newdir
   character(300)  prompt, errmsg

   prompt = 'Please enter directory name: '
   write(*,*)  TRIM(prompt)
   read *, newdir
   ISTATUS = CHDIR(newdir)
   select case (istatus)
      case (2)  ! ENOENT
         errmsg = 'The directory ' // TRIM(newdir) // ' does not exist'
      case (20) ! ENOTDIR
         errmsg = TRIM(newdir) // ' is not a directory'
   end select

case (0) ! NO error
    goto 40
  case default
    write (errmsg,*) 'Error with code ', istatus
  end select
  write(*,*) TRIM(errmsg)
  goto 10
40    write(*,*) 'Default directory successfully changed.'
end

CHANGEDIRQQ

CHMOD

Portability Function: Changes the access mode of a file.

Module
USE IFPORT

Syntax
result = CHMOD (name, mode)

(name) Character*(*). Name of the file whose access mode is to be changed. Must have a single path.

(mode) Character*(*). File permission: either Read, Write, or Execute. The mode parameter can be either symbolic or absolute. An absolute mode is specified with an octal number, consisting of any combination of the following permission bits ORed together:

<table>
<thead>
<tr>

<td>W<em>S: Ignored; assumes owner permissions L</em>X, M*X: Settable</td>
</tr>
<tr>
<td>0004, 0002, 0001</td>
<td>Read, Write, Execute by others</td>
<td>W<em>S: Ignored; assumes owner permissions L</em>X, M*X: Settable</td>
</tr>
</tbody>
</table>

The following regular expression represents a symbolic mode:

```
[ugoa]*[+=-] [rwxXst]*
```

On Windows* systems, "[ugoa]" is ignored. On Linux* and macOS* systems, a combination of the letters "ugoa" control which users' access to the file will be changed:

<table>
<thead>
<tr>
<th>u</th>
<th>g</th>
<th>o</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>The user who owns the file</td>
<td>Other users in the group that owns the file</td>
<td>Other users not in the group that owns the file</td>
<td>All users</td>
</tr>
</tbody>
</table>

"+[ - =]" indicates the operation to carry out:

- Add the permission
- Remove the permission
- Absolutely set the permission

"[rwxXst]" indicates the permission to add, subtract, or set. On Windows systems, only "w" is significant and affects write permission; all other letters are ignored. On Linux and macOS* systems, all letters are significant.

**Results**

The result type is INTEGER(4). It is zero if the mode was changed successfully; otherwise, an error code. Possible error codes are:

- ENOENT: The specified file was not found.
- EINVAL: The mode argument is invalid.
- EPERM: Permission denied; the file's mode cannot be changed.

**Example**

```fortran
USE IFORT
integer(4) I,Istatus
I = ACCESS ("DATAFILE.TXT", "w")
if (I) then
```

1340
ISTATUS = CHMOD ("datafile.txt", "+w")
end if
I = ACCESS ("DATAFILE.TXT","w")
print *, I

CLASS
Statement: Declares a polymorphic object. It takes one of the following forms:

Syntax
CLASS (name) att-list :: v-list
CLASS (*) att-list :: v-list

<table>
<thead>
<tr>
<th>name</th>
<th>Is the name of the extensible derived data type.</th>
</tr>
</thead>
<tbody>
<tr>
<td>att-list</td>
<td>Is one or more attribute specifiers. These are the same attribute specifiers allowed for a derived-type TYPE statement.</td>
</tr>
<tr>
<td>v-list</td>
<td>Is the name of one or more data objects or functions. The name can optionally be followed by any of the following:</td>
</tr>
<tr>
<td></td>
<td>• An array specification, if the object is an array.</td>
</tr>
<tr>
<td></td>
<td>In a function declaration, an array must be a deferred-shape array if it has the POINTER attribute; otherwise, it must be an explicit-shape array.</td>
</tr>
<tr>
<td></td>
<td>• A character length, if the object is of type character.</td>
</tr>
<tr>
<td></td>
<td>• A coarray specification, if the object is a coarray.</td>
</tr>
<tr>
<td></td>
<td>• A constant expression preceded by an = or, for pointer objects, =&gt; NULL().</td>
</tr>
</tbody>
</table>

Description
A polymorphic object can have differing types during program execution.
The type of the object at a particular point during execution of a program is its dynamic type.
The declared type of a data entity is the type that it is declared to have, either explicitly or implicitly.
If CLASS (*) is specified, it denotes an unlimited polymorphic object. An unlimited polymorphic entity is not declared to have a type. It is not considered to have the same declared type as any other entity, including another unlimited polymorphic entity.
An entity declared with the CLASS keyword must be a dummy argument or have the ALLOCATABLE or POINTER attribute.
A polymorphic entity that is not an unlimited polymorphic entity is type compatible with entities of the same declared type or any of its extensions. Even though an unlimited polymorphic entity is not considered to have a declared type, it is type compatible with all entities. An entity is said to be type compatible with a type if it is type compatible with entities of that type.
A polymorphic allocatable object can be allocated to be of any type with which it is type compatible.
During program execution, a polymorphic pointer or dummy argument can be associated with objects with which it is type compatible.
CLEARSTATUSFPQQ

**Portability Subroutine:** Clears the exception flags in the floating-point processor status word.

**Module**

USE IFPORT

**Syntax**

CALL CLEARSTATUSFPQQ()

**Description**

The floating-point status word indicates which floating-point exception conditions have occurred. Intel® Fortran initially clears (sets to 0) all floating-point status flags, but as exceptions occur, the status flags accumulate until the program clears the flags again. CLEARSTATUSFPQQ will clear the flags.

CLEARSTATUSFPQQ is appropriate for use in applications that poll the floating-point status register as the method for detecting a floating-point exception has occurred.

For a full description of the floating-point status word, exceptions, and error handling, see *Floating-Point Operations: Floating-Point Environment.*

**Example**

```fortran
! Program to demonstrate CLEARSTATUSFPQQ.
! This program uses polling to detect that a floating-point exception has occurred.
! So, build this console application with the default floating-point exception behavior, fpe3.
! You need to specify compiler option /debug or /Od (Windows) or -O0 (Linux) to get the correct results.
!
! PROGRAM CLEARFP

USE IFPORT

REAL*4 A,B,C
INTEGER*2 STS

A = 2.0E0
B = 0.0E0

! Poll and display initial floating point status
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'Initial fp status = ',STS

! Cause a divide-by-zero exception
! Poll and display the new floating-point status
C = A/B
CALL GETSTATUSFPQQ(STS)
WRITE(*,'(1X,A,Z4.4)') 'After div-by-zero fp status = ',STS
```
If a divide by zero error occurred, clear the floating-point status register so future exceptions can be detected.

```fortran
IF ((STS .AND. FPSW$ZERODIVIDE) > 0) THEN
   CALL CLEARSTATUSFPQQ()
   CALL GETSTATUSFPQQ(STS)
   WRITE(*,'(1X,A,Z4.4)') 'After CLEARSTATUSFPQQ fp status = ',STS
ENDIF
```

END

This program is available in the online samples.

**CLOCK**

*Portability Function: Converts a system time into an 8-character ASCII string.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = CLOCK()
```

**Results**

The result type is character with a length of 8. The result is the current time in the form hh:mm:ss, using a 24-hour clock.

**Example**

```fortran
USE IFPORT
character(8) whatimeisit
whatimeisit = CLOCK ()
print *, 'The current time is ',whatimeisit
```

**See Also**

DATE_AND_TIME

**CLOCKX**

*Portability Subroutine: Returns the processor clock in units of microseconds.*

**Module**

USE IFPORT

**Syntax**

```fortran
CALL CLOCKX (clock)
```
**clock**

(Input) REAL(8). The current time.

On Windows systems, this subroutine has millisecond precision, and the last three digits of the returned value are not significant.

**CLOSE**

**Statement:** Disconnects a file from a unit.

**Syntax**

```
CLOSE ( [UNIT=] io-unit[, {STATUS | DISPOSE | DISP} = p] [, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var])
```

- **io-unit**
  (Input) an external unit specifier.

- **p**
  (Input) a scalar default character expression indicating the status of the file after it is closed. It has one of the following values:
  - 'KEEP' or 'SAVE' - Retains the file after the unit closes.
  - 'DELETE' - Deletes the file after the unit closes (unless OPEN(READONLY) is in effect).
  - 'PRINT' - Submits the file to the line print spooler, then retains it (sequential files only).
  - 'PRINT/DELETE' - Submits the file to the line print spooler, then deletes it (sequential files only).
  - 'SUBMIT' - Forks a process to execute the file.
  - 'SUBMIT/DELETE' - Forks a process to execute the file, then deletes the file after the fork is completed.

  The default is 'DELETE' for user windows in Windows* QuickWin applications and for scratch files. For all other files, the default is 'KEEP'.

  Scratch files are temporary and are always deleted upon normal program termination; specifying STATUS='KEEP' for scratch files causes a run-time error.

  For user windows in Windows* QuickWin applications, STATUS='KEEP' causes the child window to remain on the screen even after the unit closes. The default status is 'DELETE', which removes the child window from the screen.

- **label**
  Is the label of the branch target statement that receives control if an error occurs.

- **msg-var**
  (Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

- **i-var**
  (Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**

The CLOSE statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The status specified in the CLOSE statement supersedes the status specified in the OPEN statement, except that a file opened as a scratch file cannot be saved, printed, or submitted, and a file opened for read-only access cannot be deleted.
If a CLOSE statement is specified for a unit that is not open, it has no effect.

You do not need to explicitly close open files. Normal program termination closes each file according to its default status. The CLOSE statement does not have to appear in the same program unit that opened the file.

Closing unit 0 automatically reconnects unit 0 to the keyboard and screen. Closing units 5 and 6 automatically reconnects those units to the keyboard or screen, respectively. Closing the asterisk (*) unit causes a compile-time error. In Windows QuickWin applications, use CLOSE with unit 0, 5, or 6 to close the default window. If all of these units have been detached from the console (through an explicit OPEN), you must close one of these units beforehand to reestablish its connection with the console. You can then close the reconnect unit to close the default window.

If a parameter of the CLOSE statement is an expression that calls a function, that function must not cause an I/O operation or the EOF intrinsic function to be executed, because the results are unpredictable.

**NOTE**
You may get unexpected results if you specify OPEN with a filename and a USEROPEN specifier that opens a different filename, and then use a CLOSE statement with STATUS=DELETE (or DISPOSE=DELETE). In this case, the run-time library assumes you want to delete the file named in the OPEN statement, not the one you specified in the USEROPEN function. For more information about how to use the USEROPEN specifier, see User-Supplied OPEN Procedures: USEROPEN Specifier.

**Example**

```
! Close and discard file:
CLOSE (7, STATUS = 'DELETE')
```

Consider the following statement:

```
CLOSE (UNIT=J, STATUS='DELETE', ERR=99)
```

This statement closes the file connected to unit J and deletes it. If an error occurs, control is transferred to the statement labeled 99.

Data Transfer I/O Statements
Branch Specifiers

**CMPLX**

*Elemental Intrinsic Function (Specific):* Converts the argument to complex type. This function cannot be passed as an actual argument.

**Syntax**

This intrinsic function can take one of the following forms:

```
result = CMPLX (x [,kind])
```

- `x`  
  (Input) Must be of type complex.

- `kind`  
  (Input; optional) Must be a scalar integer constant expression.

or

```
result = CMPLX (x [,y ,kind])
```

1345
Input must be of type integer, real, or a binary, octal, or hexadecimal literal constant.

\( y \) (Input; optional) Must be of type integer, real, or a binary, octal, or hexadecimal literal constant.

\( \text{kind} \) (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is complex. If \( \text{kind} \) is present, the kind parameter is that specified by \( \text{kind} \); otherwise, the kind parameter is that of default real type.

If \( x \) is type complex, \( y \) must not be specified, and the result value is \( \text{CMPLX} (\text{REAL}(x), \text{AIMAG}(x)) \), with default kind if \( \text{kind} \) is not present, otherwise with the kind type as specified by \( \text{kind} \).

If \( x \) is present and not of complex type, and \( y \) is not present, \( x \) is converted into the real part of the result value and zero is assigned to the imaginary part.

If \( x \) and \( y \) are present, the complex value is produced by converting the \( x \) into the real part of the value, and converting the \( y \) into the imaginary part.

\( \text{CMPLX} (x, y, \text{kind}) \) has the complex value whose real part is \( \text{REAL}(x, \text{kind}) \) and whose imaginary part is \( \text{REAL}(y, \text{kind}) \).

The setting of compiler options specifying real size can affect this function.

If the argument is a binary, octal, or hexadecimal literal constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

**NOTE**

The result values of \( \text{CMPLX} \) are defined by references to the intrinsic function \( \text{REAL} \) with the same arguments. Therefore, the padding and truncation of binary, octal, and hexadecimal literal constant arguments to \( \text{CMPLX} \) is the same as for the intrinsic function \( \text{REAL} \).

**Example**

\( \text{CMPLX} (-3) \) has the value \((-3.0, 0.0)\).

\( \text{CMPLX} (4.1, 2.3) \) has the value \((4.1, 2.3)\).

The following shows another example:

```fortran
COMPLEX z1, z2
COMPLEX(8) z3
z1 = CMPLX(3)  ! returns the value 3.0 + i 0.0
z2 = CMPLX(3,4) ! returns the value 3.0 + i 4.0
z3 = CMPLX(3,4,8) ! returns a COMPLEX(8) value 3.0D0 + i 4.0D0
```

**CO_BROADCAST**

*Collective Intrinsic Subroutine (Generic):*  
Broadcasts a value to other images.

**Syntax**

```fortran
CALL CO_BROADCAST (a, source_image [, stat, errmsg])
```

- `a`  
  *(Input; output)* Must have the same shape, dynamic type, and type parameter values in corresponding references across all participating images. It cannot be a coindexed object. If an error occurs, it becomes undefined. Otherwise, `a` becomes defined as if by intrinsic assignment with the value `a` on image `source_image` on all images of the current team.

- `source_image`  
  *(Input)* Must be a scalar integer. The value of `source_image` must the value of an image index of an image on the current team. Its value must be the same in corresponding references on all images participating in the collective operation.

- `stat`  
  *(Output; optional)* Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to `stat` is specified in *Overview of Collective Subroutines*. If `stat` is not present and an error condition occurs, error termination is initiated.

- `errmsg`  
  *(Input; output; optional)* Must be a non-coindexed default character scalar variable. The semantics of `errmsg` is described in *Overview of Collective Subroutines*.

**Example**

Consider the following:

```fortran
CALL CO_BROADCAST (R, 5)
```

If `R` is a four-element array defined with the value `[10, 20, 30, 40]` on image 5 when the subroutine is referenced, `R` becomes defined with the value `[10, 20, 30, 40]` on all images of the current team if no error condition occurs during the subroutine reference.

**See Also**

*Overview of Collective Subroutines*

**CO_MAX**

*Collective Intrinsic Subroutine (Generic):*  
Calculates the maximum value across images.

**Syntax**

```fortran
CALL CO_MAX (a [, result_image, stat, errmsg])
```

- `a`  
  *(Input; output)* Must be of type real, integer, or character, and have the same shape, type, and type parameter values in corresponding references across all images of the current team. It cannot be a coindexed object. If it is scalar, the computed value is the maximum
value of \( a \) in all corresponding references. If it is an array, each element of the computed value is equal to the maximum value of the corresponding element of \( a \) in all corresponding references.

If no error occurs, the computed value is assigned to \( a \) on all images of the current team if \( \text{result
d_image} \) is not present, or on the executing image if the executing image is the image identified by \( \text{result
d_image} \). Otherwise, \( a \) becomes undefined.

\( \text{result
d_image} \) (Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If \( \text{result
d_image} \) is not present, it cannot be present in any corresponding reference.

\( \text{stat} \) (Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to \( \text{stat} \) is specified in Overview of Collective Subroutines. If \( \text{stat} \) is not present and an error condition occurs, error termination is initiated.

\( \text{errmsg} \) (Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of \( \text{errmsg} \) is described in Overview of Collective Subroutines.

Example

Consider the following:

```
CALL CO_MAX (R)
```

If there are two images and \( R \) is a four-element array defined with the value \([5, 10, 20, 15] \) on image one and \([10, 15, 20, 5] \) on image two when the subroutine is referenced, \( R \) becomes defined with the value \([10, 15, 20, 15] \) on both images if no error occurs during the subroutine reference, and CALL CO_MAX (\( R, 2 \)) causes \( R \) on image to become defined with the values \([10, 15, 20, 15] \) on image 2; \( R \) on image 1 becomes undefined.

See Also
Overview of Collective Subroutines

**CO_MIN**

*Collective Intrinsic Subroutine (Generic): Calculates the minimum value across images.*

Syntax

```
CALL CO_MIN (\( a \[, \text{result
d_image}, \text{stat}, \text{errmsg}\]\)
```

\( a \) (Input; output) Must be of type real, integer, or character, and have the same shape, type, and type parameter values in corresponding references across all images of the current team. It cannot be a coindexed object. If it is scalar, the computed value is the minimum value of \( a \) in all corresponding references. If it is an array, each element of the computed value is equal to the maximum value of the corresponding element of \( a \) in all corresponding references.
If no error occurs, the computed value is assigned to a on all images of the current team if \textit{result} image is not present, or on the executing image if the executing image is the image identified by \textit{result} image. Otherwise, a becomes undefined.

\textit{result} image

(Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If \textit{result} image is not present, it cannot be present in any corresponding reference.

\textit{stat}

(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to \textit{stat} is specified in \textit{Overview of Collective Subroutines}. If \textit{stat} is not present and an error condition occurs, error termination is initiated.

\textit{errmsg}

(Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of \textit{errmsg} is described in \textit{Overview of Collective Subroutines}.

\textbf{Example}

Consider the following:

\begin{verbatim}
CALL CO_MIN (R)
\end{verbatim}

If there are two images, and R is a four-element array defined with the value [5, 10, 20, 15] on image one and [10, 15, 20, 5] on image two when the subroutine is referenced, R becomes defined with the value [5, 10, 20, 5] on both images if no error occurs during the subroutine reference, and CALL CO_MIN (R, 1) causes R on image 1 to become defined with the value [5, 10, 20, 5]; R on image 2 becomes undefined.

\textbf{See Also}

Overview of Collective Subroutines

\textbf{CO_REDUCE}

\textit{Collective Intrinsic Subroutine (Generic)}:
\textit{Performs generalized reduction across images.}

\textbf{Syntax}

\begin{verbatim}
CALL CO_REDUCE (a, operation [, result_image, stat, errmsg])
\end{verbatim}

\textit{a}

(Input; output) Must be non-polymorphic, non-coindexed, with the same shape, type and type parameters in corresponding references. It may not be a coindexed object. If \textit{a} is scalar, the computed value is the result of the reduction of applying operation to the values of \textit{a} in all corresponding references. If \textit{a} is an array, each element of the computed value is equal to the result of the reduction of the reduction operation of applying operation to corresponding elements of \textit{a} in all corresponding references.

If no error occurs, the computed value is assigned to \textit{a} on all images of the current team if \textit{result} image is not present, or on the executing image if the executing image is the image identified by \textit{result} image. Otherwise, \textit{a} becomes undefined.
**operation**

Is a pure function with exactly two arguments whose result and each argument are a scalar, nonallocatable, nonpointer, nonpolymorphic data object with the same type and kind type parameters as `a`. Neither argument can be optional. If one argument has the attribute TARGET, VOLATILE, or ASYNCHRONOUS, the other argument must have that attribute. `operation` must implement a mathematical associative operation and be the same in each corresponding reference. If operation is not commutative, the computed value may depend on the order of evaluation.

The computed value of a reduction operation over a set of values is the result of an iterative process. Each iteration evaluates operation `(x, y)` for `x` and `y` in that set, the removal of `x` and `y` from that set, and the addition of the result of operation `(x, y)` to that set. The process ends when the set has a single value, which is the computed value.

**result_image**

(Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If `result_image` is not present, it cannot be present in any corresponding reference.

**stat**

(Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to `stat` is specified in *Overview of Collective Subroutines*. If `stat` is not present and an error condition occurs, error termination is initiated.

**errmsg**

(Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of `errmsg` is described in *Overview of Collective Subroutines*.

**Example**

The following subroutine demonstrates how `CO_REDUCE` can be used to create a collective version of the intrinsic function ANY.

```fortran
SUBROUTINE CO_ANY (VALUE)
   LOGICAL, INTENT(INOUT) :: VALUE
   CALL CO_REDUCE (VALUE, COMBINER)
END SUBROUTINE CO_ANY
```

```fortran
PURE FUNCTION COMBINER (OPND1, OPND2) RESULT = LOGICAL_SUM
   LOGICAL ::= LOGICAL_SUM
   LOGICAL, INTENT(IN) :: OPND1, OPND2
   LOGICAL_SUM = OPND1 .OR. OPND2
END FUNCTION COMBINER
```

If the number of images is two, and R is a four-element logical array with the value [.T., .T., .F., .F.] on image one and [.T., .F., .T., .F.] on image two, CALL `CO_REDUCE (R, CO_ANY)` causes the value of R to become defined with the value of [.T., .T., .T., .F.] on both images if no error occurs during the reference.

**See Also**

*Overview of Collective Subroutines*

**CO_SUM**

*Collective Intrinsic Subroutine (Generic):*

Performs a sum reduction across images.
Syntax
CALL CO_SUM (a [, result_image, stat, errmsg])

a (Input; output) Must be of type real, integer, or complex, and have the same shape, type, and type parameter values in corresponding references. It may not be a coindexed object. If it is scalar, the computed value is the sum of the values of a in all corresponding references. If it as an array, each element of the computed value is equal to the sum of the values of the corresponding element of a in all corresponding references.

If no error occurs, the computed value is assigned to a on all images of the current team if result_image is not present, or on the executing image if the executing image is the image identified by result_image. Otherwise, a becomes undefined.

result_image (Input; optional) Must be a scalar integer. If present, it must be present with the same value in all corresponding references and be a valid image index in the current team. If result_image is not present, it may not be present in any corresponding reference.

stat (Output; optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least four (KIND=2 or greater). The value assigned to stat is specified in Overview of Collective Subroutines. If stat is not present and an error condition occurs, error termination is initiated.

errmsg (Input; output; optional) Must be a non-coindexed default character scalar variable. The semantics of errmsg is described in Overview of Collective Subroutines.

Example
Consider the following:

CALL CO_SUM (R, 2)

If the number of images is two and if R is a four-element array defined with the value [5, 10, 20, 15] on image one and [10, 15, 20, 5] on image two when the procedure is referenced, R becomes defined with the value [15, 25, 40, 20] on image two and undefined on image one if no error occurs during the subroutine reference, and CALL CO_SUM (R) causes R on both images to become defined with the value [15, 25, 40, 20].

Overview of Collective Subroutines

CODE_ALIGN

General Compiler Directive: Specifies the byte alignment for a loop.

Syntax
!DIR$ CODE_ALIGN [:n]
n  (Optional) A positive integer constant expression indicating the number of bytes for the minimum alignment boundary. Its value must be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on.

If you specify 1 for \( n \), no alignment is performed. If you do not specify \( n \), the default alignment is 16 bytes.

This directive must precede the loop or block of code to be aligned.

If code is compiled with the `-falign-loops=m` (Linux* and macOS*) or `/Qalign-loops:m` (Windows*) option and a "CODE_ALIGN:n" directive precedes a loop, the loop is aligned on a MAX (m, n) byte boundary.

If a procedure has the "CODE_ALIGN:k" attribute and a "CODE_ALIGN:n" directive precedes a loop, then both the procedure and the loop are aligned on a MAX (k, n) byte boundary.

**Example**

Consider the following code fragment in file `test_code_align.f90`:

```fortran
!DIR$ CODE_ALIGN
DO J = 1, N
...
END DO
```

Compiling `test_code_align.f90` aligns the code that begins the DO J loop on a (default) 16-byte boundary.

If you do not specify the CODE_ALIGN directive, the alignment of the loop is implementation-dependent and may change from compilation to compilation.

Syntax Rules for Compiler Directives
falign-loops, Qalign-loops  compiler option
ATTRIBUTES CODE_ALIGN  directive

**CODIMENSION**

**Statement and Attribute:** Specifies that an entity is a coarray, and specifies its corank and cobounds, if any.

**Syntax**

The CODIMENSION attribute can be specified in a type declaration statement or a CODIMENSION statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
type, [attr-ls,] CODIMENSION [coarray-spec] :: var-list [(array-spec)]...
```

**Statement:**

```fortran
CODIMENSION [::] var-list [coarray-spec]...
```

- `type`  Is a data type specifier.
- `attr-ls`  Is an optional list of attribute specifiers.
- `coarray-spec`  Is an allocatable (deferred-coshape) coarray or an explicit-coshape coarray.
**Description**

In Intel® Fortran, the sum of the rank and corank of an entity must not exceed 31. The Fortran 2018 Standard allows a combined rank of up to 15.

A coarray must be a component or a variable that is not a function result.

A coarray must not be of type C_PTR or C_FUNPTR from the intrinsic module ISO_C_BINDING or of type TEAM_TYPE from the intrinsic module ISO_FORTRAN_ENV.

An entity whose type has a coarray ultimate component must be a nonpointer nonallocatable scalar, must not be a coarray, and must not be a function result.

A coarray or an object with a coarray ultimate component must be an associate name, a dummy argument, or have the ALLOCATABLE or SAVE attribute.

A coarray must not be a dummy argument of a procedure that has a BIND attribute.

A coarray can be a derived type with pointer or allocatable components. The target of such a pointer component is always on the same image as the pointer.

**Examples**

Explicit-shape coarrays that are not dummy arguments must have the SAVE attribute. Because of this, automatic coarrays are not allowed. For example, coarray TASK in the following code is not valid:

```fortran
SUBROUTINE SUBA(I,C,D)
INTEGER :: I
REAL :: C(I)[*], D(I)
REAL :: TASK(I)[*]    ! Not permitted
```

The following lines show valid examples of CODIMENSION attribute specifications:

```fortran
REAL, CODIMENSION[3,*] :: B(:)    ! Assumed-shape coarray
REAL R(50,50)[0:5,*]            ! Explicit-shape coarray
REAL, CODIMENSION[*] :: A       ! Scalar coarray
REAL, CODIMENSION[:,ALLOCATABLE :: C(:,:)] ! Allocatable coarray
```

**COLLAPSE Clause**

*Parallel Directive Clause:* Specifies how many loops are associated with a loop construct.

**Syntax**

COLLAPSE \((n)\)

\(n\)

Must be a constant positive scalar integer expression.

If \(n\) is greater than one, the iterations of all associated loops are collapsed into one larger iteration, which is then divided according to the SCHEDULE clause. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration. The associated loops must be perfectly nested, that is, there must be no intervening code or any OpenMP* directive between any two loops.
The iteration count for each associated loop is computed before entry
to the outermost loop. If execution of any associated loop changes
any of the values used to compute any of the iteration counts, then
the behavior is unspecified. The integer kind used to compute the
iteration count for the collapsed loop is implementation defined.

If COLLAPSE is not specified, the only loop that is associated with the loop construct is the one that
immediately follows the construct.

At most one COLLAPSE clause can appear in a directive that allows the clause.

See Nested DO Constructs for restrictions on perfectly nested loops using COLLAPSE.

If more than one loop is associated with a TASKLOOP construct, then the iterations of all associated loops are
collapsed into one larger iteration space that is then divided according to the specifications in the GRAINSIZE
and NUM_TASKS clauses. The sequential execution of the iterations in all associated loops determines the
order of the iterations in the collapsed iteration space.

**COMMAND_ARGUMENT_COUNT**

*Inquiry Intrinsic Function (Generic):* Returns the
number of command arguments.

**Syntax**

\[
\text{result} = \text{COMMAND\_ARGUMENT\_COUNT}() \\
\]

**Results**

The result is a scalar of type default integer. The result value is equal to the number of command arguments
available. If there are no command arguments available, the result is 0. The command name does not count
as one of the command arguments.

**Example**

Consider the following:

```fortran
program echo_command_line
  integer i, cnt, len, status
  character c*30, b*100

  call get_command (b, len, status)
  if (status .ne. 0) then
    write (*,*) 'get_command failed with status = ', status
    stop
  end if
  write (*,*) 'command line = ', b (1:len)

  call get_command_argument (0, c, len, status)
  if (status .ne. 0) then
    write (*,*) 'Getting command name failed with status = ', status
    stop
  end if
  write (*,*) 'command name = ', c (1:len)

  cnt = command_argument_count()
  write (*,*) 'number of command arguments = ', cnt

  do i = 1, cnt
    call get_command_argument (i, c, len, status)
    if (status .ne. 0) then
```
If the above program is invoked with the command line "echo_command_line.exe -o 42 -a hello b", the following is displayed:

COMMITQQ
Run-Time Function: Forces the operating system to execute any pending write operations for the file associated with a specified unit to the file's physical device.

Module
USE IFCORE

Syntax
result = COMMITQQ (unit)

(unit) INTEGER(4). A Fortran logical unit attached to a file to be flushed from cache memory to a physical device.

Results
The result type is LOGICAL(4). If an open unit number is supplied, .TRUE. is returned and uncommitted records (if any) are written. If an unopened unit number is supplied, .FALSE. is returned.

Data written to files on physical devices is often initially written into operating-system buffers and then written to the device when the operating system is ready. Data in the buffer is automatically flushed to disk when the file is closed. However, if the program or the computer crashes before the data is transferred from buffers, the data can be lost. COMMITQQ tells the operating system to write any cached data intended for a file on a physical device to that device immediately. This is called flushing the file.
COMMITQQ is most useful when you want to be certain that no loss of data occurs at a critical point in your program; for example, after a long calculation has concluded and you have written the results to a file, or after the user has entered a group of data items, or if you are on a network with more than one program sharing the same file. Flushing a file to disk provides the benefits of closing and reopening the file without the delay.

Example

```
USE IFCORE
INTEGER unit / 10 /
INTEGER len
CHARACTER(80) stuff
OPEN(unit, FILE='COMMITQQ.TST', ACCESS='Sequential')
DO WHILE (.TRUE.)
   WRITE (*, '(A, \)') 'Enter some data (Hit RETURN to &
   exit): '
   len = GETSTRQQ (stuff)
   IF (len .EQ. 0) EXIT
   WRITE (unit, *) stuff
   IF (.NOT. COMMITQQ(unit)) WRITE (*,*) 'Failed'
END DO
CLOSE (unit)
END
```

PRINT
WRITE

COMMON

**Statement:** Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items. COMMON is an obsolescent language feature in Standard Fortran.

**Syntax**

```
COMMON [ /cname]/ [var-list[,] /cname]/ var-list]...
```

cname  
(Optional) Is the name of the common block. The name can be omitted for blank common (//).

var-list  
Is a list of variable names, separated by commas.

The variable must not be a dummy argument, allocatable array, automatic object, function, function result, a variable with the BIND attribute, or entry to a procedure. It must not have the PARAMETER attribute. If an object of derived type is specified, it must be a sequence type or a type with the BIND attribute.

**Description**

Common blocks can be named or unnamed (a blank common).
A common block is a global entity, and must not have the same name as any other global entity in the
program, such as a subroutine or function.

Any common block name (or blank common) can appear more than once in one or more COMMON
statements in a program unit. The list following each successive appearance of the same common block
name is treated as a continuation of the list for the block associated with that name. Consider the following
COMMON statements:

```plaintext
COMMON /glenn/ lovell, armstrong, aldrin
COMMON /     / shepard, grissom, carpenter
COMMON /glenn/ borman, anders
COMMON /young/ mcdivitt, white, conrad
COMMON schirra, cooper
```

They are equivalent to these COMMON statements:

```plaintext
COMMON /glenn/ lovell, armstrong, aldrin, borman, anders
COMMON         shepard, grissom, carpenter, schirra, cooper
COMMON /young/ mcdivitt, white, conrad
```

A variable can appear in only one common block within a scoping unit.

A common block object must **not** be one of the following:

- A dummy argument
- A result variable
- An allocatable variable
- A derived-type object with an ultimate component that is allocatable
- A procedure pointer
- An automatic object
- A variable with the BIND attribute
- An unlimited polymorphic pointer
- A coarray

If an array is specified, it can be followed by an explicit-shape array specification, each bound of which must
be a constant specification expression. Such an array must not have the POINTER attribute.

A pointer can only be associated with pointers of the same type and kind parameters, and rank.

An object with the TARGET attribute can only be associated with another object with the TARGET attribute
and the same type and kind parameters.

A nonpointer can only be associated with another nonpointer, but association depends on their types, as
follows:

<table>
<thead>
<tr>
<th>Type of Variable</th>
<th>Type of Associated Variable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric (^1) or numeric sequence (^2)</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence (^2)</td>
<td>Can be of either of these types</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

\(^1\)Default integer, default real, double precision real, default complex, **double complex**, or default logical.

\(^2\)If an object of numeric sequence or character sequence type appears in a common block, it is as if the
individual components were enumerated directly in the common list.
So, variables can be associated if they are of different numeric type. For example, the following is valid:

```
INTEGER A(20)
REAL Y(20)
COMMON /QUANTA/ A, Y
```

When common blocks from different program units have the same name, they share the same storage area when the units are combined into an executable program.

Entities are assigned storage in common blocks on a one-for-one basis. So, the data type of entities assigned by a COMMON statement in one program unit should agree with the data type of entities placed in a common block by another program unit. For example:

<table>
<thead>
<tr>
<th>Program Unit A</th>
<th>Program Unit B</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON CENTS</td>
<td>INTEGER(2) MONEY</td>
</tr>
<tr>
<td>...</td>
<td>COMMON MONEY</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

When these program units are combined into an executable program, incorrect results can occur if the 2-byte integer variable MONEY is made to correspond to the lower-addressed two bytes of the real variable CENTS.

Named common blocks must be declared to have the same size in each program unit. Blank common can have different lengths in different program units.

**NOTE**
If a common block is initialized by a DATA statement, the module containing the initialization must declare the common block to be its maximum defined length.

This limitation does not apply if you compile all source modules together.

**Example**

```
PROGRAM MyProg
COMMON i, j, x, k(10)
COMMON /mycom/ a(3)
...
END
SUBROUTINE MySub
COMMON pe, mn, z, idum(10)
COMMON /mycom/ a(3)
...
END
```

In the following example, the COMMON statement in the main program puts HEAT and X in blank common, and KILO and Q in a named common block, BLK1:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMON HEAT,X /BLK1/KILO,Q</td>
<td>SUBROUTINE FIGURE</td>
</tr>
<tr>
<td>...</td>
<td>COMMON /BLK1/LIMA,R /ALFA,BET</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
</tbody>
</table>

CALL FIGURE
The COMMON statement in the subroutine makes ALFA and BET share the same storage location as HEAT and X in blank common. It makes LIMA and R share the same storage location as KILO and Q in BLK1.

The following example shows how a COMMON statement can be used to declare arrays:

```fortran
COMMON / MIXED / SPOTTED(100), STRIPED(50,50)
```

The following example shows a valid association between subroutines in different program units. The object lists agree in number, type, and kind of data objects:

```fortran
SUBROUTINE unit1
  REAL(8)  x(5)
  INTEGER  j
  CHARACTER  str*12
  TYPE(member)  club(50)
  COMMON / blocka / x, j, str, club
...
SUBROUTINE unit2
  REAL(8)  z(5)
  INTEGER  m
  CHARACTER  chr*12
  TYPE(member)  myclub(50)
  COMMON / blocka / z, m, chr, myclub
...
```

See also the example for BLOCK DATA.

**COMPILER_OPTIONS**

**Module Intrinsic Inquiry Function:** Returns a string containing the compiler options that were used for compilation.

**Module**

USE ISO_FORTRAN_ENV

**Syntax**

```fortran
result = COMPILER_OPTIONS( )
```

**Results**

The result is a scalar of type default character of processor-defined length.
The return value is a list of the compiler options that were used for compilation.

**Example**

Consider the following file named *t.f90*:

```fortran
use ISO_FORTRAN_ENV
character (len = :), allocatable :: res
res = compiler_options ()
print *, "len of res is: ", len (res)
print *, "('<', A, '>'") res
deallocate (res)
end
```

The following is the output:

On Windows:

```
Win>ifort /exe:t /warn:alignments /assume:writeable-strings t.f90
Intel(R) Visual Fortran Compiler for applications running on architecture,
Version version Built date-and-time by user on platform in directory
Copyright (C) 1985-2016 Intel Corporation.  All rights reserved.
Microsoft (R) Incremental Linker Version version
Copyright (C) Microsoft Corporation. All rights reserved.
-out:t.exe
-subsystem:console
t.obj
Win> t.exe
len of compiler_options is: 48
"('<', A, '>'")
```

On Linux:

```
Lin$ ifort -o t.out -warn alignments -assume writeable-strings t.f90
Lin$ ./t.out
len of res is: 51
"('<', A, '>'")
```

**See Also**

COMPILER_VERSION
ISO_FORTRAN_ENV Module

**COMPILER_VERSION**

*Module Intrinsic Inquiry Function*: Returns a string containing the name and version number of the compiler used for compilation.
**Results**

The result is a scalar of type default character of processor-defined length.

The return value contains the name and version number of the compiler used for compilation.

**Example**

Consider the following file named `t.f90`:

```fortran
use ISO_FORTRAN_ENV

character (len = :), allocatable :: res

res = compiler_version()
print *, "len of res is: ", len (res)
print *, "('<<', A, '>>')", res

deallocate (res)
close (1)
end
```

The following is the output:

**On Windows, with generic labels like `user` so the length displayed is not accurate:**

```
Win> ifort /exe:t /warn:alignments /assume:writeable-strings t.f90
Intel(R) Visual Fortran Compiler for applications running on architecture,
Version version Built date-and-time by user on platform in directory
Copyright (C) 1985-2016 Intel Corporation. All rights reserved.

Microsoft (R) Incremental Linker Version version
Copyright (C) Microsoft Corporation. All rights reserved.

-out:t.exe
-subsystem:console
t.obj

Win> t.exe
len of res is: 184

<<Intel(R) Visual Fortran Compiler for applications running on architecture,
Version version Built date-and-time by user on platform in directory>>

Win>
```

**On Linux, with generic labels like `user` so the length displayed is not accurate:**

```
Lin$ ifort -o t.out -warn alignments -assume writeable-strings t.f90
Lin$ ./t.out
len of res is: 202

<<Intel(R) Fortran Intel(R) architecture Compiler for applications running
on Intel(R) architecture, Version version
Built date-and-time by user on platform in directory>>

Lin$
```

**See Also**

[COMPILER_OPTIONS](#)

[ISO_FORTRAN_ENV Module](#)
**COMPLEX Statement**

**Statement:** Specifies the COMPLEX data type.

**Syntax**

```fortran
COMPLEX
COMPLEX([KIND=] n)
COMPLEX*s
DOUBLE COMPLEX
```

- `n` is kind 4, 8, or 16.
- `s` is 8, 16, or 32. COMPLEX(4) is specified as COMPLEX*8; COMPLEX(8) is specified as COMPLEX*16; COMPLEX(16) is specified as COMPLEX*32.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is specified, the kind of both parts is default real, and the constant is of type default complex.

**Example**

```fortran
COMPLEX ch
COMPLEX (KIND=4),PRIVATE :: zz, yy !equivalent to COMPLEX*8 zz, yy
COMPLEX(8) ax, by !equivalent to COMPLEX*16 ax, by
COMPLEX(kind(4)) y(10)
complex(kind=8) x, z(10)
```

**See Also**

DOUBLE COMPLEX
Complex Data Type
COMPLEX(4) Constants
COMPLEX(8) or DOUBLE COMPLEX Constants
Data Types, Constants, and Variables

**COMPLINT, COMPREAL, COMPLLOG**

**Portability Functions:** Return a BIT-WISE complement or logical NOT. of the argument.

**Module**

USE IFPORT

**Syntax**

```fortran
result = COMPLINT (intval)
result = COMPREAL (realval)
result = COMPLLOG (logval)
```

- `intval` (Input) INTEGER(4).
- `realval` (Input) REAL(4).
logval

(Input) LOGICAL(4).

Results

The result is INTEGER(4) for COMPLINT, REAL(4) for COMPLREAL and LOGICAL(4) for COMPLLOG with a value that is the bitwise complement of the argument.

CONJG

*Elemental Intrinsic Function (Generic)*: Calculates the conjugate of a complex number.

Syntax

result = CONJG (z)

z

(Input) Must be of type complex.

Results

The result type and kind are the same as z. If z has the value (x, y), the result has the value (x, -y).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONJG</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>DCONJG</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>QCONJG</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

Example

CONJG ((2.0, 3.0)) has the value (2.0, -3.0).

CONJG ((1.0, -4.2)) has the value (1.0, 4.2).

The following shows another example:

```fortran
COMPLEX z1
COMPLEX(8) z2
z1 = CONJG((3.0, 5.6)) ! returns (3.0, -5.6)
z2 = DCONJG((3.0D0, 5.6D0)) ! returns (3.0D0, -5.6D0)
```

See Also

AIMAG

CONTAINS

*Statement*: Separates the body of a main program, module, submodule, or external subprogram from any internal or module procedures it may contain, or it introduces the type-bound procedure part of a derived-type definition. It is not executable.

Syntax

CONTAINS

Any number of internal procedures can follow a CONTAINS statement, but a CONTAINS statement cannot appear in the internal procedures themselves.

An empty CONTAINS section is allowed.
Example

```fortran
PROGRAM OUTER
    REAL, DIMENSION(10) :: A
    ...
    CALL INNER (A)
CONTAINS
    SUBROUTINE INNER (B)
    REAL, DIMENSION(10) :: B
    ...
    END SUBROUTINE INNER
END PROGRAM OUTER
```

See Also
Internal Procedures
Modules and Module Procedures
Main Program

CONTIGUOUS

**Statement and Attribute:** Specifies that the target of a pointer or an assumed-sized array is contiguous.

**Syntax**

The CONTIGUOUS attribute can be specified in a type declaration statement or an CONTIGUOUS statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls], CONTIGUOUS [, att-ls] :: object [, object] ...
```

**Statement:**

```
CONTIGUOUS [:] object [, object] ...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `object` Is an assumed-shape array or an array pointer.

**Description**

This attribute explicitly indicates that an assumed-shape array is contiguous or that a pointer will only be associated with a contiguous object.

An entity can be contiguous even if CONTIGUOUS is not specified. An object is contiguous if it is one of the following:

- An object with the CONTIGUOUS attribute
- A nonpointer whole array that is not assumed-shape
- An assumed-shape array that is argument associated with an array that is contiguous
- An array allocated by an ALLOCATE statement
- An pointer associated with a contiguous target
- A nonzero-sized array section in which the following is true:
  - Its base object is contiguous.
  - It does not have a vector subscript.
  - The elements of the section, in array element order, are a subset of the base object elements that are consecutive in array element order.
• If the array is of type character and a substring-range appears, the substring-range specifies all of the characters of the parent-string.
• Only its final reference to a structure component, if any, has nonzero rank
• It is not the real or imaginary part of an array of type complex.

An object is not contiguous if it is an array subobject, and all of the following are true:
• The object has two or more elements.
• The elements of the object in array element order are not consecutive in the elements of the base object.
• The object is not of type character with length zero.
• The object is not of a derived type that has no ultimate components other than zero-sized arrays and characters with length zero.

The CONTIGUOUS attribute can make it easier to enable optimizations that rely on the memory layout of an object occupying a contiguous block of memory.

**Examples**
The following examples show valid CONTIGUOUS statements:

```plaintext
REAL, CONTIGUOUS, DIMENSION(:, :) :: A
REAL, POINTER, CONTIGUOUS :: MY_POINTER(:)
```

**See Also**
Type Declarations
Compatible attributes

**CONTINUE**

**Statement:** Primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement.

**Syntax**

`CONTINUE`

The statement by itself does nothing and has no effect on program results or execution sequence.

**Example**
The following example shows a CONTINUE statement:

```plaintext
DO 150 I = 1, 40
  40 Y = Y + 1
    Z = COS(Y)
    PRINT *, Z
    IF (Y .LT. 30) GO TO 150
    GO TO 40
150 CONTINUE
```

The following shows another example:

```plaintext
DIMENSION narray(10)
DO 100 n = 1, 10
  narray(n) = 120
100 CONTINUE
```

**See Also**
END DO
DO
Execution Control

**COPYIN Clause**

*Parallel Directive Clause:* Specifies that the data in the primary thread of the team is to be copied to the thread private copies of the common block at the beginning of the parallel region.

**Syntax**

COPYIN (list)

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

The COPYIN clause applies only to common blocks declared as THREADPRIVATE.

You do not need to specify the whole THREADPRIVATE common block, you can specify named variables within the common block.

**COPYPRIVATE Clause**

*Parallel Directive Clause:* Uses a private variable to broadcast a value, or a pointer to a shared object, from one member of a team to the other members. The COPYPRIVATE clause can only appear in the END SINGLE directive.

**Syntax**

COPYPRIVATE (list)

*list* is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables in the list must not appear in a PRIVATE or FIRSTPRIVATE clause for the SINGLE directive construct. A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a COPYPRIVATE clause.

If the directive is encountered in the dynamic extent of a parallel region, variables in the list must be private in the enclosing context.

If a common block is specified, it must be declared as THREADPRIVATE; the effect is the same as if the variable names in its common block object list were specified.

The effect of the COPYPRIVATE clause on the variables in its list occurs after the execution of the code enclosed within the SINGLE construct, and before any threads in the team have left the barrier at the end of the construct.

**COS**

*Elemental Intrinsic Function (Generic):* Produces the cosine of an argument.

**Syntax**

result = COS (x)
\( x \)  
(Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.

**Results**

The result type and kind are the same as \( x \).

If \( x \) is of type real, the result is a value in radians.

If \( x \) is of type complex, the real part of the result is a value in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COS</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DCOS</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOS</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
<tr>
<td>CCOS (^1)</td>
<td>COMPLEX(4)</td>
<td>COMPLEX(4)</td>
</tr>
<tr>
<td>CDCOS (^2)</td>
<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQCOS</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect CCOS.

\(^2\)This function can also be specified as ZCOS.

**Example**

COS (2.0) has the value -0.4161468.

COS (0.567745) has the value 0.8431157.

**COSD**

*Elemental Intrinsic Function (Generic):* Produces the cosine of \( x \).

**Syntax**

\[
\text{result} = \text{COSD} \ (x)
\]

\( x \)  
(Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind are the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COSD</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DCOSD</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOSD</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COSD (2.0) has the value 0.9993908.
COSD (30.4) has the value 0.8625137.

**COSH**

*Elemental Intrinsic Function (Generic): Produces a hyperbolic cosine.*

**Syntax**

\[
\text{result} = \text{COSH}(x)
\]

\(x\) (Input) Must be of type real or complex.

**Results**

The result type and kind are the same as \(x\).

If \(x\) is of type complex, the imaginary part of the result is in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COSH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DCOSH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOSH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COSH (2.0) has the value 3.762196.

COSH (0.65893) has the value 1.225064.

**COSHAPE**

*Inquiry Intrinsic Function (Generic): Returns the sizes of codimensions of a coarray.*

**Syntax**

\[
\text{result} = \text{COSHAPE}(\text{coarray}, [, \text{kind}])
\]

\(\text{coarray}\) (Input) Is a coarray. It may be of any data type. It must not be an unallocated allocatable coarray.

\(\text{kind}\) (Input; optional) Must be a scalar integer constant expression.

**Results**

The result is an integer array of rank one whose size is equal to the corank of \(\text{coarray}\). If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is that of default integer.

The result has a value whose \(i\)th element is equal to the size of the \(i\)th codimension of \(\text{coarray}\) as provided by UCOBOUND(\(\text{coarray}, i\)) – LCOBOUND(\(\text{coarray}, i\)) + 1.

The setting of compiler options specifying integer size can affect this function.

**Example**

Consider the following coarray declaration:

\[
\text{REAL :: X (10, 20) [10, -1:8, 0:*]}
\]
It NUM_IMAGES() is 200, it has these properties:

- \( \text{RANK (X)} == 2 \)
- \( \text{corank of X} == 3 \)
- \( \text{SHAPE (X)} == [10,20] \)
- \( \text{COSHAPE (X)} == [10,10,2] \)
- \( \text{LCOBOUND (X)} == [1, -1, 0] \)
- \( \text{UCOBOUND (X)} == [10, 8, 1] \)

## COTAN

**Elemental Intrinsic Function (Generic):** Produces the cotangent of \( x \).

**Syntax**

```fortran
result = COTAN (x)
```

- \( x \) (Input) Must be of type real; it cannot be zero. It must be in radians and is treated as modulo 2*\( \pi \).

**Results**

The result type and kind are the same as \( x \).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COTAN</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DCOTAN</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QCOTAN</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

COTAN (2.0) has the value -4.576575E-01.

COTAN (0.6) has the value 1.461696.

---

## COTAND

**Elemental Intrinsic Function (Generic):** Produces the cotangent of \( x \).

**Syntax**

```fortran
result = COTAND (x)
```

- \( x \) (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind are the same as \( x \).
### Specific Name | Argument Type | Result Type
---|---|---
COTAND | REAL(4) | REAL(4)
DCOTAND | REAL(8) | REAL(8)
QCOTAND | REAL(16) | REAL(16)

**Example**

COTAND (2.0) has the value 0.2863625E+02.
COTAND (0.6) has the value 0.9548947E+02.

---

**COUNT**

*Transformational Intrinsic Function (Generic):*

Counts the number of true elements in an entire array or in a specified dimension of an array.

**Syntax**

```plaintext
result = COUNT (mask[, dim][, kind])
```

- **mask** *(Input)* Must be a logical array.
- **dim** *(Input; optional)* Must be a scalar integer expression with a value in the range 1 to n, where n is the rank of mask.
- **kind** *(Input; optional)* Must be a scalar integer constant expression.

**Results**

The result is an array or a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result is a scalar if dim is omitted or mask has rank one. A scalar result has a value equal to the number of true elements of mask. If mask has size zero, the result is zero.

An array result has a rank that is one less than mask, and shape (d1, d2, ..., d_dim-1, d_dim+1, ..., dn), where (d1, d2, ..., dn) is the shape of mask.

Each element in an array result equals the number of elements that are true in the one dimensional array defined by mask(s1, s2, ..., s_dim-1, :, s_dim+1, ..., sn).

**Example**

COUNT ((/.TRUE., .FALSE., .TRUE./)) has the value 2 because two elements are true.
COUNT ((/.TRUE., .TRUE., .TRUE./)) has the value 3 because three elements are true.

A is the array

```
[ 1 5 7 ]
[ 3 6 8 ]
```

and B is the array

```
[ 0 5 7 ]
[ 2 6 9 ]
```

COUNT (A .NE. B, DIM=1) tests to see how many elements in each column of A are not equal to the elements in the corresponding column of B. The result has the value (2, 0, 1) because:
• The first column of A and B have 2 elements that are not equal.
• The second column of A and B have 0 elements that are not equal.
• The third column of A and B have 1 element that is not equal.

COUNT (A .NE. B, DIM=2) tests to see how many elements in each row of A are not equal to the elements in the corresponding row of B. The result has the value (1, 2) because:

• The first row of A and B have 1 element that is not equal.
• The second row of A and B have 2 elements that are not equal.

The following shows another example:

LOGICAL mask (2, 3)
INTEGER AR1(3), AR2(2), I
mask = RESHAPE((/.TRUE., .TRUE., .FALSE., .TRUE., &
                .FALSE., .FALSE./),(/2,3/))
!
| mask is the array | true | false | false |
|                   | true | true  | false |
AR1 = COUNT(mask,DIM=1) ! counts true elements by
| column yielding   | 2 1 0 |
AR2 = COUNT(mask,DIM=2) ! counts true elements by row
| yielding          | [1 2] |
I = COUNT( mask)     ! returns 3

CPU_TIME

Intrinsic Subroutine (Generic): Returns a processor-dependent approximation of the processor time in seconds. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL CPU_TIME (time)

time (Output) Must be scalar and of type real.

The time returned is summed over all active threads. The result is the sum (in units of seconds) of the current process's user time and the user and system time of all its child processes, if any.

If a meaningful time cannot be returned, a processor-dependent negative value is returned.

NOTE
If you want to estimate performance or scaling of multithreaded applications, you should use intrinsic subroutine SYSTEM_CLOCK or portability function DCLOCK. Both of these routines return the elapsed time from a single clock.

Example

Consider the following:

REAL time_begin, time_end
...
CALL CPU_TIME ( time_begin )
!
! task to be timed
!
CALL CPU_TIME ( time_end )
WRITE (*,*) 'Time of operation was ', time_end - time_begin, ' seconds'

DCLOCK
SYSTEM_CLOCK

CRITICAL Directive

**OpenMP** Fortran Compiler Directive: Restricts access to a block of code to only one thread at a time.

Syntax

```fortran
)!$OMP CRITICAL [(name)]
  loosely-structured-block
)!$OMP END CRITICAL [(name)]
-or-
)!$OMP CRITICAL [(name)]
  strictly-structured-block
)!$OMP END CRITICAL [(name)]
```

- **name**
  Is the name of the critical section.
- **loosely-structured-block**
  Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
- **strictly-structured-block**
  Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for a CRITICAL construct is all threads in the contention group. Region execution is restricted to a single thread at a time among all threads in the contention group, without regard to the teams to which the threads belong.

A thread waits at the beginning of a critical section until no other thread in the team is executing a critical section having the same name. All unnamed CRITICAL directives map to the same name.

If a name is specified in the CRITICAL directive, the same name must appear in the corresponding END CRITICAL directive. If no name appears in the CRITICAL directive, no name can appear in the corresponding END CRITICAL directive.

Critical section names are global entities of the program. If the name specified conflicts with any other entity, the behavior of the program is undefined.

Example

The following example shows a queuing model in which a task is dequeued and worked on. To guard against multiple threads dequeuing the same task, the dequeuing operation is placed in a critical section.
Because there are two independent queues in this example, each queue is protected by CRITICAL directives having different names, XAXIS and YAXIS, respectively:

```fortran
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,Y)
!$OMP CRITICAL(XAXIS)
   CALL DEQUEUE(IX_NEXT, X)
!$OMP END CRITICAL(XAXIS)
!$OMP CRITICAL(YAXIS)
   CALL DEQUEUE(IY_NEXT, Y)
!$OMP END CRITICAL(YAXIS)
END PARALLEL
```

**See Also**

- OpenMP Fortran Compiler Directives
- Syntax Rules for Compiler Directives
- Parallel Processing Model for information about Binding Sets

**CRITICAL Statement**

**Statement:** Marks the beginning of a CRITICAL construct. A CRITICAL construct limits execution of a block to one image at a time.

**Syntax**

```fortran
[name:] CRITICAL ([([STAT=stat-var] [, ERRMSG=err-var])]
   block
END CRITICAL [name]
```

- `name` (Optional) Is the name of the CRITICAL construct.
- `stat-var` Is a scalar integer variable with an exponent range of at least 4 (KIND=2 or greater).
- `err-var` Is a scalar default character variable.
- `block` Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified in a CRITICAL statement, the same name must appear in the corresponding END CRITICAL statement. If no name is specified at the beginning of a CRITICAL statement, you cannot specify one following the END CRITICAL statement. The same construct name must not be used for different named constructs in the same scoping unit.

The block of a CRITICAL construct must not contain a RETURN statement or an image control statement.

A branch within a CRITICAL construct must not have a branch target that is outside the construct. A branch to the END CRITICAL statement is permitted from within the construct.

STAT= and ERRMSG= specifiers can appear in any order. Each may appear at most once.

Execution of the CRITICAL construct is completed when execution of its block is completed. A procedure that is invoked, directly or indirectly, from a CRITICAL construct must not execute an image control statement.
If no error condition occurs during the execution of the construct, stat-var becomes defined with the value zero. If the image that previously entered the construct failed while executing the construct, stat-var becomes defined with the value STAT_FAILED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV. If any other error occurs and STAT= is specified, stat-var becomes defined with a positive integer value other than that of STAT_FAILED_IMAGE. Otherwise, if an error occurs, error termination is initiated.

If ERRMSG= is specified and an error condition occurs during execution of the construct, err-var becomes defined with a descriptive message describing the nature of the error.

The processor ensures that once an image has commenced executing block, no other image can start executing block until this image has completed executing block. The image must not execute an image control statement during the execution of block. The sequence of executed statements is therefore a segment. If image S is the next to execute the construct after image N, the segment on image N precedes the segment on image S.

If more than one image executes the block of a CRITICAL construct, its execution by one image always precedes or succeeds its execution by another image. Normally no other statement ordering is needed.

**Example**

Consider the following example:

```fortran
CONA: CRITICAL
END CRITICAL CONA
```

The definition of MY_COUNTER [1] by a particular image will always precede the reference to the same variable by the next image to execute the block.

The following example shows a way to share a large number of tasks among images:

```fortran
INTEGER :: NUMBER_TASKS[*], TASK
IF (THIS_IMAGE() == 1) READ(*,*) NUMBER_TASKS
SYNC ALL
DO
    CRITICAL
        TASK = NUMBER_TASKS[1]
        NUMBER_TASKS[1] = TASK - 1
    END CRITICAL
    IF (TASK > 0) THEN
    ELSE
        EXIT
    END IF
END DO
SYNC ALL
```

**CSHIFT**

*Transformational Intrinsic Function (Generic):*
Performs a circular shift on a rank-one array, or performs circular shifts on all the complete rank-one sections (vectors) along a given dimension of an array of rank two or greater.
**Syntax**

Elements shifted off one end are inserted at the other end. Different sections can be shifted by different amounts and in different directions.

\[
\text{result} = \text{CSHIFT} \left( \text{array}, \text{shift} [,\text{dim}] \right)
\]

- **array** (Input) Array whose elements are to be shifted. It can be of any data type.
- **shift** (Input) The number of positions shifted. Must be a scalar integer or an array with a rank that is one less than `array`, and shape \((d_1, d_2, ..., d_{\text{dim} -1}, d_{\text{dim} +1}, ..., d_n)\), where \((d_1, d_2, ..., d_n)\) is the shape of `array`.
- **dim** (Input; optional) Optional dimension along which to perform the shift. Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of `array`. If `dim` is omitted, it is assumed to be 1.

**Results**

The result is an array with the same type and kind parameters, and shape as `array`.

If `array` has rank one, element \(i\) of the result is 
\[
\text{array}(1 + \text{MODULO} \left( i + \text{shift} - 1, \text{SIZE} \left( \text{array} \right) \right))
\]
(The same shift is applied to each element.)

If `array` has rank greater than one, each section \((s_1, s_2, ..., s_{\text{dim} -1}, :, s_{\text{dim} +1}, ..., s_n)\) of the result is shifted as follows:
- By the value of `shift`, if `shift` is scalar
- According to the corresponding value in `shift(s_1, s_2, ..., s_{\text{dim} -1}, s_{\text{dim} +1}, ..., s_n)`, if `shift` is an array

The value of `shift` determines the amount and direction of the circular shift. A positive `shift` value causes a shift to the left (in rows) or up (in columns). A negative `shift` value causes a shift to the right (in rows) or down (in columns). A zero `shift` value causes no shift.

**Example**

\(V\) is the array \((1, 2, 3, 4, 5, 6)\).

\[
\text{CSHIFT} \left( V, \text{SHIFT}=2 \right)
\]
shifts the elements in \(V\) circularly to the left by 2 positions, producing the value \((3, 4, 5, 6, 1, 2)\). 1 and 2 are shifted off the beginning and inserted at the end.

\[
\text{CSHIFT} \left( V, \text{SHIFT}=-2 \right)
\]
shifts the elements in \(V\) circularly to the right by 2 positions, producing the value \((5, 6, 1, 2, 3, 4)\). 5 and 6 are shifted off the end and inserted at the beginning.

\(M\) is the array
\[
\begin{bmatrix}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9 \\
\end{bmatrix}
\]

\[
\text{CSHIFT} \left( M, \text{SHIFT} = 1, \text{DIM} = 2 \right)
\]
produces the result
\[
\begin{bmatrix}
2 & 3 & 1 \\
5 & 6 & 4 \\
8 & 9 & 7 \\
\end{bmatrix}
\]

Each element in rows 1, 2, and 3 is shifted to the left by 1 position. The elements shifted off the beginning are inserted at the end.

\[
\text{CSHIFT} \left( M, \text{SHIFT} = -1, \text{DIM} = 1 \right)
\]
produces the result
\[
\begin{bmatrix}
7 & 8 & 9 \\
1 & 2 & 3 \\
4 & 5 & 6 \\
\end{bmatrix}
\]
Each element in columns 1, 2, and 3 is shifted down by 1 position. The elements shifted off the end are inserted at the beginning.

\[
\begin{bmatrix}
2 & 3 & 1 \\
6 & 4 & 5 \\
7 & 8 & 9
\end{bmatrix}
\]

Each element in row 1 is shifted to the left by 1 position; each element in row 2 is shifted to the right by 1 position; no element in row 3 is shifted at all.

The following shows another example:

```
INTEGER array (3, 3), AR1 (3, 3), AR2 (3, 3)
DATA array /1, 4, 7, 2, 5, 8, 3, 6, 9/

! array is
! [ 1 2 3]
! [ 4 5 6]
! [ 7 8 9]
!
!AR1 = CSHIFT(array, 1, DIM = 1) ! shifts all columns
! by 1 yielding
! [ 4 5 6]
! [ 7 8 9]
! [ 1 2 3]
!

AR2=CSHIFT(array,shift=((-1, 1, 0),DIM=2) ! shifts
! each row separately
! by the amount in
! shift yielding
! [ 3 1 2]
! [ 5 6 4]
! [ 7 8 9]
```

CSMG

**Portability Function:** Performs an effective **BIT-WISE** store under mask.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{CSMG} (x, y, z)
\]

\[
x, y, z \quad \text{(Input) INTEGER(4).}
\]

**Results**

The result type is INTEGER(4). The result is equal to the following expression:

\[
(x \& z) | (y \& \sim z)
\]

where "&" is a bitwise AND operation, | - bitwise OR, \~ - bitwise NOT.
The function returns the value based on the following rule: when a bit in \( z \) is 1, the output bit is taken from \( x \). When a bit in \( z \) is zero, the corresponding output bit is taken from \( y \).

**CTIME**

*Portability Function: Converts a system time into a 24-character ASCII string.*

**Module**

USE IFPORT

**Syntax**

\[ \text{result} = \text{CTIME}(\text{stime}) \]

\( \text{stime} \) (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.

**Results**

The result is a value in the form Mon Jan 31 04:37:23 1994. Hours are expressed using a 24-hour clock.

The value of \( \text{stime} \) can be determined by calling the TIME function. CTIME(TIME( )) returns the current time and date.

**Example**

USE IFPORT

character (24) systime

systime = CTIME (TIME( ))

print *, 'Current date and time is ', systime

**See Also**

DATE_AND_TIME

**CYCLE**

*Statement: Interrupts the current execution cycle of the innermost (or named) DO construct.*

**Syntax**

\[ \text{CYCLE } [\text{name}] \]

\( \text{name} \) (Optional) Is the name of the DO construct.

**Description**

When a CYCLE statement is executed, the following occurs:

1. The current execution cycle of the named (or innermost) DO construct is terminated.
   
   If a DO construct name is specified, the CYCLE statement must be within the range of that construct.
2. The iteration count (if any) is decremented by 1.
3. The DO variable (if any) is incremented by the value of the increment parameter (if any).

Any executable statements following the CYCLE statement (including a labeled terminal statement) are not executed.

A CYCLE statement can be labeled, but it cannot be used to terminate a DO construct.
Execution of a CYCLE statement that belongs to a DO CONCURRENT construct completes execution of that iteration of the construct.

Example

The following example shows a CYCLE statement:

```fortran
DO I = 1, 10
    A(I) = C + D(I)
    IF (D(I) < 0) CYCLE ! If true, the next statement is omitted
    A(I) = 0 ! from the loop and the loop is tested again.
END DO
```

The following shows another example:

```fortran
sample_loop: do i = 1, 5
    print *, i
    if( i .gt. 3 ) cycle sample_loop
    print *, i
    end do sample_loop
    print *, 'done!' !output:
!     1
!     1
!     2
!     2
!     3
!     3
!     4
!     5
!     done!
```

DO
DO WHILE
Execution Control

DATA

Statement: Assigns initial values to variables before program execution.

Syntax

```
DATA var-list /clist/ [[,] var-list /clist/]...
```

`var-list`

Is a list of variables or implied-DO lists, separated by commas. `var` cannot be a coarray, a dummy argument, accessed by use or host association, a function name, a function result name, an automatic variable, or a allocatable variable.

Subscript expressions, section expressions, and substring expressions must be constant expressions.

An implied-DO list in a DATA statement takes the following form:

```
( do-list, [integer-type-spec ::] do-var = expr1, expr2[, expr3])
```
**do-list**

Is a list of one or more array elements, substrings, scalar structure components, or implied-DO lists, separated by commas. Any array elements or scalar structure components must not have a constant parent.

**integer-type-spec**

Is INTEGER [kind-selector].

**kind-selector**

Is ( [KIND=] n ).

**n**

Is a constant expression whose value is 1, 2, 4, or 8.

**do-var**

Is the name of a scalar integer variable (the implied-DO variable). It cannot be a coarray.

**expr**

Implied-DO limits must be scalar constant expressions. They may contain implied-DO variables from outer nested implied-DO lists. For more details, see Iteration Loop Control.

**clist**

Is a list of scalar integer constant expressions (or names of constants), constant structure constructors, or, for pointer objects, NULL (), separated by commas. If the constant is a binary, octal, or hexadecimal literal, the corresponding var must be of type INTEGER.

A constant can be specified in the form r*constant, where r is a repeat specification. r is a nonnegative scalar integer constant (with no kind parameter). If r is a named constant, it must have been declared previously in the scoping unit or made accessible through use or host association. If r is omitted, it is assumed to be 1.

**Description**

A variable can be initialized only once in an executable program. A variable that appears in a DATA statement and is typed implicitly can appear in a subsequent type declaration which may change the implicit typing.

The number of constants in c-list must equal the number of variables in var-list. The constants are assigned to the variables in the order in which they appear (from left to right).

The following objects cannot be initialized in a DATA statement:

- A dummy argument
- A function
- A function result
- An automatic object
- An allocatable array
- A variable that is accessible by use or host association
- A variable in a named common block (unless the DATA statement is in a block data program unit)
- A variable in blank common

Except for variables in named COMMON blocks, a named variable has the SAVE attribute if any part of it is initialized in a DATA statement. You can confirm this property by specifying the variable in a SAVE statement or a type declaration statement containing the SAVE attribute.

When an unsubscripted array name appears in a DATA statement, values are assigned to every element of that array in the order of subscript progression. If the associated constant list does not contain enough values to fill the array, a warning is issued and the remaining array elements become undefined.

Array element values can be initialized in three ways: by name, by element, or by an implied-DO list (interpreted in the same way as a DO construct).

The following conversion rules and restrictions apply to variable and constant list items:
• If the constant and the variable are both of numeric type, the following conversion occurs:
  • The constant value is converted to the data type of the variable being initialized, if necessary.
  • When a binary, octal, or hexadecimal constant is assigned to a variable or array element, the number
    of digits that can be assigned depends on the data type of the data item. If the constant contains
    fewer digits than the capacity of the variable or array element, the constant is extended on the left
    with zeros. If the constant contains more digits than can be stored, the constant is truncated on the
    left. An error results if any nonzero digits are truncated.
• If the constant and the variable are both of character type, the following conversion occurs:
  • If the length of the constant is less than the length of the variable, the rightmost character positions
    of the variable are initialized with blank characters.
  • If the length of the constant is greater than the length of the variable, the character constant is
    truncated on the right.
• If the constant is of numeric type and the variable is of character type, the following restrictions apply:
  • The character variable must have a length of one character.
  • The constant must be an integer, binary, octal, or hexadecimal constant, and must have a value in the
    range 0 through 255.

When the constant and variable conform to these restrictions, the variable is initialized with the character
that has the ASCII code specified by the constant. (This lets you initialize a character object to any 8-bit
ASCII code.)

• If the constant is a Hollerith or character constant, and the variable is a numeric variable or numeric array
  element, the number of characters that can be assigned depends on the data type of the data item.

  If the Hollerith or character constant contains fewer characters than the capacity of the variable or array
  element, the constant is extended on the right with blank characters. If the constant contains more
  characters than can be stored, the constant is truncated on the right.

Example

The following example shows the three ways that DATA statements can initialize array element values:

```fortran
DIMENSION A(10,10)
DATA A/100*1.0/    ! initialization by name
DATA A(1,1), A(10,1), A(3,3) /2*2.5, 2.0/ ! initialization by element
DATA ((A(I,J), I=1,5,2), J=1,5) /15*1.0/  ! initialization by implied-DO list
```

The following example shows DATA statements containing structure components:

```fortran
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE

TYPE(EMPLOYEE) MAN_NAME, CON_NAME
DATA MAN_NAME / EMPLOYEE(417, 'Henry Adams') /
DATA CON_NAME%ID, CON_NAME%NAME /891, "David James"/
```

In the following example, the first DATA statement assigns zero to all 10 elements of array A, and four
asterisks followed by two blanks to the character variable STARS:

```fortran
INTEGER A(10), B(10)
CHARACTER BELL, TAB, LF, FF, STARS*6
DATA A,STARS /10*0,'****'/
DATA BELL,TAB,LF,FF /7,9,10,12/
DATA (B(I), I=1,10,2) /5*1/
```

In this case, the second DATA statement assigns ASCII control character codes to the character variables
BELL, TAB, LF, and FF. The last DATA statement uses an implied-DO list to assign the value 1 to the odd-
numbered elements in the array B.
The following shows another example:

```fortran
INTEGER n, order, alpha, list(100)
REAL coef(4), eps(2),
pi(5), x(5,5)
CHARACTER*12 help
COMPLEX*8 cstuff
DATA n /0/, order /3/
DATA alpha /'A'/
DATA coef /1.0, 2*3.0, 1.0/, eps(1) /.00001/
DATA cstuff /(-1.0, -1.0)/
! The following example initializes diagonal and below in
! a 5x5 matrix:
DATA ((x(j,i), i=1,j), j=1,5) /15*1.0/
DATA pi /5*3.14159/
DATA list /100*0/
DATA help(1:4), help(5:8), help(9:12) /3*'HELP'/
```

Consider the following:

```fortran
CHARACTER (LEN = 10) NAME
INTEGER, DIMENSION (0:9) :: MILES
REAL, DIMENSION (100, 100) :: SKEW
TYPE (MEMBER) MYNAME, YOURS
DATA NAME /'JOHN DOE'/, miles /10*0/
DATA ((SKEW (k, j), j = 1, k), k = 1, 100) /5050*0.0/
DATA ((SKEW (k, j), j = k + 1, 100), k = 1, 99) /4950*1.0/
DATA MYNAME /MEMBER (21, 'JOHN SMITH')/
DATA YOURS % age, YOURS % name /35, 'FRED BROWN'/
```

In this example, the character variable NAME is initialized with the value JOHN DOE with two trailing blanks to fill out the declared length of the variable. The ten elements of MILES are initialized to zero. The two-dimensional array SKEW is initialized so that its lower triangle is zero and its upper triangle is one. The structures MYNAME and YOURS are declared using the derived type MEMBER. The derived-type variable MYNAME is initialized by a structure constructor. The derived-type variable YOURS is initialized by supplying a separate value for each component.

The first DATA statement in the previous example could also be written as:

```fortran
DATA name /'JOHN DOE'/
DATA miles /10*0/
```

A pointer can be initialized as disassociated by using a DATA statement. For example:

```fortran
INTEGER, POINTER :: P
DATA P/NULL( )/
END
```

The implied-DO limits can be any constant expressions in a DATA statement. For example:

```fortran
DATA (A(I), I=LBOUND(A), UBOUND(A)) /10*4.0/
```

**DATE Intrinsic Procedure**

*Intrinsic Subroutine (Generic):* Returns the current date as set within the system. DATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL DATE (buf)
```

*buf* (Output) Is a variable, array, or array element of any data type, or a character substring. It must contain at least nine bytes of storage.

The date is returned as a 9-byte ASCII character string taking the form `dd-mmm-yy`, where:

- `dd` is the 2-digit date
- `mmm` is the 3-letter month
- `yy` is the last two digits of the year

If *buf* is of numeric type and smaller than 9 bytes, data corruption can occur.

If *buf* is of character type, its associated length is passed to the subroutine. If *buf* is smaller than 9 bytes, the subroutine truncates the date to fit in the specified length. If an array of type character is passed, the subroutine stores the date in the first array element, using the element length, not the length of the entire array.

**Caution**

The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

**Example**

```fortran
CHARACTER*1 DAY(9)

... CALL DATE (DAY)
```

The length of the first array element in CHARACTER array DAY is passed to the DATE subroutine. The subroutine then truncates the date to fit into the 1-character element, producing an incorrect result.

**See Also**

DATE_AND_TIME

DATE portability routine

**DATE Portability Routine**

*Portability Function or Subroutine:* Returns the current system date. DATE can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.
Module
USE IFPORT

Syntax
Function Syntax:
result = DATE( )

Subroutine Syntax:
CALL DATE (dstring)

dstring (Output) CHARACTER. Is a variable or array containing at least nine bytes of storage.

DATE in its function form returns a CHARACTER string of length 8 in the form mm/dd/yy, where mm, dd, and yy are two-digit representations of the month, day, and year, respectively.

DATE in its subroutine form returns dstring in the form dd-mmm-yy, where dd is a two-digit representation of the current day of the month, mmm is a three-character abbreviation for the current month (for example, Jan) and yy are the last two digits of the current year.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example
USE IFPORT
!If today's date is March 02, 2000, the following
!code prints "02-Mar-00"
CHARACTER(9) TODAY
CALL DATE(TODAY)
PRINT *, TODAY
!The next line prints "03/02/00"
PRINT *, DATE( )

See Also
DATE_AND_TIME

DATE intrinsic procedure

DATE4
Portability Subroutine: Returns the current system date.

Module
USE IFPORT

Syntax
CALL DATE4 (datestr)

datestr (Output) CHARACTER. Is a variable or array containing at least eleven bytes of storage.
This subroutine returns \texttt{datestr} in the form \texttt{dd-mm-yyyy}, where \texttt{dd} is a two-digit representation of the current day of the month, \texttt{mmm} is a three-character abbreviation for the current month (for example, \texttt{Jan}) and \texttt{yyyy} are the four digits of the current year.

\textbf{DATE\_AND\_TIME}

\textit{Intrinsic Subroutine (Generic):} Returns character and binary data on the real-time clock and date. Intrinsic subroutines cannot be passed as actual arguments.

\textbf{Syntax}

\begin{verbatim}
CALL DATE_AND_TIME ([date, time, zone, values])
\end{verbatim}

\textit{date} (Output; optional) Must be scalar and of type default character; its length must be at least 8 to contain the complete value. Its leftmost 8 characters are set to a value of the form \texttt{CCYYMMDD}, where:

\begin{tabular}{|l|}
\hline
\textit{CC} & Is the century \\
\textit{YY} & Is the year within the century \\
\textit{MM} & Is the month within the year \\
\textit{DD} & Is the day within the month \\
\hline
\end{tabular}

\textit{time} (Output; optional) Must be scalar and of type default character; its length must be at least 10 to contain the complete value. Its leftmost 10 characters are set to a value of the form \texttt{hhmmss.sss}, where:

\begin{tabular}{|l|}
\hline
\textit{hh} & Is the hour of the day \\
\textit{mm} & Is the minutes of the hour \\
\textit{ss.sss} & Is the seconds and milliseconds of the minute \\
\hline
\end{tabular}

\textit{zone} (Output; optional) Must be scalar and of type default character; its length must be at least 5 to contain the complete value. Its leftmost 5 characters are set to a value of the form \texttt{+hhmm} or \texttt{-hhmm}, where \texttt{hh} and \texttt{mm} are the time difference with respect to Coordinated Universal Time (UTC) in hours and parts of an hour expressed in minutes, respectively.

UTC is also known as Greenwich Mean Time.

\textit{values} (Output; optional) Must be of type integer. One-dimensional array with size of at least 8. The values returned in \textit{values} are as follows:

\begin{tabular}{|l|}
\hline
\textit{values(1)} & Is the 4-digit year \\
\textit{values(2)} & Is the month of the year \\
\textit{values(3)} & Is the day of the month \\
\textit{values(4)} & Is the time difference with respect to Coordinated Universal Time (UTC) in minutes \\
\hline
\end{tabular}
Example

Consider the following example executed on 2000 March 28 at 11:04:14.5:

```
INTEGER DATE_TIME (8)
CHARACTER (LEN = 12) REAL_CLOCK (3)
CALL DATE_AND_TIME (REAL_CLOCK (1), REAL_CLOCK (2), &
REAL_CLOCK (3), DATE_TIME)
```

This assigns the value "20000328" to REAL_CLOCK (1), the value "110414.500" to REAL_CLOCK (2), and the value "-0500" to REAL_CLOCK (3). The following values are assigned to DATE_TIME: 2000, 3, 28, -300, 11, 4, 14, and 500.

The following shows another example:

```
CHARACTER(10) t
CHARACTER(5) z
CALL DATE_AND_TIME(TIME = t, ZONE = z)
```

DBESJ0, DBESJ1, DBESJN, DBESY0, DBESY1, DBESYN

Portability Functions: Compute the double-precision values of Bessel functions of the first and second kinds.

Module

USE IFPORT
Syntax

result = DBESJ0 (value)
result = DBESJ1 (value)
result = DBESJN (n, value)
result = DBESY0 (posvalue)
result = DBESY1 (posvalue)
result = DBESYN (n, posvalue)

value (Input) REAL(8). Independent variable for a Bessel function.

n (Input) INTEGER(4). Specifies the order of the selected Bessel function computation.

posvalue (Input) REAL(8). Independent variable for a Bessel function. Must be greater than or equal to zero.

Results

DBESJ0, DBESJ1, and DBESJN return Bessel functions of the first kind, orders 0, 1, and n, respectively, with the independent variable value.

DBESY0, DBESY1, and DBESYN return Bessel functions of the second kind, orders 0, 1, and n, respectively, with the independent variable posvalue.

Negative arguments cause DBESY0, DBESY1, and DBESYN to return a huge negative value.

Bessel functions are explained more fully in most mathematics reference books, such as the Handbook of Mathematical Functions (Abramowitz and Stegun. Washington: U.S. Government Printing Office, 1964). These functions are commonly used in the mathematics of electromagnetic wave theory.

See the descriptions of the BESSEL_* functions, if you need to use quad-precision (REAL(16)).

Example

```
USE IFPORT
real(8) besnum, besout
10 read *, besnum
   besout = dbesj0(besnum)
   print *, 'result is ',besout
  goto 10
end
```

DBLE

**Elemental Intrinsic Function (Generic):** Converts a number to double-precision real type.

Syntax

result = DBLE (a)

a (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
Results

The result type is double precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If \( a \) is of type double precision, the result is the value of the \( a \) with no conversion (DBLE( \( a \) ) = \( a \)).

If \( a \) is of type integer or real, the result has as much precision of the significant part of \( a \) as a double precision value can contain.

If \( a \) is of type complex, the result has as much precision of the significant part of the real part of \( a \) as a double precision value can contain.

<td>COMPLEX(16)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

1These specific functions cannot be passed as actual arguments.

2 The setting of compiler options specifying double size can affect DBLE.

If the argument is a binary, octal, or hexadecimal literal constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

NOTE

The result values of DBLE are defined by references to the intrinsic function REAL with the same arguments. Therefore, the padding and truncation of binary, octal, and hexadecimal literal constant arguments to DBLE is the same as for the intrinsic function REAL.

Example

DBLE (4) has the value 4.0.

DBLE ((3.4, 2.0)) has the value 3.4.

DCLOCK

*Portability Function:* Returns the elapsed time in seconds since the start of the current process.

**Module**

USE IFPORT

**Syntax**

\[ \text{result} = \text{DCLOCK}() \]

**Results**

The result type is REAL(8). This routine provides accurate timing to the nearest millisecond (Windows*) or to the nearest microsecond (Linux* and macOS*), taking into account the frequency of the processor where the current process is running.

Note that the first call to DCLOCK performs calibration.

**Example**

```
USE IFPORT
DOUBLE PRECISION START_TIME, STOP_TIME
START_TIME = DCLOCK()
CALL FOO()
STOP_TIME = DCLOCK()
PRINT *, 'foo took:', STOP_TIME - START_TIME, 'seconds.'
```

**See Also**

DATE_AND_TIME
CPU_TIME

DCMPLX

*Elemental Intrinsic Function (Specific):* Converts the argument to double complex type. This function cannot be passed as an actual argument.

**Syntax**

\[ \text{result} = \text{DCMPLX}(x) \]  
\[ \text{result} = \text{DCMPLX}(x, y) \]

- \(x\) (Input) Must be of type integer, real, or complex.
- \(y\) (Input; optional) Must be of type integer or real. It must not be present if \(x\) is of type complex.

**Results**

The result type is double complex (COMPLEX(8) or COMPLEX*16).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If \(y\) is not specified and \(x\) is complex, the result value is CMPLX(REAL( \(x\)), AIMAG( \(x\))).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.
DCMPLX(x, y) has the complex value whose real part is REAL(x, KIND=8) and whose imaginary part is REAL(y, KIND=8).

Example
DCMPLX(-3) has the value (-3.0, 0.0).
DCMPLX(4.1, 2.3) has the value (4.1, 2.3).

DEALLOCATE

Statement: Frees the storage allocated for allocatable
variables and nonprocedure pointer targets (and
causes the pointers to become disassociated).

Syntax
DEALLOCATE (object[,object]...[, dealloc-opt])

object
Is a structure component or the name of a variable, and must be a
pointer or allocatable variable.

dealloc-opt
(Output) Is one of the following:

STAT=stat-var
stat-var is a scalar integer variable in
which the status of the deallocation is
stored.

ERRMSG=err-var
err-var is a scalar default character value
in which an error condition is stored if such a
condition occurs.

Description
If a STAT= variable or ERRMSG= variable is specified, it must not be deallocated in the DEALLOCATE
statement in which it appears. If the deallocation is successful, the STAT= variable is set to zero and the
ERRMSG= variable is unchanged. If the deallocation is not successful, an error condition occurs, the STAT=
variable is set to a positive integer value (representing the run-time error), and the ERRMSG= variable is
defined with a descriptive message about the error condition. If no STAT= variable is specified and an error
condition occurs, error termination is initiated.

If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more
images has initiated termination of execution, the STAT= variable becomes defined with the processor-
dependent positive integer value of the constant STAT_STOPPED_IMAGE from the intrinsic module
ISO_FORTRAN_ENV. Otherwise, if an allocatable object is a coarray and one or more images of the current
team has failed, the STAT= variable becomes defined with the processor-dependent positive integer value of
the constant STAT_FAILED_IMAGE from the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of the ALLOCATE or DEALLOCATE statement, the STAT=
variable becomes defined with a processor-dependent positive integer value different from
STAT_STOPPED_IMAGE or STAT_FAILED_IMAGE.
If an ALLOCATE or DEALLOCATE statement with a coarray allocatable object is executed when one or more images of the current team has failed, each allocatable object is successfully allocated or deallocated on the active images of the current team. If any other error occurs, the allocation status of each allocatable object is processor dependent:

- Successfully allocated allocatable objects have the allocation status of allocated, or associated if the allocable object is has the POINTER attribute.
- Successfully deallocated allocatable objects have the allocation status of deallocated, or disassociated if the allocatable object has the POINTER attribute.
- An allocatable object that was not successfully allocated or deallocated has its previous allocation status, or its previous association status if it has the POINTER attribute.

It is recommended that all explicitly allocated storage be explicitly deallocated when it is no longer needed.

To disassociate a pointer that was not associated with the ALLOCATE statement, use the NULLIFY statement.

For a list of run-time errors, see Error Handling in the *Compiler Reference*.

**Example**

The following example shows deallocation of an allocatable array:

```fortran
INTEGER ALLOC_ERR
REAL, ALLOCATABLE :: A(:), B(:,:)
...
ALLOCATE (A(10), B(-2:8,1:5))
...
DEALLOCATE(A, B, STAT = ALLOC_ERR)
```

The following shows another example:

```fortran
INTEGER, ALLOCATABLE :: dataset(:,,:,:)
INTEGER reactor, level, points, error
DATA reactor, level, points / 10, 50, 10 /
ALLOCATE (dataset(1:reactor,1:level,1:points), STAT = error)
DEALLOCATE (dataset, STAT = error)
```

**See Also**

ISO_FORTRAN_ENV Module

**DECLARE and NODEDECLARE**

*General Compiler Directives:* DECLARE generates warnings for variables that have been used but have not been declared (like the IMPLICIT NONE statement). NODEDECLARE (the default) disables these warnings.

**Syntax**

```fortran
!DIR$ DECLARE

!DIR$ NODEDECLARE
```

The DECLARE directive is primarily a debugging tool that locates variables that have not been properly initialized, or that have been defined but never used.
DECLARE MAPPER

OpenMP* Fortran Compiler Directive: Declares a user-defined mapper for a specified type. It also lets you optionally declare a map-identifier that can be used in a MAP clause in other directives or in a motion-clause of a TARGET UPDATE directive. This feature is only available for ifx.

Syntax

```fortran
$OMP DECLARE MAPPER ([mapper-identifier:] type::var) [clause [[,] clause]...]
```

mapper-identifier

Is a Fortran identifier, or the literal string DEFAULT. If no mapper-identifier is specified, it is as if DEFAULT was specified.

A DECLARE MAPPER directive specifying a mapper-identifier for a given type is not permitted in a scope where another DECLARE MAPPER directive specifying the same mapper-identifier for the same type is accessible.

type

Is an accessible type name within the scope where the directive appears. It cannot be an intrinsic or an abstract type.

type cannot be directly or indirectly mapped as part of the mapper through another type, except through the appearance of var as a list item in a MAP clause.

If type identifies a derived type, it can be any accessible derived type name. In the Description below, DT refers to a derived type identifier.

var

Is a Fortran identifier. It can be used in all MAP clauses of the DECLARE MAPPER directive. No subobject of var is default mapped; all parts of var must be explicitly mapped.

var, or at least one element or component of var, must appear in a MAP clause.

clause

Is MAP ([(map-type-modifier [, ] [map-type-modifier [, ] ...] map-type: ] list).

map-type-modifier is either ALWAYS or CLOSE.

map-type is ALLOC, TO, FROM or TOFROM.

Each map-type can appear only once in a MAP clause. If map-type is not specified, it is as if TOFROM appeared as the map-type.

list items are limited to references of var, or other objects that are accessible in the scope or are previously declared in the scope where the DECLARE MAPPER directive appears. A list item can be an array section.

The DECLARE MAPPER directive is a declarative directive that appears in the specification part of a program. type and mapper-identifier, if present, uniquely identify the mapper.
If a DECLARE MAPPER directive is not specified for a type DT, a predefined mapper exists for type DT as if the type DT had appeared in the directive as follows:

```
!$OMP DECLARE MAPPER (DT :: var) MAP (TOFROM: var)
```

A DECLARE MAPPER directive that uses the `mapper-identifier` DEFAULT for any type DT overrides this predefined mapper for the type DT, and the user-declared mapper becomes the default mapper for all variables of type DT.

If a MAP clause in another directive maps a list item of a type specified in an accessible DECLARE MAPPER directive, or if a motion clause of a TARGET UPDATE invokes a user-defined mapper and updates a list item of type specified by that mapper, the effect is as if the MAP or motion clause is replaced by a set of MAP or motion clauses derived from the MAP clauses specified on the DECLARE MAPPER directive.

A derived type list-item can have more than one map type: one from DECLARE MAPPER, and one from a MAP clause in a TARGET construct.

The following table shows the final map type a mapper applies for a MAP clause that maps a list item of the given type:

- The rows are the `map-type` specified by the mapper.
- The columns are the specified `map-type` of the MAP clause invoking the mapper.
- The parenthesized values in the table represent the final map type for a TARGET EXIT DATA construct that invokes a mapper.

In this case, if the mapper specifies `map-type` ALLOC or TO, and the TARGET EXIT DATA MAP clause that invokes the mapper has `map-type` FROM, the resulting `map-type` is RELEASE.

<table>
<thead>
<tr>
<th>Map result type of map type combinations</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOC</td>
</tr>
<tr>
<td>ALLOC</td>
</tr>
<tr>
<td>TO</td>
</tr>
<tr>
<td>FROM</td>
</tr>
<tr>
<td>TOFROM</td>
</tr>
</tbody>
</table>

If a set of DECLARE MAPPER directives result in a cyclic definition of mappers, it causes unspecified behavior.

**Example**

The following example contains a DECLARE MAPPER directive that maps derived types of type `my_type`. The variable `var` has the type `my_type` and is used in the MAP clause to reference the derived type and its components.

The MAP clause in the DECLARE MAPPER directive specifies that all components of `my_type` are mapped, as well as the dynamic storage in the array section `var%values(1:NUM_ELEMENTS)`. No `map-type` is specified, so the map type TOFROM is assumed.

Variables used in TARGET regions that are of type `my_type` will be implicitly mapped as prescribed in the DECLARE MAPPER directive’s MAP clause.

```fortran
program main
  integer, parameter :: nvals = 250
  type my_type
    integer :: num_vals
    integer, allocatable :: values(:)
  end type
```

1392
The following example maps the type `my_type` as seen in the previous example.

Type `my_type` is nested within another derived type, `my_type2`. `my_type2` is mapped by a second DECLARE MAPPER directive.

The array component `unmapped` is not mapped and is available on the host only. The component `temp` is allocated on the target and used as temporary storage on the target device. The component `arr` is mapped with the default map type TOFROM. The two mappers are combined when mapping variables of type `my_type2`.

The second DECLARE MAPPER directive uses a mapper-identifier, and maps the variable `x` and the array `y` as well as the type `my_type2`.

```fortran
program main
  integer, parameter :: nvals = 250
  type my_type
    integer :: num_vals
    integer, allocatable :: values(:)
  end type
  !$omp declare mapper (my_type :: var) map (var, var%values (1:var%num_vals))

  type my_type2
    type (my_type) :: my_type_var
    type (my_type) :: temp
    real,dimension(nvals) :: unmapped
    real,dimension(nvals) :: arr
  end type
  type (my_type2) :: t
  real :: x, y(num_vals)
  !$omp declare mapper (my_mapper : my_type2 :: v) map (v%arr, x, y(:)) &
  !$omp&               map (alloc : v%temp)

  !$omp target map (mapper(my_mapper), tofrom : t)
  call calculate(t, x, y)
  !$omp end target
  ...
end program
```

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
TARGET UPDATE
MAP clause
DECLARE REDUCTION

OpenMP* Fortran Compiler Directive: Declares user-defined reductions which are identified by a reduction-identifier that can be used in a reduction clause of other directives.

Syntax

```fortran
!$OMP DECLARE REDUCTION (reduction-identifier : type-list : combiner) [initializer-clause]
```

**reduction-identifier**
Is a Fortran identifier, or a defined or extended operator.

**type-list**
Is a comma-separated list of one or more type identifiers. These may be intrinsic types or accessible derived types. You cannot specify polymorphic and parameterized derived types, and coarrays.

*type-list* cannot contain a type which has previously been specified in a DECLARE REDUCTION directive with the same *reduction-identifier* if the *reduction-identifier*/type pair is accessible by use or host association.

If more than one type is specified, it is as if there is a separate DECLARE REDUCTION directive for each type.

**combiner**
Is an assignment statement, or a subroutine name followed by an argument list. It indicates how partial results are combined into a single value.

There are two special identifiers that are allowed in the *combiner*:

- **omp_out**
  This identifier refers to the storage that holds the resulting combined value following execution of the combiner.
- **omp_in**
  The above identifiers refer to variables that are the type of the reduction variables specified in *type-list* for the *reduction-identifier*. They denote values to be combined by executing the *combiner*.

No other identifiers are permitted in the *combiner*. Any number of literal or named constants can appear in the *combiner*.

If *combiner* is a subroutine name followed by an argument list, it is evaluated by calling the subroutine with the specified argument list. If *combiner* is an assignment statement, *combiner* is evaluated by executing the assignment statement.

The number of times the *combiner* is executed, and the order of these executions, is unspecified.

**initializer-clause**
Is initializer (*initializer-expression*).

At most one *initializer-clause* can be specified.

Only the identifiers `omp_priv` and `omp_orig` are allowed in the *initializer-clause*. `omp_orig` refers to the storage of the original reduction variable that appears in the list in the REDUCTION clause that specifies *reduction-identifier*. If `omp_orig` is modified in the *initializer-clause*, the behavior is unspecified.
No other identifiers are allowed in `initializer-clause`. Any number of literal or named constants are permitted.

`initializer-expression` is one of the following identifiers:

- `omp_priv = expression`
  
  This identifier refers to the storage to be initialized.

- `subroutine-name (argument-list)`

If `initializer-expression` is a subroutine name and an argument list, the `initializer` is evaluated by executing a call to the subroutine with the specified argument list. If `initializer` is an assignment statement, it is evaluated by executing the assignment.

If `initializer-expression` is a subroutine name and an argument list, one of the arguments must be `omp_priv`, and it must be associated with an `INTENT(OUT)` dummy argument of the subroutine.

The number of times `initializer-expression` is evaluated and the order of the evaluations is unspecified.

The `DECLARE REDUCTION` directive is a specification directive. It can appear in a specification part of a subroutine, function, main program, module, or block construct.

User-defined (custom) reductions can be defined using the `DECLARE REDUCTION` directive. The reduction is identified by the `reduction-identifier` and the associated type from `type-list`. The `reduction-identifier` can be used in a `REDUCTION` clause in another OpenMP* directive anywhere it is accessible by use or host association.

A `DECLARE REDUCTION` directive cannot redefine a predefined `reduction-identifier` (see the table of implicitly defined reduction identifiers in the `REDUCTION` clause section).

If a type in `type-list` has deferred or assumed-length type parameters, the `reduction-identifier` can be used in a `REDUCTION` clause with a variable of the same type and kind type parameter as type, regardless of the length parameter with which the variable is declared. The length parameter of a character type must be a constant, colon, or asterisk. An accessible `reduction-identifier` defined with a deferred or assumed-length character type cannot appear in another `DECLARE REDUCTION` directive with a `type-list` item of type character with the same kind type parameter.

The accessibility of a `reduction-identifier` is determined by the same rules as for other Fortran entities; it can be declared PUBLIC or PRIVATE, be made accessible or blocked by a USE or IMPORT statement, and it can be renamed. If the `reduction-identifier` is the same as a generic name that is also the name of a derived type, the accessibility of the `reduction-identifier` is the same as that of the generic name.

If a subroutine or function used in `initializer-expression` or `combiner` is not an intrinsic procedure, it must have an accessible interface. Defined operators and defined assignments used in `initializer` or `combiner` must have accessible interfaces. All subroutines, functions, defined operators and defined assignments used in `initializer` or `combiner` must have accessible interfaces in the subprogram in which the corresponding `REDUCTION` clause appears. Procedures referenced in `combiner` and `initializer` cannot be alternate return subprograms.

The initial value of a user-defined reduction is not known before it is specified. The `initializer-clause` can be used to specify an initial value for the reduction variable. The `initializer-clause` will be executed to establish initial values for the private copies of reduction list items indicated in a `REDUCTION` clause that specifies the `reduction-identifier`.

If `initializer` is not specified, private reduction variables are initialized as follows:

- If the reduction variable is type COMPLEX, REAL, or INTEGER, the default initializer is the value zero.
• If the reduction variable specified in list of the REDUCTION clause is LOGICAL, the default initializer is the value .FALSE..
• If the reduction variable is of a default initialized derived type, the default initializer value is used.
• Otherwise, the initial value is unspecified.

If initializer is used in a target region, then a DECLARE TARGET construct (Linux* only) must be specified for any procedures that are executed during the execution of combiner or initializer.

If the execution of combiner or initializer results in the execution of an OpenMP* construct or an OpenMP* API call, the behavior is undefined. If the variable omp_orig is defined during execution of initializer, the behavior is unspecified.

Example

Consider that a DECLARE REDUCTION directive is used to declare a sum reduction for an integer component of a type my_type that is identified by the reduction-identifier ‘+’. It is then used in a REDUCTION clause of a parallel region to produce the sum of the thread numbers (numbered 1 thru 4) of the region:

```fortran
module types
  type my_type
    integer :: component
  end type
  interface operator(+)
    module procedure :: my_add
  end interface
  !$omp declare reduction (+ : my_type : omp_out = omp_out + omp_in) initializer (omp_priv = my_type (0))
contains
  function my_add (a1, a2)
    type(my_type),intent(in) :: a1, a2
    type(my_type)            :: my_add
    my_add%component = a1%component + a2%component
    return
  end function my_add
end module types

program main
  use types
  use omp_lib
  type(my_type) :: my_var

  ! Initialize the reduction variable before entering the OpenMP region
  my_var%component = 0

  !$omp parallel reduction (+ : my_var) num_threads(4)
    my_var%component = omp_get_thread_num() + 1
  !$omp end parallel

  print *, "sum of thread numbers is ", my_var%component
end program
```

The output of the program follows:

sum of thread numbers is 10

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
DECLARE TARGET
REDUCTION clause

DECLARE SIMD

*OpenMP* Fortran Compiler Directive: Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.

Syntax

```fortran
!$OMP DECLARE SIMD(routine-name) [clause[[], clause]... ]
```

`routine-name` is the name of a routine (a function or subroutine). It cannot be a generic name; it must be a specific name. It also cannot be a procedure pointer or an entry name.

`clause` is an optional vectorization clause. It can be one or more of the following:

- **ALIGNED (list [:n])**
- **INBRANCH | NOTINBRANCH**
  The INBRANCH clause specifies that the routine must always be called from inside a conditional statement of a SIMD loop.
  The NOTINBRANCH clause specifies that the routine must never be called from inside a conditional statement of a SIMD loop.
  If neither clause is specified, then the routine may or may not be called from inside a conditional statement of a SIMD loop.
  You can only specify INBRANCH or NOTINBRANCH; you cannot specify both.
- **LINEAR (linear-list[: linear-step])**
- **PROCESSOR (cpuid) (an Intel® language extension)**
- **SIMDLEN(n)**
  Specifies the number of concurrent arguments \(n\) for the SIMD version of `routine-name`. The \(n\) must be a constant positive integer expression.
  If SIMDLEN is not specified, the number of concurrent arguments for the `routine-name` is implementation defined.
  Only one SIMDLEN clause can appear in a DECLARE SIMD directive.
- **UNIFORM(list)**
  Tells the compiler that the values of the specified arguments have an invariant value for all concurrent invocations of the routine in the execution of a single SIMD loop.
  The `list` is one or more scalar variables that are dummy arguments in the specified routine.
  Multiple UNIFORM clauses are merged as a union.

The DECLARE SIMD construct enables the creation of SIMD versions of the specified subroutine or function. You can use multiple DECLARE SIMD constructs in a single procedure to produce more than one SIMD version of a procedure. These versions can be used to process multiple arguments from a single invocation from a SIMD loop concurrently.
When routine-name is executed, it cannot have any side-effects that would change its execution for concurrent iterations of a SIMD chunk. When the routine is called from a SIMD loop, it cannot cause the execution of any OpenMP Fortran construct.

If a DECLARE SIMD directive is specified for a routine name with explicit interface and for the definition of the routine, they must match. Otherwise, the result is unspecified.

You cannot use procedure pointers to access routines created by the DECLARE SIMD directive.

You can only specify a particular variable in at most one instance of a UNIFORM or LINEAR clause.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

DECLARE TARGET
OpenMP Fortran Compiler Directive: Specifies that named variables, common blocks, functions, and subroutines are mapped to a device. This feature is only available for ifx.

Syntax

!$OMP DECLARE TARGET [(extended-list)]
-or-
!$OMP DECLARE TARGET[clause]

extended-list

Is a list of one or more variables, functions, subroutines, data pointers, procedure pointers, or common blocks. If you specify more than one extended-list item, they must be separated by commas. A common block name must appear between slashes (/ /); you cannot specify a blank common block. The specified extended-list items can be used inside a target region that executes on the device.

If the extended-list item is a function or subroutine, it must not be a generic name or entry name. A device-specific version of the routine is created that can be called from a target region.

If the extended-list item is a variable:

- It is mapped to a corresponding variable in the device data environment. If the variable is initialized, the corresponding variable in the device data environment is initialized with the same value.
- It can only appear in the scope in which it is declared.
- It must be declared in the Fortran scope of a module, or it must have the SAVE attribute (explicitly or implicitly).

You cannot specify the following variables in the DECLARE TARGET directive:

- A THREADPRIVATE variable
- A variable that is part of another variable (for example, an element in an array or a field of a structure)
- A variable that is an element of a common block
- A variable that appears in an EQUIVALENCE statement

If the extended-list item is a common block:
• It must be declared to be a common block in the same scoping unit in which the DECLARE TARGET directive appears.
• If the DECLARE TARGET directive specifying the common block name appears in one program unit, a DECLARE TARGET directive must also appear in every other program unit that contains a COMMON statement specifying the same common block name. The directive must appear after the last relevant COMMON statement in the program unit.

clause

Is the following:
• TO (extended-list)
  Is a comma-separated collection of one or more list items or procedures.
  If a list item is a routine then a device-specific version of the routine is created that can be called from a target region.
  If a list item is a variable then the original variable is mapped to a corresponding variable in the device data environment as if it had appeared in a MAP clause with the map-type TO on the implicit TARGET DATA construct for each device.
  The list item is never removed from those device data environments.

If you specify list, this directive can only appear in a specification part of a subroutine, function, program, or module.

If you do not specify list, the directive must appear in the specification part of the relevant subroutine, function, or interface block.

If a DECLARE TARGET directive is specified in an interface block for a procedure, it must match a DECLARE TARGET directive in the definition of the procedure.

If a procedure is declared in a procedure declaration statement, any DECLARE TARGET directive containing the procedure name must appear in the same specification part.

The following additional rules apply to variables and common blocks:
• The DECLARE TARGET directive must appear in the declaration section of a scoping unit in which the common block or variable is declared.
• If a variable or common block is declared with the BIND attribute, the corresponding C entities must also be specified in a DECLARE TARGET directive in the C program.

Variables with static storage and procedures used in an OMP TARGET region are implicitly treated as OMP DECLARE TARGET:

```
MODULE VARS
  INTEGER X
END MODULE

REAL FUNCTION FOO()
END FUNCTION

!$OMP TARGET
  X = FOO()   ! X and FOO are implicitly DECLARE TARGET
!$OMP END TARGET
```

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DECLARE VARIANT**

*OpenMP* Fortran Compiler Directive: Identifies a variant of a base procedure and specifies the context in which this variant is used. This feature is only available for ifx.

**Syntax**

```fortran
!$OMP DECLARE VARIANT ([base-proc-name:]variant-proc-name) clause[[,[ clause]... ]
```

- **base-proc-name**
  - Is the name of a base procedure. It is the name that appears in a procedure reference and is replaced by the variant name if the procedure reference appears in the OpenMP* context specified by the MATCH clause. `base-proc-name` must have an accessible explicit interface.

- **variant-proc-name**
  - Is the name of the variant procedure that is to be called instead of the base procedure if the base procedure is called from an OpenMP* context that matches the context specified by the MATCH clause.

- **clause**
  - Is one or more of the following:
    - **ADJUST_ARGS**
      ```fortran
      (adjust-op : argument-list)
      ```
      Causes the `adjust-op` operation to be performed to each argument specified in `argument-list` before calling the variant procedure.
      
      `adjust-op` is either `need_device_ptr` or `nothing`.
      
      If `need_device_ptr` is specified, it causes the listed arguments to be converted to corresponding device pointers of the default device. An argument in the `argument-list` following `need_device_ptr` must be of type `C_PTR`.
      
      If `nothing` is specified, the arguments listed are passed without modification.
      
      Multiple ADJUST_ARG clauses can appear for a DECLARE VARIANT directive.
    - **APPEND_ARGS**
      ```fortran
      (append-op [[, append-op] ...]
      ```
      Causes additional arguments to be passed to the call at the end of the argument list of the base procedure.
      
      `append-op` is:
      
      INTEROP (interop-type [[, interop-type] ...])
      
      where `interop-type` is as described for the INTEROP directive.
      
      Only one APPEND_ARGS clause can appear in a DECLARE VARIANT directive.
      
      An argument in an APPEND_ARGS clause can only appear in that APPEND_ARGS clause and not in another APPEND_ARGS clause in the same DECLARE VARIANT directive.
    - **MATCH**
      ```fortran
      (context-selector-specification)
      ```
      Specifies an OpenMP* context selector.
      
      `context-selector-specification` is:
construct = {DISPATCH | TARGET VARIANT DISPATCH}, device =
{ARCH (arch-id-list)}

where arch-id-list is a comma-separated list of one or more of the
implementation-defined values gen, gen9, XeLP, XeHP, or x86_64

Note: Currently ifx only allows this context-selector-specification. It
does not allow others permitted by the OpenMP* specification.
Further capability will be allowed in a subsequent release.

APPEND_ARGS and ADJUST_ARGS clauses can appear in a DECLARE
VARIANT directive only if the MATCH clause of the DECLARE VARIANT
directive contains the DISPATCH or TARGET VARIANT DISPATCH
construct selector.

The DECLARE VARIANT directive is a declarative directive and must appear in the specification part of a
subroutine or function, or in an interface in an interface block. It identifies the name of a variant procedure
that is to be called instead of the base procedure when the call appears in a context that matches the
context-selector-specification in the MATCH clause.

If base-proc-name is not specified, the name of the procedure containing the directive is the base-proc-
name. base-proc-name must not be a dummy procedure name, a statement function name, a generic name,
a procedure pointer, or an alternate entry name.

If a DECLARE VARIANT directive appears in an interface body for a procedure, it must match a DECLARE
VARIANT directive in the definition of that procedure. If a DECLARE VARIANT directive appears for a
procedure with an explicit interface, and the definition of that procedure also contains a DECLARE VARIANT
directive for that procedure, the two directives must match.

Multiple DECLARE VARIANT directives can associate different variant-proc-names with the same base-proc-
name. If more than one DECLARE VARIANT associates the same variant-proc-name with the same base-
proc-name, then the context-selector-specification must be the same for all such directives.

A variant procedure must have the same interface characteristics as the base procedure, except that a
variant procedure must have one additional final argument declared in its dummy argument list, which must
be of type C_PTR from the intrinsic module ISO_C_BINDING. When a call to the base procedure is replaced
by a call to the variant, the compiler adds the additional argument into the actual argument list.

When the ADJUST_ARGS clause is specified, an argument with the is-device-ptr property in its
interoperability requirement set will be passed as is. Otherwise, the argument will be converted in the same
way that a USE_DEVICE_PTR clause on a TARGET DATA construct converts a pointer list item into a device
pointer.

When the APPEND_ARGS clause appears, the following occurs:

- For each interop-type specified, an additional argument of type omp_interop_kind from the
  interoperability requirement set of the encountering task is added to the argument list.

  The ordering of the appended arguments is the same as the order of the interop-types that are specified
  in list of interop-types in parentheses following the INTEROP keyword in the APPEND_ARGS clause.
- Each argument is constructed as if an INTEROP construct specifying an interop-type INIT clause was
  present.
- If the interoperability requirement set contains properties that could be used as INTEROP construct
  clauses, it is as if the INTEROP construct also contained those clauses, and the properties will be removed
  from the interoperability requirement set.
- Each appended argument is destroyed after the selected variant completes executions as if the INTEROP
  construct contained a DESTROY clause.

Calling a procedure variant directly by variant-proc-name within an OpenMP* context that is different than
the context specified in the MATCH clause is non-conforming.

1401
Example

The DECLARE VARIANT directive in the module procedure vecadd_base identifies the procedure vecadd_gpu_offload as a variant that is to replace references to vecadd_base when called from a TARGET DISPATCH VARIANT construct and a GEN device is available for offloading. Notice that vecadd_base does not have any dummy arguments, while vecadd_gpu_offload has a single C_PTR dummy argument.

```
MODULE vecadd
  INTEGER, PARAMETER :: n = 1024
CONTAINS
  FUNCTION vecadd_gpu_offload (ptr) RESULT (res)
    USE, INTRINSIC :: ISO_C_BINDING, ONLY : c_ptr
    !$DEC ATTRIBUTES NOINLINE :: vecadd_gpu_offload
    TYPE (c_ptr) :: ptr
    REAL :: res
    REAL, DIMENSION(n) :: a, b
    INTEGER :: k

    !$omp TARGET PARALLEL DO REDUCTION (+: res) MAP(TO: a, b)
    DO k=0, n - 1
      a(k) = k
      b(k) = k + 1
      res = a(k) + b(k)
    END DO
    !$omp END TARGET PARALLEL DO
    PRINT *, "GPU version of vecadd called"
  END FUNCTION vecadd_gpu_offload

  FUNCTION vecadd_base ()RESULT (res)
    !$DEC ATTRIBUTES NOINLINE :: vecadd_base
    !$OMP DECLARE VARIANT (vecadd_gpu_offload) match(construct={target variant dispatch}&
      ,device = {arch (gen)} )
    REAL :: res
    REAL, DIMENSION(n) :: a, b
    INTEGER :: k

    !$omp PARALLEL DO REDUCTION (+: res)
    DO k=1, n
      a(k) = k
      a(k) = k + 1
      res = a(k) + b(k)
    END DO
    !$omp END PARALLEL DO
    PRINT *, "CPU version of vecadd called"
  END FUNCTION vecadd_base
END MODULE vecadd

PROGRAM main
  USE vecadd
  REAL :: result = 0.0

  !$OMP TARGET VARIANT DISPATCH
  result = vecadd_base()
  !$OMP END TARGET VARIANT DISPATCH

  IF (result == 1048576.0) then
    PRINT *, "PASSED: correct results"
  ELSE
    PRINT *, "FAILED: incorrect results"
  END IF
END PROGRAM main
```
DECODE

**Statement:** Translates data from character to internal form. It is comparable to using internal files in formatted sequential READ statements.

**Syntax**

```fortran
DECODE (c,f,b, IOSTAT=i-var] [, ERR=label]) [io-list]
```

- **c**
  Is a scalar integer expression. It is the number of characters to be translated to internal form.

- **f**
  Is a format identifier. An error occurs if more than one record is specified.

- **b**
  Is a scalar or array reference. If `b` is an array reference, its elements are processed in the order of subscript progression.
  
  `b` contains the characters to be translated to internal form.

- **i-var**
  Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).

- **label**
  Is the label of an executable statement that receives control if an error occurs.

- **io-list**
  Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list receives the data after translation to internal form.

  The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the DECODE statement can translate depends on the data type of `b`. For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.
Example

In the following example, the DECODE statement translates the 12 characters in A to integer form (as specified by the FORMAT statement):

```fortran
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
DECODE(12,100,A) K
100 FORMAT(3I4)
```

The 12 characters are stored in array K:

- \( K(1) = 1234 \)
- \( K(2) = 5678 \)
- \( K(3) = 9012 \)

READ
WRITE
ENCODE

DEFAULT Clause

**Parallel Directive Clause:** Lets you specify a scope for all variables in the lexical extent of a parallel region.

**Syntax**

```fortran
DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE )
```

The specifications have the following effects:

- **PRIVATE** - Makes all named objects in the lexical extent of the parallel region, including common block variables but excluding THREADPRIVATE variables, private to a thread as if you explicitly listed each variable in a PRIVATE clause.
- **FIRSTPRIVATE** - Makes all variables in the construct that have implicitly determined data-sharing attributes firstprivate as if you explicitly listed each variable in a FIRSTPRIVATE clause.
- **SHARED** - Makes all named objects in the lexical extent of the parallel region shared among the threads in a team, as if you explicitly listed each variable in a SHARED clause. If you do not specify a DEFAULT clause, this is the default.
- **NONE** - Specifies that there is no implicit default as to whether variables are PRIVATE or SHARED. In this case, you must specify the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION property of each variable you use in the lexical extent of the parallel region.

You can specify only one DEFAULT clause in a PARALLEL directive. You can exclude variables from a defined default by using the PRIVATE, SHARED, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clauses.

Variables in THREADPRIVATE common blocks are not affected by this clause.

DEFINE and UNDEFINE

**General Compiler Directives:** DEFINE creates a symbolic variable whose existence or value can be tested during conditional compilation. UNDEFINE removes a defined symbol.

**Syntax**

```fortran
!DIR$ DEFINE name[ = val]
```
DEFINE creates and UNDEFINE removes symbols for use with the IF (or IF DEFINED) compiler directive. Symbols defined with DEFINE directive are local to the directive. They cannot be declared in the Fortran program.

Because Fortran programs cannot access the named variables, the names can duplicate Fortran keywords, intrinsic functions, or user-defined names without conflict.

To test whether a symbol has been defined, use the IF DEFINED (name) directive. You can assign an integer value to a defined symbol. To test the assigned value of name, use the IF directive. IF test expressions can contain most logical and arithmetic operators.

Attempting to undefine a symbol that has not been defined produces a compiler warning.

The DEFINE and UNDEFINE directives can appear anywhere in a program, enabling and disabling symbol definitions.

Example

```fortran
!DIR$ DEFINE testflag
!DIR$ IF DEFINED (testflag)
   write (*,*) 'Compiling first line'
!DIR$ ELSE
   write (*,*) 'Compiling second line'
!DIR$ ENDIF
!DIR$ UNDEFINE testflag
```

Equivalent Compiler Options

### DEFINE FILE

**Statement:** Establishes the size and structure of files with relative organization and associates them with a logical unit number.

**Syntax**

```fortran
DEFINE FILE u(m, n, U, asv) [,u(m, n, U, asv)] ...
```

- **u**
  - Is a scalar 32-bit integer constant or variable that specifies the logical unit number.

- **m**
  - Is a scalar integer constant or variable that specifies the number of records in the file.

- **n**
  - Is a scalar integer constant or variable that specifies the length of each record in 16-bit words (2 bytes). For files with record lengths greater than $2^{32} - 1$, the OPEN statement should be used.
Specifies that the file is unformatted (binary); this is the only acceptable entry in this position.

Is a scalar integer variable, called the associated variable of the file. At the end of each direct access I/O operation, the record number of the next higher numbered record in the file is assigned to asv; asv must not be a dummy argument.

The DEFINE FILE statement is comparable to the OPEN statement. In situations where you can use the OPEN statement, OPEN is the preferable mechanism for creating and opening files.

The DEFINE FILE statement specifies that a file containing \( m \) fixed-length records, each composed of \( n16 \)-bit words, exists (or will exist) on the specified logical unit. The records in the file are numbered sequentially from 1 through \( m \).

A DEFINE FILE statement does not itself open a file. However, the statement must be executed before the first direct access I/O statement referring to the specified file. The file is opened when the I/O statement is executed.

If this I/O statement is a WRITE statement, a direct access sequential file is opened, or created if necessary. If the I/O statement is a READ or FIND statement, an existing file is opened, unless the specified file does not exist. If a file does not exist, an error occurs.

The DEFINE FILE statement establishes the variable asv as the associated variable of a file. At the end of each direct access I/O operation, the Fortran I/O system places in asv the record number of the record immediately following the one just read or written.

The associated variable always points to the next sequential record in the file (unless the associated variable is redefined by an assignment, input, or FIND statement). So, direct access I/O statements can perform sequential processing on the file by using the associated variable of the file as the record number specifier.

**Example**

```
DEFINE FILE 3(1000,48,U,NREC)
```

In this example, the DEFINE FILE statement specifies that the logical unit 3 is to be connected to a file of 1000 fixed-length records; each record is forty-eight 16-bit words long. The records are numbered sequentially from 1 through 1000 and are unformatted.

After each direct access I/O operation on this file, the integer variable NREC will contain the record number of the record immediately following the record just processed.

OPEN

**DELDIRQQ**

*Portability Function: Deletes a specified directory.*

**Module**

USE IFPORT

**Syntax**

```
result = DELDIRQQ (dir)
```

*dir* (Input) Character*(*) String containing the path of the directory to be deleted.
Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The directory to be deleted must be empty. It cannot be the current directory, the root directory, or a directory currently in use by another process.

Example

See the example for GETDRIVEDIRQQ.

CHANGEDRIVEQQ
UNLINK

DELETE

Statement: Deletes a record from a relative file.

Syntax

DELETE (UNIT=io-unit[, REC=r][, ERR=label] [, IOSTAT=i-var])

io-unit
Is an external unit specifier.

r
Is a scalar numeric expression indicating the record number to be deleted.

label
Is the label of the branch target statement that receives control if an error occurs.

i-var
Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

In a relative file, the DELETE statement deletes the direct access record specified by r. If REC= r is omitted, the current record is deleted. When the direct access record is deleted, any associated variable is set to the next record number.

The DELETE statement logically removes the appropriate record from the specified file by locating the record and marking it as a deleted record. It then frees the position formerly occupied by the deleted record so that a new record can be written at that position.

NOTE
You must use compiler option vms for READs to detect that a record has been deleted.

Example

The following statement deletes the fifth record in the file connected to I/O unit 10:

DELETE (10, REC=5)

Suppose the following statement is specified:

DELETE (UNIT=9, REC=10, IOSTAT=IOS, ERR=20)
The tenth record in the file connected to unit 9 is deleted. If an error occurs, control is transferred to the statement labeled 20, and a positive integer is stored in the variable IOS.

See Also
Data Transfer I/O Statements
Branch Specifiers
vms compiler option

DELFIESQQ

*Portability Function: Deletes all files matching the name specification, which can contain wildcards (* and ?).*

Module
USE IFPORT

Syntax
result = DELFILESQQ (files)

files (Input) Character*(*) . Files to be deleted. Can contain wildcards (* and?).

Results
The result type is INTEGER(2). The result is the number of files deleted.

You can use wildcards to delete more than one file at a time. DELFILESQQ does not delete directories or system, hidden, or read-only files. Use this function with caution because it can delete many files at once. If a file is in use by another process (for example, if it is open in another process), it cannot be deleted.

Example

USE IFPORT
USE IFCORE
INTEGER(4) len, count
CHARACTER(80) file
CHARACTER(1) ch
WRITE(*,*) "Enter names of files to delete: ", len = GETSTRQQ(file)
IF (file(1:len) .EQ. '*.*') THEN
   WRITE(*,*) "Are you sure (Y/N)?"
   ch = GETCHARQQ()
   IF ((ch .NE. 'Y') .AND. (ch .NE. 'y')) STOP
END IF
count = DELFILESQQ(file)
WRITE(*,*) "Deleted ", count, " files."
END

FINDFILEQQ

DEPEND Clause

*Parallel Directive Clause: Enforces additional constraints on the scheduling of a task by enabling dependences between sibling tasks in the task region.*
Syntax

It takes one of the following forms:

In Synchronization Directive !$OMP ORDERED

DEPEND (SOURCE) -or-

DEPEND (SINK: vec)

In all other directives:

DEPEND (dependence-type : list)

- **dependence-type**

  Can be any one of the following clauses: IN, OUT, or INOUT, MUTEXINOUTSET, or INOUTSET.

  If one or more of the **list** items specified in an **IN** **dependence-type** is the same as a **list** item appearing in a DEPEND clause with an **OUT**, **INOUT**, or **INOUTSET** **dependence-type** on a construct that previously generated a sibling task, the generated task is a dependent task of the sibling task.

  If one or more of the **list** items specified in an **OUT** or **INOUT** **dependence-type** is the same as a **list** item appearing in a DEPEND clause with an **IN**, **OUT**, **INOUT**, MUTEXINOUTSET, or **INOUTSET** **dependence-type** on a construct that previously generated a sibling task, the generated task is a dependent task of the sibling task.

  If one or more of the **list** items specified in an **MUTEXINOUTSET** **dependence-type** is the same as a **list** item appearing in a DEPEND clause with an **IN**, **OUT**, or **INOUTSET** **dependence-type** on a construct that previously generated a sibling task, the generated task is a dependent task of the sibling task.

  If a **list** item specified in a **MUTEXINOUTSET** **dependence-type** is the same as a **list** item appearing in a DEPEND clause with a **MUTEXINOUTSET** **dependence-type** on a different task generating construct and both constructs generate sibling tasks, the sibling tasks are mutually exclusive.

  If one or more of the **list** items specified in an **INOUTSET** **dependence-type** is the same as a **list** item appearing in a DEPEND clause with an **IN**, **OUT**, **INOUT**, or **MUTEXINOUTSET** **dependence-type** on a construct that previously generated a sibling task, the generated task is a dependent task of the sibling task.

- **list**

  Is one or more variables or non-zero length array sections. Any **list** items used in a DEPEND clause of the same task or sibling tasks must indicate identical storage or disjoint storage. The list items that appear in the DEPEND clause may include array sections. Zero-sized arrays and common block names are not permitted as **list** items.

  The behavior is undefined in these cases:

  - If a **list** item has the POINTER attribute and its association status is disassociated or undefined
  - If a **list** item has the ALLOCATABLE attribute and its allocation status is unallocated
Note that this enforced task dependence establishes a synchronization of accesses to each list item performed by a dependent task, with respect to accesses to the same list item performed by any previous tasks. You must properly synchronize access with respect to other concurrent accesses to each list item.

SOURCE

Specifies the satisfaction of cross-iteration dependences that arise from the current iteration.

SINK

Specifies a cross-iteration dependence, where the iteration vector vec indicates the iteration that satisfies the dependence.

vec

Is the iteration vector. It has the form:

\[ x_1 \pm d_1, x_2 \pm d_2, \ldots, x_n \pm d_n \]

where \( n \) is the value specified by the ORDERED clause in the DO loop directive, \( x_i \) denotes the loop iteration variable of the \( i \)-th nested loop associated with the loop directive, and \( d_i \) is a non-negative integer scalar constant.

If vec does not occur in the iteration space, the DEPEND clause is ignored. Note that if vec does not indicate a lexicographically earlier iteration, it can cause a deadlock.

For a vec element form of \( x_i + d_i \) or \( x_i - d_i \), the expression \( x_i + d_i \) or \( x_i - d_i \) for any value of the integer loop iteration variable \( x_i \) that can encounter the ordered construct must be computable in the loop iteration variable's type without overflow.

If a DEPEND clause appears in a TARGET or TARGET UPDATE directive, it is treated as if it had appeared on the implicit task construct that encloses the TARGET construct.

**DEVICE Clause**

**Parallel Directive Clause:** Specifies the target device for a processor control directive like TARGET.

**Syntax**

DEVICE (scalar-integer-expression)

scalar-integer-expression

Is an integer expression. It must evaluate to a positive scalar integer value.

At most one DEVICE clause can appear in a directive that allows the clause.

If DEVICE is not specified, the default device is determined by the internal control variable (ICV) named device-num-var.

**DFLOAT**

**Elemental Intrinsic Function (Generic):** Converts an integer to double-precision real type.

**Syntax**

result = DFLOAT (a)

\( a \) (Input) Must be of type integer.
Results

The result type is double-precision real (by default, REAL(8) or REAL*8). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

<table>
<thead>
<tr>
<th>Specific Name 1</th>
<th>Argument Type</th>
<th>Result Type 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>DFLoti</td>
<td>INTEGER(1)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DFLotj</td>
<td>INTEGER(2)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>DFLotk</td>
<td>INTEGER(4)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td></td>
<td>INTEGER(8)</td>
<td>REAL(8)</td>
</tr>
</tbody>
</table>

1These specific functions cannot be passed as actual arguments.

2The setting of compiler options specifying double size can affect DFLOAT.

Example

DFLOAT (-4) has the value -4.0.

See Also

REAL

DFLOAT, DFLATJ, DFLATK

Portability Functions: Convert an integer to double-precision real type.

Module

USE IFPORT

Syntax

result = DFLATI (i)
result = DFLATJ (j)
result = DFLATK (k)

i (Input) Must be of type INTEGER(2).

j (Input) Must be of type INTEGER(4).

k (Input) Must be of type INTEGER(8).

Results

The result type is double-precision real (REAL(8) or REAL*8).

See Also

DFLOAT

DIGITS

Inquiry Intrinsic Function (Generic): Returns the number of significant digits for numbers of the same type and kind parameters as the argument.
Syntax
result = DIGITS (x)

x (Input) Must be of type integer or real; it can be scalar or array valued.

Results
The result is a scalar of type default integer.
The result has the value q if x is of type integer; it has the value p if x is of type real. Integer parameter q is defined in Model for Integer Data; real parameter p is defined in Model for Real Data.

Example
If x is of type REAL(4), DIGITS(x) has the value 24.

EXPONENTIAL
RADIX
FRACTION
Data Representation Models

DIM
Elemental Intrinsic Function (Generic): Returns the difference between two numbers (if the difference is positive).

Syntax
result = DIM (x, y)

x (Input) Must be of type integer or real.
y (Input) Must have the same type and kind parameters as x.

Results
The result type and kind are the same as x. The value of the result is x - y if x is greater than y; otherwise, the value of the result is zero.
The setting of compiler options specifying integer size can affect this function.

<table>
<thead>
<tr>

<tr>
<td>DDIM</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QDIM</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>
Specific Name | Argument type | Result Type
--- | --- | ---
1 Or HDIM. | | |
2 Or JIDIM. For compatibility, IDIM can also be specified as a generic function for integer types. | | |

**Example**

DIM (6, 2) has the value 4.

DIM (-4.0, 3.0) has the value 0.0.

The following shows another example:

```plaintext
INTEGER i
REAL r
REAL(8) d
i = IDIM(10, 5) ! returns 5
r = DIM (-5.1, 3.7) ! returns 0.0
d = DDIM (10.0D0, -5.0D0) ! returns 15.0D0
```

Argument Keywords in Intrinsic Procedures

**DIMENSION**

*Statement and Attribute:* Specifies that an object is an array, and defines the shape of the array.

**Syntax**

The DIMENSION attribute can be specified in a type declaration statement or a DIMENSION statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls,] DIMENSION (a-spec) [, att-ls] :: a[(a-spec)][ , a[(a-spec)] ] ...
```

**Statement:**

```
DIMENSION [::]a(a-spec) [, a(a-spec) ] ...
```

- **type**
  
  Is a data type specifier.

- **att-ls**
  
  Is an optional list of attribute specifiers.

- **a-spec**
  
  Is an array specification. It can be any of the following:
  
  - An explicit-shape specification; for example, a(10,10)
  - An assumed-shape specification; for example, a(:)
  - A deferred-shape specification; for example, a(:,:)
  - An assumed-size specification; for example, a(10,*), a(:)
  - An assumed-rank specification; for example, a(..)
  - An implicit-shape specification; for example, a(*)
  
  For more information on array specifications, see Declaration Statements for Arrays.

  In a type declaration statement, any array specification following an array overrides any array specification following DIMENSION.

- **a**
  
  Is the name of the array being declared.
Description

The DIMENSION attribute allocates a number of storage elements to each array named, one storage element to each array element in each dimension. The size of each storage element is determined by the data type of the array.

The total number of storage elements assigned to an array is equal to the number produced by multiplying together the number of elements in each dimension in the array specification. For example, the following statement defines ARRAY as having 16 real elements of 4 bytes each and defines MATRIX as having 125 integer elements of 4 bytes each:

```
DIMENSION ARRAY(4,4), MATRIX(5,5,5)
```

An array can also be declared in the following statements: ALLOCATABLE, AUTOMATIC, COMMON, POINTER, STATIC, TARGET.

Example

The following examples show type declaration statements specifying the DIMENSION attribute:

```
REAL, DIMENSION(10, 10) :: A, B, C(10, 15)  ! Specification following C
! overrides the one following
! DIMENSION
REAL(8), DIMENSION(5,-2:2) :: A,B,C
```

The following are examples of the DIMENSION statement:

```
DIMENSION BOTTOM(12,24,10)
DIMENSION X(5,5,5), Y(4,85), Z(100)
DIMENSION MARK(4,4,4,4)
SUBROUTINE APROC(A1,A2,N1,N2,N3)
DIMENSION A1(N1:N2), A2(N3:*)
CHARACTER(LEN = 20) D
DIMENSION A(15), B(15, 40), C(-5:8, 7), D(15)
```

You can declare arrays by using type statements and ALLOCATABLE attributes and statements, for example:

```
INTEGER A(2,0:2)
COMPLEX F
ALLOCATABLE F(:,:),
REAL(8), ALLOCATABLE, DIMENSION( :, :, : ) :: E
```

You can declare an implicit-shape constant array by using a type statement and a PARAMETER attribute, for example:

```
INTEGER, PARAMETER :: R(*) = [1,2,3]
```

You can also declare arrays by using type and ALLOCATABLE statements, for example:

```
INTEGER A(2,0:2)
COMPLEX F
ALLOCATABLE F(:,:),
REAL(8), ALLOCATABLE, DIMENSION( :, :, : ) :: E
```

You can specify both the upper and lower dimension bounds. If, for example, one array contains data from experiments numbered 28 through 112, you could dimension the array as follows:

```
DIMENSION experiment(28:112)
```

Then, to refer to the data from experiment 72, you would reference experiment(72).
Array elements are stored in column-major order: the leftmost subscript is incremented first when the array is mapped into contiguous memory addresses. For example, consider the following statements:

```
INTEGER(2) a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

These are equivalent to:

```
INTEGER(2) a
DIMENSION a(2, 0:2)
DATA a /1, 2, 3, 4, 5, 6/
```

If `a` is placed at location decimal 1000 in memory, the preceding DATA statement produces the following mapping.

<table>
<thead>
<tr>
<th>Array element</th>
<th>Address (decimal)</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>a(1,0)</td>
<td>1000</td>
<td>1</td>
</tr>
<tr>
<td>a(2,0)</td>
<td>1002</td>
<td>2</td>
</tr>
<tr>
<td>a(1,1)</td>
<td>1004</td>
<td>3</td>
</tr>
<tr>
<td>a(2,1)</td>
<td>1006</td>
<td>4</td>
</tr>
<tr>
<td>a(1,2)</td>
<td>1008</td>
<td>5</td>
</tr>
<tr>
<td>a(2,2)</td>
<td>100A</td>
<td>6</td>
</tr>
</tbody>
</table>

The following DIMENSION statement defines an assumed-size array in a subprogram:

```
DIMENSION data (19,*)
```

At execution time, the array data is given the size of the corresponding array in the calling program.

The following program fragment dimensions two arrays:

```
...  
SUBROUTINE Subr (matrix, rows, vector)
REAL MATRIX, VECTOR
INTEGER ROWS
DIMENSION MATRIX (ROWS,*), VECTOR (10),
+ LOCAL (2,4,8)
MATRIX (1,1) = VECTOR (5)
...  
```

ALLOCATE
Declaration Statements for Arrays
Arrays

**DISPATCH**

*OpenMP* Fortran Compiler Directive: Determines whether a variant of a procedure is called for a given function or subroutine call. This feature is only available for ifx.

**Syntax**

```
!$OMP DISPATCH [clause[[,] clause]... ]
  statement
```

1415
Is one or more of the following:

- **DEPEND ([depend-modifier, ] dependence-type : locator-list)**
  Adds the DEPEND properties to the interoperability set.

- **DEVICE (scalar-integer-expression)**
  Causes the value of the default-device-var ICV of the generated task to be set to the value of the DEVICE clause expression.

- **IS_DEVICE_PTR (list)**
  Identifies its list items as device pointers. The IS_DEVICE_PTR property for each list item is added to the interoperability requirement set.

  Each IS_DEVICE_PTR list item must be of type C_PTR from the intrinsic module ISO_C_BINDING.

- **NOCONTEXT (scalar-logical-expression)**
  If a NOCONTEXT clause appears and the scalar-logical-expression evaluates to .TRUE., the DISPATCH construct is not added to the construct set of the OpenMP context.

  If the NOCONTEXT expression evaluates to .FALSE., the DISPATCH directive is added to the OpenMP* context.

- **NOVARIANTS (scalar-logical-expression)**
  If a NOVARIANTS clause appears, and the scalar-logical-expression evaluates to .TRUE., no function variant is selected for execution as the target-call, even if one would otherwise have been selected.

  If the NOVARIANTS expression evaluates to .FALSE., and a variant exists that specified an OpenMP* context in the MATCH clause that matches the current context, the variant is called

- **NOWAIT**
  Adds the NOWAIT property to the interoperability requirement set.

Variables used in the expression of a NOVARIANTS clause or a NOCONTEXT clause are implicitly referenced in all enclosing contexts of the DISPATCH directive.

Only one of each of the following clauses is permitted in a DISPATCH directive: NOWAIT, NOCONTEXT, and NOVARIANT.

Is a Fortran statement with one of these forms:

- var = target_proc ( [argument-list] )
- CALL target_proc [ ( [argument-list] ) ]

**target_proc** must be a procedure name; it cannot be a procedure pointer.

The DISPATCH directive creates an explicit task around the associated code as if a TASK construct was present. Properties added to the interoperability requirement set can be removed by other directives. The task will be an included task if the interoperability requirement set does not contain a NOWAIT property.

If the interoperability requirements set contains DEPEND properties, it is as if the TASK construct contained the corresponding DEPEND clauses.

Syntax Rules for Compiler Directives

DISTRIBUTE

OpenMP* Fortran Compiler Directive: Specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct.

Syntax

```fortran
!$OMP DISTRIBUTE [clause[,, clause]... ]

do-loop

[$OMP END DISTRIBUTE]
```

clause

Is one of the following:

- **ALLOCATE ([allocator :] list)**
- **COLLAPSE (n)**
- **DIST_SCHEDULE (kind [, chunk-size])**

Specifies how iterations are divided.

The **kind** must be STATIC (see SCHEDULE in DO Directive).

The **chunk-size** must be a positive scalar integer expression. If specified, iterations are divided into chunks of size **chunk-size**. Chunks are assigned round-robin to the teams of the parallel region in the order of the team numbers.

When no **chunk-size** is specified, iterations are divided into chunks that are approximately equal in size. In this case, at most one chunk is distributed to each team of the parallel region.

- **FIRSTPRIVATE (list)**
- **LASTPRIVATE ([CONDITIONAL:] list)**
- **PRIVATE (list)**

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

If an END DO directive follows a DO construct in which several loop statements share a DO termination statement, then the directive can only be specified for the outermost of these DO statements. The DISTRIBUTE construct inherits the restrictions of the loop construct.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If more than one loop is associated with the DISTRIBUTE construct, then the iterations of all associated loops are collapsed into one larger iteration space. The sequential execution of the iterations in all associated loops determines the order of the iterations in the collapsed iteration space.

You cannot branch out of a DO loop associated with a DISTRIBUTE directive.
The binding thread set for a DISTRIBUTE construct is the set of primary threads created by a TEAMS construct. A DISTRIBUTE region binds to the innermost enclosing team's parallel region. Only the threads that execute the binding team's parallel region participate in the execution of the loop iterations. A DISTRIBUTE construct must be closely nested in a team's region.

If used, the END DISTRIBUTE directive must appear immediately after the end of the loop. If you do not specify an END DISTRIBUTE directive, an END DISTRIBUTE directive is assumed at the end of the do-loop.

The DISTRIBUTE construct is associated with loop iterations that follow the directive. The iterations are distributed across the primary threads of all teams that execute the team's parallel region to which the DISTRIBUTE region binds.

A list item may appear in a FIRSTPRIVATE or LASTPRIVATE clause but not both.

DISTRIBUTE PARALLEL DO
OpenMP* Fortran Compiler Directive: Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.

Syntax

```fortran
!$OMP DISTRIBUTE PARALLEL DO [clause[[,] clause]... ]

do-loop

[!$OMP END DISTRIBUTE PARALLEL DO]
```

clause

Can be any of the clauses accepted by the DISTRIBUTE or PARALLEL DO directives with identical meanings and restrictions except for ORDERED and LINEAR.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO directive is not specified, an END DISTRIBUTE PARALLEL DO directive is assumed at the end of do-loop.

This directive specifies a composite construct.

See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
DISTRIBUTE PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.

Syntax

```fortran
!$OMP DISTRIBUTE PARALLEL DO SIMD [clause[,,] clause]... ]
  do-loop
[$OMP END DISTRIBUTE PARALLEL DO SIMD]
```

**clause**

Can be any of the clauses accepted by the DISTRIBUTE or PARALLEL DO SIMD directives with identical meanings and restrictions.

**do-loop**

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE PARALLEL DO SIMD directive is not specified, an END DISTRIBUTE PARALLEL DO SIMD directive is assumed at the end of `do-loop`.

This directive specifies a composite construct.

See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

DISTRIBUTE POINT

General Compiler Directive: Specifies loop distribution. It suggests a location at which a DO loop can be split.

Syntax

```fortran
!DIR$ DISTRIBUTE POINT
```

Loop distribution causes large loops to be distributed (split) into smaller ones. The resulting loops contain a subset of the instructions from the initial loop. Loop distribution can enable software pipelining to be applied to more loops. It can also reduce register pressure and improve both instruction and data cache use.

If the directive is placed before a loop, the compiler will determine where to distribute; data dependencies are observed.

If the directive is placed inside a loop, the distribution is performed after the directive and any loop-carried dependencies are ignored. Currently only one distribute directive is supported if the directive is placed inside the loop.
Example

```fortran
!DIR$ DISTRIBUTE POINT
  do i = 1, m
    b(i) = a(i) + 1
    ....
    c(i) = a(i) + b(i) ! Compiler will decide where to distribute.
    ! Data dependencies are observed
    ....
    d(i) = c(i) + 1
  enddo

  do i = 1, m
    b(i) = a(i) + 1
    ....
  !DIR$ DISTRIBUTE POINT
  call sub(a, n) ! Distribution will start here, ignoring all loop-carried ! dependencies
  c(i) = a(i) + b(i)
    ....
  d(i) = c(i) + 1
  enddo
```

See Also
General Compiler Directives
Syntax Rules for Compiler Directives
Rules for General Directives that Affect DO Loops

DISTRIBUTE SIMD

**OpenMP* Fortran Compiler Directive:** Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.

**Syntax**

```fortran
!$OMP DISTRIBUTE SIMD [clause[,] clause]... ]
  do-loop
[!$OMP END DISTRIBUTE SIMD]
```

Can be any of the clauses accepted by the `DISTRIBUTE` or `SIMD` directives with identical meanings and restrictions.

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.
The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

If the END DISTRIBUTE SIMD directive is not specified, an END DISTRIBUTE SIMD directive is assumed at the end of do-loop.

This directive specifies a composite construct.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**DNUM**

*Elemental Intrinsic Function (Specific):* Converts a character string to a REAL(8) value. This function cannot be passed as an actual argument.

**Syntax**

```
result = DNUM (i)
```

*i*  
(Input) Must be of type character.

**Results**

The result type is REAL(8). The result value is the double-precision real value represented by the character string *i*.

**Example**

DNUM("3.14159") has the value 3.14159 of type REAL(8).

The following sets x to 311.0:

```fortran
CHARACTER(3) i
DOUBLE PRECISION x
i = "311"
x = DNUM(i)
```

**DO Directive**

*OpenMP* Fortran Compiler Directive: Specifies that the iterations of the immediately following DO loop must be executed in parallel.

**Syntax**

```
!$OMP DO [clause[, clause] ... ]  
do_loop  
[!$OMP END DO [NOWAIT]]
```

*clause*  
Is one of the following:

- ALLOCATE ([allocator :) list)
- COLLAPSE (n)
- FIRSTPRIVATE (list)
• **LASTPRIVATE ([CONDITIONAL:] list)**
• **LINEAR (var-list[: linear-step])**
• **ORDER (CONCURRENT)**

After iterations of the associated loops are assigned to their respective threads, the iterations of the loop may execute in any order or simultaneously. This feature is only available for ifx.

This clause cannot appear if an ORDERED clause also appears on the directive.

• **ORDERED [ (n) ]**

Must be used if ordered sections are contained in the dynamic extent of the DO directive. For more information about ordered sections, see the **ORDERED directive**.

If n is specified, it must be a positive scalar integer constant expression.

• **PRIVATE (list)**
• **REDUCTION (reduction-identifier : list)**
• **SCHEDULE ([modifier [, modifier]:] kind[, chunk_size])**

Specifies how iterations of the DO loop are divided among the threads of the team. chunk_size must be a loop invariant positive scalar integer expression. The value of chunk_size must be the same for all threads in the team. The following kinds are permitted, only some of which allow the optional parameter chunk_size:

<table>
<thead>
<tr>
<th>Kinds</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATIC</td>
<td>Divides iterations into contiguous pieces by dividing the number of iterations by the number of threads in the team. Each piece is then dispatched to a thread before loop execution begins. If chunk_size is specified, iterations are divided into pieces of a size specified by chunk_size. The pieces are statically dispatched to threads in the team in a round-robin fashion in the order of the thread number.</td>
</tr>
<tr>
<td>DYNAMIC</td>
<td>Can be used to get a set of iterations dynamically. It defaults to 1 unless chunk_size is specified. If chunk_size is specified, the iterations are broken into pieces of a size specified by chunk. As each thread finishes a piece of</td>
</tr>
</tbody>
</table>
Kinds | Effect
---|---
GUIDED | the iteration space, it dynamically gets the next set of iterations. Can be used to specify a minimum number of iterations. It defaults to 1 unless chunk_size is specified. If chunk_size is specified, the chunk size is reduced exponentially with each succeeding dispatch. The chunk_size specifies the minimum number of iterations to dispatch each time. If there are less than chunk_size iterations remaining, the rest are dispatched.
AUTO¹ | Delegates the scheduling decision until compile time or run time. The schedule is processor dependent. The programmer gives the implementation the freedom to choose any possible mapping of iterations to threads in the team.
RUNTIME¹ | Defers the scheduling decision until run time. You can choose a schedule type and chunk size at run time by using the environment variable OMP_SCHEDULE.

¹No chunk_size is permitted for this type.

At most one SCHEDULE clause can appear. If the SCHEDULE clause is not used, the default schedule type is STATIC.

modifier can be one of the following:

Modifier | Effect
---|---
MONOTONIC | Each thread executes the chunks that it is assigned in increasing logical iteration order.
NONMONOTONIC¹ | Chunks are assigned to threads in any order and the behavior of an application that depends on any execution order of the chunks is unspecified.
### Modifier | Effect
--- | ---
SIMD | When `do_loop` is associated with an OMP SIMD construct, the `chunk_size` for all chunks except the first and last chunks is:

\[
\text{new\_chunk\_size} = (\text{chunk\_size} / \text{simd\_width}) * \text{simd\_width}
\]

where `simd\_width` is an implementation-defined value. The first chunk will have at least `new\_chunk\_size` iterations unless it is also the last chunk. The last chunk may have fewer iterations than `new\_chunk\_size`. If SIMD is specified and the loop is not associated with an OMP SIMD construct, the modifier is ignored.

1NONMONOTONIC can only be specified with SCHEDULE(DYNAMIC) or SCHEDULE(GUIDED).

If the schedule kind is STATIC or if the ORDERED clause appears, and if MONOTONIC does not appear, the effect will be as if MONOTONIC was specified. NONMONOTONIC cannot be specified if the ORDERED clause appears. Either MONOTONIC or NONMONOTONIC can appear but not both.

`modifier` cannot appear if the LINEAR clause appears.

The SIMD `modifier` can be used with MONOTONIC or NONMONOTONIC in either order. The SIMD `modifier` and the MONOTONIC `modifier` can be used with all `kinds`.

`do_loop` is a DO iteration (an iterative DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO directive.

The binding thread set for a DO construct is the current team. A DO loop region binds to the innermost enclosing parallel region.

If used, the END DO directive must appear immediately after the end of the loop. If you do not specify an END DO directive, an END DO directive is assumed at the end of the DO loop.

If you specify NOWAIT in the END DO directive, threads do not synchronize at the end of the parallel loop. Threads that finish early proceed straight to the instruction following the loop without waiting for the other members of the team to finish the DO directive.
Parallel DO loop control variables are block-level entities within the DO loop. If the loop control variable also appears in the LASTPRIVATE list of the parallel DO, it is copied out to a variable of the same name in the enclosing PARALLEL region. The variable in the enclosing PARALLEL region must be SHARED if it is specified in the LASTPRIVATE list of a DO directive.

Only a single SCHEDULE, COLLAPSE, or ORDERED clause can appear in a DO directive.

ORDERED (n) specifies how many loops are associated with the DO directive and it specifies that those associated loops form a doacross loop nest. n does not affect how the logical iteration space is divided.

If you specify COLLAPSE (M) ORDERED (N) for loops nested K deep, the following rules apply:
- If either M > K or N > K, the behavior is unspecified.
- N must be greater than M.

A LINEAR clause or an ORDERED (n) clause can be specified on a DO directive but not both.

DO directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.

Example
In the following example, the loop iteration variable is private by default, and it is not necessary to explicitly declare it. The END DO directive is optional:

```fortran
!$OMP PARALLEL
!$OMP DO
  DO I=1,N
    B(I) = (A(I) + A(I-1)) / 2.0
  END DO
!$OMP END DO
!$OMP END PARALLEL
```

If there are multiple independent loops within a parallel region, you can use the NOWAIT option to avoid the implied BARRIER at the end of the DO directive, as follows:

```fortran
!$OMP PARALLEL
!$OMP DO
  DO I=2,N
    B(I) = (A(I) + A(I-1)) / 2.0
  END DO
!$OMP END DO NOWAIT
!$OMP DO
  DO I=1,M
    Y(I) = SQRT(Z(I))
  END DO
!$OMP END DO NOWAIT
!$OMP END PARALLEL
```

Correct execution sometimes depends on the value that the last iteration of a loop assigns to a variable. Such programs must list all such variables as arguments to a LASTPRIVATE clause so that the values of the variables are the same as when the loop is executed sequentially, as follows:

```fortran
!$OMP PARALLEL
!$OMP DO LASTPRIVATE(I)
  DO I=1,N
    A(I) = B(I) + C(I)
  END DO
!$OMP END PARALLEL
CALL REVERSE(I)
```

In this case, the value of I at the end of the parallel region equals N+1, as in the sequential case.
Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
DO I=LB,UB,ST
   CALL WORK(I)
...  
SUBROUTINE WORK(K)
   !$OMP ORDERED
   WRITE(*,*) K
   !$OMP END ORDERED

In the next example, the loops over J1 and J2 are collapsed and their iteration space is executed by all threads of the current team:

```fortran
!$OMP DO COLLAPSE(2) PRIVATE(J1, J2, J3)
  DO J1 = J1_L, J1_U, J1_S
    DO J2 = J2_L, J2_U, J2_S
      DO J3 = J3_L, J3_U, J3_S
        CALL BAR(A, J1, J2, J3)
      ENDDO
    ENDDO
  ENDDO
!$OMP END DO
```

**DO Statement**

Statement: Marks the beginning of a DO construct. The DO construct controls the repeated execution of a block of statements or constructs. This repeated execution is called a loop.

Syntax

A DO construct takes one of the following forms:

**Block Form:**

```
[name:] DO [label[, ] ] [loop-control]
    block
[label] term-stmt
```

**Non-block Form:**

```
DO label [,] [loop-control]
    block
[label] ex-term-stmt
```

(name) (Optional) Is the name of the DO construct.

(label) (Optional) Is a statement label identifying the terminal statement.
**loop-control**

Is one of the following:

- a loop iteration (see Iteration Loop Control)
- WHILE (see the DO WHILE statement)
- CONCURRENT (see the DO CONCURRENT statement)

**block**

Is a sequence of zero or more statements or constructs that make up the DO range.

**term-stmt**

Is the terminal statement for the block form of the construct.

**ex-term-stmt**

Is the terminal statement for the non-block form of the construct.

**Description**

The terminal statement (*term-stmt*) for a block DO construct is an END DO or CONTINUE statement. If the block DO statement contains a label, the terminal statement must be identified with the same label. If no label appears, the terminal statement must be an END DO statement.

If a construct name is specified in a block DO statement, the same name must appear in the terminal END DO statement. If no construct name is specified in the block DO statement, no name can appear in the terminal END DO statement.

The terminal statement (*ex-term-stmt*) for a non-block DO construct is an executable statement (or construct) that is identified by the label specified in the non-block DO statement. A non-block DO construct can share a terminal statement with another non-block DO construct. A block DO construct cannot share a terminal statement.

The following cannot be terminal statements for non-block DO constructs:

- CONTINUE (allowed if it is a shared terminal statement)
- CYCLE
- END (for a program or subprogram)
- EXIT
- GO TO (unconditional or assigned)
- Arithmetic IF
- RETURN
- STOP

The labeled form of a DO loop is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following example shows a simple block DO construct (contains no iteration count or DO WHILE statement):

```
DO
  READ *, N
  IF (N == 0) STOP
  CALL SUBN
END DO
```

The DO block executes repeatedly until the value of zero is read. Then the DO construct terminates.

The following example shows a named block DO construct:

```
LOOP_1: DO I = 1, N
  A(I) = C * B(I)
END DO LOOP_1
```
The following example shows a nonblock DO construct with a shared terminal statement:

```
DO 20 I = 1, N
DO 20 J = 1 + I, N
20 RESULT(I,J) = 1.0 / REAL(I + J)
```

The following two program fragments are also examples of DO statements:

```
C   Initialize the even elements of a 20-element real array
DIMENSION array(20)
DO j = 2, 20, 2
   array(j) = 12.0
END DO
C
C   Perform a function 11 times
DO k = -30, -60, -3
   int = j / 3
   isb = -9 - k
   array(isb) = MyFunc (int)
END DO
```

The following shows the final value of a DO variable (in this case 11):

```
DO j = 1, 10
   WRITE (*, '(I5)') j
END DO
WRITE (*, '(I5)') j
```

Execution Control

**DO CONCURRENT**

**Statement:** Specifies that there are no data dependencies between the iterations of a DO loop.

**Syntax**

The DO CONCURRENT statement takes the following form:

```
[name:] DO [label [,]] CONCURRENT concurrent-header [locality-spec]
   block
[END DO [name]]
```

- **name**
  (Optional) Is the name of the DO CONCURRENT construct.
- **concurrent-header**
  Is (**type** :: **concurrent-spec**, **mask-expr**) where:
  - **type**
    (Optional) Is an integer data type.
  - **concurrent-spec**

---

Intel® Fortran Compiler Classic and Intel® Fortran Compiler Developer Guide and Reference
**index-name**

Is a named scalar variable of type integer. It becomes defined when the index-name value set is evaluated. It has the scope of the construct.

**concurrent-limit**

Is a scalar integer expression.

**concurrent-step**

(Optional) Is a scalar integer expression.

**mask-expr**

(Optional) Is a masked expression that is scalar and of type logical.

Any procedure referenced in mask-expr must be pure, including one referenced by a defined operator. index-name can appear in mask-expr. The set of index values to be executed is the set of all index-name values for which mask-expr is true.

**label**

(Optional) Is a label specifying an executable statement in the same program unit.

**locality-spec**

(Optional) Can be any of the following:

- LOCAL (variable-name-list)
- LOCAL_INIT (variable-name-list)
- SHARED (variable-name-list)
- DEFAULT (NONE)

You can specify DEFAULT (NONE) only once in a DO CONCURRENT statement. If specified, any variable or construct entity that is accessible in the scope containing the DO CONCURRENT statement that appears in the block of the DO CONCURRENT construct must have its locality explicitly specified.

You can specify LOCAL, LOCAL_INIT, SHARED, and DEFAULT (NONE) in the same DO CONCURRENT statement.

You can specify more than one of the following in the same DO CONCURRENT statement: LOCAL, LOCAL_INIT, and SHARED.

The following are rules for variable-name in a locality-spec:

- A variable-name must be the name of a variable that is accessible in the innermost construct containing the DO CONCURRENT statement. variable-name can appear at most once in any locality-spec of a DO CONCURRENT statement. It cannot be the same as index-name of the same DO CONCURRENT statement.
- A variable-name in a LOCAL or LOCAL_INIT locality-spec cannot have the OPTIONAL, ALLOCATABLE, or INTENT(IN) attribute, it cannot be a non-pointer polymorphic dummy argument, a coarray or an assumed-size array, or be of a type that is finalizable.
- variable-name is not permitted in a LOCAL or LOCAL_INIT locality-spec if it is not permitted in a variable-definition context.

**block**

Is a sequence of zero or more statements or constructs that make up the DO range.

A variable that appears in a mask-expr, concurrent-step, or concurrent-limit of a concurrent-header, cannot appear in a LOCAL locality-spec in the same DO CONCURRENT statement.

If a construct name is specified in a DO CONCURRENT statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO CONCURRENT statement, no name can appear in the terminal END DO statement, if one is specified.
See the **DO statement** for the semantics of labeled and block forms of DO loops.

The **DO CONCURRENT** range is executed for every active combination of the *index-name* values.

Each execution of the range is an iteration. The executions can occur in any order.

If **END DO** is specified, it terminates the construct. If **END DO** is not specified, when all of the iterations have completed execution, the loop terminates, and the **DO** construct becomes inactive. You can branch to the **END DO** statement only from within the construct.

When the **DO CONCURRENT** construct terminates, a variable that is defined or becomes undefined during more than one iteration of the construct becomes undefined.

Execution of a **CYCLE** statement that belongs to a **DO CONCURRENT** construct completes execution of that iteration of the construct.

A branch within a **DO CONCURRENT** construct must not have a branch target that is outside the construct.

If **type** appears, the *index-name* has the specified type and type parameters. Otherwise, it has the type and type parameters that it would have if it were the name of a variable in the innermost executable construct or scoping unit.

If **type** does not appear, the *index-name* must not be the same as a local identifier, an accessible global identifier, or an identifier of an outer construct entity, except for a common block name or a scalar variable name.

The *index-name* of a contained **FORALL** or **DO CONCURRENT** construct must not be the same as an *index-name* of any of its containing **FORALL** or **DO CONCURRENT** constructs.

The following cannot appear in a **DO CONCURRENT** construct:

- A **RETURN** statement
- An image control statement
- A branch to a target outside the construct block
- A statement that may result in the deallocation of a polymorphic variable
- An input/output statement with an **ADVANCE**= specifier
- A reference to a nonpure procedure
- A reference to module **IEEE_EXCEPTIONS** procedure **IEEE_GET_FLAG**, **IEEE_SET_HALTING_MODE**, or **IEEE_GET_HALTING_MODE**

An **EXIT** statement must not appear within a **DO CONCURRENT** construct if it belongs to that construct or an outer construct.

A construct or statement entity with the **SAVE** attribute and with unspecified locality in a **DO CONCURRENT** construct has **SHARED** locality. If it does not have the **SAVE** attribute, it is a different entity in each iteration of the construct.

A variable with **LOCAL** or **LOCAL_INIT** locality is a construct entity with the same type, type parameters, and rank as variable with the same name in the innermost construct or scope containing the **DO CONCURRENT** construct. The variable outside the construct is inaccessible by that name inside the **DO CONCURRENT** construct. The construct entity does not have the **BIND**, **SAVE**, **VALUE**, **PROTECTED**, or **INTENT** attribute, even if the variable with the same name outside the construct has the attribute. The construct entity does have the **VOLATILE**, **CONTIGUOUS**, **POINTER**, **TARGET** or **ASYCHRONOUS** attribute if the variable outside the construct with the same name has the attribute. If it is a non-pointer, it has the same bounds as the variable outside the construct.

At the beginning of each iteration, a variable with **LOCAL** locality that is a pointer has pointer association status of undefined; otherwise, it is undefined except for any subobjects that are default initialized. A variable with **LOCAL_INIT** locality has the definition status and pointer association status of the variable outside the construct. The variable outside the construct cannot be an undefined nonallocatable nonpointer variable, or an undefined pointer.
A pointer that becomes associated with a LOCAL or LOCAL_INIT TARGET variable becomes undefined at the end of the iteration. If a LOCAL or LOCAL_INIT variable appears in an input/output statement, the input/output operation must complete before the iteration completes.

References in a DO CONCURRENT construct to a SHARED variable are references to the variable in the innermost construct or scope containing the DO CONCURRENT construct. If the variable is defined or becomes undefined in one iteration, it cannot be referenced, defined, or become undefined in another iteration. If it becomes pointer assigned, allocated, deallocated, or nullified in an iteration, its dynamic type, allocation or allocations status, shape, bounds, or a deferred-type parameter cannot be inquired about in another iteration. A SHARED noncontiguous array cannot be an actual argument associated with a contiguous INTENT(INOUT) dummy argument.

The following are rules for variables with unspecified locality in DO CONCURRENT constructs:

- A variable that is referenced in an iteration must be previously defined during that iteration, or it must not be defined or become undefined during any other iteration.
  A variable that is defined or becomes undefined by more than one iteration becomes undefined when the loop terminates.
- An allocatable object that is allocated in more than one iteration must be subsequently deallocated during the same iteration in which it was allocated.
  An object that is allocated or deallocated in only one iteration must not be referenced, allocated, deallocated, defined, or become undefined in a different iteration.
- A pointer that is referenced in an iteration must have been pointer associated previously during that iteration, or it must not have its pointer association changed during any iteration.
  A pointer that has its pointer association changed in more than one iteration has an association status of undefined when the construct terminates.
- An input/output statement must not write data to a file record or position in one iteration and read from the same record or position in a different iteration.
- Records written by output statements in the range of the loop to a sequential-access file appear in the file in an indeterminate order.

The restrictions on referencing variables defined in an iteration of a DO CONCURRENT construct also apply to any procedure invoked within the loop.

These restrictions ensure no interdependencies occur that might affect code optimizations.

Note that if compiler option `-qopenmp` (Linux* and macOS*) or `/Qopenmp` (Windows*) is specified, the compiler will attempt to parallelize the construct.

The labeled form of a DO CONCURRENT loop is an obsolescent feature in the Fortran Standard.

**Example**

The following shows a DO CONCURRENT construct with a `mask-expr` and locality specified for variables:

```fortran
INTEGER,DIMENSION(N) :: J, K
INTEGER              :: I, M
M = 10
I = 15
DO CONCURRENT (I = 1:N, J(I) > 0) LOCAL (M) SHARED (J, K)
   M = MOD (K(I), J(I))
   K(I) = K(I) - M
END DO
PRINT *, I, M             ! Prints 15 10
```

**Language Reference**

1431
DO SIMD

OpenMP* Fortran Compiler Directive: Specifies that the iterations of the loop will be distributed across threads in the team. Iterations executed by each thread can also be executed concurrently using SIMD instructions.

Syntax

```fortran
!$OMP DO SIMD [clause[, clause] ... ]
   do-loop
   [!$OMP END DO SIMD[NOWAIT]]
```

- `clause`: Can be any of the clauses accepted by the DO or SIMD directives.
- `do-loop`: Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.
- All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.
- The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.
- You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END DO SIMD directive is not specified, an END DO SIMD directive is assumed at the end of `do-loop`.

You can specify the NOWAIT clause to avoid the implied barrier at the end of a loop construct.

The DO SIMD construct converts the associated DO loop to a SIMD loop in a way that is consistent with any clauses that apply to the SIMD construct. The resulting SIMD chunks and any remaining iterations will be distributed across the implicit tasks of the parallel region in a way that is consistent with any clauses that apply to the DO construct.

This directive specifies a composite construct.

Syntax Rules for Compiler Directives

DO WHILE

Statement: Executes the range of a DO construct while a specified condition remains true.

Syntax

```fortran
[name:] DO [label[, ]] WHILE (expr)
   block
   [END DO [name]]
```
name
(Optional) Is the name of the DO WHILE construct.

label
(Optional) Is a label specifying an executable statement in the same program unit.

eexpr
Is a scalar logical (test) expression enclosed in parentheses.

block
Is a sequence of zero or more statements or constructs that make up the DO range.

Description
If a construct name is specified in a DO WHILE statement, the same name must appear in a terminal END DO statement. If no construct name is specified in the DO WHILE statement, no name can appear in the terminal END DO statement, if one is specified.

Before each execution of the DO range, the logical expression is evaluated. If it is true, the statements in the body of the loop are executed. If it is false, the DO construct terminates and control transfers to the statement following the loop.

If END DO is specified, it terminates the construct. If END DO is not specified, when all of the iterations have completed execution, the loop terminates, and the DO construct becomes inactive.

If no label appears in a DO WHILE statement, the DO WHILE loop must be terminated with an END DO statement. See the description of the DO statement for the semantics of labeled and block forms of DO loops.

You can transfer control out of a DO WHILE loop but not into a loop from elsewhere in the program.

Terminating a DO WHILE loop with an executable statement other than a DO WHILE or a CONTINUE statement is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The labeled form of a DO WHILE loop is an obsolescent feature in the Fortran Standard.

Example
The following example shows a DO WHILE statement:

```fortran
CHARACTER*132 LINE
...
I = 1
DO WHILE (LINE(I:I) .EQ. ' ')
   I = I + 1
END DO
```

The following examples show required and optional END DO statements:

<table>
<thead>
<tr>
<th>Required</th>
<th>Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>DO WHILE (I .GT. J)</td>
<td>DO 10 WHILE (I .GT. J)</td>
</tr>
<tr>
<td>ARRAY(I,J) = 1.0</td>
<td>ARRAY(I,J) = 1.0</td>
</tr>
<tr>
<td>I = I - 1</td>
<td>I = I - 1</td>
</tr>
<tr>
<td>END DO</td>
<td>10 END DO</td>
</tr>
</tbody>
</table>

The following shows another example:

```fortran
CHARACTER(1) input
input = ''
DO WHILE ((input .NE. 'n') .AND. (input .NE. 'y'))
   WRITE (*, '('A')') 'Enter y or n: '
   READ (*, '('A')') input
END DO
```
DOT_PRODUCT
Transformational Intrinsic Function (Generic):
Performs dot-product multiplication of numeric or logical vectors (rank-one arrays).

Syntax

result = DOT_PRODUCT (vector_a, vector_b)

vector_a (Input) Must be a rank-one array of numeric (integer, real, or complex) or logical type.

vector_b (Input) Must be a rank-one array of numeric type if vector_a is of numeric type, or of logical type if vector_a is of logical type. It must be the same size as vector_a.

Results
The result is a scalar whose type depends on the types of vector_a and vector_b. If vector_a is of type integer or real, the result value is SUM (vector_a* vector_b). If vector_a is of type complex, the result value is SUM (CONJG (vector_a)* vector_b). If vector_a is of type logical, the result has the value ANY (vector_a.AND. vector_b). If either rank-one array has size zero, the result is zero if the array is of numeric type, and false if the array is of logical type.

Example

DOT_PRODUCT ((/1, 2, 3/), (/3, 4, 5/)) has the value 26, calculated as follows:

((1 x 3) + (2 x 4) + (3 x 5)) = 26

DOT_PRODUCT ((/ (1.0, 2.0), (2.0, 3.0) /), (/ (1.0, 1.0), (1.0, 4.0) /)) has the value (17.0, 4.0).

DOT_PRODUCT ((/ .TRUE., .FALSE. /), (/ .FALSE., .TRUE. /)) has the value false.

The following shows another example:

I = DOT_PRODUCT((/1,2,3/), (/4,5,6/)) ! returns the value 32

PRODUCT
MATMUL
TRANSPOSE

DOUBLE COMPLEX
Statement: Specifies the DOUBLE COMPLEX data type.
Syntax

DOUBLE COMPLEX

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(KIND=8) or DOUBLE COMPLEX constants. (For more information, see REAL and DOUBLE PRECISION.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE* binary64 format.

Example

DOUBLE COMPLEX vector, arrays(7,29)
DOUBLE COMPLEX pi, pi2 /3.141592654,6.283185308/

Valid COMPLEX(8) or DOUBLE COMPLEX constants

(547.3E0_8,-1.44_8)
(1.7039E0,-1.7039D0)
(+12739D3,0.D0)

Invalid COMPLEX(8) or DOUBLE COMPLEX constants

(1.23D0,) Second constant missing.
(1D1,2H12) Hollerith constants not allowed.
(1,1.2) Neither constant is DOUBLE PRECISION; this is a valid single-precision real constant.

See Also

General Rules for Complex Constants
COMPLEX Statement
Complex Data Types
DOUBLE PRECISION
REAL

DOUBLE PRECISION

Statement: Specifies the DOUBLE PRECISION data type.

Syntax

DOUBLE PRECISION

A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.

A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.

IEEE* binary64 format is used.
For more information, see General Rules for Real Constants.

**Example**

```fortran
DOUBLE PRECISION varnam
DOUBLE PRECISION,PRIVATE :: zz
```

**Valid REAL(8) or DOUBLE PRECISION constants**

- 123456789D+5
- 123456789E+5_8
- +2.7843D00
- -.522D-12
- 2E200_8
- 2.3_8
- 3.4E7_8

**Invalid REAL(8) or DOUBLE PRECISION constants**

- -.25D0_2
- +2.7182812846182
- 123456789.D400
- 123456789.D-400

2 is not a valid kind type for reals.
No D exponent designator is present; this is a valid single-precision constant.
Too large for any double-precision format.
Too small for any double-precision format.

**See Also**

- REAL Statement
- REAL(8) or DOUBLE PRECISION Constants
- Data Types, Constants, and Variables
- Real Data Types

**DPROD**

*Elemental Intrinsic Function (Specific):* Produces a higher precision product. This is a specific function that has no generic function associated with it.

**Syntax**

```fortran
result = DPROD (x, y)
```

- `x` (Input) Must be of type REAL(4) or REAL(8).
- `y` (Input) Must have the same type and kind parameters as `x`.

**Results**

If `x` and `y` are of type REAL(4), the result type is double-precision real (REAL(8) or REAL*8). If `x` and `y` are of type REAL(8), the result type is REAL(16). The result value is equal to `x`* `y`.

The setting of compiler options specifying real size can affect this function.
Example

DPROD (2.0, -4.0) has the value -8.00D0.
DPROD (5.0D0, 3.0D0) has the value 15.00Q0.
The following shows another example:

```fortran
REAL(4) e
REAL(8) d
  e = 123456.7
  d = 123456.7D0
  ! DPROD (e,e) returns 15241557546.4944
  ! DPROD (d,d) returns 15241556774.8899992813874268904328
```

**DRAND, DRANDM**

*Portability Functions:* Return double-precision random numbers in the range 0.0 to 1.0, not including the end points.

**Module**

USE IFPORT

**Syntax**

result = DRAND (iflag)
result = DRANDM (iflag)

`iflag`  
*(Input)* INTEGER(4). Controls the way the random number is selected.

**Results**

The result type is REAL(8). DRAND and DRANDM return random numbers in the range 0.0 to 1.0, not including the end points.

<table>
<thead>
<tr>
<th>Value of <code>iflag</code></th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using <code>iflag</code>, then restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

There is no difference between DRAND and DRANDM. Both functions are included to insure portability of existing code that references one or both of them.

The intrinsic subroutines RANDOM_INIT, RANDOM_NUMBER, and RANDOM_SEED provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

Example

```fortran
USE IFPORT
REAL(8) num
INTEGER(4) f
f=1
```
CALL print_rand
f=0
CALL print_rand
f=22
CALL print_rand
CONTAINS
  SUBROUTINE print_rand
    num = drand(f)
    print *, 'f= ',f,',':',num
  END SUBROUTINE
END

See Also
RANDOM_INIT
RANDOM_NUMBER
RANDOM_SEED

DRANSET
Portability Subroutine: Sets the seed for the random number generator.

Module
USE IFPORT

Syntax
CALL DRANSET (seed)

seed  (Input) REAL(8). The reset value for the seed.

See Also
RANGET

DREAL
Elemental Intrinsic Function (Specific): Converts the real part of a double complex argument to double-precision type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
result = DREAL (a)

a  (Input) Must be of type double complex (COMPLEX(8) or COMPLEX*16).

Results
The result type is double precision real (REAL(8) or REAL*8).

Example
DREAL ((2.0d0, 3.0d0)) has the value 2.0d0.
See Also

REAL

DSHIFTL

**Elemental Intrinsic Function (Specific):** Selects the left 64 bits after shifting a 128-bit integer value to the left. This function cannot be passed as an actual argument.

**Syntax**

```fortran
result = DSHIFTL (i, j, shift)
```

- **i**
  
  (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

- **j**
  
  (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

  If both i and j are of type integer, they must have the same kind type parameter. i and j must not both be binary, octal, or hexadecimal literal constants.

- **shift**
  
  (Input) Integer. Must be nonnegative and less than or equal to 64. This is the shift count.

**Results**

The result type is integer. The result value is the 64-bit value starting at bit 128 - shift of the 128-bit concatenation of the values of i and j.

If either i or j is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other. The rightmost shift bits of the result value are the same as the leftmost bits of i, and the remaining bits of the result value are the same as the rightmost bits of j. This is equal to IOR (SHIFTL (I, SHIFT), SHIFTR (J, BIT SIZE (J) - SHIFT)).

**Example**

Consider the following:

```fortran
INTEGER(8) ILEFT / Z'111122221111222' /  
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFF' /  
PRINT *, DSHIFTL (ILEFT, IRIGHT, 16_8) ! prints 1306643199093243919
```

See Also

- Binary, Octal, Hexadecimal, and Hollerith Constants
- Model for Bit Data

**DSHIFTR**

**Elemental Intrinsic Function (Specific):** Selects the left 64 bits after shifting a 128-bit integer value to the right. This function cannot be passed as an actual argument.

**Syntax**

```fortran
result = DSHIFTR (i, j, shift)
```

This is the shift count.
\( i \) (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

\( j \) (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

\( shift \) (Input) Integer. Must be nonnegative and less than or equal to 64. This is the shift count.

**Results**

The result type is integer. The result value is the 64-bit value starting at bit 64 + \( shift \) of the 128-bit concatenation of the values of \( i \) and \( j \).

If either \( i \) or \( j \) is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other. The leftmost \( shift \) bits of the result value are the same as the rightmost bits of \( i \), and the remaining bits of the result value are the same as the leftmost bits of \( j \). This is equal to IOR (SHIFTL (I, BIT SIZE (I) - \( shift \)), SHIFTR (J, \( shift \)).

**Example**

Consider the following:

```
INTEGER(8) ILEFT / Z'111122221111222' /
INTEGER(8) IRIGHT / Z'FFFFFFFFFFFFF' /
PRINT *, DSHIFTR (ILEFT, IRIGHT, 16_8)  ! prints 1306606910610341887
```

Binary, Octal, Hexadecimal, and Hollerith Constants

Model for Bit Data

**DTIME**

*Portability Function: Returns the elapsed CPU time since the start of program execution when first called, and the elapsed execution time since the last call to DTIME thereafter.*

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{DTIME} \ (\text{tarray})
\]

\( \text{tarray} \) (Output) REAL(4). A rank one array with two elements:

- \( \text{tarray}(1) \) - Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code.
- \( \text{tarray}(2) \) - Elapsed system time, which is time spent executing privileged code (code in the Windows Executive).

**Results**

The result type is REAL(4). The result is the total CPU time, which is the sum of \( \text{tarray}(1) \) and \( \text{tarray}(2) \). If an error occurs, -1 is returned.
Example

USE IFPORT
REAL(4) I, TA(2)
I = DTIME(TA)
write(*,*) 'Program has been running for', I, 'seconds.'
write(*,*) ' This includes', TA(1), 'seconds of user time and', &
 & TA(2), 'seconds of system time.'

E to F

This section describes language features that start with E or F.

E to F

ELEMENTAL

Keyword: Asserts that a user-defined procedure is defined on scalar arguments that may be called with array arguments. An elemental procedure may be a pure procedure or an impure procedure. An elemental procedure is an elemental intrinsic procedure, an intrinsic module procedure that is specified to be elemental, a user-defined procedure that is specified to be elemental, or a type-bound procedure that is bound to an elemental procedure. A procedure pointer or a dummy procedure can not be specified to be elemental.

Description

To specify an elemental procedure, use this keyword in a FUNCTION or SUBROUTINE statement. An explicit interface must be visible to the caller of an ELEMENTAL procedure.

An elemental procedure can be passed an array, which is acted upon one element at a time.

For functions, the result must be scalar; it cannot have the POINTER or ALLOCATABLE attribute.

Dummy arguments in ELEMENTAL procedures may appear in specification expressions in the procedure.

Dummy arguments have the following restrictions:

- They must be scalar.
- They cannot have the POINTER or ALLOCATABLE attribute.
- They cannot be an alternate return specifier (*).
- They cannot be dummy procedures.

If the actual arguments are all scalar, the result is scalar. If the actual arguments are array valued, the values of the elements (if any) of the result are the same as if the function or subroutine had been applied separately, in any order, to corresponding elements of each array actual argument.

Elemental procedures are pure procedures and all rules that apply to pure procedures also apply to elemental procedures, unless you specify that the elemental procedure is IMPURE. In that case, the rules for pure procedures do not apply.
**Example**

Consider the following:

```
MIN (A, 0, B)                ! A and B are arrays of shape (S, T)
```

In this case, the elemental reference to the MIN intrinsic function is an array expression whose elements have the following values:

```
MIN (A(I,J), 0, B(I,J)), I = 1, 2, ..., S, J = 1, 2, ..., T
```

Consider the following example:

```
ELEMENTAL REAL FUNCTION F (A, B, ORDER)
REAL, INTENT (IN) :: A, B
INTEGER, INTENT (IN) :: ORDER
REAL :: TEMP (ORDER)
```

In the above, the size of TEMP depends on the specification expression that is the value of the ORDER dummy argument.

**ELSE Directive**

**Statement:** Marks an optional branch in an IF Directive Construct.

**See Also**

See IF Directive Construct.

**ELSE Statement**

**Statement:** Marks an optional branch in an IF Construct.

**See Also**

See IF Construct.

**ELSEIF Directive**

**Statement:** Marks an optional branch in an IF Directive Construct.

**See Also**

See IF Directive Construct.

**ELSE IF**

**Statement:** Marks an optional branch in an IF Construct.

**See Also**

See IF Construct.
ELSE WHERE

Statement: Marks the beginning of an ELSE WHERE block within a WHERE construct.

Syntax

\[
\begin{align*}
\text{name:} & \text{WHERE (mask-expr1)} \\
& \quad \text{[where-body-stmt]}... \\
\text{ELSE WHERE(mask-expr2) [name]} \\
& \quad \text{[where-body-stmt]}...
\end{align*}
\]

\[
\begin{align*}
\text{ELSE WHERE[name]} \\
& \quad \text{[where-body-stmt]}...
\end{align*}
\]

END WHERE [name]

name

Is the name of the WHERE construct.

mask-expr1, mask-expr2

Are logical array expressions (called mask expressions).

where-body-stmt

Is one of the following:

- An assignment statement of the form: array variable = array expression.

  The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.

- A WHERE statement or construct

Description

Every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. mask-expr1". If ELSE WHERE specifies "mask-expr2", it is executed as "(.NOT. mask-expr1) .AND. mask-expr2" during the processing of the ELSE WHERE statement.

Example

```fortran
WHERE (pressure <= 1.0)
  pressure = pressure + inc_pressure
  temp = temp - 5.0
ELSEWHERE
  raining = .TRUE.
END WHERE
```

The variables temp, pressure, and raining are all arrays.

See Also
WHERE

ENCODE

Statement: Translates data from internal (binary) form to character form. It is comparable to using internal files in formatted sequential WRITE statements.
Syntax

ENCODE (c,f,b[, IOSTAT=i-var] [, ERR=label]) [io-list]

- **c**: Is a scalar integer expression. It is the number of characters to be translated to internal form.
- **f**: Is a format identifier. An error occurs if more than one record is specified.
- **b**: Is a scalar or array reference. If b is an array reference, its elements are processed in the order of subscript progression.
  - **b** contains the characters to be translated to internal form.
- **i-var**: Is a scalar integer variable that is defined as a positive integer if an error occurs and as zero if no error occurs (see I/O Status Specifier).
- **label**: Is the label of an executable statement that receives control if an error occurs.
- **io-list**: Is an I/O list. An I/O list is either an implied-DO list or a simple list of variables (except for assumed-size arrays). The list contains the data to be translated to character form.
  - The interaction between the format specifier and the I/O list is the same as for a formatted I/O statement.

The number of characters that the ENCODE statement can translate depends on the data type of b. For example, an INTEGER(2) array can contain two characters per element, so that the maximum number of characters is twice the number of elements in that array.

The maximum number of characters a character variable or character array element can contain is the length of the character variable or character array element.

The maximum number of characters a character array can contain is the length of each element multiplied by the number of elements.

Example

Consider the following:

```fortran
DIMENSION K(3)
CHARACTER*12 A,B
DATA A/'123456789012'/
DECODE(12,100,A) K
100 FORMAT(3I4)
ENCODE(12,100,B) K(3), K(2), K(1)
```

The DECODE statement stores the 12 characters into array K:

- \( K(1) = 1234 \)
- \( K(2) = 5678 \)
- \( K(3) = 9012 \)

The ENCODE statement translates the values \( K(3) \), \( K(2) \), and \( K(1) \) to character form and stores the characters in the character variable B.:

- \( B = '901256781234' \)

READ
WRITE
END

Statement: Marks the end of a program unit. It takes one of the following forms:

Syntax

END [PROGRAM [program-name]]
END [FUNCTION [function-name]]
END [SUBROUTINE [subroutine-name]]
END [MODULE [module-name]]
END [SUBMODULE [module-name]]
END [BLOCK DATA [block-data-name]]

In main programs, function subprograms, and subroutine subprograms, END statements are executable and can be branch target statements. If control reaches the END statement in these program units, the following occurs:

- In a main program, execution of the END statement initiates normal termination of the image that executes it.
- In a function or subroutine subprogram, a RETURN statement is implicitly executed.

The END statement cannot be continued in a program unit, and no other statement in the program unit can have an initial line that appears to be the program unit END statement.

The END statements in a module or block data program unit are nonexecutable.

Example

C   An END statement must be the last statement in a program unit:
C
PROGRAM MyProg
WRITE (*, '("Hello, world!")')
END

C   An example of a named subroutine
C
SUBROUTINE EXT1 (X,Y,Z)
   Real, Dimension (100,100) :: X, Y, Z
END SUBROUTINE EXT1

Program Units and Procedures
Branch Statements
Program Termination

END DO

Statement: Marks the end of a DO or DO WHILE loop.

Syntax

END DO
Description
There must be a matching END DO statement for every DO or DO WHILE statement that does not contain a label reference.

An END DO statement can terminate only one DO or DO WHILE statement. If you name the DO or DO WHILE statement, the END DO statement can specify the same name.

Example
The following examples both produce the same output:

```
DO ivar = 1, 10
   PRINT ivar
END DO
ivar = 0
do2: DO WHILE (ivar .LT. 10)
   ivar = ivar + 1
   PRINT ivar
END DO do2
```

See Also
DO
DO WHILE
CONTINUE

ENDIF Directive
**Statement:** Marks the end of an IF Directive Construct.

See Also
See IF Directive Construct.

END IF
**Statement:** Marks the end of an IF Construct.

See Also
See IF Construct.

ENDFILE
**Statement:** For sequential files, writes an end-of-file record to the file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.

**Syntax**
It can have either of the following forms:

```
ENDFILE ([UNIT=] io-unit[, ERR=label] [, IOMSG=msg-var] [, IOSTAT=i-var])
ENDFILE io-unit
```

*io-unit* (Input) Is an external unit specifier.
**label**  
Is the label of the branch target statement that receives control if an error occurs.

**msg-var**  
(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

**i-var**  
(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

**Description**

If the unit specified in the ENDFILE statement is not open, the default file is opened for unformatted output.

An end-of-file record can be written only to files with sequential organization that are accessed as formatted-sequential or unformatted-segmented sequential files. An ENDFILE performed on a direct access file always truncates the file.

End-of-file records should not be written in files that are read by programs written in a language other than Fortran.

**NOTE**
If you use compiler option vms and an ENDFILE is performed on a sequential unit, an actual one byte record containing a CTRL+Z is written to the file. If this option is not specified, an internal ENDFILE flag is set and the file is truncated. The option does not affect ENDFILE on relative files; such files are truncated.

If a parameter of the ENDFILE statement is an expression that calls a function, that function must not cause an I/O statement or the EOF intrinsic function to be executed, because unpredictable results can occur.

**Example**

The following statement writes an end-of-file record to I/O unit 2:

```
ENDFILE 2
```

Suppose the following statement is specified:

```
ENDFILE (UNIT=9, IOSTAT=IOS, ERR=10)
```

An end-of-file record is written to the file connected to unit 9. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable `IOS`.

The following shows another example:

```
WRITE (6, *) x
ENDFILE 6
REWIND 6
READ (6, *) y
```

Branch Specifiers
**END FORALL**

**Statement:** Marks the end of a FORALL construct. The FORALL construct is an obsolescent language feature in Fortran 2018.

**See Also**
See FORALL.

**END INTERFACE**

**Statement:** Marks the end of an INTERFACE block.

**See Also**
See INTERFACE.

**END TYPE**

**Statement:** Specifies the end of a derived type TYPE statement.

**See Also**
See TYPE Statement (Derived Types).

**END WHERE**

**Statement:** Marks the end of a WHERE construct.

**Example**

```fortran
WHERE (pressure <= 1.0)
  pressure = pressure + inc_pressure
  temp = temp - 5.0
ELSEWHERE
  raining = .TRUE.
END WHERE
```

Note that the variables temp, pressure, and raining are all arrays.

**See Also**
See WHERE.

**ENTRY**

**Statement:** Provides one or more entry points within a subprogram. It is not executable and must precede any CONTAINS statement (if any) within the subprogram.

**Syntax**

```fortran
ENTRY name[ ( [d-arg[,d-arg]...] ) [RESULT (r-name)] ]
```

*name* is the name of an entry point. If RESULT is specified, this entry name must not appear in any specification statement in the scoping unit of the function subprogram.
(Optional) Is a dummy argument. The dummy argument can be an alternate return indicator (*) if the ENTRY statement is within a subroutine subprogram.

r-name

(Optional) Is the name of a function result. This name must not be the same as the name of the entry point, or the name of any other function or function result. This parameter can only be specified for function subprograms.

Description

ENTRY statements can only appear in external procedures or module procedures.

An ENTRY statement must not appear in an executable construct.

When the ENTRY statement appears in a subroutine subprogram, it is referenced by a CALL statement. When the ENTRY statement appears in a function subprogram, it is referenced by a function reference.

An entry name within a function subprogram can appear in a type declaration statement.

Within the subprogram containing the ENTRY statement, the entry name must not appear as a dummy argument in the FUNCTION or SUBROUTINE statement, and it must not appear in an EXTERNAL or INTRINSIC statement. For example, neither of the following are valid:

```
(1)  SUBROUTINE SUB(E)
    ENTRY E
    ...

(2)  SUBROUTINE SUB
    EXTERNAL E
    ENTRY E
    ...
```

The procedure defined by an ENTRY statement can reference itself if the function or subroutine was defined as RECURSIVE.

Dummy arguments can be used in ENTRY statements even if they differ in order, number, type and kind parameters, and name from the dummy arguments used in the FUNCTION, SUBROUTINE, and other ENTRY statements in the same subprogram. However, each reference to a function, subroutine, or entry must use an actual argument list that agrees in order, number, and type with the dummy argument list in the corresponding FUNCTION, SUBROUTINE, or ENTRY statement.

Dummy arguments can be referred to only in executable statements that follow the first SUBROUTINE, FUNCTION, or ENTRY statement in which the dummy argument is specified. If a dummy argument is not currently associated with an actual argument, the dummy argument is undefined and cannot be referenced. Arguments do not retain their association from one reference of a subprogram to another.

Example

```
C  This fragment writes a message indicating whether num is positive or negative
   IF (num .GE. 0) THEN
      CALL Sign
   ELSE
      CALL Negative
   END IF
...
END
SUBROUTINE Sign
   WRITE (*, *) 'It''s positive.'
RETURN
```
ENTRY Negative
    WRITE (*, *) 'It''s negative.'
RETURN
END SUBROUTINE

Program Units and Procedures
ENTRY Statements in Function Subprograms
ENTRY Statements in Subroutine Subprograms

EOF

Inquiry Intrinsic Function (Generic): Checks whether a file is at or beyond the end-of-file record.

Syntax
result = EOF (unit)

unit (Input) Must be of type integer. It represents a unit specifier corresponding to an open file. It cannot be zero unless you have reconnected unit zero to a unit other than the screen or keyboard.

Results
The result type is default logical. The value of the result is .TRUE. if the file connected to unit is at or beyond the end-of-file record; otherwise, .FALSE..

Example
!
  Creates a file of random numbers, reads them back
    REAL x, total
    INTEGER count
    OPEN (1, FILE = 'TEST.DAT')
    DO I = 1, 20
      CALL RANDOM_NUMBER(x)
      WRITE (1, '(F6.3)') x * 100.0
    END DO
    CLOSE(1)
    OPEN (1, FILE = 'TEST.DAT')
    count = 0
    total = 0.0
    DO WHILE (.NOT. EOF(1))
      count = count + 1
      READ (1, *) value
      total = total + value
    END DO
  100 IF ( count .GT. 0) THEN
    WRITE (*,*) 'Average is: ', total / count
  ELSE
    WRITE (*,*) 'Input file is empty '
  END IF
  STOP
END

See Also
ENDFILE
READ Statement for details on an END specifier in a READ statement
Transformational Intrinsic Function (Generic):
Performs an end-off shift on a rank-one array, or performs end-off shifts on all the complete rank-one sections along a given dimension of an array of rank two or greater. Elements are shifted off at one end of a section and copies of a boundary value are filled in at the other end. Different sections can have different boundary values and can be shifted by different amounts and in different directions.

Syntax

\[
\text{result} = \text{EOSHIFT} \ (\text{array}, \text{shift} [, \text{boundary}] [, \text{dim}])
\]

**array**

(Input) Must be an array (of any data type).

**shift**

(Input) Must be a scalar integer or an array with a rank that is one less than \( \text{array} \), and shape \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\), where \((d_1, d_2, \ldots, d_n)\) is the shape of \( \text{array} \).

**boundary**

(Input; optional) Must have the same type and kind parameters as \( \text{array} \). It must be a scalar or an array with a rank that is one less than \( \text{array} \), and shape \((d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n)\). The boundary specifies a value to replace spaces left by the shifting procedure.

If \( \text{boundary} \) is not specified, it is assumed to have the following default values (depending on the data type of \( \text{array} \)):

<table>
<thead>
<tr>
<th>( \text{array Type} )</th>
<th>( \text{boundary Value} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>Integer</td>
<td>0</td>
</tr>
<tr>
<td>Real</td>
<td>0.0</td>
</tr>
<tr>
<td>Complex</td>
<td>((0.0, 0.0))</td>
</tr>
<tr>
<td>Logical</td>
<td>false</td>
</tr>
<tr>
<td>Character((\text{len}))</td>
<td>(\text{len blanks})</td>
</tr>
</tbody>
</table>

**dim**

(Input; optional) Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( \text{array} \). If \( \text{dim} \) is omitted, it is assumed to be 1.

Results

The result is an array with the same type and kind parameters, and shape as \( \text{array} \).

If \( \text{array} \) has rank one, the same shift is applied to each element. If an element is shifted off one end of the array, the boundary value is placed at the other end the array.

If \( \text{array} \) has rank greater than one, each section \((s_1, s_2, \ldots, s_{\text{dim}-1}, :, s_{\text{dim}+1}, \ldots, s_n)\) of the result is shifted as follows:

- By the value of \( \text{shift} \), if \( \text{shift} \) is scalar
• According to the corresponding value in $shift(s_1, s_2, \ldots, s_{dim-1}, s_{dim+1}, \ldots, s_n)$, if $shift$ is an array

If an element is shifted off one end of a section, the boundary value is placed at the other end of the section.

The value of $shift$ determines the amount and direction of the end-off shift. A positive $shift$ value causes a shift to the left (in rows) or up (in columns). A negative $shift$ value causes a shift to the right (in rows) or down (in columns).

**Example**

$V$ is the integer array $(1, 2, 3, 4, 5, 6)$.

$EOSHIFT (V, SHIFT=2)$ shifts the elements in $V$ to the left by 2 positions, producing the value $(3, 4, 5, 6, 0, 0)$. 1 and 2 are shifted off the beginning and two elements with the default BOUNDARY value are placed at the end.

$EOSHIFT (V, SHIFT=-3, BOUNDARY=99)$ shifts the elements in $V$ to the right by 3 positions, producing the value $(99, 99, 99, 1, 2, 3)$. 4, 5, and 6 are shifted off the end and three elements with BOUNDARY value 99 are placed at the beginning.

$M$ is the CHARACTER(LEN=1) array

```
[ 1  2  3 ]
[ 4  5  6 ]
[ 7  8  9 ].
```

$EOSHIFT (M, SHIFT = 1, BOUNDARY = '*', DIM = 2)$ produces the result

```
[ 2  3  * ]
[ 5  6  * ]
[ 8  9  * ].
```

Each element in rows 1, 2, and 3 is shifted to the left by 1 position. This causes the first element in each row to be shifted off the beginning, and the BOUNDARY value to be placed at the end.

$EOSHIFT (M, SHIFT = -1, DIM = 1)$ produces the result

```
[ ^  ^  ^ ]
[ 1  2  3 ]
[ 4  5  6 ].
```

Each element in columns 1, 2, and 3 is shifted down by 1 position. This causes the last element in each column to be shifted off the end and the BOUNDARY value (the default character boundary value <space>, represented by "^") to be placed at the beginning.

$EOSHIFT (M, SHIFT = (/1, -1, 0/), BOUNDARY = (/ '*', '?', '/' /), DIM = 2)$ produces the result

```
[ 2  3  * ]
[  ?  4  5 ]
[ 7  8  9 ].
```

Each element in row 1 is shifted to the left by 1 position, causing the first element to be shifted off the beginning and the BOUNDARY value * to be placed at the end. Each element in row 2 is shifted to the right by 1 position, causing the last element to be shifted off the end and the BOUNDARY value ? to be placed at the beginning. No element in row 3 is shifted at all, so the specified BOUNDARY value is not used.

The following shows another example:

```
INTEGER shift(3)
CHARACTER(1) array(3, 3), AR1(3, 3)
array = RESHAPE ([['A', 'D', 'G', 'B', 'E', 'H', 'C', 'F', 'I']], ([3,3]))
! array is A B C
!     D E F
```
shift = (-1, 1, 0/)
AR1 = EOSHIFT (array, shift, BOUNDARY = (/*','?','#'/), DIM= 2)
! returns         * A B
!                 E F ?
!                 G H I

TRANSPOSE

**EPSILON**

*Inquiry Intrinsic Function (Generic):* Returns a positive model number that is almost negligible compared to unity in the model representing real numbers.

**Syntax**

```
result = EPSILON (x)
```

*x*  
(Input) Must be of type real; it can be scalar or array valued.

**Results**

The result is a scalar of the same type and kind parameters as *x*. The result has the value $b^{1-p}$. Parameters $b$ and $p$ are defined in Model for Real Data.

EPSILON makes it easy to select a *delta* for algorithms (such as root locators) that search until the calculation is within *delta* of an estimate. If *delta* is too small (smaller than the decimal resolution of the data type), the algorithm might never halt. By scaling the value returned by EPSILON to the estimate, you obtain a *delta* that ensures search termination.

**Example**

If *x* is of type REAL(4), EPSILON (*X*) has the value $2^{-23}$.

PRECISION
TINY

Data Representation Models

**EQUIVALENCE**

*Statement:* Specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area. EQUIVALENCE is an obsolescent language feature in Standard Fortran.

**Syntax**

```
EQUIVALENCE (equiv-list) [, (equiv-list)]...
```
equiv-list

Is a list of two or more variable names, array elements, or substrings, separated by commas (also called an equivalence set). If an object of derived type is specified, it must be a sequence type. Objects cannot have the TARGET attribute. Each expression in a subscript or a substring reference must be an integer constant expression. A substring must not have a length of zero.

Description

The following objects cannot be specified in EQUIVALENCE statements:

- A dummy argument
- An allocatable variable
- An automatic object
- A pointer
- An object of nonsequence derived type
- A derived-type object that has an allocatable or pointer component at any level
- A component of a derived-type object
- A function, entry, or result name
- A named constant
- A structure component
- A subobject of any of the above objects
- A coarray
- An object with either the DLLIMPORT or DLLEXPORT attribute
- A variable with the BIND attribute
- A variable in a common block that has the BIND attribute

The EQUIVALENCE statement causes all of the entities in one parenthesized list to be allocated storage beginning at the same storage location.

If an equivalence object has the PROTECTED attribute, all of the objects in the equivalence set must have the PROTECTED attribute.

Association of objects depends on their types, as follows:

<table>
<thead>
<tr>
<th>Type of Object</th>
<th>Type of Associated Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>Intrinsic numeric¹ or numeric sequence</td>
<td>Can be of any of these types</td>
</tr>
<tr>
<td>Default character or character sequence</td>
<td>Can be of either of these types ²</td>
</tr>
<tr>
<td>Any other intrinsic type</td>
<td>Must have the same type and kind parameters</td>
</tr>
<tr>
<td>Any other sequence type</td>
<td>Must have the same type</td>
</tr>
</tbody>
</table>

¹Default integer, default real, double precision real, default complex, double complex, or default logical. ²The lengths do not have to be equal.

So, objects can be associated if they are of different numeric type. For example, the following is valid:

```
INTEGER A(20)
REAL Y(20)
EQUIVALENCE(A, Y)
```
Objects of default character do not need to have the same length. The following example associates character variable D with the last 4 (of the 6) characters of character array F:

```fortran
CHARACTER(Len=4) D
CHARACTER(Len=3) F(2)
EQUIVALENCE(D, F(1)(3:))
```

Entities having different data types can be associated because multiple components of one data type can share storage with a single component of a higher-ranked data type. For example, if you make an integer variable equivalent to a complex variable, the integer variable shares storage with the real part of the complex variable.

The same storage unit cannot occur more than once in a storage sequence, and consecutive storage units cannot be specified in a way that would make them nonconsecutive.

Intel® Fortran lets you associate character and noncharacter entities, for example:

```fortran
CHARACTER*1 char1(10)
REAL reala, realb
EQUIVALENCE (reala, char1(1))
EQUIVALENCE (realb, char1(2))
```

EQUIVALENCE statements require only the first subscript of a multidimensional array (unless the STRICT compiler directive is in effect). For example, the array declaration var(3,3), var(4) could appear in an EQUIVALENCE statement. The reference is to the fourth element of the array (var(1,2)), not to the beginning of the fourth row or column.

If you use the STRICT directive, the following rules apply to the kinds of variables and arrays that you can associate:

- If an EQUIVALENCE object is default integer, default real, double-precision real, default complex, default logical, or a sequenced derived type of all numeric or logical components, all objects in the EQUIVALENCE statement must be one of these types, though it is not necessary that they be the same type.
- If an EQUIVALENCE object is default character or a sequenced derived type of all character components, all objects in the EQUIVALENCE statement must be one of these types. The lengths do not need to be the same.
- If an EQUIVALENCE object is a sequenced derived type that is not purely numeric or purely character, all objects in the EQUIVALENCE statement must be the same derived type.
- If an EQUIVALENCE object is an intrinsic type other than the default (for example, INTEGER(1)), all objects in the EQUIVALENCE statement must be the same type and kind.

**Example**

The following EQUIVALENCE statement is invalid because it specifies the same storage unit for X(1) and X(2):

```fortran
REAL, DIMENSION(2) :: X
REAL :: Y
EQUIVALENCE(X(1), Y), (X(2), Y)
```

The following EQUIVALENCE statement is invalid because A(1) and A(2) will not be consecutive:

```fortran
REAL A(2)
DOUBLE PRECISION D(2)
EQUIVALENCE(A(1), D(1)), (A(2), D(2))
```

In the following example, the EQUIVALENCE statement causes the four elements of the integer array IARR to share the same storage as that of the double-precision variable DVAR:

```fortran
DOUBLE PRECISION DVAR
INTEGER(KIND=2) IARR(4)
EQUIVALENCE(DVAR, IARR(1))
```
In the following example, the EQUIVALENCE statement causes the first character of the character variables KEY and STAR to share the same storage location. The character variable STAR is equivalent to the substring KEY(1:10).

```
CHARACTER KEY*16, STAR*10
EQUIVALENCE(KEY, STAR)
```

The following shows another example:

```
CHARACTER name, first, middle, last
DIMENSION name(60), first(20), middle(20), last(20)
EQUIVALENCE (name(1), first(1)), (name(21), middle(1))
EQUIVALENCE (name(41), last(1))
```

Consider the following:

```
CHARACTER (LEN = 4) :: a, b
CHARACTER (LEN = 3) :: c(2)
EQUIVALENCE (a, c(1)), (b, c(2))
```

This causes the following alignment:

```
  1    2    3    4    5    6    7
a(1:1) a(2:2) a(3:3) a(4:4)  
b(1:1) b(2:2) b(3:3) b(4:4)  
c(1)(1:1) c(1)(2:2) c(1)(3:3) c(2)(1:1) c(2)(2:2) c(2)(3:3)
```

Note that the fourth element of a, the first element of b, and the first element of c(2) share the same storage unit.

ERF

**Elemental Intrinsic Function (Generic):** Returns the error function of an argument.

**Syntax**
```
result = ERF (x)
```

x (Input) Must be of type real.

**Results**
The result type and kind are the same as x. The result is in the range -1 to 1. ERF returns the error function of x defined as follows:

```
\[
\frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt
\]
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERF</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DERF</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QERF</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

Example

ERF (1.0) has the value 0.842700794.

See Also

ERFC

ERFC

Elemental Intrinsic Function (Generic): Returns the complementary error function of an argument.

Syntax

result = ERFC (x)

x (Input) Must be of type real.

Results

The result type and kind are the same as x. The result is in the range 0 to 2.

ERFC returns 1 - ERF(x) and is defined as follows:

\[
\frac{2}{\sqrt{\pi}} \int_{x}^{\infty} e^{-t^2} dt
\]

ERFC is provided because of the extreme loss of relative accuracy if ERF(x) is called for large x and the result is subtracted from 1.

ERF

ERFC_SCALED

Elemental Intrinsic Function (Generic): Returns the scaled complementary error function of an argument.
Syntax

\[
\text{result} = \text{ERFC\_SCALED} (x)
\]

\(x\) \hspace{1cm} \text{(Input) Must be of type real.}

Results

The result type and kind are the same as \(x\).

The result has a value equal to a processor-dependent approximation to the exponentially-scaled complementary error function of

\[
\exp\left(\frac{x^2}{2}\right) \int_x^\infty \exp\left(-t^2\right) dt
\]

**NOTE**

The complementary error function is asymptotic to \(\exp^{-\frac{x^2}{2}} / (x \sqrt{\pi})\). As such it underflows for \(X \geq 9\) when using IEEE single precision arithmetic. The exponentially-scaled complementary error function is asymptotic to \(1/(X \sqrt{\pi})\). As such it does not underflow until \(X > \text{HUGE}(X) / \sqrt{\pi}\).

Example

ERFC\_SCALED (20.0) has the approximate value 0.02817434874.

See Also

ERFC

ERRSNS

*Intrinsic Subroutine (Generic):* Returns information about the most recently detected I/O system error condition. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

\[
\text{CALL ERRSNS ([io\_err], [sys\_err], [stat], [unit], [cond])}
\]

\(\text{io\_err}\) \hspace{1cm} \text{(Output; Optional) Is an integer variable or array element that stores the most recent Run-Time Library error number that occurred during program execution. For a listing of error numbers, see Compiler Reference: Error Handling.}

A zero indicates no error has occurred since the last call to ERRSNS or since the start of program execution.

\(\text{sys\_err}\) \hspace{1cm} \text{(Output; Optional) Is an integer variable or array element that stores the most recent system error number associated with \text{io\_err}. This code is one of the following:}
• On Windows* systems, it is the value returned by GETLASTERROR( ) at the time of the error.
• On Linux* and macOS* systems, it is an errno value. (See errno(2).)

stat
(Output; Optional) Is an integer variable or array element that stores a status value that occurred during program execution. This value is always set to zero.

unit
(Output; Optional) Is an integer variable or array element that stores the logical unit number, if the last error was an I/O error.

cond
(Output; Optional) Is an integer variable or array element that stores the actual processor value. This value is always set to zero.

If you specify INTEGER(2) arguments, only the low-order 16 bits of information are returned or adjacent data can be overwritten. Because of this, it is best to use INTEGER(4) arguments.

The saved error information is set to zero after each call to ERRSNS.

Example
Any of the arguments can be omitted. For example, the following is valid:

CALL ERRSNS (SYS_ERR=I1, STAT=I2, UNIT=I4)

**ESTABLISHQQ**

**Portability Function:** Lets you specify a function to handle errors detected by the Run-Time Library (RTL). It lets you take appropriate steps in addition to the RTL’s error-handling behavior, or it lets you replace that behavior.

**Module**

USE IFESTABLISH

**Syntax**

result = ESTABLISHQQ (handler_routine, context, prev_handler, prev_context)

**handler_routine**
(Input) Is of type "procedure(establishqq_handler)"; which is defined in module IFESTABLISH. This is the function that will handle errors detected by the RTL.

**context**
(Input) INTEGER(INT_PTR_KIND()). This is the way you pass information to the handler function for use when it is called. It can be data or a pointer to a block of data.

**prev_handler**
(Optional; output) Is of type "procedure(establishqq_handler), pointer, intent(out), optional", which is defined in module IFESTABLISH. This is the previous handler function, if any.

**prev_context**
(Optional; output) INTEGER(INT_PTR_KIND()). This is the context specified for the previous handler function, if any; otherwise, zero.

**Results**

The result type for ESTABLISHQQ is LOGICAL(4). It indicates whether the handler was successfully established. .TRUE. means it was established successfully; .FALSE. means it was not.
The handler function is called when an error occurs. The result for the handler is set by your code in the handler. .TRUE. means that the error has been handled and the application should not issue an error message. .FALSE. means that the application should issue an error message and continue as if there had never been a handler.

After you use ESTABLISHQQ to specify an error handler function and an error occurs, the handler function is called with the following input arguments. They are set up by the RTL when it calls the handler function:

**Handler Function Syntax:**

```fortran
result = Handler_Function (error_code, continuable, message_string, context)
```

`Handler_Function` is a function you supply that has a compatible interface. It must use the Intel Fortran compiler defaults for calling mechanism and argument passing. When the Intel Fortran Run-Time Library detects an error, it first calls your handler function with the following arguments:

- **error_code**
  - (Input) INTEGER(4). This is the number of the error that occurred and it is the value that will be set in an IOSTAT= or STAT= specifier variable.
  - A list of run-time error codes can be found at List of Run-Time Error Messages.

- **continuable**
  - (Input) LOGICAL(4). If execution can be continued after handling this error, this argument is passed the value .TRUE., otherwise, it is passed the value .FALSE..
  - Do not compare this value using arithmetic equality operators; use logical data type tests or .EQV..
  - If an error is not continuable, the program exits after processing the error.

- **message_string**
  - (Input) CHARACTER(*). This is the text of the error message as it would otherwise be displayed to the user.

- **context**
  - (Input) INTEGER(INT_PTR_KIND()). This is the value passed for the context argument to ESTABLISHQQ.
  - Your handler function can use this for any purpose.

The function result of the handler function is type LOGICAL(4). The handler function should return .TRUE. if it successfully handled the error; otherwise, .FALSE..

If the handler function returns .TRUE. and the error is continuable, execution of the program continues. If the handler function returns .FALSE., normal error processing is performed, such as message output to the user and possible program termination.

The handler function can be written in any language, but it must follow the Intel Fortran conventions. Note that for argument `message_string`, an address-sized length is passed by value after argument `context`.

If you want to handle errors using a C/C++ handler, use the ISO_C_BINDINGS module features to call the C/C++ routine.

**Example**

```fortran
! Compile with "-fpe0 -check bounds".
!
program example
```
use ifestablish
implicit none

procedure(establishqq_handler), pointer :: old_handler_1
procedure(establishqq_handler), pointer :: old_handler_2
procedure(establishqq_handler), pointer :: old_handler_3

ETIME

**Portability Function:** On single processor systems, returns the elapsed CPU time, in seconds, of the process that calls it. On multi-core or multi-processor systems, returns the elapsed wall-clock time, in seconds.

**Module**
USE IFPORT

**Syntax**
result = ETIME (array)

(array) (Output) REAL(4). Must be a rank one array with two elements:

- array(1) – Elapsed user time, which is time spent executing user code. This value includes time running protected Windows subsystem code. On single processors, ETIME returns the elapsed CPU time, in seconds, of the process that calls it. On multiple processors, ETIME returns the elapsed wall-clock time, in seconds.
- array(2) – Elapsed system time, which is time spent executing privileged code (code in the Windows Executive) on single processors; on multiple processors, this value is zero.

**Results**
The result type is REAL(4). The result is the total CPU time, which is the sum of array(1) and array(2).

**Example**
USE IFPORT
REAL(4) I, TA(2)
I = ETIME(TA)
write(*,*) 'Program has used', I, 'seconds of CPU time.'
write(*,*) ' This includes', TA(1), 'seconds of user time and', & TA(2), 'seconds of system time.'

**See Also**
DATE_AND_TIME

**EVENT POST and EVENT WAIT**

**Statements:** The EVENT POST statement allows an image to notify another image that it can proceed to work on tasks that use common resources. The EVENT WAIT statement allows an image to wait on events posted by other images. They take the following forms:
Syntax

EVENT POST (event-var [, sync-stat-list])

EVENT WAIT (event-var [, wait-spec-list])

**event-var**

- Is a scalar variable of type EVENT_TYPE. For more information, see intrinsic module ISO_FORTRAN_ENV.
- It must not depend on the value of stat-var or err-var.
- It cannot be a coindexed variable in an EVENT WAIT statement.

**sync-stat-list**

- Is STAT=stat-var
- or ERMSG=err-var

**stat-var**

- Is a scalar integer variable in which the status of the synchronization is stored.

**err-var**

- Is a scalar default character variable in which explanatory text is stored if an error occurs.

**wait-spec-list**

- Is until-spec
- or sync-stat-list

**until-spec**

- Is UNTIL_COUNT= scalar-integer-expression.

Each specifier is optional and may appear at most once in a sync-stat-list or in a wait-spec-list.

Description

An EVENT POST statement atomically increments the value of event-var by one. Its value is processor dependent if an error condition occurs during the execution of an EVENT POST statement. The completion of an EVENT POST statement does not in any way depend on execution of a corresponding EVENT WAIT statement.

The following actions occur during the execution of an EVENT WAIT statement:

- If UNTIL_COUNT is not specified, the threshold value is one; otherwise, it is the maximum value of one and the specified scalar-integer-expression.
- The image executing the EVENT WAIT statement waits until the value of event-var is equal to or greater than the threshold value; otherwise, an error condition occurs.
- If no error condition has occurred, event-var is atomically decremented by the threshold value.

The value of event-var is processor dependent if an error condition occurs during the execution of an EVENT WAIT statement.

An EVEN POST statement execution is initially unsatisfied. The successful execution of an EVENT WAIT statement with a threshold value of \( n \) satisfies the first \( n \) unsatisfied EVENT POST statement executions for the specified event-var. The EVENT WAIT statement delays execution of the segment following the EVENT WAIT statement to execute after the segments which precede the first \( n \) EVENT POST statement executions for the specified event-var.

Example

The following example shows the use of EVENT POST and EVENT WAIT statements to synchronize each image with its left and right neighbor. Image 1 and image NUM_IMAGES() treat each other as left and right neighbors, conceptually laying the images out in a circle.

```fortran
USE, INTRINSIC :: ISO_FORTRAN_ENV
TYPE(EVENT_TYPE) :: EVENT[*]
INTEGER :: LEFT, RIGHT
```
IF ((THIS_IMAGE().NE. 1) .AND. (THIS_IMAGE() .NE. NUM_IMAGES()) THEN
   LEFT  = THIS_IMAGE() – 1
   RIGHT = THIS_IMAGE() + 1
ELSE IF (THIS_IMAGE() == 1) THEN
   LEFT  = NUM_IMAGES()
   RIGHT = 2
ELSE IF (THIS_IMAGE()== NUM_IMAGES()) THEN
   LEFT  = NUM_IMAGES() - 1
   RIGHT = 1
END IF

EVENT POST (EVENT[LEFT])            ! Signal left neighbor you got here
EVENT POST (EVENT[RIGHT])           ! Signal right neighbor you got here
EVENT WAIT (EVENT, UNTIL_COUNT = 2) ! Wait until your neighbors have both reached this point also

Image Control Statements
Coarrays
Using Coarrays

EVENT_QUERY
Intrinsic Subroutine (Generic): Queries the event count of an event variable.

Syntax
CALL EVENT_QUERY (event, count [, stat])

event (Input) Must be an event variable of type EVENT_TYPE, and must not be coindexed. The event variable is accessed atomically with respect to the execution of EVENT POST statements in unordered segments, in exact analogy to atomic subroutines.

count (Output) Must be an integer scalar with a decimal range no smaller than that of default integer. If no error condition occurs, count is assigned the value of the count of event, otherwise it is assigned the value -1.

stat (Output; optional) Must be an integer scalar with a decimal exponent range of at least four. It must not be coindexed. If the stat argument is present, it is assigned a processor-dependent positive value if an error condition occurs, or zero if no error occurs. If an error occurs and stat is not present, error termination is initiated.

Example
Consider the following example:

CALL EVENT_QUERY (EVENT, COUNT)

If there have been six successful posts to EVENT, and 3 successful waits that did not specify UNTIL_COUNT= in the preceding segments, the variable COUNT will have the value 3. If there have been no successful posts or waits in the preceding segments, COUNT will have the value 0.
EXECUTE_COMMAND_LINE

**Intrinsic Subroutine:** Executes a command line.

**Syntax**

```fortran
CALL EXECUTE_COMMAND_LINE (command [,wait,exitstat,cmdstat,cmdmsg])
```

- `command` (Input) Must be a scalar of type default character. It is the command line to be executed. The interpretation is processor dependent.
- `wait` (Input; optional) Must be a scalar of type logical. If `wait` is present with the value FALSE and the processor supports asynchronous execution of the command, the command is executed asynchronously; otherwise it is executed synchronously.
- `exitstat` (Inout; optional) Must be a scalar of type integer. If the command is executed synchronously, `exitstat` is assigned the value of the processor-dependent exit status of the executed command. Otherwise, the value of `exitstat` is unchanged.
- `cmdstat` (Output; optional) Must be a scalar of type integer. It is assigned one of the following values:
  - -1 if the processor does not support command line execution
  - A processor-dependent positive value if an error condition occurs
  - -2 if no error condition occurs but `wait` is present with the value FALSE and the processor does not support asynchronous execution.
  - 0 otherwise
- `cmdmsg` (Inout; optional) Must be a scalar of type default character. If an error condition occurs, `cmdmsg` is assigned a processor-dependent explanatory message. Otherwise, `cmdmsg` is unchanged.

**Description**

When `command` is executed synchronously, EXECUTE_COMMAND_LINE returns after the command line has completed execution. Otherwise, EXECUTE_COMMAND_LINE returns without waiting.

If a condition occurs that would assign a nonzero value to `cmdstat` but `cmdstat` is not present, execution is terminated.

**NOTE**

If the application has a standard console window, command output will appear in that window. On Windows* systems, if the application does not have a console window, including QuickWin applications, command output will not be shown.

**Example**

```fortran
INTEGER :: CSTAT, ESTAT
CHARACTER(100) :: CMSG
CALL EXECUTE_COMMAND_LINE ("dir > dir.txt", EXITSTAT=ESTAT, &
  CMDSTAT=CSTAT, CMDMSG=CMSG)
IF (CSTAT > 0) THEN
```

---

See Also

EVENT POST and EVENT WAIT

---

Language Reference

1467
PRINT *, "Command execution failed with error ", TRIM(CMSG)
ELSE IF (CSTAT < 0) THEN
    PRINT *, "Command execution not supported"
ELSE
    PRINT *, "Command completed with status ", ESTAT
END IF
END

In the above example, EXECUTE_COMMAND_LINE is called to execute a "dir" command with output redirected to a file. Since the WAIT argument was omitted, the call waits for the command to complete and the command's exit status is returned in ESTAT. If the command cannot be executed, the error message returned in CMSG is displayed, but note that this is not based on the success or failure of the command itself.

**EXIT Statement**

**Statement:** Terminates execution of a DO loop or a named construct.

**Syntax**

EXIT [name]

name (Optional) Is the name of the DO loop or construct.

**Description**

The EXIT statement causes execution of a DO loop or a named construct to be terminated.

If name is specified, the EXIT statement must be within the range of that named construct. Otherwise, the EXIT statement must be within a DO loop and it exits the innermost DO within which it appears.

If a DO loop is terminated, any inner DO loops are also terminated and the DO control variables retain their last value. If a non-DO construct is terminated, any DO loops inside that construct are also terminated.

An EXIT statement must not appear within a DO CONCURRENT construct if it belongs to that construct or an outer construct.

An EXIT statement must not appear in a CHANGE TEAM or CRITICAL construct if it belongs to an outer construct.

An EXIT statement can appear in any of the following constructs:

- ASSOCIATE
- BLOCK
- CHANGE TEAM
- CRITICAL
- DO
- IF
- SELECT CASE
- SELECT RANK
- SELECT TYPE

An EXIT statement cannot appear in a WHERE or FORALL construct.

**Example**

The following examples demonstrate EXIT statements.
Example 1:

```
LOOP_A : DO I = 1, 15
   N = N + 1
   IF (N > I) EXIT LOOP_A
END DO LOOP_A
```

Example 2:

```
INTEGER numpoints, point
REAL datarray(1000), sum
sum = 0.0
DO point = 1, 1000
   sum = sum + datarray(point)
   IF (datarray(point+1) .EQ. 0.0) EXIT
END DO
```

Example 3:

```
DO I=1,N
   MyBlock: BLOCK
      REAL :: T
      T = A(I) + B(I)
      IF (T == 0.0) EXIT MyBlock
      C(I) = T + SQRT(T)
   END BLOCK
END DO
```

Example 4:

```
DO CONCURRENT (I = 1:N)
   MyBlock: BLOCK
      REAL :: T
      T = A(I) + B(I)
      IF (T == 0.0) EXIT MyBlock
      C(I) = T + SQRT(T)
   END BLOCK
END DO
```

The following example shows illegal EXIT statements in DO CONCURRENT and CRITICAL:

```
LOOP_1 : DO CONCURRENT (I = 1:N)
   N = N + 1
   IF (N > I) EXIT LOOP_1   ! can’t EXIT DO CONCURRENT
END DO LOOP_1

LOOP_2 : DO I = 1, 15
   CRITICAL
      N = N + 1
      IF (N > I) EXIT LOOP_2   ! can’t EXIT outer construct from inside
   END CRITICAL
   ! CHANGE TEAM, DO CONCURRENT, or CRITICAL
END DO LOOP_2
```

DO
DO WHILE
EXIT Subroutine

*Intrinsic Subroutine (Generic):* Terminates program execution, closes all files, and returns control to the operating system. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

CALL EXIT ( [ status ] )

*status* (Output; optional) Is an integer argument you can use to specify the image exit-status value.

The exit-status value may not be accessible after program termination in some application environments.

**Example**

```
INTEGER(4) exvalue
! all is well, exit with 1
  exvalue = 1
  CALL EXIT(exvalue)
! all is not well, exit with diagnostic -4
  exvalue = -4
  CALL EXIT(exvalue)
! give no diagnostic, just exit
  CALL EXIT ( )
```

See Also

END

ABORT

EXP

*Elemental Intrinsic Function (Generic):* Computes an exponential value.

**Syntax**

result = EXP ( x )

*x* (Input) Must be of type real or complex.

**Results**

The result type and kind are the same as *x*. The value of the result is e^x. If *x* is of type complex, its imaginary part is regarded as a value in radians.

<table>

</tbody>
</table>
The setting of compiler options specifying real size can affect CEXP.

This function can also be specified as ZEXP.

Example

EXP (2.0) has the value 7.389056.

EXP (1.3) has the value 3.669297.

The following shows another example:

```fortran
! Given initial size and growth rate, 
! calculates the size of a colony at a given time. 
REAL sizei, sizef, time, rate 
sizei = 10000.0 
time = 40.5 
rate = 0.0875 
sizef = sizei * EXP (rate * time) 
WRITE (*, 100) sizef 
100 FORMAT (' The final size is ', E12.6) 
END
```

EXP10
LOG

**EXP10**

*Elemental Intrinsic Function (Generic):* Computes a base 10 exponential value.

**Syntax**

\[
\text{result} = \text{EXP10} \ (x)
\]

\(x\)  
(Input) Must be of type real or complex.

**Results**

The result type and kind are the same as \(x\). The value is 10 raised to the power of \(x\). If \(x\) is of type complex, its imaginary part is regarded as a value in radians.

1The setting of compiler options specifying real size can affect CEXP10.

**Example**

EXP10 (2.0) has the value 100.00.

EXP10 (1.3) has the value 19.95262.

**See Also**

LOG10

EXP

**EXPONENT**

*Elemental Intrinsic Function (Generic):* Returns the exponent part of the argument when represented as a model number.

**Syntax**

result = EXPONENT (x)

x (Input) must be of type real.

**Results**

The result type is default integer. If x is not equal to zero, the result value is the exponent part of x. The exponent must be within default integer range; otherwise, the result is undefined.

If x is zero, the exponent of x is zero. For more information on the exponent part (e) in the real model, see Model for Real Data.

**Example**

EXPONENT (2.0) has the value 2.

If 4.1 is a REAL(4) value, EXPONENT (4.1) has the value 3.

The following shows another example:

```fortran
REAL(4) r1, r2
REAL(8) r3, r4
r1 = 1.0
r2 = 123456.7
r3 = 1.0D0
r4 = 123456789123456.7
write(*,*) EXPONENT(r1) ! prints 1
write(*,*) EXPONENT(r2) ! prints 17
write(*,*) EXPONENT(r3) ! prints 1
write(*,*) EXPONENT(r4) ! prints 47
END
```

**EXTENDS_TYPE_OF**

*Inquiry Intrinsic Function (Generic):* Inquires whether the dynamic type of an object is an extension type of the dynamic type of another object.

**Syntax**

\[
\text{result} = \text{EXTENDS_TYPE_OF} \ (a, \ mold)
\]

- \(a\) (Input) Is an object of extensible type. If it is a pointer, it must not have an undefined association status.
- \(mold\) (Input) Is an object of extensible type. If it is a polymorphic pointer, it must not have an undefined association status.

**Results**
The result type is default logical scalar.

The following determines the result value:

- If \(mold\) is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is **.TRUE.**
- If \(a\) is unlimited polymorphic and is a disassociated pointer or an unallocated allocatable, the result is **.FALSE.**
- If the dynamic type of \(a\) or \(mold\) is extensible, the result is true only if the dynamic type of \(a\) is an extension type of the dynamic type of \(mold\).

Otherwise, the result is processor dependent.

**EXTERNAL**

*Statement and Attribute:* Allows an external procedure, a dummy procedure, a procedure pointer, or a block data subprogram to be used as an actual argument. (To specify intrinsic procedures as actual arguments, use the INTRINSIC attribute.)

**Syntax**
The EXTERNAL attribute can be specified in a type declaration statement or an EXTERNAL statement, and takes one of the following forms:

**Type Declaration Statement:**

\[
\text{type}, [\text{att-}ls], \text{EXTERNAL} [, \text{att-}ls] :: \text{ex-pro}[, \text{ex-pro}]...
\]

**Statement:**

\[
\text{EXTERNAL} [::] \text{ex-pro}[, \text{ex-pro}]...
\]

- **type** Is a data type specifier.
- **att-ls** Is an optional list of attribute specifiers.
- **ex-pro** Is the name of an external (user-supplied) procedure, a dummy procedure, a procedure pointer, or block data subprogram.
Description
In a type declaration statement, only functions can be declared EXTERNAL. However, you can use the EXTERNAL statement to declare subroutines and block data program units, as well as functions, to be external.

The name declared EXTERNAL is assumed to be the name of an external procedure, even if the name is the same as that of an intrinsic procedure. For example, if SIN is declared with the EXTERNAL attribute, all subsequent references to SIN are to a user-supplied function named SIN, not to the intrinsic function of the same name.

You can include the name of a block data program unit in the EXTERNAL statement to force a search of the object module libraries for the block data program unit at link time. However, the name of the block data program unit must not be used in a type declaration statement.

If you want to describe a routine with greater detail, use the INTERFACE statement. This statement automatically declares a routine as EXTERNAL, and provides information on result types and argument types.

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

Example
The following example shows type declaration statements specifying the EXTERNAL attribute:

```fortran
PROGRAM TEST
  ...
  INTEGER, EXTERNAL :: BETA
  LOGICAL, EXTERNAL :: COS
  ...
  CALL SUB(BETA) ! External function BETA is an actual argument
```

You can use a name specified in an EXTERNAL statement as an actual argument to a subprogram, and the subprogram can then use the corresponding dummy argument in a function reference or a CALL statement; for example:

```fortran
EXTERNAL FACET
CALL BAR(FACET)
SUBROUTINE BAR(F)
  EXTERNAL F
  CALL F(2)
```

Used as an argument, a complete function reference represents a value, not a subprogram; for example, FUNC(B) represents a value in the following statement:

```fortran
CALL SUBR(A, FUNC(B), C)
```

The following shows another example:

```fortran
EXTERNAL MyFunc, MySub
C MyFunc and MySub are arguments to Calc
  CALL Calc (MyFunc, MySub)
C Example of a user-defined function replacing an
C intrinsic
  EXTERNAL SIN
  x = SIN (a, 4.2, 37)
```

FORTRAN 66 Interpretation of the External Statement

FAIL IMAGE

Statement: Causes the image that executes it to stop participating in program execution, without initiating termination.

Syntax

FAIL IMAGE

This statement allows you to simulate image failure and to test and debug image failure recovery in a program, without requiring an actual image failure.

After execution of a FAIL IMAGE statement, no additional statements are executed by the image.

A FAIL IMAGE statement is not an image control statement.

The detection of a failed image may happen at different times in the execution of other images; for more information, see FAILED/Images.

NOTE

If you use a FAIL IMAGE statement to make an image fail, you should use a STAT= specifier or a STAT argument in all coarray operations that might encounter that failed image if the statement or operation permits, or you should specify either the assume failed_images or standard-semantics compiler option. If you do not use a STAT= specifier, a STAT argument, or specify one of the compiler options, those operations will not check for failed images. They may then try to coordinate with the failed image, waiting for a response from it. The response would never happen and so the application would hang.

Examples

The following example demonstrates using the STAT= specifier to prevent an application hang (see Note above):

```fortran
SUBROUTINE FAIL_AND_SYNC ( THIS_ONE )
  INTEGER THIS_ONE
  INTEGER MY_STAT
  IF (THIS_IMAGE() .EQ. THIS_ONE) THEN
    FAIL IMAGE
  END IF
  SYNC ALL (STAT=MY_STAT) ! Would hang without STAT=
END SUBROUTINE FAIL_AND_SYNC
```

If an image calls the following procedure at regular time intervals, it has a one in ten thousand chance of failure in each time step:

```fortran
SUBROUTINE RANDOM_FAILURE ()
  REAL RANDOM
  CALL RANDOM_NUMBER (RANDOM)
  IF (RANDOM > 0.9999) FAIL IMAGE
  RETURN
END SUBROUTINE RANDOM_FAILURE
```

FAILED/Images
IMAGE_STATUS
standard-semantics compiler option
assume [no]failed_images compiler option

**FAILED/Images**

*Transformational Intrinsic Function (Generic):*

*Returns an array of index images that have failed.*

**Syntax**

\[
\text{result} = \text{FAILED}/\text{IMAGES}([\text{team}, \text{kind}])
\]

- **team** (Input; optional) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV whose value represents the current or an ancestor team. If not present, the current team is assumed.

- **kind** (Input; optional) Must be a scalar integer expression with a value that is a valid INTEGER kind type parameter.

**Results**

The result is a rank-one integer array with the same type kind parameters as `kind` if present; otherwise, default integer. The size of the array is equal to the number of images in the specified team that are known to have failed.

The result array elements are the image index values of images on the current team that are known to have failed. The indices are arranged in increasing numeric order.

If the image executing the FAILED/Images reference previously executed a collective subroutine whose STAT argument returned the value STAT_FAILED/Images defined in the intrinsic module ISO_FORTRAN_ENV, or if the image executed an image control statement whose STAT= specifier returned the value STAT_FAILED_IMAGE, at least one image in the team executing the collective or image control statement is known to have failed.

**Failed images may lead to unavoidable hangs**

Coarray programs are parallel programs, so between synchronization points the relative ordering of events in different images is unknown and undefined. The failure of an image or the execution of the FAIL IMAGE statement is such an event. It happens at a definite time in the image that fails, but the other images will discover the failure at different points in their execution. Also, because a failed image does not participate in synchronization points, it is possible for the discovery to happen before a synchronization point in one image and after it in another.

This means that when other images synchronize (such as with a SYNC ALL), it is possible that some will know that that image has failed and some will not. In this case, the images that don’t know will attempt to synchronize with the failed image and the application will hang, making no progress.

There is no certain way to prevent a hang when an image fails. However, if you structure your program so that synchronizations points are infrequent, the chance of a failure happening just before a synchronization point is lower. If images frequently do coarray loads and stores, or check image status, they are more likely to discover a failed image sooner. The FAILED/Images intrinsic will check for failed images, but other images might not get the same result from that call.

**Example**

If image 5 and 12 of the current team are known to have failed, the result of FAILED/Images() is an array of default integer type with size 2 defined with the value [5, 12]. If no images in the current team are known to have failed, the result of FAILED/Images() is a zero-sized array.

IMAGE_STATUS
ISO_FORTRAN_ENV Module

**FDATE**

*Portability Function and Subroutine:* Returns the current date and time as an ASCII string.

**Module**

USE IFPORT

**Syntax**

**Function Syntax**

\[
\text{result} = \text{FDATE}()
\]

**Subroutine Syntax:**

\[
\text{CALL FDATE (} \text{[string]} \text{)}
\]

*string* (Output; optional) Character*(*). It is returned as a 24-character string in the form:

Mon Jan 31 04:37:23 2001

Any value in *string* before the call is destroyed.

**Results**

The result of the function FDATE and the value of *string* returned by the subroutine FDATE(*string*) are identical. Newline and NULL are not included in the string.

When you use FDATE as a function, declare it as:

\[
\text{CHARACTER*24 FDATE}
\]

**Example**

USE IFPORT

CHARACTER*24 today

! CALL FDATE(today)

write (*,*), 'Today is ', today

! write (*,*), 'Today is ', fdate()

**See Also**

DATE_AND_TIME

**FGETC**

*Portability Function:* Reads the next available character from a file specified by a Fortran unit number.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{FGETC (} \text{lunit, char} \text{)}
\]
**lunit**
(Input) INTEGER(4). Unit number of a file. Must be currently connected to a file when the function is called.

**char**
(Output) CHARACTER*1. Next available character in the file. If lunit is connected to a console device, then no characters are returned until the Enter key is pressed.

**Results**
The result type is INTEGER(4). The result is zero if the read is successful, or -1 if an end-of-file is detected. A positive value is either a system error code or a Fortran I/O error code, such as:

EINVAL: The specified unit is invalid (either not already open, or an invalid unit number).

If you use WRITE, READ, or any other Fortran I/O statements with lunit, be sure to read Portability Routines.

**Example**

```
USE IFPORT
CHARACTER inchar
INTEGER istatus
istatus = FGETC(5,inchar)
PRINT *, inchar
END
```

**See Also**
GETCHARQQ
READ

**FINAL Clause**

**Parallel Directive Clause:** Specifies that the generated task will be a final task.

**Syntax**

```
FINAL (scalar-logical-expression)
```

- `scalar-logical-expression` is a scalar logical expression. When the expression evaluates to .TRUE., it specifies that the generated task will be a final task.

All task constructs encountered during execution of a final task will generate included tasks.

Note that if a variable is used in a FINAL clause expression of a directive construct, it causes an implicit reference to the variable in all enclosing constructs.

Only a single FINAL clause can appear in the directive.

**FINAL Statement**

**Statement:** Denotes a finalization procedure that defines one or more final subroutines that are bound to a derived type.

**Syntax**

The FINAL statement takes the following form:

```
FINAL [:] sub1 [, sub2 ]...
```
Is a final subroutine, which is a module procedure with exactly one dummy argument of the derived type. The dummy argument cannot be INTENT(OUT), it cannot have the VALUE attribute, it cannot be optional, and it cannot be a pointer, allocatable, or a coarray. All array shape and length type parameters are assumed.

**Description**

A final subroutine must not have a dummy argument with the same kind type parameters and rank as the dummy argument of another final subroutine of the type.

You cannot specify a subroutine that was previously specified as a final subroutine for the derived type.

If a final subroutine has an assumed-rank dummy argument, no other final subroutine of that type can have a dummy argument with the same kind type parameters.

This statement is used in derived-type type-bound procedures.

A derived type is finalizable only if it has a final subroutine or a nonpointer, nonallocatable component of finalizable type. A nonpointer data entity is finalizable only if it is of finalizable type.

When an entity is finalized, the following actions occur in this order:

1. If the dynamic type of the entity has a final subroutine whose dummy argument has the same kind type parameters and rank as the entity being finalized, it is called with the entity as an actual argument.

   Otherwise, if there is an elemental final subroutine whose dummy argument has the same kind type parameters as the entity being finalized, or a final subroutine whose dummy argument is assumed-rank with the same kind type parameters as the entity being finalized, it is called with the entity as an actual argument. Otherwise, no subroutine is called.

2. Finalizable components in the type are finalized. If the entity is an array, each finalizable component of each element is finalized. The order of finalization is processor dependent.

3. If the entity is of an extended type with a finalizable parent type, the parent component is finalized.

**Effects of Finalization**

If the variable of an intrinsic assignment is not an unallocated allocatable array when the statement is executed, the variable is finalized after the expression on the right-hand side (RHS) is evaluated and before the variable is defined. If the variable is an allocated allocatable variable or has an allocated allocatable subobject that would be deallocated by intrinsic assignment, finalization occurs before deallocation.

When a pointer is deallocated, its target is finalized. When an allocatable entity is deallocated, it is finalized unless it is the variable on the left-hand side (LHS) of the intrinsic assignment or a subobject of the variable.

A nonpointer, nonallocatable object that is not a dummy argument or function result is finalized immediately before it would become undefined due to execution of a RETURN or END statement.

If the entity is of extended type and the parent type is finalizable, the parent component is finalized.

A nonpointer, nonallocatable local variable of a BLOCK construct is finalized immediately before it would become undefined due to termination of the BLOCK construct.

The following rules also apply:

- If an executable construct references a nonpointer function, the result is finalized after execution of the innermost executable construct containing the reference.
- If a specification expression in a scoping unit references a function, the result is finalized before execution of the executable constructs in the scoping unit.
A nonpointer, nonallocatable, INTENT(OUT) dummy argument of a procedure is finalized when the procedure is invoked before the dummy argument becomes undefined. Finalization of INTENT(OUT) dummy arguments occurs in the invoked procedure; for elemental procedures, an INTENT(OUT) argument will be finalized only if a scalar or elemental final subroutine is available, regardless of the rank of the argument.

If image execution is terminated, either by an error or by execution of a ERROR STOP, STOP, or END PROGRAM statement, any entities that exist immediately before termination are not finalized.

Example

The following example declares two module subroutines to be final:

```fortran
TYPE MY_TYPE
  ... ! Component declarations
CONTAINS
  FINAL :: CLEAN1, CLEAN2
END TYPE MY_TYPE
```

See Also

Type-Bound Procedures

FIND

**Statement:** Positions a direct access file at a particular record and sets the associated variable of the file to that record number. It is comparable to a direct access READ statement with no I/O list, and it can open an existing file. No data transfer takes place.

**Syntax**

```fortran
FIND ([UNIT=] io-unit, REC= r[, ERR= label] [, IOSTAT= i-var])
FIND (io-unit 'r [, ERR=label] [, IOSTAT=i-var])
```

- `io-unit`  
  Is a logical unit number. It must refer to a relative organization file (see Unit Specifier).

- `r`  
  Is the direct access record number. It cannot be less than one or greater than the number of records defined for the file (see Record Specifier).

- `label`  
  Is the label of the executable statement that receives control if an error occurs.

- `i-var`  
  Is a scalar integer variable that is defined as a positive integer if an error occurs, and as zero if no error occurs (see I/O Status Specifier).

**Example**

In the following example, the FIND statement positions logical unit 1 at the first record in the file. The file's associated variable is set to one:

```fortran
FIND(1, REC=1)
```

In the following example, the FIND statement positions the file at the record identified by the content of INDX. The file's associated variable is set to the value of INDX:

```fortran
FIND(4, REC=INDX)
```
FINDLOC

Transformational Intrinsic Function (Generic):

Finds the location of a specified value in an array.

Syntax

result = FINDLOC (array, value[, mask, kind, back])
result = FINDLOC (array, value[, mask, kind, back])

array
   (Input) Must be an array of intrinsic type.
value
   (Input) Must be a scalar and in type conformance with array.
dim
   (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of array.
mask
   (Input; optional) Must be of type logical and conformable with array.
kind
   (Input; optional) Must be a scalar integer constant expression.
back
   (Input; optional) Must be a scalar of type logical.

Results

The result is integer. If kind is present, the kind type parameter is that specified by the value of kind. Otherwise, the kind type parameter is that of default integer type. If dim does not appear, the result is an array of rank one and of size equal to the rank of array; otherwise, the result is of rank n - 1 and shape (d1, d2,...,dim-1, dim+1,...dn), where (d1, d2,...,dn) is the shape of array.

The result of FINDLOC (array, value) is a rank-one array whose element values are the values of the subscripts of an element of array whose value matches value. If there is such a value, the ith subscript returned is in the range 1 to e_i, where e_i is the extent of the ith dimension of array. If no elements match value or if array has size zero, all elements of the result are zero.

The result of FINDLOC (array, value, MASK = mask) is a rank-one array whose element values are the values of the subscripts of an element of array, corresponding to a true element of mask, whose value matches value. If there is such a value, the ith subscript returned is in the range 1 to e_i, where e_i is the extent of the ith dimension of array. If no elements match value, or array has size zero, or every element of mask has the value .FALSE., all elements of the result are zero.

If ARRAY has rank one, the result of FINDLOC (array, value, DIM = dim[, mask = mask]) is a scalar whose value is equal to that of the first element of FINDLOC (array, value[, mask = mask]). Otherwise, the value of element (s1, s2,...,sdim-1, value+1,...,sn) of the result is equal to FINDLOC (array (s1, s2,...,value+1,...,sn), value, DIM = 1[, mask = mask (s1, s2,...,sdim-1,...,sn+1,...sn)])

If both array and value are of type logical, the comparison is performed with the .EQV. operator; otherwise, the comparison is performed with the == operator. If the value of the comparison is true, that element of array matches value.

If only one element matches value, that element’s subscripts are returned. If more than one element matches value and back is absent or present with the value .FALSE., the element whose subscripts are returned is the first element, taken in array element order. If back is present with the value .TRUE., the element whose subscripts are returned is the last element, taken in array element order.

See Also

Forms for Direct-Access READ Statements
I/O Control List
The setting of compiler options specifying integer size can affect this function.

**Example**

The value of FINDLOC ([2, 6, 4, 6], VALUE = 6) is [2].

The value of FINDLOC ([2, 6, 4, 6], VALUE = 6, BACK = .TRUE.) is [4].

If A has the value

```
[ 0  -5  7  7 ]
[ 3   4  -1  2 ]
[ 1   5  6  7 ]
```

and M has the value

```
[ T   T   F   T ]
[ T   T   F   T ]
[ T   T   F   T ]
```

then FINDLOC (A, 7, MASK = M) is [1, 4] and FINDLOC (A, 7, MASK = M, BACK = .TRUE.) is [3, 4].

This is independent of the declared lower bounds for A.

The value of FINDLOC ([2, 6, 4], VALUE = 6, DIM = 1) is 2.

If B has the value

```
[ 1   2   -9 ]
[ 2   3    6 ]
```

then FINDLOC (B, VALUE = 2, DIM = 1) is [2, 1, 0] and FINDLOC (B, VALUE = 2, DIM = 2) is [2, 1].

This is independent of the declared lower bounds for B.

MAXLOC
MINLOC

**FINDFILEQQ**

*Portability Function:* Searches for a specified file in the directories listed in the path contained in the environment variable.

**Module**

USE IFPORT

**Syntax**

```
result = FINDFILEQQ (filename, varname, pathbuf)
```

- **filename** *(Input) Character*(*)*. Name of the file to be found.
- **varname** *(Input) Character*(*)*. Name of an environment variable containing the path to be searched.
- **pathbuf** *(Output) Character*(*)*. Buffer to receive the full path of the file found.
Results
The result type is INTEGER(4). The result is the length of the string containing the full path of the found file returned in pathbuf, or 0 if no file is found.

Example
USE IFPORT
CHARACTER(256) pathname
INTEGER(4) pathlen
pathlen = FINDFILEQQ("libfmt.lib", "LIB", pathname)
WRITE (*,*) pathname
END

FIRSTPRIVATE
Parallel Directive Clause: Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to each thread in a team, and initializes each of them with the value of the corresponding original variable.

Syntax
FIRSTPRIVATE (list)

list
Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different threads are initialized to the value the variable had upon entering the parallel region.

To avoid race conditions, which are caused by unintended sharing of data, concurrent updates of the original variable must be synchronized with the read of the original variable that occurs as a result of the FIRSTPRIVATE clause.

If the original variable has the POINTER attribute, the new variable receives the same association status of the original variable as if by pointer assignment.

If the original variable does not have the POINTER attribute, initialization of the new variable occurs as if by intrinsic assignment, unless the original variable has the allocation status of "not currently allocated". In this case, the new variable also has the status of "not currently un allocated".

The following are restrictions for the FIRSTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a FIRSTPRIVATE clause.
- A variable that is private within a parallel region must not appear in a FIRSTPRIVATE clause in a worksharing construct if any of the worksharing regions arising from the worksharing construct ever bind to any of the parallel regions arising from the parallel construct.
• A variable that appears in a REDUCTION clause of a PARALLEL construct must not appear in a FIRSTPRIVATE clause in a worksharing or task construct if any of the worksharing or task regions arising from the worksharing or task construct ever bind to any of the parallel regions arising from the parallel construct.
• A variable that appears in a REDUCTION clause in a WORKSHARE construct must not appear in a FIRSTPRIVATE clause in a task construct encountered during execution of any of the worksharing regions arising from the worksharing construct.
• Assumed-size arrays must not appear in a PRIVATE clause.
• Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.
• If a list item appears in both the FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all of the initializations for FIRSTPRIVATE.

NOTE
If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE.

Example
Consider the following:

A = 3
B = 4
!$OMP PARALLEL PRIVATE(A) FIRSTPRIVATE(B)

In this case, variable A has an undefined value at the beginning of the parallel region. However, variable B has the value 4, which was specified in the serial region preceding the parallel region.

See Also
PRIVATE clause
LASTPRIVATE clause

FIXEDFORMLINESIZE

General Compiler Directive: Sets the line length for fixed-form Fortran source code.

Syntax

!DIR$ FIXEDFORMLINESIZE:{72 | 80 | 132}

You can set FIXEDFORMLINESIZE to 72 (the default), 80, or 132 characters. The FIXEDFORMLINESIZE setting remains in effect until the end of the file, or until it is reset.

The FIXEDFORMLINESIZE directive sets the source-code line length in include files, but not in USE modules, which are compiled separately. If an include file resets the line length, the change does not affect the host file.

This directive has no effect on free-form source code.

Example

!DIR$ NOFREEFORM
!DIR$ FIXEDFORMLINESIZE:132
WRITE (*,*) 'Sentence that goes beyond the 72nd column without continuation.'

See Also
FREEFORM and NOFREEFORM
FLOAT

**Elemental Intrinsic Function (Generic):** Converts an integer to REAL(4).

See Also
REAL

FLOOR

**Elemental Intrinsic Function (Generic):** Returns the greatest integer less than or equal to its argument.

**Syntax**

```
result = FLOOR (a[,kind])
```

- `a` (Input) Must be of type real.
- `kind` (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is equal to the greatest integer less than or equal to `a`.

The setting of compiler options specifying integer size can affect this function.

**Example**

FLOOR (4.8) has the value 4.

FLOOR (-5.6) has the value -6.

The following shows another example:

```
I = FLOOR(3.1)  ! returns 3
I = FLOOR(-3.1) ! returns -4
```

CEILING

FLUSH Directive

**OpenMP* Fortran Compiler Directive:** Identifies synchronization points at which the threads in a team must provide a consistent view of memory.

**Syntax**

```
!$OMP FLUSH ((list))
```
Is the name of one or more variables to be flushed. Names must be separated by commas.

The binding thread set for a FLUSH construct is the encountering thread.

The FLUSH directive must appear at the precise point in the code at which the synchronization is required. To avoid flushing all variables, specify a list.

Thread-visible variables are written back to memory at the point at which this directive appears. Modifications to thread-visible variables are visible to all threads after this point. Subsequent reads of thread-visible variables fetch the latest copy of the data.

Thread-visible variables include the following data items:

- Globally visible variables (common blocks and modules)
- Local variables that do not have the SAVE attribute but have had their address taken and saved or have had their address passed to another subprogram
- Local variables that do not have the SAVE attribute that are declared shared in a parallel region within the subprogram
- Dummy arguments
- All pointer dereferences

The FLUSH directive is implied for the following directives (unless the NOWAIT keyword is used):

- ATOMIC and END ATOMIC
- BARRIER
- CRITICAL and END CRITICAL
- END DO
- END PARALLEL
- END SECTIONS
- END SINGLE
- END WORKSHARE
- ORDERED and END ORDERED
- PARALLEL and END PARALLEL
- PARALLEL DO and END PARALLEL DO
- PARALLEL SECTIONS and END PARALLEL SECTIONS
- TARGET
- TARGET DATA
- TARGET ENTER DATA on entry
- TARGET EXIT DATA on exit
- TARGET UPDATE on entry if TO is present and on exit if FROM is present

These directives are only available on Linux* systems: TARGET, TARGET DATA, TARGET ENTER DATA, TARGET EXIT DATA, TARGET UPDATE.

**Example**

The following example uses the FLUSH directive for point-to-point synchronization between pairs of threads:

```fortran
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(ISYNC)
   IAM = OMP_GET_THREAD_NUM( )
   ISYNC(IAM) = 0
!$OMP BARRIER
   CALL WORK( )
C I AM DONE WITH MY WORK, SYNCHRONIZE WITH MY NEIGHBOR
   ISYNC(IAM) = 1
!$OMP FLUSH(ISYNC)
C WAIT TILL NEIGHBOR IS DONE
   DO WHILE (ISYNC(NEIGH) .EQ. 0)
```

Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

**FLUSH Statement**

**Statement:** Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement. It takes one of the following forms:

**Syntax**

```fortran
FLUSH([UNIT=]io-unit [, ERR=label] [, IOMSG=msg-var] [IOSTAT=i-var])
```

- `io-unit` *(Input)* Is an external unit specifier.
- `label` *(Input)* Is the label of the branch target statement that receives control if an error occurs.
- `msg-var` *(Output)* Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
- `i-var` *(Output)* Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

The FLUSH statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

This statement has no effect on file position.

**FLUSH Subroutine**

**Portability Subroutine:** Flashes the contents of an external unit buffer into its associated file.

**Module**

USE IFPORT

**Syntax**

```fortran
CALL FLUSH (lunit)
```

- `lunit` *(Input)* INTEGER(4). Number of the external unit to be flushed. Must be currently connected to a file when the subroutine is called. This routine is thread-safe, and locks the associated stream before I/O is performed.
NOTE
The flush is performed in a non-blocking mode. In this mode, the command may return before the physical write is completed. If you want to use a blocking mode of FLUSH use COMMITQQ.

See Also
COMMITQQ

FMA and NOFMA

**General Compiler Directives:** Tells the compiler to allow generation of fused multiply-add (FMA) instructions, also known as floating-point contractions. NOFMA disables the generation of FMA instructions.

Syntax

```
!DIR$ FMA

!DIR$ NOFMA
```

These directives affect the current program unit but they also apply to subsequent program units in the source file, unless and until a program unit containing another FMA or NOFMA directive is encountered.

Once a NOFMA directive has been specified, it is in effect from that point forward. The setting impacts later routines in the source file. For example, consider that the following are in the same source file:

```fortran
real function fms_mul2( a, b, c, d)
  implicit none
  real :: a, b, c, d
  !       the default !dir$ fma leads to fma generation:
  !       this is transformed into FMS(a,b,FMA(c,d,0))

!dir$ nofma
  fms_mul2 = a*b - c*d                ! no fma generation here
end function fms_mul2
```

```fortran
real function fms_mul( a, b, c, d)
  implicit none
  real :: a, b, c, d
  fms_mul = (a*b) - (c*d)             ! no fma generation here
end function fms_mul
```

The NOFMA directive specified in `fms_mul2` will also impact the routine `fms_mul`. You must explicitly specify the FMA directive to override the effect of the NOFMA directive.

**FOR__SET_FTN_ALLOC**

**Run-Time Function:** Lets you specify your own routine to dynamically allocate common blocks. This function is especially useful when you are sharing libraries.
Syntax

\[
\text{result} = \text{FOR\_SET\_FTN\_ALLOC} (\text{alloc\_routine})
\]

\textit{alloc\_routine} (Input) Character. Is the name of a user-defined allocation routine. The routine takes the same arguments as the routine prototype \_FTN\_ALLOC, which is defined in module IFCORE. For more information on \_FTN\_ALLOC and its arguments, see Allocating Common Blocks.

Results

The result has the same type as the type of the argument. The return value is a pointer to the previous allocation routine you specified for allocation of COMMONs, or to a null pointer if you did not specify a previous allocation routine.

The caller of FOR\_SET\_FTN\_ALLOC must include a USE IFCOMMONALLOC statement. The allocation routine should include ISO\_C\_BINDING so it can correctly declare the arguments.

This function takes precedence over \_FTN\_ALLOC.

Example

The following shows an example of a user-defined routine that can be used with FOR\_SET\_FTN\_ALLOC.

Note that you must compile the program using option [Q]dyncom to name the commons you want to be dynamically allocated.

! User's allocation routine
!
subroutine my_Fortran_alloc_routine (mem, size, name)
use, intrinsic :: ISO\_C\_BINDING
implicit none
type(C_PTR), intent(OUT) :: mem
integer(C\_INT), intent(INOUT) :: size
character, dimension(*) , intent(IN) :: name

! Users would put their allocation code here. This example text
! does not contain code to allocate memory.

end subroutine my_Fortran_alloc_routine

! This routine uses module IFCOMMONALLOC to swap allocation
! routines for dynamic COMMONs.
!
subroutine swap_alloc_routines( for_old )
use ifcommonalloc
use, intrinsic :: ISO\_C\_BINDING
implicit none

logical for_old

! The routine to use, defined above.
!
procedure(alloc\_rtn) :: my_Fortran_alloc_routine

! Where to save the old one.
!
type(C_FUNPTR) :: saved_alloc_routine

! Do the swap
!
print *, "my_Fortran_alloc_routine"
if (for_old) then
  saved_alloc_routine = set_ftn_alloc( C_FUNLOC(my_Fortran_alloc_routine) )
else
  saved_alloc_routine = set_ftn_alloc( saved_alloc_routine )
end if

end subroutine swap_alloc_routines

! Routines with dynamic commons would go here
!
! The main program doesn't need to know about module IFCOMMONALLOC.
!
program main
  implicit none
  ! Dynamic commons in routines first called in this region will use the
  !   default allocation method.
  swap_alloc_routines( .true. )
  ! Dynamic commons in routines first called in this region will use
  !   my_Fortran_alloc_routine.
  swap_alloc_routines( .false. )
  ! Dynamic commons in routines first called in this region will use the
  !   default allocation method.
end program main

ISO_C_BINDING

FOR_DESCRIPTOR.Assign (W*S)

Run-Time Subroutine: Creates an array descriptor in memory.

Module
USE IFCORE

Syntax
CALL FOR_DESCRIPTOR_ASSIGN (dp, base, size, reserved, rank, dims_info)

dp (Input) A Fortran pointer to an array; the array can be of any data type.
(Input) INTEGER(4) or INTEGER(8). The base address of the data being described by *dp*.

*base*

Note that a Fortran pointer describes both the location and type of the data item.

*(Input) INTEGER(4). The size of the data type; for example, 4 for INTEGER(4).*

*size*

*(Input) INTEGER(4). A logical bitwise OR combination of the following constants, which are defined in IFCORE.F90:*

- **FOR_DESCRIPTOR_ARRAY_DEFINED** - Specifies whether the array pointed to has been allocated or associated. If the bit is set, the array has been allocated or associated.
- **FOR_DESCRIPTOR_ARRAY_NODEALLOC** - Specifies whether the array points to something that can be deallocated by a call to DEALLOCATE, or whether it points to something that cannot be deallocated. For example:

  ```fortran
  integer, pointer :: p(:)
  integer, target :: t
  p => t       ! t cannot be deallocated
  allocate(p(10)) ! t can be deallocated
  ```

  If the bit is set, the array cannot be deallocated.
- **FOR_DESCRIPTOR_ARRAY_CONTIGUOUS** - Specifies whether the array pointed to is completely contiguous in memory or whether it is a slice that is not contiguous. If the bit is set, the array is contiguous.

*(Input) INTEGER(4). The rank of the array pointed to.*

*rank*

*(Input) An array of derived type FOR_DIMS_INFO; you must specify a rank for this array. The derived type FOR_DIMS_INFO is defined in IFCORE.F90 as follows:

```fortran
  TYPE FOR_DIMS_INFO
  INTEGER(4) LOWERBOUND  !Lower bound for the dimension
  INTEGER(4) UPPERBOUND  !Upper bound for the dimension
  INTEGER(4) STRIDE      !Stride for the dimension
  END TYPE FOR_DIMS_INFO
```

The FOR_DESCRIPTOR_ASSIGN routine is similar to a Fortran pointer assignment, but gives you more control over the assignment, allowing, for example, assignment to any location in memory.

You can also use this routine to create an array that can be used from both Fortran or C.

**Example**

```fortran
use IFCORE
common/c_array/ array
real(8) array(5,5)
external  init_array
external  c_print_array
real(8),pointer :: p_array(:,:)
type(FOR_DIMS_INFO) dims_info(2)
call init_array()
```
do i=1,5
  do j=1,5
    print *,i,j, array(i,j)
  end do
end do

dims_info(1)%LOWERBOUND = 11
dims_info(1)%UPPERBOUND = 15
dims_info(1)%STRIDE = 1

dims_info(2)%LOWERBOUND = -5
dims_info(2)%UPPERBOUND = -1
dims_info(2)%STRIDE = 1

call FOR_DESCRIPTOR_ASSIGN(p_array, &
  LOC(array), &
  SIZEOF(array(1,1)), &
  FOR_DESCRIPTOR_ARRAY_DEFINED .or. &
  FOR_DESCRIPTOR_ARRAY_NODEALLOC .or. &
  FOR_DESCRIPTOR_ARRAY_CONTIGUOUS, &
  2, &
  dims_info )
p_array = p_array + 1
call c_print_array()
end

The following shows the C program containing init_array and c_print_array:

```
#include <stdio.h>
#if !defined(_WIN32) && !defined(_WIN64)
#define C_ARRAY c_array_
#define INIT_ARRAY init_array_
#define C_PRINT_ARRAY c_print_array_
#endif
double C_ARRAY[5][5];
void INIT_ARRAY(void);
void C_PRINT_ARRAY(void);
void INIT_ARRAY(void)
{
  int i,j;
  for(i=0;i<5;i++)
    for(j=0;j<5;j++)
      C_ARRAY[i][j] = j + 10*i;
}
void C_PRINT_ARRAY(void)
{
  int i,j;
  for(i=0;i<5;i++)
    for(j=0;j<5;j++)
      printf("%f ", C_ARRAY[i][j]);
  printf("\n");
}
```

POINTER - Fortran
**FOR_GET_FPE**

*Run-Time Function:* Returns the current settings of floating-point exception flags. This routine can be called from a C or Fortran program.

**Module**

USE IFCORE

**Syntax**

```fortran
result = FOR_GET_FPE()
```

**Results**

The result type is INTEGER(4). The return value represents the settings of the current floating-point exception flags. The meanings of the bits are defined in the IFPORT module file. To set floating-point exception flags after program initialization, use **FOR_SET_FPE**.

**Example**

```fortran
USE IFCORE
INTEGER*4 FPE_FLAGS
FPE_FLAGS = FOR_GET_FPE()
```

**See Also**

FOR_SET_FPE

**FOR_IFCORE_VERSION**

*Portability Function:* Returns the version of the Fortran run-time library (ifcore).

**Module**

USE IFPORT

**Syntax**

```fortran
result = FOR_IFCORE_VERSION(string)
```

*string* (Output) Character*(*) . The version information for the Fortran run-time library (ifcore).

**Results**

The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero. If *string* is not long enough to contain the version information, the result is truncated on the right. If *string* is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.

**Example**

Consider the following:

```fortran
program what_ifcore
  use ifport
  integer :: res
  character*56 :: str
```
res = for_ifcore_version( str )
print *("(3A)", "'", str, "'")
end program what_ifcore

The above example will produce a result similar to the following, depending on spacing and the actual version information:

'Intel Fortran RTL Core Library Vvv.m-eeeMmm dd yyyy  '

where:

<table>
<thead>
<tr>
<th>vv</th>
<th>Is a major version number</th>
</tr>
</thead>
<tbody>
<tr>
<td>m</td>
<td>Is a minor version number</td>
</tr>
<tr>
<td>eee</td>
<td>Is an edit number</td>
</tr>
<tr>
<td>Mmm</td>
<td>Is a three-character abbreviation for the month</td>
</tr>
<tr>
<td>dd</td>
<td>Is a two-digit day of the month</td>
</tr>
<tr>
<td>yyyy</td>
<td>Is a four-digit year</td>
</tr>
</tbody>
</table>

See Also
FOR_IFCORE_VERSION

FOR_IFPORT_VERSION

Portability Function: Returns the version of the Fortran portability library (ifport).

Module
USE IFPORT

Syntax
result = FOR_IFPORT_VERSION (string)

string (Output) Character*(*). The version information for the Fortran portability library (ifport).

Results
The result type is INTEGER(4). The result is non-zero if successful; otherwise, zero.

If string is not long enough to contain the version information, the result is truncated on the right. If string is longer than the version information, the result is blank-padded on the right. The result may contain multiple blank or ASCII tab characters.

Example
Consider the following:

program what_ifport
  use ifport
  integer :: res
  character*56 :: str
  res = for_ifport_version( str )
end program what_ifport
The above example will produce a result similar to the following, depending on spacing and the actual version information:

'Intel Fortran portability library   Vvv.m-eeeMmm dd yyyy'

where:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vv</td>
<td>Is a major version number</td>
</tr>
<tr>
<td>m</td>
<td>Is a minor version number</td>
</tr>
<tr>
<td>eee</td>
<td>Is an edit number</td>
</tr>
<tr>
<td>Mmm</td>
<td>Is a three-character abbreviation for the month</td>
</tr>
<tr>
<td>dd</td>
<td>Is a two-digit day of the month</td>
</tr>
<tr>
<td>yyyy</td>
<td>Is a four-digit year</td>
</tr>
</tbody>
</table>

FOR_IFPORT_VERSION

FOR_LFENCE

**Run-Time Subroutine:** Inserts a memory load fence instruction that ensures completion of preceding load instructions.

**Module**
USE IFCORE

**Syntax**

```fortran
CALL FOR_LFENCE()
```

Using this subroutine guarantees that in program order, every load instruction that precedes the load fence instruction is globally visible before any load instruction that follows the load fence.

FOR_MFENCE

**Run-Time Subroutine:** Inserts a memory fence instruction that ensures completion of all preceding load and store instructions.

**Module**
USE IFCORE

**Syntax**

```fortran
CALL FOR_MFENCE()
```

Using this subroutine guarantees that in program order, every load and store instruction that precedes the memory fence instruction is globally visible before any load or store instruction that follows the memory fence can proceed.
for_rtl_finish_

Run-Time Function: Cleans up the Fortran run-time environment; for example, flushing buffers and closing files. It also issues messages about floating-point exceptions, if any occur.

Syntax
This routine should be called from a C main program; it is invoked by default from a Fortran main program.

```c
result = for_rtl_finish_();
```

Results
The result is an I/O status value. For information on these status values, see Error Handling: Using the IOSTAT Value and Fortran Exit Codes.

To initialize the Fortran run-time environment, use function for_rtl_init_.

Example
Consider the following C code:

```c
int io_status;
int for_rtl_finish_();
io_status = for_rtl_finish_();
```

See Also
for_rtl_init_

for_rtl_init_

Run-Time Subroutine: Initializes the Fortran run-time environment and causes Fortran procedures and subroutines to behave the same as when called from a Fortran main program. On Linux and macOS, it also establishes handlers and floating-point exception handling.

Syntax
This routine should be called from a C main program; it is invoked by default from a Fortran main program.

```c
CALL for_rtl_init_(argcount, actarg)
```

argcount
Is a command-line parameter describing the argument count.

actarg
Is a command-line parameter describing the actual arguments.

To clean up the Fortran run-time environment, use function for_rtl_finish_.

Example
Consider the following C code:

```c
int argc;
char **argv;
void for_rtl_init_(int *, char **);
for_rtl_init_(&argc, argv);
```

See Also
for_rtl_finish_
**FOR_SET_FPE**

*Run-Time Function: Sets the floating-point exception flags.* This routine can be called from a C or Fortran program.

**Module**

USE IFCORE

**Syntax**

```
result = FOR_SET_FPE (a)
```

*a* Must be of type INTEGER(4). It contains bit flags controlling floating-point exception trapping, reporting, and result handling.

**Results**

The result type is INTEGER(4). The return value represents the previous settings of the floating-point exception flags. The meanings of the bits are defined in the IFCORE module file.

To get the current settings of the floating-point exception flags, use `FOR_GET_FPE`.

**Example**

```
USE IFCORE
INTEGER*4 OLD_FPE_FLAGS, NEW_FPE_FLAGS
OLD_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)

The following example program is compiled without any fpe options. However, it uses calls to `for_set_fpe` to enable the same flags as when compiling with option `fpe:0`. The new flags can be verified by compiling the program with option `-fpe:0`.

program samplefpe
use ifcore
implicit none
INTEGER(4) :: ORIGINAL_FPE_FLAGS, NEW_FPE_FLAGS
INTEGER(4) :: CURRENT_FPE_FLAGS, PREVIOUS_FPE_FLAGS
NEW_FPE_FLAGS = FPE_M_TRAP_UND + FPE_M_TRAP_OVF + FPE_M_TRAP_DIV0 &
+ FPE_M_TRAP_INV + FPE_M_ABRUPT_UND + FPE_M_ABRUPT_DMZ
ORIGINAL_FPE_FLAGS = FOR_SET_FPE (NEW_FPE_FLAGS)
CURRENT_FPE_FLAGS = FOR_GET_FPE ()
print *,"The original FPE FLAGS were:"
CALL PRINT_FPE_FLAGS(ORIGINAL_FPE_FLAGS)
print *," " print *,"The new FPE FLAGS are:"
CALL PRINT_FPE_FLAGS(CURRENT_FPE_FLAGS)
!! restore the fpe flag to their original values
PREVIOUS_FPE_FLAGS = FOR_SET_FPE (ORIGINAL_FPE_FLAGS)
end

subroutine PRINT_FPE_FLAGS(fpe_flags)
use ifcore
```

Language Reference

1497
implicit none
integer(4)   :: fpe_flags
character(3) :: toggle

print 10, fpe_flags, fpe_flags
10 format(X,'FPE FLAGS = 0X',z8.8," B'",b32.32)

if ( IAND(fpe_flags, FPE_M_TRAP_UND) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_TRAP_UND    ": toggle

write(*,*) " FPE_ABRUPT_DIV0 ": toggle

if ( IAND(fpe_flags, FPE_M_ABRUPT_DIV0) .ne. 0 ) then
  toggle = "ON"
else
  toggle = "OFF"
endif
write(*,*) " FPE_ABRUPT_DIV0 ": toggle
The following shows the output from the above program:

```
>ifort set_fpe_sample01.f90
>set_fpe_sample01.exe
The original FPE FLAGS were:
FPE FLAGS = 0X00000000 B'00000000000000000000000000000000
    FPE_TRAP_UND :OFF
    FPE_TRAP_OVF :OFF
    FPE_TRAP_DIV0 :OFF
    FPE_TRAP_INV :OFF
    FPE_ABRUPT_UND :OFF
    FPE_ABRUPT_OVF :OFF
    FPE_ABRUPT_DIV0 :OFF
    FPE_ABRUPT_INV :OFF
    FPE_ABRUPT_DMZ :OFF (ftz related)

The new FPE FLAGS are:
FPE FLAGS = 0X0011000F B'00000000000100010000000000001111
    FPE_TRAP_UND :ON
    FPE_TRAP_OVF :ON
    FPE_TRAP_DIV0 :ON
    FPE_TRAP_INV :ON
    FPE_ABRUPT_UND :ON
    FPE_ABRUPT_OVF :OFF
    FPE_ABRUPT_DIV0 :ON
    FPE_ABRUPT_INV :OFF
    FPE_ABRUPT_DMZ :ON (ftz related)
```

The following example builds a library that has to have a particular setting of the fpe flags internally, and has to work with user programs built with any combination of the fpe flags.

```
!-- file USE.F90 starts here
subroutine use_subnorms
    use, intrinsic :: ieee_arithmetic
    use ifcore

    use, intrinsic :: ieee_features, only: ieee_subnormal
    implicit none

    !--- Declaration for use in example code
    real, volatile ::  x, y
    integer  i
    !--- End declarations for example code

    integer(4) ::  orig_flags, off_flags, not_flags, new_flags
```
if (ieee_support_subnormal()) then
   print *, "Subnormals already supported"
else
   orig_flags = for_get_fpe()
   off_flags = IOR(FPE_M_ABRUPT_UND, FPE_M_ABRUPT_DMZ)
   off_flags = IOR(off_flags, FPE_M_TRAP_UND)
   off_flags = IOR(off_flags, FPE_M_MSG_UND)
   not_flags = NOT(off_flags) "INOT" is the 16-bit version!

You can specify the following lines to compile and link the above program:

```
ifort -c -fpic -no-ftz -fpe3 use.f90
ifort -c -fpic -ftz flush.f90
ifort -c -fpic main.f90
ifort -o main.exe main.o use.o flush.o
```

**FOR_SET_REENTRANCY**

**Run-Time Function:** Controls the type of reentrancy protection that the Fortran Run-Time Library (RTL) exhibits. This routine can be called from a C or Fortran program.

**Module**

USE IFCORE

**Syntax**

```
result = FOR_SET_REENTRANCY (mode)
```

`mode` Must be of type INTEGER(4) and contain one of the following options:

- **FOR_K_REENTRANCY_NONE** Tells the Fortran RTL to perform simple locking around critical sections of RTL code. This type of reentrancy should be used when the Fortran RTL will not be reentered due to asynchronous system traps (ASTs) or threads within the application.

- **FOR_K_REENTRANCY_SYNCH** Tells the Fortran RTL to perform simple locking and disables ASTs around critical sections of RTL code. This type of reentrancy should be used when the application contains AST handlers that call the Fortran RTL.

- **FOR_K_REENTRANCY_THREADED** Tells the Fortran RTL to perform thread locking. This type of reentrancy should be used in multithreaded applications.

- **FOR_K_REENTRANCY_INFO** Tells the Fortran RTL to return the current reentrancy mode.

**Results**

The result type is INTEGER(4). The return value represents the previous setting of the Fortran Run-Time Library reentrancy mode, unless the argument is FOR_K_REENTRANCY_INFO, in which case the return value represents the current setting.

You must be using an RTL that supports the level of reentrancy you desire. For example, FOR_SET_REENTRANCY ignores a request for thread protection (FOR_K_REENTRANCY_THREADED) if you do not build your program with the thread-safe RTL.

**Example**

```
PROGRAM SETREENT
USE IFCORE
INTEGER*4    MODE
CHARACTER*10 REENT_TXT(3) /'NONE    ','ASYNCH  ','THREADED'/
PRINT*, 'Setting Reentrancy mode to ',REENT_TXT(MODE+1)
```
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_NONE)
PRINT*, 'Previous Reentrancy mode was ', REENT.TXT(MODE+1)
MODE = FOR_SET_REENTRANCY(FOR_K_REENTRANCY_INFO)
PRINT*, 'Current Reentrancy mode is ', REENT.TXT(MODE+1)
END

FOR_SFENCE

Run-Time Subroutine: Inserts a memory store fence instruction that ensures completion of preceding store instructions.

Module
USE IFCORE

Syntax
CALL FOR_SFENCE()

Using this subroutine guarantees that in program order, every store instruction that precedes the store fence instruction is globally visible before any store instruction that follows the store fence.

FORALL

Statement and Construct: The FORALL statement and construct is an element-by-element generalization of the masked array assignment in the WHERE statement and construct. It allows more general array shapes to be assigned, especially in construct form. The FORALL construct is an obsolescent language feature in Fortran 2018.

Syntax
Statement:
FORALL (triplet-spec[, triplet-spec] ...[, mask-expr]) assign-stmt

Construct:
[name:] FORALL (triplet-spec[, triplet-spec] ...[, mask-expr])
  forall-body-stmt
  [forall-body-stmt]...
END FORALL [name]

Is a triplet specification with the following form:

[type::] subscript-name = subscript-1: subscript-2[: stride]

The type is an optional integer data type. If type appears, the subscript-name has the specified type and type parameters. Otherwise, it has the type and type parameters that it would have if it were the name of a variable in the innermost executable construct or scoping unit.

If type does not appear, the subscript-name must not be the same as a local identifier, an accessible global identifier, or an identifier of an outer construct entity, except for a common block name or a scalar variable name.
The subscript-name is a scalar of type integer. It is valid only within the scope of the FORALL; its value is undefined on completion of the FORALL.

The subscripts and stride cannot contain a reference to any subscript-name in triplet-spec.

The stride cannot be zero. If it is omitted, the default value is 1.

Evaluation of an expression in a triplet specification must not affect the result of evaluating any other expression in another triplet specification.

mask-expr

Is a logical array expression (called the mask expression). If it is omitted, the value TRUE. is assumed. The mask expression can reference the subscript name in triplet-spec.

Description

If a construct name is specified in the FORALL statement, the same name must appear in the corresponding END FORALL statement.

A FORALL statement is executed by first evaluating all bounds and stride expressions in the triplet specifications, giving a set of values for each subscript name. The FORALL assignment statement is executed for all combinations of subscript name values for which the mask expression is true.

The FORALL assignment statement is executed as if all expressions (on both sides of the assignment) are completely evaluated before any part of the left side is changed. Valid values are assigned to corresponding elements of the array being assigned to. No element of an array can be assigned a value more than once.

A FORALL construct is executed as if it were multiple FORALL statements, with the same triplet specifications and mask expressions. Each statement in the FORALL body is executed completely before execution begins on the next FORALL body statement.

Any procedure referenced in the mask expression or FORALL assignment statement must be pure.

Pure functions can be used in the mask expression or called directly in a FORALL statement. Pure subroutines cannot be called directly in a FORALL statement, but can be called from other pure procedures.

Starting with Fortran 2018, the FORALL statement and construct are obsolescent features.

Example

The following example, which is not expressible using array syntax, sets diagonal elements of an array to 1:

```fortran
REAL, DIMENSION(N, N) :: A
FORALL (I=1:N)  A(I, I) = 1
```

Consider the following:

```fortran
FORALL(I = 1:N, J = 1:N, A(I, J) .NE. 0.0) B(I, J) = 1.0 / A(I, J)
```

This statement takes the reciprocal of each nonzero element of array A(1:N, 1:N) and assigns it to the corresponding element of array B. Elements of A that are zero do not have their reciprocal taken, and no assignments are made to corresponding elements of B.

Every array assignment statement and WHERE statement can be written as a FORALL statement, but some FORALL statements cannot be written using just array syntax. For example, the preceding FORALL statement is equivalent to the following:

```fortran
WHERE(A /= 0.0) B = 1.0 / A
```
However, the following FORALL example cannot be written using just array syntax:

```fortran
FORALL(I = 1:N, J = 1:N) H(I, J) = 1.0/REAL(I + J - 1)
```

This statement sets array element H(I, J) to the value 1.0/REAL(I + J - 1) for values of I and J between 1 and N.

Consider the following:

```fortran
TYPE MONARCH
  INTEGER, POINTER :: P
END TYPE MONARCH

TYPE(MONARCH), DIMENSION(8) :: PATTERN
INTEGER, DIMENSION(8), TARGET :: OBJECT

FORALL(J=1:8) PATTERN(J)%P => OBJECT(1+IEOR(J-1,2))
```

This FORALL statement causes elements 1 through 8 of array PATTERN to point to elements 3, 4, 1, 2, 7, 8, 5, and 6, respectively, of OBJECT. IEOR can be referenced here because it is pure.

The following example shows a FORALL construct:

```fortran
FORALL(I = 3:N + 1, J = 3:N + 1)
  C(I, J) = C(I, J + 2) + C(I, J - 2) + C(I + 2, J) + C(I - 2, J)
  D(I, J) = C(I, J)
END FORALL
```

The assignment to array D uses the values of C computed in the first statement in the construct, not the values before the construct began execution.

See Also
WHERE

**FORMAT**

**Statement:** Specifies the form of data being transferred and the data conversion (editing) required to achieve that form.

**Syntax**

```
FORMAT (format-list)
```

Is a list of one or more of the following edit descriptors, separated by commas or slashes (/):

- **Data edit descriptors:** I, B, O, Z, F, E, EN, ES, D, G, L, and A.
- **Control edit descriptors:** T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q.
- **String edit descriptors:** H, 'c', and "c", where c is a character constant.

A comma can be omitted in the following cases:

- Between a P edit descriptor and an immediately following F, E, EN, ES, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
• Before or after a colon (:) edit descriptor

Edit descriptors can be nested and a repeat specification can precede data edit descriptors, the slash edit descriptor, or a parenthesized list of edit descriptors.

Description

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see the OPEN statement.

For formatted input, you can use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.

The first character of a record transmitted to a line printer or terminal is typically used for carriage control; it is not printed. The first character of such a record should be a blank, 0, 1, $,+, or ASCII NUL. Any other character is treated as a blank.

A format specification cannot specify more output characters than the external record can contain. For example, a line printer record cannot contain more than 133 characters, including the carriage control character.

Whenever an edit descriptor requires an integer constant, you can specify an expression enclosed in angle brackets (< and >). For more information, see Variable Format Expressions.

The integer expression can be any valid Fortran expression, including function calls and references to dummy arguments, with the following restrictions:

• Expressions cannot be used with the H edit descriptor.
• Expressions cannot contain graphical relational operators (such as > and <).

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement.

The following tables summarize the different kinds of edit descriptors:

### Data Edit Descriptors

<table>
<thead>
<tr>
<th>Code</th>
<th>Form 1</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>A[w]</td>
<td>Transfers character or Hollerith values.</td>

<tr>
<td>/</td>
<td>[r]/</td>
<td>_terminates the current record and moves to the next record.</td>
</tr>
</tbody>
</table>
| \    | \    |_continues the same record; same as $.

**String Edit Descriptors**

<table>
<thead>
<tr>
<th>Code</th>
<th>Form</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
<td>nHch[ch...]</td>
<td>_transfers characters following the H edit descriptor to an output record.</td>
</tr>
<tr>
<td>'c'</td>
<td>'c'</td>
<td>_transfers the character literal constant (between the delimiters) to an output record.</td>
</tr>
</tbody>
</table>

2 These delimiters can also be quotation marks (").

**Example**

```fortran
INTEGER width, value
width = 2
read (*,1) width, value
! if the input is 3123, prints 123, not 12
1 format ( i1, i<width>)
print *, value
END
```

**FORM TEAM**

*Statement:* Defines team variables; creates one or more teams of images from the images on the current team.
**Syntax**

The FORM TEAM statement takes the following form:

```
FORM TEAM(team-number, team-variable [, form-team-spec-list])
```

- **team-number** is a scalar-integer-expression.
- **team-variable** is a scalar variable of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV.
- **form-team-spec** can be one of:
  - `NEW_INDEX = scalar-integer-expression`
  - `sync-stat-list`
- **sync-stat-list** is a list that can include:
  - `STAT= stat-var`
  - `ERRMSG = err-var`
- **stat-var** is a scalar integer variable in which the status of the FORM TEAM operation is stored.
- **err-var** is a scalar default character variable in which explanatory text is stored if an error occurs.

The **form-team-spec** items can appear in any order. Each specifier in a FORM TEAM statement can appear at most once. **stat-var** and **err-var** cannot be coindexed variables.

**Description**

A FORM TEAM statement creates a new team for each unique **team-number** specified by the active images of the current team. The teams are identified by their team numbers, which are positive integers. An image becomes a member of the **team-number** specified on the FORM TEAM statement the image executes. The **team-variable** becomes defined with values that describe the team.

An image index must be positive and less than or equal to \( n \), the number of images on the team. If `NEW_INDEX=` is specified, the value of the `scalar-integer-expression` is the image index the image executing the FORM TEAM statement will have on its new team. Its value must be different from any value specified for every other image that is assigned to the same new team. If `NEW_IMAGE=` is not specified, the image is given a processor-dependent unique image index in the range 1, 2, ... \( n \) on the new team.

All active images of the current team must execute the same FORM TEAM statement. An implicit SYNC ALL occurs at the FORM TEAM statement. Execution of the segment following the FORM TEAM statement is delayed until other images of the current team have executed the same FORM TEAM statement the same number of times. FORM TEAM is an image control statement; all segments executed before the FORM TEAM statement precede all segments that execute after the FORM TEAM statement.

If `STAT=` appears and no error occurs, **stat-var** becomes defined with the value 0. If an image on the current team has executed a STOP statement, **stat-var** is assigned the value STAT_STOPPED_IMAGE from the intrinsic module ISO_FORTRAN_ENV. If there is a failed image on the current team and no other error occurs, **stat-var** is assigned the value STAT_FAILED_IMAGE from ISO_FORTRAN_ENV. Otherwise, **stat-var** is assigned a positive integer value different from STAT_FAILED_IMAGE and STAT_STOPPED_IMAGE. **team-variable** becomes undefined if an error condition occurs.

**Examples**

Example 1:

```fortran
USE ISO_FORTRAN
TYPE (TEAM_TYPE) :: one_or_two
IF (THIS_IMAGE() .LE. NUM_IMAGES() / 2) THEN
  new_team = 1
ELSE
```
If the initial team has seven images, and the initial team executes the above FORM TEAM statement, two teams are formed. The new image indices are assigned by the runtime system in a processor-dependent manner.

Team number 1 has three images, images [1, 2, 3] of the initial team with new image indices [1, 2, 3]. Team number 2 has four images, images [4, 5, 6, 7] from the initial team, with new image indices [1, 2, 3, 4]. The team variable one_or_two on initial team images [1, 2, 3] collectively describe team number 1, while the team variable one_or_two on the initial team images [4, 5, 6, 7] collectively describe team number 2.

Example 2:

```fortran
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE) :: odd_even
FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
```

If a team with 10 images executes the above code, two teams are formed. Team number 1 contains the odd numbered images [1, 3, 5, 7, 9] of the parent team, and team number 2 contains the even numbered images [2, 4, 6, 8, 10] of the parent. New image indices on each team are assigned by the processor. The team variable odd_even across the odd numbered images on the parent team collectively describe team number 1, and the team variable odd_even across the even numbered images on the parent team collectively describe team number 2.

Example 3:

```fortran
USE ISO_FORTRAN_ENV
INTEGER, PARAMETER :: n = 4
TYPE (TEAM_TYPE) :: column
REAL, CODIMENSION[n, *} :: co_array
INTEGER, DIMENSION(2) :: my_cosubscripts
my_cosubscripts () = THIS_IMAGE(co_array)
FORM TEAM (my_cosubscripts(2), column, NEW_INDEX = my_cosubscripts(1))
```

If there are 16 images on the initial team, the scalar coarray co_array will be distributed across a 4x4 grid of processors. The image indices of the 4x4 grid are:

```
  1  5  9 13
  2  6 10 14
  3  7 11 15
  4  8 12 16
```

THIS_IMAGE (co_array) will return a two element array of integer cosubscripts of co_array on the image that executes the reference to THIS_IMAGE. The cosubscripts of each image are:

```
  1,1 1,2 1,3 1,4
  2,1 2,2 2,3 2,4
  3,1 3,2 3,3 3,4
  4,1 4,2 4,3 4,4
```

Execution of the FORM TEAM statement divides the initial team into four teams of four images. Each team contains the images of one column of the grid of processors. The team number of each team is the column number in the processor grid, and the image indices on each new team are the row indices of the processor grid. The new image numbers on each team are shown below:

```
Team Number
  1  2  3  4
  1  1  1  1
```
Example 4:

This example divides a 4x4 grid of images into 4 2x2 grids of images. Team numbers are assigned in the FORM TEAM statement that reflect the position of each team in the grid of subteams. The example also shows the use of NEW_INDEX to assign image indices to the images of the new teams.

The image indices of the 4x4 grid are:

```
  1  5  9 13
  2  6 10 14
  3  7 11 15
  4  8 12 16
```

The 2x2 grids are laid out and identified symbolically and with team numbers as:

```
| top_left | top_right |
| t (1,1)  | t (1,2)   |
| bot_left | bot_right |
| t (2,1)  | t (2,2)   |
```

The image numbers on each of the teams in the 2x2 grids become:

```
  1  3  1  3
  2  4  2  4
  1  3  1  3
  2  4  2  4
```

```
PROGRAM MAIN
USE ISO_FORTRAN_ENV
INTEGER,PARAMETER :: top_left=11, bot_left=21, top_right=12, bot_right=22
INTEGER,DIMENSION(16) :: quads = [top_left, top_left, bot_left, bot_left, &
                                top_left, top_left, bot_left, bot_left, &
                                top_right, top_right, bot_right, bot_right, &
                                top_right, top_right, bot_right, bot_right]
INTEGER,DIMENSION(16) :: images = [1,2,1,2,3,4,3,4,1,2,1,2,3,4,3,4]
TYPE(TEAM_TYPE) :: quadrants
INTEGER :: me
me = THIS_IMAGE()
FORM TEAM (quads(me), quadrants, NEW_INDEX=images(me))
...
END PROGRAM
```

Example 5:

```
USE ISO_FORTRAN_ENV
TYPE (TEAM_TYPE) :: original
FORM TEAM (1, original, NEW_INDEX = THIS_IMAGE())
```

This example forms a single subteam described by the team variable original. The subteam has the same number of images as the initial team, and each image has the same image number on the initial team as on the subteam. However, original describes a team that is different but functionally the same as the initial team. It has a parent team, while the initial team does not.

Using Coarrays

FP_CLASS
Elemental Intrinsic Function (Generic): Returns the class of an IEEE* real (binary32, binary64, and binary128) argument. This function cannot be passed as an actual argument.

Syntax
result = FP_CLASS (x)

x (Input) Must be of type real.

Results
The result type is INTEGER(4). The return value is one of the following:

<table>
<thead>
<tr>
<th>Class of Argument</th>
<th>Return Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Signaling NaN</td>
<td>FOR_K_FP_SNAN</td>
</tr>
<tr>
<td>Quiet NaN</td>
<td>FOR_K_FP_QNAN</td>
</tr>
<tr>
<td>Positive Infinity</td>
<td>FOR_K_FP_POS_INF</td>
</tr>
<tr>
<td>Negative Infinity</td>
<td>FOR_K_FP_NEG_INF</td>
</tr>
<tr>
<td>Positive Normalized Number</td>
<td>FOR_K_FP_POS_NORM</td>
</tr>
<tr>
<td>Negative Normalized Number</td>
<td>FOR_K_FP_NEG_NORM</td>
</tr>
<tr>
<td>Positive Subnormal Number</td>
<td>FOR_K_FP_POS_DENORM</td>
</tr>
<tr>
<td>Negative Subnormal Number</td>
<td>FOR_K_FP_NEG_DENORM</td>
</tr>
<tr>
<td>Positive Zero</td>
<td>FOR_K_FP_POS_ZERO</td>
</tr>
<tr>
<td>Negative Zero</td>
<td>FOR_K_FP_NEG_ZERO</td>
</tr>
</tbody>
</table>

The preceding return values are defined in file for_fpclass.for.

Example
FP_CLASS (4.0_8) has the value 4 (FOR_K_FP_POS_NORM).

FPUTC
Portability Function: Writes a character to the file specified by a Fortran external unit, bypassing normal Fortran input/output.

Module
USE IFPORT

Syntax
result = FPUTC (lunit, char)
\textit{lunit} 
\textbf{(Input)} INTEGER(4). Unit number of a file.

\textit{char} 
\textbf{(Output)} Character(*). Variable whose value is to be written to the file corresponding to \textit{lunit}.

\textbf{Results}

The result type is INTEGER(4). The result is zero if the write was successful; otherwise, an error code, such as:

\textbf{EINVAL} - The specified unit is invalid (either not already open, or an invalid unit number)

If you use WRITE, READ, or any other Fortran I/O statements with \textit{lunit}, be sure to read Input and Output Routines in Overview of Portability Routines.

\textbf{Example}

\begin{verbatim}
use IFPORT
integer*4 lunit, i4
character*26 string
character*1 char1
lunit = 1
open (lunit, file = 'fputc.dat')
do i = 1,26
   char1 = char(123-i)
i4 = fputc(1,char1)        !make valid writes
   if (i4.ne.0) iflag = 1
endo
rewind (1)
read (1,'(a)') string
print *, string
\end{verbatim}

\textbf{See Also}

I/O Formatting

\textbf{FRACTION}

\textit{Elemental Intrinsic Function (Generic): Returns the fractional part of the model representation of the argument value.}

\textbf{Syntax}

\begin{verbatim}
result = FRACTION (x)
\end{verbatim}

\begin{verbatim}
x \hspace{1cm} \textbf{(Input)} Must be of type real.
\end{verbatim}

\textbf{Results}

The result type and kind are the same as \textit{x}.

The result has the value \(x \times b^e\). Parameters \(b\) and \(e\) are defined in Model for Real Data.

If \(x\) has the value zero, the result has the value zero.

\textbf{Example}

If 3.0 is a REAL(4) value, FRACTION (3.0) has the value 0.75.
The following shows another example:

```fortran
REAL result
result = FRACTION(3.0) ! returns 0.75
result = FRACTION(1024.0) ! returns 0.5
```

**FREE**

*Intrinsic Subroutine (Specific):* Frees a block of memory that is currently allocated. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL FREE (addr)
```

`addr` (Input) Must be of type INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. This value is the starting address of the memory block to be freed, previously allocated by `MALLOC`.

If the freed address was not previously allocated by `MALLOC`, or if an address is freed more than once, results are unpredictable.

**Example**

```fortran
INTEGER(4) SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE) ! ADDR will point to STORAGE
SIZE = 1024 ! Size in bytes
ADDR = MALLOC(SIZE) ! Allocate the memory
CALL FREE(ADDR) ! Free it
```

**FREEFORM and NOFREEFORM**

*General Compiler Directives:* `FREEFORM` specifies that source code is in free-form format. `NOFREEFORM` specifies that source code is in fixed-form format.

**Syntax**

```fortran
!DIR$ FREEFORM

!DIR$ NOFREEFORM
```

When the `FREEFORM` or `NOFREEFORM` directives are used, they remain in effect for the remainder of the source or include file in which the directive appears, or until the opposite directive is used. When in effect, they apply to include files, but do not affect USE modules, which are compiled separately.

source or include file in which the directive appears
Example
Consider the following:

```fortran
SUBROUTINE F (A, NX,NY,I1,I2,J1,J2)
! is in column 1 and fixed form
!     X is in column 7
REAL (8) :: A (NX,NY)
!DIR$ ASSUME_ALIGNED A:32
!DIR$ FREEFORM          ! what follows is freeform
!DIR$ ASSUME (MOD(NX,8) .EQ. 0)
! ensure that the first array access in the loop is aligned
!DIR$ ASSUME (MOD(I1,8) .EQ. 1)
DO J=J1,J2
    DO I=I1,I2
        A(I,J) = A(I,J) + A(I,J+1) + A(I,J-1)
    ENDDO
ENDDO
!DIR$ NOFREEFORM            ! and now back to fixed form
END SUBROUTINE F
```

Equivalent Compiler Options

FSEEK

**Portability Function:** Repositions a file specified by a Fortran external unit.

Module
USE IFPORT

Syntax

```fortran
result = FSEEK (lunit,offset,from)
```

- `lunit` (Input) INTEGER(4). External unit number of a file.
- `offset` (Input) INTEGER(4) or INTEGER(8). Offset in bytes, relative to `from`, that is to be the new location of the file marker.
- `from` (Input) INTEGER(4). A position in the file. It must be one of the following:

<table>
<thead>
<tr>
<th>Value</th>
<th>Variable</th>
<th>Position</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>SEEK_SET</td>
<td>Positions the file relative to the beginning of the file.</td>
</tr>
<tr>
<td>1</td>
<td>SEEK_CUR</td>
<td>Positions the file relative to the current position.</td>
</tr>
<tr>
<td>Value</td>
<td>Variable</td>
<td>Position</td>
</tr>
<tr>
<td>-------</td>
<td>----------</td>
<td>----------</td>
</tr>
<tr>
<td>2</td>
<td>SEEK_END</td>
<td>Positions the file relative to the end of the file.</td>
</tr>
</tbody>
</table>

**Results**

The result type is INTEGER(4). The result is zero if the repositioning was successful; otherwise, an error code, such as:

**EINVAL**: The specified unit is invalid because either the unit is not already open, an invalid unit number was specified, or the from parameter is invalid.

The file specified in *lunit* must be open.

**Example**

```fortran
USE IFPORT
integer(4) istat, offset, ipos
character ichar
OPEN (unit=1, file='datfile.dat')
offset = 5
ipos = 0
istat=fseek(1,offset,ipos)
if (.NOT. stat) then
  istat=fgetc(1,ichar)
  print *, 'data is ',ichar
end if
```

**FSTAT**

*Portability Function: Returns detailed information about a file specified by a external unit number.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = FSTAT (lunit, statb)
```

*lunit* (Input) INTEGER(4). External unit number of the file to examine.

*statb* (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. The elements of *statb* contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(1)</td>
<td>Device the file resides on</td>
<td>W<em>S: Always 0 L</em>X: System dependent</td>
</tr>
<tr>
<td>statb(2)</td>
<td>File inode number</td>
<td>W<em>S: Always 0 L</em>X: System dependent</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
<td>Values or Notes</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------------------------------------------</td>
<td>------------------------------------------------------</td>
</tr>
<tr>
<td>statb(3)</td>
<td>Access mode of the file</td>
<td>See the table in Results</td>
</tr>
<tr>
<td>statb(4)</td>
<td>Number of hard links to the file</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(5)</td>
<td>User ID of owner</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(6)</td>
<td>Group ID of owner</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(7)</td>
<td>Raw device the file resides on</td>
<td>W*S: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L*X: System dependent</td>
</tr>
<tr>
<td>statb(8)</td>
<td>Size of the file</td>
<td></td>
</tr>
<tr>
<td>statb(9)</td>
<td>Time when the file was last accessed(^1)</td>
<td>W*S: Only available on non-FAT file systems; undefined on FAT systems</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>statb(10)</td>
<td>Time when the file was last modified(^1)</td>
<td></td>
</tr>
<tr>
<td>statb(11)</td>
<td>Time of last file status change(^1)</td>
<td>W*S: Same as stat(10)</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>statb(12)</td>
<td>Blocksize for file system I/O operations</td>
<td>W*S: Always 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

\(^1\)Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, returns an error code equal to EINVAL (lunit is not a valid unit number, or is not open).

The access mode (the third element of statb) is a bitmap consisting of an IOR of the following constants:
<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Constant</th>
<th>Description</th>
<th>Notes</th>
</tr>
</thead>
<tbody>

<td>Same as S_IRUSR on Windows systems</td>
</tr>
</tbody>
</table>
### STAT

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

**Example**

```fortran
USE IFPORT
integer(4) statarray(12), istat
OPEN (unit=1, file='datfile.dat')
ISTAT = FSTAT (1, statarray)
if (.NOT. istat) then
   print *, statarray
end if
```

**See Also**

INQUIRE

STAT

### FTELL, FTELLI8

**Portability Functions:** Return the current position of a file.

**Module**

USE IFPORT

**Syntax**

```
result = FTELL (lunit)
result = FTELLI8 (lunit)
```

- **lunit** (Input) INTEGER(4). External unit number of a file.

**Results**

The result type is INTEGER(4) for FTELL; INTEGER(8) for FTELLI8. The result is the offset, in bytes, from the beginning of the file. A negative value indicates an error, which is the negation of the IERRNO error code. The following is an example of an error code:

- **EINVAL:** `lunit` is not a valid unit number, or is not open.

### FULLPATHQQ

**Portability Function:** Returns the full path for a specified file or directory.

**Module**

USE IFPORT

**Syntax**

```
result = FULLPATHQQ (name, pathbuf)
```
name  (Input) Character*(*). Item for which you want the full path. Can be the name of a file in the current directory, a relative directory or file name, or a network uniform naming convention (UNC) path.

pathbuf  (Output) Character*(*). Buffer to receive full path of the item specified in name.

Results

The result type is INTEGER(4). The result is the length of the full path in bytes, or 0 if the function fails. This function does not verify that the resulting path and file name are valid nor that they exist.

The length of the full path depends upon how deeply the directories are nested on the drive you are using. If the full path is longer than the character buffer provided to return it (pathbuf), FULLPATHQQ returns only that portion of the path that fits into the buffer.

Check the length of the path before using the string returned in pathbuf. If the longest full path you are likely to encounter does not fit into the buffer you are using, allocate a larger character buffer. You can allocate the largest possible path buffer with the following statements:

```
USE IFPORT
CHARACTER($MAXPATH) pathbuf
```

$MAXPATH is a symbolic constant defined in IFPORT.F90 as 260.

Example

```
USE IFPORT
USE IFCORE
CHARACTER($MAXPATH) buf
CHARACTER(3) drive
CHARACTER(256) dir
CHARACTER(256) name
CHARACTER(256) ext
CHARACTER(256) file
INTEGER(4) len
DO WHILE (.TRUE.)
  WRITE (*,*)
  WRITE (*,'(A, ")') ' Enter filename (Hit & RETURN to exit): '
  len = GETSTRQQ(file)
  IF (len .EQ. 0) EXIT
  len = FULLPATHQQ(file, buf)
  IF (len .GT. 0) THEN
    WRITE (*,*) buf(:len)
  ELSE
    WRITE (*,*) 'Can''t get full path'
    EXIT
  END IF

  Split path
  WRITE (*,*)
  len = SPLITPATHQQ(buf, drive, dir, name, ext)
  IF (len .NE. 0) THEN
    WRITE (*, 900) ' Drive: ', dir
    WRITE (*, 900) ' Directory: ', dir(1:len)
    WRITE (*, 900) ' Name: ', name
    WRITE (*, 900) ' Extension: ', ext
  ELSE
    WRITE (*,*) 'Can''t split path'
```

1520
FUNCTION

Statement: The initial statement of a function subprogram. A function subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression.

Syntax

```
[prefix [prefix]] FUNCTION name [([d-arg-list])] [suffix]

     [specification-part]
     [execution-part]

[C]ONTAINS
     [internal-subprogram-part]]

END [FUNCTION [name]]
```

(Optional) Is any of the following:

- A data type specifier
- **ELEMENTAL**
  Acts on one array element at a time. This is a restricted form of pure procedure.
- **IMPURE**
  Asserts that the procedure has side effects.
- **MODULE**
  Indicates a separate module procedure. See separate module procedures.
- **NON_RECURSIVE**
  Indicates the function is not recursive.
- **PURE**
  Asserts that the procedure has no side effects.
- **RECURSIVE**
  Permits direct and indirect recursion to occur. If a function is directly recursive and array valued, and RESULT is not specified, any reference to the function name in the executable part of the function is a reference to the function result variable.

At most one of each of the above can be specified. You cannot specify both NON_RECURSIVE and RECURSIVE. You cannot specify both PURE and IMPURE. You cannot specify ELEMENTAL if lang-binding is specified in suffix.
name

Is the name of the function. If RESULT is specified, the function name must not appear in any specification statement in the scoping unit of the function subprogram.

The function name can be followed by the length of the data type. The length is specified by an asterisk (*) followed by any unsigned, nonzero integer that is a valid length for the function's type. For example, REAL FUNCTION LGFUNC*8 (Y, Z) specifies the function result as REAL(8) (or REAL*8).

This optional length specification is not permitted if the length has already been specified following the keyword CHARACTER.

d-arg-list

(Optional) Is a list of one or more dummy arguments.

If there are no dummy arguments, no suffix, and no RESULT variable, the parentheses can be omitted. For example, the following is valid:

```fortran
FUNCTION F
```

suffix

(Optional) Takes one of the following forms:

- [RESULT (r-name)] lang-binding
- lang-binding [RESULT (r-name)]

r-name

(Optional) Is the name of the function result. This name must not be the same as the function name.

lang-binding

Takes the following form:

- BIND (C [, NAME=ext-name])

ext-name

Is a character scalar constant expression that can be used to construct the external name.

specification-part

Is one or more specification statements.

execution-part

Is one or more executable constructs or statements.

internal-subprogram-part

Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.

Description

The type and kind parameters (if any) of the function's result can be defined in the FUNCTION statement or in a type declaration statement within the function subprogram, but not both. If no type is specified, the type is determined by implicit typing rules in effect for the function subprogram.

Execution begins with the first executable construct or statement following the FUNCTION statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

If you specify CHARACTER(LEN=*) as the type of the function, the function assumes the length declared for it in the program unit that invokes it. This type of the resulting character function can have different lengths when it is invoked by different program units. An assumed-length character function cannot be directly recursive.
If the character length is specified as an integer constant, the value must agree with the length of the function specified in the program unit that invokes the function. If no length is specified, a length of 1 is assumed.

If the function is array-valued or a pointer, the declarations within the function must state these attributes for the function result name. The specification of the function result attributes, dummy argument attributes, and the information in the procedure heading collectively define the interface of the function.

The value of the result variable is returned by the function when it completes execution. Certain rules apply depending on whether the result is a pointer, as follows:

- If the result is a pointer, its allocation status must be determined before the function completes execution. The function must associate a target with the pointer, or cause the pointer to be explicitly disassociated from a target.

- If the pointer result points to a TARGET with the INTENT(IN) attribute, the function can give the result a value but the caller is not allowed to change the value pointed to.

- The shape of the value returned by the function is determined by the shape of the result variable when the function completes execution.

- If the result is not a pointer, its value must be defined before the function completes execution. If the result is an array, all the elements must be defined. If the result is a derived-type structure, all the components must be defined.

A function subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A function can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

**Example**

The following example uses the Newton-Raphson iteration method \((F(X) = \cosh(X) + \cos(X) - A = 0)\) to get the root of the function:

```fortran
FUNCTION ROOT(A)
    X  = 1.0
    DO
        EX = EXP(X)
        EMINX = 1./EX
        ROOT  = X - ((EX+EMINX)*.5+COS(X)-A)/((EX-EMINX)*.5-SIN(X))
        IF (ABS((X-ROOT)/ROOT) .LT. 1E-6) RETURN
        X  = ROOT
    END DO
END
```

In the preceding example, the following formula is calculated repeatedly until the difference between \(X_i\) and \(X_{i+1}\) is less than 1.0E-6:

\[
X_{i+1} = X_i - \frac{\cos(X_i) + \cos(X_i) - A}{\sinh(X_i) - \sin(X_i)}
\]

The following example shows an assumed-length character function:

```fortran
CHARACTER*(*) FUNCTION REDO(CARG)
CHARACTER*1 CARG
DO I=1,LEN(REDO)
    REDO(I:I) = CARG
END
```

Language Reference
This function returns the value of its argument, repeated to fill the length of the function.

Within any given program unit, all references to an assumed-length character function must have the same length. In the following example, the REDO function has a length of 1000:

```
CHARACTER*1000 REDO, MANYAS, MANYZS
MANYAS = REDO('A')
MANYZS = REDO('Z')
```

Another program unit within the executable program can specify a different length. For example, the following REDO function has a length of 2:

```
CHARACTER HOLD*6, REDO*2
HOLD = REDO('A')//REDO('B')//REDO('C')
```

The following example shows a dynamic array-valued function:

```
FUNCTION SUB (N)
    REAL, DIMENSION(N) :: SUB
    ...
END FUNCTION
```

The following shows another example:

```
INTEGER Divby2
10    PRINT *, 'Enter a number'
    READ *, i
    Print *, Divby2(i)
    GOTO 10
END
```

```
INTEGER FUNCTION Divby2 (num)
Divby2=num / 2
END FUNCTION
```

The following example shows an allocatable function with allocatable arguments:

```
MODULE AP
CONTAINS

FUNCTION ADD_VEC(P1,P2)
    ! Function to add two allocatable arrays of possibly differing lengths.
    ! The arrays may be thought of as polynomials (coefficients)
    REAL, ALLOCATABLE :: ADD_VEC(:), P1(:), P2(:)

    ! This function returns an allocatable array whose length is set to
    ! the length of the larger input array.
    ALLOCATE(ADD_VEC(MAX(SIZE(P1), SIZE(P2))))

    M = MIN(SIZE(P1), SIZE(P2))
    ! Add up to the shorter input array size
    ADD_VEC(:M) = P1(:M) + P2(:M)
    ! Use the larger input array elements afterwards (from P1 or P2)
    IF(SIZE(P1) > M) THEN
        ADD_VEC(M+1:) = P1(M+1:)
    ELSE IF(SIZE(P2) > M) THEN
        ADD_VEC(M+1:) = P2(M+1:)
    END IF
END FUNCTION
```

1524
PROGRAM TEST
USE AP
REAL, ALLOCATABLE :: P(:,), Q(:,), R(:,), S(:)
ALLOCATE(P(3))
ALLOCATE(Q(2))
ALLOCATE(R(3))
ALLOCATE(S(3))

! Notice that P and Q differ in length
P = (/4,2,1/)  ! P = X**2 + 2X + 4
Q = (/-1,1/)   ! Q = X - 1
PRINT *, 'Result should be:    3.000000       3.000000       1.000000'
PRINT *, 'Coefficients are: ', ADD_VEC(P, Q)  ! X**2 + 3X + 3

P = (/1,1,1/)  ! P = X**2 + X + 1
R = (/2,2,2/)  ! R = 2X**2 + 2X + 2
S = (/3,3,3/)  ! S = 3X**2 + 3X + 3
PRINT *, 'Result should be:    6.000000       6.000000       6.000000'
PRINT *, 'Coefficients are: ', ADD_VEC(ADD_VEC(P,R), S)
END

Consider the following example:

module mymodule
  type :: vec
    integer :: x(3)
  contains
    procedure :: at
  end type vec
contains
  function at( this, i ) result( p )
    implicit none
    class(vec), intent(in), target :: this
    integer, intent(in) :: i
    integer, pointer :: p
    p => this%x(i)
  end function at
end module mymodule

program test
use mymodule
implicit none
type(vec) :: myvec
myvec%x = [1,2,3]

! pointer returned by function at gives the correct values: 1, 2, and 3
write(6,*), myvec%at(1), myvec%at(2), myvec%at(3)

! changing any array element is an error
myvec%at(1) = 4
myvec%at(2) = 5
myvec%at(3) = 6
...
end program test

G

This section describes language features that start with G.

G

GAMMA

Elemental Intrinsic Function (Generic): Returns the gamma value of its argument.

Syntax

result = GAMMA (x)

x (Input) Must be of type real. It must not be zero or a negative number.

Results

The result type and kind are the same as x.
The result has a value equal to a processor-dependent approximation to the gamma function of x,

\[
\Gamma(X) = \begin{cases}
\int_0^\infty t^{X-1} \exp(-t) \, dt & \quad X > 0 \\
\int_0^\infty t^{X-1} \left[ \exp(-t) - \sum_{k=0}^{\infty} \frac{(-t)^k}{k!} \right] \, dt & \quad -n - 1 < X < -n, n \text{ an integer} \geq 0
\end{cases}
\]

Example

GAMMA (1.0) has the approximate value 1.000.

GENERIC

Statement: Declares a generic interface that is bound to a derived type-bound procedure, or specifies a generic identifier for one or more specific procedures.

Syntax

The GENERIC statement takes the following form:
GENERIC [, access-spec][,: generic-spec => binding-name1 [, binding-name2]...

access-spec  (Optional) Is the PUBLIC or PRIVATE attribute. Only one can be specified. access-spec specifies the accessibility of generic-spec.

generic-spec Is an explicit INTERFACE statement using one of the following:
- generic-name
generic-spec can be the name of a previously declared accessible generic name, in which case this statement extends that interface. For more information, see Defining Generic Names for Procedures.
- OPERATOR (op)
op is an intrinsic or a user-defined operator. For more information, see Defining Generic Operators.
- ASSIGNMENT (=)
See Defining Generic Assignment.

The same generic-spec can be used in several generic bindings. In this case, every occurrence of the same generic-spec must have the same accessibility.

binding-spec1 [, binding-
spec2,...] Is the name of a specific procedure. It cannot be the name of a specific procedure that has been specified in an accessible generic interface with the same generic identifier. At most one of the specific names can be the same as the generic name.

Examples
Consider the following:

GENERIC :: GEN_FUNC => INT_FUNC, REAL_FUNC
GENERIC :: GEN_FUNC => CMPLX_FUNC

If INT_FUNC, REAL_FUNC, and CMPLX_FUNC are all functions with accessible interfaces, the first GENERIC statement declares GEN_FUNC to be a generic function name which can resolve to INT_FUNC or REAL_FUNC. The second GENERIC statement extends GEN_FUNC to be resolvable to a third specific function, CMPLX_FUNC.

Consider the following:

TYPE MY_TYPE2
...
CONTAINS
  PROCEDURE :: MYPROC => MYPROC1
  PROCEDURE,PASS(C) :: UPROC => UPROC1
  GENERIC :: OPERATOR(+) => MYPROC, UPROC
END TYPE MY_TYPE2
...
TYPE,EXTENDS(MY_TYPE2) :: MY_TYPE3
...
CONTAINS
  PROCEDURE :: MYPROC => MYPROC2
  PROCEDURE,PASS(C) :: UPROC => UPROC2
END TYPE MY_TYPE3

The type MY_TYPE3 inherits the generic operator '+'. Invoking the generic (+) invokes the specific type-bound procedure. For entities of type MY_TYPE3, that invokes the overriding actual procedure (MYPROC2 or UPROC2).

Type-Bound Procedures
Defining Generic Names for Procedures

GERROR

Run-Time Subroutine: Returns a message for the last error detected by a Fortran run-time routine.

Module
USE IFCORE

Syntax
CALL GERROR (string)

string (Output) Character*(*) Message corresponding to the last detected error.

The last detected error does not necessarily correspond to the most recent function call. The compiler resets string only when another error occurs.

Example
USE IFCORE
character*40 errtext
character char1
integer*4 iflag, i4
...!Open unit 1 here
i4=fgetc(1,char1)
if (i4) then
  iflag = 1
  Call GERROR (errtext)
  print *, errtext
end if

See Also
PERROR
IERRNO

GETARG

Intrinsic Subroutine: Returns the specified command-line argument (where the command itself is argument number zero). Intrinsic subroutines cannot be passed as actual arguments.

Syntax
CALL GETARG (n,buffer,[,status])

n (Input) Must be a scalar of type integer. This value is the position of the command-line argument to retrieve. The command itself is argument number 0.

buffer (Output) Must be a scalar of type default character. Its value is the returned command-line argument.
GETARG returns the \( n \)th command-line argument. If \( n \) is zero, the name of the executing program file is returned.

GETARG returns command-line arguments as they were entered. There is no case conversion.

If the command-line argument is shorter than \( \text{buffer} \), GETARG pads \( \text{buffer} \) on the right with blanks. If the argument is longer than \( \text{buffer} \), GETARG truncates the argument on the right. If there is an error, GETARG fills \( \text{buffer} \) with blanks.

**Example**

Assume a command-line invocation of `PROG1 -g -c -a`, and that \( \text{buffer} \) is at least five characters long. The following calls to GETARG return the corresponding arguments in \( \text{buffer} \) and \( \text{status} \):

<table>
<thead>
<tr>
<th>Statement</th>
<th>String returned in ( \text{buffer} )</th>
<th>Length returned in ( \text{status} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL GETARG (0, buffer, status)</td>
<td>PROG1</td>
<td>5</td>
</tr>
<tr>
<td>CALL GETARG (1, buffer)</td>
<td>-g</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (2, buffer, status)</td>
<td>-c</td>
<td>2</td>
</tr>
<tr>
<td>CALL GETARG (3, buffer)</td>
<td>-a</td>
<td>undefined</td>
</tr>
<tr>
<td>CALL GETARG (4, buffer, status)</td>
<td>all blanks</td>
<td>-1</td>
</tr>
</tbody>
</table>

COMMAND_ARGUMENT_COUNT
GET_COMMAND
GET_COMMAND_ARGUMENT

**GETC**

*Portability Function*: Reads the next available character from external unit 5, which is normally connected to the console.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{GETC} (\text{char})
\]
**char**

(Output) Character*. First character typed at the keyboard after the call to GETC. If unit 5 is connected to a console device, then no characters are returned until the Enter key is pressed.

### Results

The result type is INTEGER(4). The result is zero if successful, or -1 if an end-of-file was detected.

### Example

```fortran
use IFPORT
character ans, errtxt*40
print *, 'Enter a character: '
ISTAT = GETC (ans)
if (istat) then
  call gerror(errtxt)
end if
```

### See Also

GETCHARQQ
GETSTRQQ

---

**GETCHARQQ**

**Run-Time Function:** Returns the next keystroke.

### Module

USE IFCORE

### Syntax

```fortran
result = GETCHARQQ() 
```

### Results

The result type is character with length 1. The result is the character representing the key that was pressed. The value can be any ASCII character.

If the key pressed is represented by a single ASCII character, GETCHARQQ returns the character. If the key pressed is a function or direction key, a hex Z'00' or Z'E0' is returned. If you need to know which function or direction was pressed, call GETCHARQQ a second time to get the extended code for the key.

If there is no keystroke waiting in the keyboard buffer, GETCHARQQ waits until there is one, and then returns it. Compare this to the function PEEKCHARQQ, which returns .TRUE. if there is a character waiting in the keyboard buffer, and .FALSE. if not. You can use PEEKCHARQQ to determine if GETCHARQQ should be called. This can prevent a program from hanging while GETCHARQQ waits for a keystroke that isn’t there. Note that PEEKCHARQQ is only supported in console applications.

If your application is a QuickWin or Standard Graphics application, you may want to put a call to PASSDIRKEYSQ to your program. This will enable the program to get characters that would otherwise be trapped. These extra characters are described in PASSDIRKEYSQ.

Note that the GETCHARQQ routine used in a console application is a different routine than the one used in a QuickWin or Standard Graphics application. The GETCHARQQ used with a console application does not trap characters that are used in QuickWin for a special purpose, such as scrolling. Console applications do not need, and cannot use PASSDIRKEYSQ.
Example

! Program to demonstrate GETCHARQQ
USE IFCORE
CHARACTER(1) key / 'A' /
PARAMETER (ESC = 27)
PARAMETER (NOREP = 0)
WRITE (*,*) ' Type a key: (or q to quit)'
! Read keys until ESC or q is pressed
DO WHILE (ICHAR (key) .NE. ESC)
  key = GETCHARQQ()
  ! Some extended keys have no ASCII representation
  IF(ICHAR(key) .EQ. NOREP) THEN
    key = GETCHARQQ()
    WRITE ('*, 900) 'Not ASCII. Char = NA'
    WRITE ('*,*)
  ELSE
    WRITE ('*,900) 'ASCII. Char = '
    WRITE ('*,901) key
    END IF
  IF (key .EQ. 'q' ) THEN
    EXIT
  END IF
END DO
900 FORMAT (1X, A, )
901 FORMAT (A)
END

GET_COMMAND

Intrinsic Subroutine: Returns the entire command that was used to invoke the program.

Syntax

CALL GET_COMMAND ([command, length, status, errmsg])

command

(Output; optional) Must be a scalar of type default character. If specified, its value is the entire command that was used to invoke the program. If the command cannot be determined, its value is all blanks.

length

(Output; optional) Must be a scalar of type integer. If specified, its value is the significant length of the command that was used to invoke the program. This length includes trailing blanks, but it does not include any truncation or padding used in the command. If the command length cannot be determined, its value is zero.
status

(Output; optional) Must be a scalar of type integer. If specified, its value is -1 if the command argument is present and has a length less than the significant length of the command. If the command cannot be retrieved, its value is positive; otherwise, it is assigned the value zero.

errmsg

(Input; output; optional) Must be a scalar of type default character. If an error occurs, it is assigned a processor-dependent explanatory message; otherwise, it is unchanged.

Example

See the example in COMMAND_ARGUMENT_COUNT.

See Also

GETARG
NARGS
IARGC
COMMAND_ARGUMENT_COUNT
GET_COMMAND_ARGUMENT

GET_COMMAND_ARGUMENT

Intrinsic Subroutine: Returns a command line argument of the command that invoked the program. Intrinsic subroutines cannot be passed as actual arguments.

Syntax

CALL GET_COMMAND_ARGUMENT (number [, value, length, status, errmsg])

number

(Input) Must be a scalar of type integer. It must be non-negative and less than or equal to the value returned by the COMMAND_ARGUMENT_COUNT function. Its value is the position of the command-line argument to retrieve. The command itself is argument number zero.

value

(Output; optional) Must be a scalar of type default character. If specified, its value is the returned command-line argument or all blanks if the value is unknown.

length

(Output; optional) Must be a scalar of type integer. If specified, its value is the length of the returned command-line argument or zero if the length of the argument is unknown. This length includes significant trailing blanks. It does not include any truncation or padding that occurs when the argument is assigned to the value argument.

status

(Output; optional) Must be a scalar of type integer. If specified, its value is the returned completion status. It is assigned the value -1 if the value argument is present and has a length less than the significant length of the command argument specified by number. It is assigned a processor-dependent positive value if the argument retrieval fails. Otherwise, it is assigned the value zero.
GET_COMMAND_ARGUMENT returns command-line arguments as they were entered. There is no case conversion.

Example
See the example in COMMAND_ARGUMENT_COUNT.

GET_COMMAND

GETCONTROLFPQQ

Portability Subroutine: Returns the floating-point processor control word.

Module
USE IFPORT

Syntax
CALL GETCONTROLFPQQ (controlword)

controlword

(Input) INTEGER(2). Floating-point processor control word.

The floating-point control word is a bit flag that controls various modes of the floating-point processor.

The control word can be any of the following constants (defined in IFPORT.F90):

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z’1000’</td>
<td>Infinity control mask</td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z’1000’</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z’0000’</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z’0300’</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z’0300’</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z’0200’</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z’0000’</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z’0C00’</td>
<td>Rounding control mask</td>
</tr>
</tbody>
</table>
An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. Exceptions can be disabled by setting the control bits to 1 with SETCONTROLFPQQ.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues.

You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ. If errors on floating-point exceptions are enabled (by clearing the control bits to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

You can use GETCONTROLFPQQ to retrieve the current control word and SETCONTROLFPQQ to change the control word. Most users do not need to change the default settings.

### Example

```fortran
USE IFPORT
INTEGER(2) control
CALL GETCONTROLFPQQ (control)
  ! if not rounding down
  IF (IAND(control, FPCW$DOWN) .NE. FPCW$DOWN) THEN
    control = IAND(control, NOT(FPCW$MCW_RC)) ! clear all
    ! rounding
    control = IOR(control, FPCW$DOWN)         ! set to
    ! round down
  CALL SETCONTROLFPQQ(control)
END IF
END
```

GETCWD
Portability Function: Returns the path of the current working directory.

Module
USE IFPORT

Syntax
result = GETCWD (dirname)

dirname (Output) Character(*). Name of the current working directory path, including drive letter.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

Example
USE IFPORT
character*30 dirname
! variable dirname must be long enough to hold entire string
integer(4) istat
ISTAT = GETCWD (dirname)
IF (ISTAT == 0) write *, 'Current directory is ',dirname

See Also
GETDRIVEDIRFPQQ

GETDAT
Portability Subroutine: Returns the date.

Module
USE IFPORT

Syntax
CALL GETDAT (iyr, imon, iday)

iyr (Output) INTEGER(4) or INTEGER(2). Year (xxxxAD).
imon (Output) INTEGER(4) or INTEGER(2). Month (1-12).
iday (Output) INTEGER(4) or INTEGER(2). Day of the month (1-31).

This subroutine is thread-safe.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).
If INTEGER(2) arguments are passed, you must specify USE IFPORT.
Example

! Program to demonstrate GETDAT and GETTIM
USE IFPORT
INTEGER(4) tmpday, tmpmonth, tmpyear
INTEGER(4) tmphour, tmpminute, tmpsecond, tmphund
CHARACTER(1) mer
CALL GETDAT(tmpyear, tmpmonth, tmpday)
CALL GETTIM(tmphour, tmpminute, tmpsecond, tmphund)
IF (tmphour .GT. 12) THEN
  mer = 'p'
  tmphour = tmphour - 12
ELSE
  mer = 'a'
END IF
WRITE (*, 900) tmpmonth, tmpday, tmpyear
900  FORMAT(I2, '/', I2.2, '/', I4.4)
WRITE (*, 901) tmphour, tmpminute, tmpsecond, tmphund, mer
901  FORMAT(I2, ':', I2.2, ':', I2.2, ':', I2.2, ' ', &
        A, 'm')
END

GETDRIVEDIRQQ
Portability Function: Returns the path of the current working directory on a specified drive.

Module
USE IFPORT

Syntax
result = GETDRIVEDIRQQ (drivedir)

drivedir  (Input; output) Character*(*) On input, the drive whose current working directory path is to be returned. On output, the string containing the current directory on that drive in the form d:\dir.

Results
The result type is INTEGER(4). The result is the length (in bytes) of the full path of the directory on the specified drive. Zero is returned if the path is longer than the size of the character buffer drivedir.
You specify the drive from which to return the current working directory by putting the drive letter into `drivedir` before calling `GETDRIVEDIRQQ`. To make sure you get information about the current drive, put the symbolic constant `FILE$CURDRIVE` (defined in `IFPORT.F90`) into `drivedir`.

Because drives are identified by a single alphabetic character, `GETDRIVEDIRQQ` examines only the first letter of `drivedir`. For instance, if `drivedir` contains the path `c:\fps90\bin`, `GETDRIVEDIRQQ (drivedir)` returns the current working directory on drive C and disregards the rest of the path. The drive letter can be uppercase or lowercase.

The length of the path returned depends on how deeply the directories are nested on the drive specified in `drivedir`. If the full path is longer than the length of `drivedir`, `GETDRIVEDIRQQ` returns only the portion of the path that fits into `drivedir`. If you are likely to encounter a long path, allocate a buffer of size $MAXPATH ($MAXPATH = 260).

On Linux* and macOS* systems, the function gets a path only when symbolic constant `FILE$CURDRIVE` has been applied to `drivedir`.

**Example**

```
! Program to demonstrate GETDRIVEDIRQQ
USE IFPORT
CHARACTER($MAXPATH) dir
INTEGER(4) length
! Get current directory
dir = FILE$CURDRIVE
length = GETDRIVEDIRQQ(dir)
IF (length .GT. 0) THEN
   WRITE (*,*) 'Current directory is: ', dir
ELSE
   WRITE (*,*) 'Failed to get current directory'
END IF
END
```

`CHANGEDIRQQ`
`GETDRIVESIZEQQ`
`GETDRIVESQQ`
`GETLASTERRORQQ`
`SPLITPATHQQ`

**GETDRIVESIZEQQ**

*Portability Function:* Returns the total size of the specified drive and space available on it.

**Module**

USE IFPORT

**Syntax**

`result = GETDRIVESIZEQQ (drive, total, avail)`

*drive* (Input) Character*(-). String containing the letter of the drive to get information about.
**total**

(Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8).
Total number of bytes on the drive.

**avail**

(Output) INTEGER(4) or INTEGER(4), DIMENSION(2) or INTEGER(8).
Number of bytes of available space on the drive.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The data types and dimension (if any) specified for the `total` and `avail` arguments must be the same. Specifying an array of two INTEGER(4) elements, or an INTEGER(8) argument, allows drive sizes larger than 2147483647 to be returned.

If an array of two INTEGER(4) elements is specified, the least-significant 32 bits are returned in the first element, the most-significant 32 bits in the second element. If an INTEGER(4) scalar is specified, the least-significant 32 bits are returned.

Because drives are identified by a single alphabetic character, GETDRIVESIZEQQ examines only the first letter of `drive`. The drive letter can be uppercase or lowercase. You can use the constant FILE$CURDRIVE (defined in IFPORT.F90) to get the size of the current drive.

If GETDRIVESIZEQQ fails, use GETLASTERRORQQ to determine the reason.

**Example**

```fortran
! Program to demonstrate GETDRIVESQQ and GETDRIVESIZEQQ
USE IFPORT
CHARACTER(26) drives
CHARACTER(1) adrive
LOGICAL(4) status
INTEGER(4) total, avail
INTEGER(2) i
! Get the list of drives
drives = GETDRIVESQQ()
WRITE (*,'(A, A)') ' Drives available: ', drives
!
! Cycle through them for free space and write to console
DO i = 1, 26
  adrive = drives(i:i)
  status = .FALSE.
  WRITE (*,'(A, A, A, A)') ' Drive ', CHAR(i + 64), ',
  IF (adrive .NE. ' ') THEN
    status = GETDRIVESIZEQQ(adrive, total, avail)
  END IF
  IF (status) THEN
    WRITE (*,*) avail, ' of ', total, ' bytes free.'
  ELSE
    WRITE (*,*) 'Not available'
  END IF
END DO
END
```

CHANGEDIRQQ
GETDRIVESQ

**Portability Function:** Reports which drives are available to the system.

**Module**
USE IFPORT

**Syntax**

```plaintext
result = GETDRIVESQQ( )
```

**Results**

The result type is character with length 26. It is the positional character string containing the letters of the drives available in the system.

The returned string contains letters for drives that are available, and blanks for drives that are not available. For example, on a system with A, C, and D drives, the string 'A CD' is returned.

On Linux* and macOS* systems, the function returns a string filled with spaces.

**Example**

See the example for GETDRIVESIZEQQ.

CHANGEDRIVEQQ

GETENV

**Portability Subroutine:** Returns the value of an environment variable.

**Module**
USE IFPORT

**Syntax**

```plaintext
CALL GETENV (ename,evalue)
```

- `ename` *(Input)* Character*(*). Environment variable to search for.
- `evalue` *(Output)* Character*(*). Value found for `ename`. Blank if `ename` is not found.

**Example**

```plaintext
use IFPORT
character*40 libname
CALL GETENV ("LIB",libname)
TYPE *, "The LIB variable points to ",libname
```

**See Also**
GETENVQQ
**GET_ENVIRONMENT_VARIABLE**

*Intrinsic Subroutine:* Gets the value of an environment variable.

**Syntax**

CALL GET_ENVIRONMENT_VARIABLE (name [, value, length, status, trim_name, errmsg])

- **name** (Input) Must be a scalar of type default character. It is the name of the environment variable.
- **value** (Output; optional) Must be a scalar of type default character. If specified, it is assigned the value of the environment variable specified by *name*. If the environment variable does not exist, *value* is assigned all blanks.
- **length** (Output; optional) Must be a scalar of type integer. If specified, its value is the length of the environment variable, if it exists; otherwise, *length* is set to 0.
- **status** (Output; optional) Must be a scalar of type integer. If specified, it is assigned a value of 0 if the environment variable exists and either has no value or its value is successfully assigned to *value*. It is assigned a value of -1 if the *value* argument is present and has a length less than the significant length of the environment variable value. It is assigned a value of 1 if the environment variable does not exist. For other error conditions, it is assigned a processor-dependent value greater than 2.
- **trim_name** (Input; optional) Must be a scalar of type logical. If the value is FALSE, then trailing blanks in *name* are considered significant. Otherwise, they are not considered part of the environment variable's name.
- **errmsg** (Input; output; optional) Must be a scalar of type default character. If an error occurs, it is assigned a processor-dependent explanatory message; otherwise, it is unchanged.

**Example**

The following program asks for the name of an environment variable. If the environment variable exists in the program's environment, it prints out its value:

```fortran
program print_env_var
  character name*20, val*40
  integer len, status
  write (*,*) 'enter the name of the environment variable'
  read (*,*) name
  call get_environment_variable (name, val, len, status, .true.)
  if (status .ge. 2) then
    write (*,*) 'get_environment_variable failed: status = ', status
    stop
  end if
  if (status .eq. 1) then
    write (*,*) 'env var does not exist'
    stop
end program
```
When the above program is invoked, the following line is displayed:

```
enter the name of the environment variable
```

The following shows an example of what could be displayed if you enter "HOME".

- On a Linux* or macOS* system:
  ```
  env var value = /home/our_space/usr4
  ```
- On a Windows* system:
  ```
  env var value = C:/
  ```

The following shows an example of what could be displayed if you enter "PATH".

- On a Linux or macOS* system:
  ```
  env var length = 307 truncated to 40
  env var value = /site/our_space/usr4/progs/build_area
  ```
- On a Windows system:
  ```
  env var length = 829 truncated to 40
  env var value = C:\OUR_SPACE\BUILD_AREA\build_objects\GETENVQQ
  ```

**GETENVQQ**

*Portability Function:* Returns the value of an environment variable.

**Module**

USE IFPORT

**Syntax**

```
result = GETENVQQ (varname, value)
```

- `varname` (Input) Character(*). Name of environment variable.
- `value` (Output) Character(*). Value of the specified environment variable, in uppercase.

**Results**

The result type is INTEGER(4). The result is the length of the string returned in `value`. Zero is returned if the given variable is not defined.

GETENVQQ searches the list of environment variables for an entry corresponding to `varname`. Environment variables define the environment in which a process executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.
Note that some environment variables may exist only on a per-process basis and may not be present at the command-line level.

GETENVQQ uses the C runtime routine getenv and SETENVQQ uses the C runtime routine _putenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

In a program that uses the main function, _environ is initialized at program startup to settings taken from the operating system's environment.

Changes made outside the program by the console SET command, for example, SET MY_VAR=ABCDE, will be reflected by GETENVQQ.

GETENVQQ and SETENVQQ will not work properly with the Windows* APIs GetEnvironmentVariable and SetEnvironmentVariable.

**Example**

```fortran
!  Program to demonstrate GETENVQQ and SETENVQQ
USE IFPORT
USE IFCORE
INTEGER(4) lenv, lval
CHARACTER(80) env, val, enval
WRITE (*,900) ' Enter environment variable name to create, &
               modify, or delete: '
  lenv = GETSTRQQ(env)
IF (lenv .EQ. 0) STOP
WRITE (*,900) ' Value of variable (ENTER to delete): '
  lval = GETSTRQQ(val)
IF (lval .EQ. 0) val = ' ';
enval = env(1:lenv) // '=' // val(1:lval)
IF (SETENVQQ(enval)) THEN
  lval = GETENVQQ(env(1:lenv), val)
  IF (lval .EQ. 0) THEN
    WRITE (*,*) 'Can''t get environment variable'
  ELSE IF (lval .GT. LEN(val)) THEN
    WRITE (*,*) 'Buffer too small'
  ELSE
    WRITE (*,*') env(1:lenv), ': ', val(1:lval)
    WRITE (*,*') 'Length: ', lval
  END IF
ELSE
  WRITE (*,*') 'Can''t set environment variable'
END IF
900  FORMAT (A, 
END
```

SETENVQQ
GETLASTERRORQQ
GETEXCEPTIONPTRSQQ (W*S)

**Run-Time Function:** Returns a pointer to C run-time exception information pointers appropriate for use in signal handlers established with SIGNALQQ or direct calls to the C rtl signal( ) routine.

**Module**
USE IFCORE

**Syntax**
result = GETEXCEPTIONPTRSQQ( )

**Results**
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The return value is the address of a data structure whose members are pointers to exception information captured by the C runtime at the time of an exception. This result value can then be used as the *eptr* argument to routine TRACEBACKQQ to generate a stack trace from a user-defined handler or to inspect the exception context record directly.

Calling GETEXCEPTIONPTRSQQ is only valid within a user-defined handler that was established with SIGNALQQ or a direct call to the C rtl signal( ) function.

For a full description of exceptions and error handling, see Compiler Reference: Error Handling.

**Example**

```fortran
PROGRAM SIGTEST
USE IFCORE
...
R3 = 0.0E0
STS = SIGNALQQ(MY_HANDLER)
! Cause a divide by zero exception
R1 = 3.0E0/R3
...
END
INTEGER(4) FUNCTION MY_HANDLER(SIGNUM,EXCNUM)
USE IFCORE
...
EPTRS = GETEXCEPTIONPTRSQQ()
...
CALL TRACEBACKQQ("Application SIGFPE error!",USER_EXIT_CODE=-1,EPTR=EPTRS)
...
MY_HANDLER = 1
END
```

**Portability Function:** Returns information about the specified file. File names can contain wildcards (* and ?).

**Module**

USE IFPORT

**Syntax**

```fortran
result = GETFILEINFOQQ (files, buffer, handle)
```

- **files**
  - (Input) Character*(*). Name or pattern of files you are searching for. Can include a full path and wildcards (* and ?).

- **buffer**
  - (Output) Derived type FILE$INFO or derived type FILE$INFOI8. Information about a file that matches the search criteria in `files`.

  The derived type FILE$INFO is defined in IFPORT.F90 as follows:

  ```fortran
  TYPE FILE$INFO
      INTEGER(4) CREATION             ! CREATION TIME (-1 on FAT)
      INTEGER(4) LASTWRITE            ! LAST WRITE TO FILE
      INTEGER(4) LASTACCESS           ! LAST ACCESS (-1 on FAT)
      INTEGER(4) LENGTH               ! LENGTH OF FILE
      INTEGER(4) PERMIT               ! FILE ACCESS MODE
      CHARACTER(255) NAME             ! FILE NAME
  END TYPE FILE$INFO
  ```

  The derived type FILE$INFOI8 is defined in IFPORT.F90 as follows:

  ```fortran
  TYPE FILE$INFOI8
      INTEGER(4) CREATION             ! CREATION TIME (-1 on FAT)
      INTEGER(4) LASTWRITE            ! LAST WRITE TO FILE
      INTEGER(4) LASTACCESS           ! LAST ACCESS (-1 on FAT)
      INTEGER(8) LENGTH               ! LENGTH OF FILE
      INTEGER(4) PERMIT               ! FILE ACCESS MODE
      CHARACTER(255) NAME             ! FILE NAME
  END TYPE FILE$INFOI8
  ```

- **handle**
  - (Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Control mechanism. One of the following constants, defined in IFPORT.F90:
    - FILE$FIRST - First matching file found.
    - FILE$LAST - Previous file was the last valid file.
    - FILE$ERROR - No matching file found.

**Results**

The result type is INTEGER(4). The result is the nonblank length of the file name if a match was found, or 0 if no matching files were found.

To get information about one or more files, set the handle to FILE$FIRST and call GETFILEINFOQQ. This will return information about the first file which matches the name and return a handle. If the program wants more files, it should call GETFILEINFOQQ with the handle. GETFILEINFOQQ must be called with the handle until GETFILEINFOQQ sets handle to FILE$LAST, or system resources may be lost.
The derived-type element variables FILE$INFO%CREATION, FILE$INFO%LASTWRITE, and FILE$INFO %LASTACCESS contain packed date and time information that indicates when the file was created, last written to, and last accessed, respectively.

To break the time and date into component parts, call UNPACKTIMEQQ. FILE$INFO%LENGTH contains the length of the file in bytes. FILE$INFO%PERMIT contains a set of bit flags describing access information about the file as follows:

<table>
<thead>
<tr>
<th>Bit flag</th>
<th>Access information for the file</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE$ARCHIVE</td>
<td>Marked as having been copied to a backup device.</td>
</tr>
<tr>
<td>FILE$DIR</td>
<td>A subdirectory of the current directory. Each MS-DOS directory contains two special files, &quot;.&quot; and &quot;.&quot;. These are directory aliases created by MS-DOS for use in relative directory notation. The first refers to the current directory, and the second refers to the current directory's parent directory.</td>
</tr>
<tr>
<td>FILE$HIDDEN</td>
<td>Hidden. It does not appear in the directory list you request from the command line, the Microsoft visual development environment browser, or File Manager.</td>
</tr>
<tr>
<td>FILE$READONLY</td>
<td>Write-protected. You can read the file, but you cannot make changes to it.</td>
</tr>
<tr>
<td>FILE$SYSTEM</td>
<td>Used by the operating system.</td>
</tr>
<tr>
<td>FILE$VOLUME</td>
<td>A logical volume, or partition, on a physical disk drive. This type of file appears only in the root directory of a physical device.</td>
</tr>
</tbody>
</table>

You can use the constant FILE$NORMAL to check that all bit flags are set to 0. If the derived-type element variable FILE$INFO%PERMIT is equal to FILE$NORMAL, the file has no special attributes. The variable FILE $INFO%NAME contains the short name of the file, not the full path of the file.

If an error occurs, call GETLASTERRORQQ to retrieve the error message, such as:

- ERR$NOENT: The file or path specified was not found.
- ERR$NOMEM: Not enough memory is available to execute the command, the available memory has been corrupted, or an invalid block exists, indicating that the process making the call was not allocated properly.

**Example**

```fortran
USE IFPORT
USE IFCORE
   CALL SHOWPERMISSION( )
END

! SUBROUTINE to demonstrate GETFILEINFOQQ
SUBROUTINE SHOWPERMISSION( )
USE IFPORT
   CHARACTER(80) files
   INTEGER(KIND=INT_PTR_KIND( )) handle
   INTEGER(4) length
   CHARACTER(5) permit
   TYPE (FILE$INFO) info
   WRITE (*, 900) ' Enter wildcard of files to view: '
```

Language Reference 1545
length = GETSTRQQ(files)
handle = FILE$FIRST

DO WHILE (.TRUE.)
    length = GETFILEINFOQQ(files, info, handle)
    IF ((handle .EQ. FILE$LAST) .OR. &
        (handle .EQ. FILE$ERROR)) THEN
        SELECT CASE (GETLASTERRORQQ( ))
        CASE (ERR$NOMEM)
            WRITE (*,*) 'Out of memory'
        CASE (ERR$NOENT)
            EXIT
        CASE DEFAULT
            WRITE (*,*) 'Invalid file or path name'
        END SELECT
    END IF
    permit = ' ' 
    IF ((info%permit .AND. FILE$HIDDEN) .NE. 0) &
        permit(1:1) = 'H'
    IF ((info%permit .AND. FILE$SYSTEM) .NE. 0) &
        permit(2:2) = 'S'
    IF ((info%permit .AND. FILE$READONLY) .NE. 0) &
        permit(3:3) = 'R'
    IF ((info%permit .AND. FILE$ARCHIVE) .NE. 0) &
        permit(4:4) = 'A'
    IF ((info%permit .AND. FILE$DIR) .NE. 0) &
        permit(5:5) = 'D'
    WRITE (*, 9000) info%name, info%length, permit
9000 FORMAT (1X, A5, I9, ' ',A6)
END DO
END SUBROUTINE

UNPACKTIMEQQ

GETGID

Portability Function: Returns the group ID of the user of a process.

Module
USE IFPORT

Syntax
result = GETGID( )

Results
The result type is INTEGER(4). The result corresponds to the primary group of the user under whose identity
the program is running. The result is returned as follows:
• On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts. Note that on Windows systems, domain accounts and local accounts can overlap.
• On Linux* and macOS* systems, this function returns the group identity for the current process.

Example

```fortran
USE IFPORT
ISTAT = GETGID( )
```

**GETLASTERROR**

*Portability Function: Returns the last error set.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = GETLASTERROR( )
```

**Results**

The result type is INTEGER(4). The result is the integer corresponding to the last run-time error value that was set.

For example, if you use an ERR= specifier in an I/O statement, your program will not abort if an error occurs. GETLASTERROR provides a way to determine what the error condition was, with a better degree of certainty than just examining `errno`. Your application can then take appropriate action based upon the error number.

**GETLASTERRORQQ**

*Portability Function: Returns the last error set by a run-time procedure.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = GETLASTERRORQQ( )
```

**Results**

The result type is INTEGER(4). The result is the most recent error code generated by a run-time procedure.

Library functions that return a logical or integer value sometimes also provide an error code that identifies the cause of errors. GETLASTERRORQQ retrieves the most recent error message. The error constants are defined in `IFPORT.F90`. The following table shows some library routines and the errors each routine produces:

<table>
<thead>
<tr>
<th>Library routine</th>
<th>Errors produced</th>
</tr>

</tbody>
</table>
GETLOG

Portability Subroutine: Returns the user's login name.

Module
USE IFPORT

Syntax
CALL GETLOG (name)

name (Output) Character*(*). User's login name.

The login name must be less than or equal to 64 characters. If the login name is longer than 64 characters, it is truncated. The actual parameter corresponding to name should be long enough to hold the login name. If the supplied actual parameter is too short to hold the login name, the login name is truncated.

If the login name is shorter than the actual parameter corresponding to name, the login name is padded with blanks at the end, until it reaches the length of the actual parameter.

If the login name cannot be determined, all blanks are returned.

Example
use IFPORT
character*20 username
CALL GETLOG (username)
print *, "You logged in as ", username

GETPID

Portability Function: Returns the process ID of the current process.

Module
USE IFPORT

Syntax
result = GETPID( )

Results
The result type is INTEGER(4). The result is the process ID number of the current process.

Example
USE IFPORT
INTEGER(4) istat
istat = GETPID()

GETPOS, GETPOSI8

Portability Functions: Return the current position of a file.

Module
USE IFPORT
Syntax
result = GETPOS (lunit)
result = GETPOSI8 (lunit)

(lunit) (Input) INTEGER(4). External unit number of a file. The value must be in the range 0 to 100 and the file must be connected.

Results
The result type is INTEGER(4) for GETPOS; INTEGER(8) for GETPOSI8. The result is the offset, in bytes, from the beginning of the file. If an error occurs, the result value is -1 and the following error code is returned in errno:
EINVAL: lunit is not a valid unit number, or is not open.
These functions are equivalent to FTELL, FTELLI8.

GETSTATUSFPQQ (W*S)
Portability Subroutine: Returns the floating-point processor status word.

Module
USE IFPORT

Syntax
CALL GETSTATUSFPQQ (status)

(status) (Output) INTEGER(2). Floating-point processor status word.

The floating-point status word shows whether various floating-point exception conditions have occurred. The compiler initially clears (sets to 0) all status flags, but after an exception occurs it does not reset the flags before performing additional floating-point operations. A status flag with a value of one thus shows there has been at least one occurrence of the corresponding exception. The following table lists the status flags and their values:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPSW$MSW_EM</td>
<td>Z’003F’</td>
<td>Status Mask (set all flags to 1)</td>
</tr>
<tr>
<td>FPSW$INVALID</td>
<td>Z’0001’</td>
<td>An invalid result occurred</td>
</tr>
<tr>
<td>FPSW$DENORMAL</td>
<td>Z’0002’</td>
<td>A subnormal (very small number)</td>
</tr>
<tr>
<td>FPSW$SUBNORMAL</td>
<td>Z’0002’</td>
<td>A subnormal (very small number)</td>
</tr>
<tr>
<td>FPSW$ZERODIVIDE</td>
<td>Z’0004’</td>
<td>A divide by zero occurred</td>
</tr>
<tr>
<td>FPSW$OVERFLOW</td>
<td>Z’0008’</td>
<td>An overflow occurred</td>
</tr>
<tr>
<td>FPSW$UNDERFLOW</td>
<td>Z’0010’</td>
<td>An underflow occurred</td>
</tr>
<tr>
<td>FPSW$INEXACT</td>
<td>Z’0020’</td>
<td>Inexact precision occurred</td>
</tr>
</tbody>
</table>

You can use a logical comparison on the status word returned by GETSTATUSFPQQ to determine which of the six floating-point exceptions listed in the table has occurred.
An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0. By default, all exception traps are disabled. Exceptions can be enabled and disabled by clearing and setting the flags with SETCONTROLFPQQ. You can use GETCONTROLFPQQ to determine which exceptions are currently enabled and disabled.

If an exception is disabled, it does not cause an interrupt when it occurs. Instead, floating-point processes generate an appropriate special value (NaN or signed infinity), but the program continues. You can find out which exceptions (if any) occurred by calling GETSTATUSFPQQ.

If errors on floating-point exceptions are enabled (by clearing the flags to 0 with SETCONTROLFPQQ), the operating system generates an interrupt when the exception occurs. By default, these interrupts cause run-time errors, but you can capture the interrupts with SIGNALQQ and branch to your own error-handling routines.

Example

```fortran
!  Program to demonstrate GETSTATUSFPQQ
USE IFPORT
INTEGER(2) status
CALL GETSTATUSFPQQ(status)
!  check for divide by zero
IF (IAND(status, FPSW$ZERODIVIDE) .NE. 0) THEN
  WRITE (*,*) 'Divide by zero occurred. Look &
  for NaN or signed infinity in resultant data.'
END IF
END
```

GETSTRQQ

**Run-Time Function:** Reads a character string from the keyboard using buffered input.

**Module**

USE IFCORE

**Syntax**

```fortran
result = GETSTRQQ (buffer)
```

*buffer* (Output) Character*(*) . Character string returned from keyboard, padded on the right with blanks.

**Results**

The result type is INTEGER(4). The result is the number of characters placed in *buffer*.

The function does not complete until you press Return or Enter.

**Example**

```fortran
!  Program to demonstrate GETSTRQQ
USE IFCORE
USE IFPORT
INTEGER(4) length, result
```
Intel® Fortran Compiler Classic and Intel® Fortran Compiler Developer Guide and Reference

CHARACTER(80) prog, args
WRITE (*, '(A, \)') ' Enter program to run: '
length = GETSTRQQ (prog)
WRITE (*, '(A, \)') ' Enter arguments: '
length = GETSTRQQ (args)
result = RUNQQ (prog, args)
IF (result .EQ. -1) THEN
WRITE (*,*) 'Couldn''t run program'
ELSE
WRITE (*, '(A, Z4, A)') 'Return code : ', result, 'h'
END IF
END

PEEKCHARQQ

GET_TEAM
Transformational Intrinsic Function (Generic):
Returns a copy of a team variable.

Syntax
result = GET_TEAM ([ level ])
level

(Optional, Input) Must be a scalar integer whose value is equal to one
of the named constants INITIAL_TEAM, CURRENT_TEAM, or
PARENT_TEAM defined in the ISO_FORTRAN_ENV intrinsic module.

Results
The result is type TEAM_TYPE from the ISO_FORTRAN_ENV intrinsic module. If level is not present, or if
CURRENT_TEAM is specified, the result is a team variable describing the current team. If level has the value
PARENT_TEAM, the result is a team variable describing the parent team of the current team. If level has the
value INITIAL_TEAM, the result is a team variable describing the initial team.

Example
Consider the following program fragment:

PROGRAM main
USE, INTRINSIC
:: ISO_FORTRAN_ENV
TYPE (TEAM_TYPE)
:: original
original = GET_TEAM (INITIAL_TEAM)
After execution of the GET_TEAM function, original is defined with a team value describing the initial team.

GETTIM
Portability Subroutine: Returns the time.

Module
USE IFPORT

Syntax
CALL GETTIM (ihr, imin, isec, i100th)
1552


ihr  (Output) INTEGER(4) or INTEGER(2). Hour (0-23).
imin (Output) INTEGER(4) or INTEGER(2). Minute (0-59).
isec (Output) INTEGER(4) or INTEGER(2). Second (0-59).
i100th (Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4). If INTEGER(2) arguments are passed, you must specify USE IFPORT.

Example
See the example in GETDAT.

GETTIMEOFDAY

Portability Subroutine: Returns seconds and microseconds since 00:00 Jan 1, 1970.

Module
USE IFPORT

Syntax
CALL GETTIMEOFDAY (ret, err)
**GETUID**

*Portability Function:* Returns the user ID of the calling process.

**Module**
USE IFPORT

**Syntax**
result = GETUID( )

**Results**
The result type is INTEGER(4). The result corresponds to the user identity under which the program is running. The result is returned as follows:

- On Windows* systems, this function returns the last subauthority of the security identifier for the process. This is unique on a local machine and unique within a domain for domain accounts.
  - Note that on Windows systems, domain accounts and local accounts can overlap.
- On Linux* and macOS* systems, this function returns the user identity for the current process.

**Example**
USE IFPORT
integer(4) istat
istat = GETUID( )

**GMTIME**

*Portability Subroutine:* Returns the Greenwich mean time in an array of time elements.

**Module**
USE IFPORT

**Syntax**
CALL GMTIME (stime, tarray)

**stime** (Input) INTEGER(4). Numeric time data to be formatted. Number of seconds since 00:00:00 Greenwich mean time, January 1, 1970.
tarray

(Output) INTEGER(4). One-dimensional array with 9 elements used to contain numeric time data. The elements of tarray are returned as follows:

<table>
<thead>
<tr>
<th>Element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>tarray(1)</td>
<td>Seconds (0-61, where 60-61 can be returned for leap seconds)</td>
</tr>
<tr>
<td>tarray(2)</td>
<td>Minutes (0-59)</td>
</tr>
<tr>
<td>tarray(3)</td>
<td>Hours (0-23)</td>
</tr>
<tr>
<td>tarray(4)</td>
<td>Day of month (1-31)</td>
</tr>
<tr>
<td>tarray(5)</td>
<td>Month (0-11)</td>
</tr>
<tr>
<td>tarray(6)</td>
<td>Number of years since 1900</td>
</tr>
<tr>
<td>tarray(7)</td>
<td>Day of week (0-6, where 0 is Sunday)</td>
</tr>
<tr>
<td>tarray(8)</td>
<td>Day of year (0-365)</td>
</tr>
<tr>
<td>tarray(9)</td>
<td>Daylight saving flag (0 if standard time, 1 if daylight saving time)</td>
</tr>
</tbody>
</table>

**Caution**
This subroutine may cause problems with the year 2000. Use DATE_AND_TIME instead.

**Example**

use IFPORT
integer(4) stime, timearray(9)
! initialize stime to number of seconds since
! 00:00:00 GMT January 1, 1970
stime = time()
call gmtime (stime, timearray)
print *, timearray
end

**See Also**
DATE_AND_TIME

**GOTO - Assigned**

**Statement:** Transfers control to the statement whose label was most recently assigned to a variable. This feature has been deleted in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

**Syntax**

GOTO var[, ] ( label-list)
var

Is a scalar integer variable.

label-list

Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the assigned GO TO statement. The same label can appear more than once in this list.

The variable must have a statement label value assigned to it by an ASSIGN statement (not an arithmetic assignment statement) before the GO TO statement is executed.

If a list of labels appears, the statement label assigned to the variable is not checked against the labels in the list.

Both the assigned GO TO statement and its associated ASSIGN statement must be in the same scoping unit.

Example

The following example is equivalent to GO TO 200:

```
ASSIGN 200 TO IGO
GO TO IGO
```

The following example is equivalent to GO TO 450:

```
ASSIGN 450 TO IBEG
GO TO IBEG, (300,450,1000,25)
```

The following example shows an invalid use of an assigned variable:

```
ASSIGN 10 TO I
J = I
GO TO J
```

In this case, variable J is not the variable assigned to, so it cannot be used in the assigned GO TO statement.

The following shows another example:

```
ASSIGN 10 TO N
GOTO N
10 CONTINUE
```

The following example uses an assigned GOTO statement with a label-list but it is not checked against the value of VIEW:

```
ASSIGN 300 TO VIEW
GOTO VIEW (100, 200, 400)   ! this will go to label 300
```

Obsolescent Language Features in the Fortran Standard
GOTO - Computed GOTO
GOTO - Unconditional GOTO
Execution Control

**GOTO - Computed**

**Statement:** Transfers control to one of a set of labeled branch target statements based on the value of an expression. It is an obsolescent feature in Fortran 95.

**Syntax**

```
GOTO (label-list) [,] expr
```

**label-list**
Is a list of labels (separated by commas) of valid branch target statements in the same scoping unit as the computed GO TO statement. (Also called the transfer list.) The same label can appear more than once in this list.

**expr**
Is a scalar numeric expression in the range 1 to $n$, where $n$ is the number of statement labels in label-list. If necessary, it is converted to integer data type.

When the computed GO TO statement is executed, the expression is evaluated first. The value of the expression represents the ordinal position of a label in the associated list of labels. Control is transferred to the statement identified by the label. For example, if the list contains (30,20,30,40) and the value of the expression is 2, control is transferred to the statement identified with label 20.

If the value of the expression is less than 1 or greater than the number of labels in the list, control is transferred to the next executable statement or construct following the computed GO TO statement.

**Example**
The following example shows valid computed GO TO statements:

```
GO TO (12,24,36), INDEX
GO TO (320,330,340,350,360), SITU(J,K) + 1
```

The following shows another example:

```
next = 1
C
C The following statement transfers control to statement 10:
C
  GOTO (10, 20) next
...
10 CONTINUE
...
20 CONTINUE
```

**See Also**
Obsolescent Language Features in the Fortran Standard
GOTO - Unconditional GOTO
Execution Control

**GOTO - Unconditional**

**Statement:** Transfers control to the same branch target statement every time it executes.

**Syntax**

```
GO TO label
```

*label*  
Is the label of a valid branch target statement in the same scoping unit as the GO TO statement.

The unconditional GO TO statement transfers control to the branch target statement identified by the specified label.
Example
The following are examples of GO TO statements:

```
GO TO 7734
GO TO 99999
```

The following shows another example:

```
integer(2) in
10  print *, 'enter a number from one to ten: '
    read *, in
    select case (in)
    case (1:10)
        exit
    case default
        print *, 'wrong entry, try again'
    goto 10
    end select
```

Execution Control

H to I
This section describes language features that start with H or I.

H to I

HOSTNAM

**Portability Function:** Returns the current host computer name. This function can also be specified as HOSTNM.

**Module**
USE IFPORT

**Syntax**

```
result = HOSTNAM (name)
```

`name` (Output) Character*(*) . Name of the current host. Should be at least as long as MAX_HOSTNAM_LENGTH + 1. MAX_HOSTNAM_LENGTH is defined in the IFPORT module.

**Results**
The result type is INTEGER(4). The result is zero if successful. If `name` is not long enough to contain all of the host name, the function truncates the host name and returns -1.

**Example**

```
use IFPORT
character(MAX_HOSTNAM_LENGTH + 1) hostname
integer(4) istat
ISTAT = HOSTNAM (hostname)
```
**HUGE**

*Inquiry Intrinsic Function (Generic): Returns the largest number in the model representing the same type and kind parameters as the argument.*

**Syntax**

\[
\text{result} = \text{HUGE} \left( x \right)
\]

\( x \) (Input) Must be of type integer or real; it can be scalar or array valued.

**Results**

The result is a scalar of the same type and kind parameters as \( x \). If \( x \) is of type integer, the result has the value \( r^q \cdot 1 \). If \( x \) is of type real, the result has the value \((1 - b^{-p})b^{e_{\text{max}}}\).

Integer parameters \( r \) and \( q \) are defined in *Model for Integer Data*; real parameters \( b \), \( p \), and \( e_{\text{max}} \) are defined in *Model for Real Data*.

**Example**

If \( X \) is of type REAL(4), \( \text{HUGE} \left( X \right) \) has the value \((1 - 2^{-24}) \times 2^{128}\).

**See Also**

Data Representation Models

**HYPOT**

*Elemental Intrinsic Function (Generic): Returns the value of the Euclidean distance of the arguments.*

**Syntax**

\[
\text{result} = \text{HYPOT} \left( x, y \right)
\]

\( x \) (Input) Must be of type real.

\( y \) (Input) Must be of type real. It must be the same type and kind as \( x \).

**Results**

The result type and kind are the same as \( x \).

The result has a value equal to a processor-dependent approximation to the Euclidean distance, \( \sqrt{x^2 + y^2} \), without undue overflow or underflow.

**Example**

\( \text{HYPOT} \left( 3.0, 4.0 \right) \) has the approximate value 5.0.
**IACHAR**

**Elemental Intrinsic Function (Generic):** Returns the position of a character in the ASCII character set, even if the processor's default character set is different. In Intel® Fortran, IACHAR is equivalent to the ICHAR function.

**Syntax**

```fortran
result = IACHAR (c [, kind])
```

- `c` (Input) Must be of type character of length 1.
- `kind` (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If `c` is in the ASCII collating sequence, the result is the position of `c` in that sequence and satisfies the inequality: \(0 \leq \text{IACHAR}(c) \leq 127\).

The results must be consistent with the LGE, LGT, LLE, and LLT lexical comparison functions. For example, if LLE(C, D) is true, IACHAR(C) .LE. IACHAR(D) is also true.

**Example**

- `IACHAR ( 'Y' )` has the value 89.
- `IACHAR ( '%' )` has the value 37.

IALL

**IALL**

**Transformational Intrinsic Function (Generic):** Reduces an array with a bitwise AND operation.

**Syntax**

```fortran
result = IALL (array, dim [, mask])
```

- `array` (Input) Must be an array of type integer.
- `dim` (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of array.
- `mask` (Input; optional) Must be of type logical and conformable with array.
Results
The result has the same type and kind parameters as \texttt{array}. It is scalar if \texttt{dim} does not appear or if \texttt{array} has rank one; otherwise, the result is an array of rank \( n - 1 \) and shape \([d_1, d_2, \ldots, d_{dim-1}, d_{dim+1}, \ldots, d_n] \) where \([d_1, d_2, \ldots, d_n]\) is the shape of \texttt{array}.

If \texttt{array} has size zero the result value is equal to \texttt{NOT (INT (0, KIND (array)))}. Otherwise, the result of \texttt{IALL (array)} has a value equal to the bitwise AND of all the elements of \texttt{array}.

The result of \texttt{IALL (array, MASK=mask)} has a value equal to \texttt{IALL (PACK (array, mask))}.

The result of \texttt{IALL (array, DIM=dim [ , MASK=mask])} has a value equal to that of \texttt{IALL (array [ , MASK=mask])} if \texttt{array} has rank one. Otherwise, the value of element \((s_1, s_2, \ldots, s_{dim-1}, s_{dim+1}, \ldots, s_n)\) of the result is equal to \texttt{IALL (array (s_1, s_2, \ldots, s_{dim-1} :, s_{dim+1}, \ldots, s_n) [ , MASK = mask (s_1, s_2, \ldots, s_{dim-1} :, s_{dim+1}, \ldots, s_n)])}.

Example
\texttt{IALL ([14, 13, 11])} has the value 8. \texttt{IALL ([14, 13, 11], MASK=[.true., .false., .true])} has the value 10.

See Also
\texttt{IANY}
\texttt{IPARITY}

**IAND**

Elemental Intrinsic Function (Generic): Performs a logical AND on corresponding bits. This function can also be specified as \texttt{AND}.

Syntax
\[
\text{result} = \text{IAND} (i, j)
\]

\(i\) (Input) Must be of type integer or logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.

\(j\) (Input) Must be of type integer or logical, or a binary, octal, or hexadecimal literal constant.

If both \(i\) and \(j\) are of type integer or logical, they must have the same kind type parameter. If the kinds of \(i\) and \(j\) do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. \(i\) and \(j\) must not both be binary, octal, or hexadecimal literal constants.

Results
If both \(i\) and \(j\) are of type integer or logical, the result type and kind are the same as \(i\). If either \(i\) or \(j\) is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function \texttt{INT} to type integer with the kind type parameter of the other.

The result value is derived by combining \(i\) and \(j\) bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>(i)</th>
<th>(j)</th>
<th>\texttt{IAND (i, j)}</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.
### Specific Name | Argument Type | Result Type
--- | --- | ---
BIAND | INTEGER(1) | INTEGER(1)
IIAND | INTEGER(2) | INTEGER(2)
JIAND | INTEGER(4) | INTEGER(4)
KIAND | INTEGER(8) | INTEGER(8)

1Or HIAND.

### Example
IAND (2, 3) has the value 2.
IAND (4, 6) has the value 4.
The following shows another example:

```fortran
INTEGER(1) i, m
INTEGER result
INTEGER(2) result2
i = 1
m = 3
result = IAND(i,m) ! returns an integer of default type
! (INTEGER(4) unless reset by user) whose
! value = 1
result2 = IAND(i,m) ! returns an INTEGER(2) with value = 1
```

---

**IANY**

**Transformational Intrinsic Function (Generic):**

Reduces an array with a bitwise OR operation.

**Syntax**

```
result = IANY (array, dim [, mask])
result = IANY (array [, mask])
```

- **array**
  - (Input) Must be an array of type integer.
- **dim**
  - (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of array.
- **mask**
  - (Input; optional) Must be of type logical and conformable with array.
Results
The result has the same type and kind parameters as array. It is scalar if dim does not appear; otherwise, the result is an array of rank \( n - 1 \) and shape \([d_1, d_2, \ldots, d_{dim-1}, d_{dim+1}, \ldots, d_n]\) where \([d_1, d_2, \ldots, d_n]\) is the shape of array.

The result of ANY (array) is the bitwise OR of all the elements of array. If array has size zero, the result value is equal to zero.

The result of ANY (array, MASK=mask) has a value equal to ANY (PACK (array, mask)).

The result of ANY (array, DIM=dim [ , MASK=mask]) has a value equal to that of ANY (array [ , MASK=mask]) if array has rank one. Otherwise, the value of element \((s_1, s_2, \ldots, s_{dim-1}, s_{dim+1}, \ldots, s_n)\) of the result is equal to ANY (array \((s_1, s_2, \ldots, s_{dim-1}, :, s_{dim+1}, \ldots, s_n)\) [ , MASK = mask \((s_1, s_2, \ldots, s_{dim-1}, :, s_{dim+1}, \ldots, s_n)\))].

Example
ANY ([14, 13, 8]) has the value 15. ANY ([14, 13, 8], MASK=[.true., .false., .true]) has the value 14.

IALL
IPARITY

IARGC

*Inquiry Intrinsic Function (Specific):* Returns the index of the last command-line argument. It cannot be passed as an actual argument. This function can also be specified as IARG or NUMARG.

Syntax

\[
result = \text{IARGC}( )
\]

Results
The result type is INTEGER(4). The result is the index of the last command-line argument, which is also the number of arguments on the command line. The command is not included in the count. For example, IARGC returns 3 for the command-line invocation of PROG1 -g -c -a.

IARGC returns a value that is 1 less than that returned by NARGS.

Example

```
integer(4) no_of_arguments
no_of_arguments = IARGC ()
print *, 'total command line arguments are ', no_of_arguments
```

For a command-line invocation of PROG1 -g -c -a, the program above prints:

```
total command line arguments are 3
```

GET_COMMAND_ARGUMENT
IBCHNG

**Elemental Intrinsic Function (Generic):** Reverses the value of a specified bit in an integer.

**Syntax**

```
result = IBCHNG (i,pos)
```

- **i**
  (Input) Must be of type integer or of type logical (which is treated as an integer). This argument contains the bit to be reversed.

- **pos**
  (Input) Must be of type integer. This argument is the position of the bit to be changed.
  
  The rightmost (least significant) bit of `i` is in position 0.

**Results**

The result type and kind are the same as `i`. The result is equal to `i` with the bit in position `pos` reversed.

For more information, see Bit Functions.

**Example**

```
INTEGER J, K
J = IBCHNG(10, 2)     ! returns 14 = 1110
K = IBCHNG(10, 1)     ! returns 8 = 1000
```

IBCLR

**Elemental Intrinsic Function (Generic):** Clears one bit to zero.

**Syntax**

```
result = IBCLR (i,pos)
```

- **i**
  (Input) Must be of type integer or of type logical (which is treated as an integer).

- **pos**
  (Input) Must be of type integer. It must not be negative and it must be less than `BIT_SIZE(i)`.
The rightmost (least significant) bit of $i$ is in position 0.

**Results**

The result type and kind are the same as $i$. The result has the value of the sequence of bits of $i$, except that bit $pos$ of $i$ is set to zero.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**IBITS**

*Elemental Intrinsic Function (Generic): Extracts a sequence of bits (a bit field).*

**Syntax**

```fortran
result = IBITS (i, pos, len)
```

- $i$ (Input) Must be of type integer.
pos

(Input) Must be of type integer. It must not be negative and \( pos + len \) must be less than or equal to \( \text{BIT\_SIZE}(i) \).

The rightmost (least significant) bit of \( i \) is in position 0.

len

(Input) Must be of type integer. It must not be negative.

Results

The result type and kind are the same as \( i \). The result has the value of the sequence of \( len \) bits in \( i \), beginning at \( pos \), right-adjusted and with all other bits zero.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

MVBITS

IBSET

Elemental Intrinsic Function (Generic): Sets one bit to 1.

Syntax

\[
\text{result} = \text{IBSET} \ (i, pos)
\]

\( i \)

(Input) Must be of type integer or of type logical (which is treated as an integer).

\( pos \)

(Input) Must be of type integer. It must not be negative and it must be less than \( \text{BIT\_SIZE}(i) \).

The rightmost (least significant) bit of \( i \) is in position 0.
Results
The result type and kind are the same as \(i\). The result has the value of the sequence of bits of \(i\), except that bit \(pos\) of \(i\) is set to 1.

For more information, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

NOT

ICHAR

Elemental Intrinsic Function (Generic): Returns the position of a character in the processor’s character set.

Syntax

```fortran
result = ICHAR (c [, kind])
```

- \(c\) (Input) Must be of type character of length 1.
- \(kind\) (Input; optional) Must be a scalar integer constant expression.
Results
The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer.

The result value is the position of c in the processor's character set. c is in the range zero to n - 1, where n is the number of characters in the character set.

For any characters C and D (capable of representation in the processor), C .LE. D is true only if ICHAR(C) .LE. ICHAR(D) is true, and C .EQ. D is true only if ICHAR(C) .EQ. ICHAR(D) is true.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ICHAR</td>
<td>CHARACTER</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)This specific function cannot be passed as an actual argument.

Example
ICHAR ( 'W' ) has the value 87.
ICHAR ( '#' ) has the value 35.

CHAR
ASCII and Key Code Charts

IDATE Intrinsic Procedure

**Intrinsic Subroutine (Generic):** Returns three integer values representing the current month, day, and year. IDATE can be used as an intrinsic subroutine or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT. Intrinsic subroutines cannot be passed as actual arguments.

Syntax
CALL IDATE (i, j, k)

i  (Output) Must be of type integer. It is the current month.

j  (Output) Must be of type integer with the same kind type parameter as i. It is the current day.

k  (Output) Must be of type integer with the same kind type parameter as i. It is the current year.

The current month is returned in i; the current day in j. The last two digits of the current year are returned in k.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.
Example
If the current date is September 16, 1999, the values of the integer variables upon return are: I = 9, J = 16, and K = 99.

See Also
DATE intrinsic procedure
DATE_AND_TIME
GETDAT
IDATE portability routine

IDADE Portability Routine
Portability Subroutine: Returns the month, day, and year of the current system. IDATE can be used as a portability subroutine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module
USE IFPORT

Syntax
CALL IDATE (i, j, k)
-or-
CALL IDATE (iarray)

i (Output) INTEGER(4). Is the current system month.

j (Output) INTEGER(4). Is the current system day.

k (Output) INTEGER(4). Is the current system year as an offset from 1900.

iarray (Output) INTEGER(4). Is a three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is greater than or equal to 1969 and is returned as 2 digits.

Caution
The two-digit year return value may cause problems with the year 2000. Use DATE_AND_TIME instead.

Example
Consider the following:

```
use IFPORT
integer(4) imonth, iday, iyear, datarray(3)
! If the date is July 11, 1999:
CALL IDATE(IMONTH, IDAY, IYEAR)
```
CALL IDATE (DATARRAY)

! datarray is (/11,7,99/)

See Also
DATE portability routine

DATE_AND_TIME

GETDAT

IDATE intrinsic procedure

IDATE4

**Portability Subroutine:** Returns the month, day, and year of the current system.

Module
USE IFPORT

Syntax
CALL IDATE4 (i, j, k)
-or-
CALL IDATE4 (iarray)

i  
(Output) INTEGER(4). The current system month.

j  
(Output) INTEGER(4). The current system day.

k  
(Output) INTEGER(4). The current system year as an offset from 1900.

iarray  
(Output) INTEGER(4). A three-element array that holds day as element 1, month as element 2, and year as element 3. The month is between 1 and 12. The year is returned as an offset from 1900, if the year is less than 2000. For years greater than or equal to 2000, this element simply returns the integer year, such as 2003.

IDENT

**General Compiler Directive:** Specifies a string that identifies an object module. The compiler places the string in the identification field of an object module when it generates the module for each source program unit.

Syntax
!DIR$ IDENT string

string  
Is a character constant containing printable characters. The number of characters is limited by the length of the source line.
Only the first IDENT directive is effective; the compiler ignores any additional IDENT directives in a program unit or module.

See Also
General Compiler Directives
Syntax Rules for Compiler Directives

IDFLOAT
**Portability Function:** Converts an INTEGER(4) argument to double-precision real type.

Module
USE IFPORT

Syntax
result = IDFLOAT (i)
i (Input) Must be of type INTEGER(4).

Results
The result type is double-precision real (REAL(8) or REAL*8).

See Also
DFLOAT

IEEE_CLASS
**Elemental Module Intrinsic Function (Generic):** Returns the IEEE class.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_CLASS (x)
x (Input) Must be of type REAL.

Results
The result is of type TYPE(IEEE_CLASS_TYPE). The result value is one of the following:

<table>
<thead>
<tr>
<th>IEEE_SIGNALING_NAN</th>
<th>IEEE_NEGATIVE_NORMAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_QUIET_NAN</td>
<td>IEEE_POSITIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_POSITIVE_INF</td>
<td>IEEE_NEGATIVE_DENORMAL</td>
</tr>
<tr>
<td>IEEE_NEGATIVE_INF</td>
<td>IEEE_POSITIVE_ZERO</td>
</tr>
<tr>
<td>IEEE_POSITIVE_NORMAL</td>
<td>IEEE_NEGATIVE_ZERO</td>
</tr>
</tbody>
</table>

IEEE_CLASS does not return IEEE_OTHER_VALUE in Intel® Fortran.
Example
IEEE_CLASS(1.0) has the value IEEE_POSITIVE_NORMAL.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_COPY_SIGN
Elemental Module Intrinsic Function (Generic):
Returns an argument with a copied sign. This is equivalent to the IEEE copysign function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_COPY_SIGN (x, y)

x       (Input) Must be of type REAL.
y       (Input) Must be of type REAL.

Results
The result type and kind are the same as x. The result has the value x with the sign of y. This is true even for IEEE special values, such as NaN or infinity.
The flags information is returned as a set of 1-bit flags.

Example
The value of IEEE_COPY_SIGN (X,3.0) is ABS (X), even when X is NaN.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_FLAGS
Portability Function: Gets, sets or clears IEEE flags for rounding direction and precision as well as queries or controls exception status. This function provides easy access to the modes and status required to use the features of ISO/IEC/IEEE 60559:2011 arithmetic in a Fortran program.

Module
USE IFPORT

Syntax
result = IEEE_FLAGS (action, mode, in, out)

action       (Input) Character*(*). One of the following literal values: 'GET', 'SET', 'CLEAR', or 'CLEARALL'.
**mode**

(Input) Character*. One of the following literal values: 'direction', 'precision', or 'exception'.

**in**

(Input) Character*. One of the following literal values: 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', 'common', 'nearest', 'tozero', 'negative', 'positive', 'extended', 'double', 'single', or ' ', which represents an unused (null) value.

**out**

(Output) Must be at least CHARACTER*9. One of the literal values listed for **in**.

The descriptions for the values allowed for **in** and **out** can be summarized as follows:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>'nearest'</td>
<td>Rounding direction flags</td>
</tr>
<tr>
<td>'tozero'</td>
<td></td>
</tr>
<tr>
<td>'negative'</td>
<td></td>
</tr>
<tr>
<td>'positive'</td>
<td></td>
</tr>
<tr>
<td>'single'</td>
<td>Rounding precision flags</td>
</tr>
<tr>
<td>'double'</td>
<td></td>
</tr>
<tr>
<td>'extended'</td>
<td></td>
</tr>
<tr>
<td>'inexact'</td>
<td>Math exception flags</td>
</tr>
<tr>
<td>'underflow'</td>
<td></td>
</tr>
<tr>
<td>'overflow'</td>
<td></td>
</tr>
<tr>
<td>'division'</td>
<td></td>
</tr>
<tr>
<td>'invalid'</td>
<td></td>
</tr>
<tr>
<td>'all'</td>
<td>All math exception flags above</td>
</tr>
<tr>
<td>'common'</td>
<td>The math exception flags: 'invalid', 'division', 'overflow', and 'underflow'</td>
</tr>
</tbody>
</table>

The values for **in** and **out** depend on the **action** and **mode** they are used with. The interaction of the parameters can be summarized as follows:

<table>
<thead>
<tr>
<th>Value of <strong>action</strong></th>
<th>Value of <strong>mode</strong></th>
<th>Value of <strong>in</strong></th>
<th>Value of <strong>out</strong></th>
<th>Functional value and return value</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET</td>
<td>'direction'</td>
<td>Null (' ')</td>
<td>One of 'nearest', 'tozero', 'negative', or 'positive'</td>
<td>Tests rounding direction settings.</td>
</tr>
<tr>
<td>Value of action</td>
<td>Value of mode</td>
<td>Value of in</td>
<td>Value of out</td>
<td>Functionality and return value</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------</td>
<td>-------------</td>
<td>--------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>'exception'</td>
<td>Null (' ')</td>
<td>One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common'</td>
<td>Returns the current setting, or 'not available'.</td>
<td></td>
</tr>
<tr>
<td>'precision'</td>
<td>Null (' ')</td>
<td>One of 'single', 'double', or 'extended'</td>
<td>Tests rounding precision settings. Returns the current setting, or 0.</td>
<td></td>
</tr>
</tbody>
</table>

**SET**

| 'direction'     | One of 'nearest', 'tozero', 'negative', or 'positive' | Null (' ') | Sets a rounding direction. |
| 'exception'     | One of 'inexact', 'division', 'underflow', 'overflow', 'invalid', 'all', or 'common' | Null (' ') | Sets a floating-point math exception. |
| 'precision'     | One of 'single', 'double', or 'extended' | Null (' ') | Sets a rounding precision. |
### Value of action

<table>

### Results

IEEE_FLAGS is an elemental, integer-valued function that sets IEEE flags for GET, SET, CLEAR, or CLEARALL procedures. It lets you control rounding direction and rounding precision, query exception status, and control exception enabling or disabling by using the SET or CLEAR procedures, respectively.
The flags information is returned as a set of 1-bit flags.

**Example**

The following example gets the highest priority exception that has a flag raised. It passes the input argument `in` as a null string:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*9 out
iflag = ieee_flags('get', 'exception', '', out)
PRINT *, out, ' flag raised'
```

The following example sets the rounding direction to round toward zero, unless the hardware does not support directed rounding modes:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('set', 'direction', 'tozero', out)
```

The following example sets the rounding direction to the default (‘nearest’):

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out, in
iflag = ieee_flags('clear','direction', '', '' )
```

The following example clears all exceptions:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 out
iflag = ieee_flags('clear','exception', 'all', '' )
```

The following example restores default direction and precision settings, and sets all exception flags to 0:

```fortran
USE IFPORT
INTEGER*4 iflag
CHARACTER*10 mode, out, in
iflag = ieee_flags('clearall', '', '', '')
```

The following example detects an underflow exception:

```fortran
USE IFPORT
CHARACTER*20 out, in
excep_detect = ieee_flags('get', 'exception', 'underflow', out)
if (out .eq.'underflow') stop 'underflow'
```

**IEEE_FMA**

*Elemental Module Intrinsic Function (Generic):*

*Returns the result of a fused multiply-add operation. This is equivalent to the IEEE fusedMultiplyAdd operation.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_FMA (a,b,c)
```
a  (Input) Must be of type REAL.

b  (Input) Must be of type REAL with the same kind type parameter as a.

c  (Input) Must be of type REAL with the same kind type parameter as a.

**Results**
The result type is REAL with the same kind type parameter as a. When the result is in range, the value of the
result is the mathematical value of \((a \times b) + c\) rounded according to the rounding mode of the representation
method of a. Only the final step in the calculation may cause IEEE_INEXACT, IEEE_OVERFLOW, or
IEEE_UNDERFLOW to signal; intermediate calculations do not.

This is the fusedMultiplyAdd operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

**Example**
The result value of IEEE_FMA (TINY(0.0), TINY(0.0) 1.0) is equal to 1.0 when the rounding mode is set to
NEAREST. The exception IEEE_INEXACT is signaled.

IEEE Intrinsic Modules Quick Reference Tables

**IEEE_GET_FLAG**

**Elemental Module Intrinsic Subroutine (Generic):** Returns whether an exception flag is
signaling.

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_GET_FLAG (flag, flag_value)

*flag*  (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

*flag_value*  (Output) Must be of type logical. If the exception in *flag* is signaling, the result is true; otherwise, false.

**Example**
Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS  
LOGICAL ON  
...  
CALL IEEE_GET_FLAG(IEEE_INVALID, ON)

If flag IEEE_INVALID is signaling, the value of ON is true; if it is quiet, the value of ON is false.

**See Also**
IEEE_EXCEPTIONS Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables
IEEE_GET_HALTING_MODE
Elemental Module Intrinsic Subroutine (Generic): Stores the halting mode for an exception.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
CALL IEEE_GET_HALTING_MODE (flag, halting)

flag  (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID, IEEE_OVERFLOW, or IEEE_UNDERFLOW.

halting  (Output) Must be of type logical. If the exception in flag causes halting, the result is true; otherwise, false.

Example
Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)  ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT)  ! Restores halting

IEEE_GET_MODES
Intrinsic Module Subroutine (Generic): Stores the current IEEE floating-point modes. This is an impure subroutine.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
CALL IEEE_GET_MODES (modes)

modes  (Output) Must be scalar and of type TYPE (IEEE_MODES_TYPE). It is assigned the value of the floating-point modes.
Example

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_MODE_TYPE) MODES
... CALL IEEE_GET_MODES (MODES) ! Stores the floating-point modes
CALL IEEE_SET_UNDERFLOW_MODE (.TRUE.) ! Sets the underflow mode to gradual
... CALL IEEE_SET_MODES (MODES) ! Restores the floating-point modes
```

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_GET_ROUNDING_MODE

Intrinsic Module Subroutine (Generic): Stores the current IEEE rounding mode. This is an impure subroutine.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```
CALL IEEE_GET_ROUNDING_MODE (round_value [, radix])
```

- `round_value` (Output) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It returns one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, or IEEE_UP; otherwise, IEEE_OTHER.

The result can only be used if IEEE_SET_ROUNDING_MODE is invoked.

- `radix` (Input; optional) Must be an integer scalar with a value of two or ten. The rounding mode queried is the binary rounding mode, unless `radix` is present with the value ten, in which case it is the decimal rounding mode queried.

Example

Consider the following:

```
USE, INTRINSIC :: IEEE_ARITHMETIC
TYPE(IEEE_ROUND_TYPE) ROUND
... CALL IEEE_GET_ROUNDING_MODE(ROUND) ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE(IEEE_UP) ! Resets the rounding mode
... CALL IEEE_SET_ROUNDING_MODE(ROUND) ! Restores the previous rounding mode
```

**IEEE_GET_STATUS**

**Intrinsic Module Subroutine (Generic):** Stores the current state of the floating-point environment. This is an impure subroutine.

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_GET_STATUS (status_value)

*status_value* (Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE).

It stores the floating-point status. The result can only be used if IEEE_SET_STATUS is invoked.

**Example**

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS    ! Can also use IEEE_ARITHMETIC
TYPE(IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS(STATUS)   ! Stores the floating-point status
CALL IEEE_SET_FLAG(IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS(STATUS)   ! Restores the floating-point status
```

---

**IEEE_GET_UNDERFLOW_MODE**

**Intrinsic Module Subroutine (Generic):** Stores the current underflow mode. This is an impure subroutine.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

CALL IEEE_GET_UNDERFLOW_MODE (gradual)

*gradual* (Output) Must be logical scalar.

The result is true if the current underflow mode is gradual (IEEE subnormals are allowed) and false if the current underflow mode is abrupt (underflowed results are set to zero).

**Example**

Consider the following:

```
USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL GRAD
...
```
CALL IEEE_GET_UNDERFLOW_MODE(GRAD)
IF (GRAD) THEN ! underflows are gradual
  ...
ELSE ! underflows are abrupt
  ...
END IF

IEEE_HANDLER
_Portability Function:_ Establishes a handler for IEEE exceptions.

Module
USE IFPORT

Syntax
result = IEEE_HANDLER (action, exception, handler)

action (Input) Character*(*). One of the following literal IEEE actions: 'GET', 'SET', or 'CLEAR'. For more details on these actions, see IEEE_FLAGS.

exception (Input) Character*(*). One of the following literal IEEE exception flags: 'inexact', 'underflow', 'overflow', 'division', 'invalid', 'all' (which equals the previous five flags), or 'common' (which equals 'invalid', 'overflow', 'underflow', and 'division'). The flags 'all' or 'common' should only be used for actions SET or CLEAR.

handler (Input) The address of an external signal-handling routine.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is 0 if successful; otherwise, 1.

IEEE_HANDLER calls a signal-handling routine to establish a handler for IEEE exceptions. It also enables an FPU trap corresponding to the required exception.

The state of the FPU is not defined in the handler routine. When the FPU trap occurs, the program invokes the handler routine. After the handler routine is executed, the program terminates.

The handler routine gets the exception code in the SIGINFO argument. SIGNO is the number of the system signal. The meaning of the SIGINFO constants appear in the following table (defined in the IFPORT module):

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPE$INVALID</td>
<td>Invalid operation</td>
</tr>
<tr>
<td>FPE$ZERODIVIDE</td>
<td>Divide-by-zero</td>
</tr>
<tr>
<td>FPE$OVERFLOW</td>
<td>Numeric overflow</td>
</tr>
<tr>
<td>FPE$UNDERFLOW</td>
<td>Numeric underflow</td>
</tr>
<tr>
<td>FPE$INEXACT</td>
<td>Inexact result (precision)</td>
</tr>
</tbody>
</table>

'GET' actions return the location of the current handler routine for exception cast to an INTEGER.
Example

The following example creates a handler routine and sets it to trap divide-by-zero:

```fortran
PROGRAM TEST_IEEE
  REAL :: X, Y, Z
  CALL FPE_SETUP
  X = 0.
  Y = 1.
  Z = Y / X
END PROGRAM

SUBROUTINE FPE_SETUP
  USE IFPORT
  IMPLICIT NONE
  INTERFACE
    SUBROUTINE FPE_HANDLER(SIGNO, SIGINFO)
      INTEGER(4), INTENT(IN) :: SIGNO, SIGINFO
    END SUBROUTINE
  END INTERFACE
  INTEGER IR
  IR = IEEE_HANDLER('set','division',FPE_HANDLER)
END SUBROUTINE FPE_SETUP

SUBROUTINE FPE_HANDLER(SIG, CODE)
  USE IFPORT
  IMPLICIT NONE
  INTEGER SIG, CODE
  IF(CODE.EQ.FPE$ZERODIVIDE) PRINT *, 'Occurred divide by zero.'
  CALL ABORT
END SUBROUTINE FPE_HANDLER
```

IEEE_FLAGS

IEEE_INT

Elemental Module Intrinsic Function (Generic):

Enables conversion to INTEGER type.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

```fortran
result = IEEE_INT (a, round [, kind])
```

- `a` (Input) Must be of type REAL or INTEGER.
- `round` (Input) Must be of type IEEE_ROUND_TYPE.
- `kind` (Input; optional) Must be a scalar INTEGER constant.

Results

The result type is INTEGER. If `kind` is present, the kind type parameter is that specified by `kind`; otherwise, the kind type parameter is default integer.

The result is the value of `a` converted to integer according to the rounding mode specified by `round` if the values can be represented in the representation method of the result type kind; otherwise, the result is processor dependent and IEEE_INVALID is signaled.
The result must be consistent with the ISO/IEC/IEEE 60559:2011 operation convertToInteger\{round\} or convertToIntegerExact\{round\}. The processor consistently chooses which operation is performed.

**Example**

The result value of IEEE_INT (63.5, IEEE_DOWN) is 63. If convertToIntegerExact\{round\} is used, IEEE_INEXACT will signal.

### IEEE_IS_FINITE

*Elemental Module Intrinsic Function (Generic):*

*Returns whether an IEEE value is finite.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_IS_FINITE (x)
```

\( x \)  
(Input) Must be of type REAL.

**Results**

The result type is default logical. The result has the value true if the value of \( x \) is finite; otherwise, false.

An IEEE value is finite if IEEE_CLASS(x) has one of the following values:

- IEEE_POSITIVE_NORMAL
- IEEE_NEGATIVE_DENORMAL
- IEEE_NEGATIVE_NORMAL
- IEEE_POSITIVE_ZERO
- IEEE_POSITIVE_DENORMAL
- IEEE_NEGATIVE_ZERO

**Example**

IEEE_IS_FINITE (-2.0) has the value true.

**See Also**

IEEE_ARITHMETIC Intrinsic Module

### IEEE_IS_NAN

*Elemental Module Intrinsic Function (Generic):*

*Returns whether an IEEE value is Not-a-Number (NaN).*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_IS_NAN (x)
```
x  

(Input) Must be of type REAL.

**Results**
The result type is default logical. The result has the value true if the value of x is NaN; otherwise, false.

**Example**
IEEE_IS_NAN (SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT (2.0) has the value true.

**See Also**
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

### IEEE_IS_NEGATIVE

*Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is negative.*

**Module**
USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**
result = IEEE_IS_NEGATIVE (x)

x  

(Input) Must be of type REAL.

**Results**
The result type is default logical. The result has the value true if the value of x is negative; otherwise, false.

An IEEE value is negative if IEEE_CLASS(x) has one of the following values:

<table>
<thead>
<tr>
<th>IEEE_NEGATIVE_NORMAL</th>
<th>IEEE_NEGATIVE_ZERO</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_NEGATIVE_DENORMAL</td>
<td>IEEE_NEGATIVE_INF</td>
</tr>
</tbody>
</table>

**Example**
IEEE_IS_NEGATIVE (2.0) has the value false.

**See Also**
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

### IEEE_IS_NORMAL

*Elemental Module Intrinsic Function (Generic): Returns whether an IEEE value is normal.*

**Module**
USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**
result = IEEE_IS_NORMAL (x)

---

1584
x

(Input) Must be of type REAL.

Results
The result type is default logical. The result has the value true if the value of \( x \) is normal; otherwise, false. An IEEE value is normal if IEEE_CLASS(x) has one of the following values:

\[
\begin{array}{ll}
\text{IEEE\_POSITIVE\_NORMAL} & \text{IEEE\_POSITIVE\_ZERO} \\
\text{IEEE\_NEGATIVE\_NORMAL} & \text{IEEE\_NEGATIVE\_ZERO}
\end{array}
\]

Example
IEEE\_IS\_NORMAL (SQRT(-2.0)) has the value false if IEEE\_SUPPORT\_SQRT (-2.0) has the value true.

IEEE\_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE\_LOGB
Elemental Module Intrinsic Function (Generic):
Returns a floating-point value equal to the unbiased exponent of the argument. This is equivalent to the IEEE logb function.

Module
USE, INTRINSIC :: IEEE\_ARITHMETIC

Syntax
result = IEEE\_LOGB (x)

\( x \)

(Input) Must be of type REAL.

Results
The result type and kind are the same as \( x \). The result has the value of the unbiased exponent of \( x \) if the value of \( x \) is not zero, infinity, or NaN. The value of the result is equal to EXPONENT(x) - 1.
If \( x \) is equal to 0, the result is -infinity if IEEE\_SUPPORT\_INF(x) is true; otherwise, -HUGE(x). In either case, the IEEE\_DIVIDE\_BY\_ZERO exception is signaled.

Example
IEEE\_LOGB (3.4) has the value 1.0; IEEE\_LOGB (4.0) has the value 2.0.

See Also
IEEE\_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE\_MAX\_NUM
Inquiry Module Intrinsic Function (Generic):
Returns the maximum of two values. This is equivalent to the IEEE maxNum operation.
**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

result = IEEE_MAX_NUM (x, y)

x  
(Input) Must be of type REAL.

y  
(Input) Must be of type REAL with the same kind type parameter as x.

**Results**

The result type is REAL with the same kind type parameter as x. The result is x if y < x. The result is y if x < y.

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet NaN. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either x or y (processor dependent). No exceptions are signaled unless x or y is a signaling NaN.

This is the maxNum operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

**Example**

The result value of IEEE_MAX_NUM (3.7, IEEE_VALUE (0.0, IEEE_SIGNALING_NAN)) is a NaN. The exception IEEE_INVALID is signaled.

**See Also**

IEEE_ARITHMETIC Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

**IEEE_MAX_NUM_MAG**

Inquiry Module Intrinsic Function (Generic):

Returns the maximum magnitude of two values. This is equivalent to the IEEE maxNumMag operation.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

result = IEEE_MAX_NUM_MAG (x, y)

x  
(Input) Must be of type REAL.

y  
(Input) Must be of type REAL with the same kind type parameter as x.

**Results**

The result type is REAL with the same kind type parameter as x. The result is x if ABS(y) < ABS(x). The result is the value of y if ABS(x) < ABS(y).

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet NaN. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either x or y (processor dependent). No exceptions are signaled unless x or y is a signaling NaN.

This is the maxNumMag operation as specified in the ISO/IEC/IEEE 60559:2011 standard.
**Example**

The result value of `IEEE_MAX_NUM_MAG (3.7, -7.5)` is -7.5.

**See Also**

IEEE_ARITHMETIC Intrinsic Module

### IEEE_MIN_NUM

*Inquiry Module Intrinsic Function (Generic):*

*Returns the minimum of two values. This is equivalent to the IEEE minNum operation.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```
result = IEEE_MIN_NUM (x, y)
```

- `x` (Input) Must be of type REAL.
- `y` (Input) Must be of type REAL with the same kind type parameter as `x`.

**Results**

The result type is REAL with the same kind type parameter as `x`. The result is `x` if `x < y`. The result is `y` if `y < x`.

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet NaN. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either `x` or `y` (processor dependent). No exceptions are signaled unless `x` or `y` is a signaling NaN.

This is the minNum operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

**Example**

The result value of `IEEE_MIN_NUM (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN))` is 3.7. No exceptions are signaled.

**See Also**

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

### IEEE_MIN_NUM_MAG

*Inquiry Module Intrinsic Function (Generic):*

*Returns the minimum magnitude of two values. This is equivalent to the IEEE minNumMag operation.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```
result = IEEE_MIN_NUM_MAG (x, y)
```

**Example**

The result value of `IEEE_MIN_NUM_MAG (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN))` is 3.7. No exceptions are signaled.
\( x \)  
(Input) Must be of type REAL.

\( y \)  
(Input) Must be of type REAL with the same kind type parameter as \( x \).

**Results**

The result type is REAL with the same kind type parameter as \( x \). The result is \( y \) if \( \text{ABS}(y) < \text{ABS}(x) \). The result is the value of \( x \) if \( \text{ABS}(x) < \text{ABS}(y) \).

If one of the arguments is a quiet NaN, the result is the value of the argument which is not a quiet NaN. If either or both of the arguments is a signaling NaN, the result is a NaN and IEEE_INVALID signals. Otherwise, the result value is that of either \( x \) or \( y \) (processor dependent). No exceptions are signaled unless \( x \) or \( y \) is a signaling NaN.

This is the minNumMag operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

**Example**

The result value of IEEE_MIN_NUM_MAG (3.7, -7.5) is 3.7.

**See Also**

IEEE_ARITHMETIC Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables

---

**IEEE_NEXT_AFTER**

**Elemental Module Intrinsic Function (Generic):**

Returns the next representable value after \( X \) toward \( Y \).  
This is equivalent to the IEEE nextafter function.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

\[
\text{result} = \text{IEEE\_NEXT\_AFTER}(x,y)
\]

\( x \)  
(Input) Must be of type REAL.

\( y \)  
(Input) Must be of type REAL.

**Results**

The result type and kind are the same as \( x \). If \( x \) is equal to \( y \), the result is \( x \); no exception is signaled. If \( x \) is not equal to \( y \), the result has the value of the next representable neighbor of \( x \) toward \( y \). The neighbors of zero (of either sign) are both nonzero.

The following exceptions are signaled under certain cases:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Signaled</th>
</tr>
</thead>
<tbody>
<tr>
<td>IEEE_OVERFLOW</td>
<td>When ( X ) is finite but IEEE_NEXT_AFTER(( X, Y )) is infinite</td>
</tr>
<tr>
<td>IEEE_UNDERFLOW</td>
<td>When IEEE_NEXT_AFTER(( X, Y )) is subnormal</td>
</tr>
<tr>
<td>IEEE_INEXACT</td>
<td>In both the above cases</td>
</tr>
</tbody>
</table>

**Example**

The value of IEEE\_NEXT\_AFTER (2.0,3.0) is 2.0 + EPSILON (\( X \)).
IEEE_NEXT_DOWN

Elemental Module Intrinsic Function (Generic):
Returns the next lower adjacent machine number.
This is equivalent to the IEEE nextDown operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_NEXT_DOWN (x)

x (Input) Must be of type REAL.

Results
The result type and kind are the same as x. The value of the result is the greatest value that compares less
than x - except when x has the value NaN, the result is NaN, and when x has the value - ∞ , the result is - ∞ . If x is a signaling NaN, IEEE_INVALID signals; otherwise, no exception is signaled.
This is the nextDown operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The value of IEEE_NEXT_DOWN(+0.0) is the negative subnormal number with the least magnitude if the
value if IEEE_SUPPORT_SUBNORMAL (0.0) is .TRUE..

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_NEXT_UP

Elemental Module Intrinsic Function (Generic):
Returns the next higher adjacent machine number.
This is equivalent to the IEEE nextUp operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_NEXT_UP (x)

x (Input) Must be of type REAL.

Results
The result type and kind are the same as x. The value of the result is the least value that compares greater
than x - except when x has the value NaN, the result is NaN, and when x has the value + ∞ , the result is + ∞ . If x is a signaling NaN, IEEE_INVALID signals; otherwise, no exception is signaled.
This is the nextUp operation as specified in the ISO/IEC/IEEE 60559:2011 standard.
Example
The value of IEEE_NEXT_UP (HUGE (x)) is + ∞ if the value of IEEE_SUPPORT_INF (x) is .true..

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_QUIET_EQ
Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for equality. This is equivalent to the IEEE compareQuietEqual operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_QUIET_EQ (a, b)

a (Input) Must be of type REAL.
b (Input) Must be of type REAL with the same kind type parameter as a.

Results
The result type is default LOGICAL. It has the value true if a compares equal to b. If a or b is a NaN, the result is false. IEEE_INVALID signals if either a or b is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietEqual operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The result value of IEEE_QUIET_EQ (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_QUIET_GE
Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for greater than or equal. This is equivalent to the IEEE compareQuietGreaterEqual operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_QUIET_GE (a, b)

a (Input) Must be of type REAL.
b (Input) Must be of type REAL with the same kind type parameter as a.
Results

The result type is default LOGICAL. It has the value true if \( a \) compares greater than or equal to \( b \). If \( a \) or \( b \) is a NaN, the result is false. IEEE_INVALID signals if either \( a \) or \( b \) is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietGreaterEqual operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example

The result value of IEEE_QUIET_GE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

IEEE_QUIET_GT

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for greater than. This is equivalent to the IEEE compareQuietGreater operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

\[
\text{result} = \text{IEEE\_QUIET\_GT} (a, b)
\]

(a) (Input) Must be of type REAL.

(b) (Input) Must be of type REAL with the same kind type parameter as \( a \).

Results

The result type is default LOGICAL. It has the value true if \( a \) compares greater than \( b \). If \( a \) or \( b \) is a NaN, the result is false. IEEE_INVALID signals if either \( a \) or \( b \) is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietGreater operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example

The result value of IEEE_QUIET_GT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_QUIET_LE

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for less than or equal. This is equivalent to the IEEE compareQuietLessEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC
Syntax
result = IEEE_QUIET_LE (a, b)

a (Input) Must be of type REAL.
b (Input) Must be of type REAL with the same kind type parameter as a.

Results
The result type is default LOGICAL. It has the value true if a compares less than or equal to b. If a or b is a NaN, the result is false. IEEE_INVALID signals if either a or b is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietLessEqual operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The result value of IEEE_QUIET_LE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_QUIET_LT
Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for less than. This is equivalent to the IEEE compareQuietLess operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_QUIET_LT (a, b)

a (Input) Must be of type REAL.
b (Input) Must be of type REAL with the same kind type parameter as a.

Results
The result type is default LOGICAL. It has the value true if a compares less than b. If a or b is a NaN, the result is false. IEEE_INVALID signals if either a or b is a signaling NaN, otherwise no exception is signaled.

This is the compareQuietLess operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The result value of IEEE_QUIET_LT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and no exception is signaled.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables
IEEE_QUIET_NE

Elemental Module Intrinsic Function (Generic):
Performs a non-signaling comparison for inequality.
This is equivalent to the IEEE compareQuietNotEqual
operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_QUIET_NE (a, b)

a  (Input) Must be of type REAL.
b  (Input) Must be of type REAL with the same kind type parameter as a.

Results
The result type is default LOGICAL. It has the value true if a compares not equal to b. If a or b is a NaN, the
result is true. IEEE_INVALID signals if either a or b is a signaling NaN, otherwise no exception is signaled.
This is the compareQuietNotEqual operation specified as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The result value of IEEE_QUIET_NE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is true and no exception is
signaled.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_REAL

Elemental Module Intrinsic Function (Generic):
Enables conversion to REAL type.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_REAL (a [, kind])

a  (Input) Must be of type REAL or INTEGER.
kind  (Input; optional) Must be a scalar INTEGER constant.

Results
The result type is REAL. If kind is present, the kind type parameter is that specified by kind; otherwise, the
kind type parameter is default real.
The result has the same value as a if that value is representable in the representation method of the result
type kind; otherwise, it is rounded according to the current rounding mode.
The result must be consistent with the ISO/IEC/IEEE 60559:2011 operation convertFromInt if a is an integer,
and with operation convertFormat if a is a real.
Example
The result value of IEEE_REAL (987) is 987.0.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_REM

Elemental Module Intrinsic Function (Generic):
Returns the result of an exact remainder operation.
This is equivalent to the IEEE remainder function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_REM (x, y)

\( x \) (Input) Must be of type REAL.

\( y \) (Input) Must be of type REAL with a radix that is the same as that of \( x \).

Results
The result type is real with the kind type parameter of whichever argument has greater precision.
Regardless of the rounding mode, the result value is \( x - y \times N \), where \( N \) is the integer nearest to the value \( x / y \). If \( |N - x / y| = 1/2 \), \( N \) is even. If the result value is zero, the sign is the same as \( x \).

Example
The value of IEEE_REM (5.0,4.0) is 1.0; the value of IEEE_REM (2.0,1.0) is 0.0; the value of IEEE_REM (3.0,2.0) is -1.0.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_RINT

Elemental Module Intrinsic Function (Generic):
Returns an integer value rounded according to the current rounding mode.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_RINT (x [, round])

\( x \) (Input) Must be of type REAL.

\( \text{round} \) (Input; optional) Must be of type TYPE (IEEE_ROUND_TYPE).
Results
The result type and kind are the same as \( x \).

The value of the result is \( x \) rounded to an integer according to the current rounding mode if \( \text{round} \) is not present. If \( \text{round} \) is present, the value of the result is \( x \) rounded to an integer according to the mode specified by \( \text{round} \); this is the operation \( \text{roundToInteger}(\text{rounding}) \) as specified by ISO/IEC/IEEE 60559:2011.

If the result value is zero, the sign is the same as \( x \).

The rounding mode specified by \( \text{round} \), if present, is used to perform the conversion. The rounding mode before and after the call remains unchanged.

Example
If the current rounding mode is IEEE_UP, the value of IEEE_RINT (2.2) is 3.0.

If the current rounding mode is IEEE_NEAREST, the value of IEEE_RINT (2.2) is 2.0.

The value of IEEE_RINT (7.4, IEEE_DOWN) is 7.0.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SCALB

Elemental Module Intrinsic Function (Generic):
Returns the exponent of a radix-independent floating-point number. This is equivalent to the IEEE scalb function.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SCALB (x,i)

\( x \) (Input) Must be of type REAL.

\( i \) (Input) Must be of type INTEGER.

Results
The result type and kind are the same as \( x \). The result is \( x \) multiplied by \( 2^{\text{int}} \), if the value can be represented as a normal number.

If \( x \ (2^{\text{int}}) \) is too small and there is a loss of accuracy, the exception IEEE_UNDERFLOW is signaled. The result value is the nearest number that can be represented with the same sign as \( x \).

If \( x \) is finite and \( x \ (2^{\text{int}}) \) is too large, an IEEE_OVERFLOW exception occurs. If IEEE_SUPPORT_INF \( (x) \) is true, the result value is infinity with the same sign as \( x \); otherwise, the result value is SIGN (HUGE(\( x) \), \( x) \).

If \( x \) is infinite, the result is the same as \( x \); no exception is signaled.

Example
The value of IEEE_SCALB (2.0,3) is 16.0.

IEEE Intrinsic Modules Quick Reference Tables

**IEEE_SELECTED_REAL_KIND**

*Transformational Module Intrinsic Function (Generic): Returns the value of the kind parameter of an IEEE REAL data type.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

\[
\text{result} = \text{IEEE_SELECTED_REAL_KIND} \left( \{p\}, \{r\}, \{\text{radix}\} \right)
\]

- \(p\) (Input; optional) Must be scalar and of type INTEGER.
- \(r\) (Input; optional) Must be scalar and of type INTEGER.
- \(\text{radix}\) (Input; optional) Must be scalar and of type INTEGER.

At least argument \(p\) or \(r\) must be present.

**Results**

If \(p\) or \(r\) is absent, the result is as if the argument was present with the value zero. If \(\text{radix}\) is absent, there is no requirement on the \(\text{radix}\) of the selected kind.

The result is a scalar of type default integer. The result has a value equal to a value of the kind parameter of an IEEE real data type with decimal precision, as returned by the function PRECISION, of at least \(p\) digits, a decimal exponent range, as returned by the function RANGE, of at least \(r\), and a \(\text{radix}\), as returned by the function RADIX, of \(\text{radix}\).

If no such kind type parameter is available on the processor, the result is as follows:

- -1 if the precision is not available
- -2 if the exponent range is not available
- -3 if neither the precision nor the exponent range is available
- -4 if one but not both of the precision and the exponent range is available
- -5 if the \(\text{radix}\) is not available

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision.

**Example**

\[\text{IEEE_SELECTED_REAL_KIND} \left( 6, 70, 2 \right) = 8.\]

**IEEE_SET_FLAG**

*Elemental Module Intrinsic Function (Generic): Assigns a value to an exception flag. This is a pure subroutine.*
Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

CALL IEEE_SET_FLAG (flag, flag_value)

flag  (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:

IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW.

flag_value  (Output) Must be of type logical. If it has the value true, the exception in flag is set to signal; otherwise, the exception is set to be quiet.

Example

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS  ! Can also use module IEEE_ARITHMETIC
...
CALL IEEE_SET_FLAG (IEEE_INVALID, .TRUE.)  ! Sets the IEEE_INVALID flag to signal

See Also

IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SET_HALTING_MODE

Elemental Module Intrinsic Function (Generic):
Controls halting or continuation after an exception.
This is a pure subroutine.

Module

USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax

CALL IEEE_SET_HALTING_MODE (flag, halting)

flag  (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:

IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW

halting  (Input) Must be scalar and of type logical. If the value is true, the exception specified in flag will cause halting; otherwise, execution will continue after this exception.

Example

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL HALT
...
CALL IEEE_GET_HALTING_MODE(IEEE_INVALID, HALT)  ! Stores the halting mode
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, .FALSE.) ! Stops halting
...
CALL IEEE_SET_HALTING_MODE(IEEE_INVALID, HALT)  ! Restores halting

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SET_MODES

Intrinsic Module Subroutine (Generic): Restores the current IEEE floating-point modes. This is an impure subroutine.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
CALL IEEE_SET_MODES (modes)

modes (Input) Must be scalar and of type TYPE (IEEE_MODES_TYPE). Its value must be a value that was assigned to the modes argument of a previous call to IEEE_GET_MODES.

A call to IEEE_SET_MODES restores the value of the floating-point modes to the state at the time IEEE_GET_MODES was called.

Example
Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_MODE_TYPE) MODES
...
CALL IEEE_GET_MODES (MODES) ! Stores the floating-point modes
CALL IEEE_SET_UNDERFLOW_MODE (.TRUE.) ! Sets the underflow mode to gradual
...
CALL IEEE_SET_MODES (MODES) ! Restores the floating-point modes

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SET_ROUNDING_MODE

Intrinsic Module Subroutine (Generic): Sets the IEEE rounding mode. This is an impure subroutine.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
CALL IEEE_SET_ROUNDING_MODE (round_value [, radix])
round_value

(Input) Must be scalar and of type TYPE (IEEE_ROUND_TYPE). It specifies one of the following IEEE floating-point rounding values: IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, IEEE_UP, or IEEE_OTHER.

radix

(Input; optional) Must be an integer scalar with a value of ten or two. The rounding mode set is the binary rounding mode unless radix is present with the value of ten, in which case it is the decimal rounding mode set.

Example

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_ARITHMETIC
TYPE (IEEE_ROUND_TYPE) ROUND
...
CALL IEEE_GET_ROUNDING_MODE (ROUND) ! Stores the rounding mode
CALL IEEE_SET_ROUNDING_MODE (IEEE_UP) ! Resets the rounding mode
...
CALL IEEE_SET_ROUNDING_MODE (ROUND) ! Restores the previous rounding mode
```

**IEEE_SET_STATUS**

*Intrinsic Module Subroutine (Generic): Restores the state of the floating-point environment. This is an impure subroutine.*

**Module**

USE, INTRINSIC :: IEEE_EXCEPTIONS

**Syntax**

CALL IEEE_SET_STATUS (status_value)

status_value

(Input) Must be scalar and of type TYPE (IEEE_STATUS_TYPE). Its value must be set in a previous invocation of IEEE_GET_STATUS.

Example

Consider the following:

```fortran
USE, INTRINSIC :: IEEE_EXCEPTIONS ! Can also use IEEE_ARITHMETIC
TYPE (IEEE_STATUS_TYPE) STATUS
...
CALL IEEE_GET_STATUS (STATUS) ! Stores the floating-point status
CALL IEEE_SET_FLAG (IEEE_ALL,.FALSE.) ! Sets all flags to be quiet
...
CALL IEEE_SET_STATUS (STATUS) ! Restores the floating-point status
```

**IEEE_SET_UNDERFLOW_MODE**

*Intrinsic Module Subroutine (Generic): Sets the current underflow mode. This is an impure subroutine.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC
Syntax

CALL IEEE_SET_UNDERFLOW_MODE (gradual)

gradual (Input) Must be scalar and of type logical. If it is true, the current underflow mode is set to gradual underflow (subnormals may be produced on underflow). If it is false, the current underflow mode is set to abrupt (underflowed results are set to zero).

Example

Consider the following:

USE, INTRINSIC :: IEEE_EXCEPTIONS
LOGICAL :: SG
...
CALL IEEE_GET_UNDERFLOW_MODE (SG) ! Stores underflow mode
CALL IEEE_SET_UNDERFLOW_MODE (.FALSE.) ! Resets underflow mode
... ! Abrupt underflows happens here
CALL IEEE_SET_UNDERFLOW_MODE (SG) ! Restores previous underflow mode

IEEE_SIGNALING_EQ

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for equality. This is equivalent to the IEEE compareSignalingEqual operation.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SIGNALING_EQ (a, b)

a (Input) Must be of type REAL.
b (Input) Must be of type REAL with the same kind type parameter as a.

Results

The result type is default LOGICAL. It has the value true if a compares equal to b. If a or b is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingEqual operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example

The result value of IEEE_SIGNALING_EQ (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

See Also
IEEE_ARITHMETIC Intrinsic Module

IEEE_SIGNALING_GE

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for greater than or equal. This is equivalent to the IEEE compareSignalingGreaterEqual operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SIGNALING_GE (a, b)

a  
  (Input) Must be of type REAL.
b  
  (Input) Must be of type REAL with the same kind type parameter as a.

Results
The result type is default LOGICAL. It has the value true if a compares greater than or equal to b. If a or b is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingGreaterEqual operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The result value of IEEE_SIGNALING_GE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

IEEE_SIGNALING_GT

Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for greater than. This is equivalent to the IEEE compareSignalingGreater operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SIGNALING_GT (a, b)

a  
  (Input) Must be of type REAL.
b  
  (Input) Must be of type REAL with the same kind type parameter as a.

Results
The result type is default LOGICAL. It has the value true if a compares greater than b. If a or b is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingGreater operation as specified in the ISO/IEC/IEEE 60559:2011 standard.
Example
The result value of IEEE_SIGNALING_GT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

See Also

IEEE_SIGNALING_LE
Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for less than or equal. This is equivalent to the IEEE compareSignalingLessEqual operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SIGNALING_LE (a, b)

a (Input) Must be of type REAL.
b (Input) Must be of type REAL with the same kind type parameter as a.

Results
The result type is default LOGICAL. It has the value true if a compares less than or equal to b. If a or b is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingLessEqual operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The result value of IEEE_SIGNALING_LE (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SIGNALING_LT
Elemental Module Intrinsic Function (Generic):
Performs a signaling comparison for less than. This is equivalent to the IEEE compareSignalingLess operation.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SIGNALING_LT (a, b)

a (Input) Must be of type REAL.
\( b \)  

\( a \)

**Results**

The result type is default LOGICAL. It has the value true if \( a \) compares less than \( b \). If \( a \) or \( b \) is a NaN, the result is false and IEEE_INVALID signals, otherwise no exception is signaled.

This is the compareSignalingLess operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

**Example**

The result value of IEEE_SIGNALING_LT (3.7, IEEE_VALUE (0.0, IEEE_QUIET_NAN)) is false and IEEE_INVALID is signaled.

**IEEE_SIGNBIT**

*Elemental Module Intrinsic Function (Generic):*

Tests to determine if the argument’s sign bit is set. This is equivalent to the IEEE SignMinus operation.
Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SIGNBIT (x)

x  (Input) Must be of type REAL.

Results
The result is a scalar of type default logical. The result has the value .true. if the sign bit of x is set (nonzero); otherwise, it has the value .false.. No exception is signaled even if x has the value of a signaling NaN.

This is the SignMinus operation as specified in the ISO/IEC/IEEE 60559:2011 standard.

Example
The result of IEEE_SIGNBIT (-3.14) is .true..

IEEE_SUPPORT_DATATYPE

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE arithmetic.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_DATATYPE ([x])

x  (Input; optional) Must be scalar and of type REAL.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports IEEE arithmetic for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports IEEE arithmetic for real variables of the same kind type parameter as x; otherwise, false.

If real values are implemented according to the IEEE standard except that underflowed values flush to zero (abrupt) instead of being subnormal.

Example
IEEE_SUPPORT_DATATYPE (3.0) has the value true.

See Also
IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables
**IEEE_SUPPORT_DENORMAL**

*Inquiry Module Intrinsic Function (Generic):*

*Returns whether the processor supports IEEE subnormal numbers.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_SUPPORT_DENORMAL ([x])
```

*x*  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for all real values; otherwise, false. If *x* is specified, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for real variables of the same kind type parameter as *x*; otherwise, false.

IEEE_SUPPORT_DENORMAL() and IEEE_SUPPORT_DENORMAL(0.0_16) return .TRUE. even though Intel® Fortran’s implementation does not signal when an underflow results in a REAL(16) denormal value. Intel® Fortran’s implementation does signal when an underflow results in a REAL(16) zero.

**Example**

IEEE_SUPPORT_DENORMAL () has the value true if IEEE subnormal numbers are supported for all real types.

**See Also**

IEEE_ARITHMETIC Intrinsic Module

**IEEE_SUPPORT_DIVIDE**

*Inquiry Module Intrinsic Function (Generic):*

*Returns whether the processor supports IEEE divide.*

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_SUPPORT_DIVIDE ([x])
```

*x*  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for all real values; otherwise, false. If *x* is specified, the result has the value true if the processor supports divide with the accuracy specified by the IEEE standard for real variables of the same kind type parameter as *x*; otherwise, false.
Example
IEEE_SUPPORT_DIVIDE() has the value true if IEEE divide is supported for all real types.

IEEE_SUPPORT_FLAG
Transformational Module Intrinsic Function (Generic): Returns whether the processor supports IEEE exceptions.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
result = IEEE_SUPPORT_FLAG(flag [, x])

flag      (Input) Must be a scalar of type TYPE (IEEE_FLAG_TYPE). Its value is one of the following IEEE flags:
          IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
          IEEE_OVERFLOW, or IEEE_UNDERFLOW.

x         (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports detection of the exception specified by flag for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports detection of the exception specified by flag for real variables of the same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_FLAG(IEEE_UNDERFLOW) has the value true if the IEEE_UNDERFLOW exception is supported for all real types.

See Also
IEEE_EXCEPTIONS Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables

IEEE_SUPPORT_HALTING
Transformational Module Intrinsic Function (Generic): Returns whether the processor supports IEEE halting.

Module
USE, INTRINSIC :: IEEE_EXCEPTIONS

Syntax
result = IEEE_SUPPORT_HALTING(flag)
flag  (Input) Must be of type TYPE (IEEE_FLAG_TYPE). It specifies one of the following IEEE flags:
IEEE_DIVIDE_BY_ZERO, IEEE_INEXACT, IEEE_INVALID,
IEEE_OVERFLOW, or IEEE_UNDERFLOW.

Results
The result is a scalar of type default logical. The result has the value true if the processor supports the ability
to control halting after the exception specified by flag; otherwise, false.

Example
IEEE_SUPPORT_HALTING (IEEE_UNDERFLOW) has the value true if halting is supported after an
IEEE_UNDERFLOW exception

See Also

IEEE_SUPPORT_INF
Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE infinities.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax
result = IEEE_SUPPORT_INF ([x])

x  (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results
The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor
supports IEEE infinities (positive and negative) for all real values; otherwise, false.
If x is specified, the result has the value true if the processor supports IEEE infinities for real variables of the
same kind type parameter as x; otherwise, false.

Example
IEEE_SUPPORT_INF( ) has the value true if IEEE infinities are supported for all real types.

IEEE_SUPPORT_IO
Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE base conversion rounding during formatted I/O.
Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_IO ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports base conversion rounding during formatted input and output for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports base conversion rounding during formatted input and output for real variables of the same kind type parameter as x; otherwise, false.

The base conversion rounding applies to modes IEEE_UP, IEEE_DOWN, IEEE_TO_ZERO, and IEEE_NEAREST.

Example

IEEE_SUPPORT_IO () has the value true if base conversion rounding is supported for all real types during formatted I/O.

Inquiry Module Intrinsic Function (Generic):
Returns whether the processor supports IEEE Not-a-Number feature.

Module
USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_NAN ([x])

x (Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports NaNs for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports NaNs for real variables of the same kind type parameter as x; otherwise, false.

Example

IEEE_SUPPORT_NAN () has the value true if IEEE NaNs are supported for all real types.

IEEE_ARITHMETIC Intrinsic Module
IEEE Intrinsic Modules Quick Reference Tables
IEEE_SUPPORT_ROUNDING

Transformational Module Intrinsic Function (Generic): Returns whether the processor supports IEEE rounding mode.

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_ROUNDING (round_value [, x])

round_value  
(Input) Must be of type TYPE(IEEE_ROUND_TYPE). It specifies one of the following rounding modes:
IEEE_AWAY, IEEE_DOWN, IEEE_NEAREST, IEEE_TO_ZERO, and IEEE_UP.

x  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor supports the rounding mode specified by round_value for all real values; otherwise, false.

If x is specified, the result has the value true if the processor supports the rounding mode specified by round_value for real variables of the same kind type parameter as x; otherwise, false.

Example

IEEE_SUPPORT_ROUNDING (IEEE_DOWN) has the value true if rounding mode IEEE_DOWN is supported for all real types.

IEEE_SUPPORT_SQRT

Inquiry Module Intrinsic Function (Generic): Returns whether the processor supports IEEE SQRT (square root).

Module

USE, INTRINSIC :: IEEE_ARITHMETIC

Syntax

result = IEEE_SUPPORT_SQRT ([x])

x  
(Input; optional) Must be of type REAL; it can be scalar or array valued.

Results

The result is a scalar of type default logical. If x is omitted, the result has the value true if the processor implements SQRT in accord with the IEEE standard for all real values; otherwise, false.
If \( x \) is specified, the result has the value true if the processor implements SQRT in accord with the IEEE standard for real variables of the same kind type parameter as \( x \); otherwise, false.

**Example**

IEEE_SUPPORT_SQRT ( ) has the value true if IEEE SQRT is supported for all real types.

### IEEE_SUPPORT_STANDARD

**Inquiry Module Intrinsic Function (Generic):**

Returns whether the processor supports IEEE features defined in the standard.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

\[
\text{result} = \text{IEEE_SUPPORT_STANDARD} (\left[ x \right])
\]

\( x \) (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. The result has the value true if the results of all the following functions are true (\( x \) can be omitted):

\[
\begin{align*}
\text{IEEE_SUPPORT_DATATYPE}([x]) \\
\text{IEEE_SUPPORT_DENORMAL}([x]) \\
\text{IEEE_SUPPORT_DIVIDE}([x]) \\
\text{IEEE_SUPPORT_FLAG}([flag, x])^1 \\
\text{IEEE_SUPPORT_HALTING}([flag])^1 \\
\text{IEEE_SUPPORT_INF}([x]) \\
\text{IEEE_SUPPORT_NAN}([x]) \\
\text{IEEE_SUPPORT_ROUNDING}([round\_value, x])^2 \\
\text{IEEE_SUPPORT_SQRT}([x])
\end{align*}
\]

^1 "flag" must be a valid value

^2 "round\_value" must be a valid value

Otherwise, the result has the value, false.

**Example**

IEEE_SUPPORT_STANDARD () has the value false if both IEEE and non-IEEE real kinds are supported.

**IEEE_SUPPORT_SUBNORMAL**

*Inquiry Module Intrinsic Function (Generic):* Returns whether the processor supports IEEE subnormal numbers.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_SUPPORT_SUBNORMAL ([x])
```

*x* (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for all real values; otherwise, false.

If *x* is specified, the result has the value true if the processor supports arithmetic operations and assignments with subnormal numbers for real variables of the same kind type parameter as *x*; otherwise, false.

*IEEE_SUPPORT_SUBNORMAL ()* and *IEEE_SUPPORT_SUBNORMAL (0.0_16)* return .TRUE. even though Intel® Fortran’s implementation does not signal when an underflow results in a REAL (16) subnormal value. Intel® Fortran’s implementation does signal when an underflow results in a REAL (16) zero.

**Example**

*IEEE_SUPPORT_SUBNORMAL ()* has the value true if IEEE subnormal numbers are supported for all real types.

**See Also**

IEEE_ARITHMETIC Intrinsic Module

IEEE Intrinsic Modules Quick Reference Tables

**IEEE_SUPPORT_UNDERFLOW_CONTROL**

*Inquiry Module Intrinsic Function (Generic):* Returns whether the processor supports the ability to control the underflow mode.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_SUPPORT_UNDERFLOW_CONTROL ([x])
```

*x* (Input; optional) Must be of type REAL; it can be scalar or array valued.

**Results**

The result is a scalar of type default logical. If *x* is omitted, the result has the value true if the processor supports controlling the underflow mode for all real values; otherwise, false.
If $x$ is specified, the result has the value true if the processor supports controlling the underflow mode for real variables of the same kind type parameter as $x$; otherwise, false.

**Example**

IEEE_SUPPORT_UNDERFLOW_CONTROL() has the value true if controlling the underflow mode is supported for all real types.

**See Also**

### IEEE_UNORDERED

**Elemental Module Intrinsic Function (Generic):**  
Returns whether one or more of the arguments is Not-a-Number (NaN). This is equivalent to the IEEE unordered function.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_UNORDERED (x, y)
```

$x$  
(Input) Must be of type REAL.

$y$  
(Input) Must be of type REAL.

**Results**

The result type is default logical. The result has the value true if $x$ or $y$ is a NaN, or both are NaNs; otherwise, false.

**Example**

IEEE_UNORDERED (0.0, SQRT(-2.0)) has the value true if IEEE_SUPPORT_SQRT(2.0) has the value true.

**See Also**

IEEE_ARITHMETIC Intrinsic Module  
IEEE Intrinsic Modules Quick Reference Tables

### IEEE_VALUE

**Elemental Module Intrinsic Function (Generic):**  
Creates an IEEE value.

**Module**

USE, INTRINSIC :: IEEE_ARITHMETIC

**Syntax**

```fortran
result = IEEE_VALUE (x, class)
```

$x$  
(Input) Must be of type REAL.

$class$  
(Input) Must be of type TYPE (IEEE_CLASS_TYPE). Its value is one of the following:
IEEE_SIGNALING_NAN  |  IEEE_NEGATIVE_NORMAL  
IEEE_QUIET_NAN   |  IEEE_POSITIVE_DENORMAL  
IEEE_POSITIVE_INF |  IEEE_NEGATIVE_DENORMAL  
IEEE_NEGATIVE_INF |  IEEE_POSITIVE_ZERO  
IEEE_POSITIVE_NORMAL |  IEEE_NEGATIVE_ZERO  

Results
The result type and kind are the same as \( x \). The result value is an IEEE value as specified by "class".
When IEEE_VALUE returns a signaling NaN, it is processor dependent whether or not invalid is signaled and processor dependent whether or not the signaling NaN is converted to a quiet NaN.

Example
IEEE_VALUE \((1.0, \text{IEEE\_POSITIVE\_INF})\) has the value +infinity.

IEOR
"Elemental Intrinsic Function (Generic): Performs an exclusive OR on corresponding bits. This function can also be specified as XOR or IXOR."

Syntax
\[
\text{result} = \text{IEOR} \ (i, j)
\]
\( i \)
(Input) Must be of type integer, \text{logical (which is treated as an integer)}, or a binary, octal, or hexadecimal literal constant.

\( j \)
(Input) Must be of type integer or \text{logical}, or a binary, octal, or hexadecimal literal constant.

If both \( i \) and \( j \) are of type \text{integer or logical}, they must have the same kind type parameter. If the kinds of \( i \) and \( j \) do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. \( i \) and \( j \) must not both be binary, octal, or hexadecimal literal constants.

Results
The result is the same as \( i \) if \( i \) is of type \text{integer or logical}; otherwise, the result is the same as \( j \). If either \( i \) or \( j \) is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function \text{INT} to type integer with the kind type parameter of the other.

The result value is derived by combining \( i \) and \( j \) bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>1</th>
<th>1</th>
<th>IEOR ((i, j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIEOR¹</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIIEOR²</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIEOR³</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIEOR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

¹ Or BIXOR
² Or HIEOR, HIXOR, or IIXOR
³ Or JIXOR

**Example**

IEOR (12, 7) has the value 11; binary 1100 exclusive OR with binary 0111 is binary 1011.

The following shows another example:

```fortran
INTEGER I
I = IEOR(240, 90)  ! returns 170
                 ! IEOR (B'11110000', B'1011010') == B'10101010'
```

The following shows an example using alternate option XOR:

```fortran
INTEGER i, j, k
i = 3             ! B'011'
j = 5             ! B'101'
k = XOR(i, j)     ! returns 6 = B'110'
```

Binary, Octal, Hexadecimal, and Hollerith Constants
IAND
IOR
NOT
IALL
IANY
IPARITY

**IERRNO**

**Portability Function:** Returns the number of the last detected error from any routines in the IFPORT module that return error codes.

**Module**

USE IFPORT

**Syntax**

```fortran
result = IERRNO( )
```
Results

The result type is INTEGER(4). The result value is the last error code from any portability routines that return error codes. These error codes are analogous to `errno` on a Linux* or macOS* system. The module `IFPORT.F90` provides parameter definitions for the following `errno` names (typically found in `errno.h` on Linux systems):

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPERM</td>
<td>1</td>
<td>Insufficient permission for operation</td>
</tr>
<tr>
<td>ENOENT</td>
<td>2</td>
<td>No such file or directory</td>
</tr>
<tr>
<td>ESRCH</td>
<td>3</td>
<td>No such process</td>
</tr>
<tr>
<td>EIO</td>
<td>5</td>
<td>I/O error</td>
</tr>
<tr>
<td>E2BIG</td>
<td>7</td>
<td>Argument list too long</td>
</tr>
<tr>
<td>ENOEXEC</td>
<td>8</td>
<td>File is not executable</td>
</tr>
<tr>
<td>ENOMEM</td>
<td>12</td>
<td>Not enough resources</td>
</tr>
<tr>
<td>EACCES</td>
<td>13</td>
<td>Permission denied</td>
</tr>
<tr>
<td>EXDEV</td>
<td>18</td>
<td>Cross-device link</td>
</tr>
<tr>
<td>ENOTDIR</td>
<td>20</td>
<td>Not a directory</td>
</tr>
<tr>
<td>EINVAL</td>
<td>22</td>
<td>Invalid argument</td>
</tr>
</tbody>
</table>

The value returned by IERRNO is updated only when an error occurs. For example, if an error occurs on a GETLOG call and then two CHMOD calls succeed, a subsequent call to IERRNO returns the error for the GETLOG call.

Examine IERRNO immediately after returning from a portability routine. IERRNO is set on a per thread basis.

Example

```
USE IFPORT
CHARACTER*20 username
INTEGER(4) ierrval
ierrval=0 !initialize return value
CALL GETLOG(username)
IF (IERRNO( ) == ierrval) then
   print *, 'User name is ',username
   exit
ELSE
   ierrval = ierrno()
   print *, 'Error is ',ierrval
END IF
```

IF - Arithmetic

**Statement:** Conditionally transfers control to one of three statements, based on the value of an arithmetic expression. The arithmetic IF statement is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.
**Syntax**

IF (expr) label1, label2, label3  

*expr*  
Is a scalar numeric expression of type integer or real (enclosed in parentheses).

*label1, label2, label3*  
Are the labels of valid branch target statements that are in the same scoping unit as the arithmetic IF statement.

**Description**

All three labels are required, but they do not need to refer to three different statements. The same label can appear more than once in the same arithmetic IF statement.

During execution, the expression is evaluated first. Depending on the value of the expression, control is then transferred as follows:

<table>
<thead>
<tr>
<th>If the Value of <em>expr</em> is:</th>
<th>Control Transfers To:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Less than 0</td>
<td>Statement <em>label1</em></td>
</tr>
<tr>
<td>Equal to 0</td>
<td>Statement <em>label2</em></td>
</tr>
<tr>
<td>Greater than 0</td>
<td>Statement <em>label3</em></td>
</tr>
</tbody>
</table>

**Example**

The following example transfers control to statement 50 if the real variable THETA is less than or equal to the real variable CHI. Control passes to statement 100 only if THETA is greater than CHI.

```
IF (THETA-CHI) 50,50,100
```

The following example transfers control to statement 40 if the value of the integer variable NUMBER is even. It transfers control to statement 20 if the value is odd.

```
IF (NUMBER / 2*2 - NUMBER) 20,40,20
```

The following statement transfers control to statement 10 for n < 10, to statement 20 for n = 10, and to statement 30 for n > 10:

```
IF (n-10) 10, 20, 30
```

The following statement transfers control to statement 10 if n <= 10, and to statement 30 for n > 10:

```
IF (n-10) 10, 10, 30
```

SELECT CASE...END SELECT  
Execution Control  
Deleted Language Features in the Fortran Standard

**IF - Logical**

*Statement:* Conditionally executes one statement based on the value of a logical expression. (This statement was called a logical IF statement in FORTRAN 77.)

**Syntax**

IF (expr) stmt
expr

Is a scalar logical expression enclosed in parentheses.

stmt

Is any complete, unlabeled, executable Fortran statement, except for the following:

- A CASE, DO, IF, FORALL, or WHERE construct
- Another IF statement
- The END statement for a program, function, or subroutine

When an IF statement is executed, the logical expression is evaluated first. If the value is true, the statement is executed. If the value is false, the statement is not executed and control transfers to the next statement in the program.

Example

The following examples show valid IF statements:

```fortran
IF (J.GT.4 .OR. J.LT.1) GO TO 250
IF (REF(J,K) .NE. HOLD) REF(J,K) = REF(J,K) * (-1.5D0)
IF (ENDRUN) CALL EXIT
```

The following shows another example:

```fortran
USE IFPORT
INTEGER(4) istat, errget
character(inchar)
real x
istat = getc(inchar)
IF (istat) errget = -1
...
! IF (x .GT. 2.3) call new_subr(x)
...```

See Also

IF Construct
Execution Control

IF Clause

**Parallel Directive Clause:** Specifies a conditional expression. If the expression evaluates to .FALSE., the construct is not executed.

Syntax

```fortran
IF ([directive-name-modifier:] scalar-logical-expression)
```

directive-name-modifier

Names the associated construct that the IF clause applies to. Currently, you can specify one of the following associated constructs (directives): PARALLEL, SIMD, TARGET DATA, TARGET, TARGET UPDATE, TARGET ENTER DATA, TARGET EXIT DATA, TASK, or TASKLOOP.

These directives are only available on Linux* systems: TARGET DATA, TARGET, TARGET UPDATE, TARGET ENTER DATA, TARGET EXIT DATA.

scalar-logical-expression

Must be a scalar logical expression that evaluates to .TRUE. or .FALSE..
At most one IF clause can appear in a non-combined directive. In combined directives, IF clauses with different directive-name-modifiers can occur, at most one for each constituent directive making up the combined directive where IF is allowed.

**Description**

The effect of the IF clause depends on the construct to which it is applied:

- For combined or composite constructs, the IF clause only applies to the semantics of the construct named in the directive-name-modifier if one is specified.
- If no directive-name-modifier is specified for a combined or composite construct then the IF clause applies to all constructs to which an IF clause can apply.

The following are additional rules that apply to specific OpenMP Fortran directives:

- For the CANCEL OpenMP Fortran directive, if scalar-logical-expression evaluates to false, the construct does not request cancellation. Note that directive-name-modifier cannot specify CANCEL.
- For the PARALLEL OpenMP Fortran directive:
  - The enclosed code section is executed in parallel only if scalar-logical-expression evaluates to .TRUE.. Otherwise, the parallel region is serialized. If this clause is not used, the region is executed as if an IF(.TRUE.) clause were specified.
  - This clause is evaluated in the context outside of this construct.
- For the SIMD OpenMP Fortran directive, if scalar-logical-expression evaluates to .FALSE., the number of iterations to be executed concurrently is one.
- For the TARGET OpenMP Fortran directive, if scalar-logical-expression evaluates to .FALSE., the target region is not executed by the device. It is executed by the encountering task.
- For the TARGET DATA OpenMP Fortran directive, if scalar-logical-expression evaluates to .FALSE., the new device data environment is not created.
- For the TARGET UPDATE OpenMP Fortran directive, if scalar-logical-expression evaluates to .FALSE., the TARGET UPDATE directive is ignored.
- For the TASK OpenMP Fortran directive:
  - If scalar-logical-expression evaluates to .FALSE., the encountering thread must suspend the current task region and begin execution of the generated task immediately. The suspended task region will not be resumed until the generated task is completed.
  - This clause is evaluated in the context outside of this construct.

**IF Construct**

**Statement:** Conditionally executes one block of constructs or statements depending on the evaluation of a logical expression. (This construct was called a block IF statement in FORTRAN 77.)

**Syntax**

```fortran
[name:] IF (expr) THEN
    block
[ELSE IF (expr) THEN [name]
    block]
[ELSE [name]
    block]
END IF [name]
```

*name* (Optional) Is the name of the IF construct.
expr

Is a scalar logical expression enclosed in parentheses.

block

Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of an IF THEN statement, the same name must appear in the corresponding END IF statement. If a construct name is specified on an ELSE IF or ELSE statement, the same name must appear in the corresponding IF THEN and END IF statements.

The same construct name must not be used for different named constructs in the same scoping unit.

Depending on the evaluation of the logical expression, one block or no block is executed. The logical expressions are evaluated in the order in which they appear, until a true value is found or an ELSE or END IF statement is encountered.

Once a true value is found or an ELSE statement is encountered, the block immediately following it is executed and the construct execution terminates.

If none of the logical expressions evaluate to true and no ELSE statement appears in the construct, no block in the construct is executed and the construct execution terminates.

NOTE

No additional statement can be placed after the IF THEN statement in a block IF construct. For example, the following statement is invalid in the block IF construct:

```
IF (e) THEN I = J
```

This statement is translated as the following logical IF statement:

```
IF (e) THEN I = J
```

You cannot use branching statements to transfer control to an ELSE IF statement or ELSE statement. However, you can branch to an END IF statement from within the IF construct.

The following figure shows the flow of control in IF constructs:
You can include an IF construct in the statement block of another IF construct, if the nested IF construct is completely contained within a statement block. It cannot overlap statement blocks.
Example

The following example shows the simplest form of an IF construct:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (ABS(ADJU) .GE. 1.0E-6) THEN</td>
</tr>
<tr>
<td>block</td>
<td>TOTERR = TOTERR + ABS(ADJU)</td>
</tr>
<tr>
<td></td>
<td>QUEST = ADJU/FNDVAL</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

This construct conditionally executes the block of statements between the IF THEN and the END IF statements.

The following shows another example:

```plaintext
! Simple block IF:
IF (i .LT. 10) THEN
  ! the next two statements are only executed if i < 10
  j = i
  slice = TAN (angle)
END IF
```

The following example shows a named IF construct:

```plaintext
BLOCK_A: IF (D > 0.0) THEN
  ! Initial statement for named construct
  RADIANS = ACOS(D)                       ! These two statements
  DEGREES = ACOSD(D)                      !       form a block
END IF BLOCK_A                           ! Terminal statement for named construct
```

The following example shows an IF construct containing an ELSE statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (NAME .LT. 'N') THEN</td>
</tr>
<tr>
<td>block1</td>
<td>IFRONT = IFRONT + 1</td>
</tr>
<tr>
<td></td>
<td>FRLET(IFRONT) = NAME(1:2)</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block2</td>
<td>IBACK = IBACK + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

Block1 consists of all the statements between the IF THEN and ELSE statements. Block2 consists of all the statements between the ELSE and the END IF statements.

If the value of the character variable NAME is less than 'N', block1 is executed. If the value of NAME is greater than or equal to 'N', block2 is executed.

The following example shows an IF construct containing an ELSE IF THEN statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .GT. B) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>D = B</td>
</tr>
<tr>
<td></td>
<td>F = A - B</td>
</tr>
<tr>
<td>ELSE IF (expr)</td>
<td>ELSE IF (A .GT. B/2.) THEN</td>
</tr>
<tr>
<td>block2</td>
<td>D = B/2.</td>
</tr>
<tr>
<td></td>
<td>F = A - B/2.</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is greater than B, block1 is executed. If A is not greater than B, but A is greater than B/2, block2 is executed. If A is not greater than B and A is not greater than B/2, neither block1 nor block2 is executed. Control transfers directly to the next executable statement after the END IF statement.
The following shows another example:

```fortran
! Block IF with ELSE IF statements:

IF (j .GT. 1000) THEN
  ! Statements here are executed only if J > 1000
ELSE IF (j .GT. 100) THEN
  ! Statements here are executed only if J > 100 and j <= 1000
ELSE IF (j .GT. 10) THEN
  ! Statements here are executed only if J > 10 and j <= 100
ELSE
  ! Statements here are executed only if j <= 10
END IF
```

The following example shows an IF construct containing several ELSE IF THEN statements and an ELSE statement:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .GT. B) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>D = B</td>
</tr>
<tr>
<td>F = A - B</td>
<td></td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. C) THEN</td>
</tr>
<tr>
<td>block2</td>
<td>D = C</td>
</tr>
<tr>
<td>F = A - C</td>
<td></td>
</tr>
<tr>
<td>ELSE IF (expr) THEN</td>
<td>ELSE IF (A .GT. Z) THEN</td>
</tr>
<tr>
<td>block3</td>
<td>D = Z</td>
</tr>
<tr>
<td>F = A - Z</td>
<td></td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block4</td>
<td>D = 0.0</td>
</tr>
<tr>
<td>F = A</td>
<td></td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is greater than B, block1 is executed. If A is not greater than B but is greater than C, block2 is executed. If A is not greater than B or C but is greater than Z, block3 is executed. If A is not greater than B, C, or Z, block4 is executed.

The following example shows a nested IF construct:

<table>
<thead>
<tr>
<th>Form</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>IF (expr) THEN</td>
<td>IF (A .LT. 100) THEN</td>
</tr>
<tr>
<td>block1</td>
<td>INRAN = INRAN + 1</td>
</tr>
<tr>
<td>IF (expr2) THEN</td>
<td>IF (ABS(A-AVG) .LE. 5.) THEN</td>
</tr>
<tr>
<td>block1a</td>
<td>INAVG = INAVG + 1</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block1b</td>
<td>OUTAVG = OUTAVG + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
<tr>
<td>ELSE</td>
<td>ELSE</td>
</tr>
<tr>
<td>block2</td>
<td>OUTRAN = OUTRAN + 1</td>
</tr>
<tr>
<td>END IF</td>
<td>END IF</td>
</tr>
</tbody>
</table>

If A is less than 100, the code immediately following the IF is executed. This code contains a nested IF construct. If the absolute value of A minus AVG is less than or equal to 5, block1a is executed. If the absolute value of A minus AVG is greater than 5, block1b is executed.

If A is greater than or equal to 100, block2 is executed, and the nested IF construct (in block1) is not executed.

The following shows another example:

```fortran
! Nesting of constructs and use of an ELSE statement following
! a block IF without intervening ELSE IF statements:

IF (i .LT. 100) THEN
```
! Statements here executed only if i < 100
IF (j .LT. 10) THEN
! Statements here executed only if i < 100 and j < 10
END IF
! Statements here executed only if i < 100
ELSE
! Statements here executed only if i >= 100
IF (j .LT. 10) THEN
! Statements here executed only if i >= 100 and j < 10
END IF
! Statements here executed only if i >= 100
END IF

IF - Logical
IF - Arithmetic

IF Directive Construct
General Compiler Directive: A conditional
compilation construct that begins with an IF or IF
DEFINED directive. IF tests whether a logical
expression is .TRUE. or .FALSE.. IF DEFINED tests
whether a symbol has been defined.

Syntax
!DIR$ IF (expr) -or- !DIR$ IF DEFINED (name)

    block
[!DIR$ ELSEIF (expr)
     block] ...
[!DIR$ ELSE
     block]
!DIR$ ENDIF

expr
    Is a logical expression that evaluates to .TRUE. or .FALSE..
name
    Is the name of a symbol to be tested for definition.
block
    Are executable statements that are compiled (or not) depending on
    the value of logical expressions in the IF directive construct.

The IF and IF DEFINED directive constructs end with an ENDIF directive and can contain one or more ELSEIF
directives and at most one ELSE directive. If the logical condition within a directive evaluates to .TRUE. at
compilation, and all preceding conditions in the IF construct evaluate to .FALSE., then the statements
contained in the directive block are compiled.

A name can be defined with a DEFINE directive, and can optionally be assigned an integer value. If the
symbol has been defined, with or without being assigned a value, IF DEFINED (name) evaluates to .TRUE.;
otherwise, it evaluates to .FALSE..

If the logical condition in the IF or IF DEFINED directive is .TRUE., statements within the IF or IF DEFINED
block are compiled. If the condition is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.
If the logical expression in an ELSEIF directive is .TRUE., statements within the ELSEIF block are compiled. If the expression is .FALSE., control transfers to the next ELSEIF or ELSE directive, if any.

If control reaches an ELSE directive because all previous logical conditions in the IF construct evaluated to .FALSE., the statements in an ELSE block are compiled unconditionally.

You can use any Fortran logical or relational operator or symbol in the logical expression of the directive, including: .LT., <, .GT., >, .EQ., ==, .LE., <=, .GE., >=, .NE., /=, .EQV., .NEQV., .NOT., .AND., .OR., and .XOR.. The logical expression can be as complex as you like, but the whole directive must fit on one line.

Example

```fortran
! When the following code is compiled and run,
! the output is:
! Or this compiled if all preceding conditions .FALSE.
!
!DIR$ DEFINE flag=3
!DIR$ IF (flag .LT. 2)
!   WRITE (*,*) "This is compiled if flag less than 2."
!DIR$ ELSEIF (flag >= 8)
!   WRITE (*,*) "Or this compiled if flag greater than &
!   or equal to 8."
!DIR$ ELSE
!   WRITE (*,*) "Or this compiled if all preceding &
!   conditions .FALSE."
!DIR$ ENDIF
END
```

Syntax Rules for Compiler Directives

IF DEFINED Directive

**Statement:** Marks the start of an IF Directive Construct.

See Also
See IF Directive Construct.

IFIX

*Elemental Intrinsic Function (Generic):* Converts a single-precision real argument to an integer by truncating.

See Also
See INT.

IFLOATI, IFLOATJ

*Portability Functions:* Convert an integer to single-precision real type.

Module
USE IFPORT
Syntax
result = IFLOATI (i)
result = IFLOATJ (j)

i  (Input) Must be of type INTEGER(2).
j  (Input) Must be of type INTEGER(4).

Results
The result type is single-precision real (REAL(4) or REAL*4).

See Also
DFLOAT
ILEN

ILEN
_Inquiry Intrinsic Function (Generic): Returns the length (in bits) of the two's complement representation of an integer._

Syntax
result = ILEN (i)
i  Must be of type integer.

Results
The result type and kind are the same as i. The result value is \(\log_2(i+1)\) if i is not negative; otherwise, the result value is \(\log_2(-i)\).

Example
ILEN (4) has the value 3.
ILEN (-4) has the value 2.

IMAGE_INDEX
_Transformational Intrinsic Function (Generic): Converts cosubscripts to an image index._

Syntax
result = IMAGE_INDEX (coarray, sub)
result = IMAGE_INDEX (coarray, sub, team)
result = IMAGE_INDEX (coarray, sub, team_number)

coarray  (Input) Must be a coarray; it can be of any type.
sub  (Input) Must be a rank-one integer array of size equal to the corank of coarray.
team  (Input) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV. Its value must identify the current or an ancestor team.
team_number

(Input) Must be an integer scalar. It must identify the initial team (-1) or a team formed by the same execution of the FORM TEAM statement that created the current team (a sibling team of the current team).

Results

The result is default integer scalar. The result is the index of the corresponding image if the value of sub is a valid sequence of cosubscripts for coarray on the team specified by team or team_number, or for the current team if neither team nor team_number is specified. Otherwise, the result is zero.

Examples

If coarray D is declared as D [0:*] and coarray C is declared as C(5,10) [10, 0:9, 0:*], IMAGE_INDEX (D, [0]) has the value 1 and IMAGE_INDEX (C, [3, 1, 2]) has the value 213 (on any image).

Consider the following program:

```fortran
PROGRAM main
  USE, INTRINSIC :: ISO_FORTRAN_ENV
  TYPE (TEAM_TYPE) :: initial, odd_even
  REAL :: ca1[4:*], ca2[2, *]
  INTEGER :: i, j, k, l
  initial = GET_TEAM (CURRENT_TEAM)
  FORM TEAM (2-MOD(THIS_IMAGE(), 2), odd_even)
  PRINT *, THIS_IMAGE()
  PRINT *, THIS_IMAGE (caarray1)
  PRINT *, THIS_IMAGE (caarray2, 2)
  CHANGE TEAM (odd_even)
  . . .
  i = IMAGE_INDEX(ca1, [6], 2)
  j = IMAGE_INDEX(ca1, [6], 1)
  k = IMAGE_INDEX(ca2, [2, 4], initial)
  l = IMAGE_INDEX(ca1, [12], -1)
  . . .
END TEAM
. . .
END PROGRAM
```

If there are 10 images on the initial team, ca1[4] will be on image 1, ca1[5] on image 2, and ca1[13] will be on image 10. Similarly, ca2[1, 1] will be on image 1, ca2[2, 1] on image 2, ending with ca2[2, 5] will be on image 10. The FORM TEAM statement divides the images into two teams, with team 1 having images [1, 3, 5, 7, 9] with image numbers [1, 2, 3, 4, 5] respectively, and team 2 having images [2, 4, 6, 8, 10] with image numbers [1, 2, 3, 4, 5] respectively.

After the 4 calls to IMAGE_INDEX, the value of i will be zero (ca1[6] is not on an image in team 2), j will have the value 2, k will have the value 8, and l will have the value 9. Note that the team number -1 always refers to the initial team. Note also that if the FORM TEAM does not specify NEW_INDEX, the image numbers on the new teams formed by the FORM TEAM are assigned in a processor-dependent manner.

See Also

FORM TEAM

IMAGE_STATUS

Elemental Intrinsic Function (Generic): Returns the execution status value of the specified image.

Syntax

result = IMAGE_STATUS (image [, , team])
image  (Input) Must be a positive integer with a value equal to or less than the number of executing images on the specified team.

team  (Input; optional) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV whose value represents the current or an ancestor team. If not present, the current team is assumed.

Results
The result type is default integer. If image on the specified team has initiated normal termination, the result is the value STAT_STOPPED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV. If image on the specified team has failed, the result is the value STAT_FAILED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV. Otherwise, the result value is zero.

Example
If image 5 on the specified team has initiated normal termination, and image 12 on the specified team is known to have failed, then IMAGE_STATUS (5) returns the value STAT_STOPPED_IMAGE and IMAGE_STATUS (12) returns the value STAT_FAILED_IMAGE. If image 3 on the specified team has neither initiated normal termination nor failed, IMAGE_STATUS (3) returns the value zero.

IMPLICIT
Statement: Overrides the default implicit typing rules for names. (The default data type is default INTEGER kind for names beginning with the letters I through N, and default REAL kind for names beginning with any other letter.) An IMPLICIT NONE statement overrides all implicit typing in a scoping unit, or it indicates that all dummy procedures and externals must explicitly be given the external attribute.

Syntax
The IMPLICIT statement takes one of the following forms:

IMPLICIT type(a[,a]...)[,type(a[,a]...)]...

IMPLICIT NONE [{spec-list}]

type  Is a data type specifier (CHARACTER*(*) is not allowed).

a  Is a single letter, a dollar sign ($), or a range of letters in alphabetical order. The form for a range of letters is a$_1$-a$_2$, where the second letter follows the first alphabetically (for example, A-C).

spec  Is TYPE or EXTERNAL. The keyword must appear in parentheses. If more than one keyword is present, they must be separated by commas.

The dollar sign can be used at the end of a range of letters, since IMPLICIT interprets the dollar sign to alphabetically follow the letter Z. For example, a range of X-$ would apply to identifiers beginning with the letters X, Y, Z, or $.
In Intel® Fortran, the parentheses around the list of letters are optional.

**Description**

The IMPLICIT statement assigns the specified data type (and kind parameter) to all names that have no explicit data type and begin with the specified letter or range of letters. It has no effect on the default types of intrinsic procedures.

When the data type is CHARACTER*len, len is the length for character type. The len is an unsigned integer constant or an integer specification expression enclosed in parentheses. The range for len is 1 to 2**31-1 on IA-32 architecture; 1 to 2**63-1 on Intel® 64 architecture.

Names beginning with a dollar sign ($) are implicitly INTEGER.

The IMPLICIT NONE statement disables all implicit typing defaults. When IMPLICIT NONE is used, all names in a program unit must be explicitly declared. An IMPLICIT NONE statement must precede any PARAMETER statements, and there must be no other IMPLICIT statements in the scoping unit. An IMPLICIT NONE (TYPE) statement is the same as an IMPLICIT NONE statement. If an IMPLICIT NONE (EXTERNAL) statement appears in a scoping unit, all dummy procedures and external procedures in that scope or a contained scope of BLOCK must have an accessible explicit interface or be declared EXTERNAL.

**NOTE**

To receive diagnostic messages when variables are used but not declared, you can specify compiler option `warn declarations` instead of using IMPLICIT NONE or IMPLICIT NONE (TYPE). To receive diagnostic messages when external and dummy procedures have not explicitly been given the EXTERNAL attribute, you can specify compiler option `warn externals` instead of using IMPLICIT NONE (EXTERNAL).

The following IMPLICIT statement represents the default typing as specified by the Fortran Standard for names when they are not explicitly typed:

```
IMPLICIT INTEGER (I-N), REAL (A-H, O-Z)
```

**Example**

The following are examples of the IMPLICIT statement:

```
IMPLICIT DOUBLE PRECISION (D) IMPLICIT COMPLEX (S,Y), LOGICAL(1) (L,A-C)
IMPLICIT CHARACTER*32 (T-V)
IMPLICIT CHARACTER*2 (W)
IMPLICIT TYPE(COLORS) (E-F), INTEGER (G-H)
IMPLICIT NONE (EXTERNALS, TYPE) ! Must be the only IMPLICIT statement in a scoping unit
```

The following shows another example:

```
SUBROUTINE FF (J)
IMPLICIT INTEGER (a-b), CHARACTER*(J+1) (n), TYPE(fried) (c-d)
TYPE fried
INTEGER e, f
REAL g, h
END TYPE
age = 10 ! integer
name = 'Paul' ! character
c%e = 1 ! type fried, integer component
```

warn externals compiler option
**IMPORT**

**Statement:** Controls accessibility of host entities in a submodule, module procedure, a contained procedure, a block construct, or in the interface body of an interface block.

**Syntax**

The IMPORT statement takes the following form:

```plaintext
IMPORT [[::] import-name-list]
IMPORT,ONLY: import-name-list
IMPORT,NONE
IMPORT,ALL
```

- `import-name-list` *(Input)* Is the name of one or more entities accessible in the host scoping unit.

An IMPORT statement can appear in a submodule, module procedure, a contained procedure, the specification part of a BLOCK construct, or in an interface body. It can not appear in the specification part of a main program, external procedure, module, or block data except in an interface body.

An IMPORT statement must appear after any USE statements, and before any other specification statements. Each of the named entities must be an accessible entity in the host scoping unit. Within an interface body each named entity must be explicitly declared before the interface body, or accessible by use or host association in the host containing the IMPORT statement.

If IMPORT, ONLY appears within a scoping unit, all other IMPORT statements in that scoping unit must be IMPORT, ONLY statements. An entity is host associated in a scoping unit which contains an IMPORT, ONLY statement if it appears in an `import-name-list` in that scoping unit.

If IMPORT, NONE is specified, no entities in the host are accessible by host association in that scoping unit. This is the default behavior for interface bodies for a dummy or external procedure. IMPORT, NONE must not appear in the specification part of a submodule.

If an IMPORT, ALL or an IMPORT, NONE statement appears in a scoping unit, it must be the only IMPORT statement in that scoping unit.

If `import-name-list` is not specified, and if ALL, ONLY, or NONE are not specified, all of the accessible named entities in the host scoping unit are imported unless they are made inaccessible by an entity of the same name in the local scope. This is the default behavior for a nested scoping unit, other than an interface body, for a dummy or external procedure.

If IMPORT, ALL is specified, all entities in the host are accessible by host association. If an entity is made accessible by an IMPORT, ALL statement or by its name appearing in an `import-name-list`, it cannot be made inaccessible by declaring another entity with the same name in the local scope.

If an IMPORT statement with an `import-name-list` appears, only the named entities are available by host association.

**Examples**

The following examples show how the IMPORT statement can be applied.

```plaintext
module mymod
type mytype
  integer comp
end type mytype
interface
```
subroutine sub (arg)
    import
    type(mytype) :: arg
end subroutine
end interface
end module mymod

module host
    integer :: i, j, k
contains
    subroutine sub1 ()
        import :: i, j
        k = i + j      ! only i and j are host associated, k is local to sub1
    end subroutine
    subroutine sub2 ()
        import, none
        k = i + j      ! i, j, and k are local to sub2
    end subroutine
    subroutine sub3 ()
        import all
        k = i + j      ! i, j, and k are all host associated
    end subroutine
    subroutine sub4 ()
        import, only : i
        import, only : j
        k = i + j      ! i and j are host associated, k is local
    end subroutine
end module

**IMPURE**

*Keyword:* Asserts that a user-defined procedure has side effects.

**Description**

This kind of procedure is specified by using the prefix IMPURE in a FUNCTION or SUBROUTINE statement. By default all user-defined procedures are impure, that is, they are allowed to have side effects, except for elemental procedures.

An IMPURE elemental procedure has the restrictions that apply to elemental procedures, but it does not have any of the restrictions of PURE elemental procedures.

An impure elemental procedure can have side effects and it can contain the following:

- Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit number or *)
- A PAUSE statement
- A STOP statement or an ERROR STOP statement
- An image control statement

An impure elemental procedure cannot be referenced in a context that requires a procedure to be pure; for example:

- It cannot be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
- It cannot be called from a pure procedure. Pure procedures can only call other pure procedures, including one referenced by means of a defined operator, defined assignment, or finalization.
- It cannot be passed as an actual argument to a pure procedure.
Example

```fortran
module my_rand_mod
  integer, save :: my_rand_seed (8)
  contains
  impure elemental subroutine my_rand (r)
    ! my_rand updates module variable my_rand_seed (an array)
    ! and returns the next value of a "pseudo" random sequence in
    ! output dummy argument r
    real, intent(out) :: r
    ! code goes here
  end subroutine my_rand
end module my_rand_mod
```

FUNCTION
SUBROUTINE

IN_REDUCTION

*Specifies that a task participates in a reduction. The IN_REDUCTION clause is a reduction participating clause.*

Syntax

```
IN_REDUCTION (reduction-identifier : list)
```

Arguments `reduction-identifier` and `list` are defined in the REDUCTION clause description. All the common restrictions for the REDUCTION clause apply to the IN_REDUCTION clause.

A `list` item that appears in an IN_REDUCTION clause must appear in a TASK_REDUCTION clause or a REDUCTION clause with the TASK reduction modifier. The construct associated with the innermost region that meets this condition must specify the same `reduction-identifier` as the IN_REDUCTION clause.

If the IN_REDUCTION clause appears in a TARGET construct, the target task becomes the task participating in the reduction. A private copy of each `list` item is created in the data environment of the target task. The copy is implicitly mapped into the data environment of the target device if the target device is not the parent device.

If the IN_REDUCTION clause is associated with a TASK construct, the generated task is the participating task, and a private copy of each `list` item may be created.

At the end of the region, the value of private copies of `list` items are combined with the value of a private copy created by a reduction scoping clause, and finally with the original `list` item.

The `list` items specified in an IN_REDUCTION clause must match the `list` items that appear in a TASK_REDUCTION clause or in a REDUCTION clause with the TASK reduction modifier. The construct specifying the TASK_REDUCTION or REDUCTION clause corresponds to a region in which the participating task's region is closely nested. The innermost enclosing construct that meets this condition must also specify the same `reduction-identifier` specified in the IN_REDUCTION clause.
In the following example, the IN_REDUCTION clause at (3) must name the same operator (+) and variable (a) as in the TASK_REDUCTION clause in (2). The IN_REDUCTION clause at (4) must name the same operator (*) and variable (a) as in the TASK_REDUCTION clause in (1).

```
!$omp taskgroup task_reduction(*:a)       ! (1) *:a
...                                        
!$omp taskgroup task_reduction(+:a)       ! (2) +:a
!$omp task in_reduction(+:a)              ! (3) +:a matches (2)
    a = a + x
!$omp end task                            ! ends (3) +:a
...                                        
!$omp end taskgroup                       ! ends (2) +:a
...
!$omp task in_reduction(*:a)              ! (4) *:a matches (1)
    a = a * y
!$omp end task                            ! ends (4) *:a
!$omp end taskgroup                       ! ends (1) *:a
```

TASK
TASKLOOP

INCLUDE

**Statement:** Directs the compiler to stop reading
statements from the current file and read statements
in an included file or text module.

**Syntax**

The INCLUDE line takes the following form:

```
INCLUDE 'filename/[NO]LIST'
```

*filename*  
Is a character string specifying the name of the file to be included; it must not be a named constant.

The form of the file name must be acceptable to the operating system, as described in your system documentation.

*[NO]LIST*  
Specifies whether the incorporated code is to appear in the compilation source listing. In the listing, a number precedes each incorporated statement. The number indicates the "include" nesting depth of the code. The default is /NOLIST. /LIST and /NOLIST must be spelled completely.

You can only use /[NO]LIST if you specify compiler option vms (which sets OpenVMS defaults).

**Description**

An INCLUDE line can appear anywhere within a scoping unit. The line can span more than one source line, but no other statement can appear on the same line. The source line cannot be labeled.

An included file or text module cannot begin with a continuation line, and each Fortran statement must be completely contained within a single file.
An included file or text module can contain any source text, but it cannot begin or end with an incomplete Fortran statement.

The included statements, when combined with the other statements in the compilation, must satisfy the statement-ordering restrictions shown in Statements.

Included files or text modules can contain additional INCLUDE lines, but they must not be recursive. INCLUDE lines can be nested until system resources are exhausted.

When the included file or text module completes execution, compilation resumes with the statement following the INCLUDE line.

You can use modules instead of include files to achieve encapsulation of related data types and procedures. For example, one module can contain derived type definitions as well as special operators and procedures that apply to those types. For information on how to use modules, see Program Units and Procedures.

**Example**

In the following example, a file named COMMON.FOR (in the current working directory) is included and read as input.

**Including Text from a File**

<table>
<thead>
<tr>
<th>Main Program File</th>
<th>COMMON.FOR File</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROGRAM</td>
<td>INTEGER, PARAMETER :: M=100</td>
</tr>
<tr>
<td>REAL, DIMENSION(M) :: Z</td>
<td>REAL, DIMENSION(M) :: X, Y</td>
</tr>
<tr>
<td>CALL CUBE</td>
<td>COMMON X, Y</td>
</tr>
<tr>
<td>DO I = 1, M</td>
<td></td>
</tr>
<tr>
<td>Z(I) = X(I) + SQRT(Y(I))</td>
<td>...</td>
</tr>
<tr>
<td>END DO</td>
<td></td>
</tr>
<tr>
<td>END</td>
<td></td>
</tr>
<tr>
<td>SUBROUTINE CUBE</td>
<td></td>
</tr>
<tr>
<td>INCLUDE 'COMMON.FOR'</td>
<td></td>
</tr>
<tr>
<td>DO I=1,M</td>
<td></td>
</tr>
<tr>
<td>X(I) = Y(I)**3</td>
<td></td>
</tr>
<tr>
<td>END DO</td>
<td>RETURN</td>
</tr>
<tr>
<td>END</td>
<td></td>
</tr>
</tbody>
</table>

The file COMMON.FOR defines a named constant M, and defines arrays X and Y as part of blank common.

The following example program declares its common data in an include file. The contents of the file INCLUDE.INC are inserted in the source code in place of every INCLUDE 'INCLUDE.INC' line. This guarantees that all references to common storage variables are consistent.

| INTEGER i |
| REAL x   |
| INCLUDE 'INCLUDE.INC' |

| DO i = 1, 5 |
| READ (*, '(F10.5)') x |
| CALL Push (x) |
| END DO      |

**See Also**

MODULE
INDEX

Elemental Intrinsic Function (Generic): Returns the starting position of a substring within a string.

Syntax

\[
\text{result} = \text{INDEX} \left( \text{string}, \text{substring} [, \text{back}] [, \text{kind}] \right)
\]

- `string` (Input) Must be of type character.
- `substring` (Input) Must be of type character.
- `back` (Input; optional) Must be of type logical.
- `kind` (Input; optional) Must be a scalar integer constant expression.

Results

The result is of type integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If `back` does not appear (or appears with the value false), the value returned is the minimum value of \( I \) such that \( \text{string}(I : I + \text{LEN} \left( \text{substring} \right) - 1) = \text{substring} \) (or zero if there is no such value). If \( \text{LEN} \left( \text{string} \right) < \text{LEN} \left( \text{substring} \right) \), zero is returned. If \( \text{LEN} \left( \text{substring} \right) = 0 \), 1 is returned.

If `back` appears with the value true, the value returned is the maximum value of \( I \) such that \( \text{string}(I : I + \text{LEN} \left( \text{substring} \right) - 1) = \text{substring} \) (or zero if there is no such value). If \( \text{LEN} \left( \text{string} \right) < \text{LEN} \left( \text{substring} \right) \), zero is returned. If \( \text{LEN} \left( \text{substring} \right) = 0 \), \( \text{LEN} \left( \text{string} \right) + 1 \) is returned.

Specific Name | Argument Type | Result Type
--- | --- | ---
INDEX ¹ | CHARACTER | INTEGER(1)
INDEX ¹ | CHARACTER | INTEGER(2)
INDEX ¹ | CHARACTER | INTEGER(4)
INDEX ¹ | CHARACTER | INTEGER(8)

¹The setting of compiler options specifying integer size can affect this function.

Example

INDEX ('FORTRAN', 'O', BACK = .TRUE.) has the value 2.
INDEX ('XXXX', ' ', BACK = .TRUE.) has the value 5.

The following shows another example:

\[
\begin{align*}
\text{I} &= \text{INDEX}('banana', 'an', \text{BACK} = .\text{TRUE}.) \text{ ! returns 4} \\
\text{I} &= \text{INDEX}('banana', 'an') \text{ ! returns 2}
\end{align*}
\]

See Also

SCAN
INLINE, FORCEINLINE, and NOINLINE

General Compiler Directives: Tell the compiler to perform the specified inlining on routines within statements or DO loops.

Syntax

!DIR$ INLINE [RECURSIVE]
!DIR$ FORCEINLINE [RECURSIVE]
!DIR$ NOINLINE

The INLINE directive specifies that the routines can be inlined.

The FORCEINLINE directive specifies that a routine should be inlined whenever the compiler can do so. This condition can also be specified by using compiler option [Q]inline-forceinline.

The NOINLINE directive specifies that a routine should not be inlined.

These directives apply only to the immediately following statement or DO construct. All statements within the immediately following DO construct are affected.

If keyword RECURSIVE is specified, the specified inlining is performed when the routine calls itself directly or indirectly.

The inlining can be ignored by the compiler if inline heuristics determine it may have a negative impact on performance or will cause too much of an increase in code size.

Caution

When you use directive FORCEINLINE, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

Example

Consider the following:

!DIR$ INLINE
A = F(B) + G(C)  ! inline the call to function F and inline the call to function G

!DIR$ INLINE
DO I = 1, N
   CALL F1 ( G1(A), G2(A)) ! inline the call to F1 and the function executions of G1 and G2
!DIR$ NOINLINE
   DO J = 1, M
      M(J) = F (M(J))  ! do not inline this call to F {M is a data array}
   END DO
M(I) = F2 (X) ! F2 gets inlined from the directive before DO I

!DIR$ FORCEINLINE RECURSIVE
CALL F3 ()  ! F3 must be inlined and it calls itself recursively so inline those calls too
END DO

\texttt{INQUIRE ([UNIT=\textit{io-unit} [, ERR=\textit{label} [, ID=\textit{id-var} [, IOMSG=\textit{msg-var} [, SIZE=\textit{sz} [, IOSTAT=\textit{i-var}]]]]]) list)}

\textbf{Inquiring by Directory:}

\texttt{INQUIRE (DIRECTORY=\textit{dir}, EXIST=\textit{ex} [, DIRSPEC=\textit{dirspec} [, ERR=\textit{label} [, ID=\textit{id-var} [, IOMSG=\textit{msg-var} [, SIZE=\textit{sz} [, IOSTAT=\textit{i-var}]]]]) list)}

\textbf{Inquiring by Output List:}

\texttt{INQUIRE (IOLENGTH=\textit{len}) out-item-list}

\texttt{name} Is a scalar default character expression specifying the name of the file for inquiry. For more information, see \texttt{FILE Specifier} and \texttt{STATUS Specifier}.

\texttt{label} Is the label of the branch target statement that receives control if an error occurs. For more information, see \texttt{Branch Specifiers}.

\texttt{id-var} Is a scalar integer expression identifying a data transfer operation that was returned using the \texttt{ID=} specifier in a previous asynchronous \texttt{READ} or \texttt{WRITE} statement. For more information, see \texttt{ID Specifier}.

\texttt{msg-var} Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see \texttt{I/O Message Specifier}.
**sz**

Is a scalar integer variable that is assigned the size of the file in file storage units. For more information, see Size Specifier.

**i-var**

Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs. For more information, see I/O Status Specifier.

**def**

Is a scalar default character expression specifying a default file pathname string. (For more information, see the DEFAULTFILE specifier.)

**slist**

Is one or more of the following inquiry specifiers (each specifier can appear only once):

<table>
<thead>
<tr>
<th>Access</th>
<th>Delim</th>
<th>Nextrec</th>
<th>Recl</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Direct</td>
<td>Number</td>
<td>Recordtype</td>

</tr>
<tr>
<td>Decimal</td>
<td>Named</td>
<td>Readwrite</td>
<td></td>
</tr>
</tbody>
</table>

**io-unit**

Is an external unit specifier.

The unit does not have to exist, nor does it need to be connected to a file. If the unit is connected to a file, the inquiry encompasses both the connection and the file.

**dir**

Is a scalar default character expression specifying the name of the directory for inquiry. If you are inquiring by directory, it must be present.

**ex**

Is a scalar default logical variable that is assigned the value .TRUE. if *dir* names a directory that exists; otherwise, *ex* is assigned the value .FALSE.. If you are inquiring by directory, it must be present. For more information, see the EXIST Specifier.

**dirspected**

Is a scalar default character variable that is assigned the value of the full directory specification of *dir* if *ex* is assigned the value .TRUE.. This specifier can only be used when inquiring by directory.

**len**

(Output) Is a scalar integer variable that is assigned a value corresponding to the length of an unformatted, direct-access record resulting from the use of the *out-item-list* in a WRITE statement.
The value is suitable to use as a RECL specifier value in an OPEN statement that connects a file for unformatted, direct access. The unit of the value is 4-byte longwords, by default. However, if you specify compiler option assume byterecl, the unit is bytes.

(out-item-list)

(Output) Is a list of one or more output items (see I/O Lists).

Description

The control specifiers ([UNIT=] io-unit, ERR= label, and IOSTAT= i-var) and inquiry specifiers can appear anywhere within the parentheses following INQUIRE. However, if the UNIT keyword is omitted, the io-unit must appear first in the list.

An INQUIRE statement can be executed before, during, or after a file is connected to a unit. The specifier values returned are those that are current when the INQUIRE statement executes.

To get file characteristics, specify the INQUIRE statement after opening the file.

Example

The following are examples of INQUIRE statements:

```
INQUIRE (FILE='FILE_B', EXIST=EXT)
INQUIRE (4, FORM=FM, IOSTAT=IOS, ERR=20)
INQUIRE (IOLENGTH=LEN) A, B
```

In the last statement, you can use the length returned in LEN as the value for the RECL specifier in an OPEN statement that connects a file for unformatted direct access. If you have already specified a value for RECL, you can check LEN to verify that A and B are less than or equal to the record length you specified.

The following shows another example:

```fortran
! This program prompts for the name of a data file.
! The INQUIRE statement then determines whether
! the file exists. If it does not, the program
! prompts for another file name.

CHARACTER*12 fname
LOGICAL exists

! Get the name of a file:
100  WRITE (*, '(1X, A)') 'Enter the file name: '
    READ (*, '(A)') fname

! INQUIRE about file's existence:
INQUIRE (FILE = fname, EXIST = exists)

IF (.NOT. exists) THEN
   WRITE (*, '(2A)') ' >> Cannot find file ', fname
   GOTO 100
END IF
END
```

INT

Elemental Intrinsic Function (Generic): Converts a value to integer type.

Syntax

\[
\text{result} = \text{INT} \ (a[, \text{kind}])
\]

- \(a\) (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
- \(\text{kind}\) (Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If \(\text{kind}\) is present, the kind parameter of the result is that specified by \(\text{kind}\); otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of \(a\) as follows:

- If \(a\) is of type integer, \(\text{INT}(a) = a\).
- If \(a\) is of type real and \(|a| < 1\), \(\text{INT}(a)\) has the value zero.
- If \(a\) is of type real and \(|a| \geq 1\), \(\text{INT}(a)\) is the integer whose magnitude is the largest integer that does not exceed the magnitude of \(a\) and whose sign is the same as the sign of \(a\).
- If \(a\) is of type complex, \(\text{INT}(a)\) is the value obtained by applying the preceding rules (for a real argument) to the real part of \(a\).
- If \(a\) is a binary, octal, or hexadecimal literal constant, the value of the result is the value whose bit sequence according to the model in Bit Model is the same as that of \(a\) as modified by padding or truncation according to the following:
  - If the length of the sequence of bits specified by \(a\) is less than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were extended to a length equal to the size in bits of the result by padding on the left with zero bits.
  - If the length of the sequence of bits specified by \(a\) is greater than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were truncated from the left to a length equal to the size in bits of the result.

<sup>1</sup>These specific functions cannot be passed as actual arguments.

<sup>2</sup>This function can also be specified as HFIX.

<sup>3</sup>The setting of compiler options specifying integer size or real size can affect IFIX.

<sup>4</sup>For compatibility with older versions of Fortran, IFIX is treated as a generic function.

<sup>5</sup>Or JINT.

<sup>6</sup>The setting of compiler options specifying integer size can affect INT, IDINT, and IQINT.

<sup>7</sup>Or JIFIX.

<sup>8</sup>Or JIDINT. For compatibility with older versions of Fortran, IDINT can also be specified as a generic function.

<sup>9</sup>Or JIQINT. For compatibility with older versions of Fortran, IQINT can also be specified as a generic function.

<sup>10</sup>For compatibility, these functions can also be specified as generic functions.

If the argument is a binary, octal, or hexadecimal constant, the result is affected by the `assume old-boz` option. The default option setting, `noold-boz`, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting `old-boz` is specified, the argument is treated as a signed integer and the bits are converted.

**Example**

INT (-4.2) has the value -4.

INT (7.8) has the value 7.

**See Also**

Binary, Octal, Hexadecimal, and Hollerith Constants

NINT

AINT

ANINT

REAL

DBLE

SNGL
INTC

**Portability Function:** Converts an INTEGER(4) argument to INTEGER(2) type.

**Module**

USE IFPORT

**Syntax**

```fortran
result = INTC(i)
```

**i** (Input) INTEGER(4). A value or expression.

**Results**

The result type is INTEGER(2). The result is the value of i with type INTEGER(2). Overflow is ignored.

**INT_PTR_KIND**

**Inquiry Intrinsic Function (Specific):** Returns the INTEGER KIND that will hold an address. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

**Syntax**

```fortran
result = INT_PTR_KIND()
```

**Results**

The result type is default integer. The result is a scalar with the value equal to the value of the kind parameter of the integer data type that can represent an address on the targeted platform.

The result value is 4 on IA-32 target architecture; 8 on Intel® 64 architecture.

**Example**

```fortran
REAL A(100)
POINTER (P, A)
INTEGER (KIND=INT_PTR_KIND()) SAVE_P
P = MALLOC (400)
SAVE_P = P
```

**INTEGER Statement**

**Statement:** Specifies the INTEGER data type.

**Syntax**

```fortran
INTEGER
.INTEGER([KIND=] n)
```

If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:
• If the integer constant is within the default integer kind range, the kind is default integer.
• If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind which holds the constant.

The default kind can also be changed by using the INTEGER directive or compiler options specifying integer size.

Example

! Entity-oriented declarations:
INTEGER, DIMENSION(:), POINTER :: days, hours
INTEGER (2) :: k=4
INTEGER (2), PARAMETER :: limit=12

! Attribute-oriented declarations:
INTEGER days, hours
INTEGER (2):: k=4, limit
DIMENSION days(:), hours(:)
POINTER days, hours
PARAMETER (limit=12)

See Also
INTEGER Directive
Integer Data Types
Integer Constants

INTEGER Directive

**General Compiler Directive:** Specifies the default integer kind.

**Syntax**

```
!DIR$ INTEGER:{ 2 | 4 | 8 }
```

The INTEGER directive specifies a size of 2 (KIND=2), 4 (KIND=4), or 8 (KIND=8) bytes for default integer numbers.

When the INTEGER directive is in effect, all default integer variables are of the kind specified. Only numbers specified or implied as INTEGER without KIND are affected.

The INTEGER directive can only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module or a block data program unit. INTEGER cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.

The default logical kind is the same as the default integer kind. So, when you change the default integer kind you also change the default logical kind.

**Example**

```plaintext
INTEGER i            ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2( )
WRITE(*,*) KIND(i)   ! still a 4-byte integer
                   ! not affected by setting in subroutine
END

SUBROUTINE INTEGER2( )
!DIR$ INTEGER:2
```
INTEGER j          ! a 2-byte integer
WRITE(*,*) KIND(j)
END SUBROUTINE

**INTENT**

**Statement and Attribute:** Specifies the intended use of one or more dummy arguments.

**Syntax**

The INTENT attribute can be specified in a type declaration statement or an INTENT statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls,] INTENT (intent-spec) [, att-ls] :: d-arg[, d-arg]...
```

**Statement:**

```
INTENT (intent-spec) [:] d-arg[, d-arg] ...
```

- **type**
  - Is a data type specifier.

- **att-ls**
  - Is an optional list of attribute specifiers.

- **intent-spec**
  - Is one of the following specifiers:

  **IN**
  
  Specifies that the dummy argument will be used only to provide data to the procedure. The dummy argument must not be redefined (or become undefined) during execution of the procedure.

  **OUT**

  Specifies that the dummy argument will be used to pass data from the procedure back to the calling program. The dummy argument is undefined on entry, although it may have subcomponents that are initialized by default. An undefined argument must be defined before it is referenced in the procedure.

  Any associated actual argument must be definable.

  **INOUT**

  Specifies that the dummy argument can both provide data to the procedure and return data to the calling program.
Any associated actual argument must be definable.

d-arg

Is the name of a dummy argument or dummy pointer. It cannot be a dummy procedure.

Description

The INTENT statement can only appear in the specification part of a subprogram or interface body.

If no INTENT attribute is specified for a dummy argument, its use is subject to the limitations of the associated actual argument.

If a function specifies a defined operator, the dummy arguments must have intent IN.

If a subroutine specifies defined assignment, the first argument must have intent OUT or INOUT, and the second argument must have intent IN or the VALUE attribute, or both IN and the VALUE attribute.

An entity with the INTENT (OUT) attribute must not be an allocatable coarray or have a subobject that is an allocatable coarray. It must not be of, or have a subcomponent of, type EVENT_TYPE or type LOCK_TYPE from the ISO_FORTRAN_ENV module.

A non-pointer dummy argument with intent IN (or a subobject of such a dummy argument) must not appear as any of the following:

- A DO variable
- The variable of an assignment statement
- The pointer-object of a pointer assignment statement
- An object or STAT variable in an ALLOCATE or DEALLOCATE statement
- An input item in a READ statement
- A variable name in a NAMELIST statement if the namelist group name appears in a NML specifier in a READ statement
- An internal file unit in a WRITE statement
- A definable variable in an INQUIRE statement
- An IOSTAT or SIZE specifier in an I/O statement
- An actual argument in a reference to a procedure with an explicit interface if the associated dummy argument has intent OUT or INOUT

INTENT on a pointer dummy argument refers to the pointer association status of the pointer and has no effect on the value of the target of the pointer.

A pointer dummy argument with intent IN (or a subobject of such a pointer argument) must not appear as any of the following:

- A pointer-object in a NULLIFY statement
- A pointer-object in a pointer assignment statement
- An object in an ALLOCATE or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

A pointer dummy argument with INTENT(IN) can be argument associated with a non-pointer actual argument with the TARGET attribute. During the execution of the procedure, it is pointer associated with the actual argument.

If an actual argument is an array section with a vector subscript, it cannot be associated with a dummy array that is defined or redefined (has intent OUT or INOUT).

On entry to a routine, given an INTENT(OUT) dummy argument:

- If it is a pointer, it should be deallocated.
• If it is an allocatable, all of its allocatable subcomponents should be deallocated, and then it should also be deallocated.
• If it is a non-pointer, non-allocatable, all its allocatable subcomponents should be deallocated, and then default initialization should be applied, as specified by the program.

**Example**

The following example shows type declaration statements specifying the INTENT attribute:

```fortran
SUBROUTINE TEST(I, J)
    INTEGER, INTENT(IN) :: I
    INTEGER, INTENT(OUT), DIMENSION(I) :: J
END SUBROUTINE
```

The following are examples of the INTENT statement:

```fortran
SUBROUTINE TEST(A, B, X)
    INTENT(INOUT) :: A, B
...
```

```fortran
SUBROUTINE CHANGE(FROM, TO)
    USE EMPLOYEE_MODULE
    TYPE(EMPLOYEE) FROM, TO
    INTENT(IN) FROM
    INTENT(OUT) TO
...
```

The following shows another example:

```fortran
SUBROUTINE AVERAGE(value, data1, cube_ave)
    TYPE DATA
    INTEGER count
    REAL avg
    END TYPE
    TYPE(DATA) data1
    REAL tmp
    ! value cannot be changed, while cube_ave must be defined
    ! before it can be used. Data1 is defined when the procedure is
    ! invoked, and becomes redefined in the subroutine.
    INTENT(IN)::value; INTENT(OUT)::cube_ave
    INTENT(INOUT)::data1
    ! count number of times AVERAGE has been called on the data set
    ! being passed.
    tmp = data1%count*data1%avg + value
    data1%count = data1%count + 1
    data1%avg = tmp/data1%count
    cube_ave = data1%avg**3
END SUBROUTINE
```

INTERFACE

Statement: Defines an explicit interface for an external or dummy procedure. It can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines.

Syntax

INTERFACE [generic-spec]
    [interface-body]...
    [[MODULE]PROCEDURE [::]name-list]...
END INTERFACE [generic-spec]

(generic-spec) Is one of the following:

- A generic name
  For information on generic names, see Defining Generic Names for Procedures.
- OPERATOR ( op)
  Defines a generic operator ( op). It can be a defined unary, defined binary, or extended intrinsic operator. For information on defined operators, see Defining Generic Operators.
- ASSIGNMENT (=)
  Defines generic assignment. For information on defined assignment, see Defining Generic Assignment.

(interface-body) Is one or more function or subroutine subprograms or a procedure pointer. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.

The subprogram must not contain a statement function or a DATA, ENTRY, or FORMAT statement; an entry name can be used as a procedure name.

The subprogram can contain a USE statement. It can also contain the prefix MODULE before FUNCTION or SUBROUTINE to indicate a separate module procedure.

(name-list) Is the name of one or more nonintrinsic procedures that are accessible in the host. The MODULE keyword is only allowed if the interface block specifies a generic-spec and has a host that is a module, or accesses a module by use association.

The characteristics of module procedures or internal procedures are not given in interface blocks, but are assumed from the module subprogram definitions or the USE associated interfaces.

Description

Interface blocks can appear in the specification part of the program unit that invokes the external or dummy procedure.

A generic-spec can only appear in the END INTERFACE statement if one appears in the INTERFACE statement; they must be identical.
The characteristics specified for the external or dummy procedure must be consistent with those specified in
the procedure's definition.

An interface block must not appear in a block data program unit.

An interface block comprises its own scoping unit, and does not inherit anything from its host through host
association.

Internal, module, and intrinsic procedures are all considered to have explicit interfaces. External procedures
have implicit interfaces by default; when you specify an interface block for them, their interface becomes
explicit. A procedure must not have more than one explicit interface in a given scoping unit. This means that
you cannot include internal, module, or intrinsic procedures in an interface block, unless you want to define a
generic name for them.

The function or subroutine named in the interface-body cannot have the same name as a keyword that
specifies an intrinsic type.

A interface block containing \textit{generic-spec} specifies a generic interface for the following procedures:

- The procedures within the interface block
  
  Any generic name, defined operator, or equals symbol that appears is a generic identifier for all the
  procedures in the interface block. For the rules on how any two procedures with the same generic
  identifier must differ, see \textit{Unambiguous Generic Procedure References}.
  
- The module procedures listed in the \textit{MODULE PROCEDURE} statement
  
  The module procedures must be accessible by a \textit{USE} statement.

To make an interface block available to multiple program units (through a \textit{USE} statement), place the
interface block in a module.

The following rules apply to interface blocks containing pure procedures:

- The interface specification of a pure procedure must declare the\textit{INTENT} of all dummy arguments except
  pointer and procedure arguments.
  
- A procedure that is declared pure in its definition can also be declared pure in an interface block. However,
  if it is not declared pure in its definition, it must not be declared pure in an interface block.

\textbf{Example}

The following example shows a simple procedure interface block with no generic specification:

```fortran
SUBROUTINE SUB_B (B, FB)
  REAL B
  ...
  INTERFACE
    FUNCTION FB (GN)
      REAL FB, GN
    END FUNCTION
  END INTERFACE
END SUBROUTINE SUB_B
```

The following shows another example:

```fortran
!An interface to an external subroutine \textit{SUB1} with header:
!SUBROUTINE SUB1(I1,I2,R1,R2)
!INTEGER I1,I2
!REAL R1,R2
INTERFACE
  SUBROUTINE SUB1(int1,int2,real1,real2)
    INTEGER int1,int2
    REAL real1,real2
  END SUBROUTINE SUB1
END INTERFACE
```
INTERFACE TO

**Statement:** Identifies a subprogram and its actual arguments before it is referenced or called.

**Syntax**

```
INTERFACE TO subprogram-stmt
    [formal-declarations]
END
```

**subprogram-stmt**

Is a function or subroutine declaration statement.

**formal-declarations**

(Optional) Are type declaration statements (including optional attributes) for the arguments.

The INTERFACE TO block defines an explicit interface, but it contains specifications for only the procedure declared in the INTERFACE TO statement. The explicit interface is defined only in the program unit that contains the INTERFACE TO statement.

The recommended method for defining explicit interfaces is to use an INTERFACE block.

**Example**

Consider that a C function that has the following prototype:

```
extern void Foo (int i);
```

The following INTERFACE TO block declares the Fortran call to this function:

```
INTERFACE TO SUBROUTINE Foo [C.ALIAS: '_Foo'] (I)
    INTEGER*4 I
END
```

**See Also**

INTERFACE
**INTEROP**

**OpenMP® Fortran Compiler Directive:** Identifies a foreign runtime context and identifies runtime characteristics of that context, enabling interoperability with it. This feature is only available for ifx.

**Syntax**

```
!$OMP INTEROP clause[,[, clause]... ]
```

clause

Is one or more of the following:

- **DEPEND (depend-modifier, ] dependence-type : locator-list)**
  
  A DEPEND clause can appear only if TARGETSYNC appears as the interop-type in an action-clause, or if interop-var is initialized with the TARGETSYNC interop-type.

- **DEVICE (scalar-integer-expression)**
  
  Only one DEVICE clause can appear in the directive. The integer-expression of the DEVICE clause must evaluate to a non-negative value equal to or less than the result of a call to the `omp_get_num_devices` runtime function.

- **action-clause**

action-clause

Is one of the following:

- **INIT ([interop-modifier,] interop-type [[, interop-type] ...]: interop-var)**
  
  Causes the interop-var to be initialized to refer to the list of properties associated with the specified interop-type.

  The properties `device_num`, `type`, `type_name`, `vendor`, and `vendor_name` are available for all interop-types.

  If the specified device does not exist or it is not supported, the interop-var is initialized to the value of `omp_interop_none`, which is defined to be zero.

- **DESTROY (interop-var)**
  
  Causes interop-var to be set to `omp_interop_none` after the resources associated with the interop-var are released. This action makes interop-var unusable until it is reinitialized by another INTEROP construct.

- **USE (interop-var)**
  
  Causes interop-var to be used for the effects of the directive, but interop-var is not initialized, destroyed, or modified.

- **NOWAIT**
  
  Only one NOWAIT action-clause is permitted in the directive.

You must specify at least one action-clause. Each interop-type can appear at most once in an action-clause.

For the USE and DESTROY action-clauses, the interop-type is whatever interop-type was used when initializing the interop-var.

**interop-var**

Is a scalar integer variable with kind type `omp_interop_kind`.

Intel® Fortran Compiler Classic and Intel® Fortran Compiler Developer Guide and Reference
The interop-var of an INIT or DESTROY action-clause must not be a constant. The same interop-var cannot be specified in more than one action-clause of the INTEROP construct.

**interop-type**

Is one of the following:

- **TARGET**
  Provides the following properties:
  - device - the foreign device handle
  - device_context - the foreign device context handle
  - platform - the handle to the foreign platform of the device
- **TARGETSYNC**
  Enables synchronization between foreign tasks executing in the foreign execution context and OpenMP* tasks.

**interop-modifier**

Is prefer_type (preference-list)

**preference-list**

Is a list of one or more foreign-runtime-ids, which can be character constants or integer constant expressions with kind type omp_interop_fr_kind. If you specify more than one foreign-runtime-id, they must be separated by commas.

The character values recognized by ifx are "opencl", "sycl", and "level_zero", which have corresponding integer values of 3, 4, and 6, respectively.

You can specify integer constants OMP_IFR_OPENCL, OMP_IFR_SYCL, and OMP_IFR_LEVEL_ZERO in the preference-list. Definitions for these integer constants are in module omp_lib.

The list of foreign-runtime-ids is scanned in left-to-right lexical order. The left-most supported foreign-runtime-id in preference-list is used. If the implementation does not support any of the listed foreign-runtime-ids in preference-list, the behavior is unspecified.

A task that encounters an INTEROP construct executes the region.

If a DEVICE clause is not specified, the behavior is as if a DEVICE clause is present with the integer value equal to the value of the internal control variable (ICV) default-device-var specified.

OpenMP* may interoperate with one or more foreign runtime environments using the INTEROP directive, the INTEROP clause on a DECLARE VARIANT directive, or the interoperability functions in the OpenMP* runtime API.

A task has an interoperability requirement set, which is a logical set of properties. Properties can be added to or removed from the set by different directives. The properties can be queried by other constructs that have interoperability semantics. The following properties can be added by a construct:

- **DEPEND** - requires the construct enforce the synchronization relationship specified by the DEPEND clause
- **IS_DEVICE_PTR (list-item)** - indicates that the list-item is a device pointer within the construct
- **NOWAIT** - indicates that the construct is asynchronous

The DISPATCH directive can add properties to the interoperability requirement set.

The DECLARE VARIANT directive can remove properties from the interoperability requirement set.
If the `interop-var` is initialized with `TARGETSYNC`, an empty mergeable task is generated. DEPEND clauses apply to the generated task. If NOWAIT is omitted, the generated task is also an included task. The INTEROP construct guarantees ordered execution of the generated task with respect to foreign tasks executing in foreign contexts through the foreign synchronization object accessible through the `TARGETSYNC` property of the `interop-var`.

If a foreign task is created prior to encountering an INTEROP construct, the foreign task must complete execution before the generated task executes. If the creation of a foreign task occurs after an INTEROP construct is encountered, the foreign task cannot begin execution until the generated task finishes execution. The INTEROP construct imposes no ordering between the thread that encounters it and foreign tasks or OpenMP* tasks.

DISPATCH directive

**INTRINSIC**

**Statement and Attribute:** Allows the specific name of an intrinsic procedure to be used as an actual argument.

**Syntax**

The INTRINSIC attribute can be specified in a type declaration statement or an INTRINSIC statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls,] INTRINSIC [, att-ls] :: in-pro[, in-pro]...
```

**Statement:**

```
INTRINSIC [:] in-pro[, in-pro] ...
```

- `type` Is a data type specifier.  
- `att-ls` Is an optional list of attribute specifiers.  
- `in-pro` Is the name of an intrinsic procedure.

**Description**

In a type declaration statement, only functions can be declared INTRINSIC. However, you can use the INTRINSIC statement to declare subroutines, as well as functions, to be intrinsic.

The name declared INTRINSIC is assumed to be the name of an intrinsic procedure. If a generic intrinsic function name is given the INTRINSIC attribute, the name retains its generic properties.

Some specific intrinsic function names cannot be used as actual arguments. For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures.

**Example**

The following example shows a type declaration statement specifying the INTRINSIC attribute:

```fortran
PROGRAM EXAMPLE
...
REAL(8), INTRINSIC :: DACOS
...
CALL TEST(X, DACOS)        ! Intrinsic function DACOS is an actual argument
```

1652
The following example shows an INTRINSIC statement:

<table>
<thead>
<tr>
<th>Main Program</th>
<th>Subprogram</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL CTN</td>
<td>SUBROUTINE TRIG(X,F,Y)</td>
</tr>
<tr>
<td>INTRINSIC SIN, COS</td>
<td>Y = F(X)</td>
</tr>
<tr>
<td>...</td>
<td>RETURN</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,SIN,SINE)</td>
<td></td>
</tr>
<tr>
<td>...</td>
<td>FUNCTION CTN(X)</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,COS,COSINE)</td>
<td>CTN = COS(X)/SIN(X)</td>
</tr>
<tr>
<td>...</td>
<td>RETURN</td>
</tr>
<tr>
<td>CALL TRIG(ANGLE,CTN,COTANGENT)</td>
<td>END</td>
</tr>
</tbody>
</table>

Note that when TRIG is called with a second argument of SIN or COS, the function reference F(X) references the Standard Fortran library functions SIN and COS; but when TRIG is called with a second argument of CTN, F(X) references the user function CTN.

The following shows another example:

```fortran
INTRINSIC SIN, COS
REAL X, Y, R
! SIN and COS are arguments to Calc2:
R = Calc2 (SIN, COS)
```

**INIUM**

**Elemental Intrinsic Function (Specific):** Converts a character string to an INTEGER(2) value. This function cannot be passed as an actual argument.

**Syntax**

```
result = INUM (i)
```

*i*  
(Input) Must be of type character.

**Results**

The result type is INTEGER(2). The result value is the INTEGER(2) value represented by the character string *i*.

If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.
Example

INUM ("451") has the value 451 of type INTEGER(2).

IOR

Elemental Intrinsic Function (Generic): Performs an inclusive OR on corresponding bits. This function can also be specified as OR.

Syntax

\[
\text{result} = \text{IOR} \ (i, j)
\]

i

(Input) Must be of type integer, logical (which is treated as an integer), or a binary, octal, or hexadecimal literal constant.

j

(Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both \(i\) and \(j\) are of type integer, they must have the same kind type parameter. If the kinds of \(i\) and \(j\) do not match, the value with the smaller kind is extended with its sign bit on the left and the larger kind is used for the operation and the result. \(i\) and \(j\) must not both be binary, octal, or hexadecimal literal constants.

Results

The result is the same as \(i\) if \(i\) is of type integer; otherwise, the result is the same as \(j\). If either \(i\) or \(j\) is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to type integer with the kind type parameter of the other.

The result value is derived by combining \(i\) and \(j\) bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>IOR ((i, j))</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BIOR</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IIOR(^1)</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JIOR</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KIOR</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)Or HIOR.

Example

ITOR (1, 4) has the value 5.
ITOR (1, 2) has the value 3.
The following shows another example:

```fortran
INTEGER result
result = IOR(240, 90) ! returns 250
```

IPARITY

**IPARITY**

*Transformational Intrinsic Function (Generic):*

*Returns the result of a bitwise exclusive OR operation.*

**Syntax**

```fortran
result = IPARITY (array, dim [, mask])
result = IPARITY (array [, mask])
```

- `array` (Input) Must be an array of type integer.
- `dim` (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of array.
- `mask` (Input; optional) Must be of type logical and conformable with array.

**Results**

The result has the same type and kind parameters as array. It is scalar if dim does not appear; otherwise, the result has rank n - 1 and shape [d1, d2, ..., ddim-1, ddim+1, ..., dn] where [d1, d2, ..., dn] is the shape of array.

The result of IPARITY (array) has a value equal to the bitwise exclusive OR of all the elements of array. If array has size zero, the result value is equal to zero.

The result of IPARITY (array, MASK=mask) has a value equal to IPARITY (PACK (array, mask)).

The result of IPARITY (array, DIM=dim [, MASK=mask]) has a value equal to that of IPARITY (array [, MASK=mask]) if array has rank one. Otherwise, the value of element (s1, s2, ..., sdim-1, sdim+1, ..., sn) of the result is equal to IPARITY (array (s1, s2, ..., sdim-1, :, sdim+1, ..., sn) [, MASK = mask (s1, s2, ..., sdim-1, :, sdim+1, ..., sn)])

**Example**

IPARITY ([14, 13, 8]) has the value 11. IPARITY ([14, 13, 8], MASK=[.true., .false., .true]) has the value 6.

IANY
IALL
IRAND, IRANMDM

Portability Functions: Return random numbers in the range 0 through \((2^{31})-1\), or 0 through \((2^{15})-1\) if called without an argument.

Module

USE IFPORT

Syntax

\[
\begin{align*}
\text{result} & = \text{IRAND ([iflag])} \\
\text{result} & = \text{IRANMDM ([iflag])}
\end{align*}
\]

\(\text{iflag} \quad \text{(Input) INTEGER(4). Optional for IRAND. Controls the way the returned random number is chosen. If iflag is omitted, it is assumed to be 0, and the return range is 0 through \((2^{15})-1\) (inclusive).)}\)

Results

The result type is INTEGER(4). If iflag is 1, the generator is restarted and the first random value is returned. If iflag is 0, the next random number in the sequence is returned. If iflag is neither zero nor 1, it is used as a new seed for the random number generator, and the functions return the first new random value.

IRAND and IRANMDM are equivalent and return the same random numbers. Both functions are included to ensure portability of existing code that references one or both of them.

You can use SRAND to restart the pseudorandom number generator used by these functions.

Example

USE IFPORT

INTEGER(4) istat, flag_value, r_nums(20)
flag_value=1
r_nums(1) = IRAND(flag_value)
flag_value=0
do istat=2,20
   r_nums(istat) = irand(flag_value)
end do

RANDOM_INIT

RANDOM_NUMBER

RANDOM_SEED

SRAND

IRANGET

Portability Subroutine: Returns the current seed.

Module

USE IFPORT

Syntax

CALL IRANGET (seed)
**seed**

(Output) INTEGER(4). The current seed value.

**See Also**
IRANSET

**IRANSET**

*Portability Subroutine: Sets the seed for the random number generator.*

**Module**
USE IFPORT

**Syntax**
CALL IRANSET (seed)

*seed* (Input) INTEGER(4). The reset value for the seed.

**See Also**
IRANGET

**IS_CONTIGUOUS**

*Inquiry Intrinsic Function (Generic): Tests the contiguity of an array.*

**Syntax**
result = IS_CONTIGUOUS (array)

*array* (Input) Is an array; it can be of any data type. If it is a pointer, it must be associated.

**Results**
The result is default logical scalar. The result has the value .TRUE. if array is contiguous; otherwise, .FALSE..

**Example**
After the pointer assignment MY_P => TARGET (2:20:4), IS_CONTIGUOUS (MY_P) has the value .FALSE..

**See Also**
CONTIGUOUS

**IS_DEVICE_PTR Clause**

*Parallel Directive Clause: Indicates that a list item is a device pointer currently in the device data environment and that it should be used directly.*

**Syntax**
ISDEVICE_PTR (list)
list

Is a list of one or more variables that are of type C_PTR from the intrinsic module ISO_C_BINDING, or that do not have the POINTER, ALLOCATABLE, or VALUE attribute. Each list item is a device pointer currently in the device data environment and that it should be used directly.

1 List items not of type C_PTR have been deprecated in the OpenMP* specification.

If a list item in a MAP clause is an array section, and the array section is derived from a variable with a POINTER or ALLOCATABLE attribute, then the behavior is unspecified if the corresponding list item’s variable is modified in the region.

A list item may be a device address returned as the result of a call to the OpenMP* run-time library memory management function `omp_target_alloc` function.

**IS_IOSTAT_END**

*Elemental Intrinsic Function (Generic): Tests for an end-of-file condition.*

**Syntax**

```fortran
result=IS_IOSTAT_END(i)
```

*i* (Input) Must be of type integer.

**Results**

The result type is default logical. The value of the result is true only if *i* is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-file condition.

**Example**

```fortran
INTEGER IO_STATUS
...
READ (20, IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_END(IO_STATUS)) THEN
  ...
  ! process end of file
ENDIF
...
  ! process data read
```

**IS_IOSTAT_EOR**

*Elemental Intrinsic Function (Generic): Tests for an end-of-record condition.*

**Syntax**

```fortran
result=IS_IOSTAT_EOR(i)
```

*i* (Input) Must be of type integer.

**Results**

The result type is default logical. The value of the result is true only if *i* is a value that could be assigned to the scalar integer variable in an IOSTAT= specifier to indicate an end-of-record condition.
Example

```fortran
INTEGER IO_STATUS
...
READ (30, ADVANCE='YES', IOSTAT=IO_STATUS) A, B, C
IF (IS_IOSTAT_EOR (IO_STATUS)) THEN
    ! process end of record
ENDIF
! process data read
```

**ISATTY**

*Portability Function: Checks whether a logical unit number is a terminal.*

**Module**

USE IFPORT

**Syntax**

```fortran
result = ISATTY (lunit)
```

- **lunit**  
  (Input) INTEGER(4). An integer expression corresponding to a Fortran logical unit number. Must be in the range 0 to 100 and must be connected.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the specified logical unit is connected to a terminal device; otherwise, .FALSE..

If *lunit* is out of range or is not connected, zero is returned.

**ISHA**

*Elemental Intrinsic Function (Generic): Arithmetically shifts an integer left or right by a specified number of bits.*

**Syntax**

```fortran
result = ISHA (i, shift)
```

- **i**  
  (Input) Must be of type integer. This argument is the value to be shifted.

- **shift**  
  (Input) Must be of type integer. This argument is the direction and distance of shift.

  Positive shifts are left (toward the most significant bit); negative shifts are right (toward the least significant bit).

**Results**

The result type and kind are the same as *i*. The result is equal to *i* shifted arithmetically by *shift* bits.

If *shift* is positive, the shift is to the left; if *shift* is negative, the shift is to the right. If *shift* is zero, no shift is performed.
Bits shifted out from the left or from the right, as appropriate, are lost. If the shift is to the left, zeros are
shifted in on the right. If the shift is to the right, copies of the sign bit (0 for non-negative \( i \); 1 for negative \( i \))
are shifted in on the left.

The kind of integer is important in arithmetic shifting because sign varies among integer representations (see
the following example). If you want to shift a one-byte or two-byte argument, you must declare it as
INTEGER(1) or INTEGER(2).

**Example**

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = -128       ! equal to 10000000
j = -32768     ! equal to 10000000 00000000
res1 = ISHA (i, -4)  ! returns 11111000 = -8
res2 = ISHA (j, -4)  ! returns 11111000 10100000 = -2048
```

**See Also**

ISHC
ISHL
ISHFT
ISHFTC

**ISHC**

*Elemental Intrinsic Function (Generic): Rotates an integer left or right by specified number of bits.*

*Bits shifted out one end are shifted in the other end.*

*No bits are lost.*

**Syntax**

```
result = ISHC (i,shift)
```

\( i \)

(Input) Must be of type integer. This argument is the value to be rotated.

\( shift \)

(Input) Must be of type integer. This argument is the direction and distance of rotation.

Positive rotations are left (toward the most significant bit); negative rotations are right (toward the least significant bit).

**Results**

The result type and kind are the same as \( i \). The result is equal to \( i \) circularly rotated by \( shift \) bits.

If \( shift \) is positive, \( i \) is rotated left \( shift \) bits. If \( shift \) is negative, \( i \) is rotated right \( shift \) bits. Bits shifted out one end are shifted in the other. No bits are lost.

The kind of integer is important in circular shifting. With an INTEGER(4) argument, all 32 bits are shifted. If you want to rotate a one-byte or two-byte argument, you must declare it as INTEGER(1) or INTEGER(2).

**Example**

```
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10  ! equal to 00001010
j = 10  ! equal to 00000000 00001010
```

ISHA
ISHL
ISHFT
ISHFTC

**ISHFT**

*Elemental Intrinsic Function (Generic): Performs a logical shift.*

**Syntax**

\[
\text{result} = \text{ISHFT}(i, shift)
\]

- \(i\) (Input) Must be of type integer.
- \(shift\) (Input) Must be of type integer. The absolute value for \(shift\) must be less than or equal to \(\text{BIT\_SIZE}(i)\).

**Results**

The result type and kind are the same as \(i\). The result has the value obtained by shifting the bits of \(i\) by \(shift\) positions. If \(shift\) is positive, the shift is to the left; if \(shift\) is negative, the shift is to the right. If \(shift\) is zero, no shift is performed.

Bits shifted out from the left or from the right, as appropriate, are lost. Zeros are shifted in from the opposite end.

ISHFT with a positive \(shift\) can also be specified as LSHIFT (or LSHFT). ISHFT with a negative \(shift\) can also be specified as RSHIFT (or RSHFT) with \(|shift|\).

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

- ISHFTC
- ISHA
- ISHC

**ISHFTC**

*Elemental Intrinsic Function (Generic): Performs a circular shift of the rightmost bits.*

**Syntax**

```fortran
result = ISHFTC (i, shift [, size])
```

- `i` (Input) Must be of type integer.
- `shift` (Input) Must be of type integer. The absolute value of `shift` must be less than or equal to `size`.
- `size` (Input; optional) Must be of type integer. The value of `size` must be positive and must not exceed BIT_SIZE(`i`). If `size` is omitted, it is assumed to have the value of BIT_SIZE(`i`).

**Results**

The result type and kind are the same as `i`. The result value is obtained by circular shifting the `size` rightmost bits of `i` by `shift` positions. If `shift` is positive, the shift is to the left; if `shift` is negative, the shift is to the right. If `shift` is zero, no shift is performed.

No bits are lost. Bits in `i` beyond the value specified by `size` are unaffected.

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

BIT_SIZE
ISHFT
MVBITS

ISHL

*Elemental Intrinsic Function (Generic)*: Logically shifts an integer left or right by the specified bits. Zeros are shifted in from the opposite end.

**Syntax**

```fortran
result = ISHL (i, shift)
```

**Input**: Must be of type integer. This argument is the value to be shifted.

**shift**: Must be of type integer. This argument is the direction and distance of shift.

If positive, *i* is shifted left (toward the most significant bit). If negative, *i* is shifted right (toward the least significant bit).

**Results**

The result type and kind are the same as *i*. The result is equal to *i* logically shifted by *shift* bits. Zeros are shifted in from the opposite end.

Unlike circular or arithmetic shifts, which can shift ones into the number being shifted, logical shifts shift in zeros only, regardless of the direction or size of the shift. The integer kind, however, still determines the end that bits are shifted out of, which can make a difference in the result (see the following example).

**Example**

```fortran
INTEGER(1) i, res1
INTEGER(2) j, res2
i = 10   ! equal to 00001010
```
\texttt{j = 10} \quad ! \text{equal to 00000000 00001010}
\texttt{res1 = ISHL (i, 5)} \quad ! \text{returns 01000000 = 64}
\texttt{res2 = ISHL (j, 5)} \quad ! \text{returns 00000001 01000000 = 320}

\textbf{ISNAN}

\textit{Elemental Intrinsic Function (Generic): Tests whether IEEE* real (binary32, binary64, and binary128) numbers are Not-a-Number (NaN) values.}

\textbf{Syntax}

\texttt{result = ISNAN (x)}

\texttt{x} \quad \text{(Input) Must be of type real.}

\textbf{Results}

The result type is default logical. The result is \texttt{.TRUE.} if \texttt{x} is an IEEE NaN; otherwise, the result is \texttt{.FALSE..}

\textbf{Example}

\begin{verbatim}
LOGICAL A
DOUBLE PRECISION B
...
A = ISNAN(B)
\end{verbatim}

A is assigned the value \texttt{.TRUE.} if \texttt{B} is an IEEE NaN; otherwise, the value assigned is \texttt{.FALSE..}

\textbf{ITIME}

\textit{Portability Subroutine: Returns the time in numeric form.}

\textbf{Module}

\texttt{USE IFPORT}

\textbf{Syntax}

\texttt{CALL ITIME (array)}

\texttt{array} \quad \text{(Output) INTEGER(4). A rank one array with three elements used to store numeric time data:}

\begin{itemize}
  \item \texttt{array(1)} - the hour
  \item \texttt{array(2)} - the minute
  \item \texttt{array(3)} - the second
\end{itemize}

\textbf{Example}

\begin{verbatim}
USE IFPORT
INTEGER(4) time_array(3)
CALL ITIME (time_array)
\end{verbatim}
write(*,10) time_array
10 format (1X,I2,:','I2,:','I2)
END

See Also
DATE_AND_TIME

IVDEP

**General Compiler Directive:** Assists the compiler’s dependence analysis of iterative DO loops.

**Syntax**

```bash
!DIR$ IVDEP [: option]
```

**option**
Is LOOP or BACK.

The IVDEP directive is an assertion to the compiler’s optimizer about the order of memory references inside a DO loop.

IVDEP:LOOP implies no loop-carried dependencies. IVDEP:BACK implies no backward dependencies.

When no **option** is specified, the following occurs:

- The compiler begins dependence analysis by assuming all dependences occur in the same forward direction as their appearance in the normal scalar execution order. This contrasts with normal compiler behavior, which is for the dependence analysis to make no initial assumptions about the direction of a dependence.

`!DIR$ IVDEP` with no option can also be spelled `!DIR$ INIT_DEP_FWD` (INITialize DEpEndences ForWarD).

The IVDEP directive is applied to a DO loop in which the user knows that dependences are in lexical order. For example, if two memory references in the loop touch the same memory location and one of them modifies the memory location, then the first reference to touch the location has to be the one that appears earlier lexically in the program source code. This assumes that the right-hand side of an assignment statement is "earlier" than the left-hand side.

The IVDEP directive informs the compiler that the program would behave correctly if the statements were executed in certain orders other than the sequential execution order, such as executing the first statement or block to completion for all iterations, then the next statement or block for all iterations, and so forth. The optimizer can use this information, along with whatever else it can prove about the dependences, to choose other execution orders.

**Example**

In the following example, the IVDEP directive provides more information about the dependences within the loop, which may enable loop transformations to occur:

```bash
!DIR$ IVDEP
DO I=1, N
   A(INDARR(I)) = A(INDARR(I)) + B(I)
END DO
```

In this case, the scalar execution order follows:

1. Retrieve INDARR(I).
2. Use the result from step 1 to retrieve A(INDARR(I)).
4. Add the results from steps 2 and 3.
5. Store the results from step 4 into the location indicated by A(INDARR(I)) from step 1.
IVDEP directs the compiler to initially assume that when steps 1 and 5 access a common memory location, step 1 always accesses the location first because step 1 occurs earlier in the execution sequence. This approach lets the compiler reorder instructions, as long as it chooses an instruction schedule that maintains the relative order of the array references.

Rules for Loop Directives that Affect Array Assignment Statements

J to L

This section describes language features that start with J, K, or L.

J to L

JABS

Portability Function: Returns an absolute value.

Module
USE IFPORT

Syntax
result = JABS (i)

i (Input) INTEGER(4). A value.

Results
The result type is INTEGER(4). The value of the result is | i |.

JDATE

Portability Function: Returns an 8-character string with the Julian date in the form "yyddd". Three spaces terminate this string.

Module
USE IFPORT

Syntax
result = JDATE( )

Results
The result type is character with length 8. The result is the Julian date, in the form YYDDD, followed by three spaces.

The Julian date is a five-digit number whose first two digits are the last two digits of the year, and whose final three digits represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 99032.
**Caution**  
The two-digit year return value may cause problems with the year 2000. Use **DATE_AND_TIME** instead.

**Example**

```fortran
! Sets julian to today's julian date
USE IFPORT
CHARACTER*8 julian
julian = JDATE()
```

**See Also**
```
DATE_AND_TIME
```

**JDATE4**

*Portability Function*: Returns a 10-character string with the Julian date in the form "yyyyddd". Three spaces terminate this string.

**Module**
```
USE IFPORT
```

**Syntax**
```
result = JDATE4()
```

**Results**

The result type is character with length 10. The result is the Julian date, in the form YYYYDDD, followed by three spaces.

The Julian date is a seven-digit number whose first four digits are the year, and whose final three represent the day of the year (1 for January 1, 366 for December 31 of a leap year, and so on). For example, the Julian date for February 1, 1999 is 1999032.

**See Also**
```
DATE_AND_TIME
```

**JNUM**

*Elemental Intrinsic Function (Specific)*: Converts a character string to an INTEGER(4) value. This function cannot be passed as an actual argument.

**Syntax**
```
result = JNUM(i)
```

**i**  
(Input) Must be of type character.

**Results**

The result type is INTEGER(4). The result value is the integer value represented by the character string *i*. If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.
Example
JNUM ("46616") has the value 46616 of type INTEGER(4).

KILL
Portability Function: Sends a signal to the process given by ID.

Module
USE IFPORT

Syntax
result = KILL (pid, signum)

pid (Input) INTEGER(4). ID of a process to be signaled.

signum (Input) INTEGER(4). A signal value. For the definition of signal values, see the SIGNAL function.

Results
The result type is INTEGER(4). The result is zero if the call was successful; otherwise, an error code. Possible error codes are:

- EINVAL: The signum is not a valid signal number, or PID is not the same as getpid() and signum does not equal SIGKILL.
- ESRCH: The given PID could not be found.
- EPERM: The current process does not have permission to send a signal to the process given by PID.

On Windows* systems, arbitrary signals can be sent only to the calling process (where pid= getpid( )). Other processes can send only the SIGKILL signal (signum= 9), and only if the calling process has permission.

Example
USE IFPORT
integer(4) id_number, sig_val, istat
id_number=getpid( )
ISTAT = KILL (id_number, sig_val)

See Also
SIGNAL
RAISEQQ
SIGNALQQ

KIND
Inquiry Intrinsic Function (Generic): Returns the kind parameter of the argument.

Syntax
result = KIND (x)

x (Input) Can be of any intrinsic type.

Results
The result is a scalar of type default integer. The result has a value equal to the kind type parameter value of x.
Example
KIND (0.0) has the kind value of default real type.
KIND (12) has the kind value of default integer type.
The following shows another example:

```
INTEGER i ! a 4-byte integer
WRITE(*,*) KIND(i)
CALL INTEGER2()
WRITE(*,*) KIND(i) ! still a 4-byte integer
! not affected by setting in subroutine
END
SUBROUTINE INTEGER2()
  !DIR$INTEGER:2
  INTEGER j ! a 2-byte integer
  WRITE(*,*) KIND(j)
END SUBROUTINE
```

Argument Keywords in Intrinsic Procedures

KNUM

**Elemental Intrinsic Function (Specific):** Converts a character string to an INTEGER(8) value.

**Syntax**

```
result = KNUM (i)
```

*i*  
(Input) Must be of type character.

**Results**

The result type is INTEGER(8). The result value is the integer value represented by the character string *i*. If the argument contains characters that are illegal in an integer value, an error is signaled and execution stops.

**Example**

KNUM ("46616") has the value 46616 of type INTEGER(8).
LASTPRIVATE

Parallel Directive Clause: Provides a superset of the functionality provided by the PRIVATE clause. It declares one or more variables to be private to an implicit task, and causes the corresponding original variable to be updated after the end of the region.

Syntax

LASTPRIVATE ([CONDITIONAL:] list)

CONDITIONAL

Is an optional modifier specifying that the last value assigned to a list item can be from the sequentially last iteration of the associated loops or the lexically last section construct.

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

If CONDITIONAL is present, list items must be scalar of intrinsic type (INTEGER, REAL, COMPLEX, LOGICAL, and CHARACTER) and they must have neither the POINTER nor the ALLOCATABLE attribute.

Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel region is exited, each variable has the value provided by the sequentially last section or loop iteration.

Multiple LASTPRIVATE clauses are allowed on all of the directives that accept them. A list item may not appear in more than one LASTPRIVATE clause. LASTPRIVATE (CONDITIONAL:A,B) is equivalent to LASTPRIVATE(CONDITIONAL:A) LASTPRIVATE(CONDITIONAL:B).

LASTPRIVATE (CONDITIONAL:list) can appear in the following directives:

- OMP DISTRIBUTE
- OMP DO
- OMP SECTIONS
- OMP SIMD
- OMP TASKLOOP
- Any and all of the combination directives of the above directives

The OMP PARALLEL directive does not allow the LASTPRIVATE clause.

If the original variable has the POINTER attribute, its update occurs as if by pointer assignment.

If the original variable does not have the POINTER attribute, its update occurs as if by intrinsic assignment.

When a LASTPRIVATE clause without the CONDITIONAL modifier appears in a worksharing or a SIMD directive, the value of each new list item from the sequentially last iteration of the associated loops, or the lexically last section, is assigned to the original list item.

When the CONDITIONAL modifier is specified, the final value written by the sequentially last iteration or lexically last section that writes to a list item, if any, is assigned to the original list item.

When the CONDITIONAL modifier is not specified, list items that are not assigned a value by the sequentially last iteration of the loops, or by the lexically last section, have unspecified values after the construct.

Therefore, variables specified in the list of a LASTPRIVATE clause that contains a CONDITIONAL modifier should be variables that are conditionally assigned to in the loop/region/sections. The variables in the list of a LASTPRIVATE clause that does not contain a CONDITIONAL modifier should be variables that are unconditionally assigned to in the loop or sections.
Subobjects that are not assigned a value by the last iteration of the DO or the lexically last SECTION of the SECTIONS directive are undefined after the construct.

The original variable becomes defined at the end of the construct if there is an implicit barrier at that point. To avoid race conditions, concurrent reads or updates of the original variable must be synchronized with the update of the original variable that occurs as a result of the LASTPRIVATE clause.

If the LASTPRIVATE clause is used in a construct for which NOWAIT is specified, accesses to the original variable may create a data race. To avoid this, synchronization must be inserted to ensure that the sequentially last iteration or lexically last section construct has stored and flushed that variable.

The following are restrictions for the LASTPRIVATE clause:

- A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
- A variable that is private within a parallel region, or that appears in the REDUCTION clause of a PARALLEL construct, must not appear in a LASTPRIVATE clause on a worksharing construct if any of the corresponding worksharing regions ever binds to any of the corresponding parallel regions.
- A variable that appears in a LASTPRIVATE clause must be definable.
- An original variable with the ALLOCATABLE attribute must be in the allocated state at entry to the construct containing the LASTPRIVATE clause. The variable in the sequentially last iteration or lexically last section must be in the allocated state upon exit from that iteration or section with the same bounds as the corresponding original variable.
- Assumed-size arrays must not appear in a PRIVATE clause.
- Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.
- If a list item appears in both the FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all of the initializations for FIRSTPRIVATE.

**NOTE**

If a variable appears in both FIRSTPRIVATE and LASTPRIVATE clauses, the update required for LASTPRIVATE occurs after all initializations for FIRSTPRIVATE.

**NOTE**

If a variable appears in a LASTPRIVATE clause on a combined construct for which the first construct is TARGET, it is treated as if it had appeared in a MAP clause with a map-type of FROM.

**Example**

Consider the following:

```plaintext
!$OMP DO PRIVATE(I) LASTPRIVATE(B)  
  DO I = 1, 1000  
    B = I  
  ENDDO  
!$OMP END DO
```

In this case, after the construct is exited, variable B has the value 1000.

Consider the following:

```plaintext
!$OMP SECTIONS LASTPRIVATE(B)  
!$OMP SECTION  
  B = 2  
!$OMP SECTION  
  B = 4
```
In this case the thread that executes the lexically last SECTION updates the original variable B to have a value of 4. However, variable D was not specified in the LASTPRIVATE clause, so it has an undefined value after the construct is exited.

Consider the following example:

```fortran
P = 0
!$OMP DO PRIVATE(I), FIRSTPRIVATE(P), LASTPRIVATE(CONDITIONAL:P)
  DO I = 1, 1000
    IF (A(I) .EQ. B) THEN
      P = I
      EXIT
    END IF
  ENDDO
!$OMP END DO
```

After the loop, P will be the index of the first element of A to match B; if no match is found, P will be zero.

PRIVATE Clause
FIRSTPRIVATE clause

**LBOUND**

*Inquiry Intrinsic Function (Generic): Returns the lower bounds for all dimensions of an array, or the lower bound for a specified dimension.*

**Syntax**

```
result = LBOUND (array [, dim] [, kind])
```

- **array** (Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer.
- **dim** (Input; optional) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \(array\).
- **kind** (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If **dim** is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of **array**. Each element in the result corresponds to a dimension of **array**.

If **array** is an array section or an array expression that is not a whole array or array structure component, each element of the result has the value 1.

If **array** is a whole array or array structure component, **LBOUND** ( **array**, **dim** ) has a value equal to the lower bound for subscript **dim** of **array** (if **dim** is nonzero or **array** is an assumed-size array of rank **dim**). Otherwise, the corresponding element of the result has the value 1.
If LBOUND is invoked for an assumed-rank object that is associated with a scalar and \( \textit{dim} \) is absent, the result is a zero-sized array. LBOUND cannot be invoked for an assumed-rank object that is associated with a scalar if \( \textit{dim} \) is present because the rank of a scalar is zero and \( \textit{dim} \) must be \( \geq 1 \).

The setting of compiler options specifying integer size can affect this function.

**Example**

Consider the following:

```plaintext
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
```

LBOUND(ARRAY_A) is (1, 5). LBOUND(ARRAY_A, DIM=2) is 5.

LBOUND(ARRAY_B) is (2, -3). LBOUND(ARRAY_B (5:8, :)) is (1,1) because the arguments are array sections.

The following shows another example:

```plaintext
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = LBOUND (ar1)          ! returns [2, 4, -1]
res2 = LBOUND (ar1, DIM= 3)  ! returns -1
res3 = LBOUND (vec1)         ! returns [1]
END
```

**See Also**

UBOUND

**LCOBOUND**

*Inquiry Intrinsic Function (Generic): Returns the lower cobounds of a coarray.*

**Syntax**

```plaintext
result = LCOBOUND (coarray [,dim [, kind]])
```

- \( \textit{coarray} \) 
  (Input) Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.

- \( \textit{dim} \) 
  (Input; optional) Must be an integer scalar with a value in the range 1 \( \leq \textit{dim} \leq n \), where \( n \) is the corank of \( \textit{coarray} \). The corresponding actual argument must not be an optional dummy argument.

- \( \textit{kind} \) 
  (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If \( \textit{kind} \) is present, the kind parameter is that specified by \( \textit{kind} \); otherwise, the kind parameter is that of default integer type. The result is scalar if \( \textit{dim} \) is present; otherwise, the result is an array of rank one and size \( n \), where \( n \) is the corank of \( \textit{coarray} \).

The result depends on whether \( \textit{dim} \) is specified:

- If \( \textit{dim} \) is specified, LCOBOUND (COARRAY, DIM) has a value equal to the lower cobound for cosubscript \( \textit{dim} \) of \( \textit{coarray} \).
- If \( \textit{dim} \) is not specified, LCOBOUND (COARRAY) has a value whose ith element is equal to LCOBOUND (COARRAY, i), for i = 1, 2, \ldots, n, where n is the corank of \( \textit{coarray} \).

**Example**

If B is allocated by the statement ALLOCATE (B [2:3, 8:*]), then LCOBOUND (B) is [2, 8] and LCOBOUND (B, DIM=2) is 8.
**LCWRQQ**

*Portability Subroutine:* Sets the value of the floating-point processor control word.

**Module**

USE IFPORT

**Syntax**

CALL LCWRQQ (controlword)

*controlword* (Input) INTEGER(2). Floating-point processor control word.

LCWRQQ performs the same function as the run-time subroutine SETCONTROLFPQQ and is provided for compatibility.

**Example**

USE IFPORT

INTEGER(2) control
CALL SCWRQQ(control) ! get control word
! Set control word to make processor round up
control = control .AND. (.NOT. FPCW$MCW_RC) ! Clear
! control word with inverse
! of rounding control mask
control = control .OR. FPCW$UP ! Set control word
! to round up
CALL LCWRQQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END

**See Also**

SETCONTROLFPQQ

**LEADZ**

*Elemental Intrinsic Function (Specific):* Returns the number of leading zero bits in an integer.

**Syntax**

result = LEADZ (i)

*i* (Input) Must be of type integer or logical.

**Results**

The result type is default integer. The result value is the number of leading zeros in the binary representation of the integer *i*.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

Consider the following:

INTEGER*8 J, TWO
PARAMETER (TWO=2)
DO J = -1, 40
LEN

Inquiry Intrinsic Function (Generic): Returns the length of a character expression.

Syntax

\[
\text{result} = \text{LEN}\ (\text{string} [, \text{kind}])
\]

string  \hspace{1cm} \text{(Input) Must be of type character; it can be scalar or array valued. (It can be an array of strings.)}

kind \hspace{1cm} \text{(Input; optional) Must be a scalar integer constant expression.}

Results

The result is a scalar of type integer. If \textit{kind} is present, the \textit{kind} parameter of the result is that specified by \textit{kind}; otherwise, the \textit{kind} parameter of the result is that of default integer. If the processor cannot represent the result value in the \textit{kind} of the result, the result is undefined.

The result has a value equal to the number of characters in \textit{string} (if it is scalar) or in an element of \textit{string} (if it is array valued).

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEN (^1)</td>
<td>CHARACTER</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td></td>
<td>CHARACTER</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying integer size can affect this function.

Example

Consider the following example:

| CHARACTER (15) C (50) |
| CHARACTER (25) D |

LEN (C) has the value 15, and LEN (D) has the value 25.

The following shows another example:

CHARACTER(11) STR(100)
INTEGER I
I = LEN (STR)  \hspace{1cm} \text{! returns 11}
I = LEN ("A phrase with 5 trailing blanks.^^^^") \hspace{1cm} \text{! returns 37}

See Also

LEN_TRIM
Declaration Statements for Character Types
Character Data Type
**LEN_TRIM**

**Elemental Intrinsic Function (Generic):** Returns the length of the character argument without counting trailing blank characters.

**Syntax**

\[ \text{result} = \text{LEN_TRIM} (\text{string} [, \text{kind}]) \]

- **string** (Input) Must be of type character.
- **kind** (Input; optional) Must be a scalar integer constant expression.

**Results**

The result is a scalar of type integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result has a value equal to the number of characters remaining after any trailing blanks in **string** are removed. If the argument contains only blank characters, the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

LEN_TRIM (' C D ') has the value 4.
LEN_TRIM (' ') has the value 0.

The following shows another example:

```fortran
INTEGER LEN1
LEN1 = LEN_TRIM (' GOOD DAY ') ! returns 9
LEN1 = LEN_TRIM (' ') ! returns 0
```

**See Also**

LEN
LNBLNK

**LGE**

**Elemental Intrinsic Function (Generic):**

Determines if a string is lexically greater than or equal to another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LGE is equivalent to the (.GE.) operator.

**Syntax**

\[ \text{result} = \text{LGE} (\text{string}_a, \text{string}_b) \]

- **string\_a** (Input) Must be of type character.
- **string\_b** (Input) Must be of type character.

**Results**

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.
The result is true if the strings are equal, both strings are of zero length, or if \textit{string\_a} follows \textit{string\_b} in the ASCII collating sequence; otherwise, the result is false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LGE (^1,2)</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

\(^1\) This specific function cannot be passed as an actual argument.  
\(^2\) The setting of compiler options specifying integer size can affect this function.

Example

LGE ( ‘ONE’, 'SIX' ) has the value false.
LGE ( ‘TWO’, 'THREE' ) has the value true.

The following shows another example:

```fortran
LOGICAL L
L = LGE('ABC','ABD')       ! returns .FALSE.
L = LGE ('AB', 'AAAAAAAB') ! returns .TRUE.
```

LGT  
LLE  
LLT  
ASCII and Key Code Charts

LGT

\textbf{Elemental Intrinsic Function (Generic):}

Determines whether a string is lexically greater than another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel\textsuperscript{®} Fortran, LGT is equivalent to the > (\texttt{.GT.}) operator.

\textbf{Syntax}

\[
\text{result} = \text{LGT} (\text{string\_a}, \text{string\_b})
\]

\textit{string\_a}  
\textit{string\_b}  

\textbf{Results}

The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if \textit{string\_a} follows \textit{string\_b} in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LGT (^1,2)</td>
<td>CHARACTER</td>
<td>LOGICAL(4)</td>
</tr>
</tbody>
</table>

\(^1\) This specific function cannot be passed as an actual argument.  
\(^2\) The setting of compiler options specifying integer size can affect this function.
Example
LGT ('TWO', 'THREE') has the value true.

LGT ('ONE', 'FOUR') has the value true.

The following shows another example:

```fortran
LOGICAL L
L = LGT('ABC', 'ABC')  ! returns .FALSE.
L = LGT('ABC', 'AABC') ! returns .TRUE.
```

LINEAR Clause

Parallel Directive Clause: Specifies that all variables in a list are private to a SIMD lane and that they have a linear relationship within the iteration space of a loop.

Syntax
It takes one of the following forms:

In Construct Directive !$OMP SIMD:

LINEAR (var-list[: linear-step])

In Declarative Directive !$OMP DECLARE SIMD:

LINEAR (linear-list[: linear-step])

var-list

Is a comma-separated list of one or more integer variables. Each list item must comply with PRIVATE clause semantics.

For each iteration of a scalar loop, the value of each var is incremented by linear-step. For each iteration of a vector loop, the value of each var is incremented by linear-step times the vector length for the loop.

linear-step

Is a compile-time positive, integer, scalar constant expression. If linear-step is not specified, it is assumed to be 1.

linear-list

Takes one of the following forms:

- list
- modifier (list)

list

Is a comma-separated list of one or more dummy arguments of the procedure that will be invoked concurrently on each SIMD lane. Each list item must comply with PRIVATE clause semantics.

If modifier is not specified or it is VAL or UVAL, each list item must be a scalar of type integer. If modifier is REF, each list item must be a scalar of intrinsic type.

modifier

Is one of the following:
• **REF**
  Specifies that the storage location of each list item on each lane corresponds to an array at the storage location upon entry to the function indexed by the logical number of the lane times linear-step.
  The referenced values passed into the routine (which forms a vector for calculations) are located sequentially, like in an array, with the distance between elements equal to step.
  This modifier can be used only for dummy arguments passed by reference.

• **VAL**
  Specifies that the value of each list item on each lane corresponds to the value of the list item upon entry to the function plus the logical number of the lane times linear-step.
  On each iteration of the loop from which the routine is called, the value of the parameter can be calculated as (value_on_previous_iteration + step).

• **UVAL**
  Similar to VAL but each invocation uses the same storage location for each SIMD lane. This storage location is updated with the final value of the logically last lane. It differs from VAL as follows:
  • For VAL, a vector of addresses (references) is passed to the vector variant of the routine.
  • For UVAL, only one address (reference) is passed, which may improve performance.
  This modifier can be used only for dummy arguments passed by reference.

  If modifier is not specified or it is VAL or UVAL, the value of each list item on each lane corresponds to the value of the list item upon entry to the function plus the logical number of the lane times linear-step.

  You can only use REF or VAL if the list item is a dummy argument without the Fortran Standard VALUE attribute.

If more than one linear-step is specified for a var, a compile-time error occurs. Multiple LINEAR clauses can be used to specify different values for linear-step. The linear-step expression must be invariant (must not be changed) during the execution of the associated construct. Multiple LINEAR clauses are merged as a union.

The value corresponding to the sequentially last iteration of the associated loops is assigned to the original list item.

A list item in a LINEAR clause cannot appear in any other data scope attribute clause, in another LINEAR clause, or more than once in list. For a list of data scope attribute clauses, see the first table in Clauses Used in Multiple OpenMP* Fortran Directives.

In the sequentially last iteration, any list item with the ALLOCATABLE attribute must have an allocation status of allocated upon exit from that iteration.

If a list item is a dummy argument without the Fortran Standard VALUE attribute and the REF modifier is not specified, then a read of the list item must be executed before any writes to the list item.
If a LINEAR clause appears in a directive that also contains a REDUCTION clause with the INSCAN modifier, only a loop iteration variable of a loop associated with the construct can appear as a list item in the LINEAR clause.

The following cannot appear in a LINEAR clause:

- Variables that have the POINTER attribute
- Cray* pointers

The LINEAR (REF) clause is very important because Fortran passes dummy arguments by reference. By default, the compiler places consecutive addresses in a vector register, which leads to an inefficient gather of the addresses.

In the following example, LINEAR (REF (X)) tells the compiler that the 4 addresses for the dummy argument X are consecutive, so the code only needs to dereference X once and then copy consecutive values to a vector register.

```fortran
subroutine test_linear(x, y)
  !$omp declare simd (test_linear) linear(ref(x, y))    ! arguments by reference
  real(8),intent(in)  :: x
  real(8),intent(out) :: y
  y = 1. + sin(x)**3
end subroutine test_linear

...                               ! procedure that calls test_linear
interface                       ! test_linear needs an explicit interface
...
  do j = 1,n
    call test_linear(a(j), b(j))    ! loop vectorized via qopenmp-simd
  enddo
...
```

**Example**

Consider the following:

```fortran
! universal but slowest definition; it matches the use of func in loops 1, 2, and 3:
!$OMP DECLARE SIMD
!
! matches the use of func in loop 1:
!$OMP DECLARE SIMD LINEAR(in1) LINEAR(REF(in2)) UNIFORM(mul)
!
! matches the use of func in loops 2 and 3:
!$OMP DECLARE SIMD LINEAR(REF(in2))
!
! matches the use of func in loop 2:
!$OMP DECLARE SIMD LINEAR(REF(in2)) LINEAR(mul)
!
! matches the use of func in loop 3:
!$OMP DECLARE SIMD LINEAR(VAL(in2:2))

function func(in1, in2, mul)
  integral in1
  integral in2
  integral mul
...
  integral a, k
  integral b(100)
  integral c(100)
  integral ndx(100)
...
```
The following are the loop examples referenced above.

!loop 1
!$OMP SIMD
  DO i=1,100
    c(i) = func(a + i, b(i), mul) ! the value of the 1st parameter is changed linearly,
    !   the 2nd parameter reference is changed linearly,
    !   the 3rd parameter is not changed
  END DO
!loop 2
!$OMP SIMD
  DO i=1,100
    c(i) = func(b(ndx(i)), b(i), i + 1 ! the value of the 1st parameter is unpredictable,
    !   the 2nd reference is changed linearly,
    !   the 3rd parameter is changed linearly
  END DO
!loop 3
!$OMP SIMD
  DO i=1,100
    k = i * 2                       ! during vectorization, private variables are
    c(i) = func(b(ndx(i)), k, b(i)) !     transformed into arrays: k -> k_vec(simdlen)
    ! the value of the 1st parameter is unpredictable,
    ! for the 2nd parameter both value and reference
    !   to its location can be considered linear,
    ! the value for the 3rd parameter is unpredictable
    !   the !$OMP DECLARE SIMD LINEAR(VAL(in2:2))) will
    !   be chosen from the two matching variants)
  END DO

DECLARE SIMD

LLE
Elemental Intrinsic Function (Generic):
Determines whether a string is lexically less than or equal to another string, based on the ASCII collating sequence, even if the processor's default collating sequence is different. In Intel® Fortran, LLE is equivalent to the (.LE.) operator.

Syntax
result = LLE(string_a, string_b)

string_a (Input) Must be of type character.
string_b (Input) Must be of type character.

Results
The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.

The result is true if the strings are equal, both strings are of zero length, or if string_a precedes string_b in the ASCII collating sequence; otherwise, the result is false.
Specific Name | Argument Type | Result Type
---|---|---
LLE 1,2 | CHARACTER | LOGICAL(4)

1This specific function cannot be passed as an actual argument.
2The setting of compiler options specifying integer size can affect this function.

Example
LLE ( 'TWO', 'THREE' ) has the value false.
LLE ( 'ONE', 'FOUR' ) has the value false.
The following shows another example:

```
LOGICAL L
L = LLE('ABC', 'ABC')   ! returns .TRUE.
L = LLE('ABC', 'AABCD') ! returns .FALSE.
```

**LLT**

**Elemental Intrinsic Function (Generic):**
Determines whether a string is lexically less than another string, based on the ASCII collating sequence, even if the processor’s default collating sequence is different. In Intel® Fortran, LLT is equivalent to the < ( .LT. ) operator.

**Syntax**
result = LLT (string_a,string_b)

- `string_a` (Input) Must be of type character.
- `string_b` (Input) Must be of type character.

**Results**
The result type is default logical. If the strings are of unequal length, the comparison is made as if the shorter string were extended on the right with blanks, to the length of the longer string.
The result is true if `string_a` precedes `string_b` in the ASCII collating sequence; otherwise, the result is false. If both strings are of zero length, the result is also false.

Specific Name | Argument Type | Result Type
---|---|---
LLT 1,2 | CHARACTER | LOGICAL(4)

1This specific function cannot be passed as an actual argument.
2The setting of compiler options specifying integer size can affect this function.

Example
LLT ( 'ONE', 'SIX' ) has the value true.
LLT ( 'ONE', 'FOUR' ) has the value false.
The following shows another example:

```
LOGICAL L
L = LLT ('ABC', 'ABC') ! returns .FALSE.
L = LLT ('AAXYZ', 'ABCDE') ! returns .TRUE.
```

**LNBLNK**

*Portability Function: Locates the position of the last nonblank character in a string.*

**Module**
USE IFPORT

**Syntax**

```
result = LNBLNK (string)
```

**string**  
(Input) Character*(*). String to be searched. Cannot be an array.

**Results**

The result type is INTEGER(4). The result is the index of the last nonblank character in string.  
LNBLNK is very similar to the intrinsic function LEN_TRIM, except that string cannot be an array.

**Example**

```
USE IFPORT
integer(4) p
p = LNBLNK(' GOOD DAY ') ! returns 9
p = LNBLNK(' ')          ! returns 0
```

See Also
LEN_TRIM

**LOC**

*Inquiry Intrinsic Function (Generic): Returns the internal address of a storage item. This function cannot be passed as an actual argument.*

**Syntax**

```
result = LOC (x)
```

**x**  
(Input) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.
Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the %LOC built-in function.

Example

The Fortran standard provides the C_LOC intrinsic module function as an alternative to the non-standard LOC. For more information, see the descriptions of C_LOC, C_FUNLOC, C_F_POINTER and C_FPROCPOINTER.

Example of using the LOC intrinsic

```fortran
integer :: array(2) = [10,20]
integer :: t
pointer (p,t) ! Integer pointer extension
  ! p is pointer, t is pointee (target)
  ! This declares p as an address-sized integer
  p = loc(array(1)) ! Address of array(1)
  print *, t           ! Prints 10
  p = loc(array(2)) ! Address of array(2)
  print *, t           ! Prints 20
```

%LOC

Built-in Function: Computes the internal address of a storage item.

Syntax

`result = %LOC (a)`

- `a` (Input) Is a variable, an array or record field reference, a procedure, or a constant; it can be of any data type. It must not be the name of a statement function. If it is a pointer, it must be defined and associated with a target.

Description

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The value of the result represents the address of the data object or, in the case of pointers, the address of its associated target. If the argument is not valid, the result is undefined.

This function performs the same function as the LOC intrinsic function.

LOCK and UNLOCK

Statements: A LOCK statement causes a lock variable to become locked by an image. An UNLOCK statement causes the lock variable to become unlocked. They take the following forms:

Syntax

```fortran
LOCK (lock-var [, ACQUIRED_LOCK=log-var] [, STAT=stat-var] [, ERRMSG=err-var])
UNLOCK (lock-var [, STAT=stat-var] [, ERRMSG=err-var])
```
lock-var  Is a scalar variable of type LOCK_TYPE. For more information, see intrinsic module ISO_FORTRAN_ENV.
log-var  Is a scalar logical variable.
stat-var  Is a scalar integer variable in which the status of the synchronization is stored.
err-var  Is a scalar default character variable in which explanatory text is stored if an error occurs.

ACQUIRED_LOCK=, STAT=, and ERRMSG= can appear in any order, but only once in a LOCK statement. STAT= and ERRMSG= can appear in either order, but only once in an UNLOCK statement.

Description
A lock variable is unlocked if its value is equal to that of the structure constructor LOCK_TYPE ( ). If it has any other value, it is locked.

A lock variable is locked by an image if it was locked by execution of a LOCK statement on that image and has not been subsequently unlocked by execution of an UNLOCK statement on the same image.

When a LOCK statement is specified without an ACQUIRED LOCK= specifier, it causes the lock variable to become locked by that image. If the lock variable is already locked by another image, that LOCK statement causes the lock variable to become defined after the other image causes the lock variable to become unlocked.

If the lock variable is unlocked, successful execution of a LOCK statement with an ACQUIRED LOCK= specifier causes the lock variable to become locked by that image and the log-var to become defined with the value TRUE. If the lock variable is already locked by a different image, successful execution of a LOCK statement with an ACQUIRED LOCK= specifier leaves the lock variable unchanged and causes the log-var to become defined with the value FALSE.

During the execution of the program, the value of a lock variable changes through a sequence of locked and unlocked states when LOCK and UNLOCK statements are executed. If a lock variable becomes unlocked by execution of an UNLOCK statement on image M and next becomes locked by execution of a LOCK statement on image T, the segments preceding the UNLOCK statement on image M precede the segments following the LOCK statement on image T. Execution of a LOCK statement that does not cause the lock variable to become locked does not affect segment ordering.

An error condition occurs in the following cases:
• If the lock variable in a LOCK statement is already locked by the executing image
• If the lock variable in an UNLOCK statement is not already locked by the executing image

If an error condition occurs during execution of a LOCK or UNLOCK statement, the value of the lock variable is not changed and the value of the ACQUIRED_LOCK variable, if any, is not changed.

Example
The following example shows the use of LOCK and UNLOCK statements to manage a work queue:

```fortran
USE, INTRINSIC :: ISO_FORTRAN_ENV

TYPE(Task) :: work_queue(50)[*]    ! List of tasks on queue to perform
INTEGER :: work_queue_size[*]
TYPE(LOCK_TYPE) :: work_queue_lock[*]  ! Lock to manage the work queue

TYPE(Task) :: current_task
INTEGER :: my_image
```
my_image = THIS_IMAGE()
DO
    ! Process the next task in the work queue
    LOCK (work_queue_lock)         ! Start of new segment A
    ! Segment A is ordered with respect to segment B
    ! executed by image my_image-1 below because of lock exclusion
    IF (work_queue_size>0) THEN
        ! Get the next job from the queue
        current_task = work_queue(work_queue_size)
        work_queue_size = work_queue_size-1
    END IF
    UNLOCK (work_queue_lock) ! Segment ends
    ...
    ! Process the task
    ! Add a new task on the neighboring queue:
    LOCK(work_queue_lock[my_image+1])      ! Starts segment B
    ! Segment B is ordered with respect to segment A
    ! executed by image my_image+1 above because of lock exclusion
    IF (work_queue_size[my_image+1]<SIZE(work_queue)) THEN
        work_queue_size[my_image+1] = work_queue_size[ti+1]+1
        work_queue(work_queue_size[my_image+1])[my_image+1] = current_task
    END IF
    UNLOCK (work_queue_lock[my_image+1]) ! Ends segment B
END DO

LOG

_Elemental Intrinsic Function (Generic): Returns the natural logarithm of the argument._

Syntax
result = LOG (x)

x                (Input) Must be of type real or complex. If x is real, its value must be greater than zero. If x is complex, its value must not be zero.

Results
The result type and kind are the same as x. The result value is approximately equal to log_e(x).
If the arguments are complex, the result is the principal value with imaginary part omega in the range -pi <= omega <= pi.
If the real part of x < 0 and the imaginary part of x is a positive real zero, the imaginary part of the result is pi.
If the real part of x < 0 and the imaginary part of x is a negative real zero, the imaginary part of the result is -pi.
Specific Name  | Argument Type  | Result Type  
---|---|---
ALOG | REAL(4) | REAL(4)  
DLOG | REAL(8) | REAL(8) 
QLOG | REAL(16) | REAL(16)  
CLOG | COMPLEX(4) | COMPLEX(4)  
CDLOG | COMPLEX(8) | COMPLEX(8) 
CQLOG | COMPLEX(16) | COMPLEX(16)  

1This function is treated like LOG.  
2The setting of compiler options specifying real size can affect ALOG, LOG, and CLOG.  
3This function can also be specified as ZLOG.  
4The setting of compiler options specifying double size can affect CDLOG.

Example
LOG (8.0) has the value 2.079442.
LOG (25.0) has the value 3.218876.
The following shows another example:

```
REAL r
r = LOG(10.0)  ! returns 2.302585
```

See Also
EXP
LOG10

LOG_GAMMA
Elemental Intrinsic Function (Generic): Returns the logarithm of the absolute value of the gamma function of the argument.

Syntax
```
result = LOG_GAMMA (x)
```

x  
(Input) Must be of type real. It must not be zero or a negative integer.

Results
The result type and kind are the same as x.
The result has a value equal to a processor-dependent approximation to the natural logarithm of the absolute value of the gamma function of x.

Example
LOG_GAMMA (3.0) has the approximate value 0.693.
**LOG10**

*Elemental Intrinsic Function (Generic):* Returns the common logarithm of the argument.

**Syntax**

```fortran
result = LOG10 (x)
```

**x**

(Input) Must be of type real or complex. If x is real, its value must be greater than zero. If x is complex, its value must not be zero.

**Results**

The result type and kind are the same as x. The result value is approximately equal to \( \log_{10} x \).

1This function is treated like LOG10.

2The setting of compiler options specifying real size can affect ALOG10, CLOG10, and LOG10.

3The setting of compiler options specifying double size can affect DLOG10 and CDLOG10.

**Example**

LOG10 (8.0) has the value 0.9030900.
LOG10 (15.0) has the value 1.176091.

The following shows another example:

```fortran
REAL r
r = LOG10(10.0) ! returns 1.0
```

**See Also**

LOG

**LOGICAL Function**

*Elemental Intrinsic Function (Generic):* Converts the logical value of the argument to a logical value with different kind parameters.

**Syntax**

```fortran
result = LOGICAL (l[,kind])
```

**l**

(Input) Must be of type logical.
kind (Input; optional) Must be a scalar integer constant expression.

Results
The result is of type logical. If kind is present, the kind parameter is that specified by kind; otherwise, the kind parameter is that of default logical. The result value is that of l.

The setting of compiler options specifying integer size can affect this function.

Example
LOGICAL (L .OR. .NOT. L) has the value true and is of type default logical regardless of the kind parameter of logical variable L.

LOGICAL (.FALSE., 2) has the value false, with the parameter of kind 2.

INT
REAL
Logical Data Types

LOGICAL Statement
Statement: Specifies the LOGICAL data type.

Syntax
LOGICAL
LOGICAL([KIND=] n)
LOGICAL*n

n Is kind 1, 2, 4, or 8.

If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

Example
LOGICAL, ALLOCATABLE :: flag1, flag2
LOGICAL (2), SAVE :: doit, dont=.FALSE.
LOGICAL switch

! An equivalent declaration is:
LOGICAL flag1, flag2
LOGICAL (2) doit, dont=.FALSE.
ALLOCATABLE flag1, flag2
SAVE doit, dont

LONG

Portability Function: Converts an INTEGER(2) argument to INTEGER(4) type.

Module
USE IFPORT

Syntax
result = LONG (int2)

int2 (Input) INTEGER(2). Value to be converted.

Results
The result type is INTEGER(4). The result is the value of int2 with type INTEGER(4). The upper 16 bits of the result are zeros and the lower 16 are equal to int2.

INT
KIND

LOOP

OpenMP* Fortran Compiler Directive: Specifies that the iterations of the associated loops can execute concurrently. This feature is only available for ifx.

Syntax
!$OMP LOOP [clause[,] clause]... ]
do-loop
[!$OMP END LOOP]
clause

Is one of the following:

- **BIND (binding)**

  Determines the binding region of the construct. binding is teams, parallel, or thread.

  If teams is specified, and an innermost enclosing teams region exists, the binding region is that innermost teams region. If parallel is specified, the binding region is the innermost enclosing parallel region. It may be an implicit parallel region. If thread is specified, the binding region is not defined.

  If the BIND clause does not appear and the construct is enclosed in a teams or parallel region, the binding region is the innermost enclosing team or parallel region. If no teams or parallel region encloses the loop construct, the binding region is undefined.
If the binding region is a parallel region, the binding thread set is the set of threads executing the parallel region. If the binding region is a teams region, the binding thread set is the set of primary threads executing the region. If the binding region is not defined, the binding thread is the encountering thread.

- **COLLAPSE (n)**
  For \( n \), a value greater than 1 tells the compiler the number of associated loops to collapse into a larger iterations space, which executes without ordering. The associated loop nest must not contain any OpenMP* directives between associated loops in the nest.

  If no COLLAPSE clause appears, or if it appears with a value of 1 for \( n \), only the outermost loop is associated with the LOOP construct.

  At most one COLLAPSE clause is permitted on a LOOP directive.

- **LASTPRIVATE ([CONDITIONAL:] list)**
  Only a loop iteration variable of a loop associated with the LOOP construct may appear as a list item in a LASTPRIVATE clause.

- **ORDER (CONCURRENT)**
  Indicates that the iterations of the loop may execute in any order or simultaneously. This is also the behavior when the clause is not specified.

- **PRIVATE (list)**

- **REDUCTION ([DEFAULT,]reduction-identifier : list)**

**do-loop**

Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical loop form.

The LOOP construct tells the compiler that all iterations of the associated loops can execute concurrently or in any order.

If used, the END LOOP directive must appear immediately after the end of the loop. If you do not specify an END LOOP directive, an END LOOP directive is assumed at the end of the outermost associated do-loop.

A LOOP construct can not contain calls to procedures containing other OpenMP* constructs or calls to the OpenMP* runtime library functions.

The only OpenMP* constructs permitted inside a LOOP construct are another LOOP, PARALLEL, or SIMD construct or a combined construct whose leftmost construct is a PARALLEL construct.

A LOOP construct that appears in a procedure and is not nested inside another OpenMP* construct must contain a BIND clause.

If more than one loop is associated with the construct, any intervening code between two associated loops executes at least once per iteration of the loop containing the intervening code, and at most once per execution of the innermost loop associated with the construct. If an associated loop has a trip count of zero and that loop does not contain the intervening code, the behavior is undefined.

The set of threads that may execute iterations of the LOOP construct is the binding thread set. Each iteration is executed by one of these threads.

If a loop region is bound to a teams region, the threads in the binding set can continue execution at the end of the loop region without waiting for all iterations of the region to complete execution. All iterations of the loop region must complete execution before the end of the teams region. If the binding region is not a teams region, all iterations of the associated loops must complete execution before the loop region is exited.
If a loop region is bound to a `teams` or `parallel` region, it must be encountered by all or none of the binding threads.

A LOOP construct with a BIND clause that specifies a value of `teams` must be strictly nested inside a `teams` region. The behavior of a LOOP construct with a BIND clause specifying a value of `parallel` is undefined if the loop construct is nested inside a SIMD construct.

Referencing a THREADPRIVATE variable in a LOOP construct results in undefined behavior.

If a `reduction-modifier` is present in a reduction clause, the only permitted value is `DEFAULT`.

**Example**

In the following example, the loop iteration variable is private by default, and it is not necessary to explicitly declare it. The END LOOP directive is optional. Iterations of the do loop can execute in any order, or concurrently.

```fortran
!$OMP PARALLEL
!$OMP LOOP
     DO I=1,N
         B(I) = (A(I) + A(I-1)) / 2.0
     END DO
!$OMP END LOOP
!$OMP END PARALLEL
```

In the next example, the loops over `J1` and `J2` are collapsed and their iteration space is executed by all threads of the current team. The subroutine `BAR` referenced in the innermost loop cannot contain OpenMP* constructs or calls to procedures that do, and it cannot contain calls to the OpenMP* runtime library. The END LOOP directive is optional:

```fortran
!$OMP LOOP COLLAPSE(2) PRIVATE(J1, J2, J3)
     DO J1 = J1_L, J1_U, J1_S
         DO J2 = J2_L, J2_U, J2_S
             DO J3 = J3_L, J3_U, J3_S
                 CALL BAR(A, J1, J2, J3)
             ENDDO
         ENDDO
     ENDDO
!$OMP END LOOP
```

**See Also**

OpenMP Fortran Compiler Directives  
Syntax Rules for Compiler Directives  
Rules for General Directives that Affect DO Loops  
Parallel Processing Model  for information about Binding Sets

**LOOP COUNT**

*General Compiler Directive*: Specifies the iterations (typical trip count) for a DO loop.

**Syntax**

```fortran
!DIR$ LOOP COUNT (n1[, n2]...)  
!DIR$ LOOP COUNT= n1[, n2]...  
!DIR$ LOOP COUNT qualifier(n)[, qualifier(n)]...  
!DIR$ LOOP COUNT qualifier=n[, qualifier=n]...
```
\[ n1, n2 \]

Is a non-negative integer constant. It indicates that the next DO loop will iterate \( n1, n2 \), or some other number of times.

\[ \text{qualifier} \]

Is one or more of the following:

- \text{MAX} - specifies the maximum loop trip count.
- \text{MIN} - specifies the minimum loop trip count.
- \text{AVG} - specifies the average loop trip count.

The value of the loop count affects heuristics used in software pipelining, vectorization, and loop-transformations.

**Example**

Consider the following:

\[
\text{!DIR$ LOOP COUNT (10000)}
\text{do i =1,m}
\text{b(i) = a(i) +1 ! This is likely to enable the loop to get software-pipelined}
\text{enddo}
\]

Note that you can specify more than one \text{LOOP COUNT} directive for a DO loop. For example, the following directives are valid:

\[
\text{!DIR$ LOOP COUNT (10, 20, 30)}
\text{!DIR$ LOOP COUNT MAX=100, MIN=3, AVG=17}
\text{DO}
\text{...}
\]

Syntax Rules for Compiler Directives

Rules for General Directives that Affect DO Loops

Rules for Loop Directives that Affect Array Assignment Statements

**LSHIFT**

*Elemental Intrinsic Function (Generic):* Shifts the bits in an integer left by a specified number of positions. This is the same as specifying ISHFT with a positive shift.

**See Also**

See ISHFT.

**LSTAT**

*Portability Function:* Returns detailed information about a file.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{LSTAT} (\text{name,statb})
\]
name  (Input) Character*(*). Name of the file to examine.

statb  (Output) INTEGER(4) or INTEGER(8). One-dimensional array of size 12; where the system information is stored. See STAT for the possible values returned in statb.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code (see IERRNO).
LSTAT returns detailed information about the file named in name.
On Linux* and macOS* systems, if the file denoted by name is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.
On Windows* systems, LSTAT returns exactly the same information as STAT (because there are no symbolic links on these systems). STAT is the preferred function.
INQUIRE also provides information about file properties.

Example
USE IFPORT
INTEGER(4) info_array(12), istatus
character*20 file_name
print *, "Enter name of file to examine: 
read *, file_name
ISTATUS = LSTAT (file_name, info_array)
if (.NOT. ISTATUS) then
   print *, info_array
else
   print *, 'Error ',istatus
end if

See Also

GETFILEINFOQQ
STAT
FSTAT

LTIME
Portability Subroutine: Returns the components of the local time zone time in a nine-element array.

Module
USE IFPORT

Syntax
CALL LTIME (time,array)

time  (Input) INTEGER(4). An elapsed time in seconds since 00:00:00 Greenwich mean time, January 1, 1970.

array  (Output) INTEGER(4). One-dimensional array with 9 elements to contain local date and time data derived from time.

The elements of array are returned as follows:
On Linux* and macOS*, time can be a negative number returning the time before 00:00:00 Greenwich mean time, January 1, 1970. On Windows*, time can not be negative, in which case all 9 elements of array are set to -1. On all operating systems, if there is a system error in getting the local time, all 9 elements of array are set to -1.

**Example**

```fortran
USE IFPORT
INTEGER(4) input_time, time_array(9)
! find number of seconds since 1/1/70
input_time=TIME()
! convert number of seconds to time array
CALL LTIME (input_time, time_array)
PRINT *, time_array
```

### M to N

This section describes language features that start with M or N.

**MAKEDIRQQ**

*Portability Function:* Creates a new directory with a specified name.
Module
USE IFPORT

Syntax
result = MAKEDIRQQ (dirname)

dirname (Input) Character*(*). Name of directory to be created.

Results
The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..
MAKEDIRQQ can create only one directory at a time. You cannot create a new directory and a subdirectory
below it in a single command. MAKEDIRQQ does not translate path delimiters. You can use either slash (/) or
backslash (\) as valid delimiters.
If an error occurs, call GETLASTERRORQQ to retrieve the error message. Possible errors include:
• ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified
  access.
• ERR$EXIST - The directory already exists.
• ERR$NOENT - The file or path specified was not found.

Example
USE IFPORT
LOGICAL(4) result
result = MAKEDIRQQ('mynewdir')
IF (result) THEN
  WRITE (*,*) 'New subdirectory successfully created'
ELSE
  WRITE (*,*) 'Failed to create subdirectory'
END IF
END

MALLOC
Elemental Intrinsic Function (Generic): Allocates
a block of memory. This is a generic function that has
no specific function associated with it. It must not be
passed as an actual argument.

Syntax
result = MALLOC (size)

size (Input) Must be of type integer. This value is the size (in bytes) of
memory to be allocated.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the
starting address of the allocated memory. The memory allocated can be freed by using the FREE intrinsic
function.
Example

```
INTEGER(4)  SIZE
REAL(4) STORAGE(*)
POINTER (ADDR, STORAGE)    ! ADDR will point to STORAGE
SIZE = 1024                  ! Size in bytes
ADDR = MALLOC(SIZE)         ! Allocate the memory
CALL FREE(ADDR)             ! Free it
```

MAP Clause

**Clause for TARGET Directives:** Maps a variable from the data environment of the current task to the data environment of the device associated with the construct. This clause only applies to the TARGET directives.

**Syntax**

```
MAP ([map-type-modifier[,] map-type :] list)
```

*map-type-modifier* Is one of the following:

- **ALWAYS**
  Specifies that initialization should always occur for the *list* items.

- **MAPPER (mapper-identifier)**
  Specifies the name of an accessible user-defined mapper declared in a DECLARE MAPPER directive. If MAPPER is not present, it is as if MAPPER (DEFAULT) were specified.

  The map behavior of a list item in a MAP clause with the same type as the type specified in the user-defined mapper is modified by a user-defined mapper. The effect is to remove the list item from the MAP clause and apply the clauses specified in the user-defined mapper to the construct where the MAP clause appears.

  References to *var* in the DECLARE MAPPER MAP clauses are replaced by the list item, and the map type is replaced with the final map type as determined by the table of final map types (see DECLARE MAPPER).

*map-type* Determines how a *list* item is initialized. Possible values are:

- **ALLOC**
  On entry to the outermost device region, each new corresponding list item has an undefined initial value.

- **FROM**
  On exit from the device region, the value of the corresponding list item is assigned to each original list item.

  This is ignored for nested regions unless *map-type-modifier* ALWAYS is specified.
TO
On entry to the device region, each new corresponding list item is initialized with the value of the original list item.

This is ignored for nested regions unless map-type-modifier ALWAYS is specified.

TOFROM
On entry to the device region, each new corresponding list item is initialized with the value of the original list item. On exit from the device region, the value of the corresponding list item is assigned to each original list item.

This is ignored for nested regions unless map-type-modifier ALWAYS is specified.

DELETE
On exit from the device region, if the corresponding list item is present on the device, it is then deleted from the device.

RELEASE
On exit from the outermost device region, the corresponding list item is deleted from the device.

If a map-type is not specified, the default is TOFROM.

The map initialization and assignment are done as if by intrinsic assignment, that is, through bitwise copy.

list
Is the name of one or more variables, array sections, or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /).

If a list item is an array section, it must specify contiguous storage.

A list item can appear in at most one of the TO, FROM, or TOFROM clauses. If a list item appears in an ALLOC clause, it cannot appear on a TO or TOFROM clause.

On entry to an outermost target region where this clause is used, for each original list item, a new corresponding list item is created on the device. On exit from the outermost target region, if the corresponding list item is present on the device, it is then deleted from the device.

At least one MAP clause must appear in a directive that allows the clause.

THREADPRIVATE variables cannot appear in a MAP clause.

For the TARGET ENTER DATA directive, map-type must be either TO or ALLOC.

For the TARGET EXIT DATA directive, map-type must be FROM, RELEASE, or DELETE.

For the TARGET and TARGET DATA directives, map-type must be TO, FROM, TOFROM, or ALLOC.

For the TARGET UPDATE directive, map-type must be TO or FROM.

If original and corresponding list items share storage, data races can result when intervening synchronization between tasks does not occur. If variables that share storage are mapped, it causes unspecified behavior.

Any variables within a TARGET MAP region that are not specified in a MAP clause are treated as shared variables within the region.

A list item must not contain any components that have the ALLOCATABLE attribute.
If the allocation status of a list item with the ALLOCATABLE attribute is unallocated upon entry to a target region, the list item must be unallocated upon exit from the region.

If the allocation status of a list item with the ALLOCATABLE attribute is allocated upon entry to a target region, the allocation status of the corresponding list item must not be changed and must not be reshaped in the region.

If an array section of an allocatable array is mapped and the size of the section is smaller than that of the whole array, the target region must not have any reference to the whole array.

A list item that is an array or an array section that has a type for which a user-defined mapper exists, is mapped as if the final map type is ALLOC, RELEASE, or DELETE. Then each element is mapped with the original map type, as if by a separate construct according to the user-defined mapper.

If a MAPPER map-type-modifier appears in the MAP clause, the type specified in the user-defined mapper must match the type of the list items in the MAP clause.

**See Also**
TARGET directive clause DEFAULTMAP
DECLARE MAPPER Directive

**MAP and END MAP**

**Statement:** Specifies mapped field declarations that are part of a UNION declaration within a STRUCTURE declaration.

**Example**

```fortran
UNION
  MAP
    CHARACTER*20 string
  END MAP
  MAP
    INTEGER*2 number(10)
  END MAP
END UNION

UNION
  MAP
    RECORD /Cartesian/ xcoord, ycoord
  END MAP
  MAP
    RECORD /Polar/ length, angle
  END MAP
END UNION
```

See STRUCTURE.

**MASKED**

OpenMP* Fortran Compiler Directive: Specifies a block of code to be executed by the primary thread of the team. This feature is only available for ifx.

**Syntax**

```
$OMP MASKED
  loosely-structured-block
```
strictly-structured-block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

loosely-structured-block

Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

Example

The following example forces the primary thread to execute the routines OUTPUT and INPUT:

```fortran
 !$OMP PARALLEL DEFAULT(SHARED)
     CALL WORK(X)
 !$OMP MASKED
     CALL OUTPUT(X)
     CALL INPUT(Y)
 !$OMP END MASKED
     CALL WORK(Y)
 !$OMP END PARALLEL
```

MASKED TASKLOOP

**OpenMP* Fortran Compiler Directive:** Creates a MASKED construct containing a TASKLOOP construct, with no Fortran statements in the MASKED construct that are not also in the TASKLOOP construct. This feature is only available for ifx.

Syntax

```fortran
 !$OMP MASKED TASKLOOP [clause[, clause]... ]
     loop-nest
 [!]$OMP END MASKED TASKLOOP
```

clause

Can be any of the clauses accepted by the MASKED or TASKLOOP directives with identical meanings and restrictions.

loop-nest

Is a nest of DO loops in canonical form.
This combined directive provides a shortcut for specifying a MASKED construct with a TASKLOOP construct nested inside of it. The semantics are identical to a TASKLOOP construct specified immediately after a MASKED construct.

All restrictions for MASKED and TASKLOOP constructs apply to this combined construct.

MASKED TASKLOOP SIMD
OpenMP* Fortran Compiler Directive: Creates a MASKED construct containing a TASKLOOP SIMD construct, with no Fortran statements in the MASKED construct that are not also in the TASKLOOP SIMD construct. This feature is only available for ifx.

Syntax

```
!$OMP MASKED TASKLOOP SIMD [clause[, clause]... ]
   loop-nest
   [$OMP END MASKED TASKLOOP SIMD]
```

clause Can be any of the clauses accepted by the MASKED or TASKLOOP SIMD directives with identical meanings and restrictions.

loop-nest Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a MASKED construct with a TASKLOOP SIMD construct nested inside of it. The semantics are identical to a TASKLOOP SIMD construct specified immediately after a MASKED construct.

MASKL
Elemental Intrinsic Function (Generic): Returns a left-justified mask.

Syntax

```
result = MASKL (i[,kind])
```
**MASKL**

**Elemental Intrinsic Function (Generic):** Returns a left-justified mask.

**Syntax**

result = MASKL (i[,kind])

- **i** (Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits \( s \) of the model integer defined for bit manipulation contexts.

- **kind** (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its leftmost \( I \) bits set to 1 and the remaining bits set to 0.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

**Example**

MASKL (3) has the value SHIFTL (7, BIT_SIZE (0) - 3).

**See Also**

MASKR

**MASKR**

**Elemental Intrinsic Function (Generic):** Returns a right-justified mask.

**Syntax**

result = MASKR (i[,kind])

- **i** (Input) Must be of type integer or of type logical (which is treated as an integer). It must be nonnegative and less than or equal to the number of bits \( s \) of the model integer defined for bit manipulation contexts.

- **kind** (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value has its rightmost \( I \) bits set to 1 and the remaining bits set to 0.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

**Example**

MASKR (3) has the value 7.

**See Also**

MASKL
MASTER

OpenMP* Fortran Compiler Directive:
(Deprecated; see MASKED) Specifies a block of code to be executed by the master thread of the team.

Syntax

```fortran
!$OMP MASTER
   loosely-structured-block
!$OMP END MASTER
-or-
!$OMP MASTER
   strictly-structured-block
!$OMP END MASTER
```

- `loosely-structured-block` is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
- `strictly-structured-block` is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for a MASTER construct is the current team. A master region binds to the innermost enclosing parallel region.

When the MASTER directive is specified, the other threads in the team skip the enclosed block (section) of code and continue execution. There is no implied barrier, either on entry to or exit from the master section.

The MASTER directive is deprecated; you should use the MASKED directive.

Example

The following example forces the master thread to execute the routines OUTPUT and INPUT:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
   CALL WORK(X)
!$OMP MASTER
   CALL OUTPUT(X)
   CALL INPUT(Y)
!$OMP END MASTER
   CALL WORK(Y)
!$OMP END PARALLEL
```

See Also

MASTER TASKLOOP

OpenMP* Fortran Compiler Directive:
(Deprecated; replaced by MASKED TASKLOOP)
Creates a MASTER construct containing a TASKLOOP
construct, with no Fortran statements in the MASTER construct that are not also in the TASKLOOP construct. This feature is only available for ifx.

**Syntax**

```
$OMP MASTER TASKLOOP [clause[,] clause]... ]
   loop-nest
[ !$OMP END MASTER TASKLOOP]
```

| clause | Can be any of the clauses accepted by the MASTER or TASKLOOP directives with identical meanings and restrictions. |
| loop-nest | Is a nest of DO loops in canonical form. |

This combined directive provides a shortcut for specifying a MASTER construct with a TASKLOOP construct nested inside of it. The semantics are identical to a TASKLOOP construct specified immediately after a MASTER construct.

All restrictions for MASTER and TASKLOOP constructs apply to this combined construct.

The MASTER TASKLOOP directive is deprecated; you should use the MASKED TASKLOOP directive.

**See Also**

**MASTER TASKLOOP SIMD**

*OpenMP* Fortran Compiler Directive:

(Deprecated; replaced by MASKED TASKLOOP SIMD)

Creates a MASTER construct containing a TASKLOOP SIMD construct, with no Fortran statements in the MASTER construct that are not also in the TASKLOOP SIMD construct. This feature is only available for ifx.

**Syntax**

```
$OMP MASTER TASKLOOP SIMD [clause[,] clause]... ]
   loop-nest
[ !$OMP END MASTER TASKLOOP SIMD]
```

| clause | Can be any of the clauses accepted by the MASTER or TASKLOOP SIMD directives with identical meanings and restrictions. |
| loop-nest | Is a nest of DO loops in canonical form. |

This combined directive provides a shortcut for specifying a MASTER construct with a TASKLOOP SIMD construct nested inside of it. The semantics are identical to a TASKLOOP SIMD construct specified immediately after a MASTER construct; the only Fortran statements in the construct are inside the block.

All restrictions for MASTER and TASKLOOP SIMD constructs apply to this combined construct.

The MASTER TASKLOOP SIMD directive is deprecated; you should use the MASKED TASKLOOP SIMD directive.
MATMUL
Transformational Intrinsic Function (Generic):
Performs matrix multiplication of numeric or logical matrices.

Syntax

```fortran
result = MATMUL (matrix_a, matrix_b)
```

- **matrix_a** (Input) Must be an array of rank one or two. It must be of numeric (integer, real, or complex) or logical type.
- **matrix_b** (Input) Must be an array of rank one or two. It must be of numeric type if **matrix_a** is of numeric type or logical type if **matrix_a** is logical type.

At least one argument must be of rank two. The size of the first (or only) dimension of **matrix_b** must equal the size of the last (or only) dimension of **matrix_a**.

Results

The result is an array whose type depends on the data type of the arguments, according to the rules described in Data Type of Numeric Expressions. The rank and shape of the result depends on the rank and shapes of the arguments, as follows:

- If **matrix_a** has shape (n, m) and **matrix_b** has shape (m, k), the result is a rank-two array with shape (n, k).
- If **matrix_a** has shape (m) and **matrix_b** has shape (m, k), the result is a rank-one array with shape (k).
- If **matrix_a** has shape (n, m) and **matrix_b** has shape (m), the result is a rank-one array with shape (n).

If the arguments are of numeric type, element (i, j) of the result has the value \( \text{SUM}((\text{row i of } \text{matrix_a}) \times (\text{column j of } \text{matrix_b})) \). If the arguments are of logical type, element (i, j) of the result has the value \( \text{ANY}((\text{row i of } \text{matrix_a}) \, \text{AND} \, (\text{column j of } \text{matrix_b})) \).

Example

A is matrix

```
  [ 2 3 4 ]
  [ 3 4 5 ],
```

B is matrix

```
  [ 2 3 ]
  [ 3 4 ]
  [ 4 5 ],
```

X is vector (1, 2), and Y is vector (1, 2, 3).
The result of MATMUL (A, B) is the matrix-matrix product AB with the value

\[
\begin{pmatrix}
29 & 38 \\
38 & 50
\end{pmatrix}
\]

The result of MATMUL (X, A) is the vector-matrix product XA with the value (8, 11, 14).

The result of MATMUL (A, Y) is the matrix-vector product AY with the value (20, 26).

The following shows another example:

```fortran
INTEGER a(2,3), b(3,2), c(2), d(3), e(2,2), f(3), g(2)
a = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
  ! a is
  ! 1 3 5
  ! 2 4 6
b = RESHAPE((/1, 2, 3, 4, 5, 6/), (/3, 2/))
  ! b is
  ! 1 4
  ! 2 5
  ! 3 6
c = (/1, 2/)      ! c is [1 2]
d = (/1, 2, 3/)   ! d is [1 2 3]
e = MATMUL(a, b)    ! returns 22 49
  !         28 64
f = MATMUL(c,a)   ! returns [5 11 17]
g = MATMUL(a,d)   ! returns [22 28]
WRITE(*,*) e, f, g
END
```

**See Also**
TRANSPOSE
PRODUCT

**MAX**

*Elemental Intrinsic Function (Generic):* Returns the maximum value of the arguments.

**Syntax**

\[
\text{result} = \text{MAX} (a1, a2[, a3]...)
\]

`a1`, `a2`, `a3`  
(Input) All must have the same type (integer, real, or character) and kind parameters.

**Results**

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MAX0, AMAX1, DMAX1, QMAX1, IMAX0, JMAX0, and KMAX0, the result type is the same as the arguments. For MAX1, IMAX1, JMAX1, and KMAX1, the result type is integer. For AMAX0, AIMAX0, AJMAX0, and AKMAX0, the result type is real. The value of the result is that of the largest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

<table>
<thead>

<td>REAL(16)</td>
</tr>
</tbody>
</table>

\(^1\)These specific functions cannot be passed as actual arguments.
\(^2\)Or JMA0.
\(^3\)Or AMAX0. AMAX0 is the same as REAL (MAX).
\(^4\)In Standard Fortran, AMAX0 and MAX1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.

\(^5\)Or JMAX1. MAX1 is the same as INT(MAX).
\(^6\)The setting of compiler options specifying integer size can affect MAX1.
\(^7\)The setting of compiler options specifying real size can affect AMAX1.

**Example**

MAX (2.0, -8.0, 6.0) has the value 6.0.

MAX (14, 32, -50) has the value 32.

The following shows another example:

```fortran
INTEGER m1, m2
REAL r1, r2
m1 = MAX(5, 6, 7)       ! returns 7
m2 = MAX1(5.7, 3.2, -8.3) ! returns 5
r1 = AMAX0(5, 6, 7)     ! returns 7.0
r2 = AMAX1(6.4, -12.2, 4.9) ! returns 6.4
```

**See Also**

MAXLOC

MAXVAL

MIN
MAXEXPONENT

_Inquiry Intrinsic Function (Generic):_ Returns the maximum exponent in the model representing the same type and kind parameters as the argument.

**Syntax**

\[ \text{result} = \text{MAXEXPONENT} (x) \]

\( x \) (Input) Must be of type real; it can be scalar or array valued.

**Results**

The result is a scalar of type default integer. The result has the value \( e_{\text{max}} \), as defined in Model for Real Data.

**Example**

```
REAL(4) x
INTEGER i
i = MAXEXPONENT(x)    ! returns 128.
```

**See Also**

MINEXPONENT

MAXLOC

_Transformational Intrinsic Function (Generic):_ Returns the location of the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

**Syntax**

\[ \text{result} = \text{MAXLOC} (\text{array}, \text{dim} [, \text{mask}, \text{kind}, \text{back}]) \]

\[ \text{result} = \text{MAXLOC} (\text{array} [, \text{mask}, \text{kind}, \text{back}]) \]

\( \text{array} \) (Input) Must be an array of type integer, real, or character.

\( \text{dim} \) (Input) Must be a scalar integer with a value in the range 1 to \( n \), where \( n \) is the rank of \( \text{array} \).

\( \text{mask} \) (Input; optional) Must be a logical array that is conformable with \( \text{array} \).

\( \text{kind} \) (Input; optional) Must be a scalar integer constant expression.

\( \text{back} \) (Input; optional) Must be a scalar of type logical.

**Results**

The result is an array of type integer. If \( \text{kind} \) is present, the kind parameter of the result is that specified by \( \text{kind} \); otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if \( \text{dim} \) is not specified:

- The array result has rank one and a size equal to the rank of \( \text{array} \).
- If \( \text{MAXLOC}(\text{array}) \) is specified, the elements in the array result form the subscript of the location of the element with the maximum value in \( \text{array} \).
The $i$th subscript returned lies in the range 1 to $e_i$, where $e_i$ is the extent of the $i$th dimension of $array$.

- If MAXLOC ($array$, MASK=$mask$) is specified, the elements in the array result form the subscript of the location of the element with the maximum value corresponding to the condition specified by $mask$.

The following rules apply if $dim$ is specified:

- The array result has a rank that is one less than $array$, and shape $(d_1, d_2, \ldots d_{dim-1}, d_{dim+1}, \ldots d_n)$, where $(d_1, d_2, \ldots d_n)$ is the shape of $array$.

- If $array$ has rank one, MAXLOC ($array$, $dim$, $mask$) is a scalar and has a value equal to the first element of MAXLOC ($array$, $MASK = mask$). Otherwise, the value of element $(s_1, s_2, \ldots s_{dim-1}, s_{dim+1}, \ldots s_n)$ of MAXLOC ($array$, $dim$, $mask$) is equal to MAXLOC ($array(s_1, s_2, \ldots s_{dim-1}, \cdot, s_{dim+1}, \ldots s_n)$, $MASK = mask(s_1, s_2, \ldots s_{dim-1}, \cdot, s_{dim+1}, \ldots s_n)$).

If only one element has the maximum value, that element’s subscripts are returned. Otherwise, if more than one element has the maximum value and $back$ is absent or present with the value .FALSE., the element whose subscripts are returned is the first such element, taken in array element order. If $back$ is present with the value .TRUE., the element whose subscripts are returned is the last such element, taken in array element order.

If $array$ has size zero, or every element of $mask$ has the value .FALSE., the value of the result is controlled by compiler option assume [no]old_maxminloc, which can set the value of the result to either 1 or 0.

If $array$ is of type character, the comparison is done using the ASCII collating sequence.

The setting of compiler options specifying integer size can affect this function.

**Example**

The value of MAXLOC((/3, 7, 4, 7/)) is (2), which is the subscript of the location of the first occurrence of the maximum value in the rank-one array.

$A$ is the array

```
[  4    0    4    2 ]
[  3    1   -2    6 ]
[ -1   -4    5    5 ].
```

MAXLOC ($A$, $MASK=A\.LT.5$) has the value (1, 1) because these are the subscripts of the location of the first maximum value (4) that is less than 5.

MAXLOC ($A$, $DIM=1$) has the value (1, 2, 3, 2). 1 is the subscript of the location of the first maximum value (4) in column 1; 2 is the subscript of the location of the first maximum value (1) in column 2; and so forth.

MAXLOC ($A$, $DIM=2$) has the value (1, 4, 3). 1 is the subscript of the location of the first maximum value in row 1; 4 is the subscript of the location of the first maximum value in row 2; and so forth.

MAXLOC ($A$, $DIM=2$, $BACK=\.TRUE.$) has the value (3, 4, 4). 3 is the subscript of the location of the last maximum value in row 1; 4 is the subscript of the location of the last maximum value in row 2; and so forth.

The following shows another example:

```plaintext
INTEGER  i, maxl(1), max
INTEGER array(3, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/7, 9, -1, -2, 5, 0, 3, 6, 9/), &
       (/3, 3/))
! array is  7 -2 3
!     9  5 6
!     -1  0  9
i = SIZE(SHAPE(array)) ! Get number of dimensions
! in array
```
ALLOCATE ( AR1(i))  ! Allocate AR1 to number of dimensions in array
AR1 = MAXLOC (array, MASK = array .LT. 7) ! Get the location (subscripts) of largest element less than 7 in array

! MASK = array .LT. 7 creates a mask array the same size and shape as array whose elements are .TRUE. if the corresponding element in array is less than 7, and .FALSE. if it is not. This mask causes MAXLOC to return the index of the element in array with the greatest value less than 7.

! array is 7 -2 3 and MASK=array .LT. 7 is F T T
! 9 5 6 F T T
! -1 0 9 T T F
! and AR1 = MAXLOC(array, MASK = array .LT. 7) returns (2, 3), the location of the element with value 6

maxl = MAXLOC((/1, 4, 3, 4/)) ! returns 2, the first occurrence of maximum

MAXVAL

Transformational Intrinsic Function (Generic):
Returns the maximum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax
result = MAXVAL (array [, mask])
result = MAXVAL (array, dim [, mask])

array  ! (Input) Must be an array of type integer, real, or character.
dim  ! (Input) Must be a scalar integer expression with a value in the range 1 to n, where n is the rank of array.
mask  ! (Input; optional) Must be a logical array that is conformable with array.

Results
The result is an array or a scalar of the same data type as array.
The result is a scalar if dim is not specified or array has rank one.
The following rules apply if dim is not specified:
• If \( \text{MAXVAL}( \text{array} ) \) is specified, the result has a value equal to the maximum value of all the elements in \( \text{array} \).
• If \( \text{MAXVAL}( \text{array}, \text{MASK}= \text{mask} ) \) is specified, the result has a value equal to the maximum value of the elements in \( \text{array} \) corresponding to the condition specified by \( \text{mask} \).

The following rules apply if \( \text{dim} \) is specified:

• An array result has a rank that is one less than \( \text{array} \), and shape \( (d_1, d_2, ..., d_{\text{dim}-1}, d_{\text{dim}+1}, ..., d_n) \), where \( (d_1, d_2, ..., d_n) \) is the shape of \( \text{array} \).
• If \( \text{array} \) has rank one, \( \text{MAXVAL}( \text{array}, \text{dim}[, \text{mask}] ) \) has a value equal to that of \( \text{MAXVAL}( \text{array}[, \text{MASK}= \text{mask}] ) \). Otherwise, the value of element \( (s_1, s_2, ..., s_{\text{dim}-1}, s_{\text{dim}+1}, ..., s_n) \) of \( \text{MAXVAL}( \text{array}, \text{dim}[, \text{mask}] ) \) is equal to \( \text{MAXVAL}( \text{array}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n)[, \text{MASK}= \text{mask}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n)] ) \).

If \( \text{array} \) has size zero or if there are no true elements in \( \text{mask} \), the result (if \( \text{dim} \) is omitted), or each element in the result array (if \( \text{dim} \) is specified), has the value of the negative number of the largest magnitude supported by the processor for numbers of the type and kind parameters of \( \text{array} \).

If \( \text{array} \) is of type character, the comparison is done using the ASCII collating sequence.

**Example**

The value of \( \text{MAXVAL}( (/2, 3, 4/) ) \) is 4 because that is the maximum value in the rank-one array.

\( \text{MAXVAL}( \text{B}, \text{MASK}= \text{B .LT. 0.0} ) \) finds the maximum value of the negative elements of \( \text{B} \).

\( \text{C} \) is the array

\[
\begin{bmatrix}
  2 & 3 & 4 \\
  5 & 6 & 7
\end{bmatrix}.
\]

\( \text{MAXVAL}( \text{C}, \text{DIM}=1) \) has the value \( (5, 6, 7) \). 5 is the maximum value in column 1; 6 is the maximum value in column 2; and so forth.

\( \text{MAXVAL}( \text{C}, \text{DIM}=2) \) has the value \( (4, 7) \). 4 is the maximum value in row 1 and 7 is the maximum value in row 2.

The following shows another example:

```
INTEGER array(2,3), i(2), max
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/),(/2, 3/))
! array is
!   1 5 3
!   4 2 6
i = SHAPE(array)      ! i = [2 3]
ALLOCATE (AR1(i(2)))  ! dimension AR1 to the number of
! elements in dimension 2
! (a column) of array
ALLOCATE (AR2(i(1)))  ! dimension AR2 to the number of
! elements in dimension 1
! (a row) of array
max = MAXVAL(array, MASK = array .LT. 4) ! returns 3
AR1 = MAXVAL(array, DIM = 1) ! returns [4 5 6]
AR2 = MAXVAL(array, DIM = 2) ! returns [5 6]
END
```

**See Also**

MAXLOC
MINVAL
MINLOC
**MCLOCK**

*Inquiry Intrinsic Function (Specific):* Returns time accounting for a program.

**Syntax**

\[
\text{result} = \text{MCLOCK}( )
\]

**Results**

The result type is INTEGER(4). The result is the sum (in units of milliseconds) of the current process's user time and the user and system time of all its child processes.

**MERGE**

*Elemental Intrinsic Function (Generic):* Selects between two values or between corresponding elements in two arrays, according to the condition specified by a logical mask.

**Syntax**

\[
\text{result} = \text{MERGE}(\text{tsource}, \text{fsource}, \text{mask})
\]

- \textit{tsource} (Input) May be of any data type.
- \textit{fsource} (Input) Must be of the same type and type parameters as \textit{tsource}.
- \textit{mask} (Input) Must be of type logical.

**Results**

The result type and kind are the same as \textit{tsource}. The value of \textit{mask} determines whether the result value is taken from \textit{tsource} (if \textit{mask} is true) or \textit{fsource} (if \textit{mask} is false).

**Example**

For MERGE (1.0, 0.0, R < 0), R = -3 has the value 1.0, and R = 7 has the value 0.0.

\begin{align*}
\text{TSOURCE} & \text{ is the array} \\
& [1, 3, 5]  \\
& [2, 4, 6], \\
\text{FSOURCE} & \text{ is the array} \\
& [8, 9, 0]  \\
& [1, 2, 3], \\
\text{and MASK} & \text{ is the array} \\
& [\text{T}, \text{T}, \text{T}]  \\
& [\text{T}, \text{T}, \text{F}],
\end{align*}

MERGE (TSOURCE, FSOURCE, MASK) produces the result:

\begin{align*}
[8, 3, 5]  \\
[2, 4, 3].
\end{align*}
The following shows another example:

```fortran
INTEGER tsource(2, 3), fsource(2, 3), AR1 (2, 3)
LOGICAL mask(2, 3)
tsource = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2, 3/))
fsource = RESHAPE((/7, 0, 8, -1, 9, -2/), (/2, 3/))
mask = RESHAPE((/.TRUE., .FALSE., .FALSE., .TRUE.,         &
   .TRUE., .FALSE./), (/2,3/))
! tsource is  1 2 3 , fsource is  7  8  9 , mask is  T F T
!             4 5 6               0 -1 -2            F T F
AR1 = MERGE(tsource, fsource, mask) ! returns  1 8  3
!          0 5 -2
END
```

**MERGE_BITS**

**Elemental Intrinsic Function (Generic):** Merges bits by using a mask.

**Syntax**

```fortran
result = MERGE_BITS (i,j,mask)
```

- **i**
  (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

- **j**
  (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

- **mask**
  (Input) Must be of type integer, or a binary, octal, or hexadecimal literal constant.

If both *i* and *j* are of type integer they must have the same kind type parameter. They cannot both be binary, octal, or hexadecimal literal constants.

If *mask* is of type integer, it must have the same kind type parameter as each other argument of type integer.

**Results**

The result type and kind are the same as *i* if *i* is of type integer; otherwise, the result type and kind are the same as *j*.

If any argument is a binary, octal, or hexadecimal literal constant, it is first converted as if by the intrinsic function INT to the type and kind parameter of the result. The result has the value of IOR (IAND (*i*, *mask*), IAND (*j*, NOT (*mask*))).

**Example**

MERGE_BITS (13, 18, 22) has the value 4.

**MERGEABLE Clause**

**Parallel Directive Clause:** Specifies that the implementation may generate a merged task.

**Syntax**

MERGEABLE
When the generated task is an undeferred task or an included task, it specifies that the implementation may instead generate a merged task.

When the MERGEABLE clause is present on a TASKLOOP construct, each generated task is a mergeable task.

**MESSAGE**

*General Compiler Directive:* Specifies a character string to be sent to the standard output device during the first compiler pass; this aids debugging.

**Syntax**

```
!DIR$ MESSAGE:string
```

*string* Is a character constant specifying a message.

**Example**

```
!DIR$ MESSAGE:'Compiling Sound Speed Equations'
```

**See Also**

General Compiler Directives
Syntax Rules for Compiler Directives

**MIN**

*Elemental Intrinsic Function (Generic):* Returns the minimum value of the arguments.

**Syntax**

```
result = MIN (a1,a2[,a3...])
```

*a1, a2, a3* (Input) All must have the same type (integer, real, or character) and kind parameters.

**Results**

For arguments of character type, the result type is character, and the length of the result is the length of the longest argument. For MIN0, AMIN1, DMIN1, QMIN1, JMIN0, IMIN0, and KMIN0, the result type is the same as the arguments. For MIN1, IMIN1, JMIN1, and KMIN1, the result type is integer. For AMIN0, AIMIN0, AJMIN0, and AKMIN0, the result type is real. The value of the result is that of the smallest argument. For character arguments, the comparison is done using the ASCII collating sequence. If the selected argument is shorter than the longest argument, the result is extended to the length of the longest argument by inserting blank characters on the right.

<td>REAL(16)</td>
</tr>
</tbody>
</table>

1. These specific functions cannot be passed as actual arguments.
2. Or JMIN0.
3. Or AMIN0. AMIN0 is the same as REAL (MIN).
4. In Standard Fortran, AMIN0 and MIN1 are specific functions with no generic name. For compatibility with older versions of Fortran, these functions can also be specified as generic functions.
5. Or JMIN1. MIN1 is the same as INT (MIN).
6. The setting of compiler options specifying integer size can affect MIN1.
7. The setting of compiler options specifying real size can affect AMIN1.

Example

MIN (2.0, -8.0, 6.0) has the value -8.0.
MIN (14, 32, -50) has the value -50.

The following shows another example:

```fortran
INTEGER m1, m2
REAL r1, r2
m1 = MIN (5, 6, 7)       ! returns 5
m2 = MIN1 (-5.7, 1.23, -3.8) ! returns -5
r1 = AMIN0 (-5, -6, -7)  ! returns -7.0
r2 = AMIN1(-5.7, 1.23, -3.8) ! returns -5.7
```

MINLOC
MINVAL
MAX

MINEXPONENT

**Inquiry Intrinsic Function (Generic):** Returns the minimum exponent in the model representing the same type and kind parameters as the argument.

**Syntax**

```fortran
result = MINEXPONENT (x)
```

x (Input) must be of type real; it can be scalar or array valued.
Results
The result is a scalar of type default integer. The result has the value $e_{\min}$, as defined in Model for Real Data.

Example
If X is of type REAL(4), MINEXPONENT (X) has the value -125.

The following shows another example:

```fortran
REAL(8) r1  ! DOUBLE PRECISION REAL
INTEGER i
i = MINEXPONENT (r1) ! returns - 1021.
```

See Also
MAXEXPONENT

MINLOC

Transformational Intrinsic Function (Generic):
Returns the location of the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax
```
result = MINLOC (array, dim [, mask, kind, back])
result = MINLOC (array [, mask, kind, back])
```

- **array** (Input) Must be an array of type integer, real, or character.
- **dim** (Input) Must be a scalar integer with a value in the range 1 to \(n\), where \(n\) is the rank of \(array\).
- **mask** (Input; optional) Must be a logical array that is conformable with \(array\).
- **kind** (Input; optional) Must be a scalar integer constant expression.
- **back** (Input; optional) Must be a scalar of type logical.

Results
The result is an array of type integer. If **kind** is present, the kind parameter of the result is that specified by **kind**; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rules apply if **dim** is not specified:

- The array result has rank one and a size equal to the rank of \(array\).
- If MINLOC(\(array\)) is specified, the elements in the array result form the subscript of the location of the element with the minimum value in \(array\).

  The \(i\)th subscript returned lies in the range 1 to \(e_i\), where \(e_i\) is the extent of the \(i\)th dimension of \(array\).
- If MINLOC(\(array\), MASK= mask) is specified, the elements in the array result form the subscript of the location of the element with the minimum value corresponding to the condition specified by **mask**.

The following rules apply if **dim** is specified:

- The array result has a rank that is one less than \(array\), and shape (\(d_1, d_2, \ldots d_{dim-1}, d_{dim+1}, \ldots d_n\)), where (\(d_1, d_2, \ldots d_n\)) is the shape of \(array\).
• If `array` has rank one, `MINLOC(array, dim [, mask])` is a scalar and has a value equal to the first element of `MINLOC(array [,MASK = mask])`. Otherwise, the value of element \((s_1, s_2, \ldots, s_{dim-1}, s_{dim+1}, \ldots, s_n)\) of `MINLOC(array, dim [, mask])` is equal to `MINLOC(array(s_1, s_2, \ldots, s_{dim-1}, :, s_{dim+1}, \ldots, s_n) [, MASK = mask(s_1, s_2, \ldots, s_{dim-1}, :, s_{dim+1}, \ldots, s_n)])`.

If only one element has the minimum value, that element’s subscripts are returned. Otherwise, if more than one element has the minimum value and `back` is absent or present with the value `.FALSE.`, the element whose subscripts are returned is the first such element, taken in array element order. If `back` is present with the value `.TRUE.`, the element whose subscripts are returned is the last such element, taken in array element order.

If `array` has size zero, or every element of `mask` has the value `.FALSE.`, the value of the result is controlled by compiler option `assume [no]old_maxminloc`, which can set the value of the result to either 1 or 0.

If `array` is of type character, the comparison is done using the ASCII collating sequence.

The setting of compiler options specifying integer size can affect this function.

**Example**

The value of `MINLOC ((/3, 1, 4, 1/))` is \((2)\), which is the subscript of the location of the first occurrence of the minimum value in the rank-one array.

A is the array

\[
\begin{bmatrix}
4 & 0 & 0 & 2 \\
3 & -6 & -2 & 6 \\
-1 & -4 & 5 & -4
\end{bmatrix}
\]

`MINLOC (A, MASK=A .GT. -5)` has the value \((3, 2)\) because these are the subscripts of the location of the first minimum value (-4) that is greater than -5.

`MINLOC (A, DIM=1)` has the value \((3, 2, 2, 3)\). 3 is the subscript of the location of the first minimum value (-1) in column 1; 3 is the subscript of the location of the first minimum value (-6) in column 2; and so forth.

`MINLOC (A, DIM=2)` has the value \((2, 2, 2)\). 2 is the subscript of the location of the first minimum value (0) in row 1; 2 is the subscript of the location of the first minimum value (-6) in row 2; and so forth.

`MINLOC (A, DIM=2, BACK=.TRUE.)` has the value \((3, 2, 4)\). 3 is the subscript of the location of the last minimum value (0) in row 1; 2 is the subscript of the location of the last minimum value (-6) in row 2; and so forth.

The following shows another example:

```fortran
INTEGER i, min1(1)
INTEGER array(2, 3)
INTEGER, ALLOCATABLE :: AR1(:)
! put values in array
array = RESHAPE((/-7, 1, -2, -9, 5, 0/), (/2, 3/))
! array is
!   -7  -2  5
!   1  -9  0
i = SIZE(SHAPE(array))  ! Get the number of dimensions
! in array
ALLOCATE (AR1 (i))  ! Allocate AR1 to number
! of dimensions in array
AR1 = MINLOC (array, MASK = array .GT. -5)  ! Get the
! location (subscripts) of
! smallest element greater
! than -5 in array

! MASK = array .GT. -5 creates a mask array the same
```
! size and shape as array whose elements are .TRUE. if ! the corresponding element in array is greater than ! -5, and .FALSE. if it is not. This mask causes MINLOC ! to return the index of the element in array with the ! smallest value greater than -5.
!
! array is -7 -2 5 and MASK= array .GT. -5 is F T T
! 1 -9 0 T F T
! and AR1 = MINLOC(array, MASK = array .GT. -5) returns
! (1, 2), the location of the element with value -2

minl = MINLOC((-7,2,-7,5))   ! returns 1, first
! occurrence of minimum

END

MAXLOC
MINVAL
MAXVAL
FINDLOC

MINVAL
Transformational Intrinsic Function (Generic):
Returns the minimum value of all elements in an array, a set of elements in an array, or elements in a specified dimension of an array.

Syntax
result = MINVAL (array [, mask])
result = MINVAL (array, dim [, mask])
array
(Input) Must be an array of type integer, real, or character.
dim
(Input) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array.
mask
(Input; optional) Must be a logical array that is conformable with array.

Results
The result is an array or a scalar of the same data type as array.
The result is a scalar if dim is omitted or array has rank one.
The following rules apply if dim is not specified:
• If MINVAL( array) is specified, the result has a value equal to the minimum value of all the elements in array.
• If MINVAL( array, MASK = mask) is specified, the result has a value equal to the minimum value of the elements in array corresponding to the condition specified by mask.
The following rules apply if dim is specified:
• An array result has a rank that is one less than array, and shape (d1, d2, ..., d_dim-1, d_dim+1, ..., d_n), where (d1, d2, ..., d_n) is the shape of array.
If array has rank one, \( \text{MINVAL}(\text{array}, \text{dim}, \text{mask}) \) has a value equal to that of \( \text{MINVAL}((\text{array}, \text{MASK} = \text{mask})) \). Otherwise, the value of element \((s_1, s_2, ..., s_{\text{dim}-1}, s_{\text{dim}+1}, ..., s_n)\) of \( \text{MINVAL}(\text{array}, \text{dim}, [, \text{mask}]) \) is equal to \( \text{MINVAL}(\text{array}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n) [,\text{MASK} = \text{mask}(s_1, s_2, ..., s_{\text{dim}-1}, :, s_{\text{dim}+1}, ..., s_n)]) \).

If array has size zero or if there are no true elements in mask, the result (if \( \text{dim} \) is omitted), or each element in the result array (if \( \text{dim} \) is specified), has the value of the positive number of the largest magnitude supported by the processor for numbers of the type and kind parameters of array.

If array is of type character, the comparison is done using the ASCII collating sequence.

**Example**

The value of \( \text{MINVAL}((/2, 3, 4/)) \) is 2 because that is the minimum value in the rank-one array.

The value of \( \text{MINVAL}(B, \text{MASK}=B \times 0.0) \) finds the minimum value of the positive elements of B.

C is the array

\[
\begin{bmatrix}
  2 & 3 & 4 \\
  5 & 6 & 7 \\
\end{bmatrix}.
\]

\( \text{MINVAL}(C, \text{DIM}=1) \) has the value \((2, 3, 4)\). 2 is the minimum value in column 1; 3 is the minimum value in column 2; and so forth.

\( \text{MINVAL}(C, \text{DIM}=2) \) has the value \((2, 5)\). 2 is the minimum value in row 1 and 5 is the minimum value in row 2.

The following shows another example:

```fortran
INTEGER array(2, 3), i(2), minv
INTEGER, ALLOCATABLE :: AR1(:), AR2(:)
array = RESHAPE((/1, 4, 5, 2, 3, 6/), (/2, 3/))
! array is 1 5 3
! 4 2 6
i = SHAPE(array)  ! i = [2 3]
ALLOCATE(AR1(i(2)))  ! dimension AR1 to number of
! elements in dimension 2
! (a column) of array.
ALLOCATE(AR2(i(1)))  ! dimension AR2 to number of
! elements in dimension 1
! (a row) of array
minv = \text{MINVAL}(array, \text{MASK} = \text{array} .GT. 4)  ! returns 5
AR1 = \text{MINVAL}(array, \text{DIM} = 1)  ! returns [ 1 2 3 ]
AR2 = \text{MINVAL}(array, \text{DIM} = 2)  ! returns [ 1 2 ]
END
```

MAXVAL
MINLOC
MAXLOC

**MM_PREFETCH**

*Intrinsic Subroutine (Generic)*: Prefetches data from the specified address on one memory cache line. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL MM_PREFETCH (address[,hint] [,fault] [,exclusive])
```
**address**

(Input) Is the name of a scalar or array; it can be of any type or rank. It specifies the address of the data on the cache line to prefetch.

**hint**

(Input; optional) Is an optional default integer constant with one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Prefetch Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FOR_K_PREFETCH_T 0</td>
<td>Prefetches into the L1 cache (and the L2 and the L3 cache). Use this for integer data.</td>
</tr>
<tr>
<td>1</td>
<td>FOR_K_PREFETCH_T 1</td>
<td>Prefetches into the L2 cache (and the L3 cache); floating-point data is used from the L2 cache, not the L1 cache. Use this for real data.</td>
</tr>
<tr>
<td>2</td>
<td>FOR_K_PREFETCH_T 2</td>
<td>Prefetches into the L2 cache (and the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line frequently.</td>
</tr>
<tr>
<td>3</td>
<td>FOR_K_PREFETCH_N TA</td>
<td>Prefetches into the L2 cache (but not the L3 cache); this line will be marked for early displacement. Use this if you are not going to reuse the cache line.</td>
</tr>
</tbody>
</table>

The preceding constants are defined in file `fordef.for` on Windows* systems and file `fordef.f` on Linux* and macOS* systems.

If `hint` is omitted, 0 is assumed.

**fault**

(Input; optional) Is an optional default logical constant. If .TRUE. is specified, page faults are allowed to occur, if necessary; if .FALSE. is specified, page faults are not allowed to occur. If `fault` is omitted, .FALSE. is assumed. This argument is currently ignored.
**exclusive**

(Input; optional) Is an optional default logical constant. If .TRUE. is specified, you get exclusive ownership of the cache line because you intend to assign to it; if .FALSE. is specified, there is no exclusive ownership. If exclusive is omitted, .FALSE.is assumed. This argument is currently ignored.

**Example**

```fortran
subroutine spread_lf (a, b)
PARAMETER (n = 1025)
real*8 a(n,n), b(n,n), c(n)
do j = 1,n
do i = 1,100
   a(i, j) = b(i-1, j) + b(i+1, j)
call mm_prefetch (a(i+20, j), 1)
call mm_prefetch (b(i+21, j), 1)
enddo
endo
doo
print *, a(2, 567)
stop
end
```

**MOD**

**Elemental Intrinsic Function (Generic):** Returns the remainder when the first argument is divided by the second argument.

**Syntax**

```
result = MOD (a, p)
```

- **a**
  - (Input) Must be of type integer or real.
- **p**
  - (Input) Must have the same type and kind parameters as a. It must not have a value of zero.

**Results**

The result type and kind are the same as a. If p is not equal to zero, the value of the result is a - INT(a/p) * p. If p is equal to zero, the result is undefined.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BMOD</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>IMOD¹</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>

Specific Name | Argument Type | Result Type
--- | --- | ---
1 Or HMOD. | | |
2 Or JMOD. | | |
3 The setting of compiler options specifying real size can affect AMOD and DMOD. | | |
4 The setting of compiler options specifying double size can affect DMOD. | | |

**Example**

MOD (7, 3) has the value 1.

MOD (9, -6) has the value 3.

MOD (-9, 6) has the value -3.

The following shows more examples:

```
INTEGER I
REAL R
R = MOD(9.0, 2.0) ! returns 1.0
I = MOD(18, 5) ! returns 3
I = MOD(-18, 5) ! returns -3
I = MOD(8, 5) ! returns 3
I = MOD(-8, 5) ! returns -3
I = MOD(8,-5) ! returns 3
I = MOD(-8,-5) ! returns -3
```

**See Also**

MODULO

**MODULE**

**Statement:** Marks the beginning of a module program unit, which contains specifications and definitions that can be used by one or more program units.

**Syntax**

```
MODULE name
   [specification-part]
[CONTAINS
   [module-subprogram
      [module-subprogram]... ] ]
END[ MODULE [name]]
```

*name* is the name of the module.

*specification-part* is one or more specification statements, except for the following:

- ENTRY
- FORMAT
- AUTOMATIC (or its equivalent attribute)
- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
• Statement functions

An automatic object must not appear in a specification statement.

**module-subprogram**

Is a function or subroutine subprogram that defines the module procedure. A function must end with END FUNCTION and a subroutine must end with END SUBROUTINE.

A module subprogram can contain internal procedures.

**Description**

If a name follows the END statement, it must be the same as the name specified in the MODULE statement. The module name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A module is host to any module procedures it contains, and entities in the module are accessible to the module procedures through host association.

A module must not reference itself (either directly or indirectly).

You can use the PRIVATE attribute to restrict access to procedures or variables within a module.

Although ENTRY statements, FORMAT statements, and statement functions are not allowed in the specification part of a module, they are allowed in the specification part of a module subprogram.

The following rules also apply to modules:

• The specification part of a module must not contain IMPORT, ENTRY, FORMAT, executable, or statement function statements.
• A variable, common block, or procedure pointer declared in a submodule implicitly has the SAVE attribute, which may be confirmed by explicit specification.
• If a specification or constant expression in the specification-part of a module includes a reference to a generic entity, there must be no specific procedures of the generic entity defined in the submodule subsequent to the specification or constant expression.

Any executable statements in a module can only be specified in a module subprogram.

A module can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.

A module can be extended by one or more program units called submodules. A submodule can in turn be extended by one or more submodules.

**Example**

The following example shows a simple module that can be used to provide global data:

```fortran
MODULE MOD_A
   INTEGER :: B, C
   REAL E(25,5)
END MODULE MOD_A
...
SUBROUTINE SUB_Z
   USE MOD_A               ! Makes scalar variables B and C, and array
   ...                     !   E available to this subroutine
END SUBROUTINE SUB_Z
```

1723
The following example shows a module procedure:

```fortran
MODULE RESULTS
...
CONTAINS
  FUNCTION MOD_RESULTS(X,Y)  ! A module procedure
  ...
END FUNCTION MOD_RESULTS
END MODULE RESULTS
```

The following example shows a module containing a derived type:

```fortran
MODULE EMPLOYEE_DATA
  TYPE EMPLOYEE
    INTEGER ID
    CHARACTER(LEN=40) NAME
  END TYPE
END MODULE
```

The following example shows a module containing an interface block:

```fortran
MODULE ARRAY_CALCULATOR
  INTERFACE
    FUNCTION CALC_AVERAGE(D)
      REAL :: CALC_AVERAGE
      REAL, INTENT(IN) :: D(:)
    END FUNCTION
  END INTERFACE
END MODULE
```

The following example shows a derived-type definition that is public with components that are private:

```fortran
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

This design allows you to change components of a type without affecting other program units that use the module.

If a derived type is needed in more than one program unit, the definition should be placed in a module and accessed by a USE statement whenever it is needed, as follows:

```fortran
MODULE STUDENTS
  TYPE STUDENT_RECORD
    ...
  END TYPE
CONTAINS
  SUBROUTINE COURSE_GRADE(...)
    TYPE(STUDENT_RECORD) NAME
    ...
  END SUBROUTINE
END MODULE STUDENTS
...
PROGRAM SENIOR_CLASS
  USE STUDENTS
  TYPE(STUDENT_RECORD) ID
  ...
END PROGRAM

Program SENIOR_CLASS has access to type STUDENT_RECORD, because it uses module STUDENTS. Module procedure COURSE_GRADE also has access to type STUDENT_RECORD, because the derived-type definition appears in its host.

- Separate Module Procedures

**MODULE PROCEDURE**

*Statement:* Identifies module procedures in an interface block that specifies a generic name.

**Example**

```
! A program that changes non-default integers and reals
! into default integers and reals
PROGRAM CHANGE_KIND
USE Module1
integer(2) in
integer indef
indef = DEFAULT(in)
END PROGRAM

! procedures sub1 and sub2 defined as follows:
MODULE Module1
  INTERFACE DEFAULT
    MODULE PROCEDURE Sub1, Sub2
  END INTERFACE
```
CONTAINS
  FUNCTION Sub1(y)
    REAL(8) y
    sub1 = REAL(y)
  END FUNCTION
FUNCTION Sub2(z)
  INTEGER Sub2
  INTEGER(2) z
  sub2 = INT(z)
  END FUNCTION
END MODULE

MODULO
Elemental Intrinsic Function (Generic): Returns the modulo of the arguments.

Syntax
result = MODULO (a,p)

a (Input) Must be of type integer or real.
p (Input) Must have the same type and kind parameters as a. It must not have a value of zero.

Results
The result type is the same a. The result value depends on the type of a, as follows:

- If a is of type integer and p is not equal to zero, the value of the result is \( a \ - \ \text{FLOOR}(\text{REAL}(a) / \text{REAL}(p)) \) * p, that is, the result has a value such that \( a = q \ * \ p + \text{result} \) where \( q \) is an integer. The following also applies:
  - If \( p > 0 \), then \( 0 \leq \text{result} < p \)
• If \( p < 0 \), then \( p < \text{result} <= 0 \)
• If \( a \) is of type real and \( p \) is not equal to zero, the value of the result is \( a - \text{FLOOR}(a/p) \times p \).

If \( p \) is equal to zero (regardless of the type of \( a \)), the result is undefined.

**Example**

MODULO (7, 3) has the value 1.

MODULO (9, -6) has the value -3.

MODULO (-9, 6) has the value 3.

The following shows more examples:

```
INTEGER I
REAL R
I = MODULO(8, 5) ! returns 3 Note: q=1
I = MODULO(-8, 5) ! returns 2 Note: q=-2
I = MODULO(8, -5) ! returns -2 Note: q=-2
I = MODULO(-8,-5) ! returns -3 Note: q=1
R = MODULO(7.285, 2.35) ! returns 0.2350001 Note: q=3
R = MODULO(7.285, -2.35) ! returns -2.115 Note: q=-4
```

**See Also**

MOD

**MOVE_ALLOC**

**Intrinsic Subroutine (Generic):** Moves an allocation from one allocatable object to another. **Intrinsic subroutines cannot be passed as actual arguments.**

**Syntax**

```
CALL MOVE_ALLOC (from [, to [, stat [, errmsg]])
```

- `from` (Input; output) Can be of any type, type parameters, corank, and rank; it must be allocatable.
- `to` (Output) Must be type compatible with `from` and have the same rank and corank; it must be allocatable. It must be polymorphic if `from` is polymorphic. Each nondeferred type parameter of the declared type of `to` must have the same value as the corresponding type parameter of the declared type of `from`. For more information about type compatibility, see the description in CLASS.
- `stat` (Output, optional) Must be a non-coindexed integer scalar with a decimal exponent range of at least 4 (KIND=2) or greater.
- `errmsg` (Input; output; optional) Must be a non-coindexed default character variable.

When the execution of MOVE_ALLOC is successful, or if STAT is assigned the value STAT_FAILED_IMAGE, the following occurs:

• If `to` is currently allocated, it is deallocated.
• If `from` is allocated, `to` becomes allocated with the same type, type parameters, array bounds, and values as from.
• `from` is deallocated.
If \texttt{to} has the \texttt{TARGET} attribute, any pointer associated with \texttt{from} at the time of the call to \texttt{MOVE_ALLOC} becomes correspondingly associated with \texttt{to}. If \texttt{to} does not have the \texttt{TARGET} attribute, the pointer association status of any pointer associated with \texttt{from} on entry becomes undefined.

During execution of \texttt{MOVE_ALLOC}, the internal descriptor contents are copied from \texttt{from} to \texttt{to}, so that the storage pointed to by \texttt{to} is the storage that \texttt{from} used to point to.

Typically, \texttt{MOVE_ALLOC} is used to provide an efficient way to reallocate a variable to a larger size without copying the data twice.

A reference to \texttt{MOVE_ALLOC} that has a coarray from argument has an implicit synchronization of all active images of the current team. No image proceeds until all active images of the current team have completed execution of the reference. If the current team contains any images that have stopped or failed, an error condition occurs.

If the procedure reference is successful, \texttt{stat} becomes defined with the value zero.

If an error condition occurs and \texttt{stat} is not specified, error termination is initiated. If \texttt{stat} is present and the current team contains an image that has stopped, \texttt{stat} becomes defined with the value \texttt{STAT_STOPPED_IMAGE} from the intrinsic module \texttt{ISO_FORTRAN_ENV}. Otherwise, if \texttt{stat} is present, the current team contains a failed image, and no other error condition occurs, \texttt{stat} becomes defined with the value \texttt{STAT_FAILED_IMAGE} from the intrinsic module \texttt{ISO_FORTRAN_ENV}. Otherwise, \texttt{stat} becomes defined with a positive integer value different from \texttt{STAT_STOPPED_IMAGE} and \texttt{STAT_FAILED_IMAGE}.

The definition status of \texttt{errmsg}, if present, remains unchanged if the execution of the reference is successful. If \texttt{errmsg} is present and an error condition occurs, \texttt{errmsg} becomes defined with an explanatory message describing the error.

\textbf{Example}

The following shows an example of how to increase the allocated size of \texttt{X} and keep the old values with only one copy of the old values. Using only assignment, a temporary variable named \texttt{Y} will be allocated and \texttt{X} assigned to \texttt{Y}. Then \texttt{X} will be deallocated and reallocated to be twice the size; then \texttt{Y} will be assigned to the first half of \texttt{X}. Finally, the temporary \texttt{Y} is deallocated.

```fortran
! This program uses MOVE_ALLOC to make an allocated array X bigger and
! keep the old values of X in the variable X. Only one copy of the old values
! of X is needed.
integer :: I, N = 2
real, allocatable :: X(:,), Y(:)
allocate (X(N), Y(2*N))  ! Y is twice as big as X
X = (/(/I,I=1,N)/)       ! put "old values" into X
Y = -1                   ! put different "old values" into Y
print *, ' allocated of X is ', allocated (X)
print *, ' allocated of Y is ', allocated (Y)
print *, ' old X is ', X
print *, ' old Y is ', Y
Y (1:N) = X             ! copy all of X into the first half of Y
! this is the only copying of values required
print *, ' new Y is ', Y
call move_alloc (Y, X)  ! X is now twice as big as it was, Y is
! deallocated, the values were not copied from Y to X
print *, ' allocated of X is ', allocated (X)
print *, ' allocated of Y is ', allocated (Y)
print *, ' new X is ', X
end
```
The following shows the output for the above example:

<table>
<thead>
<tr>
<th>allocated of X is T</th>
<th>allocated of Y is T</th>
</tr>
</thead>
<tbody>
<tr>
<td>old X is 1.000000</td>
<td>2.000000</td>
</tr>
<tr>
<td>old Y is -1.000000</td>
<td>-1.000000</td>
</tr>
<tr>
<td>new Y is 1.000000</td>
<td>2.000000</td>
</tr>
<tr>
<td>allocated of X is T</td>
<td>allocated of Y is T</td>
</tr>
<tr>
<td>new X is 1.000000</td>
<td>2.000000</td>
</tr>
</tbody>
</table>

ISO_FORTRAN_ENV Module

**MVBITS**

*Elemental Intrinsic Subroutine (Generic):* Copies a sequence of bits (a bit field) from one location to another. Intrinsic subroutines cannot be passed as actual arguments.

**Syntax**

```fortran
CALL MVBITS (from, frompos, len, to, topos)
```

- `from` (Input) Integer. Can be of any integer type. It represents the location from which a bit field is transferred.
- `frompos` (Input) Can be of any integer type; it must not be negative. It identifies the first bit position in the field transferred from `from`. `frompos + len` must be less than or equal to `BIT_SIZE(from)`.
- `len` (Input) Can be of any integer type; it must not be negative. It identifies the length of the field transferred from `from`.
- `to` (Input; output) Can be of any integer type, but must have the same kind parameter as `from`. It represents the location to which a bit field is transferred. `to` is set by copying the sequence of bits of length `len`, starting at position `frompos` of `from` to position `topos` of `to`. No other bits of `to` are altered.
- `topos` (Input) Can be of any integer type; it must not be negative. It identifies the starting position (within `to`) for the bits being transferred. `topos + len` must be less than or equal to `BIT_SIZE(to)`.

For more information on bit functions, see Bit Functions.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

You can also use the following specific routines:

- **BMVBITS** Arguments `from` and `to` must be INTEGER(1).
- **HMVBITS** Arguments `from` and `to` must be INTEGER(2).
- **IMVBITS** Arguments `from` and `to` must be INTEGER(2).
- **JMVBITS** Arguments `from` and `to` must be INTEGER(4).
- **KMVBITS** Arguments `from` and `to` must be INTEGER(8).
Example

If TO has the initial value of 6, its value after a call to MVBITS(7, 2, 2, TO, 0) is 5.

The following shows another example:

```
INTEGER(1) :: from = 13  ! 00001101
INTEGER(1) :: to = 6     ! 00000110
CALL MVBITS(from, 2, 2, to, 0) ! returns to = 00000111
END
```

NAMELIST

**Statement:** Associates a name with a list of variables. This group name can be referenced in some input/output operations.

**Syntax**

```
NAMELIST /group/ var-list[, ]/group/ var-list]...
```

- `group` is the name of the group.
- `var-list` is a list of variables (separated by commas) that are to be associated with the preceding group name. The variables can be of any data type.

**Description**

The namelist group name is used by namelist I/O statements instead of an I/O list. The unique group name identifies a list whose entities can be modified or transferred.

A variable can appear in more than one namelist group.

Each variable in `var-list` must be accessed by use or host association, or it must have its type, type parameters, and shape explicitly or implicitly specified in the same scoping unit. If the variable is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

You cannot specify an assumed-size array in a namelist group.

Only the variables specified in the namelist can be read or written in namelist I/O. It is not necessary for the input records in a namelist input statement to define every variable in the associated namelist.

The order of variables in the namelist controls the order in which the values appear on namelist output. Input of namelist values can be in any order.

If the group name has the PUBLIC attribute, no item in the variable list can have the PRIVATE attribute.

The group name can be specified in more than one NAMELIST statement in a scoping unit. The variable list following each successive appearance of the group name is treated as a continuation of the list for that group name.
Example

In the following example, D and E are added to the variables A, B, and C for group name LIST:

```
NAMELIST /LIST/ A, B, C
NAMELIST /LIST/ D, E
```

In the following example, two group names are defined:

```
CHARACTER*30 NAME(25)
NAMELIST /INPUT/ NAME, GRADE, DATE /OUTPUT/ TOTAL, NAME
```

Group name INPUT contains variables NAME, GRADE, and DATE. Group name OUTPUT contains variables TOTAL and NAME.

The following shows another example:

```
NAMELIST /example/ i1, l1, r4, r8, z8, z16, c1, c10, iarray
! The corresponding input statements could be:
example
i1   = 11
l1   = .TRUE.
r4   = 24.0
r8   = 28.0d0
z8   = (38.0, 0.0)
z16  = (316.0d0, 0.0d0)
c1   = 'A'
c10  = 'abcdefghij'
iarray(8) = 41, 42, 43
/```

A sample program, NAMELIST.F90, is included in the `<install-dir>/samples` subdirectory.

NARGS

*Inquiry Intrinsic Function (Specific): Returns the total number of command-line arguments, including the command. This function cannot be passed as an actual argument.*

Syntax

```
result = NARGS( )
```

Results

The result type is INTEGER(4). The result is the number of command-line arguments, including the command. For example, NARGS returns 4 for the command-line invocation of `PROG1 -g -c -a`.

Example

```
INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
```
! MYPROG.F90 responds to command switches -r, -c, 
! and/or -d
INTEGER(4) count, num, i, status
CHARACTER(80) buf
REAL r1 / 0.0 /
COMPLEX c1 / (0.0,0.0) /
REAL(8) d1 / 0.0 /

num = 5
count = NARGS()
DO i = 1, count-1
  CALL GETARG(i, buf, status)
  IF (status .lt. 0) THEN
    WRITE (*,*) 'GETARG error - exiting'
    EXIT
  END IF
  IF (buf(2:status) .EQ.'r') THEN
    r1 = REAL(num)
    WRITE (*,*) 'r1 = ', r1
  ELSE IF (buf(2:status) .EQ.'c') THEN
    c1 = CMPLX(num)
    WRITE (*,*) 'c1 = ', c1
  ELSE IF (buf(2:status) .EQ.'d') THEN
    d1 = DBLE(num)
    WRITE (*,*) 'd1 = ', d1
  ELSE
    WRITE(*,*) 'Invalid command switch: ', buf (1:status)
  END IF
END DO
END

GET_COMMAND_ARGUMENT

NEAREST

Elemental Intrinsic Function (Generic): Returns
the nearest different number (representable on the
processor) in a given direction.

Syntax
result = NEAREST (x, s)

x (Input) Must be of type real.

s (Input) Must be of type real and nonzero.

Results
The result type and kind are the same as x. The result has a value equal to the machine representable
number that is different from and nearest to x, in the direction of the infinity with the same sign as s.
Example

If 3.0 and 2.0 are REAL(4) values, NEAREST (3.0, 2.0) has the value $3 + 2^{-22}$, which equals approximately 3.0000002. (For more information on the model for REAL(4), see Model for Real Data.

The following shows another example:

```fortran
REAL(4) r1
REAL(8) r2, result
r1 = 3.0
result = NEAREST (r1, -2.0)
WRITE(*,*) result           ! writes 2.999999761581421

! When finding nearest to REAL(8), can't see
! the difference unless output in HEX
r2 = 111502.07D0
result = NEAREST(r2, 2.0)
WRITE(*,'(1x,Z16)') result  ! writes 40FB38E11EB851ED
result = NEAREST(r2, -2.0)
WRITE(*,'(1x,Z16)') result  ! writes 40FB38E11EB851EB
END
```

EPSILON

NEW_LINE

Inquiry Intrinsic Function (Generic): Returns a new line character.

Syntax

```fortran
result = NEW_LINE(a)
```

a (Input) Must be of type default character. It may be a scalar or an array.

Results

The result is a character scalar of length one with the same kind type parameter as a.

The result value is the ASCII newline character ACHAR(10).

NINT

Elemental Intrinsic Function (Generic): Returns the nearest integer to the argument.

Syntax

```fortran
result = NINT (a[,kind])
```

a (Input) Must be of type real.

kind (Input; optional) Must be a scalar integer constant expression.

Results

The result type is integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.
If \( a \) is greater than zero, \( \text{NINT}(a) \) has the value \( \text{INT}(a + 0.5) \); if \( a \) is less than or equal to zero, \( \text{NINT}(a) \) has the value \( \text{INT}(a - 0.5) \).

</tbody>
</table>

\(^1\)Or JNINT.

\(^2\)The setting of compiler options specifying integer size can affect NINT, IDNINT, and IQNINT.

\(^3\)Or JIDNNT. For compatibility with older versions of Fortran, IDNINT can also be specified as a generic function.

\(^4\)Or JIQNNT. For compatibility with older versions of Fortran, IQNINT can also be specified as a generic function.

**Example**

NINT (3.879) has the value 4.

NINT (-2.789) has the value -3.

The following shows another example:

```fortran
INTEGER(4) i1, i2
i1 = NINT(2.783) ! returns 3
i2 = IDNINT(-2.783D0) ! returns -3
```

**See Also**

ANINT
INT

**NOFREEFORM**

**Statement:** Specifies that source code is in fixed-form format.

For more information, see FREEFORM and NOFREEFORM.

**NOFUSION**

**General Compiler Directive:** Prevents a loop from fusing with adjacent loops.

**Syntax**

```fortran
!DIR$ NOFUSION
```
The NOFUSION directive lets you fine tune your program on a loop-by-loop basis. This directive should be placed immediately before the DO statement of the loop that should not be fused.

**Example**

Consider the following example that demonstrates use of the NOFUSION directive:

```fortran
subroutine sub (b,a,n)
    real a(n), b(n)
    do i=1,n
        a(i) = a(i) + b(i)
    enddo
    !DIR$ NOFUSION
    do i=1,n
        a(i) = a(i) + 1
    enddo
end
```

The following shows the same example, but it uses Standard Fortran array assignments, which allow implicit arrays:

```fortran
subroutine sub (b,a,n)
    real a(n), b(n)
    a = a + b
    !DIR$ NOFUSION
    a = a + 1
end
```

General Compiler Directives

Syntax Rules for Compiler Directives
Rules for General Directives that Affect DO Loops
Rules for Loop Directives that Affect Array Assignment Statements

**NON_RECURSIVE**

*Keyword:* Specifies that a subroutine or function does not call itself directly or indirectly.

For more information, see RECURSIVE and NON_RECURSIVE.

**NOOPTIMIZE**

*Statement:* Disables optimizations.

For more information, see OPTIMIZE and NOOPTIMIZE.

**NOPREFETCH**

*Statement:* Disables data prefetching.

For more information, see PREFETCH and NOPREFETCH.

**NORM2**

*Transformational Intrinsic Function (Generic):* Returns the L2 norm of an array.
Syntax

result = NORM2 (x)
result = NORM2 (x, dim)

x            (Input) Must be a real array.
dim          (Input) Must be a scalar integer with a value in the range 1 <= dim <= n, where n is the rank of x.

Results

The result is of the same type and kind parameters as x.
The result is a scalar if dim is not specified; otherwise, the result has rank n - 1 and shape \([d_1, d_2, ..., d_{dim-1}, d_{dim+1}, ..., d_n]\), where n is the rank of x and \([d_1, d_2, ..., d_n]\) is the shape of x.
The result of NORM2 (x) has a value equal to a processor-dependent approximation to the generalized L_2 norm of x, which is the square root of the sum of the squares of the elements of x.
The result of NORM2 (x, DIM=dim) has a value equal to that of NORM2 (x) if x has rank one.
Otherwise, the value of element \((s_1, s_2, ..., s_{dim-1}, s_{dim+1}, ..., s_n)\) of the result is equal to NORM2 \((x(s_1, s_2, ..., s_{dim-1}, :, s_{dim+1}, ..., s_n))\).
It is recommended that the processor compute the result without undue overflow or underflow.

Example

The value of NORM2 ([3.0, 4.0]) is 5.0 (approximately).
If X has the value:

\[
\begin{bmatrix}
1.0 & 2.0 \\
3.0 & 4.0
\end{bmatrix}
\]

then the value of NORM2 (X, DIM=1) is approximately [3.162, 4.472] and the value of NORM2 (X, DIM=2) is approximately [2.236,5.0].

NOSTRICT

Statement: Enables language features not found in the language standard specified on the command line.

For more information, see STRICT and NOSTRICT.

NOT

Elemental Intrinsic Function (Generic): Returns the logical complement of the argument.

Syntax

result = NOT (i)

i            (Input) Must be of type integer.
Results

The result type and kind are the same as $i$. The result value is obtained by complementing $i$ bit-by-bit according to the following truth table:

<table>
<thead>
<tr>
<th>$\text{INOT} (i)$</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BNOT</td>
<td>INTEGER(1)</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>INOT$^1$</td>
<td>INTEGER(2)</td>
<td>INTEGER(2)</td>
</tr>
<tr>
<td>JNOT</td>
<td>INTEGER(4)</td>
<td>INTEGER(4)</td>
</tr>
<tr>
<td>KNOT</td>
<td>INTEGER(8)</td>
<td>INTEGER(8)</td>
</tr>
</tbody>
</table>

$^1$Or HNOT.

Example

If $I$ has a value equal to 10101010 (base 2), \text{NOT} (I) has the value 01010101 (base 2).

The following shows another example:

```plaintext
INTEGER(2) i(2), j(2)
i = (/4, 132/)
! $i(1) = 0000000000000100$
! $i(2) = 0000000010000100$

j = NOT(i)
! returns (-5, -133)
! $j(1) = 1111111111111011$
! $j(2) = 1111111101111011$
```

\textbf{NOUNROLL}

\textit{Statement:} Disables the unrolling of a DO loop.

For more information, see UNROLL and NOUNROLL.
NOUNROLL_AND_JAM

Statement: Hints to the compiler to disable loop unrolling and jamming.

For more information, see UNROLL_AND_JAM and NOUNROLL_AND_JAM.

NOVECTOR

Statement: Disables vectorization of a DO loop.

For more information, see VECTOR and NOVECTOR.

NOWAIT Clause

Parallel Directive Clause: Specifies that threads may resume execution before the execution of the region completes.

Syntax

NOWAIT

When you specify this clause, it removes the synchronization barrier implied at the end of the region.

Note that NOWAIT can also be specified as a keyword in several directives.

At most one NOWAIT clause or keyword can appear in a directive that allows the clause or keyword.

NULL

Transformational Intrinsic Function (Generic): Initializes a pointer as disassociated when it is declared.

Syntax

result = NULL ([ mold])

mold

(Optional) Must be a pointer; it can be of any type. Its pointer association status can be associated, disassociated, or undefined. If its status is associated, the target does not have to be defined with a value.

Results

The result type and kind are the same as mold, if present; otherwise, it is determined as follows:

<table>
<thead>
<tr>
<th>If NULL ( ) Appears...</th>
<th>Type is Determined From...</th>
</tr>
</thead>
<tbody>
<tr>
<td>On the right side of pointer assignment</td>
<td>The pointer on the left side</td>
</tr>
<tr>
<td>As initialization for an object in a declaration</td>
<td>The object</td>
</tr>
<tr>
<td>As default initialization for a component</td>
<td>The component</td>
</tr>
<tr>
<td>In a structure constructor</td>
<td>The corresponding component</td>
</tr>
<tr>
<td>As an actual argument</td>
<td>The corresponding dummy argument</td>
</tr>
<tr>
<td>In a DATA statement</td>
<td>The corresponding pointer object</td>
</tr>
</tbody>
</table>
The result is a pointer with disassociated association status.

**Caution**

If you use module IFWIN or IFWINTY, you will have a name conflict if you use the NULL intrinsic. To avoid this problem, rename the integer parameter constant NULL to something else; for example:

```
USE IFWIN, NULL0 => NULL
```

This example lets you use both NULL0 and NULL( ) in the same program unit with no conflict.

**Example**

Consider the following:

```
INTEGER, POINTER :: POINT1 => NULL( )
```

This statement defines the initial association status of POINT1 to be disassociated.

**NULLIFY**

**Statement:** Disassociates a pointer from a target.

**Syntax**

```
NULLIFY (pointer-object[,pointer-object]...)
```

*pointer-object* is a structure component or the name of a variable; it must be a pointer (have the POINTER attribute).

**Description**

The initial association status of a pointer is undefined. You can use NULLIFY to initialize an undefined pointer, giving it disassociated status. Then the pointer can be tested using the intrinsic function ASSOCIATED.

**Example**

The following is an example of the NULLIFY statement:

```
REAL, TARGET :: TAR(0:50)
REAL, POINTER :: PTR_A(:), PTR_B(:)
PTR_A => TAR
PTR_B => TAR
...
NULLIFY(PTR_A)
```

After these statements are executed, PTR_A will have disassociated status, while PTR_B will continue to be associated with variable TAR.

The following shows another example:

```
! POINTER2.F90  Pointing at a Pointer and Target
!DIR$ FIXEDFORMLINESIZE:80

REAL, POINTER :: arrow1 (;)
REAL, POINTER :: arrow2 (;)
REAL, ALLOCATABLE, TARGET :: bullseye (;)

ALLOCATE (bullseye (7))
bullseye = 1.
bullseye (1:7:2) = 10.
```
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye

arrow1 => bullseye
WRITE (*,'(/1x,a,7f8.0)') 'pointer',arrow1

arrow2 => arrow1
IF (ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is pointed.'
WRITE (*,'(1x,a,7f8.0)') 'pointer',arrow2

NULLIFY (arrow2)
IF (.NOT.ASSOCIATED(arrow2)) WRITE (*,'(/a/)') ' ARROW2 is not pointed.'
WRITE (*,'(1x,a,7f8.0)') 'pointer',arrow1
WRITE (*,'(/1x,a,7f8.0)') 'target ',bullseye

END

Dynamic Allocation

NUM_IMAGES
Transformational Intrinsic Function (Generic):
Returns the number of images on the current or specified team.

Syntax
result = NUM_IMAGES()
result = NUM_IMAGES (team)
result = NUM_IMAGES (team_number)

team
(Input) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV. Fortran 2018 requires the team specified by team to be the current or an ancestor team. ifort accepts any team variable defined by a FORM TEAM statement, and will diagnose use of a team variable which does not describe the current or an ancestor team with a run-time message when the check standard-behavior compiler option is selected.

team_number
(Input) Must be an integer scalar. It must identify the initial team (-1), or a valid team number of a team created by the same execution of the FORM TEAM statement that created the current team executing the function reference (a sibling of the current team).

Results
The result type is default integer. The result is the number of images on the current or specified team.
If neither team nor team_number are specified, the team is the current team. team and team_number may not both be specified.
You can specify a compiler option or environment variable to modify the number of images. If both are specified, the environment variable setting overrides the compiler option setting.

A compiler option must be specified to enable coarrays. If it is not specified and you use this intrinsic function, an error occurs.

**Example**

In the following example, image 1 is used to read data. The other images then copy the data:

```fortran
REAL :: R[*]
IF (THIS_IMAGE()==1) THEN
  READ (7,*), R
  DO I = 2, NUM_IMAGES()
    R[I] = R
  END DO
END IF
SYNC ALL
```

---

**OBJCOMMENT**

*General Compiler Directive: Specifies a library search path in an object file.*

**Syntax**

```
!DIR$ OBJCOMMENT LIB: library
```

*library* is a character constant specifying the name and, if necessary, the path of the library that the linker is to search.

The linker searches for the library named in OBJCOMMENT as if you named it on the command line, that is, before default library searches. You can place multiple library search directives in the same source file. Each search directive appears in the object file in the order it is encountered in the source file.

If the OBJCOMMENT directive appears in the scope of a module, any program unit that uses the module also contains the directive, just as if the OBJCOMMENT directive appeared in the source file using the module.

If you want to have the OBJCOMMENT directive in a module, but do not want it in the program units that use the module, place the directive outside the module that is used.

**Example**

```fortran
! MOD1.F90
MODULE a
!DIR$ OBJCOMMENT LIB: "opengl32.lib"
END MODULE a

! MOD2.F90
!DIR$ OBJCOMMENT LIB: "graftools.lib"
```
MODULE b
! END MODULE b

! USER.F90
PROGRAM go
  USE a  ! library search contained in MODULE a
  ! included here
  USE b  ! library search not included
END

Equivalent Compiler Options

OPEN
Statement: Connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection.

Syntax
OPEN ([UNIT=] io-unit[, FILE= name] [, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var], slist)

io-unit
Is an external unit specifier.

name
Is a character or numeric expression specifying the name of the file to be connected. For more information, see FILE Specifier.

label
Is the label of the branch target statement that receives control if an error occurs. For more information, see Branch Specifiers.

msg-var
Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs. For more information, see I/O Message Specifier.

i-var
Is a scalar integer variable that is defined as a positive integer (the number of the error message) if an error occurs, a negative integer if an end-of-file record is encountered, and zero if no error occurs. For more information, see I/O Status Specifier.

slist
Is one or more of the following OPEN specifiers in the form specifier=value or specifier (each specifier can appear only once):

<table>
<thead>
<tr>
<th>ACCESS</th>
<th>DECIMAL</th>
<th>NAME</th>
<th>ROUND</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACTION</td>
<td>DEFAULTFILE</td>
<td>NEWUNIT</td>
<td>SHARE</td>
</tr>
<tr>
<td>ASSOCIATEVARIABLE</td>
<td>DELIM</td>
<td>NOSHARED</td>
<td>SHARED</td>
</tr>
<tr>
<td>ASYNCHRONOUS</td>
<td>DISPOSE</td>
<td>ORGANIZATION</td>
<td>SIGN</td>
</tr>
</tbody>
</table>
The OPEN specifiers and their acceptable values are summarized in the OPEN Statement Overview.

The control specifiers that can be specified in an OPEN statement are discussed in I/O Control List in the Language Reference.

Description

The control specifiers ([UNIT=] io-unit, ERR= label, and IOSTAT= i-var) and OPEN specifiers can appear anywhere within the parentheses following OPEN. However, if the UNIT specifier is omitted, the io-unit must appear first in the list.

If you specify BLANK=, DECIMAL=, PAD=, ROUND=, or SIGN=, you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

Specifier values that are scalar numeric expressions can be any integer or real expression. The value of the expression is converted to integer data type before it is used in the OPEN statement.

If the NEWUNIT= specifier does not appear, an io-unit must be specified. If the keyword UNIT= is omitted, the io-unit must be first in the control list.

If the NEWUNIT= specifier appears, an io-unit must not be specified.

If the NEWUNIT= specifier appears, either the FILE= specifier or the STATUS=SCRATCH specifier must also appear.

Only one unit at a time can be connected to a file, but multiple OPENs can be performed on the same unit. If an OPEN statement is executed for a unit that already exists, the following occurs:

- If FILE is not specified, or FILE specifies the same file name that appeared in a previous OPEN statement, the current file remains connected.

  If the file names are the same, the values for the BLANK, CARRIAGECONTROL, CONVERT, DELIM, DISPOSE, ERR, IOSTAT, and PAD specifiers can be changed. Other OPEN specifier values cannot be changed, and the file position is unaffected.

- If FILE specifies a different file name, the previous file is closed and the new file is connected to the unit.

The ERR and IOSTAT specifiers from any previously executed OPEN statement have no effect on any currently executing OPEN statement. If an error occurs, no file is opened or created.

Secondary operating system messages do not display when IOSTAT is specified. To display these messages, remove IOSTAT or use a platform-specific method.
Example

You can specify character values at run time by substituting a character expression for a specifier value in the OPEN statement. The character value can contain trailing blanks but not leading or embedded blanks; for example:

```fortran
CHARACTER*6 FINAL /' '/
...
IF (expr) FINAL = 'DELETE'
OPEN (UNIT=1, STATUS='NEW', DISP=FINAL)
```

The following statement creates a new sequential formatted file on unit 1 with the default file name fort.1:

```fortran
OPEN (UNIT=1, STATUS='NEW', ERR=100)
```

The following example opens the existing file /usr/users/someone/test.dat:

```fortran
OPEN (unit=10, DEFAULTFILE='/usr/users/someone/', FILE='test.dat',
1 FORM='FORMATTED', STATUS='OLD')
```

The following example opens a new file:

```fortran
! Prompt user for a filename and read it:
CHARACTER*64 filename
WRITE (*, '(A)') ' enter file to create: '
READ (*, '(A)') filename
! Open the file for formatted sequential access as unit 7.
! Note that the specified access need not have been specified,
! since it is the default (as is "formatted").
OPEN (7, FILE = filename, ACCESS = 'SEQUENTIAL', STATUS = 'NEW')
```

The following example opens an existing file called DATA3.TXT:

```fortran
! Open a file created by an editor, "DATA3.TXT", as unit 3:
OPEN (3, FILE = 'DATA3.TXT')
```

OPEN Statement Overview

OPTIONAL

Statement and Attribute: Permits dummy arguments to be omitted in a procedure reference.

Syntax

The OPTIONAL attribute can be specified in a type declaration statement or an OPTIONAL statement, and takes one of the following forms:

Type Declaration Statement:

```
type,[att-ls] OPTIONAL [, att-ls] :: d-arg[, d-arg]...
```

Statement:

```
OPTIONAL [::] d-arg[, d-arg] ...
```

```
type
```

Is a data type specifier.
Is an optional list of attribute specifiers.

d-arg

Is the name of a dummy argument.

Description

The OPTIONAL attribute can only appear in the scoping unit of a subprogram or an interface body, and can only be specified for dummy arguments. It cannot be specified for arguments that are passed by value.

A dummy argument is "present" if it associated with an actual argument that is itself present. A dummy argument that is not optional must be present. You can use the PRESENT intrinsic function to determine whether an optional dummy argument is associated with an actual argument.

To call a procedure that has an optional argument, you must use an explicit interface.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

Example

The following example shows a type declaration statement specifying the OPTIONAL attribute:

```fortran
SUBROUTINE TEST(A)
REAL, OPTIONAL, DIMENSION(-10:2) :: A
END SUBROUTINE
```

The following is an example of the OPTIONAL statement:

```fortran
SUBROUTINE TEST(A, B, L, X)
OPTIONAL :: B
INTEGER A, B, L, X
IF (PRESENT(B)) THEN        ! Printing of B is conditional
   PRINT *, A, B, L, X       ! on its presence
ELSE
   PRINT *, A, L, X
ENDIF
END SUBROUTINE

INTERFACE
   SUBROUTINE TEST(ONE, TWO, THREE, FOUR)
      INTEGER ONE, TWO, THREE, FOUR
      OPTIONAL :: TWO
   END SUBROUTINE
END INTERFACE

INTEGER I, J, K, L
I = 1
J = 2
K = 3
L = 4
CALL TEST(I, J, K, L)            ! Prints:  1  2  3  4
CALL TEST(I, THREE=K, FOUR=L)    ! Prints:  1  3  4
END
```

Note that in the second call to subroutine TEST, the second positional (optional) argument is omitted. In this case, all following arguments must be keyword arguments.
The following shows another example:

```fortran
SUBROUTINE ADD (a,b,c,d)
  REAL              a, b, d
  REAL, OPTIONAL :: c
  IF (PRESENT(c)) THEN
    d = a + b + c + d
  ELSE
    d = a + b + d
  END IF
END SUBROUTINE
```

Consider the following:

```fortran
SUBROUTINE EX (a, b, c)
  REAL, OPTIONAL :: b,c
```

This subroutine can be called with any of the following statements:

- `CALL EX (x, y, z)`  !All 3 arguments are passed.
- `CALL EX (x)`       !Only the first argument is passed.
- `CALL EX (x, c=z)`   !The first optional argument is omitted.

Note that you *cannot* use a series of commas to indicate omitted optional arguments, as in the following example:

- `CALL EX (x,,z)`   !Invalid statement.

This results in a compile-time error.

- Compatible attributes

**OPTIMIZE and NOOPTIMIZE**

**General Compiler Directive:** Enables or disables optimizations for the program unit.

**Syntax**

```fortran
!DIR$ OPTIMIZE[: n]
!DIR$ NOOPTIMIZE
```

`n` is the number denoting the optimization level. The number can be 0, 1, 2, or 3, which corresponds to compiler options O0, O1, O2, and O3. If `n` is omitted, the default is 2, which corresponds to option O2.

The OPTIMIZE and NOOPTIMIZE directives can only appear once at the top of a procedure program unit. A procedure program unit is a main program, an external subroutine or function, or a module. OPTIMIZE and NOOPTIMIZE cannot appear between program units or in a block data program unit. They do not affect any modules invoked with the USE statement in the program unit that contains them. They do affect CONTAINed procedures that do not include an explicit OPTIMIZE or NOOPTIMIZE directive.

NOOPTIMIZE is the same as OPTIMIZE:0. They are both equivalent to `-O0` (Linux* and macOS*) and `/Od` (Windows*).}

1746
The procedure is compiled with an optimization level equal to the smaller of \( n \) and the optimization level specified by the O compiler option on the command line. For example, if the procedure contains the directive NOOPTIMIZE and the program is compiled with compiler option O3, this procedure is compiled at O0 while the rest of the program is compiled at O3.

See Also
General Compiler Directives
Syntax Rules for Compiler Directives
O compiler option

OPTIONS Directive
General Compiler Directive: Affects data alignment and warnings about data alignment. Also controls whether a target attribute is assigned to a section of program declarations.

Syntax

```plaintext
!DIR$ OPTIONS option[option]
...
!DIR$ END OPTIONS
```

Is one (or more) of the following:

- `/WARN=[NO]ALIGNMENT` Controls whether warnings are issued by the compiler for data that is not naturally aligned. By default, you receive compiler messages when misaligned data is encountered (`/WARN=ALIGNMENT`).

- `/[NO]ALIGN[= p]` Controls alignment of fields in record structures and data items in common blocks. The fields and data items can be naturally aligned (for performance reasons) or they can be packed together on arbitrary byte boundaries.

\( p \) Is a specifier with one of the following forms:

- `[class=]rule`
- `(class= rule,...)`
- ALL
- NONE

\( class \) Is one of the following keywords:
- COMMONS: For common blocks
- RECORDS: For records
• **STRUCTURES:**
  A synonym for RECORDS

**rule**
Is one of the following keywords:

- **PACKED**
Packs fields in records or data items in common blocks on arbitrary byte boundaries.

- **NATURAL**
Naturally aligns fields in records and data items in common blocks on up to 64-bit boundaries (inconsistent with the Standard Fortran). This keyword causes the compiler to naturally align all data in a common block, including INTEGER(KIND=8), REAL(KIND=8),
and all COMPLEX data.

Naturally aligns data items in common blocks on up to 32-bit boundaries (consistent with the Standard Fortran).

This keyword only applies to common blocks; so, you can specify / ALIGN=COMMONS=STANDARD, but you cannot specify / ALIGN=STANDARD.

ALL

Is the same as specifying OPTIONS / ALIGN, OPTIONS / ALIGN=NATURAL, and OPTIONS / ALIGN=(RECORDS=NATURAL,COMMONS=NATURAL).
The OPTIONS (and accompanying END OPTIONS) directives must come after OPTIONS, SUBROUTINE, FUNCTION, and BLOCK DATA statements (if any) in the program unit, and before the executable part of the program unit.

The OPTIONS directive supersedes the compiler option `align`.

For performance reasons, Intel® Fortran aligns local data items on natural boundaries. However, EQUIVALENCE, COMMON, RECORD, and STRUCTURE data declaration statements can force misaligned data. If `/WARN=NOALIGNMENT` is specified, warnings will not be issued if misaligned data is encountered.

**NOTE**

Misaligned data significantly increases the time it takes to execute a program. As the number of misaligned fields encountered increases, so does the time needed to complete program execution. Specifying `/ALIGN` (or compiler option `align`) minimizes misaligned data.

If you want aligned data in common blocks, do one of the following:

- Specify `OPTIONS /ALIGN=COMMONS=STANDARD` for data items up to 32 bits in length.
- Specify `OPTIONS /ALIGN=COMMONS=NATURAL` for data items up to 64 bits in length.
- Place source data declarations within the common block in descending size order, so that each data item is naturally aligned.

If you want packed, unaligned data in a record structure, do one of the following:

- Specify `OPTIONS /ALIGN=RECORDS=PACKED`.
- Place source data declarations in the record structure so that the data is naturally aligned.

**Example**

Consider the following:

```
! directives can be nested up to 100 levels
!DIR$ OPTIONS /ALIGN=PACKED     ! Start of Group A
    declarations
!DIR$ OPTIONS /ALIGN=RECO=NATU  ! Start of nested Group B
    more declarations
!DIR$ END OPTIONS        ! End of Group B
    still more declarations
!DIR$ END OPTIONS       ! End of Group A
```

The OPTIONS specification for Group B only applies to RECORDS; common blocks within Group B will be PACKED. This is because COMMONS retains the previous setting (in this case, from the Group A specification).

<td></td>
</tr>
<tr>
<td>/[NO]I4</td>
<td></td>
</tr>
<tr>
<td>/[NO]RECURSIVE</td>
<td></td>
</tr>
</tbody>
</table>

Note that an option must always be preceded by a slash (/).
Some OPTIONS statement options are equivalent to compiler options.

The OPTIONS statement must be the first statement in a program unit, preceding the PROGRAM, SUBROUTINE, FUNCTION, MODULE, and BLOCK DATA statements.
OPTIONS statement options override compiler options, but only until the end of the program unit for which they are defined. If you want to override compiler options in another program unit, you must specify the OPTIONS statement before that program unit.
Example

The following are valid OPTIONS statements:

```fortran
OPTIONS /CHECK=ALL/F77
OPTIONS /I4
```

See Also

OPEN Statement CONVERT Method
OPTIONS Statement Method

For details on compiler options, see your Compiler Options reference

OR

**Elemental Intrinsic Function (Generic):** Performs a bitwise inclusive OR on its arguments.

See [IOR](#).

Example

```fortran
INTEGER i
i = OR(3, 10)  ! returns 11
```

ORDERED

**OpenMP** Fortran Compiler Directive: Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations, or, as a stand-alone directive, it specifies cross-iteration dependences in a doacross loop nest.

Syntax

It takes one of the following forms:

**Form 1:**

```fortran
!$OMP ORDERED [clause [,] clause ]
   loosely-structured-block
!$OMP END ORDERED
-or-
!$OMP ORDERED [clause [,] clause ]
   strictly-structured-block
!$OMP END ORDERED
```

**Form 2:**

```fortran
!$OMP ORDERED clause [[,] clause ]...
```

Form 1 clause Is an optional clause. It can be one of the following:

- SIMD [keyword [, keyword]...]
  Applies an ordered region inside a SIMD loop. Possible values are:
  - MONOTONIC (list [: linear-step ] )
The list is a comma-separated list of one or more integer scalar variables. The linear-step is a positive, integer, scalar constant expression. The linear-step expression must be invariant (it must not be changed) during the execution of the associated construct. If linear-step is omitted, a default value of 1 is used.

Multiple MONOTONIC keywords may appear; they are merged into a single MONOTONIC list. You cannot specify multiple MONOTONIC keywords with different linear-steps for the same variable.

Each list item may have the POINTER attribute but not the ALLOCATABLE attribute. Each list item must comply with PRIVATE clause semantics.

- **OVERLAP (expr)**

  The expr is an integer expression. It specifies a block of code that has to be executed in scalar mode for overlapping loop index values and in parallel for different loop index values within the SIMD loop.

  The OVERLAP keyword can appear no more than once in an ORDERED directive.

- **THREADS**

  Applies an ordered region inside a PARALLEL DO loop. If no clause is specified, the directive behaves as if THREADS was specified.

  At most one THREADS clause can appear in an ORDERED construct. At most one SIMD clause can appear in an ORDERED construct.

Form 2 clause

Is one of the following:

- **DEPEND (SOURCE)**
- **DEPEND (SINK : vec)**

  At most one DEPEND (SOURCE) clause can appear on an ORDERED construct.

  Either DEPEND (SINK : vec) clauses or DEPEND (SOURCE) clauses can appear in an ORDERED construct, but not both.

- **loosely-structured-block**

  Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

- **strictly-structured-block**

  Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding thread set for an ORDERED construct is the current team. An ordered region binds to the innermost enclosing loop region or the innermost enclosing SIMD region if the SIMD clause is present.

A doacross loop nest is a loop nest that has cross-iteration dependences. An iteration is dependent on one or more lexicographically earlier iterations. The ORDERED clause parameter on a loop directive identifies the loops associated with the doacross loop nest.

An ORDERED directive with no clause or with the THREADS clause specified can appear only in the dynamic extent of a DO or PARALLEL DO directive. The DO directive to which the ordered section binds must have the ORDERED clause specified.

An iteration of a loop using a DO directive must not execute the same ORDERED directive more than once, and it must not execute more than one ORDERED directive.
One thread is allowed in an ordered section at a time. Threads are allowed to enter in the order of the loop iterations. No thread can enter an ordered section until it can be guaranteed that all previous iterations have completed or will never execute an ordered section. This sequentializes and orders code within ordered sections while allowing code outside the section to run in parallel.

Ordered sections that bind to different DO directives are independent of each other.

If the SIMD clause is specified, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

You can only specify the SIMD clause (!$OMP ORDERED SIMD) within an !$OMP SIMD loop or an !$OMP DECLARE SIMD procedure.

When a thread executing any subsequent iteration encounters an ORDERED construct with one or more DEPEND (SINK : vec) clauses, it waits until its dependences on all valid iterations specified by the DEPEND clauses are satisfied before it completes execution of the ORDERED region. A specific dependence is satisfied when a thread executing the corresponding iteration encounters an ORDERED construct with a DEPEND (SOURCE) clause.

For MONOTONIC (list : linear-step), the following rules apply:

- The value of the new list item on each iteration of the associated SIMD loop corresponds to the value of the original list item before entering the associated loop, plus the number of the iterations for which the conditional update happens prior to the current iteration, times linear-step.
- The value corresponding to the sequentially last iteration of the associated loop is assigned to the original list item.
- A list item must not be used in statements that lexically precede the ORDERED SIMD to which it is bound, that is, in the region from the OMP SIMD to the OMP ORDERED SIMD. A list item must not be modified outside the ORDERED SIMD to which it is bound, that is, in the region from the OMP END ORDERED to the OMP END SIMD.

Example

Ordered sections are useful for sequentially ordering the output from work that is done in parallel. Assuming that a reentrant I/O library exists, the following program prints out the indexes in sequential order:

```fortran
!$OMP DO ORDERED SCHEDULE(DYNAMIC)
DO I=LB,UB,ST
   CALL WORK(I)
END DO
...
SUBROUTINE WORK(K)
   !$OMP ORDERED
   WRITE(*,*) K
   !$OMP END ORDERED
!$OMP END ORDERED
```

Ordered SIMD sections are useful for resolving cross-iteration data dependencies in otherwise data-parallel computations. For example, it may handle histogram updates such the following:

```fortran
!$OMP SIMD
DO I=0,N
   AMOUNT = COMPUTE_AMOUNT(I)
   CLUSTER = COMPUTE_CLUSTER(I)  ! Multiple I’s may belong to the same cluster within SIMD chunk
   !$OMP ORDERED SIMD
   TOTALS(CLUSTER) = TOTALS(CLUSTER) + AMOUNT  ! Requires ordering to process multiple updates to the same cluster
   !$OMP END ORDERED SIMD
END DO
!$OMP END SIMD
```
The MONOTONIC keyword on the OMP ORDERED SIMD directive specifies that the body of a loop must be executed in the natural order of the loop iterations. In the following example, the block of code in the OMP ORDERED SIMD is executed in the ascending, monotonic order of the loop index \( I \):

```fortran
COUNT = 0
!$OMP SIMD
DO I = 1, N
   IF (COND(I)) THEN
      !$OMP ORDERED SIMD MONOTONIC (COUNT:1)
      A(COUNT) = A(COUNT) + B(I)
      COUNT = COUNT + 1
      B(I) = C(COUNT)
   !$OMP END ORDERED
   END IF
END DO
!$OMP END SIMD
```

In the following example, the OVERLAP keyword specifies that the block of code after the OMP ORDERED SIMD directive may contain overlap between the loop iterations:

```fortran
!$OMP SIMD
DO I = 1, N
   INX = INDEX(I)
   !$OMP ORDERED SIMD OVERLAP (INX)
   A(INX) = A(INX) + B(I)
   !$OMP END ORDERED
END DO
!$OMP END SIMD
```

OUT_OF_RANGE

**Elemental Intrinsic Function (Generic):** Indicates if a value can be safely converted to a specified type.

**Syntax**

```
result = OUT_OF_RANGE (value, mold [, round])
```

- **value** (Input) Must be of type integer or real.
- **mold** (Input) Must be a scalar of type real or integer. It need not be defined if it is a variable.
- **round** (Input; optional) Must be a scalar logical. round can only be present if value is type real and mold is type integer.

**Results**

The result type is default logical.

If round is not present or has the value .false., and mold is an integer type, the result is .true. if value is a NaN or an IEEE infinity, or if the integer with the largest magnitude between zero and value (inclusively) is not representable by an object with the type and kind of mold.
If `round` has the value `.true.` and `mold` is an integer type, the result is `.true.` if `value` is a NaN or an IEEE infinity, or if the integer value nearest `value`, or the integer of greater magnitude if the two integers are equally near `value`, is not representable by an object with the type and kind of `mold`.

Otherwise, the result is `.true.` if `value` is a NaN or IEEE infinity that is not supported by an object of type and kind of `mold`, or X is a finite number and the result of rounding value to the extended model for the kind of `mold` has a magnitude larger than that of the largest finite number with the same size as `value` that can be represented by objects with the type and kind of `mold`.

**Example**

If `J8` is a variable with type INTEGER (KIND=1), `OUT_OF_RANGE (-128.5, J8)` will have the result `.false.` and `OUT_OF_RANGE (-128.5, J8, .TRUE.)` will have the value `.true.`.

**PACK Directive**

**General Compiler Directive:** Specifies the memory alignment of derived-type items (and record structure items).

**Syntax**

```fortran
!DIR$ PACK[: {1 | 2 | 4 | 8} ]
```

Items of derived types, unions, and structures are aligned in memory on the smaller of two sizes: the size of the type of the item, or the current alignment setting. The current alignment setting can be 1, 2, 4, or 8 bytes. The default initial setting is 8 bytes (unless compiler option vms or align rec n bytes is specified). By reducing the alignment setting, you can pack variables closer together in memory.

The PACK directive lets you control the packing of derived-type or record structure items inside your program by overriding the current memory alignment setting.

For example, if PACK:1 is specified, all variables begin at the next available byte, whether odd or even. Although this slightly increases access time, no memory space is wasted. If PACK:4 is specified, INTEGER(1), LOGICAL(1), and all character variables begin at the next available byte, whether odd or even. INTEGER(2) and LOGICAL(2) begin on the next even byte; all other variables begin on 4-byte boundaries.

If the PACK directive is specified without a number, packing reverts to the compiler option setting (if any), or the default setting of 8.

The directive can appear anywhere in a program before the derived-type definition or record structure definition. It cannot appear inside a derived-type or record structure definition.

**Example**

```fortran
! Use 4-byte packing for this derived type
! Note PACK is used outside of the derived type definition
!DIR$ PACK:4
TYPE pair
    INTEGER a, b
END TYPE
! revert to default or compiler option
!DIR$ PACK
```

vms compiler option
Equivalent Compiler Options

**PACK Function**

*Transformational Intrinsic Function (Generic):*
*Takes elements from an array and packs them into a rank-one array under the control of a mask.*

**Syntax**

\[
\text{result} = \text{PACK}(\text{array}, \text{mask}[, \text{vector}])
\]

- **array**
  - (Input) Must be an array. It may be of any data type.

- **mask**
  - (Input) Must be of type logical and conformable with *array*. It determines which elements are taken from *array*.

- **vector**
  - (Input; optional) Must be a rank-one array with the same type and type parameters as *array*. Its size must be at least \( t \), where \( t \) is the number of true elements in *mask*. If *mask* is a scalar with value true, *vector* must have at least as many elements as there are in *array*.

  Elements in *vector* are used to fill out the result array if there are not enough elements selected by *mask*.

**Results**

The result is a rank-one array with the same type and kind parameters as *array*. If *vector* is present, the size of the result is that of *vector*. Otherwise, the size of the result is the number of true elements in *mask*, or the number of elements in *array* (if *mask* is a scalar with value true).

Elements in *array* are processed in array element order to form the result array. Element \( i \) of the result is the element of *array* that corresponds to the \( i \)th true element of *mask*. If *vector* is present and has more elements than there are true values in *mask*, any result elements that are empty (because they were not true according to *mask*) are set to the corresponding values in *vector*.

**Example**

N is the array

\[
\begin{bmatrix}
0 & 8 & 0 \\
0 & 0 & 0 \\
7 & 0 & 0 \\
\end{bmatrix}
\]

PACK (N, MASK=N .NE. 0, VECTOR= (/1, 3, 5, 9, 11, 13/)) produces the result (7, 8, 5, 9, 11, 13).

PACK (N, MASK=N .NE. 0) produces the result (7, 8).

The following shows another example:

```plaintext
INTEGER array(2, 3), vec1(2), vec2(5)
LOGICAL mask (2, 3)
array = RESHAPE((/7, 0, 0, -5, 0, 0/), (/2, 3/))
mask = array .NE. 0
! array is  7  0 0  and mask is  T F F
!                0 -5 0               F T F
VEC1 = PACK(array, mask)  ! returns ( 7, -5 )
VEC2 = PACK(array, array .GT. 0, VECTOR= (/1,2,3,4,5/))
! returns ( 7, 2, 3, 4, 5 )
```
PORTABILITY Subroutine: Packs time and date values.

Module
USE IFPORT

Syntax
CALL PACKTIMEQQ (timedate, iyr, imon, iday, ihr,imin, isec)

timedate (Output) INTEGER(4). Packed time and date information.
iyr (Input) INTEGER(2). Year (xxxxAD).
imon (Input) INTEGER(2). Month (1 - 12).
iday (Input) INTEGER(2). Day (1 - 31)
ihr (Input) INTEGER(2). Hour (0 - 23)
imin (Input) INTEGER(2). Minute (0 - 59)
isec (Input) INTEGER(2). Second (0 - 59)

The input values are interpreted as being in the time zone set on the local computer and following the daylight savings rules for that time zone.

The packed time is the number of seconds since 00:00:00 Greenwich mean time, January 1, 1970. Because packed time values can be numerically compared, you can use PACKTIMEQQ to work with relative date and time values. Use UNPACKTIMEQQ to unpack time information. SETFILETIMEQQ uses packed time.

Example
USE IFPORT
INTEGER(2) year, month, day, hour, minute, second, &
    hund
INTEGER(4) timedate
CALL GETDAT (year, month, day)
CALL GETTIM (hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, hour, &
    minute, second)
END

PARALLEL Directive (OpenMP* API)
OpenMP* Fortran Compiler Directive: Defines a parallel region.
Syntax

```
!$OMP PARALLEL [clause[ [, ] clause] ... ]
        loosely-structured-block
!$OMP END PARALLEL
-or-
!$OMP PARALLEL [clause[ [, ] clause] ... ]
        strictly-structured-block
!$OMP END PARALLEL
```

`clause` is one or more of the following:

- `ALLOCATE ([allocator :] list)`
- `COPYIN (list)`
- `DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)`
- `FIRSTPRIVATE (list)`
- `IF ([PARALLEL:] scalar-logical-expression)`
- `NUM_THREADS ( scalar_integer_expression)`
  Specifies the number of threads to be used in a parallel region. The `scalar_integer_expression` must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive.
- `PRIVATE (list)`
- `PROC_BIND (PRIMARY | MASTER | CLOSE | SPREAD)`
  Specifies a method for mapping the threads in the team to the "places" in the current partition.
  Once a thread is assigned to a place, the OpenMP* implementation should not move it to another place.
  PRIMARY instructs the execution environment to assign every thread in the team to the same place as the primary thread. MASTER has been deprecated and replaced by PRIMARY. CLOSE instructs the execution environment to assign the threads to places close to the place of the parent thread. SPREAD creates a sparse distribution for a team of T threads among the P places of the parent's place partition.
  For CLOSE and SPREAD, the threads with the smallest numbers are assigned starting with the place of the primary thread. For CLOSE, threads are packed into consecutive places within the parent's partition. For SPREAD, the partition of the primary thread is subdivided and threads in the team are assigned round-robin to those subpartitions.
  Only a single PROC_BIND clause can appear in the directive.
- `REDUCTION (reduction-identifier : list)`
- `SHARED (list)`

`loosely-structured-block` is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

`strictly-structured-block` is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.
The PARALLEL and END PARALLEL directive pair must appear in the same routine in the executable section of the code.

The END PARALLEL directive denotes the end of the parallel region. There is an implied barrier at this point. Only the primary thread of the team continues execution at the end of a parallel region.

The number of threads in the team can be controlled by the NUM_THREADS clause, the environment variable OMP_NUM_THREADS, or by calling the run-time library routine OMP_SET_NUM_THREADS from a serial portion of the program.

NUM_THREADS supersedes the OMP_SET_NUM_THREADS routine, which supersedes the OMP_NUM_THREADS environment variable. Subsequent parallel regions, however, are not affected unless they have their own NUM_THREADS clauses.

Once specified, the number of threads in the team remains constant for the duration of that parallel region.

If the dynamic threads mechanism is enabled by an environment variable or a library routine, then the number of threads requested by the NUM_THREADS clause is the maximum number to use in the parallel region.

The code contained within the dynamic extent of the parallel region is executed on each thread, and the code path can be different for different threads.

If a thread executing a parallel region encounters another parallel region, it creates a new team and becomes the primary thread of that new team. By default, nested parallel regions are always serialized and executed by a team of one thread.

**Example**

You can use the PARALLEL directive in coarse-grain parallel programs. In the following example, each thread in the parallel region decides what part of the global array X upon which to work based on the thread number:

```fortran
!$OMP PARALLEL DEFAULT(PRIVATE) SHARED(X,NPOINTS)
   IAM = OMP_GET_THREAD_NUM( )
   NP = OMP_GET_NUM_THREADS( )
   IPOINTS = NPOINTS/NP
   CALL SUBDOMAIN(X,IAM,IPOINTS)
!$OMP END PARALLEL
```

Assuming you previously used the environment variable OMP_NUM_THREADS to set the number of threads to six, you can change the number of threads between parallel regions as follows:

```fortran
CALL OMP_SET_NUM_THREADS(3)
!$OMP PARALLEL
...
!$OMP END PARALLEL
CALL OMP_SET_NUM_THREADS(4)
!$OMP PARALLEL DO
...
!$OMP END PARALLEL DO
```

PARALLEL and NOPARALLEL Loop Directives

**General Compiler Directives:** PARALLEL facilitates auto-parallelization by assisting the compiler’s dependence analysis of the immediately following DO loop. NOPARALLEL prevents this auto-parallelization.

**Syntax**

```
!DIR$ PARALLEL [clause[,] clause] ... 

!DIR$ NOPARALLEL
```

**clause**

Is one or more of the following:

- **ALWAYS [ASSERT]**
- **FIRSTPRIVATE (list)**
  - Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, private (local) copies of each variable in the different iterations are initialized to the value the variable had upon entering the parallel loop.
- **LASTPRIVATE (list)**
  - Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, once the parallel loop is exited, each variable has the value that resulted from the sequentially last iteration of the parallel loop.
- **NUM_THREADS (scalar_integer_expression)**
  - Specifies the number of threads to be used to parallelize the immediately following DO loop. The `scalar_integer_expression` must evaluate to a positive scalar integer value. Only a single NUM_THREADS clause can appear in the directive. Once specified, the number of threads used remains constant for the duration of that parallelized DO loop.
- **PRIVATE (list)**
  - Declares specified variables to be private to each thread in a team. The declared variables become private to a task.

**list**

Is one or more items in the form: `var [:expr]...`. Each list item must be separated by a comma.

**var**

Is a scalar or array variable. The following rules apply:

- Assumed-size arrays cannot appear in a PRIVATE clause.
- A variable that is part of another variable (for example, as an array or structure element) cannot appear in a PRIVATE clause.
- A variable that appears in a PRIVATE clause must either be definable, or an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
- Variables that appear in namelist statements, in variable format expressions, and in expressions for statement function definitions, cannot appear in a PRIVATE clause.
expr

Is an integer expression denoting the number of array elements to privatize. When expr is specified, var must be an array or a pointer variable. The following rules also apply:

- If var is an array, then only its first expr elements are privatized. If expr is omitted, the entire array is privatized.
- If var is a pointer, then the first expr elements are privatized (element size is provided by the pointer’s target type). If expr is omitted, only the pointer variable itself is privatized.
- Program behavior is undefined if expr evaluates to a non-positive value, or if it exceeds the array size.

PARALLEL helps the compiler to resolve dependencies, facilitating auto-parallelization of the immediately following DO loop. It instructs the compiler to ignore dependencies that it assumes may exist and which would prevent correct parallelization in the loop. However, if dependencies are proven, they are not ignored.

In addition, PARALLEL ALWAYS overrides the compiler heuristics that estimate the likelihood that parallelization of a loop will increase performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the ASSERT keyword is added, the compiler will generate an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

NOPARALLEL prevents auto-parallelization of the immediately following DO loop.

These directives take effect only if you specify the compiler option that enables auto-parallelization.

Caution
The directive PARALLEL ALWAYS should be used with care. Overriding the heuristics of the compiler should only be done if you are absolutely sure the parallelization will improve performance.

Example

```fortran
program main
parameter (n=100)
integer x(n), a(n), k
!DIR$ NOPARALLEL
  do i=1,n
    x(i) = i
  enddo
!DIR$ PARALLEL LASTPRIVATE (k)
  do i=1,n
    a( x(i) ) = i
    k = x(i)
  enddo
print *, k  ! print 100, the value of x(n)
end
```

General Compiler Directives

Syntax Rules for Compiler Directives
Rules for General Directives that Affect DO Loops
Rules for Loop Directives that Affect Array Assignment Statements
PARALLEL DO

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single DO directive.

Syntax

```fortran
!$OMP PARALLEL DO [clause[,] clause] ... ]
  do-loop
[$OMP END PARALLEL DO]
clause
  Can be any of the clauses accepted by the DO or PARALLEL directives.
do-loop
  Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.
  You cannot branch out of a DO loop associated with a DO directive.

If the END PARALLEL DO directive is not specified, the PARALLEL DO is assumed to end with the DO loop that immediately follows the PARALLEL DO directive. If used, the END PARALLEL DO directive must appear immediately after the end of the DO loop.

The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a DO directive.

Example

In the following example, the loop iteration variable is private by default and it is not necessary to explicitly declare it. The END PARALLEL DO directive is optional:

```fortran
!$OMP PARALLEL DO
  DO I=1,N
    B(I) = (A(I) + A(I-1)) / 2.0
  END DO
!$OMP END PARALLEL DO
```

The following example shows how to use the REDUCTION clause in a PARALLEL DO directive:

```fortran
!$OMP PARALLEL DO DEFAULT(PRIVATE) REDUCTION(+: A,B)
  DO I=1,N
    CALL WORK(ALOCAL,BLOCAL)
    A = A + ALOCAL
    B = B + BLOCAL
  END DO
!$OMP END PARALLEL DO
```

See Also

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: Specifies a PARALLEL construct that contains one DO SIMD construct and no other statement.
Syntax

!$OMP PARALLEL DO SIMD [clause[,] clause] ... ]
  do-loop
[!$OMP END PARALLEL DO SIMD]

clause

Can be any of the clauses accepted by the PARALLEL, DO, or SIMD directives.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END PARALLEL DO SIMD directive is not specified, an END PARALLEL DO SIMD directive is assumed at the end of do-loop.

You cannot specify NOWAIT in a PARALLEL DO SIMD directive.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARALLEL LOOP

OpenMP* Fortran Compiler Directive: Specifies a shortcut for indicating that a loop or loop nest can execute concurrently across multiple threads. This feature is only available for ifx.

Syntax

!$OMP PARALLEL LOOP [clause[,] clause]... ]
  do-loop
[!$OMP END PARALLEL LOOP]

clause

Can be any of the clauses accepted by the PARALLEL or LOOP directives with identical meanings and restrictions.

do-loop

Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical form. The DO loop iteration variable must be of type integer.

This combined directive is semantically equivalent to a LOOP construct that immediately follows a PARALLEL directive. All restrictions for PARALLEL and LOOP constructs apply to this combined construct.
If used, the END PARALLEL LOOP directive must appear immediately after the end of the loop. If you do not specify an END PARALLEL LOOP directive, an END PARALLEL LOOP directive is assumed at the end of the do-loop.

LOOP construct

PARALLEL MASKED
OpenMP* Fortran Compiler Directive: Creates a PARALLEL construct containing a MASKED construct, with no Fortran statements in the PARALLEL construct which are not also in the MASKED construct. This feature is only available for ifx.

Syntax

```fortran
!$OMP PARALLEL MASKED [clause[, clause]...] 
   loosely-structured-block
!$OMP END PARALLEL MASKED
-or-

!$OMP PARALLEL MASKED [clause[, clause]...] 
   strictly-structured-block
!$OMP END PARALLEL MASKED
```

**clause** Can be any of the clauses accepted by the PARALLEL or MASKED directives with identical meanings and restrictions.

**loosely-structured-block** Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

**strictly-structured-block** Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASKED construct nested inside of it. The semantics are identical to a MASKED construct specified immediately after a PARALLEL construct; the only Fortran statements in the construct are inside the block.

All restrictions for PARALLEL and MASKED constructs apply to this combined construct.

See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

MASKED directive
PARALLEL MASKED TASKLOOP

**OpenMP Fortran Compiler Directive:** Creates a PARALLEL construct containing a MASKED TASKLOOP construct, with no Fortran statements in the PARALLEL construct that are not also in the MASKED TASKLOOP construct. This feature is only available for ifx.

**Syntax**

```fortran
!$OMP PARALLEL MASKED TASKLOOP [clause[, clause]... ]

  loop-nest

[!$OMP END PARALLEL MASKED TASKLOOP]
```

- `clause`: Can be any of the clauses accepted by the PARALLEL or MASKED TASKLOOP directives with identical meanings and restrictions.
- `loop-nest`: Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASKED TASKLOOP construct nested inside of it. The semantics are identical to a MASKED TASKLOOP construct specified immediately after a PARALLEL construct.

All restrictions for PARALLEL and MASKED TASKLOOP constructs apply to this combined construct.

**See Also**

**PARALLEL MASTER**

*OpenMP* Fortran Compiler Directive:
(Deprecated; see PARALLEL MASKED) Creates a PARALLEL construct containing a MASTER construct, with no Fortran statements in the PARALLEL construct that are not also in the MASTER construct. This feature is only available for ifx.

**Syntax**

```fortran
!$OMP PARALLEL MASTER [clause[[,] clause]... ]
    loosely-structured-block
!$OMP END PARALLEL MASTER
-or-
!$OMP PARALLEL MASTER [clause[[,] clause]... ]
    strictly-structured-block
!$OMP END PARALLEL MASTER
```

*clause* Can be any of the clauses accepted by the PARALLEL or MASTER directives with identical meanings and restrictions.

*loosely-structured-block* Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

*strictly-structured-block* Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASTER construct nested inside of it. The semantics are identical to a MASTER construct specified immediately after a PARALLEL construct; the only Fortran statements in the construct are inside block.

All restrictions for PARALLEL and MASTER constructs apply to this combined construct.

The PARALLEL MASTER directive is deprecated; you should use the PARALLEL MASKED directive.

**See Also**
OpenMP Fortran Compiler Directives

PARALLEL MASTER TASKLOOP

OpenMP* Fortran Compiler Directive:
(Deprecated, replaced by PARALLEL MASKED TASKLOOP) Creates a PARALLEL construct containing a MASTER TASKLOOP construct, with no Fortran statements in the PARALLEL construct that are not also in the MASTER TASKLOOP construct. This feature is only available for ifx.

Syntax

```fortran
!$OMP PARALLEL MASTER TASKLOOP [clause[,] clause]...
   loop-nest

[!$OMP END PARALLEL MASTER TASKLOOP]
```

clause Can be any of the clauses accepted by the PARALLEL or MASTER TASKLOOP directives with identical meanings and restrictions.

loop-nest Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASTER TASKLOOP construct nested inside of it. The semantics are identical to a MASTER TASKLOOP construct specified immediately after a PARALLEL construct.

All restrictions for PARALLEL and MASTER TASKLOOP constructs apply to this combined construct.

The PARALLEL MASTER TASKLOOP directive is deprecated; you should use the PARALLEL MASKED TASKLOOP directive.

PARALLEL MASTER TASKLOOP SIMD

OpenMP* Fortran Compiler Directive:
(Deprecated, replaced by PARALLEL MASKED TASKLOOP SIMD) Creates a PARALLEL construct containing a MASTER TASKLOOP SIMD construct, with no Fortran statements in the PARALLEL construct that are not also in the MASTER TASKLOOP SIMD construct. This feature is only available for ifx.

Syntax

```fortran
!$OMP PARALLEL MASTER TASKLOOP SIMD [clause[,] clause]...
   loop-nest

[!$OMP END PARALLEL MASTER TASKLOOP SIMD]
```

clause Can be any of the clauses accepted by the PARALLEL or MASTER TASKLOOP SIMD directives with identical meanings and restrictions.
loop-nest

Is a nest of DO loops in canonical form.

This combined directive provides a shortcut for specifying a PARALLEL construct with a MASTER TASKLOOP SIMD construct nested inside of it. The semantics are identical to a MASTER TASKLOOP SIMD construct specified immediately after a PARALLEL construct.

All restrictions for PARALLEL and MASTER TASKLOOP SIMD constructs apply to this combined construct.

The PARALLEL MASTER TASKLOOP SIMD directive is deprecated; you should use the PARALLEL MASKED TASKLOOP SIMD directive.

PARALLEL SECTIONS

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.

Syntax

```f90
!$OMP PARALLEL SECTIONS [clause[,,] clause] ...)
[!$OMP SECTION]
  block
[!$OMP SECTION
  block]...
!$OMP END PARALLEL SECTIONS
```

can be any of the clauses accepted by the PARALLEL or SECTIONS directives.

block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

The last section ends at the END PARALLEL SECTIONS directive.

Example

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```f90
!$OMP PARALLEL SECTIONS
!$OMP SECTION
  CALL XAXIS
!$OMP SECTION
  CALL YAXIS
!$OMP SECTION
  CALL ZAXIS
!$OMP END PARALLEL SECTIONS
```
See Also
OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARALLEL WORKSHARE

OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.

Syntax

```fortran
!$OMP PARALLEL WORKSHARE [clause[, clause] ... ]
    loosely-structured-block
!$OMP END PARALLEL WORKSHARE
-or-
!$OMP PARALLEL WORKSHARE [clause[, clause] ... ]
    strictly-structured-block
!$OMP END PARALLEL WORKSHARE
```

`clause` Can be any of the clauses accepted by the PARALLEL directive.

`loosely-structured-block` Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

`strictly-structured-block` Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

PARAMETER

Statement and Attribute: Defines a named constant.

Syntax

The PARAMETER attribute can be specified in a type declaration statement or a PARAMETER statement, and takes one of the following forms:

Type Declaration Statement:

```fortran
type, [att-ls] PARAMETER [, att-ls] :: c = expr[, c = expr] ...
```

Statement:

```fortran
PARAMETER [( ]c= expr[, c= expr] ... [ ] )
```

`type` Is a data type specifier.

`att-ls` Is an optional list of attribute specifiers.

`c` Is the name of the constant.

`expr` Is a constant expression. It can be of any data type.
Description
The type, type parameters, and shape of the named constant are determined in one of the following ways:

- By an explicit type declaration statement in the same scoping unit.
- By the implicit typing rules in effect for the scoping unit. If the named constant is implicitly typed, it can appear in a subsequent type declaration only if that declaration confirms the implicit typing.

For example, consider the following statement:

```
PARAMETER (MU=1.23)
```

According to implicit typing, MU is of integer type, so MU=1. For MU to equal 1.23, it should previously be declared REAL in a type declaration or be declared in an IMPLICIT statement.

A named array constant defined by a PARAMETER statement must have its rank specified in a previous specification statement.

A named constant must not appear in a format specification or as the character count for Hollerith constants. For compilation purposes, writing the name is the same as writing the value.

If the named constant is used as the length specifier in a CHARACTER declaration, it must be enclosed in parentheses.

The name of a constant cannot appear as part of another constant, although it can appear as either the real or imaginary part of a complex constant.

You can only use the named constant within the scoping unit containing the defining PARAMETER statement.

Any named constant that appears in the constant expression must have been defined previously in the same type declaration statement (or in a previous type declaration statement or PARAMETER statement), or made accessible by use or host association.

An entity with the PARAMETER attribute must not be a variable, a coarray, or a procedure.

Omission of the parentheses in a PARAMETER statement is an extension controlled by compiler option altparam. In this form, the type of the name is taken from the form of the constant rather than from implicit or explicit typing of the name.

Example
The following example shows a type declaration statement specifying the PARAMETER attribute:

```
REAL, PARAMETER :: C = 2.9979251, Y = (4.1 / 3.0)
```

The following is an example of the PARAMETER statement:

```
REAL(4) PI, PIOV2
REAL(8) DPI, DPIOV2
LOGICAL FLAG
CHARACTER(*)(*) LONGNAME
PARAMETER (PI=3.1415927, DPI=3.141592653589793238D0)
PARAMETER (PIOV2=PI/2, DPIOV2=DPI/2)
PARAMETER (FLAG=.TRUE., LONGNAME='A STRING OF 25 CHARACTERS')
```

The following shows implicit-shape arrays declared using a PARAMETER attribute and PARAMETER statements:

```
INTEGER, PARAMETER :: R(*) = [1,2,3]
REAL :: M (2:*, -1:*)
PARAMETER (M = RESHAPE ([R,R], [3,2]))
```
The following shows other examples:

```fortran
! implicit integer type
PARAMETER (nblocks = 10)
!
! implicit real type
IMPLICIT REAL (L-M)
PARAMETER (loads = 10.0, mass = 32.2)
!
! typed by PARAMETER statement
! Requires compiler option
PARAMETER mass = 47.3, pi = 3.14159
PARAMETER bigone = 'This constant is larger than forty characters'
!
! PARAMETER in attribute syntax
REAL, PARAMETER :: mass=47.3, pi=3.14159, loads=10.0, mass=32.2
```

PARITY

Transformational Intrinsic Function (Generic):
Reduces an array by using an exclusive OR (.NEQV.) operation.

Syntax

```
result = PARITY (mask)
result = PARITY (mask, dim)
```

- `mask` (Input) Must be an array of type logical.
- `dim` (Input) Must be a scalar integer with a value in the range `1 <= dim <= n`, where `n` is the rank of `mask`.

Results

The result has the same type and kind parameters as `mask`. It is scalar if `dim` is not specified; otherwise, the result has rank `n - 1` and shape `[\(d_1, d_2, \ldots, d_{dim-1}, d_{dim+1}, \ldots, d_n\)]` where `[\(d_1, d_2, \ldots, d_n\)]` is the shape of `mask`.

The result of `PARITY(mask)` has the value .TRUE. if an odd number of the elements of `mask` are true; otherwise, .FALSE.. If `mask` has rank one, `PARITY(mask, dim)` is equal to `PARITY(mask)`. Otherwise, the value of element `(s_1, s_2, \ldots, s_{dim-1}, s_{dim+1}, \ldots, s_n)` of `PARITY(mask, dim)` is equal to `PARITY(mask)` (\(s_1, s_2, \ldots, s_{dim-1}, s_{dim+1}, \ldots, s_n\)).
Example

If A is the array

\[
\begin{bmatrix}
T & F & T \\
T & T & F \\
\end{bmatrix}
\]

and T has the value .TRUE. and F has the value .FALSE., then

PARITY (A, DIM=1) has the value [F, T, T] and PARITY (A, DIM=2) has the value [F, F].

PAUSE

**Statement:** Temporarily suspends program execution and lets you execute operating system commands during the suspension. The PAUSE statement is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

**Syntax**

```
PAUSE [pause-code]
```

*pause-code* (Optional) Is an optional message. It can be either of the following:

- A scalar character constant of type default character.
- A string of up to six digits; leading zeros are ignored. (Standard Fortran limits digits to five.)

If you specify *pause-code*, the PAUSE statement displays the specified message and then displays the default prompt.

If you do not specify *pause-code*, the system displays the following default message:

```
FORTRAN PAUSE
```

The following prompt is then displayed:

- On Windows* systems:

  `Fortran Pause - Enter command<CR> or <CR> to continue.`

- On Linux* and macOS* systems:

  `PAUSE prompt>`

For alternate methods of pausing while reading from and writing to a device, see **READ** and **WRITE**.

**Effect on Windows* Systems**

The program waits for input on stdin. If you enter a blank line, execution resumes at the next executable statement.

Anything else is treated as a DOS command and is executed by a system() call. The program loops, letting you execute multiple DOS commands, until a blank line is entered. Execution then resumes at the next executable statement.

**Effect on Linux* and macOS* Systems**

The effect of PAUSE differs depending on whether the program is a foreground or background process, as follows:

- If a program is a foreground process, the program is suspended until you enter the CONTINUE command. Execution then resumes at the next executable statement.
- Any other command terminates execution.
If a program is a background process, the behavior depends on stdin, as follows:

- If stdin is redirected from a file, the system displays the following (after the pause code and prompt):
  
  To continue from background, execute 'kill -15 n'

  In this message, n is the process id of the program.

- If stdin is not redirected from a file, the program becomes a suspended background job, and you must specify fg to bring the job into the foreground. You can then enter a command to resume or terminate processing.

Example

The following examples show valid PAUSE statements:

```
PAUSE 701
PAUSE 'ERRONEOUS RESULT DETECTED'
```

The following shows another example:

```
CHARACTER*24 filename
PAUSE 'Enter DIR to see available files or press RETURN' & &' if you already know filename.'
READ(*, '(A)') filename
OPEN(1, FILE=filename)
... 
```

STOP
SYSTEM

Deleted and Obsolescent Language Features

**PEEKCHARQQ**

**Run-Time Function**: Checks the keystroke buffer for a recent console keystroke and returns .TRUE. if there is a character in the buffer or .FALSE. if there is not.

**Module**

USE IFCORE

**Syntax**

```
result = PEEKCHARQQ( )
```

**Results**

The result type is LOGICAL(4). The result is .TRUE. if there is a character waiting in the keyboard buffer; otherwise, .FALSE..

To find out the value of the key in the buffer, call GETCHARQQ. If there is no character waiting in the buffer when you call GETCHARQQ, GETCHARQQ waits until there is a character in the buffer. If you call PEEKCHARQQ first, you prevent GETCHARQQ from halting your process while it waits for a keystroke. If there is a keystroke, GETCHARQQ returns it and resets PEEKCHARQQ to .FALSE..

**Example**

```
USE IFCORE
LOGICAL(4) pressed / .FALSE. /
DO WHILE (.NOT. pressed)
  WRITE(*,*) 'Press any key'
```

PERROR

Run-Time Subroutine: Sends a message to the standard error stream, preceded by a specified string, for the last detected error.

Module
USE IFCORE

Syntax
CALL PERROR (string)

string (Input) Character*(*) . Message to precede the standard error message.

The string sent is the same as that given by GERROR.

Example
USE IFCORE
character*24 errtext
errtext = 'In my opinion, '
   . .
! any error message generated by errtext is
! preceded by 'In my opinion, '
Call PERROR (errtext)

IERRNO

POINTER - Fortran

Statement and Attribute: Specifies that an object or a procedure is a pointer (a dynamic variable). A pointer does not contain data, but points to a scalar or array variable where data is stored. A pointer has no initial storage set aside for it; memory storage is created for the pointer as a program runs.

Syntax
The POINTER attribute can be specified in a type declaration statement or a POINTER statement, and takes one of the following forms:

Type Declaration Statement:

\[
\text{type, [\text{att-}\text{ls},] \text{POINTER [, \text{att-}\text{ls} :: ptr[(d-spec)]|, ptr[(d-spec)]]...}}
\]
Statement:
POINTER [::]ptr[(d-spec)][ , ptr[(d-spec)]] ...

<table>
<thead>
<tr>
<th>Type Spec</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type-spec</td>
<td>Is a data type specifier.</td>
</tr>
<tr>
<td>att-ls</td>
<td>Is an optional list of attribute specifiers.</td>
</tr>
<tr>
<td>ptr</td>
<td>Is the name of the pointer. The pointer cannot be declared with the INTENT or PARAMETER attributes.</td>
</tr>
<tr>
<td>d-spec</td>
<td>(Optional) Is a deferred-shape specification (: [:] ...). Each colon represents a dimension of the array.</td>
</tr>
</tbody>
</table>

Description

No storage space is created for a data pointer until it is allocated with an ALLOCATE statement or until it is assigned to a allocated target.

Each pointer has an association status, which tells whether the pointer is currently associated with a target object. When a pointer is initially declared, its status is undefined. You can use the ASSOCIATED intrinsic function to find the association status of a pointer if the pointer's association status is defined.

Entities with the POINTER attribute can be associated with different data objects or procedures during execution of a program.

A data pointer must not be referenced or defined unless it is pointer associated with a target object that can be referenced or defined. A procedure pointer must not be referenced unless it is pointer associated with a target procedure.

If the data pointer is an array, and it is given the DIMENSION attribute elsewhere in the program, it must be declared as a deferred-shape array.

A pointer cannot be specified in an EQUIVALENCE or NAMELIST statement. A pointer in a DATA statement can only be associated with NULL().

A procedure that has both the EXTERNAL and POINTER attributes is a procedure pointer.

An entity with the POINTER attribute must not have the ALLOCATABLE, INTRINSIC, or TARGET attribute, and it must not be a coarray.

Fortran pointers are not the same as integer pointers. For more information, see the POINTER - Integer statement.

Example

The following example shows type declaration statements specifying the POINTER attribute:

```fortran
TYPE(SYSTEM), POINTER :: CURRENT, LAST
REAL, DIMENSION(:,:), POINTER :: I, J, REVERSE
```

The following is an example of the POINTER statement:

```fortran
TYPE(SYSTEM) :: TODAYS
POINTER :: TODAYS, A(:,:)
```

The following shows another example:

```fortran
REAL, POINTER :: arrow ()
REAL, ALLOCATABLE, TARGET :: bullseye (:, :)
! The following statement associates the pointer with an unused
```
! block of memory.

ALLOCATE (arrow (1:8), STAT = ierr)
IF (ierr.eq.0) WRITE (*,'(/1x,a)') 'ARROW allocated'
arrow = 5.
WRITE (*,'(1x,8f8.0/)') arrow
ALLOCATE (bullseye (1:8,3), STAT = ierr)
IF (ierr.eq.0) WRITE (*)' BULLSEYE allocated'
bullseye = 1.
bullseye (1:8:2,2) = 10.
WRITE (*,'(1x,8f8.0/)') bullseye

! The following association breaks the association with the first
! target, which being unnamed and unassociated with other pointers,
! becomes lost. ARROW acquires a new shape.

arrow => bullseye (2:7,2)
WRITE (*,'(/1x,a)') 'ARROW is repointed & resized, all the 5s are lost'
WRITE (*,'(1x,8f8.0/)') arrow

NULLIFY (arrow)
IF (.NOT.ASSOCIATED(arrow)) WRITE (*,'(/a/)') ' ARROW is not pointed'

DEALLOCATE (bullseye, STAT = ierr)
IF (ierr.eq.0) WRITE (*)'Deallocation successful.'
END

POINTER - Integer

Statement: Establishes pairs of objects and pointers,
in which each pointer contains the address of its
paired object. This statement is different from the
Fortran POINTER statement.

Syntax
POINTER (pointer,pointee) [, (pointer,pointee)] . . .

pointer Is a variable whose value is used as the address of the pointee.
Is a variable; it can be an array name or array specification. It can also be a procedure named in an EXTERNAL statement or in a specific (non-generic) procedure interface block.

The following are pointer rules and behavior:

- Two pointers can have the same value, so pointer aliasing is allowed.
- When used directly, a pointer is treated like an integer variable. On IA-32 architecture, a pointer occupies one numeric storage unit, so it is a 32-bit quantity (INTEGER(4)). On Intel® 64 architecture, a pointer occupies two numeric storage units, so it is a 64-bit quantity (INTEGER(8)).
- A pointer cannot be a pointee.
- A pointer cannot appear in an ASSIGN statement and cannot have the following attributes:

<table>
<thead>
<tr>
<th>ALLOCATABLE</th>
<th>INTRINSIC</th>
<th>POINTER</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXTERNAL</td>
<td>PARAMETER</td>
<td>TARGET</td>
</tr>
</tbody>
</table>

A pointer can appear in a DATA statement with integer literals only.

- Integers can be converted to pointers, so you can point to absolute memory locations.
- A pointer variable cannot be declared to have any other data type.
- A pointer cannot be a function return value.
- You can give values to pointers by doing the following:
  - Retrieve addresses by using the LOC intrinsic function (or the %LOC built-in function)
  - Allocate storage for an object by using the MALLOC intrinsic function (or by using malloc(3f) on Linux* and macOS* systems)

For example:

Using %LOC:

| INTEGER I(10)               | INTEGER I(10) |
| INTEGER I1(10) /10*10/     | POINTER (P,I) |
| POINTER (P,I)               | P = MALLOC(40) |
| P = %LOC(I1)                | I = 10 |
| I(2) = I(2) + 1            | I(2) = I(2) + 1 |

The value in a pointer is used as the pointee's base address.

The following are pointee rules and behavior:

- A pointee is not allocated any storage. References to a pointee look to the current contents of its associated pointer to find the pointee's base address.
- A pointee cannot be data-initialized or have a record structure that contains data-initialized fields.
- A pointee can appear in only one integer POINTER statement.
- A pointee array can have fixed, adjustable, or assumed dimensions.
- A pointee cannot appear in a COMMON, DATA, EQUIVALENCE, or NAMELIST statement, and it cannot have the following attributes:

<table>
<thead>
<tr>
<th>ALLOCATABLE</th>
<th>OPTIONAL</th>
<th>SAVE</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMATIC</td>
<td>PARAMETER</td>
<td>STATIC</td>
</tr>
<tr>
<td>INTENT</td>
<td>POINTER</td>
<td></td>
</tr>
</tbody>
</table>

- A pointee cannot be:
  - A dummy argument
  - A function return value
  - A record field or an array element
  - Zero-sized
  - An automatic object
• The name of a generic interface block
• If a pointee is of derived type, it must be of sequence type.

Example

```fortran
POINTER (p, k)
INTEGER j(2)
! This has the same effect as j(1) = 0, j(2) = 5
p = LOC(j)
k = 0
p = p + SIZEOF(k) ! 4 for 4-byte integer
k = 5
```

POPCNT

**Elemental Intrinsic Function (Generic):** Returns the number of 1 bits in the integer argument.

**Syntax**

```fortran
result = POPCNT (i)
```

`i` (Input) Must be of type integer or logical.

**Results**

The result type and kind are the same as `i`. The result value is the number of 1 bits in the binary representation of the integer `i`.

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.

**Example**

If the value of `I` is `B'0...00011010110'`, the value of POPCNT(I) is 5.

POPPAR

**Elemental Intrinsic Function (Generic):** Returns the parity of the integer argument.

**Syntax**

```fortran
result = POPPAR (i)
```

`i` (Input) Must be of type integer or logical.

**Results**

The result type and kind are the same as `i`. The result value is 1 if there are an odd number of 1 bits in the binary representation of the integer `I`. The result value is zero if there are an even number.

POPPAR( `i`) is the same as 1 .AND. POPCNT( `i`).

The model for the interpretation of an integer value as a sequence of bits is shown in Model for Bit Data.
Example
If the value of I is B'0...00110110', the value of POPPAR(I) is 1.

PRECISION
Inquiry Intrinsic Function (Generic): Returns the decimal precision in the model representing real numbers with the same kind parameter as the argument.

Syntax
result = PRECISION (x)

(Input) Must be of type real or complex; it can be scalar or array valued.

Results
The result is a scalar of type default integer. The result has the value INT((DIGITS(x) - 1) * LOG10(RADIX(x))). If RADIX(x) is an integral power of 10, 1 is added to the result.

Example
If X is a REAL(4) value, PRECISION(X) has the value 6. The value 6 is derived from INT ((24-1) * LOG10 (2.)) = INT (6.92...). For more information on the model for REAL(4), see Model for Real Data.

PREFETCH and NOPREFETCH
General Compiler Directives: PREFETCH hints to the compiler to prefetch data into closer levels of cache. Prefetching data can minimize the effects of memory latency. NOPREFETCH disables data prefetching. These directives give fine-level control to the programmer to influence the prefetches generated by the compiler.

Syntax
!DIR$ PREFETCH [var1[: hint1[: distance1]] [,var2[: hint2[: distance2]]]...]
!DIR$ PREFETCH *: hint[: distance]
!DIR$ NOPREFETCH [var1[,var2]...]

var
Is an optional memory reference.

hint
Is an optional integer constant expression with the integer value 0, 1, 2, or 3. These are the same as the defined values FOR_K_PREFETCH_T0, FOR_K_PREFETCH_T1, FOR_K_PREFETCH_T2, or FOR_K_PREFETCH_NTA for hint in the intrinsic subroutine MM_PREFETCH. To use this argument, you must also specify var.

distance
Is an optional integer constant expression with a value greater than 0. It indicates the number of (possibly vectorized) loop iterations ahead of which a prefetch is issued, before the corresponding load or store instruction. To use this argument, you must also specify var and hint.
To use these directives, compiler option [q or Q]opt-prefetch must be set. Note that this option is turned on by default if the compiler general optimization level is O2 or higher.

This directive affects the DO loop it precedes.

If you specify PREFETCH *, the hint and optional distance are used to prefetch all array accesses in the DO loop.

If you specify NOPREFETCH with no arguments, the following occurs:

- All arrays accessed in the DO loop will NOT be prefetched.
- It negates all other PREFETCH directives for the following DO loop.

If a loop includes expression A(j), placing !DIR$ PREFETCH A:0:d in front of the loop instructs the compiler to insert a vprefetch0 instruction for A within the loop that is d iterations ahead.

The PREFETCH directive takes precedence over the [q or Q]opt-prefetch-distance options.

The variables in a NOPREFETCH or PREFETCH directive take precedence over PREFETCH *.

A NOPREFETCH directive with no arguments negates all other PREFETCH directives for the following DO loop.

**Example**

```
! Issue no prefetches for A1
! Issue vector prefetch from L2 and higher caches for B with a distance
! of 16 vectorized iterations ahead
! Issue vector prefetch from L1 and higher caches for B with a distance
! of 4 vectorized iterations ahead
!DIR$ NOPREFETCH A1
!DIR$ PREFETCH B:1:16
!DIR$ PREFETCH B:0:4
  DO  J = 1,N
    A1(J) = B(J-1) + B(J+1)
  END DO
```

In the following example, array A will be prefetched with hint 0 and distance 5, arrays B and C will be prefetched with hint 1 and distance 10, and array D will not be prefetched:

```
!DIR$ PREFETCH *:1:10
!DIR$ PREFETCH A:0:5
!DIR$ NOPREFETCH D
  DO  J = 1, N
    A (J) = B (J) + C (J) + D (J)
  END DO
```

O compiler option

qopt-prefetch-distance, Qopt-prefetch-distance compiler option

**PRESENT**

*Inquiry Intrinsic Function (Generic):* Returns whether or not an optional dummy argument is present, that is, whether it has an associated actual argument.
Syntax
result = PRESENT (a)

(Input) Must be an argument of the current procedure and must have the OPTIONAL attribute. An explicit interface for the current procedure must be visible to its caller; for more information, see Procedure Interfaces.

Results
The result is a scalar of type default logical. The result is .TRUE. if a is present; otherwise, the result is .FALSE..

Example
Consider the following:

MODULE MYMOD
CONTAINS
SUBROUTINE CHECK (X, Y)
  REAL X, Z
  REAL, OPTIONAL :: Y
  ...
  IF (PRESENT (Y)) THEN
    Z = Y
  ELSE
    Z = X * 2
  END IF
END SUBROUTINE CHECK
END MODULE MYMOD
...
USE MYMOD
CALL CHECK (15.0, 12.0) ! Causes Z to be set to 12.0
CALL CHECK (15.0) ! Causes Z to be set to 30.0

The following shows another example:

CALL who( 1, 2 ) ! prints "A present" "B present"
CALL who( 1 ) ! prints "A present"
CALL who( b = 2 ) ! prints "B present"
CALL who( ) ! prints nothing
CONTAINS
  SUBROUTINE who( a, b )
    INTEGER(4), OPTIONAL :: a, b
    IF (PRESENT(a)) PRINT *, 'A present'
    IF (PRESENT(b)) PRINT *, 'B present'
  END SUBROUTINE who
END

See Also
OPTIONAL
Optional Arguments

PRINT
Statement: Displays output on the screen. TYPE is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.
Syntax
The `PRINT` statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units. You can override this restriction by using environment variable FOR_PRINT.

A PRINT statement takes one of the following forms:

**Formatted:**

```
PRINT form[, io-list]
```

**Formatted - List-Directed:**

```
PRINT *[, io-list]
```

**Formatted - Namelist:**

```
PRINT nml
```

- `form` Is the nonkeyword form of a format specifier (no FMT=).
- `io-list` Is an I/O list.
- `*` Is the format specifier indicating list-directed formatting.
- `nml` Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist formatting.

Example
In the following example, one record (containing four fields of data) is printed to the implicit output device:

```plaintext
CHARACTER*16 NAME, JOB
PRINT 400, NAME, JOB
400   FORMAT ('NAME=', A, 'JOB=', A)
```

The following shows another example:

```plaintext
! The following statements are equivalent:
PRINT   '(A11)', 'Abbottsford'
WRITE (*, '(A11)') 'Abbottsford'
TYPE    '(A11)', 'Abbottsford'
```

PRIORITY

**Parallel Directive Clause:** Specifies that the generated tasks have the indicated priority for execution.

**Syntax**

```
PRIORITY (priority-value)
```
priority-value

Provides a hint for the priority of task execution order. priority-value must evaluate to a non-negative scalar integer value.

Among all tasks ready to be executed, higher priority tasks (those with a higher numerical value of priority-value) are recommended to execute before lower priority tasks. A program that relies on task execution order being determined by this priority-value may have unspecified behavior.

At most one PRIORITY clause can appear in the directive.

If this clause is not specified, tasks generated by the construct have a task priority of zero (the default).

PRIVATE Clause

Parallel Directive Clause: Declares one or more variables to be private to each thread in a team.

Syntax

PRIVATE (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

This clause allows each thread to have its own copy of the variable and makes it a local variable to the thread.

The following occurs when variables are declared in a PRIVATE clause:

- A new object of the same type is declared once for each thread in the team (or for each implicit task in a region) and it is used by each thread (or task) inside the scope of the directive construct instead of the original variable. The new object is no longer storage associated with the original object.
- All references to the original object in the lexical extent of the directive construct are replaced with references to the private object.
- Variables defined as PRIVATE are undefined for each thread upon entering the construct and the corresponding shared variable is undefined when the parallel construct is exited. Within a parallel, worksharing, or task region, the initial status of a private pointer is undefined.

The value and allocation status of the original variable will change only in the following cases:

- If it is accessed and modified by means of a pointer
- If it is accessed in the region but outside of the construct
- As a side effect of directives or clauses
- If accessed and modified via construct association.

If a variable has the ALLOCATABLE attribute, the following rules apply:

- If the variable is not currently allocated, the new list item will have an initial state of "unallocated".
- If the variable is allocated, the new list item will have an initial state of allocated with the same array bounds.

A variable that appears in a PRIVATE clause may be storage-associated with other variables when the PRIVATE clause is encountered by constructs such as EQUIVALENCE or COMMON. If A is a variable appearing in a PRIVATE clause and B is a variable that is storage-associated with A, then the following applies:

- The contents, allocation, and association status of B are undefined on entry to the parallel or task region.
- Any definition of A, or any definition of its allocation or association status, causes the contents, allocation, and association status of B to become undefined.
- Any definition of B, or any definition of its allocation or association status, causes the contents, allocation, and association status of A to become undefined.
• A list item that appears in a private clause can be a *selector* in an ASSOCIATE construct. If the ASSOCIATE construct association is established before entry to a parallel region, the association between the associate *name* and the original PRIVATE list item will be retained in the parallel region.

The following are restrictions for the PRIVATE clause:

• A variable that is part of another variable (as an array or structure element) must not appear in a PRIVATE clause.
• A variable that appears in a PRIVATE clause must either be definable or it must be an allocatable array. This restriction does not apply to the FIRSTPRIVATE clause.
• Assumed-size arrays must not appear in a PRIVATE clause.
• A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a PRIVATE clause. This restriction does not apply to the FIRSTPRIVATE clause.
• Variables that appear in NAMELIST statements, in variable format expressions, and in expressions for statement function definitions, must not appear in a PRIVATE clause.

Variables in a *list* can appear in other clauses as follows:

• Variables that appear in a PRIVATE, FIRSTPRIVATE, or REDUCTION clause in a parallel construct can also appear in a PRIVATE clause in an enclosed parallel, task, or worksharing construct.
• Variables that appear in a PRIVATE or FIRSTPRIVATE clause in a task construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.
• Variables that appear in a PRIVATE, FIRSTPRIVATE, LASTPRIVATE, or REDUCTION clause in a worksharing construct can also appear in a PRIVATE clause in an enclosed parallel or task construct.

**NOTE**

Variables that are used as counters for explicit or implicit DO loops or FORALL commands, or common blocks that are specified to be THREADPRIVATE become automatically private to each thread, even though they are not explicitly included inside a PRIVATE clause at the beginning of the scope of the parallel region.

**Example**

Consider the following:

```!
$OMP PARALLEL PRIVATE(A, B)
```

In this simple case, each thread will have its own copy of variables A and B. The variables can have different values in each thread because the variables are local to the thread.

**See Also**

FIRSTPRIVATE clause
LASTPRIVATE clause

**PRIVATE Statement**

*Statement and Attribute:* Specifies that entities in a module can be accessed only within the module itself.

**Syntax**

The PRIVATE attribute can be specified in a type declaration statement or a PRIVATE statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls] PRIVATE [, att-ls] :: entity[, entity]...
```

**Statement:**

```
PRIVATE [[::] entity[, entity] ...]```
**Description**

The PRIVATE attribute can only appear in the scoping unit of a module.

Only one PRIVATE statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module and any entities accessed from a module by USE association whose names do not appear in a PUBLIC statement.

A module name can appear at most once in all the PUBLIC or PRIVATE statements in a scoping unit. If a module name is specified in a PRIVATE statement, the module name must have appeared in a USE statement within the same scoping unit.

A PRIVATE attribute can be specified on the TYPE statement of a derived-type definition in a module. This specifies the derived-type definition is not accessible outside the module or the module's descendants.

A PRIVATE statement without an entity-list can appear in the component-definition part of a derived-type definition, specifying the default accessibility of all components as PRIVATE. A PRIVATE statement with no entity-list can appear in the type-bound-procedure-part of a derived-type definition specifying the default accessibility of all type-bound procedures of that type as PRIVATE. In such cases, the default accessibility of components and type-bound procedures can be overridden by explicitly declaring a component or type-bound procedure PUBLIC.

A PRIVATE attribute can be specified in the statement declaring a component or a type-bound procedure of a derived type. This specifies that the component or type-bound procedure is not accessible outside the module or its descendants.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility. Entities with PUBLIC accessibility can be accessed from outside the module by means of a USE statement.

If a derived type is declared PRIVATE in a module, its components are also PRIVATE. The derived type and its components are accessible to any subprograms within the defining module and the module's descendants through host association, but they are not accessible from outside the module.

If the derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module has a generic identifier, it must also be declared PRIVATE.
If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:

- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the definition.

Example

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```
REAL, PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```
MODULE SOME_DATA
  REAL ALL_B
  PUBLIC ALL_B
  TYPE RESTRICTED_DATA
    REAL LOCAL_C(50)
  END TYPE RESTRICTED_DATA
  PRIVATE RESTRICTED_DATA
END MODULE
```

The following derived-type declaration statement indicates that the type is restricted to the module:

```
TYPE, PRIVATE :: DATA
  ...
END TYPE DATA
```

The following example shows a PUBLIC type with PRIVATE components:

```
MODULE MATTER
  TYPE ELEMENTS
    PRIVATE
    INTEGER C, D
  END TYPE
  ...
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

The following shows another example:

```
!LENGTH in module VECTRLEN calculates the length of a 2-D vector.
!The module contains both private and public procedures
MODULE VECTRLEN
  PRIVATE SQUARE
  PUBLIC LENGTH
  CONTAINS
    SUBROUTINE LENGTH(x,y,z)
      REAL, INTENT(IN) x,y
    END SUBROUTINE LENGTH
END MODULE
```
REAL, INTENT(OUT) z
CALL SQUARE(x, y)
z = SQRT(x + y)
RETURN
END SUBROUTINE

SUBROUTINE SQUARE(x1, y1)
REAL x1, y1
x1 = x1**2
y1 = y1**2
RETURN
END SUBROUTINE
END MODULE

PROCEDURE
Statement: Declares procedure pointers, dummy procedures, and external procedures.

Syntax
PROCEDURE ([proc-interface]) [[, proc-attr-spec]... :: ] proc-decl-list

proc-interface
(Optional) Is the name of an interface, an intrinsic type specifier, or a derived-type TYPE statement.

If an interface name is specified, it must be the name of an abstract interface, a procedure that has an explicit interface, or a procedure pointer. It must have been previously declared and it cannot be the same as a keyword that specifies an intrinsic type.

If proc-interface is a type specifier, the declared procedures or procedure pointers are functions that have implicit interfaces and the specified result type. If a type is specified for an external function, its function definition must specify the same result type and type parameters.

proc-attr-spec
(Optional) Is one of the following attributes:

- PUBLIC
- PRIVATE
- BIND (C [, NAME = init-expr])
  This is also called a language-binding-spec. The init-expr is a scalar character constant expression of default character kind. If NAME= is specified, there can only be one proc-decl item, which cannot have the POINTER attribute or be a dummy procedure.
- INTENT(INOUT)
Each `proc-attr-spec` gives the corresponding attribute to all procedures declared in that statement.

If a procedure entity has the INTENT attribute or SAVE attribute, it must also have the POINTER attribute.

`proc-decl-list` is one or more of the following:

```fortran
procedure-name [=> null-init]
```

where `null-init` is a reference to intrinsic function NULL with no arguments. If `=> null-init` appears, the procedure must have the POINTER attribute. `procedure-name` is the name of a nonintrinsic procedure.

**Description**

A PROCEDURE statement declares nonintrinsic procedures (procedure pointers, dummy procedures, internal procedures, and external procedures). If the procedure is not a procedure pointer, a module procedure, or an internal procedure, it specifies the EXTERNAL attribute for the procedure.

You cannot use the PROCEDURE statement to identify a BLOCK DATA subprogram.

If `=> null-init` appears, it specifies that the initial association status of the corresponding procedure entity is disassociated. It also implies the SAVE attribute.

You can also declare procedures by using an EXTERNAL statement or a procedure component definition statement.

If the BIND attribute is specified for a procedure, each dummy argument must be:

- An interoperable procedure or a variable that is interoperable
- Assumed shape
- Assumed rank
- Assumed type
- Of assumed-character length or has the ALLOCATABLE or POINTER attribute

If the BIND attribute is specified for a function, the function result must be an interoperable scalar variable.

A Fortran procedure is interoperable if it has the BIND attribute; that is, if its interface is specified with a `language-binding-spec`.

The ALLOCATABLE or POINTER attribute must not be specified for a default-initialized dummy argument of a procedure that has a BIND attribute.

A dummy argument of a procedure that has a BIND attribute must not have both the OPTIONAL and VALUE attributes.

A variable that is a dummy argument of a procedure that has a BIND attribute must be of interoperable type or assumed type.

When a procedure whose interface has the BIND attribute is called, any actual argument corresponding to a dummy argument with the ALLOCATABLE or POINTER attribute is passed by C descriptor. Similarly, if a Fortran procedure with a BIND attribute has such dummy arguments, they are received by C descriptor.
Example
Consider the following:

```
PROCEDURE (NAME_TEMP) :: NAME37
```

The above declares NAME37 to be a procedure with an identical interface to that of NAME_TEMP.

The following are equivalent:

```
PROCEDURE (INTEGER) X
INTEGER, EXTERNAL :: X
```

Consider the following:

```
ABSTRACT INTERFACE
FUNCTION SIM_FUNC (X)
  REAL, INTENT (IN) :: X
  REAL :: SIM_FUNC
END FUNCTION SIM_FUNC
END INTERFACE

INTERFACE
  SUBROUTINE SUB2 (X)
    REAL, INTENT (IN) :: X
  END SUBROUTINE SUB2
END INTERFACE
```

The following shows external and dummy procedures with explicit interfaces:

```
PROCEDURE (SIM_FUNC) :: VMAC, KAPPA
PROCEDURE (SUB2) :: PRINGLES
```

The following shows procedure pointers with an explicit interface, one initialized to NULL():

```
PROCEDURE (SIM_FUNC), POINTER :: P1, R1 => NULL()
PROCEDURE (SIM_FUNC), POINTER :: KAPPA_POINTER
```

The following shows a derived type with a procedure pointer component:

```
TYPE MEMO_TYPE
  PROCEDURE (SIM_FUNC), POINTER :: COMPONENT
END TYPE MEMO_TYPE
```

The following shows a variable of the above type:

```
TYPE (MEMO_TYPE) :: STRUCTA
```

The following shows an external or dummy function with an implicit interface:

```
PROCEDURE (INTEGER) :: PHIL0
```

PROCESSOR Clause

Parallel Directive Clause: Tells the compiler to create a vector version of the routine for the specified processor. When running on a processor that does not match "cpuid", a scalar version will be invoked multiple times based on vector length.

Syntax

PROCESSOR (cpuid)

Is one of the following:

- **ato**: Intel Atom® processors with Supplemental Streaming SIMD Extensions 3 (SSSE3)
- **atom**: Intel Atom® processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2)
- **atom_se4**: Intel Atom® processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) with MOVBE instructions enabled
- **bro**: Intel® 45nm Hi-k next generation Intel® Core™ microarchitecture processors with Intel® Streaming SIMD Extensions 4.1 (Intel® SSE4.1)
- **core_2_duo_ssse3**: Intel® Core™2 Duo processors with Intel® Supplemental Streaming SIMD Extensions 3 (SSSE3)
- **core_2nd_gen_avx**: 2nd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX)
3rd generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions (Intel® AVX) including the RDRND instruction

4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction

4th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDRND instruction, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)

5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions

5th generation Intel® Core™ processor family with support for Intel® Advanced Vector Extensions 2 (Intel® AVX2) including the RDSEED and Multi-Precision Add-Carry Instruction Extensions (ADX) instructions, and support for Intel® Transactional Synchronization Extensions (Intel® TSX)

Intel® Core™ processors with support for Advanced Encryption Standard (AES) instructions and carry-less multiplication instruction

Intel® Core™ i7 processors with Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) instructions

Other Intel processors for IA-32 or Intel® 64 architecture or compatible processors not provided by Intel Corporation
This is a synonym for core_4th_gen_avx.

Intel® Pentium® processor

Intel® Pentium® 4 processor

Intel® Pentium® 4 processor with Intel® Streaming SIMD Extensions 3 (Intel® SSE3) instructions, Intel® Core™ Duo processors, Intel® Core™ Solo processors

Intel® Pentium® II processors

Intel® Pentium® III processors

Intel® Pentium® III processors with no XMM registers

Intel® Pentium® M processors

Intel® Pentium® processors with MMX™ technology

Intel® Pentium® Pro processors

Intel® microarchitecture code name Skylake. This keyword targets the Client CPU without support for Intel® AVX-512 instructions.
Intel® microarchitecture code name Skylake. This keyword targets the Server CPU with support for Intel® AVX-512 instructions.

The vector version of the routine that is created by the compiler is not affected by processor options specified on the command line.

Multiple PROCESSOR clauses cause a syntax error.

DECLARE SIMD
ATTRIBUTES VECTOR

PRODUCT
Transformational Intrinsic Function (Generic):
Returns the product of all the elements in an entire array or in a specified dimension of an array.

Syntax
result = PRODUCT (array [, mask])
result = PRODUCT (array, dim [, mask])

array (Input) Must be an array of type integer, real, or complex.
dim (Input) Must be a scalar integer with a value in the range 1 to n, where n is the rank of array.
mask (Input; optional) Must be of type logical and conformable with array.

Results
The result is an array or a scalar of the same data type as array.
The result is a scalar if dim is not specified or array has rank one.
The following rules apply if dim is not specified:
• If PRODUCT(array) is specified, the result is the product of all elements of array. If array has size zero, the result is 1.
• If PRODUCT(array, MASK= mask) is specified, the result is the product of all elements of array corresponding to true elements of mask. If array has size zero, or every element of mask has the value .FALSE., the result is 1.
The following rules apply if dim is specified:
• If array has rank one, the value is the same as PRODUCT(array[,MASK= mask]).
• An array result has a rank that is one less than array, and shape (d1, d2, ..., dim-1, dim+1, ..., dn), where (d1, d2, ..., dn) is the shape of array.
• The value of element (s1, s2, ..., sdim-1, sdim+1, ..., sn) of PRODUCT(array, dim[, mask]) is equal to
  PRODUCT(array(s1, s2, ..., sdim-1, :, sdim+1, ..., sn) [,MASK= mask(s1, s2, ..., sdim-1, :, sdim+1, ..., sn)]).

Example
PRODUCT ((/2, 3, 4/)) returns the value 24 (the product of 2 * 3 * 4). PRODUCT ((/2, 3, 4/), DIM=1) returns the same result.
PRODUCT (C, MASK=C .LT. 0.0) returns the product of the negative elements of C.
A is the array

\[
\begin{bmatrix}
1 & 4 & 7 \\
2 & 3 & 5 \\
\end{bmatrix}
\]

PRODUCT (A, DIM=1) returns the value (2, 12, 35), which is the product of all elements in each column. 2 is the product of 1 * 2 in column 1. 12 is the product of 4 * 3 in column 2, and so forth.

PRODUCT (A, DIM=2) returns the value (28, 30), which is the product of all elements in each row. 28 is the product of 1 * 4 * 7 in row 1. 30 is the product of 2 * 3 * 5 in row 2.

If array has shape (2, 2, 2), mask is omitted, and dim is 1, the result is an array result with shape (2, 2) whose elements have the following values.

<table>
<thead>
<tr>
<th>Resultant array element</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>result(1, 1)</td>
<td>( \text{array}(1, 1, 1) \times \text{array}(2, 1, 1) )</td>
</tr>
<tr>
<td>result(2, 1)</td>
<td>( \text{array}(1, 2, 1) \times \text{array}(2, 2, 1) )</td>
</tr>
<tr>
<td>result(1, 2)</td>
<td>( \text{array}(1, 1, 2) \times \text{array}(2, 1, 2) )</td>
</tr>
<tr>
<td>result(2, 2)</td>
<td>( \text{array}(1, 2, 2) \times \text{array}(2, 2, 2) )</td>
</tr>
</tbody>
</table>

The following shows another example:

```plaintext
INTEGER array (2, 3)
INTEGER AR1(3), AR2(2)
array = RESHAPE((/1, 4, 2, 5, 3, 6/),(/2,3/))
! array is  1 2 3  
!           4 5 6
AR1 = PRODUCT(array, DIM = 1) ! returns [ 4 10 18 ]
AR2 = PRODUCT(array, MASK = array .LT. 6, DIM = 2)
        ! returns [ 6 20 ]
END
```

See Also

SUM

PROGRAM

Statement: Identifies the program unit as a main program and gives it a name.

Syntax

```plaintext
[PROGRAM name]
    [specification-part]
    [execution-part]
[CONTAINS
    internal-subprogram-part]
END[PROGRAM [name]]
```

name

specification-part

Is the name of the program.

Is one or more specification statements, except for the following:

- INTENT (or its equivalent attribute)
• Optional (or its equivalent attribute)
• Public and private (or their equivalent attributes)

An automatic object must not appear in a specification statement. If a SAVE statement is specified, it has no effect.

**Execution-part**
Is one or more executable constructs or statements, except for **ENTRY** or **RETURN** statements.

**Internal-subprogram-part**
Is one or more internal subprograms (defining internal procedures). The **internal-subprogram-part** is preceded by a **CONTAINS** statement.

**Description**
The PROGRAM statement is optional. Within a program unit, a PROGRAM statement can be preceded only by comment lines or an OPTIONS statement.

The END statement is the only required part of a program. If a name follows the END statement, it must be the same as the name specified in the PROGRAM statement.

The program name is considered global and must be unique. It cannot be the same as any local name in the main program or the name of any other program unit, external procedure, or common block in the executable program.

A main program must not reference itself (either directly or indirectly).

**Example**
The following is an example of a main program:

```fortran
PROGRAM TEST
  INTEGER C, D, E(20,20) ! Specification part
  CALL SUB_1           ! Executable part
  ...
  CONTAINS
    SUBROUTINE SUB_1    ! Internal subprogram
    ...
    END SUBROUTINE SUB_1
END PROGRAM TEST
```

The following shows another example:

```fortran
PROGRAM MyProg
  PRINT *, 'hello world'
END
```

**Protected**

**Statement and Attribute:** Specifies limitations on the use of module entities.

**Syntax**
The PROTECTED attribute can be specified in a type declaration statement or a PROTECTED statement, and takes one of the following forms:

**Type Declaration Statement:**

```fortran
type, [att-ls, ] PROTECTED [, att-ls] :: entity[, entity] ...
```

**Statement:**

```fortran
PROTECTED [::]entity[, entity] ...
```
**type**  
Is a data type specifier.

**att-ls**  
Is an optional list of attribute specifiers.

**entity**  
Is the name of an entity in a module.

The PROTECTED attribute can only appear in the specification part of a module.

The PROTECTED attribute can only be specified for a procedure pointer or named variable that is not in a common block.

A non-pointer object that has the PROTECTED attribute and is accessed by use association cannot appear in a variable definition or as the target in a pointer assignment statement.

A pointer object that has the PROTECTED attribute and is accessed by use association must not appear as any of the following:

- A pointer-object in a NULLIFY statement
- A pointer-object in a pointer assignment statement
- An object in an ALLOCATE or DEALLOCATE statement
- An actual argument in a reference to a procedure if the associated dummy argument is a pointer with the INTENT(OUT) or INTENT(INOUT) attribute.

The following restrictions apply outside of the module in which the entity has been given the PROTECTED attribute:

- A non-pointer entity may not be defined or redefined.
- A pointer entity may not have its association status changed through the pointer.
- A data entity with the TARGET and the PROTECTED attribute that is USE associated may not appear in a pointer initialization expression or a constructor if it corresponds to a pointer component.

**Example**

The following example shows a type declaration statement specifying the PROTECTED attribute:

```plaintext
INTEGER, PROTECTED :: D, E
```

Consider the following example:

```plaintext
MODULE counter_mod
  INTEGER, PROTECTED :: current = 0
  CONTAINS

  INTEGER FUNCTION next()
  current = current + 1    ! current can be modified here
  next = current
  RETURN
  END FUNCTION next
END MODULE counter_mod

PROGRAM test_counter
  USE counter_mod
  PRINT *, next()           ! Prints 1
  current = 42              ! Error: variable is protected
END PROGRAM test_counter
```

**See Also**

- Modules and Module Procedures
- Type Declarations
- Compatible attributes
- Pointer Assignments
PSECT

**General Compiler Directive:** Modifies characteristics of a common block.

**Syntax**

```fortran
!DIR$ PSECT /common-name/ a[,a] ... 
```

- `common-name` is the name of the common block. The slashes (`/`) are required.
- `a` is one of the following:
  - `ALIGN= val` or `ALIGN= keyword`
    - Specifies minimum alignment for the common block. ALIGN only has an effect when specified on Windows* and Linux* systems.
    - The `val` is a constant ranging from 0 through 6 on Windows* systems and 0 through 4 on Linux* systems. The specified number is interpreted as a power of 2. The value of the expression is the alignment in bytes.
    - The `keyword` is one of the following:
      - `BYTE` equivalent to `val = 0`
      - `WORD` equivalent to `val = 1`
      - `LONG` equivalent to `val = 2`
      - `QUAD` equivalent to `val = 3`
      - `OCTA` equivalent to `val = 4`
      - `PAGE` on IA-32 architecture: range is 0 through 13 for Windows*; 0 through 12 for Linux*
  - `[NO]WRT`
    - Determines whether the contents of a common block can be modified during program execution.

If one program unit changes one or more characteristics of a common block, all other units that reference that common block must also change those characteristics in the same way.

The defaults are `ALIGN=OCTA` and `WRT`.

**See Also**

General Compiler Directives

Syntax Rules for Compiler Directives

PUBLIC

**Statement and Attribute:** Specifies that entities in a module can be accessed from outside the module by specifying a USE statement.
Syntax
The PUBLIC attribute can be specified in a type declaration statement or a PUBLIC statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls,] PUBLIC [, att-ls] :: entity [, entity]...
```

**Statement:**

```
PUBLIC [[::] entity [, entity] ...]
```

type
Is a data type specifier.

att-ls
Is an optional list of attribute specifiers.

entity
Is one of the following:

- A variable name
- A procedure name
- A derived type name
- A named constant
- A namelist group name
- An OpenMP* reduction-identifier

In statement form, an entity can also be one of the following:

- A module name
- A generic name
- A defined operator
- A defined assignment
- A defined I/O generic specification

Description
The PUBLIC attribute can only appear in the scoping unit of a module.

Only one PUBLIC statement without an entity list is permitted in the scoping unit of a module; it sets the default accessibility of all entities in the module and any entities accessed from a module by use association.

If no PRIVATE statements are specified in a module, the default is PUBLIC accessibility for all entities in the module and entities accessible from other modules by use association.

A module name can appear at most once in all the PUBLIC or PRIVATE statements in a scoping unit. If a module name is specified in a PUBLIC statement, the module name must have appeared in a USE statement within the same scoping unit.

A PUBLIC attribute can be specified on the TYPE statement of a derived-type definition in a module. This specifies that the derived-type definition is accessible by USE association where the module is used.

A PUBLIC attribute can be specified in the statement declaring a component or a type-bound procedure of a derived type. This specifies that the component or type-bound procedure is accessible by USE association where the module is used, even if the default accessibility of the components and type-bound procedures of the derived type has been set to PRIVATE in the definition of the derived type.

If a derived type is declared PUBLIC in a module, but its components are declared PRIVATE, any scoping unit accessing the module though use association (or host association) can access the derived-type definition, but not its components.

If a module procedure has a dummy argument or a function result of a type that has PRIVATE accessibility, the module procedure must have PRIVATE accessibility. If the module procedure has a generic identifier, it must also be declared PRIVATE.
If a procedure has a generic identifier, the accessibility of the procedure's specific name is independent of the accessibility of its generic identifier. One can be declared PRIVATE and the other PUBLIC.

The accessibility of the components of a type is independent of the accessibility of the type name. The following combinations are possible:

- A private type name with a private component
- A public type name with a public component
- A private type name with a public component
- A public type name with a private component

The accessibility of a type does not affect, and is not affected by, the accessibility of its components and type-bound procedures. If a type definition is private, then the type name, and thus the structure constructor for the type, are accessible only within the module containing the derived-type definition or in the module's descendants.

**Example**

The following examples show type declaration statements specifying the PUBLIC and PRIVATE attributes:

```fortran
REAL, PRIVATE :: A, B, C
INTEGER, PUBLIC :: LOCAL_SUMS
```

The following is an example of the PUBLIC and PRIVATE statements:

```fortran
MODULE SOME_DATA
 REAL ALL_B
 PUBLIC ALL_B
 TYPE RESTRICTED_DATA
  REAL LOCAL_C(50)
 END TYPE RESTRICTED_DATA
 PRIVATE RESTRICTED_DATA
END MODULE
```

The following example shows a PUBLIC type with PRIVATE components:

```fortran
MODULE MATTER
 TYPE ELEMENTS
 PRIVATE
  INTEGER C, D
 END TYPE
 ... 
END MODULE MATTER
```

In this case, components C and D are private to type ELEMENTS, but type ELEMENTS is not private to MODULE MATTER. Any program unit that uses the module MATTER, can declare variables of type ELEMENTS, and pass as arguments values of type ELEMENTS.

The following shows another example:

```fortran
! LENGTH in module VECTRLEN calculates the length of a 2-D vector.  
! The module contains both private and public procedures
 MODULE VECTRLEN
 PRIVATE SQUARE
 PUBLIC LENGTH
 CONTAINS
 SUBROUTINE LENGTH(x,y,z)
  REAL, INTENT(IN) x, y
  REAL, INTENT(OUT) z
  CALL SQUARE(x,y)
  z = SQRT(x + y)
 RETURN
END SUBROUTINE LENGTH
END MODULE VECTRLEN
```

PURE

**Keyword:** Asserts that a user-defined procedure has no side effects.

**Description**
This kind of procedure is specified by using the prefix PURE or the prefix ELEMENTAL without the prefix IMPURE in a FUNCTION or SUBROUTINE statement.

A pure procedure has no side effects. It has no effect on the state of the program, except for the following:

- For functions: It returns a value.
- For subroutines: It modifies INTENT(OUT) and INTENT(INOUT) parameters.

The following intrinsic and library procedures are implicitly pure:

- All intrinsic functions
- The elemental intrinsic subroutine MVBITS
- The intrinsic subroutine MOVE_ALLOC
- Intrinsic module procedures that are specified to be pure

A dummy argument or a procedure pointer may be specified to be pure. A type-bound procedure that is bound to a pure procedure is also pure.

A statement function is pure only if all functions that it references are pure and its definition does not reference any data object with the VOLATILE attribute.

Except for procedure arguments and pointer arguments, the following intent must be specified in the specification part of the procedure for all dummy arguments:

- For functions: INTENT(IN) or the VALUE attribute
- For subroutines: any INTENT (IN, OUT, or INOUT) or the VALUE attribute

A local variable declared in a pure procedure (including variables declared in any internal procedure) must not:

- Specify the SAVE attribute
- Specify the VOLATILE attribute
- Be initialized in a type declaration statement or a DATA statement

The following variables have restricted use in pure procedures (and any internal procedures):
• Global variables
• Dummy arguments with INTENT(IN)
• Dummy arguments with no declared intent that do not have the VALUE attribute
• Objects that are storage associated with any part of a global variable

They must not be used in any context that does either of the following:
• Causes their value to change. For example, they must not be used as:
  • The left side of an assignment statement or pointer assignment statement
  • An actual argument associated with a dummy argument with INTENT(OUT), INTENT(INOUT), or the
    POINTER attribute
  • An index variable in a DO or FORALL statement, or an implied-DO clause
  • The variable in an ASSIGN statement
  • An input item in a READ statement
  • An internal file unit in a WRITE statement
  • An object in an ALLOCATE, DEALLOCATE, or NULLIFY statement
  • An IOSTAT or SIZE specifier in an I/O statement, the STAT specifier in a ALLOCATE, DEALLOCATE, or
    image control statement, or as the STAT argument to the intrinsic MOVE_ALLOC or a collective or
    atomic intrinsic subroutine.
• Creates a pointer to that variable. For example, they must not be used as:
  • The target in a pointer assignment statement
  • The right side of an assignment to a derived-type variable (including a pointer to a derived type) if the
    derived type has a pointer component at any level
  • The actual argument to the C_LOC function defined in the intrinsic module ISO_C_BINDING

A pure procedure must not contain the following:
• Any external I/O statement (including a READ or WRITE statement whose I/O unit is an external file unit
  number or *)
• A PAUSE statement
• A STOP statement
• An image control statement
• An OpenMP* directive

A pure procedure can be used in contexts where other procedures are restricted; for example:
• It can be called directly in a FORALL statement or be used in the mask expression of a FORALL statement.
• It can be called from a pure procedure. Pure procedures can only call other pure procedures, including
  one referenced by means of a defined operator, defined assignment, or finalization.
• It can be passed as an actual argument to a pure procedure.

If a procedure is used in any of these contexts, its interface must be explicit and it must be declared pure in
that interface.

Example

Consider the following:

```
PURE FUNCTION DOUBLE(X)
    REAL, INTENT(IN) :: X
    DOUBLE = 2 * X
END FUNCTION DOUBLE
```

The following shows another example:

```
PURE INTEGER FUNCTION MANDELBROT(X)
    COMPLEX, INTENT(IN) :: X
    COMPLEX :: XTMP
    INTEGER :: K
    ! Assume SHARED_DEFS includes the declaration
```
! INTEGER ITOL
USE SHARED_DEFS

K = 0
XTMP = -X
DO WHILE (ABS(XTMP) < 2.0 .AND. K < ITOL)
   XTMP = XTMP**2 - X
   K = K + 1
END DO
MANDELBROT = K
END FUNCTION

The following shows the preceding function used in an interface block:

INTERFACE
   PURE INTEGER FUNCTION MANDELBROT(X)
   COMPLEX, INTENT(IN) :: X
END FUNCTION MANDELBROT
END INTERFACE

The following shows a FORALL construct calling the MANDELBROT function to update all the elements of an array:

FORALL (I = 1:N, J = 1:M)
   A(I,J) = MANDELBROT(COMPLEX((I-1)*1.0/(N-1), (J-1)*1.0/(M-1))
END FORALL

PUTC

Portability Function: Writes a character to Fortran external unit number 6.

Module
USE IFPORT

Syntax
result = PUTC (char)

char (Input) Character. Character to be written to external unit 6.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, an error code.

Example
use IFPORT
integer(4) i4
character*1 char1
do i = 1,26
   char1 = char(123-i)
i4 = putc(char1)
if (i4.ne.0) iflag = 1
enddo

Q to R
This section describes language features that start with Q or R.

Q to R

QCMPLX

Elemental Intrinsic Function (Specific): Converts an argument to COMPLEX(16) type. This function cannot be passed as an actual argument.

Syntax
result = QCMPLX (x[,y])

x  (Input) Must be of type integer, real, or complex.
y  (Input; optional) Must be of type integer or real. It must not be present if x is of type complex.

Results
The result type is COMPLEX(16) (or COMPLEX*32).

If only one noncomplex argument appears, it is converted into the real part of the result value and zero is assigned to the imaginary part. If y is not specified and x is complex, the result value is COMPLEX(REAL( x), AIMAG( x)).

If two noncomplex arguments appear, the complex value is produced by converting the first argument into the real part of the value, and converting the second argument into the imaginary part.

QCMPLX( x, y) has the complex value whose real part is REAL( x, kind=16) and whose imaginary part is REAL( y, kind=16).

Example
QCMPLX (-3) has the value (-3.0Q0, 0.0Q0).
QCMPLX (4.1, 2.3) has the value (4.1Q0, 2.3Q0).

**REAL**

**SNGL**

**QEXT**

*Elemental Intrinsic Function (Generic): Converts a number to quad precision (REAL(16)) type.*

**Syntax**

\[ \text{result} = \text{QEXT}(a) \]

\[ a \] (Input) Must be of type integer, real, or complex.

**Results**

The result type is REAL(16) (REAL*16). Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

If \( a \) is of type REAL(16), the result is the value of the \( a \) with no conversion (QEXT\( (a) = a \)).

If \( a \) is of type integer or real, the result has as much precision of the significant part of \( a \) as a REAL(16) value can contain.

If \( a \) is of type complex, the result has as much precision of the significant part of the real part of \( a \) as a REAL(16) value can contain.

</tr>
</tbody>
</table>

\( ^1 \)These specific functions cannot be passed as actual arguments.

**Example**

QEXT (4) has the value 4.0 (rounded; there are 32 places to the right of the decimal point).

QEXT ((3.4, 2.0)) has the value 3.4 (rounded; there are 32 places to the right of the decimal point).

**QFLOAT**

*Elemental Intrinsic Function (Generic): Converts an integer to quad precision (REAL(16)) type.*
Syntax
result = QFLOAT (a)

a  (Input) Must be of type integer.

Results
The result type is REAL(16) (REAL*16).
Functions that cause conversion of one data type to another type have the same affect as the implied conversion in assignment statements.

Example
QFLOAT (-4) has the value -4.0 (rounded; there are 32 places to the right of the decimal point).

QNUM
*Elemental Intrinsic Function (Specific): Converts a character string to a REAL(16) value. This function cannot be passed as an actual argument.*

Syntax
result = QNUM (i)

i  (Input) Must be of type character.

Results
The result type is REAL(16). The result value is the real value represented by the character string i.

Example
QNUM ("-174.23") has the value -174.23 of type REAL(16).

QRANSET
*Portability Subroutine: Sets the seed for a sequence of pseudo-random numbers.*

Module
USE IFPORT

Syntax
CALL QRANSET (rseed)

rseed  (Input) INTEGER(4). The reset value for the seed.

QREAL
*Elemental Intrinsic Function (Specific): Converts the real part of a COMPLEX(16) argument to REAL(16) type. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.*

Syntax
result = QREAL (a)
a

(Input) Must be of type COMPLEX(16) (or COMPLEX*32).

Results
The result type is quad-precision real (REAL(16) or REAL*16).

Example
QREAL ((2.0q0, 3.0q0)) has the value 2.0q0.

See Also
REAL
DREAL

QSORT
Portability Subroutine: Performs a quick sort on an array of rank one.

Module
USE IFPORT

Syntax
CALL QSORT (array, len, isize, compar)

array

(Input) Any type except assumed-length character. A one-dimensional array to be sorted.

If the data type does not conform to one of the predefined interfaces for QSORT, you may have to create a new interface (see Note and Example below).

len

(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Number of elements in array.

isize

(Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Size, in bytes, of a single element of array:

- 4 if array is of type REAL(4)
- 8 if array is of type REAL(8) or complex
- 16 if array is of type COMPLEX(8)

compar

(Input) INTEGER(2). Name of a user-defined ordering function that determines sort order. The type declaration of compar takes the form:

INTEGER(2) FUNCTION compar(arg1, arg2)

where arg1 and arg2 have the same type as array (above) and are not assumed-length character. Assume-length characters should be wrapped in a derived type. After you have created an ordering scheme, implement your sorting function so that it returns the following:

- Negative if arg1 should precede arg2
- Zero if arg1 is equivalent to arg2
- Positive if arg1 should follow arg2

Dummy argument compar must be declared as external.
In place of an INTEGER kind, you can specify the constant SIZEOF_SIZE_T, defined in IFPORT.F90, for argument len or isize. Use of this constant ensures correct compilation.

NOTE
If you use QSORT with different data types, your program must have a USE IFPORT statement so that all the calls work correctly. In addition, if you wish to use QSORT with a derived type or a type that is not in the predefined interfaces, you must include an overload for the generic subroutine QSORT. Examples of how to do this are in the portability module's source file, IFPORT.F90.

Example

```fortran
! program showing how to call 'QSORT' on
! a user-defined type.
!
! Define the type to be shared.
!
module share_type
    type element_type
        integer       :: data
        character(10) :: key
    end type
end module

! Main program calls QSORT.
!
program main

    use, intrinsic :: iso_c_binding, only: c_size_t
    use IFPORT       ! To get QSORT
    use share_type   ! To get shared type

    ! Define an overload of the default QSORT signature
    ! with a signature using the shared type.
    !
    interface
        subroutine QSORT_element_types(array, len, isize, comp)
            use, intrinsic :: iso_c_binding, only:c_size_t
            use share_type
            type(element_type) array(len)
            integer(C_SIZE_T) len, isize
            integer(2), external :: comp
        end subroutine QSORT_element_types
    end interface

    ! Hook the overload to the real thing but be careful
    ! to connect to the correct qsort: the Fortran one, not
    ! the C one!
    !
    ! We need to call the _Fortran_qsort, not the _C_one, or
    ! there will be errors from the 1-origin vs. 0-origin indexing
    ! and the row-major vs. column-major ordering.
    !
    ! The symptom is that "OrderCharCI" is called with pointer values
    ! which are outside the bounds of the array to be sorted.
    !
    !DIR$ IF DEFINED(_WIN64)
```
end subroutine QSORT_element_types
end interface

type(element_type) :: c(7)

integer(2), external :: OrderCharCI

integer (C_SIZE_T) :: size_of_element, size_of_array
!
! Fill in the array to be sorted. The data value is chosen so
! that the sorted array will have the values in numeric order.
! Thus we can check the result of the sort.
!
  c(1)%key  = 'aisjdop'
  c(1)%data = 3
  c(2)%key  = '35djf2'
  c(2)%data = 1
  c(3)%key  = 'ss:ss'
  c(3)%data = 6
  c(4)%key  = 'mmhQQ'
  c(4)%data = 4
  c(5)%key  = 'mmHqq'
  c(5)%data = 5
  c(6)%key  = 'aaaa'
  c(6)%data = 2
  c(7)%key  = '"/\'
  c(7)%data = 7

size_of_array   = size(c)         !  7
size_of_element = sizeof(c(1))    ! 16

write(*,*) ' "C" is:
do i = 1, 7
   write(*,*) ' "', c(i)%key, '" value ', c(i)%data
end do

write(*,*) ' size of C is               ', size_of_array, ' elements'
write(*,*) ' size of element C(1) is    ', size_of_element, ' bytes'
write(*,*) ' len of key in C(1) is      ', len(c(1)%key)
write(*,*) ' ' 
!
! Call the overloaded QSORT routine.
!
Call QSORT_element_types(C, size_of_array, size_of_element, OrderCharCI)

write(*,*) ' Sorted "C" is '
do i = 1, 7
   write(*,*) ' "', c(i)%key, '" value ', c(i)%data
end do

end program main

! Computes order of character strings using a case insensitive ordering.
!
function OrderCharCI(c1, c2)
    implicit none
    type(element_type), intent(in) :: c1 ! Character strings to be ordered.
    type(element_type), intent(in) :: c2 !

    ! Function result:
    !
    integer(2) :: OrderCharCI

    ! Locals:
    !
    character(10) :: c1L !} Local copies of c1 and c2.
    character(10) :: c2L }

    integer :: i ! Loop index.

    ! SEGV on access to C2
    !
write(*,*) 'OrderCharCI, parameter C1 is ''', c1%key, '''', c1%data, '''', len is '''', len(c1%key)
write(*,*) ' len_trim is '''', len_trim(c1%key)
write(*,*) ' about to start do loop'

    do i = 1, len_trim(C1L)
        if ('a' <= C1L(i:i) .and. c1L(i:i) <= 'z') c1L(i:i) = char(ichar(c1L(i:i)) - ichar('a')
                           +  ichar('A'))
    end do

    do i = 1, len_trim(C2L)
        if ('a' <= c2L(i:i) .and. c2L(i:i) <= 'z') c2L(i:i) = char(ichar(c2L(i:i)) - ichar('a')
                           + ichar('A'))
    end do

    if (c1L == c2L) Then
        OrderCharCI = 0
        write(*,*) ' - equal'
    else if (c1L < c2L) Then
        OrderCharCI = -1
        write(*,*) ' - c1 is less'
    else
        OrderCharCI = 1
The following shows another example:

```fortran
PROGRAM SORTQ
  use, intrinsic :: iso_c_binding, only: c_size_t
  use IFPORT
  integer(2), external :: cmp_function
  integer(2) insort(26), i
  integer (C_SIZE_T) array_len, array_size
  array_len = 26
  array_size = 2
  do i=90,65,-1
    insort(i-64)=91 - i
  end do
  print *, "Before: ", insort
  CALL qsort(insort,array_len,array_size,cmp_function)
  print *, 'After: ', insort
END
!
  integer(2) function cmp_function(a1, a2)
    integer(2) a1, a2
    cmp_function=a1-a2
  end function
```

**RADIX**

Inquiry Intrinsic Function (Generic): Returns the base of the model representing numbers of the same type and kind as the argument.

**Syntax**

```fortran
result = RADIX (x)
```

- **X** (Input) Must be of type integer or real; it can be scalar or array valued.

**Results**

The result is a scalar of type default integer. For an integer argument, the result has the value r (as defined in Model for Integer Data). For a real argument, the result has the value b (as defined in Model for Real Data).

**Example**

If X is a REAL(4) value, RADIX (X) has the value 2.

**See Also**

- DIGITS
- EXPONENT
- FRACTION
- Data Representation Models
RAISEQQ

Portability Function: Sends a signal to the executing program.

Module
USE IFPORT

Syntax
result = RAISEQQ (sig)

sig (Input) INTEGER(4). Signal to raise. One of the following constants (defined in IFPORT.F90):
- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+C signal
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

If you do not install a signal handler (with SIGNALQQ, for example), when a signal occurs the system by default terminates the program with exit code 3.

Results
The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

If a signal-handling routine for sig has been installed by a prior call to SIGNALQQ, RAISEQQ causes that routine to be executed. If no handler routine has been installed, the system terminates the program (the default action).

See Also
SIGNALQQ
SIGNAL
KILL

RAN

Nonelemental Intrinsic Function (Specific):
Returns the next number from a sequence of pseudorandom numbers of uniform distribution over the range 0 to 1. This is a specific function that has no generic function associated with it. It cannot be passed as an actual argument.

Syntax
result = RAN (i)
i (Input; output) Must be an INTEGER(4) variable or array element.

It should initially be set to a large, odd integer value. The RAN function stores a value in the argument that is later used to calculate the next random number.
There are no restrictions on the seed, although it should be initialized with different values on separate runs to obtain different random numbers.

**Results**
The result type is REAL(4). The result is a floating-point number that is uniformly distributed in the range between 0.0 inclusive and 1.0 exclusive. The result is set equal to the value associated with the argument \( i \).

RAN is not a pure function.

**Example**
In RAN \((I)\), if variable \( I \) has the value 3, RAN has the value 4.8220158E-05.

**See Also**
RANDOM
RANDOM_NUMBER

**RAND, RANDOM**
*Portability Functions:* Return real random numbers in the range 0.0 to 1.0, not including the end points.

**Module**
USE IFPORT

**Syntax**

\[
\text{result} = \text{RAND} ([ \text{iflag}])
\]

\[
\text{result} = \text{RANDOM} (\text{iflag})
\]

(iflag) (Input) INTEGER(4). Optional for RAND. Controls the way the random number is selected.

**Results**
The result type is REAL(4). RAND and RANDOM return random numbers in the range 0.0 to 1.0, not including the end points.

<table>
<thead>
<tr>
<th>Value of iflag</th>
<th>Selection process</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>The generator is restarted and the first random value is selected.</td>
</tr>
<tr>
<td>0</td>
<td>The next random number in the sequence is selected.</td>
</tr>
<tr>
<td>Otherwise</td>
<td>The generator is reseeded using iflag, restarted, and the first random value is selected.</td>
</tr>
</tbody>
</table>

When RAND is called without an argument, the following applies:
- The value of iflag is assumed to be 0.
- You must specify USE IFPORT.

There is no difference between RAND and RANDOM. Both functions are included to ensure portability of existing code that references one or both of them.
The intrinsic subroutines RANDOM_INIT, RANDOM_NUMBER, and RANDOM_SEED provide the same functionality and they are the recommended functions to use when writing programs to generate random numbers.

You can use SRAND to restart the pseudorandom number generator used by RAND.

**NOTE**
RANDOM is available as a function or subroutine.

### Example

The following example shows how to use both the RANDOM function and the RANDOM subroutine:

```fortran
use ifport
real(4) ranval
call seed(1995) ! initialize
call random(ranval) ! get next random number
print *,ranval
ranval = random(1) ! initialize
ranval = random(0) ! get next random number
print *,ranval
end
```

### See Also

- RANDOM_INIT
- RANDOM_NUMBER
- RANDOM_SEED
- SRAND

### RANDOM Subroutine

**Portability Subroutine:** Returns a pseudorandom number greater than or equal to zero and less than one from the uniform distribution.

**Module**

- USE IFPORT

**Syntax**

```fortran
CALL RANDOM (ranval)
```

ranval (Output) REAL(4). Pseudorandom number, 0 < ranval < 1, from the uniform distribution.

A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFCORE.F90) to SEED before the first call to RANDOM.
The portability routines DRAND, DRANDM, IRAND, IRANDM, RAN, RAND, and the RANDOM portability function and subroutine use the same algorithms and thus return the same answers. They are all compatible and can be used interchangeably. The algorithm used is a "Prime Modulus M Multiplicative Linear Congruential Generator," a modified version of the random number generator by Park and Miller in "Random Number Generators: Good Ones Are Hard to Find," CACM, October 1988, Vol. 31, No. 10.

Example

```
USE IFPORT
REAL(4) ran

CALL SEED(1995)
CALL RANDOM(ran)
```

The following example shows how to use both the RANDOM subroutine and the RANDOM function:

```
use ifport
real(4) ranval
! from libifcore.lib
call seed(1995) ! initialize
! also from for_m_irand.c in libfor
call random(ranval) ! get next random number
print *,ranval
! from libifport.lib
ranval = random(1) ! initialize
! same
ranval = random(0) ! get next random number
print *,ranval
end
```

SEED
DRAND and DRANDM
IRAND and IRANDM
RAN
RAND

RANDOM_INIT

**Intrinsic Subroutine:** Initializes the pseudorandom number generator used by RANDOM_NUMBER.

**Syntax**

```
CALL RANDOM_INIT (repeatable, image_distinct)
```

- **repeatable** (Input) Must be scalar of type logical.
- **image_distinct** (Input) Must be scalar of type logical.

If `repeatable` has the value .true. and `image_distinct` has the value .true., the effect of a call to RANDOM_INIT is equivalent to calling RANDOM_SEED with a different processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is the same each time the program is executed.
If \textit{repeatable} has the value .true. and \textit{image\_distinct} has the value .false., the effect of a call to \texttt{RANDOM\_INIT} is equivalent to calling \texttt{RANDOM\_SEED} with the same processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is the same each time the program is executed.

If \textit{repeatable} has the value .false. and \textit{image\_distinct} has the value .true., the effect of a call to \texttt{RANDOM\_INIT} is equivalent to calling \texttt{RANDOM\_SEED} with a different processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is different each time the program is executed.

If \textit{repeatable} has the value .false. and \textit{image\_distinct} has the value .false., the effect of a call to \texttt{RANDOM\_INIT} is equivalent to calling \texttt{RANDOM\_SEED} with the same processor-dependent value of PUT on each image that executes the call. If the invoking image index on the initial team is the same, the value of PUT is different each time the program is executed.

\textbf{NOTE}
\par
This routine is thread safe.

\textbf{Example}

Consider the following:

\begin{verbatim}
PROGRAM main
 REAL,DIMENSION(1000) :: y
 CALL RANDOM_INIT (REPEATABLE=.TRUE., IMAGE_DISTINCT=.TRUE.)
 CALL RANDOM_NUMBER (y)
 . . .
END
\end{verbatim}

After executing the above code, the array \( y \) contains a different sequence of pseudorandom numbers on each image that executes the code. If the program is executed multiple times, for an image that has the same image index in the initial team, the value of \( y \) is the same each time the program is run.

Consider another example:

\begin{verbatim}
PROGRAM main
 REAL,DIMENSION(1000) :: y
 CALL RANDOM_INIT (REPEATABLE=.FALSE., IMAGE_DISTINCT=.FALSE.)
 CALL RANDOM_NUMBER (y)
 . . .
END
\end{verbatim}

After executing the above code, the array \( y \) contains the same sequence of pseudorandom numbers on each image that executes the code. If the program is executed multiple times, the value of \( y \) is different each time the program is run.

RANDOM_NUMBER

_Intrinsic Subroutine:_ Returns one pseudorandom number or an array of such numbers.

Syntax

```call random_number (harvest)`
```

*harvest* (Output) Must be of type real. It can be a scalar or an array variable. It is set to contain pseudorandom numbers from the uniform distribution within the range $0 \leq x < 1$.

The seed for the pseudorandom number generator used by RANDOM_NUMBER can be set or queried with RANDOM_SEED. If RANDOM_SEED is not used, the processor sets the seed for RANDOM_NUMBER to a processor-dependent value.

The RANDOM_NUMBER generator uses two separate congruential generators together to produce a period of approximately $10^{18}$, and produces real pseudorandom results with a uniform distribution in $[0, 1)$. It accepts two integer seeds, the first of which is reduced to the range $[1, 2147483562]$. The second seed is reduced to the range $[1, 2147483398]$. This means that the generator effectively uses two 31-bit seeds.

The RANDOM_NUMBER generator does not produce subnormal numbers.

For more information on the algorithm, see the following:

**NOTE**

This routine is thread safe.

Example

Consider the following:

```fortran
real y, z (5, 5)
! Initialize y with a pseudorandom number
call random_number (harvest = y)
call random_number (z)
```

Y and Z contain uniformly distributed random numbers.

The following shows another example:

```fortran
real x, array1 (5, 5)
call random_seed()
call random_number (x)
call random_number (array1)
```

The following shows another example:

```fortran
program testrand
   intrinsic random_seed, random_number
```

1817
integer size
integer, allocatable :: seed(:), gseed(:), hiseed(:), zseed(:)
real harvest(10)
call random_seed(SIZE=size)
print *, "size ", size
allocate(seed(size), gseed(size), hiseed(size), zseed(size))
hiseed = -1
zseed = 0
seed = 123456789
seed(size) = 987654321
call random_seed(PUT=hiseed(1:size))
call random_seed(GET=gseed(1:size))
print *, "hiseed gseed", hiseed, gseed
call random_seed(PUT=zseed(1:size))
call random_seed(GET=gseed(1:size))
print *, "zseed gseed ", zseed, gseed
call random_seed(PUT=seed(1:size))
call random_seed(GET=gseed(1:size))
call random_number(HARVEST=harvest)
print *, "seed gseed ", seed, gseed
print *, "harvest"
print *, harvest
call random_seed(GET=gseed(1:size))
print *, "gseed after harvest ", gseed
end program testrand

RAND and RANDOM

RANDOM_SEED

Intrinsic Subroutine (Generic): Changes or queries the seed (starting point) for the pseudorandom number generator used by intrinsic subroutine RANDOM_NUMBER. Intrinsic subroutines cannot be passed as actual arguments.

Syntax
CALL RANDOM_SEED ([size] [,put] [,get])

size (Output; optional) Must be scalar and of type integer. Set to the number of integers (N) that the processor uses to hold the value of the seed.
**put**

(Input; optional) Must be an integer array of rank one and size greater than or equal to N. It is used to reset the value of the seed.

**get**

(Output; optional) Must be an integer array of rank one and size greater than or equal to N. It is set to the current value of the seed.

No more than one argument can be specified. If no argument is specified, a random number based on the date and time is assigned to the seed.

You can determine the size of the array the processor uses to store the seed by calling RANDOM_SEED with the `size` argument (see the second example below).

If RANDOM_SEED is called with no arguments, the seed is set to a different, unpredictable value on each call.

---

**NOTE**

This routine is thread safe.

---

**Example**

Consider the following:

```fortran
CALL RANDOM_SEED                        ! Processor initializes the 
!   seed randomly from the date           
!   and time                             
CALL RANDOM_SEED (SIZE = M)             ! Sets M to N
CALL RANDOM_SEED (PUT = SEED (1 : M))   ! Sets user seed
CALL RANDOM_SEED (GET = OLD (1 : M))    ! Reads the current seed
```

The following shows another example:

```fortran
INTEGER I
INTEGER, ALLOCATABLE :: new (:), old(:)
CALL RANDOM_SEED ( )  ! Processor reinitializes the seed
                      !   randomly from the date and time
CALL RANDOM_SEED (SIZE = I)  ! I is set to the size of
                            !   the seed array
ALLOCATE (new(I))
ALLOCATE (old(I))
CALL RANDOM_SEED (GET=old(1:I)) ! Gets the current seed
WRITE(*,*) old
new = 5
CALL RANDOM_SEED (PUT=new(1:I)) ! Sets seed from array
                             ! new
END
```

**See Also**

RANDOM_INIT

RANDOM_NUMBER

SEED

SRAND
**RANDU**

*Intrinsic Subroutine (Generic):* Computes a pseudorandom number as a single-precision value. *Intrinsic subroutines cannot be passed as actual arguments.*

**Syntax**

```fortran
CALL RANDU (i1, i2, x)
```

- `i1, i2` *(Input; output)* Must be scalars of type `INTEGER(2)` or `INTEGER(4)`. They contain the seed for computing the random number. These values are updated during the computation so that they contain the updated seed.

- `x` *(Output)* Must be a scalar of type `REAL(4)`. This is where the computed random number is returned.

The result is returned in `x`, which must be of type `REAL(4)`. The result value is a pseudorandom number in the range 0.0 to 1.0. The algorithm for computing the random number value is based on the values for `i1` and `i2`.

If `i1 = 0` and `i2 = 0`, the generator base is set as follows:

\[ x(n + 1) = 2^{16} + 3 \]

Otherwise, it is set as follows:

\[ x(n + 1) = (2^{16} + 3) \times x(n) \mod 2^{32} \]

The generator base `x(n + 1)` is stored in `i1, i2`. The result is `x(n + 1)` scaled to a real value `y(n + 1)`, for `0.0 \leq y(n + 1) < 1`.

**Example**

Consider the following:

```fortran
REAL X
INTEGER(2) I, J
...
CALL RANDU (I, J, X)
```

If `I` and `J` are values 4 and 6, `X` has the value 5.4932479E-04.

**RANF Intrinsic Procedure**

*Elemental Intrinsic Function (Generic):* Generates a random number between 0.0 and RAND_MAX. This function must not be passed as an actual argument. RANF can be used as an intrinsic procedure or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.

**Syntax**

```fortran
result = RANF ()
```
Results

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and \((2^{31}) - 1\).

The initial seed is set by the following:

```
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

The intrinsic function RANF generates a different sequence of random numbers than the RANF portability function generates for the same seed. The intrinsic function RANF used inside a loop can be vectorized into one call that returns four results, but the portability function RANF cannot be so optimized.

See Also

RANDOM_NUMBER

RANF portability routine

SRAND

RANF Portability Routine

**Portability Function:** Generates a random number between 0.0 and RAND_MAX. RANF can be used as a portability routine or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

```
result = RANF ( )
```

Results

The result type is REAL(4). The result value is a single-precision pseudo-random number between 0.0 and \((2^{31}) - 1\).

The initial seed is set by the following:

```
CALL SRAND(ISEED)
```

where ISEED is type INTEGER(4).

See Also

RANDOM_NUMBER

RANF intrinsic procedure

SRAND
RANGE

Inquiry Intrinsic Function (Generic): Returns the decimal exponent range in the model representing numbers with the same kind parameter as the argument.

Syntax

\[ \text{result} = \text{RANGE} (x) \]

\(x\) (Input) Must be of type integer, real, or complex; it can be scalar or array valued.

Results

The result is a scalar of type default integer.

For an integer argument, the result has the value \(\text{INT} (\log_{10} (\text{HUGE}(x)))\). For information on the integer model, see Model for Integer Data.

For a real or complex argument, the result has the value \(\text{INT} (\min (\log_{10} (\text{HUGE}(x)), -\log_{10} (\text{TINY}(x))))\). For information on the real model, see Model for Real Data.

Example

If \(X\) is a REAL(4) value, RANGE (X) has the value 37. (HUGE(X) = (1 - 2^{-24}) \times 2^{128} and TINY(X) = 2^{-126})

See Also

HUGE
TINY

RANGET

Portability Subroutine: Returns the current seed.

Module

USE IFPORT

Syntax

CALL RANGET (seed)

\(seed\) (Output) INTEGER(4). The current seed value.

RANK

Inquiry Intrinsic Function (Generic): Returns the rank of a data object.

Syntax

\[ \text{result} = \text{RANK} (a) \]

\(a\) (Input) Is a data object. It can be of any type.

Results

The result type is default integer scalar. The result value is the rank of \(a\).
Example
If object C is an assumed-rank dummy argument and its associated argument is an array of rank 5, RANK(C) returns the value 5.
If D is an array declared DIMENSION (2, 3, 4), RANK(D) returned the value 3.

Assumed-Rank Specifications

RANSET
Portability Subroutine: Sets the seed for the random number generator.

Module
USE IFPORT

Syntax
CALL RANSET (seed)

seed (Input) REAL(4). The reset value for the seed.

READ Statement
Statement: Transfers input data from external sequential, direct-access, or internal records.

Syntax
Sequential
Formatted:

READ form[, io-list]

Formatted - List-Directed:

READ *[, io-list]

Formatted - Namelist:

READ nml

Unformatted:

Direct-Access
Formatted:
Unformatted:

```fortran
Internal
READ (iunit, format [, nml-group] [, iostat] [, err] [, end] [, iomsg]) [io-list]
Internal Namelist
READ (iunit, nml-group [, iostat] [, err] [, end] [, iomsg]) [io-list]
```

- **eunit**: Is an external unit specifier, optionally prefaced by UNIT=. UNIT= is required if `eunit` is not the first specifier in the list.

- **format**: Is a format specifier. It is optionally prefaced by FMT= if `format` is the second specifier in the list and the first specifier indicates a logical or internal unit specifier without the optional keyword UNIT=.

  For internal READs, an asterisk (*) indicates list-directed formatting.

  For direct-access READs, an asterisk is not permitted.

- **advance**: Is an advance specifier (ADVANCE=c-expr). If the value of c-expr is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.

- **asynchronous**: Is an asynchronous specifier (ASYNCHRONOUS=i-expr). If the value of i-expr is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.

- **blank**: Is a blank control specifier (BLANK = blnk). If the value of blnk is 'NULL', all blanks are ignored. If the value is 'ZERO', all blanks are treated as zeros. The default value is 'NULL'.

- **decimal**: Is a decimal mode specifier (DECIMAL=dmode) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.

- **id**: Is an id specifier (ID=id-var). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.

- **pad**: Is a blank padding specifier (PAD = pd). If the value of pad is 'YES', the record will be padded with blanks when necessary. If the value is 'NO', the record will not be padded with blanks. The default value is 'YES'.

- **pos**: Is a pos specifier (POS=p) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

- **round**: Is a rounding specifier (ROUND=rmode) that determines the I/O rounding mode for this READ statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.

- **size**: Is a character count specifier (SIZE=i-var).
**iostat**

Is the name of a variable to contain the completion status of the I/O operation. Optionally prefaced by IOSTAT=.

**err, end, eor**

Are branch specifiers if an error (ERR=label), end-of-file (END=label), or end-of-record (EOR=label) condition occurs.

EOR can only be specified for nonadvancing READ statements.

**iomsg**

Is an I/O message specifier (IOMSG=msg-var).

**io-list**

Is an I/O list: the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.

If an item in io-list is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as eunit.

If I/O is to or from a formatted device, io-list cannot contain derived-type variables, but it can contain components of derived types. If I/O is to a binary or unformatted device, io-list can contain either derived type components or a derived type variable.

**form**

Is the nonkeyword form of a format specifier (no FMT=).

*****

Is the format specifier indicating list-directed formatting. (It can also be specified as FMT=*.)

**nml-group**

Is the namelist group specification for namelist I/O. Optionally prefaced by NML=. NML= is required if nml-group is not the second I/O specifier. For more information, see Namelist Specifier.

**nml**

Is the nonkeyword form of a namelist specifier (no NML=) indicating namelist I/O.

**rec**

Is the cell number of a record to be accessed directly. It must be prefaced by REC=.

**iunit**

Is an internal unit specifier, optionally prefaced by UNIT=. UNIT= is required if iunit is not the first specifier in the list. It must be a character variable. It must not be an array section with a vector subscript.

If you specify EOR= or SIZE=, you must also specify ASYNCHRONOUS='NO'.

If you specify BLANK=, DECIMAL=, PAD=, or ROUND=, you must also specify FMT= or NML=.

If you specify ID=, you must also specify ASYNCHRONOUS='YES'.

---

**Caution**

The READ statement can disrupt the results of certain graphics text functions (such as SETTEXTWINDOW) that alter the location of the cursor. You can avoid the problem by getting keyboard input with the GETCHARQQ function and echoing the keystrokes to the screen using OUTTEXT. Alternatively, you can use SETTEXTPOSITION to control cursor location.
Example

```fortran
DIMENSION ia(10,20)
! Read in the bounds for the array.
! Then read in the array in nested implied-DO lists
! with input format of 8 columns of width 5 each.
READ (6, 990) il, jl, ((ia(i,j), j = 1, jl), i =1, il)
990 FORMAT (2I5, /, (8I5))

! Internal read gives a variable string-represented numbers
CHARACTER*12 str
str = '123456'
READ (str,'(i6)') i

! List-directed read uses no specified format
REAL x, y
INTEGER i, j
READ (*,*) x, y, i, j
```

See Also

REAL Directive
General Compiler Directive: Specifies the default real kind.

Syntax
```
!DIR$ REAL: { 4 | 8 | 16 }
```

The REAL directive selects a size of 4 (KIND=4), 8 (KIND=8), or 16 (KIND=16) bytes for default real numbers. When the directive is in effect, all default real and complex variables are of the kind specified in the directive. Only numbers specified or implied as REAL without KIND are affected.

The REAL directive can appear only at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. REAL cannot appear at the beginning of internal subprograms. It does not affect modules invoked with the USE statement in the program unit that contains it.

Example
```
REAL r          !$ a 4-byte REAL
WRITE(*,*) KIND(r)
CALL REAL8( )
WRITE(*,*) KIND(r)  !$ still a 4-byte REAL
             ! not affected by setting in subroutine
END
SUBROUTINE REAL8( )
     !DIR$ REAL:8
```
REAL s ! an 8-byte REAL
WRITE(*,*) KIND(s)
END SUBROUTINE

See Also
REAL
COMPLEX
General Compiler Directives
Syntax Rules for Compiler Directives

REAL Function

*Elemental Intrinsic Function (Generic):* Converts a value to real type.

**Syntax**

```
result = REAL (a[,kind])
```

- `a` (Input) Must be of type integer, real, or complex, or a binary, octal, or hexadecimal literal constant.
- `kind` (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is real. If `kind` is present, the kind parameter is that specified by `kind`; otherwise, the kind parameter of the result is shown in the following table. If the processor cannot represent the result value in the kind of the result, the result is undefined.

Functions that cause conversion of one data type to another type have the same effect as the implied conversion in assignment statements.

The result value depends on the type and absolute value of `a` as follows:

- If `a` is integer or real, the result is equal to an approximation of `a`. If `a` is complex, the result is equal to an approximation of the real part of `a`.
- If `a` is a binary, octal, or hexadecimal literal constant, the value of the result is the value whose bit sequence according to the model in Bit Model is the same as that of `a` as modified by padding or truncation according to the following:
  - If the length of the sequence of bits specified by `a` is less than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were extended to a length equal to the size in bits of the result by padding on the left with zero bits.
  - If the length of the sequence of bits specified by `a` is greater than the size in bits of a scalar variable of the same type and kind type parameter as the result, the binary, octal, or hexadecimal literal constant is treated as if it were truncated from the left to a length equal to the size in bits of the result.
- If a binary, octal, or hexadecimal literal constant is truncated as an argument to intrinsic function REAL, the discarded bits must all be zero.

**Specific Name**

<table>
<thead>
<tr>
<th>Specific Name</th>

<td>REAL(8)</td>
</tr>
</tbody>
</table>

1 These specific functions cannot be passed as actual arguments.

2 The setting of compiler options specifying real size can affect FLOAT, REAL, and SNGL.

3 Or FLOATJ. For compatibility with older versions of Fortran, FLOAT is generic, allowing any kind of INTEGER argument, and returning a default real result.

4 For compatibility with older versions of Fortran, SNGL is generic, allowing any kind of REAL argument, and returning a default real result.

If the argument is a a binary, octal, or hexadecimal constant, the result is affected by the assume old-boz option. The default option setting, noold-boz, treats the argument as a bit string that represents a value of the data type of the intrinsic, that is, the bits are not converted. If setting old-boz is specified, the argument is treated as a signed integer and the bits are converted.

**Example**

REAL (-4) has the value -4.0.

REAL (Y) has the same kind parameter and value as the real part of complex variable Y.

If C is complex, C%RE is the same as REAL (C).

**See Also**

Binary, Octal, Hexadecimal, and Hollerith Constants

Model for Bit Data

DFLOAT

DREAL

DBLE

assume compiler option

**REAL Statement**

*Statement: Specifies the REAL data type.*

**Syntax**

REAL

REAL([KIND=] n)

REAL* n

DOUBLE PRECISION
Description

If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.

Default real is affected by compiler options specifying real size and by the REAL directive.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).

No kind parameter is permitted for data declared with type DOUBLE PRECISION.

REAL(4) and REAL*4 (single precision) are the same data type. REAL(8), REAL*8, and DOUBLE PRECISION are the same data type.

Example

```
! type declarations with attribute specifiers
REAL (8), PARAMETER :: testval=50.d0
REAL, SAVE :: a(10), b(20,30)
REAL, PARAMETER :: x = 100.

! attribute statements to declare the same entities
REAL x, a, b, testval*8
DIMENSION a(10), b(20,30)
SAVE a, b
PARAMETER (x = 100., testval=50.d0)
```

Model for Real Data

**RECORD**

**Statement:** Declares a record structure as an entity with a name.

**Syntax**

```
RECORD /structure-name/record-namelist [, /structure-name/record-namelist]...
```

*structure-name*

Is the name of a previously declared structure.

*record-namelist*

Is a list of one or more variable names, array names, or array specifications, separated by commas. All of the records named in this list have the same structure and are allocated separately in memory.

You can use record names in COMMON and DIMENSION statements, but not in DATA or NAMELIST statements.

Records initially have undefined values unless you have defined their values in structure declarations.
STRUCTURE and RECORD constructs have been replaced by derived types, which should be used in writing new code. See Derived Data Types.

Example

```
STRUCTURE /address/
  LOGICAL*2 house_or_apt
  INTEGER*2 apt
  INTEGER*2 housenumber
  CHARACTER*30 street
  CHARACTER*20 city
  CHARACTER*2 state
  INTEGER*4 zip
END STRUCTURE

RECORD /address/ mailing_addr(20), shipping_addr(20)
```

The following shows another example:

```
RECORD /T1/ a, b, /T2/ c, /T3/ d, e, f
```

**RECURSIVE and NON_RECURSIVE**

*Keywords:* RECURSIVE specifies that a subroutine or function can call itself directly or indirectly. NON_RECURSIVE specifies that a subroutine or function does not call itself directly or indirectly.

**Description**

RECURSIVE or NON_RECURSIVE can be specified once in a FUNCTION or SUBROUTINE statement. They cannot both appear in the same statement.

Procedures not specified as RECURSIVE or NON_RECURSIVE are currently compiled as NON_RECURSIVE. The default behavior can be changed by using the `-assume [no]recursion` option, or in an `OPTIONS` statement.

**NOTE**

The Fortran 2018 Standard specifies that the default mode is recursion; previous standards specified the default was no recursion. The default compilation mode will change to recursion in a future release.

If a function is directly recursive and array valued, and if the keyword RESULT is not specified in the FUNCTION statement, the result variable is the function name, and all occurrences of the function name in the executable part of the function are references to the function result variable.

A directly recursive function cannot have a declared type of CHARACTER if the character length is declared as `*`.

A procedure interface is always explicit within the subprogram that defines the procedure.
The keyword RECURSIVE *must* be specified if the compilation mode is set to non-recursive by a compiler option and if any of the following applies (directly or indirectly):

- The subprogram invokes itself.
- The subprogram invokes a subprogram defined by an ENTRY statement in the same subprogram.
- An ENTRY procedure in the same subprogram invokes one of the following:
  - Itself
  - Another ENTRY procedure in the same subprogram
  - The subprogram defined by the FUNCTION or SUBROUTINE statement

The keyword NON_RECURSIVE must be specified if the compilation mode is set to recursion by a compiler option and the procedure is not to be compiled for recursion.

**Example**

```fortran
! RECURS.F90
!
i = 0
CALL Inc (i)
END

RECURSIVE SUBROUTINE Inc (i)
i = i + 1
CALL Out (i)
IF (i.LT.20) CALL Inc (i) ! This also works in OUT
END SUBROUTINE Inc

SUBROUTINE Out (i)
WRITE (*,*) i
END SUBROUTINE Out
```

**REDUCE**

*Transformational Intrinsic Function (Generic):*

*Performs general array reduction.*

**Syntax**

```
result = REDUCE (array, operation [, mask] [, identity] [, ordered])
result = REDUCE (array, operation, dim [, mask] [, identity] [, ordered])
array

operation
```

(Input) Must be an array of any data type.

(Input) Must be a pure function with two non-optional, scalar, nonallocatable, nonpointer, nonpolymorphic dummy arguments with the same declared type and type-parameters as `array`. If one argument has the ASYNCHRONOUS, TARGET, or VALUE attribute, the other argument must have the same attribute. The function result
must be non-polymorphic and scalar, with the same declared type and
type parameters as array. The function should implement a
mathematically associated operation; it need not be commutative.

dim
   (Input) Must be a scalar integer whose value is greater than or equal
to 1 and less than or equal to the rank of array.

mask
   (Input; optional) Must be of type logical and conformable with array.

identity
   (Input; optional) Must be scalar with the same declared type and type
parameters as array.

ordered
   (Input; optional) Must be a scalar of type logical.

Results
The result has the same declared type and type parameters as array. If dim does not appear the result is
scalar; otherwise if n=RANK (array) the result has shape \([d_1, d_2, \ldots, d_{\text{dim}-1}, d_{\text{dim}+1}, \ldots, d_n]\) and rank n–1.

The result value is calculated differently depending on the form of the call:

1. The result of REDUCE (array, operation \([,\) identity, ordered]) is calculated iteratively over the values of
   array. The initial order of the sequence is array element order. While there is more than one element in
   the sequence, each iteration calculates \(r = \text{operation} (a, b)\) replacing \(a\) and \(b\) with \(r\).
   
   If ordered is present with the value .true., \(a\) and \(b\) must be the first two elements of the sequence. The
   process continues until the sequence has one value, and that is the value of the reduction. If array is a
   zero-sized array and identity is present, the result is the value of identity; otherwise error termination
   is initiated.

2. The result of REDUCE (array, operation, mask \([,\) identity, ordered]) is calculated as for case 1, but the
   sequence of values consists only of those values of array for which the corresponding element of mask
   has the value .true..

3. If array is a rank 1 array, REDUCE (array, operation, dim \([,\) mask, identity, ordered]) is equivalent to
   REDUCE (array, operation \([,\) mask, identity, ordered]); otherwise, the value of element \((s_1, s_2, \ldots,
   s_{\text{dim}-1}, s_{\text{dim}+1}, \ldots, s_n)\) of REDUCE (array, operation, dim \([,\) mask, identity, ordered]) is equal to REDUCE
   (array \((s_1, s_2, \ldots, s_{\text{dim}-1}, \ldots, s_{\text{dim}+1}, \ldots, s_n)\), operation, dim = 1 \([,\) mask \((s_1, s_2, \ldots, s_{\text{dim}-1}, \ldots, s_{\text{dim}+1}, \ldots, s_n)\),
   identity, ordered]).

Example
The following examples all use the function my_add, which returns the sum of its two real arguments.

1. The result of REDUCE ([2.0, 4.0, 6.0], my_add) is 12.0.
2. REDUCE (array, my_add, mask = array < 0.0, identity = 0.0) returns the sum of the negative elements
   of array, or 0.0 if array is zero sized or all of arrays elements are non-negative.
3. If array is declared as

   REAL, DIMENSION(2, 3) :: array = [1.0, 2.0, 3.0, 4.0, 5.0, 6.0]

   then REDUCE (array, my_add, DIM = 2) has the result [5.0, 7.0, 9.0] and REDUCE (array, my_add,
   DIM = 1) has the result [6.0, 15.0].
Is INSCAN, TASK, or DEFAULT.

Is an identifier, user defined operator, or generic name which has appeared in an accessible DECLARE REDUCTION directive, or one of the predefined reduction operators or intrinsic names in the table of predefined reduction-identifiers below.

Is the name of one or more variables that are accessible to the scoping unit. Each list item must be definable. Each name must be separated by a comma. The type of each variable must be compatible with a type for which the reduction-identifier has an accessible definition.

Assumed-size arrays, procedure pointers, and dummy arguments that are pointers with the INTENT (IN) attribute are not allowed. Array sections are allowed.

For each list item, the number of copies is unspecified.

The same list item cannot appear in both a REDUCTION and an IN_REDUCTION clause in the same directive.

If a reduction-modifier is not present or if DEFAULT is specified for PARALLEL, LOOP, and worksharing constructs, one or more copies of each reduction list item is created for each implicit task in the region as if the list item had been specified in a PRIVATE clause.

If the REDUCTION clause appears in a SIMD statement, one or more private copies of each reduction list item is created for each SIMD lane. If the REDUCTION clause is in a TASKLOOP directive, private copies of reduction list items are created as if a PRIVATE clause had been specified containing the list item. For a REDUCTION clause in a TEAMS construct, one or more private copies of each reduction list item are created for the initial task of each team in the league.

If the TASK reduction-modifier is specified for a PARALLEL or worksharing construct, it is as if each reduction list item appeared in a PRIVATE clause in the directive, and any number of additional private copies can be created to support task reductions. If the TASK reduction-modifier appears in REDUCTION clause, a NOWAIT clause cannot appear for the same construct.

List items in a REDUCTION clause of the inner most enclosing worksharing or PARALLEL construct must not be accessed in an explicit task generated by a construct unless that construct contains an IN_REDUCTION clause that contains the same list items.

The INSCAN reduction-modifier is allowed only in a worksharing construct, a SIMD construct, or a composite construct for which these constructs are a constituent construct, and the DISTRIBUT is not a constituent construct. It indicates that in each iteration of the loop, a scan computation is performed over the updates to each list item. Each list item is made PRIVATE in the construct. Upon completion of the region, the value of the private copy of a list item from the last logical iteration of the loops of the construct is assigned to the original list item.

Each list item of a REDUCTION clause with the INSCAN reduction-modifier must appear as a list item in an INCLUSIVE or EXCLUSIVE clause on a SCAN directive contained in the loop (nest) enclosed in the construct. If INSCAN appears in one REDUCTION clause of a construct, all REDUCTION clauses of that construct must contain an INSCAN reduction-modifier. If an INSCAN reduction-modifier is applied to a construct that is combined with a TARGET construct, it is as if each list item also appears in a MAP clause with a map-type of TOFROM.

Variables that appear in a REDUCTION clause must be SHARED in the enclosing context. A private copy of each variable in list is created for each thread as if the PRIVATE clause had been used. The private copy is initialized according to the initializer-clause of the reduction-identifier. A dummy argument that is a pointer with the INTENT (IN) attribute must not appear in a REDUCTION clause.
At the end of the REDUCTION, the shared variable is updated to reflect the result of combining the original value of the shared reduction variable with the final value of each of the private copies using the combiner specified for the reduction-identifier. Reduction operations should all be associative (except for subtraction), and the compiler can freely reassociate the computation of the final value; the partial results of a subtraction reduction are added to form the final value.

The value of the shared variable becomes undefined when the first thread reaches the clause containing the reduction, and it remains undefined until the reduction computation is complete. Normally, the computation is complete at the end of the construct containing the REDUCTION clause.

However, if the REDUCTION clause is used in a construct to which NOWAIT is also applied, the shared variable remains undefined until a barrier synchronization has been performed. This ensures that all the threads complete the REDUCTION clause.

Any list item copies associated with the reduction must be initialized before they are accessed by the tasks participating in the reduction. After the end of the region, the original list item contains the result of the reduction.

An original list item with the POINTER attribute, or any pointer component of an original list item that is referenced, must be associated at entry to the construct that contains the REDUCTION clause. Also, the list item, or the pointer component of the list item, must not be deallocated, allocated, or pointer assigned within the region.

An original list item with the ALLOCATABLE attribute, or any allocatable component of an original list item that is referenced, must be in the allocated state at entry to the construct that contains the REDUCTION clause. Also, the list item, or the allocatable component of the list item, must be neither deallocated nor allocated within the region.

Any number of REDUCTION clauses can be specified on the directive, but a list item can appear only once in REDUCTION clauses for that directive.

If a list item is an array section, the following applies:

- The array section must specify contiguous storage and it cannot be a zero-length array section.
- Accesses to the elements of the array outside the specified array section result in unspecified behavior.
- The reduction clause will be applied to each separate element of the array section.
- Access to the elements of the array outside the specified array section result in unspecified behavior.

The following table lists predefined reduction-identifiers. These reduction-identifiers are implicitly defined and cannot be redefined in a DECLARE REDUCTION directive for the types shown here. The actual initialization value will be consistent with the data type of the reduction variable.

### Predefined reduction-identifiers

<table>
<thead>
<tr>
<th>reduction-identifier</th>
<th>Type</th>
<th>Combiner</th>
<th>Initializer</th>
</tr>
</thead>
<tbody>
<tr>
<td>+</td>
<td>INTEGER, REAL, COMPLEX</td>
<td>omp_out = omp_out + omp_in</td>
<td>omp_priv = 0</td>
</tr>
<tr>
<td>*</td>
<td>INTEGER, REAL, COMPLEX</td>
<td>omp_out = omp_out * omp_in</td>
<td>omp_priv = 1</td>
</tr>
<tr>
<td>-</td>
<td>INTEGER, REAL, COMPLEX</td>
<td>omp_out = omp_out + omp_in</td>
<td>omp_priv = 0</td>
</tr>

<td>.AND.</td>
<td>LOGICAL</td>
<td>omp_out = omp_out .AND. omp_in</td>
<td>omp_priv = .TRUE.</td>
</tr>
<tr>
<td>.OR.</td>
<td>LOGICAL</td>
<td>omp_out = omp_out .OR. omp_in</td>
<td>omp_priv = .FALSE.</td>
</tr>
</tbody>
</table>
If a directive allows REDUCTION clauses, the number you can specify is not limited. However, each variable name can appear only once in only one of the clauses.

**NOTE**
If a variable appears in a REDUCTION clause on a combined construct for which the first construct is TARGET, it is treated as if it had appeared in a MAP clause with a map-type of TOFROM.

**Example**
In the following program fragment, time will be the sum of the time spent in the do loop across all threads:

```fortran
use omp_lib
integer i
double precision t1, time
call omp_set_num_threads(4)
...
!$omp do reduction(+:time)
do i = 1, omp_get_num_threads()
t1 = omp_get_wtime()
  ...
time = omp_get_wtime() - t1
end do
!here time is equal to the total time across all threads
...
```

%REF

**Built-in Function:** Changes the form of an actual argument. Passes the argument by reference. In Intel® Fortran, passing by reference is the default.

**Syntax**

%REF (a)

*(Input) An expression, record name, procedure name, array, character array section, or array element.*

You must specify %REF in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following table lists the Intel® Fortran defaults for argument passing, and the allowed uses of %REF:

<table>
<thead>
<tr>

¹A character argument is passed by address and hidden length.
The %REF and %VAL functions override related !DIR$ ATTRIBUTE settings.

Example

```
CHARACTER(LEN=10) A, B
CALL SUB(A, %REF(B))
```

Variable A is passed by address and hidden length. Variable B is passed by reference.

Note that on Windows* systems, compiler option `iface` determines how the character argument for variable B is passed.

RENAME

Portability Function: Renames a file.

Module

USE IFPORT

Syntax

```
result = RENAME (from, to)
```

- `from` (Input) Character*(*) Path of an existing file.
- `to` (Input) Character*(*) The new path for the file (see Caution note below).

Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code, such as:

- EACCES - The file or directory specified by `to` could not be created (invalid path). This error is also returned if the drive specified is not currently connected to a device.
- ENOENT - The file or path specified by `from` could not be found.
- EXDEV - Attempt to move a file to a different device.

Caution

This routine can cause data to be lost. If the file specified in `to` already exists, RENAME deletes the pre-existing file.

It is possible to rename a file to itself without error.

The paths can use forward (/) or backward (\) slashes as path separators and can include drive letters (if permitted by your operating system).
Example

```
use IFPORT
integer(4) istatus
character*12 old_name, new_name
print *, "Enter file to rename:"
read *, old_name
print *, "Enter new name:"
read *, new_name
ISTATUS = RENAME (old_name, new_name)
```

See Also
RENAMEFILEQQ

RENAMEFILEQQ

**Portability Function:** Renames a file or directory.

Module
USE IFPORT

Syntax
```
result = RENAMEFILEQQ (oldname, newname)
```

oldname  
(Input) Character*(*) . Current name of the file or directory to be renamed.

newname  
(Input) Character*(*) . New name of the file or directory.

Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.. You can use RENAMEFILEQQ to move a file from one directory to another on the same drive by giving a different path in the newname parameter.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERR$ACCES - Permission denied. The file's or directory's permission setting does not allow the specified access.
- ERR$EXIST - The file or directory already exists.
- ERR$NOENT - File or directory or path specified by oldname not found.
- ERR$XDEV - Attempt to move a file or directory to a different device.

Example

```
USE IFPORT
USE IFCORE
INTEGER(4) len
character(80) oldname, newname
LOGICAL(4) result

WRITE(*,'(A, \)') ' Enter old name: '
len = GETSTRQQ(oldname)
WRITE(*,'(A, \)') ' Enter new name: '
len = GETSTRQQ(newname)
result = RENAMEFILEQQ(oldname, newname)
END
```

GETLASTERROR

REPEAT
Transformational Intrinsic Function (Generic):
Concatenates several copies of a string.

Syntax
result = REPEAT (string, ncopies)

string (Input) Must be scalar and of type character.
ncopies (Input) Must be scalar and of type integer. It must not be negative.

Results
The result is a scalar of type character and length ncopies x LEN(string). The kind parameter is the same as string. The value of the result is the concatenation of ncopies copies of string.

Example
REPEAT ('S', 3) has the value SSS.
REPEAT ('ABC', 0) has the value of a zero-length string.

The following shows another example:

```fortran
CHARACTER(6) str
str = REPEAT('HO', 3)  ! returns HOHOHO
```

SPREAD

REQUIRES
OpenMP* Fortran Compiler Directive: Lists the features that an implementation must support so that the program compiles and runs correctly. This feature is only available for ifx.

Syntax
!$OMP REQUIRES [clause[,] clause]... }

clause Is one or more of the following:

- ATOMIC_DEFAULT_MEM_ORDER (SEQ_CST | ACQ_REL | RELAXED)
  Specifies the default memory ordering behavior that an implementation must support for ATOMIC constructs.

  If more than one REQUIRES directive contains an ATOMIC_DEFAULT_MEM_ORDER clause, each REQUIRES directive in the same compilation unit that specifies ATOMIC_DEFAULT_MEM_ORDER must specify the same parameter for that clause.
When this clause is specified, it must appear lexically prior to any ATOMIC construct that does not contain a memory order clause.

For information about settings SEQ_CST, ACQ_REL, and RELAXED, see the ATOMIC construct.

- **DYNAMIC_ALLOCATORS**

  Tells the compiler that the USES_ALLOCATORS clause is optional in TARGET constructs that use allocators in the corresponding TARGET regions.

  If DYNAMIC_ALLOCATORS are supported:
  - Calls to OMP_INIT_ALLOCATOR and OMP_DESTROY_ALLOCATOR are permitted in TARGET regions.
  - Default allocators can be used by ALLOCATE directives and clauses, and in the OMP_ALLOC routines in TARGET regions.

- **UNIFIED_ADDRESS**

  Tells the compiler that all devices available through OpenMP* directives and API procedures must have a unified address space.

  A pointer to this address space will refer to the same memory location when referenced from all available devices. OpenMP* mechanisms returning device pointers, return device addresses supporting pointer arithmetic.

  When this clause is specified, the IS_DEVICE_POINTER clause is not needed to obtain device addresses from device pointers for use in TARGET regions.

  Host device pointers can be passed as device pointer arguments to device memory procedures, and device pointers can be passed as host pointer arguments to device procedures. A non-host device may have discreet memory. In this case, referencing a host pointer on such a device or referencing a device pointer on the host will result in unspecified behavior.

  Memory local to a specific execution context may be exempt from the UNIFIED_ADDRESS requirements. It may adhere to the requirements of locality to a given thread, contention group, or execution context.

- **UNIFIED_SHARED_MEMORY**

  This clause implies the UNIFIED_ADDRESS clause. It also causes memory addresses to be accessible to threads on all available devices, with the exception of memory that is local to a specific execution context as described in UNIFIED_ADDRESS.

  All device addresses referring to memory allocated through OpenMP* device memory routines are valid host pointers that may be dereferenced.

  If UNIFIED_SHARED_MEMORY is supported:
  - The MAP clause in TARGET constructs is optional.
  - The DECLARE TARGET directive is optional for static variables accessed in procedures to which a DECLARE TARGET directive is applied.
By default, scalar variables are FIRSTPRIVATE inside TARGET constructs.

A value stored to memory by one device may not be visible to another device until the two devices have synchronized, or both devices synchronize with the host.

Only one occurrence of each clause is permitted in the REQUIRES directive. At least one clause is required.

The REQUIRES directive identifies the requirements needed for execution of the code in the compilation unit in which the directive appears.

The REQUIRES directive must appear in the specification part of the program unit, lexically following all USE, IMPORT, and IMPLICIT statements.

The clauses specified in the REQUIRES directive are added to the requires trait in the OpenMP* context for all points in the compilation unit.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives

**RESHAPE**

*Transformational Intrinsic Function (Generic):* Constructs an array with a different shape from the argument array.

**Syntax**

\[
\text{result} = \text{RESHAPE}(\text{source}, \text{shape}[\text{pad} [,\text{order}]])
\]

- **source**
  (Input) Must be an array. It may be of any data type. It supplies the elements for the result array. Its size must be greater than or equal to \(\text{PRODUCT(\text{shape})}\) if \(\text{pad}\) is omitted or has size zero.

- **shape**
  (Input) Must be an integer array of up to 31 elements, with rank one and constant size. It defines the shape of the result array. Its size must be positive; its elements must not have negative values.

- **pad**
  (Input; optional) Must be an array with the same type and kind parameters as \(\text{source}\). It is used to fill in extra values if the result array is larger than \(\text{source}\).

- **order**
  (Input; optional) Must be an integer array with the same shape as \(\text{shape}\). Its elements must be a permutation of \((1,2,...,n)\), where \(n\) is the size of \(\text{shape}\). If \(\text{order}\) is omitted, it is assumed to be \((1,2,...,n)\).

**Results**

The result is an array of shape \(\text{shape}\) with the same type and kind parameters as \(\text{source}\). The size of the result is the product of the values of the elements of \(\text{shape}\).

In the result array, the array elements of \(\text{source}\) are placed in the order of dimensions specified by \(\text{order}\). If \(\text{order}\) is omitted, the array elements are placed in normal array element order.

The array elements of \(\text{source}\) are followed (if necessary) by the array elements of \(\text{pad}\) in array element order. If necessary, additional copies of \(\text{pad}\) follow until all the elements of the result array have values.
NOTE
In standard Fortran array element order, the first dimension varies fastest. For example, element order in a two-dimensional array would be (1,1), (2,1), (3,1) and so on. In a three-dimensional array, each dimension having two elements, the array element order would be (1,1,1), (2,1,1), (1,2,1), (2,2,1), (1,1,2), (2,1,2), (1,2,2), (2,2,2).
RESHAPE can be used to reorder a Fortran array to match C array ordering before the array is passed from a Fortran to a C procedure.

Example
RESHAPE ((/3, 4, 5, 6, 7, 8/), (/2, 3/)) has the value

```
[ 3  5  7 ]
[ 4  6  8 ].
```

RESHAPE ((/3, 4, 5, 6, 7, 8/), (/2, 4/), (/1, 1/), (/2, 1/)) has the value

```
[ 3  4  5  6 ]
[ 7  8  1  1 ].
```

The following shows another example:

```
INTEGER ARI( 2, 5)
REAL F(5,3,8)
REAL C(8,3,5)
ARI = RESHAPE((/1,2,3,4,5,6/),(/2,5/),(/0,0/),(/2,1/))
! returns  1 2 3 4 5
! 6 0 0 0 0
!
! Change Fortran array order to C array order
C = RESHAPE(F, (/8,3,5/), ORDER = (/3, 2, 1/))
END
```

RESULT
Keyword: Specifies a name for a function result.

Description
Normally, a function result is returned in the function's name, and all references to the function name are references to the function result.

However, if you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. In this case, all references to the function name are recursive calls, and the function name must not appear in specification statements.

The RESULT name must be different from the name of the function.
Example

The following shows an example of a recursive function specifying a RESULT variable:

```fortran
RECURSIVE FUNCTION FACTORIAL(P) RESULT(L)
  INTEGER, INTENT(IN) :: P
  INTEGER L
  IF (P == 1) THEN
    L = 1
  ELSE
    L = P * FACTORIAL(P - 1)
  END IF
END FUNCTION
```

The following shows another example:

```fortran
recursive function FindSame(Aindex,Last,Used) &
&  result(FindSameResult)
type(card) Last
integer Aindex, i
logical matched, used(5), FindSameResult
if( Aindex > 5 ) then
  FindSameResult = .true.
  return
endif
...
```

ENTRY
RECURSIVE
Program Units and Procedures

RETURN

**Statement:** Transfers control from a subprogram to the calling program unit.

**Syntax**

```fortran
RETURN [expr]
```

- `expr` is a scalar expression that is converted to an integer value if necessary.
- The `expr` is only allowed in subroutines; it indicates an alternate return. (An alternate return is an obsolescent feature in Standard Fortran.)

**Description**

When a RETURN statement is executed in a function subprogram, control is transferred to the referencing statement in the calling program unit.

When a RETURN statement is executed in a subroutine subprogram, control is transferred to the first executable statement following the CALL statement that invoked the subroutine, or to the alternate return (if one is specified).
Example

The following shows how alternate returns can be used in a subroutine:

```fortran
CALL CHECK(A, B, *10, *20, C)
...
10 ...
20 ...
SUBROUTINE CHECK(X, Y, *, *, C)
...
50   IF (X) 60, 70, 80
60   RETURN
70   RETURN 1
80   RETURN 2
END
```

The value of X determines the return, as follows:

- If X < 0, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the calling program.
- If X = 0, the first alternate return (RETURN 1) occurs and control is transferred to the statement identified with label 10.
- If X > 0, the second alternate return (RETURN 2) occurs and control is transferred to the statement identified with label 20.

Note that an asterisk (*) specifies the alternate return. An ampersand (&) can also specify an alternate return in a CALL statement, but not in a subroutine's dummy argument list.

The following shows another example:

```fortran
SUBROUTINE Loop
  CHARACTER in
10  READ (*, '(A)') in
IF (in .EQ. 'Y') RETURN
GOTO 10
!   RETURN implied by the following statement:
END
!

! The following example shows alternate returns:
CALL AltRet (i, *10, *20, *30)
WRITE (*, *) 'normal return'
GOTO 40
10  WRITE (*, *) 'I = 10'
GOTO 40
20  WRITE (*, *) 'I = 20'
GOTO 40
30  WRITE (*, *) 'I = 30'
40  CONTINUE
END
SUBROUTINE AltRet (i, *, *, *)
IF (i .EQ. 10) RETURN 1
IF (i .EQ. 20) RETURN 2
IF (i .EQ. 30) RETURN 3
END
```

In the above example, RETURN 1 specifies the list's first alternate-return label, which is a symbol for the actual argument *10 in the CALL statement. RETURN 2 specifies the second alternate-return label, and RETURN 3 specifies the third alternate-return label.

CALL
REWIND

Statement: Positions a sequential or direct access file at the beginning of the file (the initial point). It takes one of the following forms:

Syntax

REWIND ([UNIT=] io-unit[, ERR= label] [, IOMSG=msg-var] [, IOSTAT=i-var])

REWIND io-unit

io-unit

(Input) Is an external unit specifier.

label

Is the label of the branch target statement that receives control if an error occurs.

msg-var

(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.

i-var

(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

Description

The unit number must refer to a file on disk or magnetic tape, and the file must be open for sequential, direct, or append access.

If a REWIND is done on a direct access file, the NEXTREC specifier is assigned a value of 1.

If a file is already positioned at the initial point, a REWIND statement has no effect.

If a REWIND statement is specified for a unit that is not open, it has no effect.

Example

The following statement repositions the file connected to I/O unit 3 to the beginning of the file:

REWIND 3

Consider the following statement:

REWIND (UNIT=9, IOSTAT=IOS, ERR=10)

This statement positions the file connected to unit 9 at the beginning of the file. If an error occurs, control is transferred to the statement labeled 10, and a positive integer is stored in variable IOS.

The following shows another example:

WRITE (7, '(I10)') int
REWIND (7)
READ (7, '(I10)') int

Data Transfer I/O Statements
Branch Specifiers
**REWRITE**

**Statement:** Rewrites the current record.

**Syntax**

**Formatted:**

REWRITE (eunit, format[, iostat] [, err]) [io-list]

**Unformatted:**

REWRITE (eunit[, iostat][ , err]) [io-list]

- **eunit**
  - Is an external unit specifier ([UNIT=]io-unit).
- **format**
  - Is a format specifier ([FMT=]format).
- **iostat**
  - Is a status specifier (IOSTAT=i-var).
- **err**
  - Is a branch specifier (ERR=label) if an error condition occurs.
- **io-list**
  - Is an I/O list.

**Description**

In the REWRITE statement, data (translated if formatted; untranslated if unformatted) is written to the current (existing) record in a file with direct access.

The current record is the last record accessed by a preceding, successful sequential or direct-access READ statement.

Between a READ and REWRITE statement, you should not specify any other I/O statement (except INQUIRE) on that logical unit. Execution of any other I/O statement on the logical unit destroys the current-record context and causes the current record to become undefined.

Only one record can be rewritten in a single REWRITE statement operation.

The output list (and format specification, if any) must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the number of characters specified by the I/O list (and format, if any) do not fill a record, blank characters are added to fill the record.

**Example**

In the following example, the current record (contained in the relative organization file connected to logical unit 3) is updated with the values represented by NAME, AGE, and BIRTH:

```
  REWRITE (3, 10, ERR=99) NAME, ,AGE, BIRTH
  10 FORMAT (A16, I2, A8)
```

**RINDEX**

**Portability Function:** Locates the index of the last occurrence of a substring within a string.

**Module**

USE IFPORT

**Syntax**

result = RINDEX (string, substr)
string *(Input) Character*(*). Original string to search.

substr *(Input) Character*(*). String to search for.

**Results**

The result type is INTEGER(4). The result is the starting position of the final occurrence of substr in string. The result is zero if substring does not occur in string.

**Example**

```fortran
USE IFPORT
character*80 mainstring
character*4 shortstr
integer(4) where
mainstring="Hello Hello Hello Hello There There There"
shortstr="Hello"
where=rindex(mainstring,shortstr)
! where is 19
```

**See Also**

INDEX

**RNUM**

*Elemental Intrinsic Function (Specific)*: Converts a character string to a REAL(4) value. This function cannot be passed as an actual argument.

**Syntax**

```fortran
result = RNUM (i)
```

*i* *(Input) Must be of type character.*

**Results**

The result type is REAL(4). The result value is the real value represented by the character string *i*.

**Example**

RNUM ("821.003") has the value 821.003 of type REAL(4).

**RRSPACING**

*Elemental Intrinsic Function (Generic)*: Returns the reciprocal of the relative spacing of model numbers near the argument value.

**Syntax**

```fortran
result = RRSPACING (x)
```

*x* *(Input) Must be of type real.*

**Results**

The result type and kind are the same as *x*. The result has the value $|x^* b^{-e}| x b^p$. Parameters $b$, $e$, $p$ are defined in Model for Real Data.
**Example**

If -3.0 is a REAL(4) value, RRSPACING(-3.0) has the value $0.75 \times 2^{24}$.

The following shows another example:

```fortran
REAL(4) res4
REAL(8) res8, r2
res4 = RRSPACING(3.0)  ! returns 1.258291E+07
res4 = RRSPACING(-3.0) ! returns 1.258291E+07
r2 = 487923.3
res8 = RRSPACING(r2)   ! returns 8.382458680573952E+015
END
```

SPACING

Data Representation Models

---

**RSHIFT**

*Elemental Intrinsic Function (Generic):* Shifts the bits in an integer right by a specified number of positions. This is the same as specifying ISHFT with a negative shift.

**See Also**

See ISHFT.

---

**RTC**

*Portability Function:* Returns the number of seconds elapsed since a specific Greenwich mean time.

**Module**

USE IFPORT

**Syntax**

```fortran
result = RTC()
```

**Results**

The result type is REAL(8). The result is the number of seconds elapsed since 00:00:00 Greenwich mean time, January 1, 1970.

**Example**

```fortran
USE IFPORT
real(8) s, s1, time_spent
INTEGER(4) i, j
s = RTC()
call sleep(4)
s1 = RTC()
time_spent = s1 - s
PRINT *, 'It took ',time_spent, 'seconds to run.'
```

**See Also**

DATE_AND_TIME
TIME portability routine

**RUNQQ**

*Portability Function:* Executes another program and waits for it to complete.

**Module**

USE IFPORT

**Syntax**

\[
\text{result} = \text{RUNQQ}(\text{filename}, \text{commandline})
\]

*filename* (Input) Character*(*)*. File name of a program to be executed.

*commandline* (Input) Character*(*)*. Command-line arguments passed to the program to be executed.

**Results**

The result type is INTEGER(2). If the program executed with RUNQQ terminates normally, the exit code of that program is returned to the program that launched it. If the program fails, -1 is returned.

The RUNQQ function executes a new process for the operating system using the same path, environment, and resources as the process that launched it. The launching process is suspended until execution of the launched process is complete.

**Example**

```fortran
USE IFPORT
INTEGER(2) result
result = RUNQQ('myprog', '-c -r')
END
```

See also the example in NARGS.

NARGS

**S**

This section describes language features that start with S.

**S**

**SAME_TYPE_AS**

*Inquiry Intrinsic Function (Generic):* Inquires whether the dynamic type of one object is the same as the dynamic type of another object.

**Syntax**

\[
\text{result} = \text{SAME_TYPE_AS}(a, b)
\]
(Input) Is an object of extensible type. If it is a polymorphic pointer, it must not have an undefined association status.

(b) (Input) Is an object of extensible type. If it is a polymorphic pointer, it must not have an undefined association status.

**Results**

The result type is default logical scalar. The result is true only if the dynamic type of \( a \) is the same as the dynamic type of \( b \).

**SAVE**

**Statement and Attribute:** Causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram.

**Syntax**

The SAVE attribute can be specified in a type declaration statement or a SAVE statement, and takes one of the following forms:

**Type Declaration Statement:**

\[
\text{type, [att-ls,] SAVE [\(,\) att-ls] :: entity\[,\] entity \[\ldots\]}
\]

**Statement:**

\[
\text{SAVE [\[::<\] entity\[,\] entity \[\ldots\]}
\]

- **type** Is a data type specifier.
- **att-ls** Is an optional list of attribute specifiers.
- **entity** Is the name of an object, the name of a procedure pointer, or the name of a common block enclosed in slashes (/common-block-name/).

**Description**

In Intel® Fortran, certain variables are given the SAVE attribute, or not, by default. Variables are implicitly given the SAVE attribute depending on whether a program unit is compiled for recursion.

**NOTE**

In the following lists, “initialized” means that the variable has been given an initial value in a DATA statement, it has been initialized in a type declaration statement, it is of a derived type that is default initialized, or it has a component that is default initialized.

The following variables are not saved by default:

- Scalar variables that are local to a recursive procedure and are not initialized (see above Note)
- Arrays of any type that are local to a recursive procedure and are not initialized (see above Note)
- **Variables that are declared AUTOMATIC**
- Local variables with the ALLOCATABLE attribute

The following variables are saved by default:

- Variables in COMMON blocks
- **Scalar variables not of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that are local to a non-recursive subprogram**
• Non-scalar local variables of non-recursive subprograms
• Module or submodule variables
• Initialized (see above Note) variables
• RECORD variables that are data initialized by default initialization specified in its STRUCTURE declaration

Local variables that are not described in the preceding two lists are saved by default.

**NOTE**
Certain compiler options (such as options [Q]save, assume no-recursion, and auto) and the use of OpenMP* features can change the defaults.

**NOTE**
Coarrays that do not have the ALLOCATABLE attribute and are local to the main program unit or to a procedure are not statically allocated, but are allocated at program startup. They are not deallocated until the program terminates.

To enhance portability and avoid possible compiler warning messages, Intel recommends that you use the SAVE statement to name variables whose values you want to preserve between subprogram invocations.

When a SAVE statement does not explicitly contain a list, all allowable items in the scoping unit are saved.

A SAVE statement cannot specify the following (their values cannot be saved):

• A blank common
• An object in a common block
• A procedure
• A dummy argument
• A function result
• An automatic object
• A PARAMETER (named) constant

Even though a common block can be included in a SAVE statement, individual variables within the common block can become undefined (or redefined) in another scoping unit.

If a common block is saved in any scoping unit of a program (other than the main program), it must be saved in every scoping unit in which the common block appears.

A SAVE statement has no effect in a main program.

**Example**
The following example shows a type declaration statement specifying the SAVE attribute:

```
SUBROUTINE TEST()
  REAL, SAVE :: X, Y
```

The following is an example of the SAVE statement:
```
SAVE A, /BLOCK_B/, C, /BLOCK_D/, E
```

The following shows another example:
```
SUBROUTINE MySub
  COMMON /z/ da, in, a, idum(10)
  REAL(8) x, y
  ...
  SAVE x, y, /z/
```

SAVE value in CLOSE

SCALE

**Elemental Intrinsic Function (Generic):** Returns the value of the exponent part (of the model for the argument) changed by a specified value.

**Syntax**

```fortran
result = SCALE (x,i)
```

- `x`  (Input) Must be of type real.
- `i`  (Input) Must be of type integer.

**Results**

The result type and kind are the same as `x`. The result has the value `x \times b^i`. Parameter `b` is defined in Model for Real Data.

**Example**

If 3.0 is a REAL(4) value, SCALE (3.0, 2) has the value 12.0 and SCALE (3.0, 3) has the value 24.0.

The following shows another example:

```fortran
REAL r
r = SCALE(5.2, 2)  ! returns 20.8
```

LSHIFT
Data Representation Models

**SCAN Directive**

**OpenMP* Fortran Compiler Directive:** Specifies a scan computation that updates each list item in each iteration of the loop. This feature is only available for ifort.

**Syntax**

```fortran
loop-associated-directive
do-loop-headers
  block
```

1852
The SCAN directive can appear in the body of a loop or loop nest that is in a worksharing construct, a worksharing-loop SIMD, or a SIMD construct.

There are two phases for each iteration of a SCAN loop, as follows:

- The input phase
  - For each iteration of an INCLUSIVE scan loop, the statements that appear lexically prior to the SCAN directive constitute the input phase.
  - For each iteration, except the last iteration of an EXCLUSIVE scan loop, the statements that lexically precede the directive constitute the input phase.

- The scan phase
  - For each iteration of an INCLUSIVE scan loop, the statements that follow the directive constitute the scan phase.
  - For each iteration, except the last iteration of an EXCLUSIVE scan loop, the statements that lexically follow the directive constitute the scan phase.

The last loop iteration does not have an input phase. For this iteration, all statements lexically preceding and following the directive constitute the scan phase. All computations that update a list item during an iteration are contained in the input phase. A statement that references a list item in the scan phase uses the result of the scan operation for that iteration.

For a given iteration, the result of a scan operation is calculated according to the last generalized prefixed sum (PRESUMtail) applied to the sequence of values given by the original value of the list item upon entry of the loop construct, and updated values given the list item in each of the iterations of the loop. The PRESUMtail \((op, a_1, \ldots, a_n)\) is defined for a binary operation \(op\) and a sequence of \(N\) values \(a_1, \ldots, a_n\) as follows:

- If \(N = 1, a_1\)
- If \(N > 1, op (PRESUM_{tail} (op, a_1, \ldots, a_k), PRESUM_{tail} (op, a_{k+1}, \ldots, a_n))\) where \(1 <= K <= N\)
At the beginning of the input phase for each iteration, the list item is initialized with the initializer value of the reduction-identifier specified by the REDUCTION clause on the innermost enclosing OpenMP* construct. For a given iteration, the update value of a list item is the value of the list item upon completion of the iteration’s input phase.

If orig_value is the initial value of a list item upon entry to a worksharing-loop, worksharing SIMD, or SIMD construct, if combiner is the combiner for the reduction-identifier specified in the REDUCTION clause on the construct, and update_value, is the value for the list item for iteration i, then at the beginning of the scan phase of the first iteration, a list item of an INCLUSIVE clause on a SCAN directive is assigned the result of the operation PRESUM_{last} (combiner, orig_value, update-value\_1 \ldots update-value\_i). At the beginning of the scan phase of the first iteration, a list item of an EXCLUSIVE clause on a SCAN directive is assigned the value orig_value. At the beginning of the scan phase of each subsequent iteration, i > 1, a list item of an EXCLUSIVE clause on a SCAN directive is the result of the operation PRESUM_{last} (combiner, orig_value, update-value\_1 \ldots update-value\_{i-1}).

A worksharing-loop, worksharing-loop SIMD, or a SIMD construct that has a REDUCTION clause with the INSCAN modifier must contain exactly one SCAN directive in the loop body of the construct, and a list item in an INCLUSIVE or EXCLUSIVE clause must be a list item in the REDUCTION clause of the construct.

With the exception of dependencies for list items in the INCLUSIVE or EXCLUSIVE clause, cross-iteration dependencies across loop iterations are not permitted. Except for INCLUSIVE or EXCLUSIVE clause list-item dependencies, intra-iteration dependencies between a statement lexically preceding the SCAN directive and a statement lexically following a SCAN directive are not permitted.

**NOTE**
 Currently, ifort only supports SCAN directives on SIMD and TARGET SIMD construct directives.

**Example**

The following contains an inclusive and an exclusive scan SIMD loop:

```fortran
real,dimension(10)   :: a, b
real                :: s
integer             :: i
...

do i = 1, 10
   a(i) = real (i)
end do
s = 0.0
! Inclusive scan
!$omp simd reduction (inscan, +:s)
do i = 1, 10
   s   = s + a(i)
!$omp scan inclusive (s)
b(i) = s
end do
print *, b

s = 0.0
! Exclusive scan
!$omp simd reduction (inscan, +:s)
do i = 1, 10
   b(i) = s
!$omp scan exclusive (s)
```
The first print statement prints the sequence 1.0 3.0 6.0 10.0 15.0 21.0 28.0 36.0 45.0 55.0. The second print statement prints the sequence 0.0 1.0 3.0 6.0 10.0 15.0 21.0 28.0 36.0 45.0.

 REDUCTION clause
 SIMD  OpenMP* Fortran directive
 TARGET SIMD
 DO  statement

SCAN Function

**Elemental Intrinsic Function (Generic):** Scans a string for any character in a set of characters.

**Syntax**

```fortran
result = SCAN (string, set [, back] [, kind])
```

- `string` (Input) Must be of type character.
- `set` (Input) Must be of type character with the same kind parameter as `string`.
- `back` (Input; optional) Must be of type logical.
- `kind` (Input; optional) Must be a scalar integer constant expression.

**Results**

The result type is integer. If `kind` is present, the kind parameter of the result is that specified by `kind`; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If `back` is omitted (or is present with the value false) and `string` has at least one character that is in `set`, the value of the result is the position of the leftmost character of `string` that is in `set`.

If `back` is present with the value true and `string` has at least one character that is in `set`, the value of the result is the position of the rightmost character of `string` that is in `set`.

If no character of `string` is in `set` or the length of `string` or `set` is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

**Example**

SCAN (‘ASTRING’, ‘ST’) has the value 2.
SCAN (‘ASTRING’, ‘ST’, BACK=.TRUE.) has the value 3.
SCAN (‘ASTRING’, ‘GHA’) has the value 6.
SCAN (‘ASTRING’, ‘ora’) has the value 0.

The following shows another example:

```fortran
INTEGER i
INTEGER array(2)
i = SCAN (‘FORTRAN’, ’TR’)         ! returns 3
i = SCAN (‘FORTRAN’, ’TR’, BACK = .TRUE.) ! returns 5
i = SCAN (‘FORTRAN’, ’GHA’)          ! returns 6
i = SCAN (‘FORTRAN’, ’ora’)          ! returns 0
```
array = SCAN ((/'FORTRAN','VISUALC'/),(/'A', 'A'/))
    ! returns (6, 5)

! Note that when using SCAN with arrays, the string
! elements must be the same length. When using string
! constants, blank pad to make strings the same length.
! For example:
array = SCAN ((/'FORTRAN','MASM '/),(/'A', 'A'/))
    ! returns (6, 2)
END

See Also
VERIFY

SCANENV

Portability Subroutine: Scans the environment for the value of an environment variable.

Module
USE IFPORT

Syntax
CALL SCANENV (envname, envtext, envvalue)

envname
(Input) Character(*). Contains the name of an environment variable you need to find the value for.

envtext
(Output) Character(*). Set to the full text of the environment variable if found, or to '' if nothing is found.

envvalue
(Output) Character(*). Set to the value associated with the environment variable if found or to '' if nothing is found.

SCANENV scans for an environment variable that matches envname and returns the value or string it is set to.

SCWRQQ

Portability Subroutine: Returns the floating-point processor control word.

Module
USE IFPORT

Syntax
CALL SCWRQQ (control)

control
(Output) INTEGER(2). Floating-point processor control word.

SCWRQQ performs the same function as the run-time subroutine GETCONTROLFPQQ, and is provided for compatibility.

Example
See the example in LCWRQQ.
SECNDS Intrinsic Procedure

**Elemental Intrinsic Function (Generic):** Provides the system time of day, or elapsed time, as a floating-point value in seconds. SECNDS can be used as an intrinsic function or as a portability routine. It is an intrinsic procedure unless you specify USE IFPORT.

**Syntax**

This function must not be passed as an actual argument. It is not a pure function, so it cannot be referenced inside a FORALL construct.

\[
\text{result} = \text{SECNDS}(x)
\]

\( x \quad \text{(Input) Must be of type real.} \)

**Results**

The result type and kind are the same as \( x \).

If \( x \) is zero, the result value is the time in seconds since the most recent midnight (in local time).

If \( x \) is not zero, it is compared to \( \text{now} \): the value that would be returned if \( x \) had been zero. If \( x \) is less than \( \text{now} \), then the result value is \( \text{now} - x \). If \( x \) is more than \( \text{now} \), the function assumes that \( x \) is the result of a call to SECONDS made the previous day and returns the value between that time and \( \text{now} \).

This function cannot detect a delay of more than one day between calls. For timing intervals longer than 24 hours, use DCLOCK.

This function does not account for daylight savings changes in either direction.

The value of SECNDS is accurate to 0.01 second, which is the resolution of the system clock.

The 24 bits of precision provide accuracy to the resolution of the system clock for about one day. However, loss of significance can occur if you attempt to compute very small elapsed times late in the day.

**Example**

The following shows how to use SECNDS to perform elapsed-time computations:

```
C    START OF TIMED SEQUENCE
T1 = SECNDS(0.0)
C    CODE TO BE TIMED
...  
DELTA = SECNDS(T1) ! DELTA gives the elapsed time
```

**See Also**

DATE_AND_TIME

RTC

SYSTEM_CLOCK

TIME intrinsic procedure
SECNDS portability routine

DCLOCK

SECNDS Portability Routine

Portability Function: Returns the number of seconds that have elapsed since midnight, less the value of its argument. SECNDS can be used as a portability function or as an intrinsic procedure. It is an intrinsic procedure unless you specify USE IFPORT.

Module

USE IFPORT

Syntax

result = SECNDS (time)

(time) (Input) REAL(4). Number of seconds, precise to a hundredth of a second (0.01), to be subtracted.

Results

The result type is REAL(4). The result value is the number of seconds that have elapsed since midnight, minus time, with a precision of a hundredth of a second (0.01).

To start the timing clock, call SECNDS with 0.0, and save the result in a local variable. To get the elapsed time since the last call to SECNDS, pass the local variable to SECNDS on the next call.

Example

USE IFPORT
REAL(4) s
INTEGER(4) i, j
s = SECNDS(0.0)
DO I = 1, 100000
   J = J + 1
END DO
s = SECNDS(s)
PRINT *, 'It took ', s, ' seconds to run.'

SECNDS intrinsic procedure
SECTIONS

**OpenMP Fortran Compiler Directive:** Specifies that the enclosed SECTION directives define blocks of code to be divided among threads in a team. Each section is executed once by a thread in the team.

**Syntax**

```fortran
!$OMP SECTIONS [clause[, clause] ... ]

[!$OMP SECTION]
  block

[!$OMP SECTION]
  block]...

!$OMP END SECTIONS[NOWAIT]
```

*clause* is one of the following:

- `ALLOCATE ([allocator :] list)`
- `FIRSTPRIVATE (list)`
- `LASTPRIVATE ([CONDITIONAL:] list)`
- `PRIVATE (list)`
- `REDUCTION (reduction-identifier : list)`

*block* is a structured block (section) of statements or constructs. Any constituent section must also be a structured block.

You cannot branch into or out of the block.

The binding thread set for a SECTIONS construct is the current team. A SECTIONS region binds to the innermost enclosing parallel region.

Each section of code is preceded by a SECTION directive, although the directive is optional for the first section. The SECTION directives must appear within the lexical extent of the SECTIONS and END SECTIONS directive pair.

The last section ends at the END SECTIONS directive. Threads that complete execution of their SECTIONs encounter an implied barrier at the END SECTIONS directive unless NOWAIT is specified.

SECTIONS directives must be encountered by all threads in a team or by none at all.

**Example**

In the following example, subroutines XAXIS, YAXIS, and ZAXIS can be executed concurrently:

```fortran
!$OMP PARALLEL
  !$OMP SECTIONS
  !$OMP SECTION
    CALL XAXIS
  !$OMP SECTION
    CALL YAXIS
  !$OMP SECTION
    CALL ZAXIS
  !$OMP END SECTIONS
!$OMP END PARALLEL
```

**See Also**

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
Parallel Processing Model for information about Binding Sets

**SEED**

**Portability Subroutine:** Changes the starting point of the pseudorandom number generator.

**Module**

USE IFPORT

**Syntax**

CALL SEED (iseed)

*iseed* (Input) INTEGER(4). Starting point for RANDOM.

SEED uses *iseed* to establish the starting point of the pseudorandom number generator. A given seed always produces the same sequence of values from RANDOM.

If SEED is not called before the first call to RANDOM, RANDOM always begins with a seed value of one. If a program must have a different pseudorandom sequence each time it runs, pass the constant RND$TIMESEED (defined in IFPORT.F90) to the SEED routine before the first call to RANDOM.

This routine is not thread-safe.

**Example**

USE IFPORT
REAL myrand
CALL SEED(7531)
CALL RANDOM(myrand)

**See Also**

RANDOM
RANDOM_INIT
RANDOM_SEED
RANDOM_NUMBER

SELECT CASE and END SELECT

**Statement:** Transfers program control to a selected block of statements according to the value of a controlling expression.

**Example**

CHARACTER*1 cmdchar
.
.
Files: SELECT CASE (cmdchar)
CASE ('0')
   WRITE (*, *) "Must retrieve one to nine files"
CASE ('1': '9')
   CALL RetrieveNumFiles (cmdchar)
CASE ('A', 'a')
   CALL AddEntry
CASE ('D', 'd')
   CALL DeleteEntry
SELECT RANK

Statement: Marks the beginning of a SELECT RANK construct. The construct selects for execution at most one of its constituent blocks. The selection is based on the rank of an assumed-rank variable.

Syntax

[name:] SELECT RANK ([ assoc-name => ] selector)
  [rank-case-stmt
   block]...
END SELECT [name]

name

(Optional) Is the name of the SELECT RANK construct.

assoc-name

(Optional) Is an identifier that becomes associated with the selector. It becomes the associating entity. The identifier name must be unique within the construct. If unspecified, the associate name for the construct is selector.

selector

Is the name of an assumed-rank array.

rank-case-stmt

(Optional) Is one of the following:

- RANK (scalar-int-const-expr) [name]
- RANK (*) [name]
- RANK DEFAULT [name]

The scalar-int-const-expr must be non-negative. The same rank value can only be specified in one rank-case-stmt. RANK DEFAULT and RANK (*) can be specified only once in the construct. RANK (*) cannot be specified if selector has the ALLOCATABLE or POINTER attribute.

block

(Optional) Is a sequence of zero or more statements or constructs.

Description

If a construct name is specified at the beginning of a SELECT RANK statement, the same name must appear in the corresponding END SELECT statement. If a rank-case-stmt specifies a construct name, the corresponding SELECT RANK statement must specify the same name. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a SELECT RANK statement, you cannot specify one following the END SELECT statement or any corresponding rank-case-stmt.

If no other rank-case-stmt of the construct matches the selector, a RANK DEFAULT statement, if present, identifies the block of code to be executed.

A SELECT RANK construct selects at most one block to be executed. During execution of that block, the associate name identifies an entity that is associated with the selector.
The following steps determine which block is selected for execution:

1. If the selector is argument associated with an assumed-size array, a RANK (*) statement identifies the block to be executed.
2. If the selector is not argument associated with an assumed-size array, a RANK (scalar-int-const-exp) statement identifies the block to be executed if the selector has that rank.
3. Otherwise, if there is a RANK DEFAULT statement, the block following that statement is executed.

A branch is allowed from within a block of a SELECT RANK construct to the END SELECT statement. Branches to the END SELECT from outside the construct are not allowed.

The associating entity in the block following a RANK DEFAULT statement is assumed rank and has the same attributes as the selector; it can used only in contexts that an assumed-rank entity can be used. The associating entity in the block following a RANK (*) statement is an assumed-size one dimensional array and lower bound 1, as if declared DIMENSION(1:*).

The associating entity in the block following a RANK (scalar-int-const-exp) statement has the rank specified. The lower bound is the lower bound of the selector for each corresponding dimension, and the upper bound is the upper bound of the selector for each corresponding dimension of the selector. The associating entity in a RANK(*) or a RANK (scalar-int-const-exp) block is a variable and may appear in variable definition contexts.

If the selector has the POINTER, TARGET or ALLOCATABLE attribute, the associating entity has the same attributes.

Example

The following example shows a SELECT RANK construct that initializes scalars, rank 1, and rank 2 arrays to zero. If the dummy argument rank is greater than 2, an error message is printed.

```fortran
SUBROUTINE INITIALIZE (ARG)
    REAL :: ARG(..)
    SELECT RANK (ARG)
        RANK (0)   ! Scalar
            ARG = 0.0
        RANK (1)
            ARG(:) = 0.0
        RANK (2)
            ARG(:, :) = 0.0
        RANK DEFAULT
            PRINT *, "Subroutine initialize called with unexpected rank argument"
    END SELECT
RETURN
END SUBROUTINE
```

The following example shows how to use a select rank to initialize assumed-size arrays of any rank to zero:

```fortran
SUBROUTINE INITIALIZE (ARG, SIZE)
    REAL, CONTIGUOUS :: ARG(..)
    INTEGER :: SIZE, I
    SELECT RANK (ARG)
        RANK (0)   ! Special case the scalar case
            ARG = 0.0
        RANK (*)
            DO I = 1, SIZE
                ARG(I) = 0.0
            END DO
    END SELECT
RETURN
END SUBROUTINE
```
See Also
Construct Association

SELECT TYPE

**Statement:** Marks the beginning of a SELECT TYPE construct. The construct selects for execution at most one of its constituent blocks. The selection is based on the dynamic type of a specified expression.

**Syntax**

```
[name:] SELECT TYPE ([ assoc-name => ] selector)
   [type-guard-stmt
   block]...
END SELECT [name]
```

- **name**
  (Optional) Is the name of the SELECT TYPE construct.
- **assoc-name**
  (Optional) Is an identifier that becomes associated with the `selector`. It becomes the associating entity. The identifier name must be unique within the construct. If selector is not a named variable, `assoc-name =>` must appear.
- **selector**
  Is an expression or variable. It must be polymorphic. It is evaluated when the SELECT TYPE statement is executed.
- **type-guard-stmt**
  (Optional) Is one of the following:
  - TYPE IS (type) [name]
  - CLASS IS (type) [name]
  - CLASS DEFAULT [name]

CLASS DEFAULT can be specified only once in the construct. The same type and kind parameter values can only be specified in one TYPE IS statement and one CLASS IS statement.

- **type**
  Is an intrinsic type specifier or a derived-type specifier. It must specify that each length type parameter is assumed. It cannot be a sequence derived type or a type with the BIND attribute.

- **block**
  (Optional) Is a sequence of zero or more statements or constructs.

**Description**

If a construct name is specified at the beginning of a SELECT TYPE statement, the same name must appear in the corresponding END SELECT statement. The same construct name must not be used for different named constructs in the same scoping unit. If no name is specified at the beginning of a SELECT TYPE statement, you cannot specify one following the END SELECT statement or any `type-guard-stmt`. If a `type-guard-stmt` specifies a construct name, it must match the construct name on the corresponding SELECT TYPE statement.

A branch to the END SELECT statement is allowed from within the SELECT TYPE construct, but it is not allowed from anywhere outside the construct.

Execution of a SELECT TYPE construct whose selector is not a variable causes the selector expression to be evaluated.
A SELECT TYPE construct selects at most one block to be executed. During execution of that block, the associate name identifies an entity that is associated with the selector. The entity associated with the associate name has the declared type and type parameters of the selector. The entity is polymorphic only if the selector is polymorphic.

The following steps determine which block is selected for execution:

1. If a TYPE IS statement matches the selector, the block following that statement is executed. A TYPE IS statement matches the selector if the dynamic type and type parameter values of the selector are the same as those specified by the statement.

2. Otherwise, if exactly one CLASS IS statement matches the selector, the block following that statement is executed. A CLASS IS statement matches the selector if the dynamic type of the selector is an extension of the type specified by the statement and the kind type parameters specified by the statement are the same as the corresponding type parameters of the dynamic type of the selector.

3. Otherwise, if several CLASS IS statements match the selector, one of these statements must specify a type that is an extension of all the types specified in the others. In this case, the block following that statement is executed.

4. Otherwise, if there is a CLASS DEFAULT statement, the block following that statement is executed.

Within the block following a TYPE IS statement, the associating entity is not polymorphic, it has the type named in the TYPE IS statement, and has the type parameters of the selector.

Within the block following a CLASS IS statement, the associating entity is polymorphic and has the declared type named in the CLASS IS statement. The type parameters of the associating entity are the corresponding type parameters of the selector.

Within the block following a CLASS DEFAULT statement, the associating entity is polymorphic and has the same declared type as the selector. The type parameters of the associating entity are those of the declared type of the selector.

If the declared type of the selector is M, specifying CLASS DEFAULT has the same effect as specifying CLASS IS (M).

A type-guard-stmt cannot be a branch target statement. You can branch to an END SELECT statement only from within its SELECT TYPE construct.

Example

The following example shows a SELECT TYPE construct:

```
TYPE POINT
  REAL :: X, Y
END TYPE POINT

TYPE, EXTENDS(POINT) :: POINT_3D
  REAL :: Z
END TYPE POINT_3D

TYPE, EXTENDS(POINT) :: COLOR_POINT
  INTEGER :: COLOR
END TYPE COLOR_POINT

TYPE(POINT), TARGET :: P
TYPE(POINT_3D), TARGET :: P3D
TYPE(COLOR_POINT), TARGET :: CP
CLASS(POINT), POINTER :: P_OR_CP
P_OR_CP=> CP

SELECT TYPE ( AN => P_OR_CP )
  CLASS IS ( POINT )
  ! "CLASS ( POINT ) :: AN" is implied here
  PRINT *, AN%X, AN%Y ! This block gets executed
TYPE IS ( POINT_3D )
```
The following example uses declarations from the above example, but it omits the associate name AN:

```
P_OR_CP => P3D
SELECT TYPE ( P_OR_CP )
CLASS IS ( POINT )
! "CLASS ( POINT ) :: P_OR_CP" is implied here
PRINT *, P_OR_CP%X, P_OR_CP%Y
TYPE IS ( POINT_3D )
! "TYPE ( POINT_3D ) :: P_OR_CP" is implied here
PRINT *, P_OR_CP%X, P_OR_CP%Y, P_OR_CP%Z    ! This block gets executed
END SELECT
```

Additional Attributes Of Associate Names

### SELECTED_CHAR_KIND

**Transformational Intrinsic Function (Generic):**

*Returns the value of the kind type parameter of the character set named by the argument.*

**Syntax**

```
result = SELECTED_CHAR_KIND(name)
```

`name` (Input) Must be scalar and of type default character. Its value must be 'DEFAULT' or 'ASCII'.

**Results**

The result is a scalar of type default integer. The result is a scalar of type default integer. The result value is 1 if NAME has the value 'DEFAULT' or 'ASCII'; otherwise, the result value is -1.

### SELECTED_INT_KIND

**Transformational Intrinsic Function (Generic):**

*Returns the value of the kind parameter of an integer data type.*

**Syntax**

```
result = SELECTED_INT_KIND (r)
```

`r` (Input) Must be scalar and of type integer.

**Results**

The result is a scalar of type default integer. The result has a value equal to the value of the kind parameter of the integer data type that represents all values `n` in the range of values `n` with `-10^r < n < 10^r`.

If no such kind type parameter is available on the processor, the result is -1. If more than one kind type parameter meets the criteria, the value returned is the one with the smallest decimal exponent range. For more information, see Model for Integer Data.
Example

SELECTED_INT_KIND (6) = 4

The following shows another example:

```fortran
i = SELECTED_INT_KIND(8)  ! returns 4
i = SELECTED_INT_KIND(3)  ! returns 2
i = SELECTED_INT_KIND(10) ! returns 8
i = SELECTED_INT_KIND(20) ! returns -1 because 10**20
          !   is bigger than 2**63
```

See Also

SELECTED_REAL_KIND

SELECTED_REAL_KIND

Transformational Intrinsic Function (Generic):
Returns the value of the kind parameter of a real data type.

Syntax

```
result = SELECTED_REAL_KIND ([p] [,r] [,radix])
```

- **p** (Input; optional) Must be scalar and of type integer.
- **r** (Input; optional) Must be scalar and of type integer.
- **radix** (Input; optional) Must be scalar and of type integer.

At least argument p or r must be present.

Results

If p or r is absent, the result is as if the argument was present with the value zero. If radix is absent, there is no requirement on the radix of the selected kind.

The result is a scalar of type default integer. If both arguments are absent, the result is zero. Otherwise, the result has a value equal to a value of the kind parameter of a real data type with decimal precision, as returned by the function PRECISION, of at least p digits, a decimal exponent range, as returned by the function RANGE, of at least r, and a radix, as returned by the function RADIX, of radix.

If no such kind type parameter is available on the processor, the result is as follows:

- -1 if the precision is not available but the range is available
- -2 if the exponent range is not available but the precision is available
- -3 if neither is available
- -4 if real types for the precision and the range are available separately but not together
- -5 if no real type of the specified radix is available

If more than one kind type parameter value meets the criteria, the value returned is the one with the smallest decimal precision. Intel® Fortran currently does not return -4 for any combination of p and r, and supports only a radix of 2. For more information, see Model for Real Data.

Example

SELECTED_REAL_KIND (6, 70) = 8

The following shows another example:

```fortran
i = SELECTED_REAL_KIND(r=200, radix=2)  ! returns 8
i = SELECTED_REAL_KIND(13)     ! returns 8
i = SELECTED_REAL_KIND (100, 200)  ! returns -1
```
The following example gives a compile-time error:

```
i = SELECTED_REAL_KIND ()
```

**See Also**

SELECTED_INT_KIND
IEEE_SELECTED_REAL_KIND

**SEQUENCE**

*Statement:* Preserves the storage order of a derived-type definition.

**Syntax**

```
SEQUENCE
```

**Description**

The SEQUENCE statement allows derived types to be used in common blocks and to be equivalenced.

The SEQUENCE statement appears only as part of derived-type definitions. It causes the components of the derived type to be stored in the same sequence they are listed in the type definition. If you do not specify SEQUENCE, the physical storage order is not necessarily the same as the order of components in the type definition.

If a derived type is a sequence derived type, then any other derived type that includes it must also be a sequence type.

**Example**

```fortran
!DIR$ PACK:1
TYPE NUM1_SEQ
  SEQUENCE
  INTEGER(2)::int_val
  REAL(4)::real_val
  LOGICAL(2)::log_val
END TYPE NUM1_SEQ
TYPE num2_seq
  SEQUENCE
  logical(2)::log_val
  integer(2)::int_val
  real(4)::real_val
end type num2_seq
end type
type (num1_seq) num1
type (num2_seq) num2
character*8 t, t1
equivalence (num1,t)
equivalence (num2,t1)
um1%int_val=2
num1%real_val=3.5
num1%log_val=.TRUE.
t1(1:2)=t(7:8)
t1(3:4)=t(1:2)
t1(5:8)=t(3:6)
print *, num2%int_val, num2%real_val, num2%log_val
end
```
SETCONTROLFPQQ

**Portability Subroutine:** Sets the value of the floating-point processor control word.

**Module**

USE IFPORT

**Syntax**

CALL SETCONTROLFPQQ (controlword)

controlword  (Input) INTEGER(2). Floating-point processor control word.

The floating-point control word specifies how various exception conditions are handled by the floating-point math processor, sets the floating-point precision, and specifies the floating-point rounding mechanism used.

The control word can be any of the following constants (defined in IFPORT.F90):

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Hex value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FPCW$MCW_IC</td>
<td>Z'1000'</td>
<td>Infinity control mask</td>
</tr>
<tr>
<td>FPCW$AFFINE</td>
<td>Z'1000'</td>
<td>Affine infinity</td>
</tr>
<tr>
<td>FPCW$PROJECTIVE</td>
<td>Z'0000'</td>
<td>Projective infinity</td>
</tr>
<tr>
<td>FPCW$MCW_PC</td>
<td>Z'0300'</td>
<td>Precision control mask</td>
</tr>
<tr>
<td>FPCW$64</td>
<td>Z'0300'</td>
<td>64-bit precision</td>
</tr>
<tr>
<td>FPCW$53</td>
<td>Z'0200'</td>
<td>53-bit precision</td>
</tr>
<tr>
<td>FPCW$24</td>
<td>Z'0000'</td>
<td>24-bit precision</td>
</tr>
<tr>
<td>FPCW$MCW_RC</td>
<td>Z'0C00'</td>
<td>Rounding control mask</td>
</tr>
<tr>
<td>FPCW$CHOP</td>
<td>Z'0C00'</td>
<td>Truncate</td>
</tr>
<tr>
<td>FPCW$UP</td>
<td>Z'0800'</td>
<td>Round up</td>
</tr>
<tr>
<td>FPCW$DOWN</td>
<td>Z'0400'</td>
<td>Round down</td>
</tr>
<tr>
<td>FPCW$NEAR</td>
<td>Z'0000'</td>
<td>Round to nearest</td>
</tr>
<tr>
<td>FPCW$MCW_EM</td>
<td>Z'003F'</td>
<td>Exception mask</td>
</tr>
<tr>
<td>FPCW$INVALID</td>
<td>Z'0001'</td>
<td>Allow invalid numbers</td>
</tr>
<tr>
<td>FPCW$DENORMAL</td>
<td>Z'0002'</td>
<td>Allow subnormals (very small numbers)</td>
</tr>
<tr>
<td>FPCW$SUBNORMAL</td>
<td>Z'0002'</td>
<td>Allow subnormals (very small numbers)</td>
</tr>
<tr>
<td>FPCW$ZERODIVIDE</td>
<td>Z'0004'</td>
<td>Allow divide by zero</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Hex value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>FPCW$OVERFLOW</td>
<td>Z'0008'</td>
<td>Allow overflow</td>
</tr>
<tr>
<td>FPCW$UNDERFLOW</td>
<td>Z'0010'</td>
<td>Allow underflow</td>
</tr>
<tr>
<td>FPCW$INEXACT</td>
<td>Z'0020'</td>
<td>Allow inexact precision</td>
</tr>
</tbody>
</table>

An exception is disabled if its control bit is set to 1. An exception is enabled if its control bit is cleared to 0.

Setting the floating-point precision and rounding mechanism can be useful if you are reusing old code that is sensitive to the floating-point precision standard used and you want to get the same results as on the old machine.

You can use GETCONTROLFPQ to retrieve the current control word and SETCONTROLFPQ to change the control word. Most users do not need to change the default settings. If you need to change the control word, always use SETCONTROLFPQ to make sure that special routines handling floating-point stack exceptions and abnormal propagation work correctly.

**NOTE**
The Intel® Fortran exception handler allows for software masking of invalid operations, but does not allow the math chip to mask them. If you choose to use the software masking, be aware that this can affect program performance if you compile code written for Intel Fortran with another compiler.

**Example**

```fortran
USE IFPORT
INTEGER(2) status, control, controlo
CALL GETCONTROLFPQ(control)
WRITE (*, 9000) 'Control word: ', control
!   Save old control word
carrolo = control
!   Clear all flags
controlo = controlo .AND. Z'0000'
!   Set new control to round up
controlo = controlo .OR. FPCW$UP
CALL SETCONTROLFPQ(control)
CALL GETCONTROLFPQ(control)
WRITE (*, 9000) 'Control word: ', control
9000 FORMAT (1X, A, Z4)
END
```

**See Also**

- GETCONTROLFPQ
- GETSTATUSFPQ
- LCWRQQ
- SCWRQQ
- CLEARSTATUSFPQ

**SETDAT**

*Portability Function: Sets the system date. This function is only available on Windows*® and Linux* systems.*
**Module**
USE IFPORT

**Syntax**
result = SETDAT (iyr, imon, iday)

- **iyr** (Input) INTEGER(2) or INTEGER(4). Year (xxxxAD).
- **imon** (Input) INTEGER(2) or INTEGER(4). Month (1-12).
- **iday** (Input) INTEGER(2) or INTEGER(4). Day of the month (1-31).

**Results**
The result type is LOGICAL(4). The result is .TRUE. if the system date is changed; .FALSE. if no change is made.

Actual arguments of the function SETDAT can be any valid INTEGER(2) or INTEGER(4) expression.
All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4).
If INTEGER(2) arguments are passed, you must specify USE IFPORT.
Refer to your operating system documentation for the range of permitted dates.

**NOTE**
On Linux systems, you must have root privileges to execute this function.

**Example**

```fortran
USE IFPORT
LOGICAL(4) success
success = SETDAT(INT2(1997+1), INT2(2*3), INT2(30))
END
```

**See Also**
GETDAT
GETTIM
SETTIM

**SETENVQQ**

*Portability Function:* Sets the value of an existing environment variable, or adds and sets a new environment variable.

**Module**
USE IFPORT

**Syntax**
result = SETENVQQ (varname=value)
varname=value  (Input) Character*(*). String containing both the name and the value of the variable to be added or modified. Must be in the form: \texttt{varname=value}, where \texttt{varname} is the name of an environment variable and \texttt{value} is the value being assigned to it.

Results
The result is of type LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

Environment variables define the environment in which a program executes. For example, the LIB environment variable defines the default search path for libraries to be linked with a program.

SETENVQQ deletes any terminating blanks in the string. Although the equal sign (=) is an illegal character within an environment value, you can use it to terminate \texttt{value} so that trailing blanks are preserved. For example, the string \texttt{PATH=} sets \texttt{value} to ' '.

You can use SETENVQQ to remove an existing variable by giving a variable name followed by an equal sign with no value. For example, \texttt{LIB=} removes the variable LIB from the list of environment variables. If you specify a value for a variable that already exists, its value is changed. If the variable does not exist, it is created.

SETENVQQ affects only the environment that is local to the current process. You cannot use it to modify the command-level environment. When the current process terminates, the environment reverts to the level of the parent process. In most cases, this is the operating system level. However, you can pass the environment modified by SETENVQQ to any child process created by RUNQQ. These child processes get new variables and/or values added by SETENVQQ.

SETENVQQ uses the C runtime routine _putenv and GETENVQQ uses the C runtime routine getenv. From the C documentation:

getenv and _putenv use the copy of the environment pointed to by the global variable _environ to access the environment. getenv operates only on the data structures accessible to the run-time library and not on the environment segment created for the process by the operating system.

SETENVQQ and GETENVQQ will not work properly with the Windows* APIs SetEnvironmentVariable and GetEnvironmentVariable.

Example

```
USE IFPORT
LOGICAL(4) success
success = SETENVQQ("PATH=c:\mydir\tmp")
success = &
SETENVQQ("LIB=c:\mylib\bessel.lib;c:\math\difq.lib")
END
```

See Also
GETENVQQ
RUNQQ

SETERRORMODEQQ

\textbf{Portability Subroutine:} Sets the prompt mode for critical errors that by default generate system prompts.

Module
USE IFPORT
Syntax
CALL SETERRORMODEQQ (pmode)

*pmode* (Input) LOGICAL(4). Flag that determines whether a prompt is displayed when a critical error occurs.

Certain I/O errors cause the system to display an error prompt. For example, attempting to write to a disk drive with the drive door open generates an "Abort, Retry, Ignore" message. When the system starts up, system error prompting is enabled by default (*pmode* = .TRUE.). You can also enable system error prompts by calling SETERRORMODEQQ with *pmode* set to ERR$HARDPROMPT (defined in IFPORT.F90).

If prompt mode is turned off, critical errors that normally cause a system prompt are silent. Errors in I/O statements such as OPEN, READ, and WRITE fail immediately instead of being interrupted with prompts. This gives you more direct control over what happens when an error occurs. For example, you can use the ERR= specifier to designate an executable statement to branch to for error handling. You can also take a different action than that requested by the system prompt, such as opening a temporary file, giving a more informative error message, or exiting.

You can turn off prompt mode by setting *pmode* to .FALSE. or to the constant ERR$HARDFAIL (defined in IFPORT.F90).

Note that SETERRORMODEQQ affects only errors that generate a system prompt. It does not affect other I/O errors, such as writing to a nonexistent file or attempting to open a nonexistent file with STATUS='OLD'.

Example

```fortran
! PROGRAM 1
!  DRIVE B door open
OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
!  Generates a system prompt error here and waits for the user
!  to respond to the prompt before continuing
100  WRITE(*,*) ' Continuing'
END

! PROGRAM 2
!  DRIVE B door open
USE IFPORT
CALL SETERRORMODEQQ(.FALSE.)
OPEN (10, FILE = 'B:\NOFILE.DAT', ERR = 100)
! Causes the statement at label 100 to execute
! without system prompt
100  WRITE(*,*) ' Drive B: not available, opening alternative drive.'
OPEN (10, FILE = 'C:\NOFILE.DAT')
END
```

**SET_EXPONENT**

*Elemental Intrinsic Function (Generic):* Returns the value of the exponent part (of the model for the argument) set to a specified value.

Syntax

```fortran
result = SET_EXPONENT (x, i)
```

*x* (Input) Must be of type real.

*i* (Input) Must be of type integer.
Results

The result type and kind are the same as \( x \). The result has the value \( x \times b^{-e} \). Parameters \( b \) and \( e \) are defined in \texttt{Model for Real Data}. If \( x \) has the value zero, the result is zero.

Example

If 3.0 is a \texttt{REAL(4)} value, \texttt{SET_EXPONENT (3.0, 1)} has the value 1.5.

See Also

\texttt{EXPONENT}

Data Representation Models

\textbf{SETFILEACCESSQQ}

\textit{Portability Function:} Sets the file access mode for a specified file.

Module

\texttt{USE IFPORT}

Syntax

\[
\texttt{result = SETFILEACCESSQQ (filename, access)}
\]

\texttt{filename} (Input) Character*(*) . Name of a file to set access for.

\texttt{access} (Input) INTEGER(4) . Constant that sets the access. Can be any combination of the following flags, combined by an inclusive OR (such as \texttt{IOR} or \texttt{OR}):

- \texttt{FILE$ARCHIVE} - Marked as having been copied to a backup device.
- \texttt{FILE$HIDDEN} - Hidden. The file does not appear in the directory list that you can request from the command console.
- \texttt{FILE$NORMAL} - No special attributes (default).
- \texttt{FILE$READONLY} - Write-protected. You can read the file, but you cannot make changes to it.
- \texttt{FILE$SYSTEM} - Used by the operating system.

The flags are defined in module \texttt{IFPORT.F90}.

Results

The result type is \texttt{LOGICAL(4)}. The result is \texttt{.TRUE.} if successful; otherwise, \texttt{.FALSE.}.

To set the access value for a file, add the constants representing the appropriate access.

Example

\[
\begin{align*}
\texttt{USE IFPORT} \\
\texttt{INTEGER(4) permit} \\
\texttt{LOGICAL(4) result} \\
\texttt{permit = 0 ! clear permit} \\
\texttt{permit = IOR(FILE$READONLY, FILE$HIDDEN)} \\
\texttt{result = SETFILEACCESSQQ ('formula.f90', permit)} \\
\texttt{END}
\end{align*}
\]

See Also

\texttt{GETFILEINFOQQ}
SETFILETIMEQQ

**Portability Function:** Sets the modification time for a specified file.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SETFILETIMEQQ (filename, timedate)
```

- `filename` (Input) Character(*) Name of a file.
- `timedate` (Input) INTEGER(4) Time and date information, as packed by PACKTIMEQQ.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The modification time is the time the file was last modified and is useful for keeping track of different versions of the file. The process that calls SETFILETIMEQQ must have write access to the file; otherwise, the time cannot be changed. If you set `timedate` to FILE$CURTIME (defined in IFPORT.F90), SETFILETIMEQQ sets the modification time to the current system time.

If the function fails, call GETLASTERRORQQ to determine the reason. It can be one of the following:

- ERR$ACCES - Permission denied. The file's (or directory's) permission setting does not allow the specified access.
- ERR$INVAL - Invalid argument; the `timedate` argument is invalid.
- ERR$MFILE - Too many open files (the file must be opened to change its modification time).
- ERR$NOENT - File or path not found.
- ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.

**Example**

```fortran
USE IFPORT
INTEGER(2) day, month, year
INTEGER(2) hour, minute, second, hund
INTEGER(4) timedate
LOGICAL(4) result
CALL GETDAT(year, month, day)
CALL GETTIM(hour, minute, second, hund)
CALL PACKTIMEQQ (timedate, year, month, day, &
                 hour, minute, second)
result = SETFILETIMEQQ('myfile.dat', timedate)
END
```

**See Also**

PACKTIMEQQ
UNPACKTIMEQQ
GETLASTERRORQQ
SETTIM

**Portability Function:** Sets the system time in your programs. This function is only available on Windows* and Linux* systems.

**Module**

USE IFPORT

**Syntax**

result = SETTIM (ihr, imin, isec, i100th)

- **ihr** (Output) INTEGER(4) or INTEGER(2). Hour (0-23).
- **imin** (Output) INTEGER(4) or INTEGER(2). Minute (0-59).
- **isec** (Output) INTEGER(4) or INTEGER(2). Second (0-59).
- **i100th** (Output) INTEGER(4) or INTEGER(2). Hundredths of a second (0-99).

**Results**

The result type is LOGICAL(4). The result is .TRUE. if the system time is changed; .FALSE. if no change is made.

All arguments must be of the same integer kind, that is, all must be INTEGER(2) or all must be INTEGER(4). If INTEGER(2) arguments are passed, you must specify USE IFPORT.

**NOTE**

On Linux systems, you must have root privileges to execute this function.

**Example**

```fortran
USE IFPORT
LOGICAL(4) success
success = SETTIM(INT2(21),INT2(53+3),
                 INT2(14*2),INT2(88))
END
```

**See Also**

GETDAT
GETTIM
SETDAT

SHAPE

**Inquiry Intrinsic Function (Generic):** Returns the shape of an array or scalar argument.

**Syntax**

result = SHAPE (source [, kind])
source  (Input) Is a scalar or array. It may be of any data type. It must not be
an assumed-size array, a disassociated pointer, or an allocatable array
that is not allocated. It cannot be an assumed-size array.

kind  (Input; optional) Must be a scalar integer constant expression.

Results
The result is a rank-one integer array whose size is equal to the rank of source. If kind is present, the kind
parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default
integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The value of the result is the shape of source, unless source is assumed-rank and is associated with an
assumed-size array. In that case, the last element of the value returned by SHAPE is -1.

The setting of compiler options specifying integer size can affect this function.

Example
SHAPE (2) has the value of a rank-one array of size zero.

If B is declared as B(2:4, -3:1), then SHAPE (B) has the value (3, 5).

The following shows another example:

```
INTEGER VEC(2)
REAL array(3:10, -1:3)
VEC = SHAPE(array)
WRITE(*,*) VEC ! prints 8  5
END
!
! Check if a mask is conformal with an array
REAL, ALLOCATABLE :: A(:, :, :)
LOGICAL, ALLOCATABLE :: MASK(:, :, :)
INTEGER B(3), C(3)
LOGICAL conform
ALLOCATE (A(5, 4, 3))

SIZE

SHARED Clause

Parallel Directive Clause: Specifies variables that
will be shared by all the threads in a team.
Syntax

SHARED (list)

list

Is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a named common block must appear between slashes (/ /).

All threads within a team access the same storage area for SHARED data.

SHIFTA

*Elemental Intrinsic Function (Specific):* Performs a right shift with fill. This function cannot be passed as an actual argument.

Syntax

\[
\text{result} = \text{SHIFTA} \left( i, \text{shift} \right)
\]

\(i\) (Input) Must be of type integer. This is the value to be shifted.

\(\text{shift}\) (Input) Must be of type integer. It must be nonnegative and \(\leq \text{BIT_SIZE}(i)\). This value is the number of positions to shift.

Results

The result type and kind are the same as \(i\).

The result has the value obtained by shifting the bits of \(i\) to the right \(\text{shift}\) bits and replicating the leftmost bit of \(i\) in the left \(\text{shift}\) bits.

If \(\text{shift}\) is zero the result is \(i\). Bits shifted off the right end are lost.

The model for the interpretation of an integer value as a sequence of bits is in Model for Bit Data.

Example

\(\text{SHIFTA} \left( \text{IBSET} \left( 0, \text{BIT_SIZE} \left( 0 \right) - 1 \right), 2 \right)\) is equal to \(\text{SHIFTL} \left( 7, \text{BIT_SIZE} \left( 0 \right) - 3 \right)\).

SHIFTL

*Elemental Intrinsic Function (Specific):* Logically shifts an integer left by a specified number of bits. This function cannot be passed as an actual argument.

Syntax

\[
\text{result} = \text{SHIFTL} \left( i, \text{shift} \right)
\]

\(i\) (Input) Must be of type integer. This is the value to be shifted.

\(\text{shift}\) (Input) Must be of type integer. The value must be nonnegative and \(\leq \text{BIT_SIZE}(i)\). This value is the number of positions to shift.

Results

The result type and kind are the same as \(i\). The result is the value of \(i\) shifted left by \(\text{shift}\) bit positions. Bits shifted off the left end are lost; zeros are shifted in from the opposite end.

\(\text{SHIFTL} \left( i, j \right)\) is the same as \(\text{ISHFT} \left( i, j \right)\).

ISHFT

SHIFTR

*Elemental Intrinsic Function (Specific):* Logically shifts an integer right by a specified number of bits. This function cannot be passed as an actual argument.

**Syntax**

```
result = SHIFTR (i, shift)
```

*i*  
(Input) Must be of type integer. This is the value to be shifted.

*shift*  
(Input) Must be of type integer. The value must be nonnegative and <= BIT_SIZE(*i*). This value is the number of positions to shift.

**Results**

The result type and kind are the same as *i*. The result is the value of *i* shifted right by *shift* bit positions. Bits shifted off the right end are lost; zeros are shifted in from the opposite end.

SHIFTR (*i*, *j*) is the same as ISHFT (*i*, -*j*).

See Also
ISHFT

SHORT

*Portability Function*: Converts an INTEGER(4) argument to INTEGER(2) type.

**Module**

```
USE IFPORT
```

**Syntax**

```
result = SHORT (int4)
```

*int4*  
(Input) INTEGER(4). Value to be converted.

**Results**

The result type is INTEGER(2). The result is equal to the lower 16 bits of *int4*. If the *int4* value is greater than 32,767, the converted INTEGER(2) value is not equal to the original.

**Example**

```
USE IFPORT
INTEGER(4) this_one
INTEGER(2) that_one
READ(*,*) this_one
THAT_ONE = SHORT(this_one)
WRITE(*,10) THIS_ONE, THAT_ONE
END
```
SIGN
Elemental Intrinsic Function (Generic): Returns the absolute value of the first argument times the sign of the second argument.

Syntax
result = SIGN (a, b)

- a (Input) Must be of type integer or real.
- b (Input) Must have the same type as a.

Results
The result type and kind are the same as a. The value of the result is as follows:
- | a | if b > zero and -| a | if b < zero.
- | a | if b is of type integer and is zero.
- If b is of type real and zero and compiler option assume minus0 is not specified, the value of the result is | a |.
- If b is of type real and zero and compiler option assume minus0 is specified, the processor can distinguish between positive and negative real zero and the following occurs:
  - If b is positive real zero, the value of the result is | a |.
  - If b is negative real zero, the value of the result is -| a |.

The specific named versions of the function require that the arguments have the same kind parameters. The generic form of the function permits the kind types of the arguments to differ.

<table>
<thead>

<td>REAL(16)</td>
</tr>
</tbody>
</table>

1 Or HSIGN.
2 Or JISIGN. For compatibility with older versions of Fortran, ISIGN is treated as a generic function.
3 The setting of compiler options specifying real size can affect SIGN and DSIGN.
4 The setting of compiler options specifying double size can affect DSIGN.

Example
SIGN (4.0, -6.0) has the value -4.0.
SIGN (-5.0, 2.0) has the value 5.0.

The following shows another example:

```
c = SIGN (5.2, -3.1) ! returns -5.2
c = SIGN (-5.2, -3.1)  ! returns -5.2
c = SIGN (-5.2, 3.1)   ! returns  5.2
```

assume minus0 compiler option

**SIGNAL**

*Portability Function:* Controls interrupt signal handling and changes the action for a specified signal.

**Module**
USE IFPORT

**Syntax**

```
result = SIGNAL (signum, proc, flag)
```

- **signum** (Input) INTEGER(4). Number of the signal to change. The numbers and symbolic names are listed in a table below.
- **proc** (Input) Name of a signal-handler routine. It must be declared EXTERNAL and INTEGER(4). This routine is called only if **flag** is negative.
- **flag** (Input) INTEGER(4). If negative, the user's **proc** routine is called. If 0, the signal retains its default action; if 1, the signal should be ignored.

**Results**

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is the previous value of **proc** associated with the specified signal. For example, if the previous value of **proc** was SIG_IGN, the return value is also SIG_IGN. You can use this return value in subsequent calls to SIGNAL if the signal number supplied is greater than 1, or to restore a previous action definition.

A return value of SIG_ERR indicates an error, in which case a call to IERRNO returns EINVAL. If the signal number supplied is invalid, or if the flag value is greater than 1, SIGNAL returns -(EINVAL) and a call to IERRNO returns EINVAL.

An initial signal handler is in place at startup for SIGFPE (signal 8); its address is returned the first time SIGNAL is called for SIGFPE. No other signals have initial signal handlers.

Be careful when you use SIGNALQQ or the C signal function to set a handler, and then use the Portability SIGNAL function to retrieve its value. If SIGNAL returns an address that was not previously set by a call to SIGNAL, you cannot use that address with either SIGNALQQ or C's signal function, nor can you call it directly. You can, however, use the return value from SIGNAL in a subsequent call to SIGNAL. This allows you to restore a signal handler, no matter how the original signal handler was set.

The signal-handler argument **proc** accepts a single INTEGER(4) argument, which is the number of the signal to be handled. The function must use the compiler's default calling conventions. If you have used compiler options, such as option interface, to change the default conventions, add the following directive to the signal handler function to reset the calling conventions:
The signal-handler function returns an INTEGER(4) value. If the function has handled the signal, the value returned is an integer, but the value is not used.

Because signal-handler routines are usually called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. You cannot use the following kinds of signal-handler routines:

- Routines that perform low-level (such as FGETC) or high-level (such as READ) I/O.
- Heap routines or any routine that uses the heap routines (such as MALLOC and ALLOCATE).
- Functions that generate a system call (such as TIME).

The following table lists signals, their names and values:

<table>
<thead>
<tr>
<th>Symbolic name</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGABRT</td>
<td>6</td>
<td>Abnormal termination</td>
</tr>
<tr>
<td>SIGFPE</td>
<td>8</td>
<td>Floating-point error</td>
</tr>
<tr>
<td>SIGKILL¹</td>
<td>9</td>
<td>Kill process</td>
</tr>
<tr>
<td>SIGILL</td>
<td>4</td>
<td>Illegal instruction</td>
</tr>
<tr>
<td>SIGINT</td>
<td>2</td>
<td>CTRL+C signal</td>
</tr>
<tr>
<td>SIGSEGV</td>
<td>11</td>
<td>Illegal storage access</td>
</tr>
<tr>
<td>SIGTERM</td>
<td>15</td>
<td>Termination request</td>
</tr>
</tbody>
</table>

¹SIGKILL can be neither caught nor ignored.

The default action for all signals is to terminate the program with exit code.

ABORT does not assert the SIGABRT signal. The only way to assert SIGABRT or SIGTERM is to use KILL.

SIGNAL can be used to catch SIGFPE exceptions, but it cannot be used to access the error code that caused the SIGFPE. To do this, use SIGNALQQ instead.

Example

```fortran
USE IFORT
EXTERNAL h_abort
INTEGER(4) :: h_abort
INTEGER(4) iret1, iret2, procnum
iret1 = SIGNAL(SIGABRT, h_abort, -1)
WRITE(*,*) 'Set signal handler #1. Return = ', iret1

procnum = getpid( )
iret2 = KILL(procnum, SIGABRT)
WRITE(*,*) 'Raised signal. Return = ', iret2
END

! Signal-handler routine
!
INTEGER(4) FUNCTION h_abort (sig_num)
INTEGER(4) sig_num
!DIR$ ATTRIBUTES DEFAULT :: h_abort
WRITE(*,*) 'In signal handler function h_abort for SIG$ABORT'
WRITE(*,*) 'signum = ', sig_num
h_abort = 1
END
```

Language Reference

See Also
SIGNALQQ

SIGNALQQ
Portability Function: Registers the function to be called if an interrupt signal occurs.

Module
USE IFPORT

Syntax
result = SIGNALQQ (sig, func)

sig
(Input) INTEGER(4). Interrupt type. One of the following constants, defined in IFPORT.F90:

- SIG$ABORT - Abnormal termination
- SIG$FPE - Floating-point error
- SIG$ILL - Illegal instruction
- SIG$INT - CTRL+CSIGNAL
- SIG$SEGV - Illegal storage access
- SIG$TERM - Termination request

func
(Input) Function to be executed on interrupt. It must be declared EXTERNAL.

Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is a positive integer if successful; otherwise, -1 (SIG$ERR).

SIGNALQQ installs the function func as the handler for a signal of the type specified by sig. If you do not install a handler, the system by default terminates the program with exit code 3 when an interrupt signal occurs.

The argument func is the name of a function and must be declared with either the EXTERNAL or IMPLICIT statements, or have an explicit interface. A function described in an INTERFACE block is EXTERNAL by default, and does not need to be declared EXTERNAL.

NOTE
All signal-handler functions must be declared with the directive !DIR$ ATTRIBUTES C.

When an interrupt occurs, except a SIG$FPE interrupt, the sig argument SIG$INT is passed to func, and then func is executed.

When a SIG$FPE interrupt occurs, the function func is passed two arguments: SIG$FPE and the floating-point error code (for example, FPE$ZERODIVIDE or FPE$OVERFLOW) which identifies the type of floating-point exception that occurred. The floating-point error codes begin with the prefix FPE$ and are defined in IFPORT.F90.

If func returns, the calling process resumes execution immediately after the point at which it received the interrupt signal. This is true regardless of the type of interrupt or operating mode.
Because signal-handler routines are normally called asynchronously when an interrupt occurs, it is possible that your signal-handler function will get control when a run-time operation is incomplete and in an unknown state. Therefore, do not call heap routines or any routine that uses the heap routines (for example, I/O routines, ALLOCATE, and DEALLOCATE).

To test your signal handler routine you can generate interrupt signals by calling RAISEQQ, which causes your program either to branch to the signal handlers set with SIGNALQQ, or to perform the system default behavior if SIGNALQQ has set no signal handler.

The example below shows a signal handler for SIG$ABORT.

Example

! This program shows a signal handler for SIG$ABORT
USE IFPORT
INTERFACE
  FUNCTION h_abort (signum)
    !DIR$ ATTRIBUTES C :: h_abort
    INTEGER(4) h_abort
    INTEGER(2) signum
  END FUNCTION
END INTERFACE

INTEGER(2) i2ret
INTEGER(4) i4ret

i4ret = SIGNALQQ(SIG$ABORT, h_abort)
WRITE(*,*) 'Set signal handler. Return = ', i4ret

i2ret = RAISEQQ(SIG$ABORT)
WRITE(*,*) 'Raised signal. Return = ', i2ret

END

! Signal handler routine
!
INTEGER(4) FUNCTION h_abort (signum)
  !DIR$ ATTRIBUTES C :: h_abort
  INTEGER(2) signum
  WRITE(*,*) 'In signal handler for SIG$ABORT'
  WRITE(*,*) 'signum = ', signum
  h_abort = 1
END

SIMD Directive (OpenMP* API)
OpenMP* Fortran Compiler Directive: Transforms a loop into a loop that will be executed concurrently using Single Instruction Multiple Data (SIMD) instructions.
Syntax

!$OMP SIMD [clause[,] clause]... ]

  do-loop

[!$OMP END SIMD]

clause

Is one of the following:

- **ALIGNED** (list [:n])
- **[NO]ASSERT**

  Directs the compiler to assert (produce an error) or not to assert (produce a warning) when the vectorization fails. The default is NOASSERT. If this clause is specified more than once, a compile-time error occurs.

- **COLLAPSE** (n)
- **EARLY_EXIT**

  Allows vectorization of multiple exit loops. When this clause is specified the following occurs:

  - Each operation before the last lexical early exit of the loop may be executed as if the early exit were not triggered within the SIMD chunk.
  - After the last lexical early exit of the loop, all operations are executed as if the last iteration of the loop was found.
  - The last value for LINEARs and conditional LASTPRIVATEs are preserved with respect to scalar execution.
  - The last value for REDUCTIONs are computed as if the last iteration in the last SIMD chunk was executed upon exiting the loop.
  - The shared memory state may not be preserved with regard to scalar execution.
  - Exceptions are not allowed.

When a SIMD loop is specified with the EARLY_EXIT clause, each list item specified in the LINEAR clause is computed based on the last iteration number upon exiting the loop.

- **IF** ([SIMD:] scalar-logical-expression)
- **LASTPRIVATE** ([CONDITIONAL:] list)
- **LINEAR** (var-list[: linear-step])
- **NONTEMPORAL** [(var1 [, var2]...)]

  Directs the compiler to use non-temporal (that is, streaming) stores.

  By default, the compiler automatically determines whether a streaming store should be used for each variable.

  Streaming stores may cause significant performance improvements over non-streaming stores for large trip-count loops on certain processors. However, the misuse of streaming stores can significantly degrade performance.

  A variable cannot appear more than once in a NONTEMPORAL clause, and it cannot appear in more than one NONTEMPORAL clause.

- **ORDER** (CONCURRENT)
Indicates that the iterations of the loop may execute in any order or simultaneously. This feature is only available for ifx.

- **PRIVATE (list)**
- **REDUCTION (reduction-identifier : list)**
- **SAFELEN(m)**

Limits the number of iterations in a SIMD chunk (set of concurrent iterations).

The m must be a constant positive integer expression; it indicates the number of iterations allowed in a SIMD chunk.

When this clause is used, no two iterations executed concurrently with SIMD instructions can have a greater distance in the logical iteration space than m.

The number of iterations that are executed concurrently at any given time is defined by the implementation. Each concurrent iteration is executed by a different SIMD vector lane.

At most one SAFELEN clause can appear in a SIMD directive.

- **SIMDLEN(n)**

Specifies the preferred number of iterations to be executed concurrently. n must be a positive scalar integer constant. The number of iterations that are executed concurrently at any given time is implementation defined. Each concurrent iteration will be executed by a different SIMD lane.

If both SIMDLEN (n) and SAFELEN (m) are specified, the value of the n must be less than or equal to the value of m.

At most one SIMDLEN clause can appear in a SIMD directive.

A SIMD construct binds to the current task region. The binding thread set of the SIMD region is the current team.

If used, the END SIMD directive must appear immediately after the end of the loop. If you do not specify an END SIMD directive, an END SIMD directive is assumed at the end of do-loop.

The SIMD construct enables the execution of multiple iterations of the associated loops concurrently by means of SIMD instructions. No other OpenMP Fortran construct can appear in a SIMD directive.

A SIMD region binds to the current task region. The binding thread set of the SIMD region is the current team.

When any thread encounters a SIMD construct, the iterations of the loop associated with the construct may be executed concurrently using the SIMD lanes that are available to the thread.
If an ORDERED directive with the SIMD clause is specified inside the SIMD region, the ordered regions encountered by any thread will use only a single SIMD lane to execute the ordered regions in the order of the loop iterations.

**Example**

The following is an example using the SIMD directive:

```fortran
subroutine subr(a, b, c, n)
    implicit none
    real(kind=kind(0.0d0)),dimension(*) :: a, b, c
    integer :: n, i

    !$omp simd
    do i = 1, n
        a(i) = a(i) * b(i) + c(i)
    end do
end subroutine
```

The following example demonstrates the EARLY_EXIT clause:

```fortran
!$omp simd early_exit
    do i = 1, n
        if (a(i) == i) exit
    enddo
```

**SIMD Loop Directive**

*General Compiler Directive: Requires and controls*  
SIMD vectorization of loops. This directive is deprecated and will be removed in a future release.

**Syntax**

```fortran
!DIR$ SIMD [clause[, clause]...]
```

**clause**  
Is an optional vectorization clause. It can be one or more of the following:

- **[NO]ASSERT**
  
  Directs the compiler to assert (produce an error) or not to assert (produce a warning) when the vectorization fails. The default is NOASSERT. If this clause is specified more than once, a compile-time error occurs.
- **FIRSTPRIVATE(list)**
**list**  
Is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a FIRSTPRIVATE list are subject to PRIVATE clause semantics. In addition, each variable has its initial value broadcast to all private instances for each iteration upon entering the SIMD loop.

A variable in a FIRSTPRIVATE clause can appear in a LASTPRIVATE clause.

A variable in a FIRSTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.

- **LASTPRIVATE** *(list)*

  list  
  Is a list of names of one or more variables or common blocks that are accessible to the scoping unit.

  Provides a superset of the functionality provided by the PRIVATE clause. Variables that appear in a LASTPRIVATE list are subject to PRIVATE clause semantics. In addition, when the SIMD loop is exited, each variable has the value that resulted from the sequentially last iteration of the SIMD loop (which may be undefined if the last iteration does not assign to the variable).

A variable in a LASTPRIVATE clause can appear in a FIRSTPRIVATE clause.

A variable in a LASTPRIVATE clause cannot appear in a LINEAR, REDUCTION, or PRIVATE clause.

- **LINEAR** *(var1:step1 [, var2:step2]...)*

  var  
  Is a scalar variable.

  step  
  Is a positive, integer, scalar expression.

  For each iteration of a scalar loop, var1 is incremented by step1, var2 is incremented by step2, and so on. Therefore, every iteration of the vector loop increments the variables by VL (vector length)*step1, VL*step2, ... , to VL*stepN, respectively. If more than one step is specified for a var, a compile-time error occurs. Multiple LINEAR clauses are merged as a union.

A variable in a LINEAR clause cannot appear in a REDUCTION, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.

- **PRIVATE** *(list)*

  list  
  Is a list of names of one or more variables or common blocks that are accessible to the scoping unit. A variable that is part of another variable (for example, subobjects such as an array or structure element) cannot appear. Each name must be
Causes each variable to be private to each iteration of a loop. Its initial and last values are undefined upon entering and exiting the SIMD loop. Multiple PRIVATE clauses are merged as a union.

A variable in a PRIVATE clause cannot appear in a LINEAR, REDUCTION, FIRSTPRIVATE, or LASTPRIVATE clause.

- **REDUCTION** *(reduction-identifier : var1 [, var2]...)*
  
  **reduction-identifier**
  
  Is a predefined reduction identifier ( +, *, -, .AND., .OR., .EQV., or .NEQV.), or an accessible user-defined reduction identifier declared in a DECLARE REDUCTION directive.

  **var**
  
  Is a scalar variable.

Applies the vector reduction indicated by reduction-identifier to var1, var2, ..., varN. A SIMD directive can have multiple REDUCTION clauses using the same or different operators. If more than one reduction operator is associated with a var, a compile-time error occurs.

A variable in a REDUCTION clause cannot appear in a LINEAR, PRIVATE, FIRSTPRIVATE, or LASTPRIVATE clause.

- `[NO]VECREMAINDER`
- **VECTORLENGTH** *(n1 [, n2]...)*
  
  **n**
  
  Is a vector length (VL). It must be an integer that is a power of 2; the value must be 2, 4, 8, 16, 32 or 64. If you specify more than one n, the vectorizer will choose the VL from the values specified.

Causes each iteration in the vector loop to execute the computation equivalent to n iterations of scalar loop execution.

The VECTORLENGTH and VECTORLENGTHFOR clauses are mutually exclusive. You cannot use the VECTORLENGTH clause with the VECTORLENGTHFOR clause, and vice versa.

Multiple VECTORLENGTH clauses cause a syntax error.

- **VECTORLENGTHFOR** *(data-type)*
  
  **data-type**
  
  Is one of the following intrinsic data types:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Fortran Intrinsic Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Default INTEGER</td>
</tr>
<tr>
<td>INTEGER(1)</td>
<td>INTEGER (KIND=1)</td>
</tr>
<tr>
<td>Data Type</td>
<td>Fortran Intrinsic Type</td>
</tr>
<tr>
<td>--------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>INTEGER(2)</td>
<td>INTEGER (KIND=2)</td>
</tr>
<tr>
<td>INTEGER(4)</td>
<td>INTEGER (KIND=4)</td>
</tr>
<tr>
<td>INTEGER(8)</td>
<td>INTEGER (KIND=8)</td>
</tr>
<tr>
<td>REAL</td>
<td>Default REAL</td>
</tr>
<tr>
<td>REAL(4)</td>
<td>REAL (KIND=4)</td>
</tr>
<tr>
<td>REAL(8)</td>
<td>REAL (KIND=8)</td>
</tr>
<tr>
<td>COMPLEX</td>
<td>Default COMPLEX</td>
</tr>
<tr>
<td>COMPLEX(4)</td>
<td>COMPLEX (KIND=4)</td>
</tr>
<tr>
<td>COMPLEX(8)</td>
<td>COMPLEX (KIND=8)</td>
</tr>
</tbody>
</table>

Causes each iteration in the vector loop to execute the computation equivalent to \(n\) iterations of scalar loop execution where \(n\) is computed from \(\frac{\text{size of vector register}}{\text{sizeof(data type)}}\).

For example, \(\text{VECTORLENGTHFOR (REAL (KIND=4))}\) results in \(n=4\) for SSE2 to SSE4.2 targets (packed float operations available on 128-bit XMM registers) and \(n=8\) for AVX target (packed float operations available on 256-bit YMM registers).

\(\text{VECTORLENGTHFOR(INTEGER (KIND=4))}\) results in \(n=4\) for SSE2 to AVX targets.

The \(\text{VECTORLENGTHFOR}\) and \(\text{VECTORLENGTH}\) clauses are mutually exclusive. You cannot use the \(\text{VECTORLENGTHFOR}\) clause with the \(\text{VECTORLENGTH}\) clause, and vice versa.

Multiple \(\text{VECTORLENGTHFOR}\) clauses cause a syntax error.

Without explicit \(\text{VECTORLENGTH}\) and \(\text{VECTORLENGTHFOR}\) clauses, the compiler will choose a \(\text{VECTORLENGTH}\) using its own cost model. Misclassification of variables into \text{PRIVATE, \text{FIRSTPRIVATE, \text{LASTPRIVATE, LINEAR, and REDUCTION}}, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.

If you specify the SIMD directive with no clause, default rules are in effect for variable attributes, vector length, and so forth.

If you do not explicitly specify a \(\text{VECTORLENGTH}\) clause, the compiler will choose a \(\text{VECTORLENGTH}\) using its own cost model. Misclassification of variables into \text{PRIVATE, FIRSTPRIVATE, LASTPRIVATE, LINEAR, and REDUCTION}, or the lack of appropriate classification of variables, may lead to unintended consequences such as runtime failures and/or incorrect results.
You can only specify a particular variable in at most one instance of a PRIVATE, LINEAR, or REDUCTION clause.

If the compiler is unable to vectorize a loop, a warning occurs by default. However, if ASSERT is specified, an error occurs instead.

If the vectorizer has to stop vectorizing a loop for some reason, the fast floating-point model is used for the SIMD loop.

A SIMD loop may contain one or more nested loops or be contained in a loop nest. Only the loop preceded by the SIMD directive is processed for SIMD vectorization.

The vectorization performed on this loop by the SIMD directive overrides any setting you may specify for options -fp-model (Linux* and macOS*) and /fp (Windows*) for this loop.

Note that the SIMD directive may not affect all auto-vectorizable loops. Some of these loops do not have a way to describe the SIMD vector semantics.

The following restrictions apply to the SIMD directive:

- The countable loop for the SIMD directive has to conform to the DO-loop style of an OpenMP worksharing loop construct. Additionally, the loop control variable must be a signed integer type.
- The vector values must be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating-point numbers, or single- or double-precision complex numbers.
- A SIMD directive loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially.

To disable the SIMD transformations for vectorization, specify option -no-simd (Linux* and macOS*) or /Qsimd- (Windows*).

To disable transformations that enable more vectorization, specify options -no-vec-no-simd (Linux and macOS*) or /Qvec-/Qsimd- (Windows).

Example
Consider the following:

```fortran
... subroutine add(A, N, X)
  integer N, X
  real    A(N)
cDIR$ SIMD
  DO I=X+1, N
    A(I) = A(I) + A(I-X)
  ENDDO
end
...```

When the program containing this subroutine is compiled, the DO loop will be vectorized.

Because no optional clause was specified for the directive, default rules will apply for variable attributes, vector length, and so forth.

1890
SIN

**Elemental Intrinsic Function (Generic):** Produces the sine of an argument.

**Syntax**

\[
\text{result} = \text{SIN} \ (x)
\]

*\(x\) (Input) Must be of type real or complex. It must be in radians and is treated as modulo 2*pi.

**Results**

The result type and kind are the same as \(x\).

If \(x\) is of type real, the result is a value in radians.

If \(x\) is of type complex, the real part of the result is a value in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIN</td>

<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQSIN</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect CSIN.

\(^2\)This function can also be specified as ZSIN.

**Example**

SIN (2.0) has the value 0.9092974.

SIN (0.8) has the value 0.7173561.

SIND

**Elemental Intrinsic Function (Generic):** Produces the sine of an argument.

**Syntax**

\[
\text{result} = \text{SIND} \ (x)
\]

*\(x\) (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind are the same as \(x\).
<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIND</td>

</tr>
<tr>
<td>DSIND</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSIND</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

SIND (2.0) has the value 3.4899496E-02.
SIND (0.8) has the value 1.3962180E-02.

**SINGLE**

*OpenMP* Fortran Compiler Directive: Specifies that a block of code is to be executed by only one thread in the team at a time.

**Syntax**

```fortran
!$OMP SINGLE [clause[ [, clause] ... ] ]
   loosely-structured-block
!$OMP END SINGLE [modifier]
-or-

!$OMP SINGLE [clause[ [, clause] ... ] ]
   strictly-structured-block
!$OMP END SINGLE [modifier]
```

- **clause**
  
  Is one of the following:
  
  - ALLOCATE ([allocator :] list)
  - FIRSTPRIVATE (list)
  - PRIVATE (list)

- **loosely-structured-block**
  
  Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

- **strictly-structured-block**
  
  Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

- **modifier**
  
  Is one of the following:
  
  - COPYPRIVATE (list)
  - NOWAIT

The binding thread set for a SINGLE construct is the current team. A SINGLE region binds to the innermost enclosing parallel region.

Threads in the team that are not executing this directive wait at the END SINGLE directive unless NOWAIT is specified.

SINGLE directives must be encountered by all threads in a team or by none at all. It must also be encountered in the same order by all threads in a team.
Example
In the following example, the first thread that encounters the SINGLE directive executes subroutines OUTPUT and INPUT:

```fortran
!$OMP PARALLEL DEFAULT(SHARED)
   CALL WORK(X)
!$OMP BARRIER
!$OMP SINGLE
   CALL OUTPUT(X)
   CALL INPUT(Y)
!$OMP END SINGLE
   CALL WORK(Y)
!$OMP END PARALLEL
```

You should not make assumptions as to which thread executes the SINGLE section. All other threads skip the SINGLE section and stop at the barrier at the END SINGLE construct. If other threads can proceed without waiting for the thread executing the SINGLE section, you can specify NOWAIT in the END SINGLE directive.

SINH

*Elemental Intrinsic Function (Generic):* Produces a hyperbolic sine.

**Syntax**

```fortran
result = SINH (x)
```

- `x` is (Input) Must be of type real or complex.

**Results**

The result type and kind are the same as `x`.

If `x` is of type complex, the imaginary part of the result is in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SINH</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>
<tr>
<td>DSINH</td>
<td>REAL(8)</td>
<td>REAL(8)</td>
</tr>
<tr>
<td>QSINH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

SINH (2.0) has the value 3.626860.

SINH (0.8) has the value 0.8881060.

SIZE Function

*Inquiry Intrinsic Function (Generic):* Returns the total number of elements in an array, or the extent of an array along a specified dimension.
Syntax

\[
\text{result} = \text{SIZE}(\text{array}[, \text{dim}][, \text{kind}])
\]

\textit{array}  
\hspace{1cm} (Input) Must be an array; it can be assumed-rank. It can be of any data type. It must not be a disassociated pointer or an allocatable array that is not allocated. It can be an assumed-size array if \textit{dim} is present with a value less than the rank of \textit{array}.

\textit{dim}  
\hspace{1cm} (Input; optional) Must be a scalar integer with a value in the range 1 to \textit{n}, where \textit{n} is the rank of \textit{array}.

\textit{kind}  
\hspace{1cm} (Input; optional) Must be a scalar integer constant expression.

Results

The result is a scalar of type integer. If \textit{kind} is present, the kind parameter of the result is that specified by \textit{kind}; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

In general, if \textit{dim} is present, the result is the extent of dimension \textit{dim} in \textit{array}; otherwise, the result is the total number of elements in \textit{array}. However, the following exceptions apply:

- If \textit{array} is assumed-rank and associated with an assumed-size array and \textit{dim} is present with a value equal to the rank of \textit{ARRAY}, the result has a value of -1.
- If \textit{dim} is absent and \textit{array} is assumed-rank, the result has a value equal to \text{PRODUCT(SHAPE(ARRAY, KIND))}.

The setting of compiler options specifying integer size can affect this function.

Example

If \textit{B} is declared as \textit{B(2:4, -3:1)}, then \text{SIZE (B, DIM=2)} has the value 5 and \text{SIZE (B)} has the value 15.

The following shows another example:

```
REAL(8) array (3:10, -1:3)
INTEGER i
i = SIZE(array, DIM = 2) ! returns 5
i = SIZE(array)          ! returns 40
```

See Also

SHAPE
Character Count Specifier

\section*{SIZEOF}

\textbf{Inquiry Intrinsic Function (Generic):} Returns the number of bytes of storage used by the argument. It cannot be passed as an actual argument.

Syntax

\[
\text{result} = \text{SIZEOF}(\text{x})
\]

\textit{x}  
\hspace{1cm} (Input) Can be a scalar or array. It may be of any data type. It must not be an assumed-size array. If it is an assumed-rank array, it must not be associated with an assumed-size array. If it is type CHARACTER, it cannot be a dummy argument with LEN=*.
Results
The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result value is the number of bytes of storage used by \( x \).

If \( x \) is of derived type, the result includes storage used by padding and descriptors for pointer or allocatable components, if any, but not the storage used for the data of pointer or allocatable components. If \( x \) is an assumed-rank array associated with an assumed-size array, the result is undefined.

Example

<table>
<thead>
<tr>
<th>SIZEOF (3.44)</th>
<th>! has the value 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIZEOF ('SIZE')</td>
<td>! has the value 4</td>
</tr>
</tbody>
</table>

See Also
C_SIZEOF

SLEEP

**Portability Subroutine:** Suspends the execution of a process for a specified interval.

Module

USE IFPORT

Syntax

CALL SLEEP (time)

\( \text{time} \) (Input) INTEGER(4). Length of time, in seconds, to suspend the calling process.

Example

```
USE IFPORT
integer(4) hold_time
hold_time = 1    ! lets the loop execute
DO WHILE (hold_time .NE. 0)
   write(*,'(A)') "Enter the number of seconds to suspend"
   read(*,*) hold_time
   CALL SLEEP (hold_time)
END DO
END
```

See Also
SLEEPQQ

SLEEPQQ

**Portability Subroutine:** Delays execution of the program for a specified duration.

Module

USE IFPORT
Syntax
CALL SLEEPQQ (duration)

duration (Input) INTEGER(4). Number of milliseconds the program is to sleep (delay program execution).

Example
USE IFPORT
INTEGER(4) delay, freq, duration
delay = 2000
delay = 4000
duration = 1000
CALL SLEEPQQ(delay)
CALL BEEPQQ(freq, duration)
END

SNGL
Converts a REAL value to a default REAL result.

See Also
See REAL function.

SORTQQ
Portability Subroutine: Sorts a one-dimensional array. The array elements cannot be derived types or record structures.

Module
USE IFPORT

Syntax
CALL SORTQQ (adrarray,count,size)

adrarray (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Address of the array (returned by LOC).

count (Input; output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. On input, number of elements in the array to be sorted. On output, number of elements actually sorted.

To be certain that SORTQQ is successful, compare the value returned in count to the value you provided. If they are the same, then SORTQQ sorted the correct number of elements.

size (Input) INTEGER(4). Positive constant less than 32,767 that specifies the kind of array to be sorted. The following constants, defined in IFPORT.F90, specify type and kind for numeric arrays:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type of array</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRT$INTEGER1</td>
<td>INTEGER(1)</td>
</tr>
<tr>
<td>SRT$INTEGER2</td>
<td>INTEGER(2) or equivalent</td>
</tr>
<tr>
<td>Constant</td>
<td>Type of array</td>
</tr>
<tr>
<td>-------------</td>
<td>------------------------</td>
</tr>
<tr>
<td>SRT$INTEGER4</td>
<td>INTEGER(4) or equivalent</td>
</tr>
<tr>
<td>SRT$INTEGER8</td>
<td>INTEGER(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL4</td>
<td>REAL(4) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL8</td>
<td>REAL(8) or equivalent</td>
</tr>
<tr>
<td>SRT$REAL16</td>
<td>REAL(16) or equivalent</td>
</tr>
</tbody>
</table>

If the value provided in \textit{size} is not a symbolic constant and is less than 32,767, the array is assumed to be a character array with \textit{size} characters per element.

**Caution**

The location of the array must be passed by address using the LOC function. This defeats Fortran type-checking, so you must make certain that the \textit{count} and \textit{size} arguments are correct.

If you pass invalid arguments, \textsc{sortqq} attempts to sort random parts of memory. If the memory it attempts to sort is allocated to the current process, that memory is sorted; otherwise, the operating system intervenes, the program is halted, and you get a General Protection Violation message.

**Example**

```fortran
! Sort a 1-D array
! USE IFPORT
INTEGER(2) array(10)
INTEGER(2) i DATA ARRAY /143, 99, 612, 61, 712, 9112, 6, 555, 2223, 67/
! Sort the array
Call SORTQQ (LOC(array), 10, SRT$INTEGER2)
! Display the sorted array
DO i = 1, 10
   WRITE (*, 9000) i, array (i) 9000 FORMAT(1X, ' Array(',I2, '): ', I5)
END DO
END
```

**See Also**

BSEARCHQQ
LOC

**SPACING**

\textit{Elemental Intrinsic Function (Generic):} Returns the absolute spacing of model numbers near the argument value.

**Syntax**

\[
\text{result} = \text{SPACING} \ (x)
\]

\(x\) (Input) Must be of type real.

**Results**

The result type and kind are the same as \(x\). The result has the value \(b \cdot 2^{-p}\). Parameters \(b\), \(e\), and \(p\) are defined in \textit{Model for Real Data}. If the result value is outside of the real model range, the result is TINY(\(x\)).
Example

If 3.0 is a REAL(4) value, SPACING (3.0) has the value $2^{-22}$.

The following shows another example:

```fortran
REAL(4) res4
REAL(8) res8, r2
res4 = SPACING(3.0)  ! returns 2.384186E-07
res4 = SPACING(-3.0) ! returns 2.384186E-07
r2 = 487923.3
res8 = SPACING(r2)  ! returns 5.820766091346741E-011
```

TINY
RRSPACING

Data Representation Models

SPLITPATHQQ

**Portability Function**: Breaks a file path or directory path into its components.

Module

USE IFPORT

Syntax

```
result = SPLITPATHQQ (path, drive, dir, name, ext)
```

- **path**
  (Input) Character*(*). Path to be broken into components. Forward slashes (/), backslashes (\), or both can be present in path.

- **drive**
  (Output) Character*(*). Drive letter followed by a colon.

- **dir**
  (Output) Character*(*). Path of directories, including the trailing slash.

- **name**
  (Output) Character*(*). Name of file or, if no file is specified in path, name of the lowest directory. A file name must not include an extension.

- **ext**
  (Output) Character*(*). File name extension, if any, including the leading period (.)

Results

The result type is INTEGER(4). The result is the length of dir.

The path parameter can be a complete or partial file specification.

$\$MAXPATH$ is a symbolic constant defined in module IFPORT.F90 as 260.

Example

```fortran
USE IFPORT
CHARACTER(\$MAXPATH) buf
CHARACTER(3)    drive
CHARACTER(256)  dir
CHARACTER(256)  name
```
CHARACTER(256)      ext
CHARACTER(256)      file
INTEGER(4)          length

buf = 'b:\fortran\test\runtime\tsplit.for'
length = SPLITPATHQQ(buf, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
file = 'partial.f90'
length = SPLITPATHQQ(file, drive, dir, name, ext)
WRITE(*,*) drive, dir, name, ext
END

See Also
FULLPATHQQ

SPREAD

Transformational Intrinsic Function (Generic):
Creates a replicated array with an added dimension by making copies of existing elements along a specified dimension.

Syntax
result = SPREAD (source, dim, ncopies)

source          (Input) Must be a scalar or array. It may be of any data type. The rank must be less than 31.
dim             (Input) Must be scalar and of type integer. It must have a value in the range 1 to n + 1 (inclusive), where n is the rank of source.
ncopies         Must be scalar and of type integer. It becomes the extent of the additional dimension in the result.

Results
The result is an array of the same type as source and of rank that is one greater than source.
If source is an array, each array element in dimension dim of the result is equal to the corresponding array element in source.
If source is a scalar, the result is a rank-one array with ncopies elements, each with the value source.
If ncopies less than or equal to zero, the result is an array of size zero.

Example
SPREAD ("B", 1, 4) is the character array ("B", "B", "B", "B").
B is the array [3, 4, 5] and NC has the value 4.
SPREAD (B, DIM=1, NCOPIES=NC) produces the array

[ 3 4 5 ]
[ 3 4 5 ]
[ 3 4 5 ]
[ 3 4 5 ].
SPREAD (B, DIM=2, NCOPIES=NC) produces the array

\[
\begin{bmatrix}
3 & 3 & 3 & 3 \\
4 & 4 & 4 & 4 \\
5 & 5 & 5 & 5 \\
\end{bmatrix}
\]

The following shows another example:

```fortran
INTEGER AR1(2, 3), AR2(3, 2)
AR1 = SPREAD((/1,2,3/),DIM= 1,NCOPIES= 2) ! returns
! 1 2 3
! 1 2 3
AR2 = SPREAD((/1,2,3/), 2, 2)   ! returns   1 1
!           2 2
!           3 3
```

PACK
RESHAPE

**SQRT**

*Elemental Intrinsic Function (Generic): Produces the square root of its argument.*

**Syntax**

\[
\text{result} = \text{SQRT} (x)
\]

\(x\) (Input) must be of type real or complex. If \(x\) is type real, its value must be greater than or equal to zero.

**Results**

The result type and kind are the same as \(x\). The result has a value equal to the square root of \(x\).

A result of type complex is the principal value, with the real part greater than or equal to zero.

When the real part of the result is zero, the imaginary part of the result has the same sign as the imaginary part of \(x\), even if the imaginary part of \(x\) is a negative real zero.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQRT</td>
<td>REAL(4)</td>
<td>REAL(4)</td>
</tr>

<td>COMPLEX(8)</td>
<td>COMPLEX(8)</td>
</tr>
<tr>
<td>CQSQRT</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

\(^1\)The setting of compiler options specifying real size can affect CSQRT.

\(^2\)This function can also be specified as ZSQRT.
**Example**

SQRT (16.0) has the value 4.0.

SQRT (3.0) has the value 1.732051.

The following shows another example:

```
! Calculate the hypotenuse of a right triangle
! from the lengths of the other two sides.
REAL sidea, sideb, hyp
sidea = 3.0
sideb = 4.0
hyp = SQRT (sidea**2 + sideb**2)
WRITE (*, 100) hyp
100 FORMAT (/ ' The hypotenuse is ', F10.3)
END
```
SSWRQQ

**Portability Subroutine:** Returns the floating-point processor status word.

**Module**

USE IFPORT

**Syntax**

CALL SSWRQQ (status)

*status* *(Output) INTEGER(2).* Floating-point processor status word.

SSWRQQ performs the same function as the run-time subroutine GETSTATUSFPQQ and is provided for compatibility.

**Example**

```fortran
USE IFPORT
INTEGER(2) status
CALL SSWRQQ (status)
```

**See Also**

LCWRQQ
GETSTATUSFPQQ

STAT

**Portability Function:** Returns detailed information about a file.

**Module**

USE IFPORT

**Syntax**

result = STAT (name, statb)

*name* *(Input) Character*. Name of the file to examine.

*statb* *(Output) INTEGER(4) or INTEGER(8).* One-dimensional array of size 12; where the system information is stored. The elements of *statb* contain the following values:

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
<th>Values or Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>statb(1)</td>
<td>Device the file resides on</td>
<td>W*S: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: System dependent</td>
</tr>
<tr>
<td>statb(2)</td>
<td>File inode number</td>
<td>W*S: Always 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>L<em>X, M</em>X: System dependent</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
<td>Values or Notes</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>statb(3)</td>
<td>Access mode of the file</td>
<td>See the table in Results</td>
</tr>
</tbody>
</table>
| statb(4) | Number of hard links to the file | W*S: Always 1  
L*X, M*X: System dependent |
| statb(5) | User ID of owner | W*S: Always 1  
L*X, M*X: System dependent |
| statb(6) | Group ID of owner | W*S: Always 1  
L*X, M*X: System dependent |
| statb(7) | Raw device the file resides on | W*S: Always 0  
L*X, M*X: System dependent |
| statb(8) | Size of the file | |
| statb(9) | Time when the file was last accessed<sup>1</sup> | W*S: Only available on non-FAT file systems; undefined on FAT systems  
L*X, M*X: System dependent |
| statb(10) | Time when the file was last modified<sup>1</sup> | |
| statb(11) | Time of last file status change<sup>1</sup> | W*S: Same as stat(10)  
L*X, M*X: System dependent |
| statb(12) | Blocksize for file system I/O operations | W*S: Always 1  
L*X, M*X: System dependent |

<sup>1</sup>Times are in the same format returned by the TIME function (number of seconds since 00:00:00 Greenwich mean time, January 1, 1970).

**Results**

The result type is INTEGER(4).

On Windows* systems, the result is zero if the inquiry was successful; otherwise, the error code ENOENT (the specified file could not be found). On Linux* and macOS* systems, the file inquired about must be currently connected to a logical unit and must already exist when STAT is called; if STAT fails, errno is set.

For a list of other error codes, see IERRNO.
The access mode (the third element of \textit{statb}) is a bitmap consisting of an IOR of the following constants:

<table>

STAT returns the same information as FSTAT, but accesses files by name instead of external unit number.

On Windows* systems, LSTAT returns exactly the same information as STAT. On Linux and macOS* systems, if the file denoted by name is a link, LSTAT provides information on the link, while STAT provides information on the file at the destination of the link.

You can also use the INQUIRE statement to get information about file properties.

#### Example

```fortran
USE IFPORT
CHARACTER*12 file_name
INTEGER(4) info_array(12)
p
rint *, 'Enter file to examine: '
read *, file_name
ISTATUS = STAT (file_name, info_array)
if (.not. istatus) then
  p
rint *, info_array else
  p
rint *, 'Error = ',istatus
end if
end
```

#### See Also
INQUIRE
GETFILEINFOQQ
FSTAT

#### Statement Function

**Statement**: Defines a function in a single statement in the same program unit in which the procedure is referenced.

**Syntax**

```fortran
fun([d-arg [,d-arg]...]) = expr
```

- **fun**
  - Is the name of the statement function.

- **d-arg**
  - Is a dummy argument. A dummy argument can appear only once in any list of dummy arguments, and its scope is local to the statement function.

- **expr**
  - Is a scalar expression defining the computation to be performed.

Named constants and variables used in the expression must have been declared previously in the specification part of the scoping unit or made accessible by use or host association.

If the expression contains a function or statement function reference, that function must have been defined previously as a function or statement function in the same program unit.
A statement function reference takes the following form:

\[ \text{fun}( [ \text{a-arg}, \text{a-arg} ] ... ) \]

- \text{fun} is the name of the statement function.
- \text{a-arg} is an actual argument.

**Description**

When a statement function reference appears in an expression, the values of the actual arguments are associated with the dummy arguments in the statement function definition. The expression in the definition is then evaluated. The resulting value is used to complete the evaluation of the expression containing the function reference.

The data type of a statement function can be explicitly defined in a type declaration statement. If no type is specified, the type is determined by implicit typing rules in effect for the program unit.

Actual arguments must agree in number, order, and data type with their corresponding dummy arguments. Except for the data type, declarative information associated with an entity is not associated with dummy arguments in the statement function; for example, declaring an entity to be an array or to be in a common block does not affect a dummy argument with the same name.

The name of the statement function cannot be the same as the name of any other entity within the same program unit.

Any reference to a statement function must appear in the same program unit as the definition of that function.

A statement function reference must appear as (or be part of) an expression. The reference cannot appear on the left side of an assignment statement.

A statement function must not be provided as a procedure argument.

A statement function is PURE if the only functions it references are PURE and it does not reference a data object with the VOLATILE attribute.

**Example**

The following are examples of statement functions:

```fortran
REAL VOLUME, RADIUS
VOLUME(RADIUS) = 4.189*RADIUS**3

CHARACTER*10 CSF,A,B
CSF(A,B) = A(6:10)//B(1:5)
```

The following example shows a statement function and some references to it:

```fortran
AVG(A,B,C) = (A+B+C)/3.
...
GRADE = AVG(TEST1,TEST2,XLAB)
IF (AVG(P,D,Q) .LT. AVG(X,Y,Z)) STOP
FINAL = AVG(TEST3,TEST4,LAB2)    ! Invalid reference; implicit
...
...                               ! type of third argument does not
...                               ! match implicit type of dummy argument
```

Implicit typing problems can be avoided if all arguments are explicitly typed.

The following statement function definition is invalid because it contains a constant, which cannot be used as a dummy argument:

```fortran
REAL COMP, C, D, E
COMP(C,D,E,3.) = (C + D - E)/3.
```
The following shows another example:

```fortran
Add (a, b) = a + b
REAL(4) y, x(6)
  . . .
DO n = 2, 6
  x(n) = Add (y, x(n-1))
END DO
```

Argument Association
Use and Host Association

**STATIC**

*Statement and Attribute:* Controls the storage allocation of variables in subprograms (as does AUTOMATIC). Variables declared as STATIC and allocated in memory reside in the static storage area, rather than in the stack storage area.

**Syntax**

The STATIC attribute can be specified in a type declaration statement or a STATIC statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls], STATIC [, att-ls] :: v[, v] ...
```

**Statement:**

```
STATIC[::] v[, v] ...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `v` Is the name of a variable or an array specification. It can be of any type.

STATIC declarations only affect how data is allocated in storage.

If you want to retain definitions of variables upon reentry to subprograms, you must use the SAVE attribute.

By default, the compiler allocates local scalar variables of non-recursive subprograms in the static storage area. Local arrays, except for allocatable arrays, are in the static storage area by default.

The compiler may choose to allocate a variable in temporary (stack or register) storage if it notices that the variable is always defined before use. Appropriate use of the SAVE attribute can prevent compiler warnings if a variable is used before it is defined.

To change the default for variables, specify them as AUTOMATIC or specify RECURSIVE in one of the following ways:

- As a keyword in a FUNCTION or SUBROUTINE statement
- As a compiler option
- As an option in an OPTIONS statement

To override any compiler option that may affect variables, explicitly specify the variables as STATIC.
NOTE
Variables that are data-initialized, and variables in COMMON and SAVE statements are always static. This is regardless of whether a compiler option specifies recursion.

A variable cannot be specified as STATIC more than once in the same scoping unit.
If the variable is a pointer, STATIC applies only to the pointer itself, not to any associated target.
Some variables cannot be specified as STATIC. The following table shows these restrictions:

<table>
<thead>
<tr>
<th>Variable</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dummy argument</td>
<td>No</td>
</tr>
<tr>
<td>Automatic object</td>
<td>No</td>
</tr>
<tr>
<td>Common block item</td>
<td>Yes</td>
</tr>
<tr>
<td>Use-associated item</td>
<td>No</td>
</tr>
<tr>
<td>Function result</td>
<td>No</td>
</tr>
<tr>
<td>Component of a derived type</td>
<td>No</td>
</tr>
</tbody>
</table>

A variable can be specified with both the STATIC and SAVE attributes.
If a variable is in a module's outer scope, it can be specified as STATIC.

Example
The following example shows a type declaration statement specifying the STATIC attribute:

```fortran
INTEGER, STATIC :: ARRAY_A
```

The following example shows a STATIC statement:

```fortran
... CONTAINS
INTEGER FUNCTION REDO_FUNC
   INTEGER I, J(10), K
   REAL C, D, E(30)
   AUTOMATIC I, J, K(20)
   STATIC C, D, E
   ...
END FUNCTION
...
INTEGER N1, N2
N1 = -1
DO WHILE (N1)
   N2 = N1*2
   call sub1(N1, N2)
   read *, N1
END DO
CONTAINS
SUBROUTINE sub1 (iold, inew)
   INTEGER, intent(INOUT):: iold
   integer, STATIC ::N3
   integer, intent(IN) :: inew
   if (iold .eq. -1) then
      N3 = iold
   end if
```

STOP and ERROR STOP

Statements: The STOP statement initiates normal termination of an image before the execution of an END statement of the main program. The ERROR STOP statement initiates error termination.

Syntax

STOP [stop-code] [, QUIET = scalar-logical-exp]

ERROR STOP [stop-code] [, QUIET = scalar-logical-exp]

stop-code (Optional) A message. It can be any of the following:

• A scalar character expression of type default character
• A scalar default integer expression

An ERROR STOP statement can appear in a PURE procedure, a STOP statement cannot appear.

If QUIET= is not specified, or if scalar-logical-exp is false, the STOP or ERROR STOP statement does the following:

• If stop-code is specified, writes the specified message to the standard error device.
• Writes one or more of the following messages to the standard error device indicating which IEEE floating-point exceptions are signaling if assume fpe-summary is specified:

  IEEE_DIVIDE_BY_ZERO is signaling
  IEEE_INVALID is signaling
  IEEE_OVERFLOW is signaling
  IEEE_UNDERFLOW is signaling

• STOP initiates normal termination on the image that executes it. ERROR STOP initiates error termination.

  If stop-code is a character expression, STOP returns a status of zero and ERROR STOP returns a status of non-zero. If stop-code is an integer, a status equal to stop-code is returned for both STOP and ERROR_STOP.

  If stop-code is not specified, or if QUIET= is specified and scalar-logical-exp has the value .TRUE., the executing image initiates normal or error termination, and no message is printed; for STOP, a status of zero is returned; for ERROR STOP, a positive status value of 128 is returned.
When a program is running on multiple images, a STOP statement on one image does not affect the other images; they can continue to reference and define the coarrays located on the stopped image. An ERROR STOP initiates execution termination on all images, which may include flushing of I/O buffers, closing of I/O files, and reporting error status on one or more images.

**Effect on Windows* Systems**

In QuickWin programs, the following is displayed in a message box:

```
Program terminated with Exit Code stop-code
```

If the application has no console window, the stop-code is displayed in a message box.

**Effect on Linux* and macOS* Systems**

Operating system shells (such as bash, sh, csh, dash, etc.) work with a one byte exit status. So, when stop-code is an integer, only the lowest byte is significant. For example, consider the following statement:

```
STOP 99999
```

In this case, the program returns a status equal to 159 because integer 99999 = Z'1869F', and the lowest byte is equal to Z'9F', which equals 159.

**Example**

The following examples show valid STOP statements:

```
STOP 98
STOP 'END OF RUN', QUIET=(J.EQ.K)
DO
   READ *, X, Y
   IF (X > Y) STOP 5555
END DO
```

The following shows another example:

```
OPEN(1,FILE='file1.dat', status='OLD', ERR=100)
   ...
100 STOP 'ERROR DETECTED!'
END
```

`assume` compiler option

`EXIT` Program Termination

**STOPPED_IMAGES**

*Transformational Intrinsic Function (Generic):*

`STOPPED_IMAGES` returns an array of index images that have initiated normal termination.

**Syntax**

```
result = STOPPED_IMAGES ([team, kind])
```

(team (Input; optional) Must be a scalar of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV whose value represents the current or an ancestor team. If not present, the current team is assumed.)
kind (Input; optional) Must be a scalar integer expression with a value that is a valid INTEGER kind type parameter.

Results
The result is a rank-one integer array with the same type kind parameters as kind if present; otherwise, default integer. The size of the array is equal to the number of images in the specified team that have initiated normal termination.

The result array elements are the image index values of images on the specified team that have initiated normal termination. The indices are arranged in increasing numeric order.

Example
If image 5 and 12 of the current team have initiated normal termination, the result of STOPPED_IMAGES () is an array of default integer type with size 2 defined with the value [5, 12]. If no images in the current team are known to have failed, the result of STOPPED_IMAGES () is a zero-sized array.

FAILED_IMAGES
IMAGE_STATUS

STORAGE_SIZE
_Inquiry Intrinsic Function (Generic): Returns the storage size in bits._

Syntax
result = STORAGE_SIZE (a [, kind])

a (Input) Must be a scalar or array. It can be of any type. If it has any deferred type parameters it must not be an unallocated allocatable variable, or a disassociated, or undefined pointer.

kind (Input; optional) Must be a scalar integer constant expression.

Results
The result is a scalar of type integer. If kind is present, the kind parameter of the result is that specified by kind; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is the size expressed in bits for an element of an array that has the dynamic type and kind parameters of a.

If the type and kind parameters are such that storage association applies, the result is consistent with the named constants defined in the intrinsic module ISO_FORTRAN_ENV.

An array element may take more bits to store than a scalar, since any hardware-imposed alignment requirements for array elements may not apply to a scalar variable.

NOTE
The result is intended to be the size in memory that an object takes when it is stored. This size may differ from the size it takes during expression handling (which may be the native register size) or when stored in a file. If an object is never stored in memory but only in a register, this function returns the size it would take if it were stored in memory.
Example

STORAGE_SIZE (1.0) has the same value as the named constant NUMERIC_STORAGE_SIZE in the intrinsic module ISO_FORTRAN_ENV.

ISO_FORTRAN_ENV Module

STRICT and NOSTRICT

**General Compiler Directive:** STRICT disables language features not found in the language standard specified on the command line (Fortran 2018, Fortran 2008, Fortran 2003, Fortran 95, or Fortran 90). NOSTRICT (the default) enables these features.

Syntax

```
!DIR$ STRICT
!DIR$ NOSTRICT
```

If STRICT is specified and no language standard is specified on the command line, the default is to disable features not found in Fortran 2018.

The STRICT and NOSTRICT directives can appear only appear at the top of a program unit. A program unit is a main program, an external subroutine or function, a module, or a block data program unit. STRICT and NOSTRICT cannot appear between program units, or at the beginning of internal subprograms. They do not affect any modules invoked with the USE statement in the program unit that contains them.

Example

```
! NOSTRICT by default
TYPE stuff
  INTEGER(4) k
  INTEGER(4) m
  CHARACTER(4) name
END TYPE stuff
TYPE (stuff) examp
DOUBLE COMPLEX cd  ! non-standard data type, no error
cd = (3.0D0, 4.0D0)
examp.k = 4        ! non-standard component designation,
                  ! no error
END

SUBROUTINE STRICTDEMO( )
  !DIR$ STRICT
  TYPE stuff
    INTEGER(4) k
    INTEGER(4) m
    CHARACTER(4) name
  END TYPE stuff
  TYPE (stuff) samp
  DOUBLE COMPLEX cd  ! ERROR
cd = (3.0D0, 4.0D0)
samp.k = 4        ! ERROR
END SUBROUTINE
```

**STRUCTURE and END STRUCTURE**

**Statement:** Defines the field names, types of data within fields, and order and alignment of fields within a record structure. Fields and structures can be initialized, but records cannot be initialized.

**Syntax**

```fortran
STRUCTURE [/[structure-name/] [field-namelist]
  [field-declaration]
  [field-declaration]
  ...
  [field-declaration]
END STRUCTURE

structure-name
```

- Is the name used to identify a structure, enclosed by slashes.

- Subsequent RECORD statements use the structure name to refer to the structure. A structure name must be unique among structure names, but structures can share names with variables (scalar or array), record fields, PARAMETER constants, and common blocks.

- Structure declarations can be nested (contain one or more other structure declarations). A structure name is required for the structured declaration at the outermost level of nesting, and is optional for the other declarations nested in it. However, if you wish to reference a nested structure in a RECORD statement in your program, it must have a name.

- Structure, field, and record names are all local to the defining program unit. When records are passed as arguments, the fields in the defining structures within the calling and called subprograms must match in type, order, and dimension.

```fortran
field-namelist
```

- Is a list of fields having the structure of the associated structure declaration. A field namelist is allowed only in nested structure declarations.

```fortran
field-declaration
```

- Also called the declaration body. A `field-declaration` consists of any combination of the following:
  - Type declarations
    These are ordinary Fortran data type declarations.
  - Substructure declarations
    A field within a structure can be a substructure composed of atomic fields, other substructures, or a combination of both.
  - Union declarations
    A union declaration is composed of one or more mapped field declarations.
PARAMETER statements

PARAMETER statements can appear in a structure declaration, but cannot be given a data type within the declaration block.

Type declarations for PARAMETER names must precede the PARAMETER statement and be outside of a STRUCTURE declaration, as follows:

```
INTEGER*4 P
STRUCTURE /ABC/
  PARAMETER (P=4)
  REAL*4 F
END STRUCTURE
REAL*4 A(P)
```

The Standard Fortran derived type replaces STRUCTURE and RECORD constructs, and should be used in writing new code. See Derived Data Types.

Unlike type declaration statements, structure declarations do not create variables. Structured variables (records) are created when you use a RECORD statement containing the name of a previously declared structure. The RECORD statement can be considered as a kind of type declaration statement. The difference is that aggregate items, not single items, are being defined.

Within a structure declaration, the ordering of both the statements and the field names within the statements is important, because this ordering determines the order of the fields in records.

In a structure declaration, each field offset is the sum of the lengths of the previous fields, so the length of the structure is the sum of the lengths of its fields. The structure is packed; you must explicitly provide any alignment that is needed by including, for example, unnamed fields of the appropriate length.

By default, fields are aligned on natural boundaries; misaligned fields are padded as necessary. To avoid padding of records, you should lay out structures so that all fields are naturally aligned.

To pack fields on arbitrary byte boundaries, you must specify a compiler option. You can also specify alignment for fields by using the OPTIONS or PACK general directive.

A field name must not be the same as any intrinsic or user-defined operator (for example, EQ cannot be used as a field name).

Example

An item can be a RECORD statement that references a previously defined structure type:

```
STRUCTURE /full_address/
  RECORD /full_name/ personsname
  RECORD /address/   ship_to
  INTEGER*1           age
  INTEGER*4           phone
END STRUCTURE
```

You can specify a particular item by listing the sequence of items required to reach it, separated by a period (.). Suppose you declare a structure variable, `shippingaddress`, using the `full_address` structure defined in the previous example:

```
RECORD /full_address/ shippingaddress
```

In this case, the `age` item would then be specified by `shippingaddress.age`, the first name of the receiver by `shippingaddress.personsname.first_name`, and so on.
In the following example, the declaration defines a structure named `APPOINTMENT`. `APPOINTMENT` contains the structure `DATE` (field `APP_DATE`) as a substructure. It also contains a substructure named `TIME` (field `APP_TIME`, an array), a `CHARACTER*20` array named `APP_MEMO`, and a `LOGICAL*1` field named `APP_FLAG`.

```
STRUCTURE /DATE/
  INTEGER*1 DAY, MONTH
  INTEGER*2 YEAR
END STRUCTURE

STRUCTURE /APPOINTMENT/
  RECORD /DATE/    APP_DATE
  STRUCTURE /TIME/ APP_TIME (2)
    INTEGER*1 HOUR, MINUTE
  END STRUCTURE
  CHARACTER*20 APP_MEMO (4)
  LOGICAL*1 APP_FLAG
END STRUCTURE
```

The length of any instance of structure `APPOINTMENT` is 89 bytes.
The following figure shows the memory mapping of any record or record array element with the structure APPOINTMENT.

**Memory Map of Structure APPOINTMENT**

<table>
<thead>
<tr>
<th>Byte offset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

Record Structures

**SUBDEVICE**

**Parallel Directive Clause:** Specifies which tiles or compute slices (c-slices) of the offload device the offloaded code will run on. This feature is only available for ifx.

**Syntax**

```plaintext
SUBDEVICE ( [level,] start [:length [:stride]])
```

- **level**
  - Is a non-negative integer constant. If *level* is not specified, the value 0 is used.
- **start**
  - Is a non-negative integer expression.
- **length**
  - Is a positive integer expression. If *length* is not specified, the value 1 is used.
- **stride**
  - Is a positive integer expression. If *stride* is not specified, the value 1 is used.

The SUBDEVICE clause specifies which sub-devices the offloaded code is to execute on. A GPU device may be made up of multiple tiles, and each tile may be made up of multiple compute slices (also called c-slices).

Specifying level 0 selects tiles, specifying level 1 selects c-slices. The tiles and c-slices are numbered 0 to \( n \).

start, length, and stride act like an array section subscript to select the indices of the tiles or c-slices the offloaded code will execute on.

At most one SUBDEVICE clause can appear in a directive that allows the clause.

**Example**

- subdevice (0, 2:5) runs on tiles 2, 3, 4, and 5.
- subdevice (1, 2:6:2) runs on compute slices 2, 4 and 6.

**SUBMODULE**

**Statement:** Marks the beginning of a submodule program unit, which contains specifications and definitions that can be used by one or more program units.

**Syntax**

```plaintext
SUBMODULE (ancestor-module-name [:parent-submodule-name]) name
    [specification-part]
    [module-subprogram
     [module-subprogram]...]
END [SUBMODULE [name]]
```

- **ancestor-module-name**
  - Must be the name of a nonintrinsic module. It is the name of the module at the root of the module or submodule tree.
- **parent-submodule-name**
  - (Optional) Is the name of the parent submodule, if any. The parent submodule must be a descendant of *ancestor-module-name*. 

Language Reference

1917
name

**specification-part**

Is the name of the submodule.

Is one or more specification statements, except for the following:

- ENTRY
- FORMAT
- **AUTOMATIC** (or its equivalent attribute)
- INTENT (or its equivalent attribute)
- OPTIONAL (or its equivalent attribute)
- Statement functions

An automatic object must not appear in a specification statement.

**module-subprogram**

Is a function or subroutine subprogram that defines the **module procedure**. A function must end with **END FUNCTION** and a subroutine must end with **END SUBROUTINE**.

A module subprogram can contain internal procedures.

**Description**

If a name follows the END statement, it must be the same as the name specified in the **SUBMODULE** statement.

Each submodule has exactly one ancestor module and exactly one parent module or submodule. If the parent is a module then it must be the ancestor module. The relationship is tree-like, with the parent module or submodule at the root of the tree, and its descendant submodules as the branches of the tree.

A module or submodule may have one or more descendent submodules.

A submodule can access the entities from its parent module or submodule by host association. Unlike a module, a submodule cannot be referenced in other program units by use association. Entities declared in a submodule are only accessible from the submodule and its descendent submodules. Furthermore, a module procedure can have its interface declared in a module or submodule and its implementation contained in a descendent submodule in a separate file.

Submodules help the modularization of a large module in several ways:

- Internal data can be shared among submodules without being exposed to users of the module. Without the submodule feature, when a large module is split into smaller modules, internal data may be forced to become public in order to be shared among the modules.
- Even if a module procedure implementation in a submodule is changed, as long as the module procedure interface declared in the ancestor module remains the same, a recompilation would not be needed for the user of the module. This could reduce the rebuilding time for a complex system.
- Separate concepts with circular dependencies can now be implemented in different submodules. It cannot be done with just modules.

A submodule is uniquely identified by a _submodule identifier_ which consists of its _ancestor-module-name_ and the name of the submodule. The name of a submodule can therefore be the same as the name of another submodule so long as they do not have the same ancestor module.

The following rules also apply to submodules:

- The specification part of a submodule must not contain IMPORT, ENTRY, FORMAT, executable, or statement function statements.
- A variable, common block, or procedure pointer declared in a submodule implicitly has the SAVE attribute, which may be confirmed by explicit specification.
- If a specification or constant expression in the **specification-part** of a submodule includes a reference to a generic entity, there must be no specific procedures of the generic entity defined in the submodule subsequent to the specification or constant expression.

Unlike a module, the specification part of a submodule must not contain PUBLIC and PRIVATE specifications.
Any executable statements in a module or submodule can only be specified in a module or submodule subprogram.

A submodule can contain one or more procedure interface blocks, which let you specify an explicit interface for an external subprogram or dummy subprogram.

**Example**

Consider the following example of a multilevel submodule system:

<table>
<thead>
<tr>
<th>Module M</th>
<th>Submodule B</th>
<th>Submodule C</th>
</tr>
</thead>
<tbody>
<tr>
<td>Submodule A</td>
<td>Submodule Y</td>
<td>Submodule Z</td>
</tr>
<tr>
<td>Submodule X</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In the above example, module M is extended by submodules up to two levels. Module M is the ancestor module of all the submodules. Entities declared in module M can be shared among all the submodules. A is the parent submodule of X, Y, and Z. Entities declared in submodule A can be shared among submodules X, Y, and Z, but not by B or C.

Only public entities declared in M can be available to other program units by use association.

The SUBMODULE declarations for A and X are:

```fortran
SUBMODULE (M) A
...
END SUBMODULE A

SUBMODULE (M : A) X
...
END SUBMODULE X
```

The following example shows modules and submodules, separate module procedures, and how circular dependency can be avoided with submodules. There are five parts in the example:

1. module color_points
2. level-1 submodule color_points_a
3. level-2 submodule color_points_b
4. module palette_stuff
5. program main

```fortran
! part 1
module color_points  ! This is the ancestor module
type color_point
private
  real :: x, y
  integer :: color
end type color_point

! Below is the interface declaration of the separate module procedures.
! No IMPORT statement is used in the interface bodies.
! The separate module procedures are implemented in the two submodules.
interface
  module subroutine color_point_del ( p )
    type(color_point), allocatable :: p
  end subroutine color_point_del

  real module function color_point_dist ( a, b )
    type(color_point), intent(in) :: a, b
```
module subroutine color_point_draw ( p )
type(color_point), intent(in) :: p
end subroutine color_point_draw

module subroutine color_point_new ( p )
type(color_point), allocatable :: p
end subroutine color_point_new
end interface
end module color_points

! part 2
submodule ( color_points ) color_points_a  ! submodule of color_points
integer :: instance_count = 0

! Below is the interface declaration of the separate module procedure
! inquire_palette, which is implemented in the submodule color_points_b.
interface
module subroutine inquire_palette ( pt, pal )
use palette_stuff
! Later you will see that module palette_stuff uses color_points.
! This use of palette_stuff however does not cause a circular
! dependence because this use is not in the module.
type(color_point), intent(in) :: pt
type(palette), intent(out) :: pal
end subroutine inquire_palette
end interface
contains
! Here are the implementations of three of the four separate module
! procedures declared in module color_point.
module subroutine color_point_del ( p )
type(color_point), allocatable :: p
instance_count = instance_count - 1
deallocate ( p )
end subroutine color_point_del

real module function color_point_dist ( a, b ) result ( dist )
type(color_point), intent(in) :: a, b
dist = sqrt( (b%x - a%x)**2 + (b%y - a%y)**2 )
end function color_point_dist

module subroutine color_point_new ( p )
type(color_point), allocatable :: p
instance_count = instance_count + 1
allocate ( p )
end subroutine color_point_new
end submodule color_points_a

! part 3
submodule ( color_points:color_points_a ) color_points_b  ! submodule of color_point_a
contains
! Implementation of a module procedure declared in the ancestor module
module subroutine color_point_draw ( p )
    use palette_stuff, only: palette
    type(color_point), intent(in) :: p
    type(palette) :: MyPalette

SUBROUTINE
References to Generic Procedures

SUBROUTINE
Statement: The initial statement of a subroutine subprogram. A subroutine subprogram is invoked in a CALL statement or by a defined assignment or operator, and does not return a particular value.

Syntax

[prefix [prefix]] SUBROUTINE name [([d-arg-list]) [lang-binding]]

   [specification-part]
   [execution-part]

[CONTAINS
   [internal-subprogram-part] ]
END [SUBROUTINE [name]]

prefix

(Optional) Is any of the following:

- **ELEMENTAL**
  Acts on one array element at a time. This is a restricted form of pure procedure.
- **IMPURE**
  Asserts that the procedure has side effects.
- **MODULE**
  Indicates a separate module procedure. See separate module procedures.
- **NON_RECURSIVE**
  Indicates a procedure is not recursive.
- **PURE**
  Asserts that the procedure has no side effects.
- **RECURSIVE**
  Permits direct or indirect recursion to occur.

At most one of each of the above can be specified. You cannot specify both NON_RECURSIVE and RECURSIVE. You cannot specify both PURE and IMPURE. You cannot specify ELEMENTAL if lang-binding is specified.
name

Is the name of the subroutine.

d-arg-list

(Optional) Is a list of one or more dummy arguments or alternate return specifiers (*).

lang-binding

(Optional) Takes the following form:

\[
\text{BIND} \left( C \left[ , \text{NAME}=\text{ext-name} \right] \right)
\]

ext-name

Is a character scalar constant expression that can be used to construct the external name.

specification-part

Is one or more specification statements.

execution-part

Is one or more executable constructs or statements.

internal-subprogram-part

Is one or more internal subprograms (defining internal procedures). The internal-subprogram-part is preceded by a CONTAINS statement.

**Description**

A subroutine is invoked by a CALL statement or defined assignment. When a subroutine is invoked, dummy arguments (if present) become associated with the corresponding actual arguments specified in the call.

Execution begins with the first executable construct or statement following the SUBROUTINE statement. Control returns to the calling program unit once the END statement (or a RETURN statement) is executed.

A subroutine subprogram cannot contain a BLOCK DATA statement, a PROGRAM statement, a MODULE statement, or a SUBMODULE statement. A subroutine can contain SUBROUTINE and FUNCTION statements to define internal procedures. ENTRY statements can be included to provide multiple entry points to the subprogram.

You need an interface block for a subroutine when:

- Calling arguments use argument keywords.
- Some arguments are optional.
- A dummy argument is an assumed-shape array, a pointer, or a target.
- The subroutine extends intrinsic assignment.
- The subroutine can be referenced by a generic name.
- The subroutine is in a dynamic-link library.

If the subroutine is in a DLL and is called from your program, use the option DLLEXPORT or DLLIMPORT, which you can specify with the ATTRIBUTES directive.

Note that if you specify lang-binding, you have to use the parentheses even if there are no arguments. For example, without lang-binding you can specify SUBROUTINE F but with lang-binding you have to specify SUBROUTINE F( ) BIND (C).

**Example**

The following example shows a subroutine:

```plaintext
Main Program Subroutine
CALL HELLO_WORLD SUBROUTINE HELLO_WORLD
... PRINT *, "Hello World"
END END SUBROUTINE
```
The following example uses alternate return specifiers to determine where control transfers on completion of the subroutine:

```
Main Program Subroutine
CALL CHECK(A,B,*10,*20,C)             SUBROUTINE CHECK(X,Y,*,*,Q)
TYPE *, 'VALUE LESS THAN ZERO'        ...
GO TO 30                          50  IF (Z)  60,70,80
10  TYPE*, 'VALUE EQUALS ZERO'        60  RETURN
GO TO 30                          70  RETURN 1
20  TYPE*, 'VALUE MORE THAN ZERO'     80  RETURN 2
30  CONTINUE                              END
...
```

The SUBROUTINE statement argument list contains two dummy alternate return arguments corresponding to the actual arguments *10 and *20 in the CALL statement argument list.

The value of Z determines the return, as follows:

- If Z < zero, a normal return occurs and control is transferred to the first executable statement following CALL CHECK in the main program.
- If Z = = zero, the return is to statement label 10 in the main program.
- If Z > zero, the return is to statement label 20 in the main program.

Note that an alternate return is an obsolescent feature in the Fortran Standard.

The following shows another example:

```
SUBROUTINE GetNum (num, unit)  
INTEGER num, unit  
10 READ (unit, '(I10)', ERR = 10) num  
END
...
```

**SUM**

*Transformational Intrinsic Function (Generic):*

Returns the sum of all the elements in an entire array or in a specified dimension of an array.

**Syntax**

```
result = SUM (array [, mask])
result = SUM (array, dim [, mask])
```

*array* (Input) Must be an array of type integer, real, or complex.
**Results**

The result is an array or a scalar of the same data type as `array`.

The result is a scalar if `dim` is not specified or `array` has rank one.

The following rules apply if `dim` is not specified:

- If `SUM( array )` is specified, the result is the sum of all elements of `array`. If `array` has size zero, the result is zero.
- If `SUM( array, MASK= mask )` is specified, the result is the sum of all elements of `array` corresponding to true elements of `mask`. If `array` has size zero, or every element of `mask` has the value .FALSE., the result is zero.

The following rules apply if `dim` is specified:

- If `array` has rank one, the value is the same as `SUM( array[,MASK= mask] )`.
- An array result has a rank that is one less than `array`, and shape `(d_1, d_2, ..., d_dim-1, d_dim+1, ..., d_n)`, where `(d_1, d_2, ..., d_n)` is the shape of `array`.
- The value of element `(s_1, s_2, ..., s_dim-1, s_dim+1, ..., s_n)` of `SUM( array, dim[, mask] )` is equal to `SUM( array(s_1, s_2, ..., s_dim-1, :, s_dim+1, ..., s_n) [,MASK = mask(s_1, s_2, ..., s_dim-1, :, s_dim+1, ..., s_n)] )`.

**Example**

`SUM ((/2, 3, 4/))` returns the value 9 (sum of 2 + 3 + 4). `SUM ((/2, 3, 4/), DIM=1)` returns the same result.

`SUM (B, MASK=B .LT. 0.0)` returns the arithmetic sum of the negative elements of B.

C is the array

```
[ 1 2 3 ]
[ 4 5 6 ].
```

`SUM (C, DIM=1)` returns the value (5, 7, 9), which is the sum of all elements in each column. 5 is the sum of 1 + 4 in column 1. 7 is the sum of 2 + 5 in column 2, and so forth.

`SUM (C, DIM=2)` returns the value (6, 15), which is the sum of all elements in each row. 6 is the sum of 1 + 2 + 3 in row 1. 15 is the sum of 4 + 5 + 6 in row 2.

The following shows another example:

```
INTEGER array (2, 3), i, j(3)
array = RESHAPE((/1, 2, 3, 4, 5, 6/), (/2, 3/))
! array is  1 3 5
!          2 4 6
i = SUM((/ 1, 2, 3 /)) ! returns 6
j = SUM(array, DIM = 1) ! returns [3 7 11]
WRITE(*,*) i, j
END
```

PRODUCT

**SYNC ALL**

*Statement:* Performs a synchronization of all images on the current team.
Syntax
The SYNC ALL statement takes the following form:

\[
\text{SYNC ALL}([\text{STAT}=\text{stat-var}], [\text{ERRMSG}=\text{err-var}])
\]

\text{stat-var} \quad \text{Is a scalar integer variable in which the status of the synchronization is stored.}

\text{err-var} \quad \text{Is a scalar default character variable in which an error condition is stored if such a condition occurs.}

\text{STAT=} \text{ and } \text{ERRMSG=} \text{ can appear in either order, but only once in a SYNC ALL statement.}

Description
Execution on an image, for example, C, of the segment following the SYNC ALL statement is delayed until each other image has executed a SYNC ALL statement as many times as has image C.

The segments that executed before the SYNC ALL statement on an image, precede the segments that execute after the SYNC ALL statement on another image.

Example
In the following example, image 5 reads data and transmits the data to other images:

\begin{verbatim}
REAL :: W[*]
SYNC ALL
IF (THIS_IMAGE()==5) THEN
   READ (*,*) W
   DO I = 6, NUM_IMAGES()
      W[I] = W
   END DO
END IF
...
SYNC ALL
\end{verbatim}

Coarrays
Using Coarrays

SYNC IMAGES

**Statement:** Performs a synchronization of the image with each of the other images in the image set.

Syntax
The SYNC IMAGES statement takes the following form:

\[
\text{SYNC IMAGES} \ (\text{image-set}[, \text{STAT}=\text{stat-var}[[, \text{ERRMSG}=\text{err-var}])}
\]

\text{image-set} \quad \text{Is an integer expression or *. If it is an integer expression, it must be scalar or of rank one. If it is an array expression, the value of each element must be positive and not greater than the number of images; there must be no repeated values. If it is a scalar expression, the value must be positive and not greater than the number of images.}
If * is specified, it indicates all images.

stat-var

Is a scalar integer variable in which the status of the synchronization is stored.

err-var

Is a scalar default character variable in which an error condition is stored if such a condition occurs.

STAT= and ERRMSG= can appear in either order, but only once in a SYNC IMAGES statement.

Description

When SYNC IMAGES statements are executed on images C and G, they correspond if the number of times image C has executed a SYNC IMAGES statement in the current team with G in its image set is the same as the number of times image G has executed a SYNC IMAGES statement with C in its image set in this team. The segments that executed before the SYNC IMAGES statement on either image, precede the segments that execute after the corresponding SYNC IMAGES statement on the other image.

In a program that uses SYNC ALL as its only synchronization mechanism, every SYNC ALL statement can be replaced by a SYNC IMAGES (*) statement. However, SYNC ALL may provide better performance. SYNC IMAGES statements are not required to specify the entire image set, or even the same image set, on all images that participate in the synchronization.

Example

In the following example, image 5 waits for each of the other images to complete using the data. The other images wait for image 5 to set up the data, but do not wait for any other image:

```fortran
IF (THIS_IMAGE() == 5) then
    SYNC IMAGES(*)       ! Sets up coarray data for other images
ELSE
    SYNC IMAGES(5)       ! Other images use the data set up by image 5
END IF
```

In the following example, each image synchronizes with its neighbor:

```fortran
INTEGER :: THIS_STEP, TOTAL_STEPS, TOTAL_IMAGES, MY_IMAGE
MY_IMAGE = THIS_IMAGE()
TOTAL_IMAGES = NUM_IMAGES()
    ! Set up calculation
SYNC ALL
DO THIS_STEP = 1, TOTAL_STEPS
    IF (MY_IMAGE > 1) SYNC IMAGES (MY_IMAGE - 1)     ! Do the calculations
    IF (MY_IMAGE < TOTAL_IMAGES) SYNC IMAGES (MY_IMAGE + 1)
END DO
SYNC ALL
```

The calculation starts on image 1 since all the others will be waiting on SYNC IMAGES (TOTAL_IMAGES-1). When this is done, image 2 starts and image 1 performs its second calculation. This continues until they are all executing different steps at the same time. Eventually, image 1 finishes and then the others finish one by one.

Image Control Statements
Coarrays
Using Coarrays
SYNC MEMORY

**Statement:** Ends one image segment and begins another. Each segment can then be ordered in some way with respect to segments on other images.

**Syntax**

The SYNC MEMORY statement takes the following form:

```
SYNC MEMORY [(STAT=stat-var[, ERRMSG=err-var])]
```

- **stat-var** Is a scalar integer variable in which the status of the synchronization is stored.
- **err-var** Is a scalar default character variable in which an error condition is stored if such a condition occurs.

**Description**

Unlike the other image control statements, this statement does not have any built-in synchronization effect.

The action regarding X on image Q precedes the action regarding Y on image Q if, by execution of statements on image P, the following is true:

- A variable X on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement
- That statement precedes a successful execution of a SYNC MEMORY statement
- A variable Y on image Q is defined, referenced, becomes undefined, or has its allocation status, pointer association status, array bounds, dynamic type, or type parameters changed or inquired about by execution of a statement that succeeds execution of that SYNC MEMORY statement,

User-defined ordering of segment Pi on image P to precede segment Qj on image Q occurs when the following happens:

- Image P executes an image control statement that ends segment Pi, and then executes statements that initiate a cooperative synchronization between images P and Q
- Image Q executes statements that complete the cooperative synchronization between images P and Q and then executes an image control statement that begins segment Qj

Execution of the cooperative synchronization between images P and Q must include a dependency that forces execution on image P of the statements that initiate the synchronization to precede the execution on image Q of the statements that complete the synchronization. The mechanisms available for creating such a dependency are processor dependent.

**NOTE**

SYNC MEMORY usually suppresses compiler optimizations that may reorder memory operations across the segment boundary defined by the SYNC MEMORY statement. It ensures that all memory operations initiated in the preceding segments in its image complete before any memory operations in the subsequent segment in its image are started.
Example

The following example should be run on two images:

```fortran
use, intrinsic :: iso_fortran_env
logical (atomic_logical_kind), save :: locked[*] = .true.
logical val
integer :: iam

iam = this_image()
if (iam == 1) then
    sync memory
    call atomic_define(locked[2], .false.)
else if (iam == 2) then
    val = .true.
    do while (val)
        call atomic_ref(val, locked)
    end do
    sync memory
end if
print *, 'success'
end
```

Coarrays
Using Coarrays

SYNC TEAM

**Statement:** Performs a synchronization of all images on the specified team.

**Syntax**

The SYNC TEAM statement takes the following form:

```
SYNC TEAM(team-value [, STAT = stat-var] [, ERRMSG = err-var])
```

- **team-value**: Identifies the team to synchronize.
- **stat-var**: (Optional) Is a scalar integer variable in which the status of the synchronization is stored.
- **err-var**: (Optional) Is a scalar default character variable in which an error condition is stored if such a condition exists.

**Description**

A SYNC TEAM statement performs a synchronization of all images on the specified team. The team specified must be the current team or an ancestor team, or a team whose parent is the current team. The executing image must be a member of the specified team.

Execution of the segment following the SYNC TEAM statement is delayed on all images of the specified team until all images of the specified team have executed the same SYNC TEAM statement the same number of times.
A SYNC TEAM statement synchronizes a specific team, while a SYNC ALL statement synchronizes the current team.

**Example**

In the following example, two teams are created by the FORM TEAM statement. Team number 1 consists of the odd numbered images of the initial team; team number 2 consists of the even numbered images of the initial team.

The SYNC TEAM statement when executed by an odd numbered image on the initial team prevents all other odd numbered images of the initial team from proceeding to segment 2 until all odd images of the initial team have executed the SYNC TEAM statement. Similarly, all even numbered images of the initial team are prevented from executing segment 2 until all the even numbered images on the initial team have executed the SYNC TEAM statement.

Using a SYNC ALL statement would prevent all images of the initial team from executing segment 2 until all images had executed the SYNC ALL statement.

```fortran
PROGRAM MAIN
  USE ISO_FORTRAN_ENV
  TYPE (TEAM_TYPE) odd_even
  FORM TEAM (2-MOD (THIS_IMAGE(), 2), odd_even)
    ! Segment 1
    SYNC TEAM (odd_even)
    ! Segment 2
END PROGRAM
```

Image Control Statements
Coarrays
Using Coarrays

**SYSTEM**

*Portability Function: Sends a command to the shell as if it had been typed at the command line.*

**Module**

USE IFPORT

**Syntax**

```
result = SYSTEM (string)
```

*string* (Input) Character*(*) . Operating system command.

**Results**

The result type is INTEGER(4). The result is the exit status of the shell command. If -1, use IERRNO to retrieve the error. Errors can be one of the following:

- **E2BIG:** The argument list is too long.
- **ENOENT:** The command interpreter cannot be found.
- **ENOEXEC:** The command interpreter file has an invalid format and is not executable.
- **ENOMEM:** Not enough system resources are available to execute the command.

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.
Commands run with the SYSTEM routine are run in a separate shell. Defaults set with the SYSTEM function, such as current working directory or environment variables, do not affect the environment the calling program runs in.

The command line character limit for the SYSTEM function is the same limit that your operating system command interpreter accepts.

Example

```fortran
USE IFPORT
INTEGER(4) I, errnum
I = SYSTEM("dir > file.lst")
If (I .eq. -1) then
    errnum = ierrno()
    print *, 'Error ', errnum
end if
END
```

See Also
SYSTEMQQ

SYSTEM_CLOCK

**Intrinsic Subroutine:** Returns data from a real-time clock. SYSTEM_CLOCK returns the number of seconds from 00:00 Coordinated Universal Time (CUT) on 1 JAN 1970. The number is returned with no bias. To get the elapsed time, you must call SYSTEM_CLOCK twice, and subtract the starting time value from the ending time value.

Syntax

```
CALL SYSTEM_CLOCK ([count] [, count_rate] [, count_max])
```

**count**

(Output; optional) Must be scalar and of type integer with a kind type parameter greater than 1. It is set to a value based on the current value of the processor clock. The value is increased by one for each clock count until the value count_max is reached, and is reset to zero at the next count. count lies in the range 0 to count_max.

**count_rate**

(Output; optional) Must be scalar and of type integer or real. It is set to the number of processor clock counts per second.

If the type is INTEGER(1), count_rate is 0. If the type is INTEGER(2), count_rate is 1000. If the type is INTEGER(4) or REAL(4), count_rate is 10000. If the type is INTEGER(8), REAL(8), or REAL(16), count_rate is 1000000.

If the count argument is also supplied, the value returned for count_rate is determined by the integer kind of count, not count_rate.

**count_max**

(Output; optional) Must be scalar and of type integer. It is set to the value HUGE(INT(0,KIND(count))).

If the type of count_rate or count_max is INTEGER(1), count_rate and count_max are zero, indicating that there is no clock available to Intel® Fortran with an 8-bit range. If count is INTEGER(1), a compile time message is issued indicating that the kind type is too small.

The values of count_rate and count_max are valid only for calls to SYSTEM_CLOCK where count is the same-sized integer (or INTEGER(8) for the case where count_rate is REAL(16)).
Example

Consider the following:

```fortran
integer(2) :: ic2, crate2, cmax2
integer(4) :: ic4, crate4, cmax4
call system_clock(count=ic2, count_rate=crate2, count_max=cmax2)
call system_clock(count=ic4, count_rate=crate4, count_max=cmax4)
print *, ic2, crate2, cmax2
print *, ic4, crate4, cmax4
end
```

This program was run on Thursday Dec 11, 1997 at 14:23:55 EST and produced the following output:

```
13880   1000  32767
1129498807       10000  2147483647
```

DATE_AND_TIME
HUGE
GETTIM

SYSTEMQQ

**Portability Function:** Executes a system command by passing a command string to the operating system's command interpreter.

**Module**

USE IFPORT

**Syntax**

```fortran
result = SYSTEMQQ (commandline)
```

*commandline* (Input) Character*(*).. Command to be passed to the operating system.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The SYSTEMQQ function lets you pass operating-system commands as well as programs. SYSTEMQQ refers to the COMSPEC and PATH environment variables that locate the command interpreter file (usually named COMMAND.COM).

On Windows* systems, the calling process waits until the command terminates. To insure compatibility and consistent behavior, an image can be invoked directly by using the Windows API CreateProcess( ) in your Fortran code.

If the function fails, call GETLASTERRORQQ to determine the reason. One of the following errors can be returned:

- ERR$2BIG - The argument list exceeds 128 bytes, or the space required for the environment formation exceeds 32K.
- ERR$NOINT - The command interpreter cannot be found.
- ERR$NOEXEC - The command interpreter file has an invalid format and is not executable.
- ERR$NOMEM - Not enough memory is available to execute the command; or the available memory has been corrupted; or an invalid block exists, indicating that the process making the call was not allocated properly.
The command line character limit for the SYSTEMQQ function is the same limit that your operating system command interpreter accepts.

Example

```fortran
USE IFPORT
LOGICAL(4) result
result = SYSTEMQQ('copy c:\bin\fmath.dat & c:\dat\fmath2.dat')
```

T to Z

TAN

*Elemental Intrinsic Function (Generic):* Produces the tangent of an argument.

**Syntax**

```fortran
result = TAN (x)
```

**x** (Input) Must be of type real or complex. If `x` is of type real, it must be in radians and is treated as modulo.

**Results**

The result type and kind are the same as `x`.

If `x` is of type real, the result is a value in radians.

If `x` is of type complex, the real part of the result is a value in radians.

<table>
<thead>
<tr>
<th>Specific Name</th>
<th>Argument Type</th>
<th>Result Type</th>

</tr>
<tr>
<td>CQTAN</td>
<td>COMPLEX(16)</td>
<td>COMPLEX(16)</td>
</tr>
</tbody>
</table>

1The setting of compiler options specifying real size can affect CTAN.

2This function can also be specified as ZTAN.

**Example**

TAN (2.0) has the value -2.185040.
TAN (0.8) has the value 1.029639.

**TAND**

*Elemental Intrinsic Function (Generic): Produces the tangent of an argument.*

**Syntax**

\[ \text{result} = \text{TAND} \left( x \right) \]

\( x \) (Input) Must be of type real. It must be in degrees and is treated as modulo 360.

**Results**

The result type and kind are the same as \( x \).

<table>
<thead>
<tr>

<tr>
<td>QTANH</td>
<td>REAL(16)</td>
<td>REAL(16)</td>
</tr>
</tbody>
</table>

**Example**

TANH (2.0) has the value 0.9640276.
TANH (0.8) has the value 0.6640368.
TARGET

OpenMP Fortran Compiler Directive: Creates a device data environment and executes the construct on that device. This feature is only available for ifx.

Syntax

```fortran
!$OMP TARGET [clause[, clause]]... ]
   loosely-structured-block
!$OMP END TARGET
-or-
!$OMP TARGET [clause[, clause]]... ]
   strictly-structured-block
!$OMP END TARGET
```

clause

Is one or more of the following:

- **ALLOCATE ([allocator :] list)**
- **DEFAULTMAP (implicit-behavior:SCALAR)**

Causes a scalar variable to be treated as if it appeared in a MAP clause with the map-type specified by implicit-behavior.

- **DEPEND (dependence-type : list)**
- **DEVICE (integer-expression)**
- **FIRSTPRIVATE (list)**
- **HAS_DEVICE_ADDR (list)**

Specifies variables that have device addresses and can be directly accessed by the target device. Each list item must have valid device address for the device data environment. You can specify an array section as a list item.
If you access a list item whose device address is on a device other than the device that executes the TARGET construct, it causes undefined behavior.

A list item that appears in a HAS_DEVICE_ADDR clause cannot also appear in an IS_DEVICE_PTR clause in the same TARGET directive.

- IF ([TARGET:] scalar-logical-expression)
- IN_REDUCTION (reduction-identifier : list)
- IS_DEVICE_PTR (list)
- MAP ([[map-type-modifier[,] map-type:] list)
- NOWAIT
- PRIVATE (list)
- SUBDEVICE ([integer-constant ,] integer-expression [ : integer-expression ] )

loosely-structured-block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding task for a TARGET construct is the encountering task. The target region binds to the enclosing parallel or task region.

This construct provides a superset of the functionality provided by the TARGET DATA construct, except for the clauses USE_DEVICE_PTR and USE_DEVICE_ADDR.

A list item in an IS_DEVICE_PTR clause that has a type other than C_PTR is the same as if it was a list item in a HAS_DEVICE_ADDR clause. List items specified in a ISDEVICE_PTR or HAS_DEVICE_ADDR clause cannot appear in a data sharing attribute clause in the same TARGET directive. Note that the OpenMP* Specification has deprecated non-C_PTR type list items in an IS_DEVICE_PTR clause.

The TARGET construct also specifies that the region is executed by a device. The encountering task waits for the device to complete the target region at the end of the construct.

If a TARGET, TARGET DATA, or TARGET UPDATE construct appears within an OMP TARGET region, the construct is ignored.

Execution of the target task may be deferred if the NOWAIT clause is specified; if it is not specified, the target task is an included task.

If a variable or part of a variable does not appear in an IN_REDUCTION clause and is mapped by the TARGET construct, the variable's default data-sharing attribute is shared in the data environment of the target task.

A variable that appears as a list item in an IN_REDUCTION clause is implicitly mapped as if it appears in a MAP clause with a map-type of TOFROM, and a map-type-modifier of ALWAYS.

A variable that is fully or partially mapped by the TARGET construct and that is not a list item in an IN_REDUCTION clause within the construct has a default data-sharing attribute of SHARED in the target tasks data environment.

If a variable appears in a REDUCTION or LASTPRIVATE clause in a combined TARGET construct, it is treated as if it had appeared in a MAP clause with a map-type of TOFROM for REDUCTION and a map-type of FROM for LASTPRIVATE:

```
! SUM is treated as MAP (TOFROM)
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO REDUCTION(+:SUM)

! X is treated as MAP (FROM)
!$OMP TARGET TEAMS DISTRIBUTE PARALLEL DO LASTPRIVATE(X)
```
A non-scalar variable referenced in a TARGET region and not explicitly mapped is implicitly treated as MAP (TOFROM):

```
INTEGER A(10)
!$OMP TARGET
  A(5) = 5          ! A is treated as MAP (TOFROM)
!$OMP END TARGET
```

If only a subsection of a non-scalar variable has been mapped in an outer target region, and that variable is then mapped implicitly inside a nested target region, that variable should not access memory outside of the mapped subsection of the variable.

**TARGET DATA**

*OpenMP* Fortran Compiler Directive: Maps variables to a device data environment for the extent of the region. This feature is only available for ifx.

**Syntax**

```
!$OMP TARGET DATA [clause[[], clause]...] 
  loosely-structured-block
!$OMP END TARGET DATA
-or-
!$OMP TARGET DATA [clause[[], clause]...] 
  strictly-structured-block
!$OMP END TARGET DATA
```

**clause**

Is one or more of the following:

- DEVICE (integer-expression)
- IF ([TARGET DATA:] scalar-logical-expression)
- MAP ([[map-type-modifier[,] map-type:] list])
- SUBDEVICE ([integer-constant [,] integer-expression [: integer-expression :] integer-expression])
- USE_DEVICE_ADDR (list)
- USE_DEVICE_PTR (ptr-list)

At most one DEVICE clause and one IF clause can appear for the construct.

At least one USE_DEVICE_PTR, USE_DEVICE_ADDR, or MAP clause must appear for the construct.

The map-type in a MAP clause must be TO, FROM, TOFROM, or ALLOC.
loosely-structured-block is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The binding task region for a TARGET DATA construct is the encountering task. The target region binds to the enclosing parallel or task region.

When a TARGET DATA construct is encountered, a new device data environment is created, and the encountering task executes the target data region.

Occurrences of a list item appearing in a USE_DEVICE_ADDR clause in the structured block of the construct are references to the device address of the item if the item has corresponding storage in the device data environment. If the list item is not mapped, it is assumed to be accessible on the target device. The host storage of a list item that has a device address may not be accessible from within the structured block. List items can include array sections.

If a list item in a USE_DEVICE_PTR clause is not of type C_PTR from the intrinsic module ISO_C_BINDING, it is treated as if it appeared in a USE_DEVICE_ADDR clause. The use of non-C_PTR types in a USE_DEVICE_PTR clause has been deprecated.

A program must not depend on any ordering of the evaluations of the clauses of the TARGET DATA directive, or on any side effects of the evaluations of the clauses, except that list items in any MAP clause are data mapped prior to the conversion of any list items in a USE_DEVICE_PTR or USE_DEVICE_ADDR clause to their device storage locations within the structured block.

List items in USE_DEVICE_PTR and USE_DEVICE_ADDR clauses can not be specified more than once in the same or any other USE_DEVICE_PTR or USE_DEVICE_ADDR clause for the construct.

A list item in a USE_DEVICE_PTR or a USE_DEVICE_ADDR clause must not be a component of a derived type.

List items in a USE_DEVICE_ADDR clause must have been mapped to the device, or be accessible on the device from the host data environment. Similarly, the value of a list item in a USE_DEVICE_PTR that is of type C_PTR must be the address of an entity that has storage in the device data environment or that is accessible on the device from the host data environment.

If a list item in a USE_DEVICE_ADDR is an array section, the designator of the base expression cannot contain any construct association selectors.

The same variable can be used in both the MAP clause and the USE_DEVICE_PTR clause or a USE_DEVICE_ADDR clause:

```fortran
!$OMP TARGET DATA MAP(X, Y) USE_DEVICE_PTR(X) USE_DEVICE_ADDR (Y) block
!$OMP END TARGET DATA
```

**TARGET Statement**

**Statement and Attribute:** Specifies that an object can become the target of a pointer (it can be pointed to).
Syntax

The TARGET attribute can be specified in a type declaration statement or a TARGET statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type,[att-ls] TARGET [,', att-ls] :: object [(a-spec)] [[coarray-spec]] [, object[(a-
spec)] [[coarray-spec]]]...
```

**Statement:**

```
TARGET [::] object [(a-spec)] [[coarray-spec]] [, object[(a-spec)] [[coarray-spec]]]...
```

- `type` Is a data type specifier.
- `att-ls` Is an optional list of attribute specifiers.
- `object` Is the name of the object. The object must not be declared with the PARAMETER attribute.
- `a-spec` (Optional) Is an array specification or a coarray specification.
- `coarray-spec` (Optional) Is a deferred-coshape specification. The left bracket and right bracket are required.

Description

A pointer is associated with a target by pointer assignment or by an ALLOCATE statement.

If an object does not have the TARGET attribute or has not been allocated (using an ALLOCATE statement), no part of it can be accessed by a pointer.

Example

The following example shows type declaration statements specifying the TARGET attribute:

```
TYPE(System), TARGET :: FIRST
REAL, DIMENSION(20, 20), TARGET :: C, D
```

The following is an example of a TARGET statement:

```
TARGET :: C(50, 50), D
```

The following fragment is from the program POINTER2.F90 in the <install-dir>/samples subdirectory:

```
! An example of pointer assignment.
REAL, POINTER :: arrow1(:)
REAL, POINTER :: arrow2(:)
REAL, ALLOCATABLE, TARGET :: bullseye(:)

ALLOCATE(bullseye(7))
bullseye = 1.
bullseye(1:7:2) = 10.
WRITE(*,'(/1x,a,7f8.0)') 'target ',bullseye

arrow1 => bullseye
WRITE(*,'(/1x,a,7f8.0)') 'pointer',arrow1
```

ALLOCATE
ASSOCIATED
POINTER
TARGET ENTER DATA

OpenMP* Fortran Compiler Directive: Specifies that variables are mapped to a device data environment. This feature is only available for ifx.

Syntax

```fortran
!$OMP TARGET ENTER DATA [clause[, clause]... ]
```

clause Is one or more of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
- IF ([TARGET ENTER DATA:] scalar-logical-expression)
- MAP (map-type : list)
- NOWAIT
- SUBDEVICE ([integer-constant ,] integer-expression [ : integer-expression] )

The binding task for the TARGET ENTER DATA construct is the encountering task. TARGET ENTER DATA is a stand-alone directive.

When a TARGET ENTER DATA construct is encountered, the list items in the MAP clauses are mapped to the device data environment according to map-type. A map-type must be specified in all MAP clauses and must be either TO or ALLOC.

The TARGET ENTER DATA construct executes as if it was enclosed in a TASK construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit TASK construct that encloses the TARGET ENTER DATA construct.

If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named default-device-var.

When an IF clause is present and the IF clause scalar-logical-expression evaluates to .FALSE., the device is the host.

Parallel Processing Model for information about Binding Sets

TARGET EXIT DATA

OpenMP* Fortran Compiler Directive: Specifies that variables are unmapped from a device data environment. This feature is only available for ifx.

Syntax

```fortran
!$OMP TARGET EXIT DATA [clause[, clause]... ]
```
The binding task for the TARGET EXIT DATA construct is the encountering task. TARGET EXIT DATA is a stand-alone directive.

When a TARGET EXIT DATA construct is encountered, the list items in the MAP clauses are unmapped from the device data environment according to map-type. A map-type must be specified in all MAP clauses and must be FROM, RELEASE, or DELETE.

The TARGET EXIT DATA construct executes as if it was enclosed in a task construct.

When a DEPEND clause is present, it acts as if it appeared on the implicit task construct that encloses the TARGET EXIT DATA construct.

If there is no DEVICE clause, the default device is determined by the internal control variable (ICV) named default-device-var.

When an IF clause is present and the IF clause scalar-logical-expression evaluates to .FALSE., the device is the host.

TARGET PARALLEL

OpenMP* Fortran Compiler Directive: Creates a device data environment in a parallel region and executes the construct on that device.

Syntax

```fortran
!$OMP TARGET PARALLEL [clause[, clause] ... ]
   loosely-structured-block
!$OMP END TARGET PARALLEL
-or-
!$OMP TARGET PARALLEL [clause[, clause] ... ]
   strictly-structured-block
!$OMP END TARGET PARALLEL
```

clause Can be any of the clauses accepted by the TARGET or PARALLEL directives with identical meanings and restrictions.

loosely-structured-block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.
strictly-structured-block

Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This directive provides a shortcut for specifying a TARGET construct immediately followed by a PARALLEL construct. The effect of any clause that applies to both constructs is as if it were applied to both constructs separately. The only exceptions are the following:

- If any IF clause in the directive includes a *directive-name-modifier* then all IF clauses in the directive must include a directive-name-modifier.
- At most one IF clause with no *directive-name-modifier* can appear on the directive.
- At most one IF clause with the PARALLEL *directive-name-modifier* can appear on the directive.
- At most one IF clause with the TARGET *directive-name-modifier* can appear on the directive.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
IF Clause
TARGET Directive
PARALLEL Directive

**TARGET PARALLEL DO**

*OpenMP* Fortran Compiler Directive: Provides an abbreviated way to specify a TARGET directive containing a PARALLEL DO directive and no other statements.

**Syntax**

```fortran
!$OMP TARGET PARALLEL DO [clause[,] clause] ... ]
  do-loop
![$OMP END TARGET PARALLEL DO]
```

clause

Can be any of the clauses accepted by the TARGET or PARALLEL DO directives, except for the COPYIN clause.

do-loop

Is a DO iteration (a DO loop). It cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

You cannot branch out of a DO loop associated with a DO directive.

If the END TARGET PARALLEL DO directive is not specified, the TARGET PARALLEL DO is assumed at the end of do-loop. If used, the END TARGET PARALLEL DO directive must appear immediately after the end of do-loop.

The semantics are identical to explicitly specifying a TARGET directive immediately followed by a PARALLEL DO directive.

The restrictions for the TARGET and PARALLEL DO constructs apply to this directive except for the following:

- If any IF clause in the directive includes a *directive-name-modifier* then all IF clauses in the directive must include a directive-name-modifier.
- At most one IF clause with no *directive-name-modifier* can appear on the directive.
- At most one IF clause with the PARALLEL *directive-name-modifier* can appear on the directive.
- At most one IF clause with the TARGET *directive-name-modifier* can appear on the directive.

OpenMP Fortran Compiler Directives
Syntax Rules for Compiler Directives
IF Clause
TARGET Directive
PARALLEL DO

TARGET PARALLEL DO SIMD

OpenMP* Fortran Compiler Directive: Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement.

Syntax

```fortran
!$OMP TARGET PARALLEL DO SIMD [clause[,] clause] ... ]
  do-loop
[
!$OMP END TARGET PARALLEL DO SIMD]
```

clause

Can be any of the clauses accepted by the TARGET or PARALLEL DO SIMD directives, except for the COPYIN clause.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END TARGET PARALLEL DO SIMD directive is not specified, an END TARGET PARALLEL DO SIMD directive is assumed at the end of do-loop.

The restrictions for the TARGET and PARALLEL DO SIMD constructs apply to this directive except for the following:

- If any IF clause in the directive includes a directive-name-modifier then all IF clauses in the directive must include a directive-name-modifier.
- At most one IF clause with no directive-name-modifier can appear on the directive.
- At most one IF clause with the PARALLEL directive-name-modifier can appear on the directive.
- At most one IF clause with the TARGET directive-name-modifier can appear on the directive.

IF Clause
TARGET Directive
PARALLEL DO SIMD
TARGET PARALLEL LOOP

**OpenMP* Fortran Compiler Directive:** Specifies a shortcut for specifying a parallel loop inside a TARGET construct that contains no other statements than the parallel loop. This feature is only available for ifx.

**Syntax**

```fortran
!$OMP TARGET PARALLEL LOOP [clause[,] clause]... ]
   do-loop

   [!$OMP END TARGET PARALLEL LOOP]
```

- **clause**
  - Can be any of the clauses accepted by the TARGET or PARALLEL LOOP constructs with identical meanings and restrictions.
- **do-loop**
  - Is a DO loop that may contain other nested DO loops. The DO loops must all be in canonical form. The DO loop iteration variable must be of type integer.

This combined directive is semantically equivalent to a TARGET directive followed immediately by a PARALLEL LOOP construct. The restrictions for TARGET and PARALLEL LOOP constructs apply to this combined construct.

If used, the END TARGET PARALLEL LOOP directive must appear immediately after the end of the loop. If you do not specify an END TARGET PARALLEL LOOP directive, an END TARGET PARALLEL LOOP directive is assumed at the end of the `do-loop`.

PARALLEL LOOP directive

TARGET SIMD

**OpenMP* Fortran Compiler Directive:** Specifies a TARGET construct that contains a SIMD construct and no other statement.

**Syntax**

```fortran
!$OMP TARGET SIMD [clause[,] clause] ... ]
   do-loop

   [!$OMP END TARGET SIMD]
```

- **clause**
  - Can be any of the clauses accepted by the TARGET or SIMD directive, with identical meanings and restrictions.
- **do-loop**
  - Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

1944
The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

You cannot branch out of a DO loop associated with a DO SIMD directive.

If the END TARGET SIMD directive is not specified, an END TARGET SIMD directive is assumed at the end of do-loop.

The restrictions for the TARGET and SIMD constructs apply to this directive.

TARGET TEAMS

*OpenMP* Fortran Compiler Directive: Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.

Syntax

\[
\text{!$OMP TARGET TEAMS } [\text{clause}[, , \text{clause}]... ] \]

loosely-structured-block

\[
\text{!$OMP END TARGET TEAMS}
\]

-or-

\[
\text{!$OMP TARGET TEAMS } [\text{clause}[, , \text{clause}]... ] \]

strictly-structured-block

\[
\text{!$OMP END TARGET TEAMS}
\]

clause

Can be any of the clauses accepted by the TARGET or TEAMS directives with identical meanings and restrictions.

loosely-structured-block

Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block

Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

This directive provides a shortcut for specifying a TARGET construct immediately followed by a TEAMS construct.

TEAMS
TARGET TEAMS DISTRIBUTE

OpenMP* Fortran Compiler Directive: Creates a device data environment and executes the construct on the same device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a TEAMS construct.

Syntax

```fortran
!$OMP TARGET TEAMS DISTRIBUTE [clause[, clause]... ]
    do-loop
$$OMP END TARGET TEAMS DISTRIBUTE
```

clause

Can be any of the clauses accepted by the TARGET or TEAMS DISTRIBUTE directives with identical meanings and restrictions.

do-loop

Is one or more DO iterations (DO loops). The DO iteration cannot be a DO WHILE or a DO loop without loop control. The DO loop iteration variable must be of type integer.

All loops associated with the construct must be structured and perfectly nested; that is, there must be no intervening code and no other OpenMP* Fortran directives between any two loops.

The iterations of the DO loop are distributed across the existing team of threads. The values of the loop control parameters of the DO loop associated with a DO directive must be the same for all the threads in the team.

This directive provides a shortcut for specifying a TARGET construct followed immediately by a TEAMS DISTRIBUTE construct.

If the END TARGET TEAMS DISTRIBUTE directive is not specified, an END TARGET TEAMS DISTRIBUTE directive is assumed at the end of do-loop.

TEAMS LOOP directive

TARGET UPDATE

OpenMP* Fortran Compiler Directive: Makes the list items in the device data environment consistent with their corresponding original list items.

Syntax

```fortran
!$OMP TARGET UPDATE motion-clause [, clause[, clause]...] 
```

motion-clause

Is one of the following:

- FROM ([MAPPER (map-identifier) :] list)
- TO ([MAPPER (map-identifier) :] list)

The map-identifier must be an accessible map-identifier that is given a user-defined mapper in a DECLARE MAPPER directive. If MAPPER is not present, it is as if MAPPER (DEFAULT) was specified. An accessible user-defined mapper with the same map-identifier that is specified in the MAPPER motion-clause modifies the mapping of a list item with the same type as the user-defined mapper.
If the motion-clause is TO, each list item is replaced with the list items that the specified mapper indicates are to be mapped with a TO or TOFROM map type. Similarly, if the motion-clause is FROM, each list item is replaced with list items that the specified mapper indicates are to be mapped with a FROM or TOFROM map type.

The list is the name of one or more variables or common blocks that are accessible to the scoping unit. Subobjects cannot be specified. Each name must be separated by a comma, and a common block name must appear between slashes (/ /). A list item can be a strided array section.

For each list item in a TO or FROM clause, there is a corresponding list item and an original list item; for more information, see the MAP clause. Note that if the corresponding list item is not present in the device data environment, the behavior is unspecified.

For each list item in a TO clause, the value of the original list item is assigned to the corresponding list item.

For each list item in a FROM clause, the value of the corresponding list item is assigned to the original list item.

A list item or subobject of a list item that has the ALLOCATABLE attribute is updated only if it is allocated. A list item that has the POINTER attribute whose association status is associated, the update is performed with respect to the pointer target.

A list item can only appear in a TO or FROM clause, but not both.

clause

Is one of the following:

- DEPEND (dependence-type : list)
- DEVICE (integer-expression)
  
  At most one DEVICE clause can be specified.
- IF ([TARGET UPDATE:] scalar-logical-expression)
- NOWAIT
- SUBDEVICE ([integer-constant ,] integer-expression [ : integer-expression ])

The binding task for a TARGET UPDATE construct is the encountering task. The TARGET UPDATE directive is a stand-alone directive.

A TARGET UPDATE construct must not appear inside of a target region.

DECLARE MAPPER Directive
TARGET Directive
TARGET DATA
Parallel Processing Model for information about Binding Sets
TARGET VARIANT DISPATCH

**Offloading Compiler Directive:** Conditionally calls a procedure offload variant if the device is free; otherwise, executes the procedure on the host. This directive is an Intel® language extension. This feature is only available for ifx.

**Syntax**

```plaintext
!$OMP TARGET VARIANT DISPATCH [clause[, clause]]
CALL subr (...)
-or-
!$OMP TARGET VARIANT DISPATCH [clause[, clause]]
var = func (...)
```

Is one or more of the following:

- DEVICE (integer-expression)
- NOWAIT
- SUBDEVICE ([integer-constant ,] integer-expression [ : integer-expression [ : integer-expression ] ])
- USE_DEVICE_PTR (ptr-list)

This directive causes the compiler to emit conditional dispatch code around the associated subroutine or function call that follows the directive. If the default device is available, the variant version is called. If DEVICE (integer-expression) is specified, the variant is called only if device integer-expression is available. If SUBDEVICE is specified, the variant is called only if the specified tiles or compute slices are available. If both DEVICE(n) and SUBDEVICE are specified, the variant is called only if the specified tiles or compute slices are available on device n. Otherwise, the base version of the procedure is called on the host.

The NOWAIT clause, if present, indicates calls to the procedure can occur asynchronously. If NOWAIT is not present, calls occur synchronously.

The name of the subroutine or function associated with the TARGET VARIANT DISPATCH directive must have appeared in a DECLARE VARIANT directive in the specification part of the calling scope. The interface of the variant procedure must be accessible in the base procedure where the DECLARE VARIANT directive appears.

The procedure called in the statement following the TARGET VARIANT DISPATCH directive must have an explicit interface accessible at the call site.

The variant version of the procedure has an identical interface as the base function, except the variant has an additional argument in the last position which is of type C_PTR. This final argument does not appear in the TARGET VARIANT DISPATCH call, rather, the compiler inserts it if the variant is called.

**Example**

```plaintext
MODULE vecadd
  INTEGER,PARAMETER :: n = 1024
CONTAINS
  FUNCTION vecadd_gpu_offload (ptr)RESULT (res)
    USE,INTRINSIC :: ISO_C_BINDING, ONLY : c_ptr
    !$DEC ATTRIBUTES NOINLINE :: vecadd_gpu_offload
    REAL :: res
    REAL,DIMENSION(n) :: a, b
    INTEGER :: k
    res   = a(k) + b(k)
```

Language Reference

1951
FUNCTION vecadd_base ()RESULT (res)
  !$DEC ATTRIBUTES NOINLINE :: vecadd_base
  !$OMP DECLARE VARIANT (vecadd_gpu_offload) match(construct={target variant dispatch}&
  !$OMP&                  ,device = {arch (gen)})
  REAL :: res
  REAL, DIMENSION(n) :: a, b
  INTEGER :: k

  res = a(k) + b(k)
  PRINT *, "CPU version of vecadd called"
END FUNCTION vecadd_base
END MODULE vecadd

PROGRAM main
  USE vecadd
  REAL :: result = 0.0

  !$OMP TARGET VARIANT DISPATCH
  result = vecadd_base()
  !$OMP END TARGET VARIANT DISPATCH

  IF (result == 1048576.0) THEN
    PRINT *, "PASSED: correct results"
  ELSE
    PRINT *, "FAILED: incorrect results"
  ENDIF
END PROGRAM

DECLARE VARIANT

TASK
OpenMP* Fortran Compiler Directive: Defines a task region.

Syntax
!$OMP TASK [clause[,] clause] ... ]
block
!$OMP END TASK

clause
Is one of the following:
-ALLOCATE ([allocator :] list)
-DEFAULT (PRIVATE | FIRSTPRIVATE | SHARED | NONE)
-DEPEND (dependence-type : list)
-FINAL (scalar-logical-expression)
-FIRSTPRIVATE (list)
-IF ([TASK:] scalar-logical-expression)
The binding thread set of a TASK construct is the current team. A task region binds to the innermost enclosing parallel region.

The TASK and END TASK directive pair must appear in the same routine in the executable section of the code.

The END TASK directive denotes the end of the task.

When a thread encounters a task construct, a task is generated from the code for the associated structured block. The encountering thread may immediately execute the task, or defer its execution. In the latter case, any thread in the team may be assigned the task.

A thread that encounters a task scheduling point within the task region may temporarily suspend the task region. By default, a task is then tied and its suspended task region can only be resumed by the thread that started its execution. However, if the untied clause is specified in a TASK construct, any thread in the team can resume the task region after a suspension. The untied clause is ignored in these cases:

- If a final clause has been specified in the same TASK construct and the final clause expression evaluates to .TRUE..
- If a task is an included task.

A TASK construct may be nested inside an outer task, but the task region of the inner task is not a part of the task region of the outer task.

The TASK construct includes a task scheduling point in the task region of its generating task, immediately following the generation of the explicit task. Each explicit task region includes a task scheduling point at its point of completion. An implementation may add task scheduling points anywhere in untied task regions.

Note that when storage is shared by an explicit task region, you must add proper synchronization to ensure that the storage does not reach the end of its lifetime before the explicit task region completes its execution.

A program must not depend on any ordering of the evaluations of the clauses of the TASK directive and it must not depend on any side effects of the evaluations of the clauses. A program that branches into or out of a task region is non-conforming.

Unsynchronized use of Fortran I/O statements by multiple tasks on the same unit has unspecified behavior.

Example

The following example calculates a Fibonacci number. The Fibonacci sequence is 1,1,2,3,5,8,13, etc., where the current number is the sum of the previous two numbers. If a call to function fib is encountered by a single thread in a parallel region, a nested task region will be spawned to carry out the computation in parallel.

```fortran
RECURSIVE INTEGER FUNCTION fib(n)
INTEGER n, i, j
IF ( n .LT. 2) THEN
  fib = n
ELSE
  !$OMP TASK SHARED(i)
  i = fib( n-1 )
```
The following example generates a large number of tasks in one thread and executes them with the threads in the parallel team. While generating these tasks, if the implementation reaches the limit generating unassigned tasks, the generating loop may be suspended and the thread used to execute unassigned tasks. When the number of unassigned tasks is sufficiently low, the thread resumes execution of the task generating loop.

```fortran
real*8 item(10000000)
integer i
!$omp parallel
!$omp single ! loop iteration variable i is private
   do i=1,10000000
!$omp task ! i is firstprivate, item is shared
      call process(item(i))
!$omp end task
   end do
!$omp end single
!$omp end parallel
end
```

The following example modifies the previous one to use an untied task to generate the unassigned tasks. If the implementation reaches the limit generating unassigned tasks and the generating loop is suspended, any other thread that becomes available can resume the task generation loop.

```fortran
real*8 item(10000000)
!$omp parallel
!$omp single!
$omp task untied
! loop iteration variable i is private
   do i=1,10000000
!$omp task ! i is firstprivate, item is shared
      call process(item(i))
!$omp end task
   end do
!$omp end task
!$omp end single
!$omp end parallel
```

The following example demonstrates four tasks with dependences:

```fortran
integer :: a

!$omp task depend(out:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task

!$omp task depend(in:a)
!$omp end task
```
In the above example, the first task does not depend on any previous one. The second and third tasks depend on the first task but not on each other. The last task depends on the second and third tasks. The following shows the dependency graph:

The following example shows a set of sibling tasks that have dependences between them:

```
INTEGER :: A(0:N*B-1)

DO I=0,N-1
  !$OMP TASK DEPEND(OUT:A(I*B:(I+1)*B-1))
  CALL FILL(A(I*B:(I+1)*B-1))
  !$OMP END TASK
END DO

DO I=1,N-1
  IB = (I-1)*B+1
  BB = I*B+1
  !$OMP TASK DEPEND(INOUT:A(I*B:(I+1)*B-1)) DEPEND(IN:A((I+1)*B:(I+2)*B-1))
  CALL PROCESS(A(I*B:(I+1)*B-1), A((I+1)*B:(I+2)*B-1))
  !$OMP END TASK
END DO

DO I=1,N
```

In the above example, the tasks of the first loop will be independent of any other tasks since there is no previous task that expresses a dependence on the same list items. Tasks of the second loop will depend on two tasks from the first loop. Also, because dependences are constructed in a sequential order, the IN dependences force the tasks of the second loop to be dependent on the task from the previous iteration to be processed. Finally, tasks of the third loop can be executed when the corresponding Process task from the second loop has been executed. For example, if N was 4, the following shows the dependency graph:

TASK_REDUCTION
Specifies a reduction among tasks. The TASK_REDUCTION clause is a reduction scoping clause.

Syntax
TASK_REDUCTION (reduction-identifier : list)

Arguments reduction-identifier and list are defined in REDUCTION clause. All the common restrictions for the REDUCTION clause apply to this clause.

IN_REDUCTION
DECLARE REDUCTION
REDUCTION
TASKGROUP

TASKGROUP
OpenMP* Fortran Compiler Directive: Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.

Syntax
!$OMP TASKGROUP [clause[, clause] ... ]
    loosely-structured-block
!$OMP END TASKGROUP
-or-
!$OMP TASKGROUP [clause[, clause] ... ]
    strictly-structured-block
!$OMP END TASKGROUP

clause Is one of the following:
• ALLOCATE ([allocator :] list)
• TASK_REDUCTION (reduction-identifier : list)

loosely-structured-block Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

strictly-structured-block Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

A TASKGROUP construct binds to the current task region. The binding thread set of the taskgroup region is the current team.
When a thread encounters a TASKGROUP construct, it starts executing the region. There is an implicit task scheduling point at the end of the TASKGROUP region. The current task is suspended at the task scheduling point until all child tasks that it generated in the TASKGROUP region and all of their descendant tasks complete execution.

Any number of reduction clauses can be specified in the TASKGROUP directive, but a list item can appear only once in reduction clauses for that directive.
