  INTEGER(4)            :: zip = 0
  TYPE (list_node), POINTER :: next => NULL()
```

```

END TYPE

TYPE (list_node) :: x = list_node (zip = 03054)
PRINT *, x%state, x%zip
END

```

The above prints the following:

```
NH 3054
```

Coarrays are a Fortran 2008 feature. The following example shows a derived-type definition with a coarray component:

```

TYPE NEW_TYPE
  REAL,ALLOCATABLE,CODIMENSION[:,::] :: NEW(:,::)
END TYPE NEW_TYPE

```

An object of type NEW\_TYPE must be a scalar and it cannot be a pointer, allocatable, or a coarray.

The following example shows a derived-type definition containing a *coarray-spec*:

```

type t
  integer :: k
  real, allocatable :: x (:,:)[:,:]
end type t

```

In the following example, when the assignment to DEST occurs, DEST%TA is unallocated: it is first allocated with the size of SOURCE%TA and then the value of SOURCE%TA is assigned into DEST%TA:

```

TYPE T
  INTEGER I
END TYPE T
TYPE T2
  TYPE (T), ALLOCATABLE :: TA
END TYPE T2

TYPE (T2) SOURCE, DEST

ALLOCATE (SOURCE%TA)
DEST = SOURCE

```

The use of allocatable components of recursive type can involve direct recursion, in which the type has a component that is the same type as its parent. The following example creates a five-element linked list using allocatable components of recursive type:

```

TYPE T
  INTEGER I
  TYPE(T), ALLOCATABLE :: NEXT
END TYPE

TYPE (T), ALLOCATABLE, TARGET :: ORIG, COPY
TYPE (T), POINTER :: TA

ALLOCATE (ORIG)
TA => ORIG

DO I=1,5
  TA%I = I
  ALLOCATE (TA%NEXT)
  TA => TA%NEXT
END DO

```

By using allocatable components rather than pointer components, there is no need to explicitly nullify component NEXT - it is set to an unallocated state automatically by the compiler. Because the semantics of ALLOCATE(SOURCE=) require the allocation and copying of all allocated allocatable components from ORIG into COPY, we can create a complete, unique copy of the entire linked list in one easy statement:

```
ALLOCATE (COPY, SOURCE=ORIG)
```

In addition to direct recursion, indirect recursion or forward referencing can also be used. In the following example, component A of type T is of type T2, a forward reference to a type not yet defined, while component B of type T2 is of type T:

```
TYPE T
  TYPE(T2), ALLOCATABLE :: A
END TYPE

TYPE T2
  TYPE(T), ALLOCATABLE :: B
END TYPE

TYPE(T2) TY
```

## UBOUND

***Inquiry Intrinsic Function (Generic):*** Returns the upper bounds for all dimensions of an array, or the upper bound for a specified dimension.

---

### Syntax

```
result = UBOUND (array [, dim] [, kind])
```

*array*

(Input) Must be an array; it can be assumed-rank. It may be of any data type. It must not be an allocatable array that is not allocated, or a disassociated pointer. It can be an assumed-size array if *dim* is present with a value less than the rank of *array*.

<i>dim</i>	(Input; optional) Must be a scalar integer with a value in the range 1 to $n$ , where $n$ is the rank of <i>array</i> .
<i>kind</i>	(Input; optional) Must be a scalar integer constant expression.

## Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The following rule applies if *array* is not assumed-rank:

- If *dim* is present, the result is a scalar. Otherwise, the result is a rank-one array with one element for each dimension of *array*. Each element in the result corresponds to a dimension of *array*.

The following rules apply if *array* is assumed-rank:

- If *dim* is present and *array* is assumed-rank, the value of the result is as if *array* were a whole array, with the extent of the final dimension of *array* when *array* is associated with an assumed-size array being considered to be  $-1$ .
- If UBOUND is invoked for an assumed-rank object that is associated with a scalar and *dim* is absent, the result is a zero-sized array. UBOUND cannot be invoked for an assumed-rank object that is associated with a scalar if *dim* is present because the rank of a scalar is zero and *dim* must be  $\geq 1$ .

If *array* is an array section or an array expression that is not a whole array or array structure component, UBOUND(*array*, *dim*) has a value equal to the number of elements in the given dimension.

If *array* is a whole array or array structure component, UBOUND(*array*, *dim*) has a value equal to the upper bound for subscript *dim* of *array* (if *dim* is nonzero). If *dim* has size zero, the corresponding element of the result has the value zero.

The setting of compiler options specifying integer size can affect this function.

## Example

Consider the following:

```
REAL ARRAY_A (1:3, 5:8)
REAL ARRAY_B (2:8, -3:20)
```

UBOUND (ARRAY\_A) is (3, 8). UBOUND (ARRAY\_A, DIM=2) is 8.

UBOUND (ARRAY\_B) is (8, 20). UBOUND (ARRAY\_B (5:8, :)) is (4,24) because the number of elements is significant for array section arguments.

The following shows another example:

```
REAL ar1(2:3, 4:5, -1:14), vec1(35)
INTEGER res1(3), res2, res3(1)
res1 = UBOUND (ar1)           ! returns [3, 5, 14]
res2 = UBOUND (ar1, DIM= 3)   ! returns 14
res3 = UBOUND (vec1)          ! returns [35]
END
```

## See Also

LBOUND

## UCOBOUND

***Inquiry Intrinsic Function (Generic):*** Returns the upper cobounds of a coarray.

## Syntax

```
result = UCBOUND (coarray [,dim [, kind])
```

*coarray*

(Input) Must be a coarray; it can be of any type. It can be a scalar or an array. If it is allocatable, it must be allocated.

*dim*

(Input; optional) Must be an integer scalar with a value in the range  $1 \leq dim \leq n$ , where  $n$  is the corank of *coarray*. The corresponding actual argument must not be an optional dummy argument.

*kind*

(Input; optional) Must be a scalar integer constant expression.

## Results

The result type is integer. If *kind* is present, the kind parameter is that specified by *kind*; otherwise, the kind parameter is that of default integer type. The result is scalar if *dim* is present; otherwise, the result is an array of rank one and size  $n$ , where  $n$  is the corank of *coarray*.

The final upper cobound is the final cosubscript in the cosubscript list for the coarray that selects the image whose index is equal to the number of images in the current team. The result depends on whether *dim* is specified:

- If *dim* is specified, UCBOUND (COARRAY, DIM) has a value equal to the upper cobound for cosubscript *dim* of *coarray*.
- If *dim* is not specified, UCBOUND (COARRAY) has a value whose *i*th element is equal to UCBOUND (COARRAY, *i*), for  $i = 1, 2, \dots, n$ , where  $n$  is the corank of *coarray*.

## Examples

If *A* is allocated by the statement `ALLOCATE (A [2:3, 7:*])`, then `LCBOUND (A)` is `[2, 7]` and `LCBOUND (A, DIM=2)` is 7.

If `NUM_IMAGES( )` has the value 30, and coarray *B* is allocated by the statement `ALLOCATE (B[2:3, 0:7, *])`, then `UCBOUND (B)` is `[3, 7, 2]` and `UCBOUND (B, DIM=2)` is 7. Note that the cosubscripts `[3, 7, 2]` do not correspond to an actual image.

## UNDEFINE

**Statement:** *Removes a defined symbol.*

---

### See Also

See [DEFINE](#) and [UNDEFINE](#).

## UNION and END UNION

**Statements:** *Define a data area that can be shared intermittently during program execution by one or more fields or groups of fields. A union declaration must be within a structure declaration.*

---

## Syntax

Each unique field or group of fields is defined by a separate map declaration.

```
UNION
```

```
    map-declaration
```

```
    map-declaration
```

```
    [map-declaration]
```

```

. . .
[map-declaration]
END UNION

```

*map-declaration*

Takes the following form:

```

MAP
    field-declaration
    [field-declaration]
    . . .
    [field-declaration]
END MAP

```

*field-declaration*

Is a structure declaration or RECORD statement contained within a union declaration, a union declaration contained within a union declaration, or the declaration of a data field (having a data type) within a union. It can be of any intrinsic or derived type.

As with normal Fortran type declarations, data can be initialized in field declaration statements in union declarations. However, if fields within multiple map declarations in a single union are initialized, the data declarations are initialized in the order in which the statements appear. As a result, only the final initialization takes effect and all of the preceding initializations are overwritten.

The size of the shared area established for a union declaration is the size of the largest map defined for that union. The size of a map is the sum of the sizes of the fields declared within it.

Manipulating data by using union declarations is similar to using EQUIVALENCE statements. The difference is that data entities specified within EQUIVALENCE statements are concurrently associated with a common storage location and the data residing there; with union declarations you can use one discrete storage location to alternately contain a variety of fields (arrays or variables).

With union declarations, only one map declaration within a union declaration can be associated at any point in time with the storage location that they share. Whenever a field within another map declaration in the same union declaration is referenced in your program, the fields in the prior map declaration become undefined and are succeeded by the fields in the map declaration containing the newly referenced field.

## Example

In the following example, the structure WORDS\_LONG is defined. This structure contains a union declaration defining two map fields. The first map field consists of three INTEGER\*2 variables (WORD\_0, WORD\_1, and WORD\_2), and the second, an INTEGER\*4 variable, LONG:

```

STRUCTURE /WORDS_LONG/
  UNION
    MAP
      INTEGER*2  WORD_0, WORD_1, WORD_2
    END MAP
    MAP
      INTEGER*4  LONG
    END MAP
  END UNION
END STRUCTURE

```

The length of any record with the structure WORDS\_LONG is 6 bytes. The following figure shows the memory mapping of any record with the structure WORDS\_LONG:

### Memory Map of Structure WORDS\_LONG

In the following example, note how the first 40 characters in the string2 array are overlayed on 4-byte integers, while the remaining 20 are overlayed on 2-byte integers:

```

UNION
  MAP
    CHARACTER*20 string1, CHARACTER*10 string2(6)
  END MAP
  MAP
    INTEGER*2 number(10), INTEGER*4 var(10), INTEGER*2
+    datum(10)
  END MAP
END UNION

```

## UNLINK

**Portability Function:** *Deletes the file given by path.*

### Module

USE IFPORT

### Syntax

```
result = UNLINK (name)
```

*name*

(Input) Character\*(\*). Path of the file to delete. The path can use forward (/) or backward (\) slashes as path separators and can contain drive letters.

### Results

The result type is INTEGER(4). The result is zero if successful; otherwise, an error code. Errors can be one of the following:

- ENOENT: The specified file could not be found.

- EACCES: The specified file is read-only.

You must have adequate permission to delete the specified file.

On Windows systems, you will get the EACCES error if the file has been opened by any process.

## Example

```
USE IFPORT
INTEGER(4) ISTATUS
CHARACTER*20 dirname
READ *, dirname
ISTATUS = UNLINK (dirname)
IF (ISTATUS) then
    print *, 'Error ', ISTATUS
END IF
END
```

SYSTEM

DEDIRQQ

## UNPACK

### **Transformational Intrinsic Function (Generic):**

*Takes elements from a rank-one array and unpacks them into another (possibly larger) array under the control of a mask.*

## Syntax

```
result = UNPACK (vector,mask,field)
```

<i>vector</i>	(Input) Must be a rank-one array. It may be of any data type. Its size must be at least <i>t</i> , where <i>t</i> is the number of true elements in <i>mask</i> .
<i>mask</i>	(Input) Must be a logical array. It determines where elements of <i>vector</i> are placed when they are unpacked.
<i>field</i>	(Input) Must be of the same type and type parameters as <i>vector</i> and conformable with <i>mask</i> . Elements in <i>field</i> are inserted into the result array when the corresponding <i>mask</i> element has the value false.

## Results

The result is an array with the same shape as *mask*, and the same type and type parameters as *vector*.

Elements in the result array are filled in array element order. If element *i* of *mask* is true, the corresponding element of the result is filled by the next element in *vector*. Otherwise, it is filled by *field* (if *field* is scalar) or the *i*th element of *field* (if *field* is an array).

## Example

N is the array

```
[ 0  0  1 ]
[ 1  0  1 ]
[ 1  0  0 ],
```

P is the array (2, 3, 4, 5), and Q is the array

```
[ T F F ]  
[ F T F ]  
[ T T F ].
```

UNPACK (P, MASK=Q, FIELD=N) produces the result

```
[ 2 0 1 ]  
[ 1 4 1 ]  
[ 3 5 0 ].
```

UNPACK (P, MASK=Q, FIELD=1) produces the result

```
[ 2 1 1 ]  
[ 1 4 1 ]  
[ 3 5 1 ].
```

The following shows another example:

```
LOGICAL mask (2, 3)  
INTEGER vector(3) /1, 2, 3/, AR1(2, 3)  
mask = RESHAPE((/.TRUE.,.FALSE.,.FALSE.,.TRUE.,&  
                .TRUE.,.FALSE./), (/2, 3/))  
! vector = [1 2 3] and mask =  T F T  
!                               F T F  
AR1 = UNPACK(vector, mask, 8) ! returns  1 8 3  
!                               !         8 2 8  
END
```

## UNPACKTIMEQQ

**Portability Subroutine:** *Unpacks a packed time and date value into its component parts.*

---

### Module

USE IFPORT

### Syntax

CALL UNPACKTIMEQQ (*timedate*, *iy*, *imon*, *iday*, *ihr*, *imin*, *isec*)

<i>timedate</i>	(Input) INTEGER(4). Packed time and date information.
<i>iy</i>	(Output) INTEGER(2). Year ( xxxxAD).
<i>imon</i>	(Output) INTEGER(2). Month (1 - 12).
<i>iday</i>	(Output) INTEGER(2). Day (1 - 31).
<i>ihr</i>	(Output) INTEGER(2). Hour (0 - 23).
<i>imin</i>	(Output) INTEGER(2). Minute (0 - 59).
<i>isec</i>	(Output) INTEGER(2). Second (0 - 59).

GETFILEINFOQQ returns time and date in a packed format. You can use UNPACKTIMEQQ to unpack these values.

The output values reflect the time zone set on the local computer and the daylight savings rules for that time zone.

Use PACKTIMEQQ to repack times for passing to SETFILETIMEQQ. Packed times can be compared using relational operators.

### Example

```
USE IFPORT
CHARACTER(80)    file
TYPE (FILE$INFO) info
INTEGER(4) handle, result
INTEGER(2) iyr, imon, iday, ihr, imin, isec

file = 'd:\f90ps\bin\t???.*'
handle = FILE$FIRST
result = GETFILEINFOQQ(file, info, handle)
CALL UNPACKTIMEQQ(info%lastwrite, iyr, imon, &
                  iday, ihr, imin, isec)
WRITE(*,*) iyr, imon, iday
WRITE(*,*) ihr, imin, isec
END
```

GETFILEINFOQQ

## UNROLL Directive for OpenMP

**OpenMP\* Fortran Compiler Directive:** Partially or fully unrolls a DO loop. This feature is only available for ifx.

### Syntax

```
!$OMP UNROLL [clause]
```

*loop-nest*

```
[!$OMP END UNROLL]
```

*clause*

Is FULL or PARTIAL [ (*count*) ], where *count* is a compile-time integer constant expression.

If FULL is specified, and *n* is the iteration count of the outermost DO loop, the outermost loop is replaced by *n* copies of the loop body.

If PARTIAL is specified, the outermost loop is first tiled with a tile size of *count*, and then the tiled loop is fully unrolled. If PARTIAL is specified without *count*, the compiler determines the count.

If *clause* is omitted, the compiler determines if and how the loop is transformed.

*loop-nest*

Is a nest of DO loops in canonical form.

### Description

The UNROLL construct applies to the outermost loop of the loop nest.

The transformed loop will be in canonical form only when PARTIAL is specified.

The iteration count of the outermost DO loop must be constant if FULL is specified.

## Examples

In the following example, the FULL clause is specified in the UNROLL directive, so the loop iteration count must be a compile-time constant. In this case, a worksharing loop construct cannot be used because there is no loop to apply it to after the loop is unrolled.

```
INTEGER,DIMENSION (5) :: arr
INTEGER               :: i
!$OMP UNROLL FULL
DO i = 1, 5
    arr(i) = 100
END DO
```

Unrolling the above DO loops produces the following transformed code:

```
INTEGER,DIMENSION (5) :: arr
INTEGER               :: i
arr(1) = 100
arr(2) = 100
arr(3) = 100
arr(4) = 100
arr(5) = 100
```

In the following example, the loop is partially unrolled. The trip count is a multiple of *count* specified in the PARTIAL clause:

```
INTEGER,DIMENSION (64) :: arr
INTEGER               :: i
!$OMP PARALLEL DO
!$OMP UNROLL PARTIAL(4)
DO i = 1, 64
    arr(i) = arr(i) * 10
END DO
```

Unrolling the above DO loops 4 times produces the following result:

```
INTEGER,DIMENSION (64) :: arr
INTEGER               :: i
!$OMP PARALLEL DO
DO i = 0, 15
    arr(i*4 + 1) = arr(i*4 + 1) * 10
    arr(i*4 + 2) = arr(i*4 + 2) * 10
    arr(i*4 + 3) = arr(i*4 + 3) * 10
    arr(i*4 + 4) = arr(i*4 + 4) * 10
END DO
```

The following example shows how a loop with an unknown trip count that is partially unrolled may be transformed:

```
SUBROUTINE FOO (arr, n)
INTEGER               :: i,n
INTEGER,DIMENSION (n) :: arr
!$OMP PARALLEL DO
!$OMP UNROLL PARTIAL(4)
DO i = 1, n
    arr(i) = arr(i) * 10
END DO
END SUBROUTINE
```

Unrolling the above DO loop 4 times produces code equivalent to the following:

```
SUBROUTINE FOO (arr, n)
  INTEGER                :: i,n
  INTEGER,DIMENSION (n) :: arr
  !$OMP PARALLEL DO
  DO i = 0, (n+3)/4 - 1
    arr(i*4 + 1) = arr(i*4 + 1) * 10
    if ((i*4 + 2) < n) arr(i*4 + 2) = arr(i*4 + 2) * 10
    if ((i*4 + 3) < n) arr(i*4 + 3) = arr(i*4 + 3) * 10
    if ((i*4 + 4) < n) arr(i*4 + 4) = arr(i*4 + 4) * 10
  END DO
END SUBROUTINE
```

## See Also

[OpenMP Fortran Compiler Directives](#)

[Syntax Rules for Compiler Directives](#)

To learn more about canonical form loops, see the [OpenMP\\* specification](#).

## UNROLL and NOUNROLL General Directives

**General Compiler Directive:** Tells the compiler's optimizer how many times to unroll a DO loop or disables the unrolling of a DO loop. These directives can only be applied to iterative DO loops.

### Syntax

```
!DIR$ UNROLL [(n)] -or- !DIR$ UNROLL [=n]
!DIR$ NOUNROLL
```

*n* Is an integer constant. The range of *n* is 0 through 255.

If *n* is specified, the optimizer unrolls the loop *n* times. If *n* is omitted, or if it is outside the allowed range, the optimizer picks the number of times to unroll the loop.

The UNROLL directive overrides any setting of loop unrolling from the command line.

To use these directives, compiler option O2 or O3 must be set.

### Example

```
!DIR$ UNROLL
do i =1, m
  b(i) = a(i) + 1
  d(i) = c(i) + 1
enddo
```

The following shows another example:

```
!DIR$ UNROLL= 4
do i =1, m
  b(i) = a(c(i)) + 1
enddo
```

## O compiler option

### UNROLL\_AND\_JAM and NOUNROLL\_AND\_JAM

**General Compiler Directive:** Hints to the compiler to enable or disable loop unrolling and jamming. These directives can only be applied to iterative DO loops.

---

#### Syntax

```
!DIR$ UNROLL_AND_JAM [(n)] -or- !DIR$ UNROLL_AND_JAM [=n]
```

```
!DIR$ NOUNROLL_AND_JAM
```

*n* Is an integer constant. The range of *n* is 0 through 255.

The UNROLL\_AND\_JAM directive partially unrolls one or more loops higher in the nest than the innermost loop and fuses (jams) the resulting loops back together. This transformation allows more reuses in the loop.

This directive is not effective on innermost loops. You must ensure that the immediately following loop is not the innermost loop after compiler-initiated interchanges are completed.

Specifying this directive is a hint to the compiler that the unroll and jam sequence is legal and profitable. The compiler will enable this transformation whenever possible.

The UNROLL\_AND\_JAM directive must precede the DO statement for each DO loop it affects. If *n* is specified, the optimizer unrolls the loop *n* times. If *n* is omitted or if it is outside the allowed range, the optimizer chooses the number of times to unroll the loop. The compiler generates correct code by comparing *n* and the loop count.

This directive is supported only when compiler option O3 is set. The UNROLL\_AND\_JAM directive overrides any setting of loop unrolling from the command line.

When unrolling a loop increases register pressure and code size, it may be necessary to prevent unrolling of a nested or imperfect nested loop. In such cases, use the NOUNROLL\_AND\_JAM directive, which hints to the compiler not to unroll a specified loop.

#### Example

```
integer a(10,10), b(10,10), c(10,10), d(10,10)
integer i, j, k

!dir$ unroll_and_jam = 6

do i=1,10
  !dir$ unroll_and_jam (6)
  do j=1,10
    do k=1,10
      a (j, i) = a (j, i) + b (k, i) *c (k, j)
    end do          ! k
  end do           ! j
end do             ! i

end
```

#### See Also

## O compiler option

### UNTIED Clause

**Parallel Directive Clause:** *Specifies that the task is never tied to the thread that started its execution.*

#### Syntax

UNTIED

Any thread in the team can resume the task region after a suspension. For example, during runtime, the execution of a given task can start on thread A, break execution, and later resume on thread B.

### USE

**Statement:** *Gives a program unit accessibility to public entities in a module.*

#### Syntax

```
USE [[, mod-nature] ::] name [, rename-list]
```

```
USE [[, mod-nature] ::] name, ONLY : [ only-list]
```

*mod-nature*

Is INTRINSIC or NON\_INTRINSIC. If INTRINSIC is used, *name* must be the name of an intrinsic module. If NON\_INTRINSIC is used, *name* must be the name of a nonintrinsic module. If *mod-nature* is not specified, *name* must be the name of an intrinsic or nonintrinsic module. If both are provided, the nonintrinsic module is used. It is an error to specify a user module and an intrinsic module of the same name in the same program unit (see [Examples](#)).

*name*

Is the name of the module.

*rename-list*

Is one or more items, separated by commas, having the following form:

*local-name* => *mod-name*

*local-name*

Is the name of the entity in the program unit using the module or is "OPERATOR (*op-name*)", where *op-name* is the name of a defined operator in the program unit using the module.

*mod-name*

Is the name of a public entity in the module or is "OPERATOR (*op-name*)", where *op-name* is the name of a public entity in the module.

*only-list*

Is one or more items, separated by commas, where each item is the name of a public entity in the module or a generic identifier (a generic name, a defined operator specified as "OPERATOR (*op-name*)", or defined assignment).

An entity in the *only-list* can also take the form:

[*local-name* =>] *mod-name*

## Description

If the USE statement is specified without the ONLY option, the program unit has access to all public entities in the named module.

If the USE statement is specified with the ONLY option, the program unit has access to only those entities following the option.

If more than one USE statement for a given module appears in a scoping unit, the following rules apply:

- If one USE statement does not have the ONLY option, all public entities in the module are accessible, and any *rename-lists* and *only-lists* are interpreted as a single, concatenated *rename-list*.
- If all the USE statements have ONLY options, all the *only-lists* are interpreted as a single, concatenated *only-list*. Only those entities named in one or more of the *only-lists* are accessible.

If two or more generic interfaces that are accessible in a scoping unit have the same name, the same operator, or are both assignments, they are interpreted as a single generic interface. Otherwise, multiple accessible entities can have the same name only if no reference to the name is made in the scoping unit.

The local names of entities made accessible by a USE statement must not be declared locally other than in a PUBLIC, PRIVATE, VOLATILE, or ASYNCHRONOUS statement. Within a module, if a use-associated entity is declared VOLATILE or ASYNCHRONOUS, it has the default accessibility of a locally declared identifier.

The local names of use-associated entities can appear in namelist group lists, but not in a COMMON or EQUIVALENCE statement.

If the name of every module from which a use-associated entity is accessed appears in an accessibility statement, the default accessibility of the entity is PRIVATE if every such accessibility statement is PRIVATE, and PUBLIC if any such accessibility statement is PUBLIC.

The accessibility of a use associated entity within a module can be determined by applying the following rules in the specified order:

1. It is PUBLIC if the entity is specified in the entity-list of a PUBLIC statement. It is PRIVATE if the entity is specified in the entity-list of a PRIVATE statement.
2. If the entity is declared locally in an ASYNCHRONOUS or VOLATILE statement, go to 5.
3. It is PUBLIC if any module through which the entity is accessible appears in a PUBLIC statement.
4. It is PRIVATE if every module thru which the entity is accessible appears in a PRIVATE statement.
5. It is PUBLIC if there is a PUBLIC statement with no entity-list specified in the module. It is PRIVATE if there is a PRIVATE statement with no entity-list specified in the module.
6. It is PUBLIC.

## Examples

The following shows examples of the USE statement:

```

MODULE MOD_A
  INTEGER :: B, C
  REAL E(25,5), D(100)
END MODULE MOD_A
...
SUBROUTINE SUB_Y
  USE MOD_A, DX => D, EX => E      ! Array D has been renamed DX and array E
  ...                             ! has been renamed EX. Scalar variables B
END SUBROUTINE SUB_Y              ! and C are also available to this
...                               ! subroutine (using their module names).
SUBROUTINE SUB_Z
  USE MOD_A, ONLY: B, C            ! Only scalar variables B and C are
  ...                             ! available to this subroutine
END SUBROUTINE SUB_Z
...

```

You must not specify a user module and an intrinsic module of the same name in the same program unit. For example, if you specify a user module named `ISO_FORTRAN_ENV`, then it is illegal to specify the following in the same program unit:

```
USE :: ISO_FORTRAN_ENV
USE, INTRINSIC :: ISO_FORTRAN_ENV
```

The following example shows a module containing common blocks:

```
MODULE COLORS
  COMMON /BLOCKA/ C, D(15)
  COMMON /BLOCKB/ E, F
  ...
END MODULE COLORS
...
FUNCTION HUE(A, B)
  USE COLORS
  ...
END FUNCTION HUE
```

The `USE` statement makes all of the variables in the common blocks in module `COLORS` available to the function `HUE`.

To provide data abstraction, a user-defined data type and operations to be performed on values of this type can be packaged together in a module. The following example shows such a module:

```
MODULE CALCULATION
  TYPE ITEM
    REAL :: X, Y
  END TYPE ITEM

  INTERFACE OPERATOR (+)
    MODULE PROCEDURE ITEM_CALC
  END INTERFACE

CONTAINS
  FUNCTION ITEM_CALC (A1, A2)
    TYPE(ITEM) A1, A2, ITEM_CALC
    ...
  END FUNCTION ITEM_CALC
  ...
END MODULE CALCULATION

PROGRAM TOTALS
  USE CALCULATION
  TYPE(ITEM) X, Y, Z
  ...
  X = Y + Z
  ...
END
```

The `USE` statement allows program `TOTALS` access to both the type `ITEM` and the extended intrinsic operator `+` to perform calculations.

The following shows another example:

```
! Module containing original type declarations
MODULE geometry
  type square
    real side
    integer border
  end type
```

```
type circle
  real radius
  integer border
end type
END MODULE

! Program renames module types for local use.
PROGRAM test
USE GEOMETRY, LSQUARE=>SQUARE, LCIRCLE=>CIRCLE
! Now use these types in declarations
type (LSQUARE) s1,s2
type (LCIRCLE) c1,c2,c3
```

The following shows a defined operator in a USE statement:

```
USE mymod, OPERATOR(.localop.) => OPERATOR(.moduleop.)
```

Entities in modules can be accessed either through their given name, or through aliases declared in the USE statement of the main program unit. For example:

```
USE MODULE_LIB, XTABS => CROSSTABS
```

This statement accesses the routine called `CROSSTABS` in `MODULE_LIB` by the name `XTABS`. This way, if two modules have routines called `CROSSTABS`, one program can use them both simultaneously by assigning a local name in its USE statement.

When a program or subprogram renames a module entity, the local name (`XTABS`, in the preceding example) is accessible throughout the scope of the program unit that names it.

The **ONLY** option also allows public variables to be renamed. Consider the following:

```
USE MODULE_A, ONLY: VARIABLE_A => VAR_A
```

In this case, the host program accesses only `VAR_A` from module `A`, and refers to it by the name `VARIABLE_A`.

Consider the following example:

```
MODULE FOO
  integer foos_integer
  PRIVATE
  integer foos_my_integer
END MODULE FOO
```

**PRIVATE**, in this case, makes the **PRIVATE** attribute the default for the entire module `FOO`. To make `foos_integer` accessible to other program units, add the line:

```
PUBLIC :: foos_integer
```

Alternatively, to make only `foos_my_integer` inaccessible outside the module, rewrite the module as follows:

```
MODULE FOO
  integer foos_integer
  integer, private::foos_my_integer
END MODULE FOO
```

Given the following module declarations:

```
MODULE mod1
  INTEGER x1
END MODULE
```

```

MODULE mod2
  USE mod1
  INTEGER x2
END MODULE

```

Then in module mod3 below, x1 has default accessibility of PRIVATE:

```

MODULE mod3
  USE mod2
  PUBLIC x2      ! x2 is PUBLIC
  PRIVATE       ! x1 is PRIVATE
END MODULE

```

In mod4 below, even though x1 is declared in mod1, and mod1 is declared PRIVATE in mod4, x1 is PUBLIC since it is declared VOLATILE and it assumes the default accessibility of PUBLIC of a locally declared identifier in mod4:

```

MODULE mod4
  USE mod1
  PRIVATE mod1
  VOLATILE x1    ! x1 is PUBLIC
END MODULE

```

In mod5 below, x1 and x2 are both PRIVATE since all modules from which they are accessed appear in PRIVATE statements:

```

MODULE mod5
  USE mod1
  USE mod2
  PRIVATE mod1
  PRIVATE mod2    ! x1 and x2 are PRIVATE
END MODULE

```

However, in mod6 below, both x1 and x2 are PUBLIC since they are accessible thru the use of mod2 which is declared PUBLIC:

```

MODULE mod6
  USE mod1
  USE mod2
  PRIVATE mod1
  PUBLIC mod2     ! x1 and x2 are PUBLIC
END MODULE

```

## USE\_DEVICE\_PTR Clause

**Parallel Directive Clause:** Tells the construct to use a device pointer currently in the device data environment.

### Syntax

```
USE_DEVICE_PTR (ptr-list)
```

*ptr-list*

Is a list of one or more variables of type C\_PTR from the intrinsic module ISO\_C\_BINDING<sup>1</sup>. The pointers are converted into device pointers to the corresponding list item in the device data environment.

<sup>1</sup> List items not of type C\_PTR have been deprecated in the OpenMP\* specification.

The pointers listed in *ptr-list* become private pointers in the device data environment. The device pointers to the corresponding list items in the device data environment are assigned to the private pointers.

References in the construct to a *ptr-list* item that appears in this clause must be to the address of the *ptr-list* item.

## %VAL

**Built-in Function:** *Changes the form of an actual argument. Passes the argument as an immediate value.*

### Syntax

%VAL (*a*)

*a*

(Input) An expression, record name, procedure name, array, character array section, or array element.

### Description

The argument is passed as follows:

- On IA-32 architecture, as a 32-bit immediate value. If the argument is integer (or logical) and shorter than 32 bits, it is sign-extended to a 32-bit value. For complex data types, %VAL passes two 32-bit arguments.
- On Intel® 64 architecture, as a 64-bit immediate value. If the argument is integer (or logical) and shorter than 64 bits, it is sign-extended to a 64-bit value. For complex data types, %VAL passes two 64-bit arguments.

You must specify %VAL in the actual argument list of a CALL statement or function reference. You cannot use it in any other context.

The following tables list the Intel® Fortran defaults for argument passing, and the allowed uses of %VAL:

### Expressions

Actual Argument Data Type	Default	%VAL
Logical	REF	Yes <sup>1</sup>
Integer	REF	Yes <sup>1</sup>
REAL(4)	REF	Yes
REAL(8)	REF	No
REAL(16)	REF	No
COMPLEX(4)	REF	Yes
COMPLEX(8)	REF	Yes
COMPLEX(16)	REF	No
Character	See table note <sup>2</sup>	No
Hollerith	REF	No
Aggregate <sup>3</sup>	REF	No
Derived	REF	No

**Array Name**

Actual Argument Data Type	Default	%VAL
Numeric	REF	No
Character	See table note <sup>2</sup>	No
Aggregate <sup>3</sup>	REF	No
Derived	REF	No

**Procedure Name**

Actual Argument Data Type	Default	%VAL
Numeric	REF	No
Character	See table note <sup>2</sup>	No

<sup>1</sup> If a logical or integer value occupies less than 64 bits of storage on Intel® 64 architecture, or 32 bits of storage on IA-32 architecture, it is converted to the correct size by sign extension. Use the [ZEXT](#) intrinsic function if zero extension is desired.

<sup>2</sup> A character argument is passed by address and hidden length.

<sup>3</sup> In Intel® Fortran record structures

The %VAL and %REF functions override related !DIR\$ ATTRIBUTE settings.

**Example**

```
CALL SUB(2, %VAL(2))
```

Constant 2 is passed by reference. The second constant 2 is passed by immediate value.

[CALL](#)

[%REF](#)

[%LOC](#)

**VALUE**

**Statement and Attribute:** *Specifies a type of argument association for a dummy argument.*

**Syntax**

The VALUE attribute can be specified in a type declaration statement or a VALUE statement, and takes one of the following forms:

**Type Declaration Statement:**

```
type, [att-ls, ] VALUE [, att-ls] :: arg [, arg] ...
```

**Statement:**

```
VALUE [::] arg [, arg]...
```

*type* Is a data type specifier.

*att-ls* Is an optional list of attribute specifiers.

*arg* Is the name of a dummy argument.

## Description

The VALUE attribute can be used in INTERFACE body or in a procedure. It can only be specified for dummy arguments. It cannot be specified for a dummy procedure.

An entity with the VALUE attribute must be a dummy data object that is not an assumed-size array or a coarray, and does not have a coarray ultimate component.

When this attribute is specified for a present dummy argument, the dummy argument becomes associated with a temporary, definable data object whose initial value is that of the corresponding actual argument. The actual mechanism by which this happens is determined by the compiler. If the procedure also has the BIND(C) attribute, the dummy argument is interoperable with the corresponding formal parameter of the C language prototype, causing the argument to be passed or received by value if C would do so.

When the VALUE attribute is used in a type declaration statement, any length type parameter values must be omitted or they must be specified by initialization expressions.

If the VALUE attribute is specified, you cannot specify a PARAMETER, EXTERNAL, POINTER, ALLOCATABLE, VOLATILE, or INTENT (INOUT or OUT) attribute in the same scoping unit.

You can use option `assume nostd_value` to tell the compiler to use non-standard semantics for VALUE so that the value of the actual argument is passed to the called procedure, not the address of the actual argument nor the address of a copy of the actual argument.

## Example

The following example shows how the VALUE attribute can be applied in a type declaration statement.

```
j = 3
call sub (j)
write (*,*) j ! Writes 3
contains
subroutine sub (i)
integer, value :: I
i = 4
write (*,*) i ! Writes 4
end subroutine sub
end
```

## VECREMAINDER Clause

**General Directive Clause:** *Allows the compiler to vectorize (or not to vectorize) any peel or remainder loops when the original loop is vectorized.*

---

## Syntax

[NO] VECREMAINDER

If `!DIR$ VECTOR ALWAYS` is specified, the following occurs:

- If VECREMAINDER is specified, the compiler vectorizes peel and remainder loops when the original main loop is vectorized.
- If NOVECREMAINDER is specified, the compiler does not vectorize peel or remainder loops when the original main loop is vectorized.

- If neither the VECREMAINDER or NOVECREMAINDER clause is specified, the compiler overrides efficiency heuristics of the vectorizer and it determines whether the loop can be vectorized.

## See Also

VECTOR and NOVECTOR

SIMD Loop Directive

## VECTOR and NOVECTOR

**General Compiler Directive:** Overrides default heuristics for vectorization of DO loops. It can also affect certain optimizations.

### Syntax

```
!DIR$ VECTOR [clause[[, clause]]...]
```

```
!DIR$ NOVECTOR
```

*clause*

Is an optional vectorization or optimizer clause. It can be one or more of the following:

- `ALIGNED` | `UNALIGNED`

Specifies that all data is aligned or no data is aligned in a DO loop. These clauses override efficiency heuristics in the optimizer.

The `ALIGNED` clause instructs the compiler to assume all array references are aligned. As a result, misalignment properties analyzed from the program context, if any, will be discarded. The `UNALIGNED` clause is a hint to the compiler to avoid alignment optimizations; the compiler can still use available alignment information. These clauses disable advanced alignment optimizations of the compiler, such as dynamic or static loop peeling to make references aligned.

Be careful when using the `ALIGNED` clause. The compiler may choose to use aligned data movement instructions, instructions with memory operands that require alignment, and/or nontemporal stores. Such instructions will cause a runtime exception if some of the access patterns are actually unaligned.

- `ALWAYS` [`ASSERT`]

Enables or disables vectorization of a DO loop.

The `ALWAYS` clause overrides efficiency heuristics of the vectorizer, but it only works if the loop can actually be vectorized. If the `ASSERT` keyword is added, the compiler will generate an error-level assertion message saying that the compiler efficiency heuristics indicate that the loop cannot be vectorized. You should use the `IVDEP` directive to ignore assumed dependences.

- `DYNAMIC_ALIGN` [(*var*)] | `NODYNAMIC_ALIGN`

Enables or disables dynamic alignment optimization. Dynamic alignment is an optimization the compiler attempts to perform by default. It involves peeling iterations from the vector loop into a scalar loop before the vector loop so that the vector loop aligns with a particular memory reference.

If you specify (*var*) for DYNAMIC\_ALIGN, you can indicate a scalar or array variable name on which to align. Specifying DYNAMIC\_ALIGN, with or without (*var*) does not guarantee the optimization is performed; the compiler still uses heuristics to determine feasibility of the optimization. The NODYNAMIC\_ALIGN clause disables the optimization for the loop.

- MASK\_READWRITE | NOMASK\_READWRITE

Enables or disables the generation of masked load and store operations within conditional statements.

The MASK\_READWRITE clause directs the compiler to disable memory speculation, causing the generation of masked load and store operations within conditional statements. The NOMASK\_READWRITE clause directs the compiler to enable memory speculation, causing the generation of unmasked loads and stores within conditional statements.

- [NO]MULTIPLE\_GATHER\_SCATTER\_BY\_SHUFFLES (can also be specified as [NO]G2S, which is deprecated)

Enables or disables the optimization for multiple adjacent gathers/scatters.

The MULTIPLE\_GATHER\_SCATTER\_BY\_SHUFFLES clause is an optimization hint to encourage use of unit-strided loads/stores plus a set of shuffles instead of multiple gathers/scatters (or straightforward gather/scatter emulation software sequences). The NOMULTIPLE\_GATHER\_SCATTER\_BY\_SHUFFLES clause tells the compiler not to try optimizing multiple gathers/scatters into unit-strided loads/stores plus a set of shuffles.

- TEMPORAL | NONTEMPORAL [(*var1* [, *var2*]...)]

*var*

Is an optional memory reference in the form of a variable name.

Controls how the "stores" of register contents to memory are performed (streaming versus non-streaming).

The TEMPORAL clause directs the compiler to use temporal (that is, non-streaming) stores. The NONTEMPORAL clause directs the compiler to use non-temporal (that is, streaming) stores.

By default, the compiler automatically determines whether a streaming store should be used for each variable.

Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.

- [NO]VECREMAINDER
- VECTORLENGTH (*n1* [, *n2*]...)

Tells the vectorizer which vector length/factor to use when generating the main vector loop. *n* is an integer power of 2; the value must be 2, 4, 8, 16, 32, or 64. If more than one value is specified, the vectorizer will choose one of the specified vector lengths based on a cost model decision.

The VECTOR and NOVECTOR directives control vectorization of the DO loop that directly follows the directive.

If the `MASK_READWRITE` clause is specified, the compiler generates masked loads and stores within all conditional branches in the loop. If the `NOMASK_READWRITE` clause is specified, the compiler generates unmasked loads and stores for increased performance.

### Caution

The `VECTOR` directive should be used with care. Overriding the efficiency heuristics of the compiler should only be done if you are absolutely sure the vectorization will improve performance.

## Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

Notice revision #20201201

## Example

The compiler normally does not vectorize DO loops that have a large number of non-unit stride references (compared to the number of unit stride references).

In the following example, vectorization would be disabled by default, but the directive overrides this behavior:

```
!DIR$ VECTOR ALWAYS
do i = 1, 100, 2
  ! two references with stride 2 follow
  a(i) = b(i)
enddo
```

There may be cases where you want to explicitly avoid vectorization of a loop; for example, if vectorization would result in a performance regression rather than an improvement. In these cases, you can use the `NOVECTOR` directive to disable vectorization of the loop.

In the following example, vectorization would be performed by default, but the directive overrides this behavior:

```
!DIR$ NOVECTOR
do i = 1, 100
  a(i) = b(i) + c(i)
enddo
```

## VERIFY

**Elemental Intrinsic Function (Generic):** Verifies that a set of characters contains all the characters in a string by identifying the first character in the string that is not in the set.

---

### Syntax

```
result = VERIFY (string, set [, back] [, kind])
```

<i>string</i>	(Input) Must be of type character.
<i>set</i>	(Input) Must be of type character with the same kind parameter as <i>string</i> .
<i>back</i>	(Input; optional) Must be of type logical.
<i>kind</i>	(Input; optional) Must be a scalar integer constant expression.

### Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

If *back* is omitted (or is present with the value false) and *string* has at least one character that is not in *set*, the value of the result is the position of the leftmost character of *string* that is not in *set*.

If *back* is present with the value true and *string* has at least one character that is not in *set*, the value of the result is the position of the rightmost character of *string* that is not in *set*.

If each character of *string* is in *set* or the length of *string* is zero, the value of the result is zero.

The setting of compiler options specifying integer size can affect this function.

### Example

VERIFY ('CDDDC', 'C') has the value 2.

VERIFY ('CDDDC', 'C', BACK=.TRUE.) has the value 4.

VERIFY ('CDDDC', 'CD') has the value zero.

The following shows another example:

```
INTEGER(4) position

position = VERIFY ('banana', 'nbc') ! returns 2
position = VERIFY ('banana', 'nbc', BACK=.TRUE.)
                                ! returns 6
position = VERIFY ('banana', 'nbca') ! returns 0
```

SCAN

## VIRTUAL

**Statement:** Has the same form and effect as the DIMENSION statement. It is included for compatibility with PDP-11 FORTRAN.

---

## See Also

### DIMENSION

## VOLATILE

**Statement and Attribute:** *Specifies that the value of an object is entirely unpredictable, based on information local to the current program unit. It prevents objects from being optimized during compilation.*

### Syntax

The VOLATILE attribute can be specified in a type declaration statement or a VOLATILE statement, and takes one of the following forms:

#### Type Declaration Statement:

```
type, [att-1s, ] VOLATILE [, att-1s] :: object[, object] ...
```

#### Statement:

```
VOLATILE [::] object[, object] ...
```

<i>type</i>	Is a data type specifier.
<i>att-1s</i>	Is an optional list of attribute specifiers.
<i>object</i>	Is the name of an object, <b>or the name of a common block enclosed in slashes.</b>

A variable **or COMMON block** must be declared VOLATILE if it can be read or written in a way that is not visible to the compiler. For example:

- If an operating system feature is used to place a variable in shared memory (so that it can be accessed by other programs), the variable must be declared VOLATILE.
- If a variable is accessed or modified by a routine called by the operating system when an asynchronous event occurs, the variable must be declared VOLATILE.

If an array is declared VOLATILE, each element in the array becomes volatile. **If a common block is declared VOLATILE, each variable in the common block becomes volatile.**

If an object of derived type is declared VOLATILE, its components become volatile.

If a pointer is declared VOLATILE, the pointer itself becomes volatile.

A VOLATILE statement cannot specify the following:

- A procedure
- A namelist group

The VOLATILE attribute must not be specified for a coarray that is accessed by use or host association. A noncoarray object that has the VOLATILE attribute can be associated with an object that does not have the VOLATILE attribute, including by use or host association. A data object with the VOLATILE attribute may not be declared in a PURE procedure or referenced by a PURE statement function.

### Example

The following example shows a type declaration statement specifying the VOLATILE attribute:

```
INTEGER, VOLATILE :: D, E
```

The following example shows a VOLATILE statement:

```
PROGRAM TEST
LOGICAL(KIND=1) IPI(4)
INTEGER(KIND=4) A, B, C, D, E, ILOOK
INTEGER(KIND=4) P1, P2, P3, P4
COMMON /BLK1/ A, B, C
VOLATILE /BLK1/ D, E
EQUIVALENCE(ILOOK, IPI)
EQUIVALENCE(A, P1)
EQUIVALENCE(P1, P4)
```

The named common block, BLK1, and the variables D and E are volatile. Variables P1 and P4 become volatile because of the direct equivalence of P1 and the indirect equivalence of P4.

## WAIT

**Statement:** *Performs a wait operation for a specified pending asynchronous data transfer operation. It takes one of the following forms:*

---

### Syntax

```
WAIT([UNIT=io-unit] [, END=label] [, EOR=label] [, ERR=label] [, ID=id-var] [, IOMSG=msg-var] [, IOSTAT=i-var])
```

```
WAIT io-unit
```

<i>io-unit</i>	(Input) Is an external unit specifier.
<i>label</i>	(Input) Is the label of the branch target statement that receives control if an error occurs.
<i>id-var</i>	(Input) Is a scalar integer variable that is the identifier of a pending data transfer operation for the specified unit. If it is specified, a wait operation is performed for that pending operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.
<i>msg-var</i>	(Output) Is a scalar default character variable that is assigned an explanatory message if an I/O error occurs.
<i>i-var</i>	(Output) Is a scalar integer variable that is defined as a positive integer if an error occurs and zero if no error occurs.

A wait operation completes the processing of a pending data transfer operation. Each wait operation completes only a single data transfer operation, although a single statement may perform multiple wait operations.

The WAIT statement specifiers can appear in any order. An I/O unit must be specified, but the UNIT= keyword is optional if the unit specifier is the first item in the I/O control list.

The EOR= specifier only has effect if the pending data transfer operation is a nonadvancing read. The END= specifier only has effect if the pending data transfer operation is a READ.

## Example

The following example shows how the WAIT statement can be applied.

```
program test
integer, asynchronous, dimension(100) :: array
open (unit=1,file='asynch.dat',asynchronous='YES',&
     form='unformatted')
write (1) (i,i=1,100)
rewind (1)
read (1,asynchronous='YES') array
wait(1)
write (*,*) array(1:10)
end
```

## WHERE

**Statement and Construct:** Lets you use masked array assignment, which performs an array operation on selected elements. This kind of assignment applies a logical test to an array on an element-by-element basis.

### Syntax

#### Statement:

```
WHERE (mask-expr1) assign-stmt
```

#### Construct:

```
[name:]WHERE (mask-expr1)
    [where-body-stmt] ...
[ELSE WHERE (mask-expr2) [name]
    [where-body-stmt] ...]
[ELSE WHERE [name]
    [where-body-stmt] ...]
END WHERE [name]
```

*mask-expr1, mask-expr2*

Are logical array expressions (called mask expressions).

*assign-stmt*

Is an assignment statement of the form: array variable = array expression.

*name*

Is the name of the WHERE construct.

*where-body-stmt*

Is one of the following:

- An *assign-stmt*  
The assignment can be a defined assignment only if the routine implementing the defined assignment is elemental.
- A WHERE statement or construct

## Description

If a construct *name* is specified in a WHERE statement, the same name must appear in the corresponding END WHERE statement. The same construct name can optionally appear in any ELSE WHERE statement in the construct. (ELSE WHERE cannot specify a different name.)

In each assignment statement, the mask expression, the variable being assigned to, and the expression on the right side, must all be conformable. Also, the assignment statement cannot be a defined assignment.

Only the WHERE statement (or the first line of the WHERE construct) can be labeled as a branch target statement.

The following shows an example using a WHERE statement:

```
INTEGER A, B, C
DIMENSION A(5), B(5), C(5)
DATA A /0,1,1,1,0/
DATA B /10,11,12,13,14/
C = -1

WHERE(A .NE. 0) C = B / A
```

The resulting array C contains: -1,11,12,13, and -1.

The assignment statement is only executed for those elements where the mask is true. Think of the mask expression as being evaluated first into a logical array that has the value true for those elements where A is positive. This array of trues and falses is applied to the arrays A, B and C in the assignment statement. The right side is only evaluated for elements for which the mask is true; assignment on the left side is only performed for those elements for which the mask is true. The elements for which the mask is false do not get assigned a value.

In a WHERE construct, the mask expression is evaluated first and only once. Every assignment statement following the WHERE is executed as if it were a WHERE statement with "*mask-expr1*" and every assignment statement following the ELSE WHERE is executed as if it were a WHERE statement with ".NOT. *mask-expr1*". If ELSE WHERE specifies "*mask-expr2*", it is executed as "(.NOT. *mask-expr1*) .AND. *mask-expr2*" during the processing of the ELSE WHERE statement.

You should be careful if the statements have side effects, or modify each other or the mask expression.

The following is an example of the WHERE construct:

```
DIMENSION PRESSURE(1000), TEMP(1000), PRECIPITATION(1000)
WHERE(PRESSURE .GE. 1.0)
  PRESSURE = PRESSURE + 1.0
  TEMP = TEMP - 10.0
ELSEWHERE
  PRECIPITATION = .TRUE.
ENDWHERE
```

The mask is applied to the arguments of functions on the right side of the assignment if they are considered to be elemental functions. Only elemental intrinsics are considered elemental functions. Transformational intrinsics, inquiry intrinsics, and functions or operations defined in the subprogram are considered to be nonelemental functions.

Consider the following example using LOG, an elemental function:

```
WHERE(A .GT. 0) B = LOG(A)
```

The mask is applied to A, and LOG is executed only for the positive values of A. The result of the LOG is assigned to those elements of B where the mask is true.

Consider the following example using SUM, a nonelemental function:

```
REAL A, B
DIMENSION A(10,10), B(10)
WHERE(B .GT. 0.0) B = SUM(A, DIM=1)
```

Since SUM is nonelemental, it is evaluated fully for all of A. Then, the assignment only happens for those elements for which the mask evaluated to true.

Consider the following example:

```
REAL A, B, C
DIMENSION A(10,10), B(10), C(10)
WHERE (C .GT. 0.0) B = SUM(LOG(A), DIM=1)/C
```

Because SUM is nonelemental, all of its arguments are evaluated fully regardless of whether they are elemental or not. In this example, LOG(A) is fully evaluated for all elements in A even though LOG is elemental. Notice that the mask is applied to the result of the SUM and to C to determine the right side. One way of thinking about this is that everything inside the argument list of a nonelemental function does not use the mask, everything outside does.

## Example

```
REAL(4) a(20)
. . .
WHERE (a > 0.0)
  a = LOG (a)
  !LOG is invoked only for positive elements
END WHERE
```

Arrays

## WORKSHARE

**OpenMP\* Fortran Compiler Directive:** Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.

## Syntax

```
!$OMP WORKSHARE
```

```
    loosely-structured-block
```

```
!$OMP END WORKSHARE [NOWAIT]
```

-or-

```
!$OMP WORKSHARE
```

```
    strictly-structured-block
```

```
!$OMP END WORKSHARE [NOWAIT]
```

*loosely-structured-block* Is a structured block (section) of statements or constructs. You cannot branch into or out of the block.

*strictly-structured-block* Is a Fortran BLOCK construct. You cannot branch into or out of the BLOCK construct.

The *loosely-structured-block* or *strictly-structured-block* is executed so that each statement is completed before the next statement is started and the evaluation of the right hand side of an assignment is completed before the effects of assigning to the left hand side occur.

The following are additional rules for the block:

- It may contain statements that bind to lexically enclosed PARALLEL constructs. Statements in these PARALLEL constructs are not restricted.

- It may contain ATOMIC directives and CRITICAL constructs.
- It must only contain array assignment statements, scalar assignment statements, FORALL statements, FORALL constructs, WHERE statements, or WHERE constructs.
- It must not contain any user-defined function calls unless the function is ELEMENTAL.

The binding thread set for a WORKSHARE construct is the current team. A workshare region binds to the innermost enclosing parallel region.

If you do not specify the NOWAIT keyword, synchronization is implied following the code.

Multithreaded code is not always generated for the statements inside the block of an OMP WORKSHARE construct. Some statements parallelize; others do not parallelize and instead execute sequentially inside an OMP SINGLE construct to preserve the correct semantics of WORKSHARE. Some specific details follow:

- Simple array assignments such as  $A = B + C$  parallelize.
- Simple array assignments with overlap such as  $A = A + B + C$  parallelize.
- Array assignments with user-defined function calls parallelize such as  $A = A + F(B)$ .  $F$  must be ELEMENTAL.
- Array assignments with array slices on the right hand side of the assignment such as  $A = A + B(1:4) + C(1:4)$  parallelize. If the lower bound of the left hand side or the array slice lower bound or the array slice stride on the right hand side is not 1, then the statement does not parallelize.
- Assigning into array slices does not parallelize.
- Scalar assignments do not parallelize – there is no work that needs to be done in parallel.
- FORALL and WHERE constructs do not parallelize.

## WRITE Statement

**Statement:** *Transfers output data to external sequential, direct-access, or internal records.*

---

### Syntax

#### Sequential

##### Formatted:

```
WRITE (eunit, format [, advance] [, asynchronous] [, decimal] [, id] [, pos] [, round] [, sign] [, iostat] [, err] [, iomsg))[io-list]
```

##### Formatted - List-Directed:

```
WRITE (eunit, * [, asynchronous] [, decimal] [, delim] [, id] [, pos] [, round] [, sign] [, iostat] [, err] [, iomsg))[io-list]
```

##### Formatted - Namelist:

```
WRITE (eunit, nml-group [, asynchronous] [, decimal] [, delim] [, id] [, pos] [, round] [, sign] [, iostat] [, err] [, iomsg])
```

##### Unformatted:

```
WRITE (eunit [, asynchronous] [, id] [, pos] [, iostat] [, err] [, iomsg))[io-list]
```

#### Direct-Access

##### Formatted:

```
WRITE (eunit, format, rec [, asynchronous] [, decimal] [, delim] [, id] [, pos] [, round] [, sign] [, iostat] [, err] [, iomsg))[io-list]
```

**Unformatted:**

```
WRITE (eunit, rec [, asynchronous] [, id] [, pos] [, iostat] [, err] [, iomsg))[io-list]
```

**Internal**

```
WRITE (iunit, format [, nml-group] [, iostat] [, err] [, iomsg))[io-list]
```

**Internal Namelist**

```
WRITE (iunit, nml-group [, iostat] [, err] [, iomsg))[io-list]
```

<i>eunit</i>	Is an external <a href="#">unit specifier</a> , optionally prefaced by UNIT=. UNIT= is required if <i>eunit</i> is not the first specifier in the list.
<i>format</i>	Is a <a href="#">format specifier</a> . It is optionally prefaced by FMT= if <i>format</i> is the second specifier in the list and the first specifier indicates a logical or internal unit specifier <i>without</i> the optional keyword UNIT=.
<i>advance</i>	Is an <a href="#">advance specifier</a> (ADVANCE= <i>c-expr</i> ). If the value of <i>c-expr</i> is 'YES', the statement uses advancing input; if the value is 'NO', the statement uses nonadvancing input. The default value is 'YES'.
<i>asynchronous</i>	Is an <a href="#">asynchronous specifier</a> (ASYNCHRONOUS= <i>i-expr</i> ). If the value of <i>i-expr</i> is 'YES', the statement uses asynchronous input; if the value is 'NO', the statement uses synchronous input. The default value is 'NO'.
<i>decimal</i>	Is a decimal mode specifier (DECIMAL= <i>dmode</i> ) that evaluates to 'COMMA' or 'POINT'. The default value is 'POINT'.
<i>delim</i>	Is a delimiter specifier (DELIM= <i>del</i> ). If the value of <i>del</i> is 'APOSTROPHE', apostrophes delimit character constants. If the value is 'QUOTE', quotes delimit character constants. If the value of <i>del</i> is 'NONE', character constants have no delimiters.
<i>id</i>	Is an <a href="#">id specifier</a> (ID= <i>id-var</i> ). If ASYNCHRONOUS='YES' is specified and the operation completes successfully, the id specifier becomes defined with an implementation-dependent value that can be specified in a future WAIT or INQUIRE statement to identify the particular data transfer operation. If an error occurs, the id specifier variable becomes undefined.
<i>pos</i>	Is a <a href="#">pos specifier</a> (POS= <i>p</i> ) that indicates a file position in file storage units in a stream file (ACCESS='STREAM'). It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.
<i>round</i>	Is a <a href="#">rounding specifier</a> (ROUND= <i>rmode</i> ) that determines the I/O rounding mode for this WRITE statement. If omitted, the rounding mode is unchanged. Possible values are UP, DOWN, ZERO, NEAREST, COMPATIBLE or PROCESSOR_DEFINED.
<i>sign</i>	Is a <a href="#">plus sign specifier</a> (SIGN= <i>sn</i> ). This controls whether optional plus characters appear in formatted numeric output.
<i>iostat</i>	Is the name of a variable to contain the <a href="#">completion status</a> of the I/O operation. Optionally prefaced by IOSTAT=.
<i>err</i>	Are <a href="#">branch specifiers</a> if an error (ERR= <i>label</i> ) condition occurs.

<i>iomsg</i>	Is an <a href="#">I/O message specifier</a> ( <code>IOMSG=msg-var</code> ).
<i>io-list</i>	Is an <a href="#">I/O list</a> : the names of the variables, arrays, array elements, or character substrings from which or to which data will be transferred. Optionally an implied-DO list.
<i>form</i>	Is the nonkeyword form of a format specifier (no <code>FMT=</code> ).
<i>*</i>	Is the format specifier indicating list-directed formatting. (It can also be specified as <code>FMT= *</code> .)
<i>nml-group</i>	Is the namelist group specification for namelist I/O. Optionally prefaced by <code>NML=</code> . <code>NML=</code> is required if <i>nml-group</i> is not the second I/O specifier. For more information, see <a href="#">Namelist Specifier</a> .
<i>rec</i>	Is the cell number of a <a href="#">record</a> to be accessed directly. It must be prefaced by <code>REC=</code> .
<i>iunit</i>	<p>Is an internal unit specifier, optionally prefaced by <code>UNIT=</code>. <code>UNIT=</code> is required if <i>iunit</i> is not the first specifier in the list.</p> <p>It must be a character variable. It must not be an array section with a vector subscript.</p> <p>If an item in <i>io-list</i> is an expression that calls a function, that function must not execute an I/O statement or the EOF intrinsic function on the same external unit as <i>eunit</i>.</p>

If you specify `DECIMAL=`, `ROUND=`, or `SIGN=` you must also specify `FMT=` or `NML=`.

If you specify `ID=`, you must also specify `ASYNCHRONOUS='YES'`.

### Example

```
! write to file
open(1,FILE='test.dat')
write (1, '(A20)') namedef
! write with FORMAT statement
WRITE (*, 10) (n, SQRT(FLOAT(n)), FLOAT(n)**(1.0/3.0), n = 1, 100)
10 FORMAT (I5, F8.4, F8.5)
```

The following shows another example:

```
WRITE(6, '("Expected ",F12.6)') 2.0
```

## XOR

**Elemental Intrinsic Function (Generic):** An alternative name for intrinsic function IEOR.

---

### See Also

See [IEOR](#).

## ZEXT

**Elemental Intrinsic Function (Generic):** Extends an argument with zeros. This function is used primarily for bit-oriented operations. It cannot be passed as an actual argument.

---

### Syntax

```
result = ZEXT (x [,kind])
```

*x* (Input) Must be of type logical or integer.

*kind* (Input; optional) Must be a scalar integer constant expression.

### Results

The result type is integer. If *kind* is present, the kind parameter of the result is that specified by *kind*; otherwise, the kind parameter of the result is that of default integer. If the processor cannot represent the result value in the kind of the result, the result is undefined.

The result value is *x* extended with zeros and treated as an unsigned value.

The storage requirements for integer constants are never less than two bytes. Integer constants within the range of constants that can be represented by a single byte still require two bytes of storage.

The setting of compiler options specifying integer size can affect this function.

Specific Name <sup>1</sup>	Argument Type	Result Type
IZEXT	LOGICAL(1)	INTEGER(2)
	LOGICAL(2)	INTEGER(2)
	INTEGER(1)	INTEGER(2)
	INTEGER(2)	INTEGER(2)
JZEXT	LOGICAL(1)	INTEGER(4)
	LOGICAL(2)	INTEGER(4)
	LOGICAL(4)	INTEGER(4)
	INTEGER(1)	INTEGER(4)
	INTEGER(2)	INTEGER(4)
	INTEGER(4)	INTEGER(4)
KZEXT	LOGICAL(1)	INTEGER(8)
	LOGICAL(2)	INTEGER(8)

Specific Name <sup>1</sup>	Argument Type	Result Type
	LOGICAL(4)	INTEGER(8)
	LOGICAL(8)	INTEGER(8)
	INTEGER(1)	INTEGER(8)
	INTEGER(2)	INTEGER(8)
	INTEGER(4)	INTEGER(8)
	INTEGER(8)	INTEGER(8)

<sup>1</sup>These specific functions cannot be passed as actual arguments.

## Example

Consider the following example:

```
INTEGER(2) W_VAR  /'FFFF'X/
INTEGER(4) L_VAR
L_VAR = ZEXT( W_VAR )
```

This example stores an INTEGER(2) quantity in the low-order 16 bits of an INTEGER(4) quantity, with the resulting value of L\_VAR being '0000FFFF'X. If the ZEXT function had not been used, the resulting value would have been 'FFFFFFFF'X, because W\_VAR would have been converted to the left-hand operand's data type by sign extension.

## POSIX\* Library Routines

This section contains descriptions of the POSIX\* library routines. They are listed in alphabetical order.

To access the POSIX library, you must specify a USE IFPOSIX statement in your program.

Certain POSIX\* routines are restricted to Linux\* and macOS systems. If a routine is restricted, it will say that in the description.

### IPXFARGC

**POSIX Function:** Returns the index of the last command-line argument.

#### Module

USE IFPOSIX

#### Syntax

```
result = IPXFARGC( )
```

#### Results

The result type is INTEGER(4). The result value is the number of command-line arguments, excluding the command name, in the command used to invoke the executing program. A return value of zero indicates there are no command-line arguments other than the command name itself.

#### See Also

PXFGETARG

## IPXFCONST

**POSIX Function:** Returns the value associated with a constant defined in the C POSIX standard.

---

### Module

USE IFPOSIX

### Syntax

```
result = IPXFCONST (constname)
```

*constname* (Input) Character. The name of a C POSIX standard constant.

### Results

The result type is INTEGER(4). If *constname* corresponds to a defined constant in the C POSIX standard, the result value is the integer that is associated with the constant. Otherwise, the result value is -1.

### See Also

PXFGETARG

PXFCONST

## IPXFLENTTRIM

**POSIX Function:** Returns the index of the last non-blank character in an input string.

---

### Module

USE IFPOSIX

### Syntax

```
result = IPXFLENTTRIM (string)
```

*string* (Input) Character. A character string.

### Results

The result type is INTEGER(4). The result value is the index of the last non-blank character in the input argument *string*, or zero if all characters in *string* are blank characters.

## IPXFWEXITSTATUS

**POSIX Function:** Returns the exit code of a child process. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

```
result = IPXFWEXITSTATUS (istat)
```

*istat* (Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

## Results

The result type is `INTEGER(4)`. The result is the low-order eight bits of the output argument of `PXFWAIT` or `PXFWAITPID`.

The `IPXFWEXITSTATUS` function should only be used if `PXFWIFEXITED` returns `TRUE`.

## Example

```
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, " the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET, IERROR)
if(IPID.EQ.0) then
  print *, " I am a child process"
  print *, " My child's pid is", IPID_RET
  call PXFGETPPID(IPID_RET, IERROR)
  print *, " The pid of my parent is", IPID_RET
  print *, " Now I have exited with code 0xABCD"
  call PXFEXIT(Z'ABCD')
else
  print *, " I am a parent process"
  print *, " My parent pid is ", IPID_RET
  print *, " I am creating the process with pid", IPID
  print *, " Now I am waiting for the end of the child process"
  call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *, " The child with pid ", IPID_RET, " has exited"
  if( PXFWIFEXITED(ISTAT) ) then
    print *, " The child exited normally"
    istat_ret = IPXFWEXITSTATUS(ISTAT)
    print 10, " The low byte of the child exit code is", istat_ret
  end if
end if
10 FORMAT (A,Z)
end program
```

## See Also

## IPXFWSTOPSIG

**POSIX Function:** Returns the number of the signal that caused a child process to stop. This routine is only available for Linux and macOS.

---

## Module

`USE IFPOSIX`

## Syntax

```
result = IPXFWSTOPSIG (istat)
```

*istat* (Input) `INTEGER(4)`. The value of output argument *istat* from `PXFWAIT` or `PXFWAITPID`.

## Results

The result type is INTEGER(4). The result is the number of the signal that caused the child process to stop. The IPXFWSTOPSIG function should only be used if PXFWIFSTOPPED returns TRUE.

## See Also

PXFWAIT  
PXFWAITPID  
PXFWIFSTOPPED

## IPXFWTERMSIG

**POSIX Function:** Returns the number of the signal that caused a child process to terminate. This routine is only available for Linux and macOS.

## Module

USE IFPOSIX

## Syntax

```
result = IPXFWTERMSIG (istat)
```

*istat* (Input) INTEGER(4). The value of output argument *istat* from PXFWAIT or PXFWAITPID.

## Results

The result type is INTEGER(4). The result is the number of the signal that caused the child process to terminate.

The IPXFWTERMSIG function should only be used if PXFWIFSIGNALLED returns TRUE.

## See Also

PXFWAIT  
PXFWAITPID  
PXFWIFSIGNALLED

## PXFGET

**POSIX Subroutine:** Gets the value stored in a component (or field) of a structure.

## Module

USE IFPOSIX

## Syntax

```
CALL PXF(type)GET (jhandle, compname, value, ierror)
```

```
CALL PXF(type)GET (jhandle, compname, value, ilen, ierror) ! syntax when (type) is STR
```

(type)

A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFINTGET

Value	Data Type	Routine Name
REAL	REAL(4)	PXFREALGET
LGCL	LOGICAL(4)	PXFLGCLGET
STR	CHARACTER*(*)	PXFSTRGET
CHAR	CHARACTER(1)	PXFCHARGET
DBL	REAL(8)	PXFDBLGET
INT8	INTEGER(8)	PXFINT8GET

<i>jhandle</i>	(Input) INTEGER(4). A handle of a structure.
<i>compname</i>	(Input) Character. The name of the component (or field) of the structure to retrieve data from.
<i>value</i>	(Output) A variable, whose data type depends on the value of <i>(type)</i> . See the table above for the data types for each value; for example, if the value for <i>(type)</i> is INT, the data type is INTEGER(4). Stores the value of the component (or field).
<i>ilen</i>	(Output) INTEGER(4). This argument can only be used when <i>(type)</i> is STR (PXFSTRGET). Stores the length of the returned string.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXF(*type*)GET subroutines retrieve the value from component (or field) *compname* of the structure associated with handle *jhandle* into variable *value*.

## Example

See the example in [PXFTIMES](#) (which shows PXFINTGET and PXFINT8GET)

## See Also

PXF(*type*)SET

## PXFSET

**POSIX Subroutine:** Sets the value of a component (or field) of a structure.

## Module

USE IFPOSIX

## Syntax

```
CALL PXF(type)SET (jhandle,compname,value,ierror)
```

```
CALL PXF(type)SET (jhandle,compname,value,ilen,ierror) ! syntax when (type) is STR
```

*(type)*

A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFINTSET
REAL	REAL(4)	PXFREALSET
LGCL	LOGICAL(4)	PXFLGCLSET
STR	CHARACTER*(*)	PXFSTRSET
CHAR	CHARACTER(1)	PXFCHARSET
DBL	REAL(8)	PXFDBLSET
INT8	INTEGER(8)	PXFINT8SET

*jhandle* (Input) INTEGER(4). A handle of a structure.

*compname* (Input) Character. The name of the component (or field) of the structure to write data to.

*value* (Input) A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). The value for the component (or field).

*ilen* (Input) INTEGER(4). This argument can only be used when *(type)* is STR (PXFSSTRSET). The length of the string in *value*.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## Example

See the example in [PXFSSTRUCTCREATE](#) (which shows PXFSSTRSET)

## See Also

PXF(type)GET

## PXFAGET

**POSIX Subroutine:** Gets the array values stored in a component (or field) of a structure.

## Module

USE IFPOSIX

## Syntax

```
CALL PXFA(type)GET (jhandle, compname, value, ialen, ierror)
```

```
CALL PXFA(type)GET (jhandle, compname, value, ialen, ilen, ierror) ! syntax when (type) is STR
```

*(type)*

A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFAINTGET
REAL	REAL(4)	PXFAREALGET
LGCL	LOGICAL(4)	PXFALGCLGET
STR	CHARACTER*(*)	PXFASTRGET
CHAR	CHARACTER(1)	PXFACHARGET
DBL	REAL(8)	PXFADBLGET
INT8	INTEGER(8)	PXFAINT8GET

<i>jhandle</i>	(Input) INTEGER(4). A handle of a structure.
<i>compname</i>	(Input) Character. The name of the component (or field) of the structure to retrieve data from.
<i>value</i>	(Output) An array, whose data type depends on the value of <i>(type)</i> . See the table above for the data types for each value; for example, if the value for <i>(type)</i> is INT, the data type of the array is INTEGER(4). Stores the value of the component (or field).
<i>ialen</i>	(Input) INTEGER(4). The size of array <i>value</i> .
<i>ilen</i>	(Output) INTEGER(4). This argument can only be used when <i>(type)</i> is STR (PXFASTRGET). An array that stores the lengths of elements of array <i>value</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFA(*type*)GET subroutines are similar to the PXF(*type*)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(*type*)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

## See Also

PXFA(*type*)SET  
PXF(*type*)GET

## PXFASET

**POSIX Subroutine:** Sets the value of an array component (or field) of a structure.

## Module

USE IFPOSIX

## Syntax

```
CALL PXFA(type)SET (jhandle, compname, value, ialen, ierror)
```

```
CALL PXFA(type)SET (jhandle, compname, value, ialen, ilen, ierror) ! syntax when (type) is STR
```

*(type)*

A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFAINTSET
REAL	REAL(4)	PXFAREALSET
LGCL	LOGICAL(4)	PXFALGCLSET
STR	CHARACTER*(*)	PXFASTRSET
CHAR	CHARACTER(1)	PXFACHARSET
DBL	REAL(8)	PXFADBLSET
INT8	INTEGER(8)	PXFAINT8SET

*jhandle*

(Input) INTEGER(4). A handle of a structure.

*compname*

(Input) Character. The name of the component (or field) of the structure to write data to.

*value*(Input) An array, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type of the array is INTEGER(4). The value for the component (or field).*ialen*(Input) INTEGER(4). The size of array *value*.*ilen*(Input) INTEGER(4). This argument can only be used when *(type)* is STR (PXFASTRSET). An array that specifies the lengths of elements of array *value*.*ierror*

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFA(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFA(type)GET subroutines are used, the entire array is accessed (read from the component or field) as a unit.

**See Also**

PXFA(type)GET

PXF(type)SET

**PXFACCESS****POSIX Subroutine:** Determines the accessibility of a file.**Module**

USE IFPOSIX

**Syntax**CALL PXFACCESS (*path,ilen,iamode,ierror*)

<i>path</i>	(Input) Character. The name of the file.
<i>ilen</i>	(Input) INTEGER(4). The length of the <i>path</i> string.
<i>iamode</i>	(Input) INTEGER(4). One or more of the following: <hr/>
0	Checks for existence of the file.
1 <sup>1</sup>	Checks for execute permission.
2	Checks for write access.
4	Checks for read access.
6	Checks for read/write access.
1L*X only	

---

<i>ierror</i>	(Output) INTEGER(4). The error status.
---------------	--

If access is permitted, the result value is zero; otherwise, an error code. Possible error codes are:

- -1: A bad parameter was passed.
- ENOENT: The named directory does not exist.
- EACCES: Access requested was denied.

On Windows\* systems, if the name given is a directory name, the function only checks for existence. All directories have read/write access on Windows\* systems.

## PXFALARM

**POSIX Subroutine:** *Schedules an alarm.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFALARM (*iseconds*,*isecleft*,*ierror*)

<i>iseconds</i>	(Input) INTEGER(4). The number of seconds before the alarm signal should be delivered.
<i>isecleft</i>	(Output) INTEGER(4). The number of seconds remaining until any previously scheduled alarm signal is due to be delivered. It is set to zero if there was no previously scheduled alarm signal.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFALARM subroutine arranges for a SIGALRM signal to be delivered to the process in seconds *iseconds*.

On Linux\* and macOS systems, SIGALRM is a reserved defined constant that is equal to 14. You can use any other routine to install the signal handler. You can get SIGALRM and other signal values by using PXFCONST or IPXFCONST.

On Windows\* systems, the SIGALRM feature is not supported, but the POSIX library has an implementation you can use. You can provide a signal handler for SIGALRM by using PXFSIGACTION.

**See Also**

PXFCNST  
IPXFCNST  
PXFSIGACTION

**PXFCALLSUBHANDLE**

**POSIX Subroutine:** *Calls the associated subroutine.*

---

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCALLSUBHANDLE (*jhandle2*,*ival*,*ierror*)

*jhandle2* (Input) INTEGER(4). A handle to the subroutine.

*ival* (Input) INTEGER(4). The argument to the subroutine.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFCALLSUBHANDLE subroutine, when given a subroutine handle, calls the associated subroutine.

PXFGETSUBHANDLE should be used to obtain a subroutine handle.

---

**NOTE**

The subroutine cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

---

**See Also**

PXFGETSUBHANDLE

**PXFCFGETISPEED**

**POSIX Subroutine:** *Returns the input baud rate from a `termios` structure. This routine is only available for Linux and macOS.*

---

**Module**

USE IFPOSIX

**Syntax**

CALL PXFCFGETISPEED (*jtermios*,*iospeed*,*ierror*)

*jtermios* (Input) INTEGER(4). A handle of structure `termios`.

*iospeed* (Output) INTEGER(4). The returned value of the input baud rate from the structure associated with handle *jtermios*.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

**NOTE**

To get a handle for an instance of the `termios` structure, use `PXFSTRUCTCREATE` with the string 'termios' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`

`PXFCFSETISPEED`

**PXFCFGETOSPEED**

**POSIX Subroutine:** Returns the output baud rate from a `termios` structure. This routine is only available for Linux and macOS.

---

**Module**

`USE IFPOSIX`

**Syntax**

`CALL PXFCFGETOSPEED (jtermios, iospeed, ierror)`

`jtermios` (Input) INTEGER(4). A handle of structure `termios`.

`iospeed` (Output) INTEGER(4). The returned value of the output baud rate from the structure associated with handle `jtermios`.

`ierror` (Output) INTEGER(4). The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

---

**NOTE**

To get a handle for an instance of the `termios` structure, use `PXFSTRUCTCREATE` with the string 'termios' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`

`PXFCFSETOSPEED`

**PXFCFSETISPEED**

**POSIX Subroutine:** Sets the input baud rate in a `termios` structure. This routine is only available for Linux and macOS.

---

**Module**

`USE IFPOSIX`

**Syntax**

`CALL PXFCFSETISPEED (jtermios, ispeed, ierror)`

`jtermios` (Input) INTEGER(4). A handle of structure `termios`.

*ispeed* (Input) INTEGER(4). The value of the input baud rate for the structure associated with handle *jtermios*.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

**NOTE**

To get a handle for an instance of the `termios` structure, use `PXFSTRUCTCREATE` with the string 'termios' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`  
`PXFCFGETISPEED`

**PXFCFSETOSPEED**

**POSIX Subroutine:** *Sets the output baud rate in a termios structure. This routine is only available for Linux and macOS.*

---

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFCFSETOSPEED (jtermios, ispeed, ierror)
```

*jtermios* (Input) INTEGER(4). A handle of structure `termios`.

*ispeed* (Input) INTEGER(4). The value of the output baud rate for the structure associated with handle *jtermios*.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

**NOTE**

To get a handle for an instance of the `termios` structure, use `PXFSTRUCTCREATE` with the string 'termios' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`  
`PXFCFGETOSPEED`

**PXFCHDIR**

**POSIX Subroutine:** *Changes the current working directory.*

---

**Module**

USE IFPOSIX

## Syntax

```
CALL PXFCHDIR (path,ilen,ierror)
```

<i>path</i>	(Input) Character. The directory to be changed to.
<i>ilen</i>	(Input) INTEGER(4). The length of the <i>path</i> string.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## See Also

PXFMKDIR

## PXFCHMOD

**POSIX Subroutine:** *Changes the ownership mode of the file.*

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFCHMOD (path,ilen,imode,ierror)
```

<i>path</i>	(Input) Character. The path to the file.
<i>ilen</i>	(Input) INTEGER(4). The length of the <i>path</i> string.
<i>imode</i>	(Input) INTEGER(4). The ownership mode of the file. On Windows* systems, see your Microsoft* Visual C++ Installation in the <code>\include</code> directory under <code>sys\stat.h</code> for the values of <i>imode</i> . On Linux* and macOS systems, use octal file-access mode.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

### NOTE

On Linux\* and macOS systems, you must have sufficient ownership permissions, such as being the owner of the file or having read/write access of the file.

---

## PXFCHOWN

**POSIX Subroutine:** *Changes the owner and group of a file. This routine is only available for Linux and macOS.*

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFCHOWN (path,ilen,iowner,igroup,ierror)
```

<i>path</i>	(Input) Character. The path to the file.
<i>ilen</i>	(Input) INTEGER(4). The length of the <i>path</i> string.
<i>iowner</i>	(Input) INTEGER(4). The owner UID.
<i>igroup</i>	(Input) INTEGER(4). The group GID.
<i>error</i>	(Output) INTEGER(4). The error status.

If successful, *error* is set to zero; otherwise, an error code.

## PXFCLEARENV

**POSIX Subroutine:** *Clears the process environment.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFCLEARENV (*error*)

<i>error</i>	(Output) INTEGER(4). The error status.
--------------	--

If successful, *error* is set to zero; otherwise, an error code.

After a call to PXFCLEARENV, no environment variables are defined.

## PXFCLOSE

**POSIX Subroutine:** *Closes the file associated with the descriptor.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFCLOSE (*fd*, *error*)

<i>fd</i>	(Input) INTEGER(4). A file descriptor.
<i>error</i>	(Output) INTEGER(4). The error status.

If successful, *error* is set to zero; otherwise, an error code.

### See Also

PXFOPEN

## PXFCLOSEDIR

**POSIX Subroutine:** *Closes the directory stream.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFCLOSEDIR (*idirid*, *error*)

*idirid* (Input) INTEGER(4). The directory ID obtained from PXFOPENDIR.  
*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFCLOSEDIR subroutine closes the directory associated with *idirid*.

## See Also

PXFOPENDIR

## PXFCONST

**POSIX Subroutine:** Returns the value associated with a constant.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFCONST (*constname*, *ival*, *ierror*)

*constname* (Input) Character. The name of one of the following constants:

- STDIN\_UNIT
- STDOUT\_UNIT
- STDERR\_UNIT
- EINVAL
- ENONAME
- ENOHANDLE
- EARRAYLEN
- ENOENT
- ENOTDIR
- EACCES

The constants beginning with E signify various error values for the system variable `errno`.

*ival* (Output) INTEGER(4). The returned value of the constant.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, it is set to -1.

For more information on these constants, see your Microsoft\* Visual C++ documentation (Windows\* systems) or the `errno.h` file (Linux\* and macOS systems).

## See Also

PXFISCONST

## PXFCREAT

**POSIX Subroutine:** Creates a new file or rewrites an existing file.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFCREAT (*path,ilen,imode,ifildes,ierror*)

<i>path</i>	(Input) Character. The pathname of the file.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>imode</i>	(Input) INTEGER(4). The mode of the newly created file. On Windows* systems, see your Microsoft* Visual C++ documentation for permitted mode values. On Linux* and macOS systems, use octal file-access mode.
<i>ifildes</i>	(Output) INTEGER(4). The returned file descriptor.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFCTERMID

**POSIX Subroutine:** *Generates a terminal pathname.*  
*This routine is only available for Linux and macOS.*

---

## Module

USE IFPOSIX

## Syntax

CALL PXFCTERMID (*s,ilen,ierror*)

<i>s</i>	(Output) Character. The returned pathname of the terminal.
<i>ilen</i>	(Output) INTEGER(4). The length of the returned value in the <i>s</i> string.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

This subroutine returns a string that refers to the current controlling terminal for the current process.

## PXFDUP, PXFDUP2

**POSIX Subroutine:** *Duplicates an existing file descriptor.*

---

## Module

USE IFPOSIX

## Syntax

CALL PXFDUP (*ifildes,ifid,ierror*)

CALL PXFDUP2 (*ifildes,ifildes2,ierror*)

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor to duplicate.
<i>ifid</i>	(Output) INTEGER(4). The returned new duplicated file descriptor.
<i>ifildes2</i>	(Input) INTEGER(4). The number for the new file descriptor.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFDUP subroutine creates a second file descriptor for an opened file.

The PXFDUP2 subroutine copies the file descriptor associated with *ifildes*. Integer number *ifildes2* becomes associated with this new file descriptor, but the value of *ifildes2* is not changed.

## PXFEGET

**POSIX Subroutine:** Gets the value stored in an array element component (or field) of a structure.

### Module

USE IFPOSIX

### Syntax

CALL PXFE(*type*)GET (*jhandle*, *compname*, *index*, *value*, *ierror*)

CALL PXFE(*type*)GET (*jhandle*, *compname*, *index*, *value*, *ilen*, *ierror*) ! syntax when (*type*) is STR

(*type*)

A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFEINTGET
REAL	REAL(4)	PXFEREALGET
LGCL	LOGICAL(4)	PXFELGCLGET
STR	CHARACTER*(*)	PXFESTRGET
CHAR	CHARACTER(1)	PXFECHARGET
DBL	REAL(8)	PXFEDBLGET
INT8	INTEGER(8)	PXFEINT8GET

*jhandle*

(Input) INTEGER(4). A handle of a structure.

*compname*

(Input) Character. The name of the component (or field) of the structure to retrieve data from.

*index*

(Input) INTEGER(4). The index of the array element to get data for.

*value*

(Output) A variable, whose data type depends on the value of (*type*). See the table above for the data types for each value; for example, if the value for (*type*) is INT, the data type is INTEGER(4). Stores the value of the component (or field).

*ilen*

(Output) INTEGER(4). This argument can only be used when (*type*) is STR (PXFESTRGET). Stores the length of the returned string.

*ierror*

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFE(type)GET subroutines are similar to the PXF(type)GET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)GET subroutines are used, the array element with index *index* is accessed (read from the component or field).

### See Also

PXFE(type)SET

PXF(type)GET

## PXFESET

**POSIX Subroutine:** Sets the value of an array element component (or field) of a structure.

### Module

USE IFPOSIX

### Syntax

```
CALL PXFE(type)SET (jhandle, compname, index, value, ierror)
```

```
CALL PXFE(type)SET (jhandle, compname, index, value, ilen, ierror) ! syntax when (type) is STR
```

(type)

A placeholder for one of the following values:

Value	Data Type	Routine Name
INT	INTEGER(4)	PXFEINTSET
REAL	REAL(4)	PXFEREALSET
LGCL	LOGICAL(4)	PXFELGCLSET
STR	CHARACTER*(*)	PXFESTRSET
CHAR	CHARACTER(1)	PXFECHARSET
DBL	REAL(8)	PXFEDBLSET
INT8	INTEGER(8)	PXFEINT8SET

*jhandle*

(Input) INTEGER(4). A handle of a structure.

*compname*

(Input) Character. The name of the component (or field) of the structure to write data to.

*index*

(Input) INTEGER(4). The index of the array element to write data to.

*value*

(Input) A variable, whose data type depends on the value of *(type)*. See the table above for the data types for each value; for example, if the value for *(type)* is INT, the data type is INTEGER(4). The value for the component (or field).

*ilen*

(Input) INTEGER(4). This argument can only be used when *(type)* is STR (PXFESTRSET). The length of the string *value*.

*ierror*

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFE(type)SET subroutines are similar to the PXF(type)SET subroutines, but they should be used when the component (or field) of the structure is an array.

When the PXFE(type)SET subroutines are used, the array element with index *index* is accessed (written to the component or field).

### See Also

PXF(type)SET

## PXFEEXECV

**POSIX Subroutine:** *Executes a new process by passing command-line arguments.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFEEXECV (path, lenpath, argv, lenargv, iargc, ierror)
```

<i>path</i>	(Input) Character. The path to the new executable process.
<i>lenpath</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>argv</i>	(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
<i>lenargv</i>	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in <i>argv</i> .
<i>iargc</i>	(Input) INTEGER(4). The number of command-line arguments
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFEEXECV subroutine executes a new executable process (file) by passing command-line arguments specified in the *argv* array. If execution is successful, no return is made to the calling process.

### See Also

PXFEEXECVE

PXFEEXECVP

## PXFEEXECVE

**POSIX Subroutine:** *Executes a new process by passing command-line arguments.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFEEXECVE (path, lenpath, argv, lenargv, iargc, env, lenenv, ienvc, ierror)
```

<i>path</i>	(Input) Character. The path to the new executable process.
-------------	--

<i>lenpath</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>argv</i>	(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
<i>lenargv</i>	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in <i>argv</i> .
<i>iargc</i>	(Input) INTEGER(4). The number of command-line arguments.
<i>env</i>	(Input) An array of character strings. Contains the environment settings for the new process.
<i>lenenv</i>	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in <i>env</i> .
<i>ienvc</i>	(Input) INTEGER(4). The number of environment settings in <i>env</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFEXECVE subroutine executes a new executable process (file) by passing command-line arguments specified in the *argv* array and environment settings specified in the *env* array.

## See Also

PXFEXECV

PXFEXECVP

## PXFEXECVP

**POSIX Subroutine:** *Executes a new process by passing command-line arguments.*

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFEXECVP (file,lenfile,argv,lenargv,iargc,ierror)
```

<i>file</i>	(Input) Character. The filename of the new executable process.
<i>lenfile</i>	(Input) INTEGER(4). The length of <i>file</i> string.
<i>argv</i>	(Input) An array of character strings. Contains the command-line arguments to be passed to the new process.
<i>lenargv</i>	(Input) INTEGER(4). An array that contains the lengths for each corresponding character string in <i>argv</i> .
<i>iargc</i>	(Input) INTEGER(4). The number of command-line arguments.
<i>ierror</i>	(Input) Character. The filename of the new executable process.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFEXECVP subroutine executes a new executable process(file) by passing command-line arguments specified in the *argv* array. It uses the PATH environment variable to find the file to execute.

## See Also

PXFEXECV  
PXFECEVE

## PXFEXIT, PXFFASTEXIT

**POSIX Subroutine:** *Exits from a process.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFEXIT (*istatus*)

CALL PXFFASTEXIT (*istatus*)

*istatus* (Input) INTEGER(4). The exit value.

The PXFEXIT subroutine terminates the calling process. It calls, in last-in-first-out (LIFO) order, the functions registered by C runtime functions `atexit` and `onexit`, and flushes all file buffers before terminating the process. The *istatus* value is typically set to zero to indicate a normal exit and some other value to indicate an error.

The PXFFASTEXIT subroutine terminates the calling process without processing `atexit` or `onexit`, and without flushing stream buffers.

### Example

```
program t1
  use ifposix
  integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *, " the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET, IERROR)
  if(IPID.EQ.0) then
    print *, " I am a child process"
    print *, " My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET, IERROR)
    print *, " The pid of my parent is", IPID_RET
    print *, " Now I have exited with code 0xABCD"
    call PXFEXIT(Z'ABCD')
  else
    print *, " I am a parent process"
    print *, " My parent pid is ", IPID_RET
    print *, " I am creating the process with pid", IPID
    print *, " Now I am waiting for the end of the child process"
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *, " The child with pid ", IPID_RET, " has exited"
    if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10, " The low byte of the child exit code is", istat_ret
    end if
  end if
10 FORMAT (A,Z)
end program
```

## PXFFCNTL

**POSIX Subroutine:** Manipulates an open file descriptor. This routine is only available for Linux and macOS.

### Module

USE IFPOSIX

### Syntax

CALL PXFFCNTL (*ifildes*, *icmd*, *iarg*<sub>in</sub>, *iarg*<sub>out</sub>, *ierror*)

<i>ifildes</i>	(Input) INTEGER(4). A file descriptor.
<i>icmd</i>	(Input) INTEGER(4). Defines an action for the file descriptor.
<i>iarg</i> <sub>in</sub>	(Input; output) INTEGER(4). Interpretation of this argument depends on the value of <i>icmd</i> .
<i>iarg</i> <sub>out</sub>	(Output) INTEGER(4). Interpretation of this argument depends on the value of <i>icmd</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFFCNTL is a multi-purpose subroutine that causes an action to be performed on a file descriptor. The action, defined in *icmd*, can be obtained by using the values of predefined macros in C header `fcntl.h`, or by using PXFCONST or IPXFCONST with one of the following constant names:

Constant	Action
F_DUPFD	Returns into <i>iarg</i> <sub>out</sub> the lowest available unopened file descriptor greater than or equal to <i>iarg</i> <sub>in</sub> . The new file descriptor refers to the same open file as <i>ifildes</i> and shares any locks. The system flag FD_CLOEXEC for the new file descriptor is cleared so the new descriptor will not be closed on a call to PXFEXEC subroutine.
F_GETFD	Returns into <i>iarg</i> <sub>out</sub> the value of system flag FD_CLOEXEC associated with <i>ifildes</i> . In this case, <i>iarg</i> <sub>in</sub> is ignored.
F_SETFD	Sets or clears the system flag FD_CLOEXEC for file descriptor <i>ifildes</i> . The PXFEXEC family of functions will close all file descriptors with the FD_CLOEXEC flag set. The value for FD_CLOEXEC is obtained from argument <i>iarg</i> <sub>in</sub> .
F_GETFL	Returns the file status flags for file descriptor <i>ifildes</i> . Unlike F_GETFD, these flags are associated with the file and shared by all descriptors. A combination of the following flags, which are symbolic names for PXFCONST or IPXFCONST, can be returned:

Constant	Action
	<ul style="list-style-type: none"> <li>• <code>O_APPEND</code> - Specifies the file is opened in append mode.</li> <li>• <code>O_NONBLOCK</code> - Specifies when the file is opened, it does not block waiting for data to become available.</li> <li>• <code>O_RDONLY</code> - Specifies the file is opened for reading only.</li> <li>• <code>O_RDWR</code> - Specifies the file is opened for both reading and writing.</li> <li>• <code>O_WRONLY</code> - Specifies the file is opened for writing only.</li> </ul>
<code>F_SETFL</code>	Sets the file status flags from <i>iarg</i> for file descriptor <i>ifildes</i> . Only <code>O_APPEND</code> or <code>O_NONBLOCK</code> flags can be modified. In this case, <i>iargout</i> is ignored.
<code>F_GETLK</code>	Gets information about a lock. Argument <i>iarg</i> must be a handle of structure <code>flock</code> . This structure is taken as the description of a lock for the file. If there is a lock already in place that would prevent this lock from being locked, it is returned to the structure associated with handle <i>iarg</i> . If there are no locks in place that would prevent the lock from being locked, field <code>l_type</code> in the structure is set to the value of the constant with symbolic name <code>F_UNLCK</code> .
<code>F_SETLK</code>	Sets or clears a lock. Argument <i>iarg</i> must be a handle of structure <code>flock</code> . The lock is set or cleared according to the value of structure field <code>l_type</code> . If the lock is busy, an error is returned.
<code>F_SETLKW</code>	Sets or clears a lock, but causes the process to wait if the lock is busy. Argument <i>iarg</i> must be a handle of structure <code>flock</code> . The lock is set or cleared according to the value of structure field <code>l_type</code> . If the lock is busy, <code>PXFCNTL</code> waits for an unlock.

**NOTE**

To get a handle for an instance of the `flock` structure, use `PXFSTRUCTCREATE` with the string 'flock' for the structure name.

**See Also**

[PXFCSTRUCTCREATE](#)

[IPXFCNST](#)

[PXFCNST](#)

## PXFFDOPEN

**POSIX Subroutine:** *Opens an external unit.*

### Module

USE IFPOSIX

### Syntax

CALL PXFFDOPEN (*ifildes*, *iunit*, *access*, *ierror*)

*ifildes* (Input) INTEGER(4). The file descriptor of the opened file.

*iunit* (Input) INTEGER(4). The Fortran logical unit to connect to file descriptor *ifildes*.

*access* (Input) Character. A character string that specifies the attributes for the Fortran unit. The string must consist of one or more of the following keyword/value pairs. Keyword/value pairs should be separated by a comma, and blanks are ignored.

Keyword	Possible Values	Description	Default
'NEWLINE'	'YES' or 'NO'	I/O type	'YES'
'BLANK'	'NULL' or 'ZERO'	Interpretation of blanks	'NULL'
'STATUS'	'OLD', 'SCRATCH', or 'UNKNOWN'	File status at open	'UNKNOWN'
'FORM'	'FORMATTED' or 'UNFORMATTE D'	Format type	'FORMATTED'

Keywords should be separated from their values by the equals ('=') character; for example:

```
call PXFFDOPEN (IFILDES, IUNIT, 'BLANK=NULL, STATUS=UNKNOWN',  
IERROR)
```

*ierror* (Output) INTEGER(4). The error status.

The PXFFDOPEN subroutine connects an external unit identified by *iunit* to a file descriptor *ifildes*. If unit is already connected to a file, the file should be closed before using PXFFDOPEN.

### NOTE

On Windows\* systems, the default value of the POSIX/IO flag is 0, which causes PXFFDOPEN to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1.

### See Also

PXFPOSIXIO

## PXFFFLUSH

**POSIX Subroutine:** *Flushes a file directly to disk.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFFFLUSH (lunit, ierror)
```

*lunit* (Input) INTEGER(4). A Fortran logical unit.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFFLUSH subroutine writes any buffered output to the file connected to unit *lunit*.

## PXFFGETC

**POSIX Subroutine:** *Reads a character from a file.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFFGETC (lunit, char, ierror)
```

*lunit* (Input) INTEGER(4). A Fortran logical unit.

*char* (Input) Character. The character to be read.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFGETC subroutine reads a character from a file connected to unit *lunit*.

### See Also

PXFFPUTC

## PXFFILENO

**POSIX Subroutine:** *Returns the file descriptor associated with a specified unit.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFFILENO (lunit, fd, ierror)
```

*lunit* (Input) INTEGER(4). A Fortran logical unit.

*fd* (Output) INTEGER(4). The returned file descriptor.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. Possible error codes are:

- EINVAL: *lunit* is not an open unit.
- EBADF: *lunit* is not connected with a file descriptor.

The PXFFILENO subroutine returns in *fd* the file descriptor associated with *lunit*.

---

#### NOTE

On Windows\* systems, the default value of the POSIX/IO flag is 0, which prevents OPEN from connecting a unit to a file descriptor and causes PXFFILENO to return an error.

To prevent this, call subroutine PXFPOSIXIO and set the value of the POSIX/IO flag to 1. This setting allows a connection to a file descriptor.

---

---

#### NOTE

The file-descriptor used by POSIX is not the same as the corresponding file handle used by Windows, so it does not have the same value.

---

### See Also

PXFPOSIXIO

### PXFFORK

**POSIX Subroutine:** *Creates a child process that differs from the parent process only in its PID. This routine is only available for Linux and macOS.*

---

#### Module

USE IFPOSIX

#### Syntax

CALL PXFFORK (*ipid*, *ierror*)

*ipid* (Output) INTEGER(4). The returned PID of the new child process.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFORK subroutine creates a child process that differs from the parent process only in its PID. If successful, the PID of the child process is returned in the parent's thread of execution, and a zero is returned in the child's thread of execution. Otherwise, a -1 is returned in the parent's context and no child process is created.

#### Example

```
program t1
  use ifposix
  integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *, " the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET, IERROR)
  if(IPID_EQ.0) then
```

```

    print *, " I am a child process"
    print *, " My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET, IERROR)
    print *, " The pid of my parent is", IPID_RET
    print *, " Now I have exited with code 0xABCD"
    call PXFEXIT(Z'ABCD')
else
    print *, " I am a parent process"
    print *, " My parent pid is ", IPID_RET
    print *, " I am creating the process with pid", IPID
    print *, " Now I am waiting for the end of the child process"
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *, " The child with pid ", IPID_RET, " has exited"
    if( PXFWIFEXITED(ISTAT) ) then
        print *, " The child exited normally"
        istat_ret = IPXFWEXITSTATUS(ISTAT)
        print 10, " The low byte of the child exit code is", istat_ret
    end if
end if
10 FORMAT (A,Z)
end program

```

IPXWEXITSTATUS

## PXFFPATHCONF

**POSIX Subroutine:** Gets the value for a configuration option of an opened file.

## Module

USE IFPOSIX

## Syntax

CALL PXFFPATHCONF (*ifildes*, *name*, *ival*, *ierror*)

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor of the opened file.
<i>name</i>	(Input) INTEGER(4). The configurable option.
<i>ival</i>	(Output) INTEGER(4). The value of the configurable option.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFPATHCONF subroutine gets a value for the configuration option named for the opened file with descriptor *ifildes*.

The configuration option, defined in *name*, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

Constant	Action
<code>_PC_LINK_MAX</code>	Returns the maximum number of links to the file. If <i>ifildes</i> refers to a directory, then the value applies to the whole directory.

Constant	Action
<code>_PC_MAX_CANON</code> <sup>1</sup>	Returns the maximum length of a formatted input line; the file descriptor <i>ifildes</i> must refer to a terminal.
<code>_PC_MAX_INPUT</code> <sup>1</sup>	Returns the maximum length of an input line; the file descriptor <i>ifildes</i> must refer to a terminal.
<code>_PC_NAME_MAX</code>	Returns the maximum length of a filename in <i>ifildes</i> that the process is allowed to create.
<code>_PC_PATH_MAX</code>	Returns the maximum length of a relative pathname when <i>ifildes</i> is the current working directory.
<code>_PC_PIPE_BUF</code>	Returns the size of the pipe buffer; the file descriptor <i>ifildes</i> must refer to a pipe or FIFO.
<code>_PC_CHOWN_RESTRICTED</code> <sup>1</sup>	Returns nonzero if <code>PXFCCHOWN</code> may not be used on this file. If <i>ifildes</i> refers to a directory, then this applies to all files in that directory.
<code>_PC_NO_TRUNC</code> <sup>1</sup>	Returns nonzero if accessing filenames longer than <code>_POSIX_NAME_MAX</code> will generate an error.
<code>_PC_VDISABLE</code> <sup>1</sup>	Returns nonzero if special character processing can be disabled; the file descriptor <i>ifildes</i> must refer to a terminal.
<sup>1</sup> <code>L*X, M*X</code>	

On Linux\* and macOS systems, the corresponding macros are defined in `<unistd.h>`. The values for *name* can be obtained by using `PXFCNST` or `IPXFCNST` when passing the string names of predefined macros in `<unistd.h>`. The following table shows the corresponding macro names for the above constants:

Constant	Corresponding Macro
<code>_PC_LINK_MAX</code>	<code>_POSIX_LINK_MAX</code>
<code>_PC_MAX_CANON</code>	<code>_POSIX_MAX_CANON</code>
<code>_PC_MAX_INPUT</code>	<code>_POSIX_MAX_INPUT</code>
<code>_PC_NAME_MAX</code>	<code>_POSIX_NAME_MAX</code>
<code>_PC_PATH_MAX</code>	<code>_POSIX_PATH_MAX</code>
<code>_PC_PIPE_BUF</code>	<code>_POSIX_PIPE_BUF</code>
<code>_PC_CHOWN_RESTRICTED</code>	<code>_POSIX_CHOWN_RESTRICTED</code>
<code>_PC_NO_TRUNC</code>	<code>_POSIX_NO_TRUNC</code>
<code>_PC_VDISABLE</code>	<code>_POSIX_VDISABLE</code>

## PXFFPUTC

**POSIX Subroutine:** *Writes a character to a file.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFFPUTC (lunit, char, ierror)
```

<i>lunit</i>	(Input) INTEGER(4). A Fortran logical unit.
<i>char</i>	(Input) Character. The character to be written.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

The PXFFPUTC subroutine writes a character to the file connected to unit *lunit*.

### See Also

PXFFGETC

## PXFFSEEK

**POSIX Subroutine:** *Modifies a file position.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFFSEEK (lunit, ioffset, iwhence, ierror)
```

<i>lunit</i>	(Input) INTEGER(4). A Fortran logical unit.
<i>ioffset</i>	(Input) INTEGER(4). The number of bytes away from <i>iwhence</i> to place the pointer.
<i>iwhence</i>	(Input) INTEGER(4). The position within the file. The value must be one of the following constants (defined in <code>stdio.h</code> ):  SEEK_SET = 0            Offset from the beginning of the file.  SEEK_CUR = 1           Offset from the current position of the file pointer.  SEEK_END = 2           Offset from the end of the file.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. Possible error codes are:

- EINVAL: No file is connected to *lunit*, *iwhence* is not a proper value, or the resulting offset is invalid.
- ESPIPE: *lunit* is a pipe or FIFO.
- EEND: The end of the file has been reached.

The PXFFSEEK subroutine modifies the position of the file connected to unit *lunit*.

## PXFFSTAT

**POSIX Subroutine:** *Gets a file's status information.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFFSTAT (*ifildes*, *jstat*, *ierror*)

*ifildes* (Input) INTEGER(4). The file descriptor for an opened file.

*jstat* (Input) INTEGER(4). A handle of structure *stat*.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFFSTAT subroutine puts the status information for the file associated with *ifildes* into the structure associated with handle *jstat*.

---

#### NOTE

To get a handle for an instance of the *stat* structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

---

### See Also

PXFSTRUCTCREATE

## PXFFTELL

**POSIX Subroutine:** *Returns the relative position in bytes from the beginning of the file.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFFTELL (*lunit*, *ioffset*, *ierror*)

*lunit* (Input) INTEGER(4). A Fortran logical unit.

*ioffset* (Output) INTEGER(4). The returned relative position in bytes from the beginning of the file.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFGETARG

**POSIX Subroutine:** *Gets the specified command-line argument.*

---

## Module

USE IFPOSIX

## Syntax

CALL PXFGETARG (*argnum*,*str*,*istr*,*ierror*)

<i>argnum</i>	(Input) INTEGER(4). The number of the command-line argument.
<i>str</i>	(Output) Character. The returned string value.
<i>istr</i>	(Output) INTEGER(4). The length of the returned string; it is zero if an error occurs.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFGETARG subroutine places the command-line argument with number *argnum* into character string *str*. If *argnum* is equal to zero, the value of the argument returned is the command name of the executable file.

## See Also

IPXFARGC

## PXFGETC

**POSIX Subroutine:** Reads a character from standard input unit 5.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFGETC (*nextcar*,*ierror*)

<i>nextcar</i>	(Output) Character. The returned character that was read.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## See Also

PXFPUTC

## PXFGETCWD

**POSIX Subroutine:** Returns the path of the current working directory.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFGETCWD (*buf*,*ilen*,*ierror*)

<i>buf</i>	(Output) Character. The returned pathname of the current working directory.
<i>ilen</i>	(Output) INTEGER(4). The length of the returned pathname.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EINVAL if the size of *buf* is insufficient.

## PXFGETEGID

**POSIX Subroutine:** Gets the effective group ID of the current process. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETEGID (*iegid*,*ierror*)

<i>iegid</i>	(Output) INTEGER(4). The returned effective group ID.
<i>ierror</i>	(Output) INTEGER(4). The error status.

### Description

If successful, *ierror* is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

## PXFGETENV

**POSIX Subroutine:** Gets the setting of an environment variable.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETENV (*name*,*lenname*,*value*,*lenval*,*ierror*)

<i>name</i>	(Input) Character. The name of the environment variable.
<i>lenname</i>	(Input) INTEGER(4). The length of <i>name</i> .
<i>value</i>	(Output) Character. The returned value of the environment variable.
<i>lenval</i>	(Output) INTEGER(4). The returned length of <i>value</i> . If an error occurs, it returns zero.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### See Also

PXFSETENV

## PXFGETEUID

**POSIX Subroutine:** Gets the effective user ID of the current process. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFGETEUID (ieuid,ierror)
```

*ieuid* (Output) INTEGER(4). The returned effective user ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The effective ID corresponds to the set ID bit on the file being executed.

## PXFGETGID

**POSIX Subroutine:** Gets the real group ID of the current process. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFGETGID (igid,ierror)
```

*igid* (Output) INTEGER(4). The returned real group ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

### Example

See the example in [PXFGETGROUPS](#)

### See Also

PXFSETGID

## PXFGETGRGID

**POSIX Subroutine:** Gets group information for the specified GID. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

## Syntax

```
CALL PXFGETGRGID (jgid, jgroup, ierror)
```

<i>jgid</i>	(Input) INTEGER(4). The group ID to retrieve information about.
<i>jgroup</i>	(Input) INTEGER(4). A handle of structure <i>group</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFGETGRGID subroutine stores the group information from `/etc/group` for the entry that matches the group GID *jgid* in the structure associated with handle *jgroup*.

---

### NOTE

To get a handle for an instance of the `group` structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

---

## Example

See the example in [PXFGETGROUPS](#)

## See Also

PXFSTRUCTCREATE

## PXFGETGRNAM

**POSIX Subroutine:** Gets group information for the named group. This routine is only available for Linux and macOS.

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFGETGRNAM (name, ilen, jgroup, ierror)
```

<i>name</i>	(Input) Character. The name of the group to retrieve information about.
<i>ilen</i>	(Input) INTEGER(4). The length of the <i>name</i> string.
<i>jgroup</i>	(Input) INTEGER(4). A handle of structure <i>group</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFGETGRNAM subroutine stores the group information from `/etc/group` for the entry that matches the group name *name* in the structure associated with handle *jgroup*.

---

### NOTE

To get a handle for an instance of the `group` structure, use PXFSTRUCTCREATE with the string 'group' for the structure name.

---

## See Also

PXFSTRUCTCREATE

## PXFGETGROUPS

**POSIX Subroutine:** Gets supplementary group IDs.

*This routine is only available for Linux and macOS.*

### Module

USE IFPOSIX

### Syntax

CALL PXFGETGROUPS (*igidsetsize*,*igrouplist*,*ngroups*,*ierror*)

<i>igidsetsize</i>	(Input) INTEGER(4). The number of elements in the <i>igrouplist</i> array.
<i>igrouplist</i>	(Output) INTEGER(4). The array that has the returned supplementary group IDs.
<i>ngroups</i>	(Output) INTEGER(4). The total number of supplementary group IDs for the process.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFGETGROUPS subroutine returns, up to size *igidsetsize*, the supplementary group IDs in array *igrouplist*. It is unspecified whether the effective group ID of the calling process is included in the returned list. If the size is zero, the list is not modified, but the total number of supplementary group IDs for the process is returned.

### Example

```
program test5
  use ifposix
  implicit none
  integer(4) number_of_groups, ierror, isize,i, igid
  integer(4),allocatable,dimension(:):: igrouplist
  integer(JHANDLE_SIZE) jgroup

  ! Get total number of groups in system
  ! call PXFGETGROUPS with 0
  call PXFGETGROUPS(0, igrouplist, number_of_groups, ierror)
  if(ierror.NE.0) STOP 'Error: first call of PXFGETGROUPS fails'
  print *, " The number of groups in system ", number_of_groups

  ! Get Group IDs
  isize = number_of_groups
  ALLOCATE( igrouplist(isize))
  call PXFGETGROUPS(isize, igrouplist, number_of_groups, ierror)
  if(ierror.NE.0) then
    DEALLOCATE(igrouplist)
    STOP 'Error: first call of PXFGETGROUPS fails'
  end if

  print *, " Create an instance for structure 'group' "
  call PXFSTRUCTCREATE("group",jgroup, ierror)
```

```

if(ierrone.NE.0) then
    DEALLOCATE(igrouplist)
    STOP 'Error: PXFSTRUCTCREATE failed to create an instance of group'
end if

do i=1, number_of_groups
    call PXFGETGRGID( igrouplist(i), jgroup, ierror)
    if(ierrone.NE.0) then
        DEALLOCATE(igrouplist)
        call PXFSTRUCTFREE(jgroup, ierror)
        print *, 'Error: PXFGETGRGID failed for i=', i, " gid=", igrouplist(i)
        STOP 'Abnormal termination'
    end if
    call PRINT_GROUP_INFO(jgroup)
end do

call PXFGETGID(igid, ierror)
if(ierrone.NE.0) then
    DEALLOCATE(igrouplist)
    call PXFSTRUCTFREE(jgroup, ierror)
    print *, 'Error: PXFGETGID failed'
    STOP 'Abnormal termination'
end if
call PXFGETGRGID( igid, jgroup, ierror)
if(ierrone.NE.0) then
    DEALLOCATE(igrouplist)
    call PXFSTRUCTFREE(jgroup, ierror)
    print *, "Error: PXFGETGRGID failed for gid=", igid
    STOP 'Abnormal termination'
end if

call PRINT_GROUP_INFO(jgroup)
DEALLOCATE(igrouplist)
call PXFSTRUCTFREE(jgroup, ierror)
print *, " Program will normal terminated"
call PXFEXIT(0)
end

```

## PXFGETLOGIN

**POSIX Subroutine:** *Gets the name of the user.*

### Module

USE IFPOSIX

### Syntax

CALL PXFGETLOGIN (*s*, *ilen*, *ierror*)

<i>s</i>	(Output) Character. The returned user name.
<i>ilen</i>	(Output) INTEGER(4). The length of the string stored in <i>s</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFGETPGRP

**POSIX Subroutine:** Gets the process group ID of the calling process. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETPGRP (*ipgrp*,*ierror*)

*ipgrp* (Output) INTEGER(4). The returned process group ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

Each process group is a member of a session and each process is a member of the session in which its process group is a member.

## PXFGETPID

**POSIX Subroutine:** Gets the process ID of the calling process.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETPID (*ipid*,*ierror*)

*ipid* (Output) INTEGER(4). The returned process ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### Example

```
program t1
  use ifposix
  integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *, " the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET,IERROR)
  if(IPID.EQ.0) then
    print *, " I am a child process"
    print *, " My child's pid is", IPID_RET
    call PXFGETPID(IPID_RET,IERROR)
    print *, " The pid of my parent is",IPID_RET
    print *, " Now I have exited with code 0xABCD"
    call PXFEXIT(Z'ABCD')
  else
    print *, " I am a parent process"
    print *, " My parent pid is ", IPID_RET
    print *, " I am creating the process with pid", IPID
```

```

print *, " Now I am waiting for the end of the child process"
call PXFWAIT(ISTAT, IPID_RET, IERROR)
print *, " The child with pid ", IPID_RET, " has exited"
if( PXFWIFEXITED(ISTAT) ) then
  print *, " The child exited normally"
  istat_ret = IPXFWEXITSTATUS(ISTAT)
  print 10, " The low byte of the child exit code is", istat_ret
end if
end if
10 FORMAT (A,Z)
end program

```

## PXFGETPPID

**POSIX Subroutine:** Gets the process ID of the parent of the calling process.

### Module

USE IFPOSIX

### Syntax

CALL PXFGETPPID (*ippid*,*ierror*)

*ippid* (Output) INTEGER(4). The returned process ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### Example

```

program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, " the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPPID(IPID_RET,IERROR)
if(IPID.EQ.0) then
  print *, " I am a child process"
  print *, " My child's pid is", IPID_RET
  call PXFGETPPID(IPID_RET,IERROR)
  print *, " The pid of my parent is",IPID_RET
  print *, " Now I have exited with code 0xABCD"
  call PXFEXIT(Z'ABCD')
else
  print *, " I am a parent process"
  print *, " My parent pid is ", IPID_RET
  print *, " I am creating the process with pid", IPID
  print *, " Now I am waiting for the end of the child process"
  call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *, " The child with pid ", IPID_RET, " has exited"
  if( PXFWIFEXITED(ISTAT) ) then
    print *, " The child exited normally"
    istat_ret = IPXFWEXITSTATUS(ISTAT)
    print 10, " The low byte of the child exit code is", istat_ret
  end if
end if

```

```
end if
10 FORMAT (A,Z)
end program
```

## PXFGETPWNAM

**POSIX Subroutine:** Gets password information for a specified name. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETPWNAM (*name*, *ilen*, *jpasswd*, *ierror*)

<i>name</i>	(Input) Character. The login name of the user to retrieve information about. For example, a login name might be "jsmith", while the actual name is "John Smith".
<i>ilen</i>	(Input) INTEGER(4). The length of the <i>name</i> string.
<i>jpasswd</i>	(Input) INTEGER(4). A handle of structure <i>compnam</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFGETPWNAM subroutine stores the user information from `/etc/passwd` for the entry that matches the user name *name* in the structure associated with handle *jpasswd*.

---

#### NOTE

To get a handle for an instance of the `compnam` structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

---

### See Also

PXFSTRUCTCREATE

## PXFGETPWUID

**POSIX Subroutine:** Gets password information for a specified UID. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETPWUID (*iuid*, *jpasswd*, *ierror*)

<i>iuid</i>	(Input) INTEGER(4). The user ID to retrieve information about.
<i>jpasswd</i>	(Output) INTEGER(4). A handle of structure <code>compnam</code> .

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFGETPWUID subroutine stores the user information from `/etc/passwd` for the entry that matches the user ID *iuid* in the structure associated with handle *jpasswd*.

---

**NOTE**

To get a handle for an instance of the `compnam` structure, use PXFSTRUCTCREATE with the string 'compnam' for the structure name.

---

## See Also

PXFSTRUCTCREATE

## PXFGETSUBHANDLE

**POSIX Subroutine:** Returns a handle for a subroutine.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETSUBHANDLE (*sub*, *jhandle1*, *ierror*)

*sub* (Input) The Fortran subroutine to get a handle for.

*jhandle1* (Output) INTEGER(4). The returned handle for the subroutine.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

**NOTE**

The argument *sub* cannot be a function, an intrinsic, or an entry point, and must be defined with exactly one integer argument.

---

## PXFGETUID

**POSIX Subroutine:** Gets the real user ID of the current process. This routine is only available for Linux and macOS.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFGETUID (*iuid*, *ierror*)

*iuid* (Output) INTEGER(4). The returned real user ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The real ID corresponds to the ID of the calling process.

## See Also

PXFSETUID

## PXFISATTY

**POSIX Subroutine:** Tests whether a file descriptor is connected to a terminal. This routine is only available for Linux and macOS.

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFISATTY (ifildes,isatty,ierror)
```

*ifildes* (Input) INTEGER(4). The file descriptor.

*isatty* (Output) LOGICAL(4). The returned value.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

If file descriptor *ifildes* is open and connected to a terminal, *isatty* returns .TRUE.; otherwise, .FALSE..

## See Also

PXFOPEN

## PXFISBLK

**POSIX Function:** Tests for a block special file.

---

## Module

USE IFPOSIX

## Syntax

```
result = PXFISBLK (m)
```

*m* (Input) INTEGER(4). The value of the `st_modecomponent` (field) in the structure `stat`.

## Results

The result type is logical. If the file is a block special file, the result value is .TRUE.; otherwise, .FALSE..

## See Also

PXFISCHR

## PXFISCHR

**POSIX Function:** Tests for a character file.

---

## Module

USE IFPOSIX

## Syntax

```
result = PXFISCHR (m)
```

*m* (Input) INTEGER(4). The value of the `st_mode` component (field) in the structure `stat`.

## Results

The result type is logical. If the file is a character file, the result value is `.TRUE.`; otherwise, `.FALSE.`.

## See Also

PXFISBLK

## PXFISCONST

**POSIX Function:** Tests whether a string is a valid constant name.

---

## Module

USE IFPOSIX

## Syntax

```
result = PXFISCONST (s)
```

*s* (Input) Character. The name of the constant to test.

## Results

The result type is logical. The PXFISCONST function confirms whether the argument is a valid constant name that can be passed to functions PXFCONST and IPXFCONST. It returns `.TRUE.` only if IPXFCONST will return a valid value for name *s*.

## See Also

IPXFCONST

PXFCONST

## PXFISDIR

**POSIX Function:** Tests whether a file is a directory.

---

## Module

USE IFPOSIX

## Syntax

```
result = PXFISDIR (m)
```

*m* (Input) INTEGER(4). The value of the `st_mode` component (field) in the structure `stat`.

## Results

The result type is logical. If the file is a directory, the result value is `.TRUE.`; otherwise, `.FALSE.`.

## PXFISFIFO

**POSIX Function:** Tests whether a file is a special FIFO file.

---

### Module

USE IFPOSIX

### Syntax

```
result = PXFISFIFO (m)
```

*m* (Input) INTEGER(4). The value of the `st_mode` component (field) in the structure `stat`.

### Results

The result type is logical.

The PXFISFIFO function tests whether the file is a special FIFO file created by PXFMKFIFO. If the file is a special FIFO file, the result value is `.TRUE.`; otherwise, `.FALSE.`.

### See Also

PXFMKFIFO

PXFISREG

## PXFISREG

**POSIX Function:** Tests whether a file is a regular file.

---

### Module

USE IFPOSIX

### Syntax

```
result = PXFISREG (m)
```

*m* (Input) INTEGER(4). The value of the `st_mode` component (field) in the structure `stat`.

### Results

The result type is logical. If the file is a regular file, the result value is `.TRUE.`; otherwise, `.FALSE.`.

### See Also

PXFMKFIFO

PXFISFIFO

## PXFKILL

**POSIX Subroutine:** Sends a signal to a specified process.

---

### Module

USE IFPOSIX

## Syntax

CALL PXFKILL (*ipid*,*isig*,*ierror*)

<i>ipid</i>	(Input) INTEGER(4). The process to kill. It is determined by one of the following values:	
	> 0	Kills the specific process.
	< 0	Kills all processes in the group.
	== 0	Kills all processes in the group except special processes.
	== pid_t-1	Kills all processes.
<i>isig</i>	(Input) INTEGER(4). The value of the signal to be sent.	
<i>ierror</i>	(Output) INTEGER(4). The error status.	

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFKILL subroutine sends a signal with value *isig* to a specified process. On Windows\* systems, only the *ipid* for the current process can be used.

## PXFLINK

**POSIX Subroutine:** Creates a link to a file or a directory. This routine is only available for Linux and macOS.

### Module

USE IFPOSIX

## Syntax

CALL PXFLINK (*existing*,*lenexist*,*new*,*lennew*,*ierror*)

<i>existing</i>	(Input) Character. The path to the file or directory that you want to link to.
<i>lenexist</i>	(Input) INTEGER(4). The length of the <i>existing</i> string.
<i>new</i>	(Input) Character. The name of the new link file.
<i>lennew</i>	(Input) INTEGER(4). The length of the <i>new</i> string.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is not changed; otherwise, an error code.

The PXFLINK subroutine creates a new link (also known as a hard link) to an existing file or directory.

This new name can be used exactly as the old one for any operation. Both names refer to the same entity (so they have the same permissions and ownership) and it is impossible to tell which name was the "original".

## PXFLOCALTIME

**POSIX Subroutine:** Converts a given elapsed time in seconds to local time.

## Module

USE IFPOSIX

## Syntax

CALL PXFLOCALTIME (*isecnds*,*iatime*,*ierror*)

*isecnds* (Input) INTEGER(4). The elapsed time in seconds since 00:00:00 Greenwich Mean Time, January 1, 1970.

*iatime* (Output) INTEGER(4). One-dimensional array with 9 elements containing numeric time data. The elements of *iatime* are returned as follows:

Element	Value
<i>iatime</i> (1)	Seconds (0-59)
<i>iatime</i> (2)	Minutes (0-59)
<i>iatime</i> (3)	Hours (0-23)
<i>iatime</i> (4)	Day of month (1-31)
<i>iatime</i> (5)	Month (1-12)
<i>iatime</i> (6)	Gregorian year (for example, 1990)
<i>iatime</i> (7)	Day of week (0-6, where 0 is Sunday)
<i>iatime</i> (8)	Day of year (1-366)
<i>iatime</i> (9)	Daylight savings flag (1 if daylight savings time is in effect; otherwise, 0)

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFLOCALTIME subroutine converts the time (in seconds since epoch) in the *isecnds* argument to the local date and time as described by the array *iatime* above.

## PXFLSEEK

**POSIX Subroutine:** *Positions a file a specified distance in bytes.*

---

## Module

USE IFPOSIX

## Syntax

CALL PXFLSEEK (*ifildes*,*ioffset*,*ihence*,*iposition*,*ierror*)

*ifildes* (Input) INTEGER(4). A file descriptor.

*ioffset* (Input) INTEGER(4). The number of bytes to move.

<i>iwhence</i>	(Input) INTEGER(4). The starting position. The value must be one of the following: <ul style="list-style-type: none"><li>• SEEK_SET = 0 Sets the offset to <i>ioffset</i> bytes.</li><li>• SEEK_CUR = 1 Sets the offset to its current location plus <i>ioffset</i> bytes.</li><li>• SEEK_END = 2 Sets the offset to the size of the file plus <i>ioffset</i> bytes.</li></ul>
<i>iposition</i>	(Output) INTEGER(4). The ending position; the resulting offset location as measured in bytes from the beginning of the file.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFLSEEK subroutine repositions the offset of file descriptor *ifildes* to the argument *ioffset* according to the value of argument *iwhence*.

PXFLSEEK allows the file offset to be set beyond the end of the existing end-of-file. If data is later written at this point, subsequent reads of the data in the gap return bytes of zeros (until data is actually written into the gap).

## PXFMKDIR

**POSIX Subroutine:** *Creates a new directory.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFMKDIR (*path*,*ilen*,*imode*,*ierror*)

<i>path</i>	(Input) Character. The path for the new directory.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>imode</i> (L*X only)	(Input) INTEGER(4). The mode mask. Octal file-access mode.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### See Also

PXFRMDIR

PXFCHDIR

## PXFMKFIFO

**POSIX Subroutine:** *Creates a new FIFO. This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

## Syntax

CALL PXFMKFIFO (*path*,*ilen*,*imode*,*ierror*)

<i>path</i>	(Input) Character. The path for the new FIFO.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>imode</i>	(Input) INTEGER(4). The mode mask; specifies the FIFO's permissions. Octal file-access mode.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFMKFIFO subroutine creates a FIFO special file with name *path*. A FIFO special file is similar to a pipe, except that it is created in a different way. Once a FIFO special file is created, any process can open it for reading or writing in the same way as an ordinary file.

However, the FIFO file has to be open at both ends simultaneously before you can proceed to do any input or output operations on it. Opening a FIFO for reading normally blocks it until some other process opens the same FIFO for writing, and vice versa.

## See Also

PXFISFIFO

## PXFOPEN

**POSIX Subroutine:** *Opens or creates a file.*

---

## Module

USE IFPOSIX

## Syntax

CALL PXFOPEN (*path*,*ilen*,*iopenflag*,*imode*,*ifildes*,*ierror*)

<i>path</i>	(Input) Character. The path of the file to be opened or created.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>iopenflag</i>	(Input) INTEGER(4). The flags for the file. (For possible constant names that can be passed to PXFCONST or IPXFCONST, see below.)
<i>imode</i>	(Input) INTEGER(4). The permissions for a new file. This argument should always be specified when <i>iopenflag</i> =O_CREAT; otherwise, it is ignored. (For possible permissions, see below.)
<i>ifildes</i>	(Output) INTEGER(4). The returned file descriptor for the opened or created file.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

For *iopenflag*, you should specify one of the following constant values:

- O\_RDONLY (read only)
- O\_WRONLY (write only)
- O\_RDWR (read and write)

In addition, you can also specify one of the following constant values by using a bitwise inclusive OR (IOR):

Value	Action
O_CREAT	Creates a file if the file does not exist.
O_EXCL	When used with O_CREAT, it causes the open to fail if the file already exists. In this case, a symbolic link exists, regardless of where it points to.
O_NOCTTY <sup>1</sup>	If <i>path</i> refers to a terminal device, it prevents it from becoming the process's controlling terminal even if the process does not have one.
O_TRUNC	If the file already exists, it is a regular file, and <i>imode</i> allows writing (its value is O_RDWR or O_WRONLY), it causes the file to be truncated to length 0.
O_APPEND	Opens the file in append mode. Before each write, the file pointer is positioned at the end of the file, as if with PXFLSEEK.
O_NONBLOCK (or O_NDELAY) <sup>1</sup>	When possible, opens the file in non-blocking mode. Neither the open nor any subsequent operations on the file descriptor that is returned will cause the calling process to wait. This mode need not have any effect on files other than FIFOs.
O_SYNC	Opens the file for synchronous I/O. Any writes on the resulting file descriptor will block the calling process until the data has been physically written to the underlying hardware.
O_NOFOLLOW <sup>1</sup>	If <i>path</i> is a symbolic link, it causes the open to fail.
O_DIRECTORY <sup>1</sup>	If <i>path</i> is not a directory, it causes the open to fail.
O_LARGEFILE <sup>1</sup>	On 32-bit systems that support the Large Files System, it allows files whose sizes cannot be represented in 31 bits to be opened.
O_BINARY <sup>2</sup>	Opens the file in binary (untranslated) mode.
O_SHORT_LIVED <sup>2</sup>	Creates the file as temporary. If possible, it does not flush to the disk.
O_TEMPORARY <sup>2</sup>	Creates the file as temporary. The file is deleted when last file handle is closed.
O_RANDOM <sup>2</sup>	Specifies primarily random access from the disk.
O_SEQUENTIAL <sup>2</sup>	Specifies primarily sequential access from the disk.
O_TEXT <sup>2</sup>	Opens the file in text (translated) mode. <sup>3</sup>
<sup>1</sup> L*X only	
<sup>2</sup> W*S	
<sup>2</sup> W*S	
<sup>3</sup> For more information, see "Text and Binary Modes" in the Visual C++* programmer's guide.	

Argument *imode* specifies the permissions to use if a new file is created. The permissions only apply to future accesses of the newly created file. The value for *imode* can be any of the following constant values (which can be obtained by using `PXFCNST` or `IPXFCNST`):

Value	Description
<code>S_IRWXU</code>	00700 user (file owner) has read, write and execute permission.
<code>S_IRUSR, S_IREAD</code>	00400 user has read permission.
<code>S_IWUSR, S_IWRITE</code>	00200 user has write permission.
<code>S_IXUSR, S_IEXEC</code>	00100 user has execute permission.
<code>S_IRWXG</code> <sup>1</sup>	00070 group has read, write and execute permission.
<code>S_IRGRP</code> <sup>1</sup>	00040 group has read permission.
<code>S_IWGRP</code> <sup>1</sup>	00020 group has write permission.
<code>S_IXGRP</code> <sup>1</sup>	00010 group has execute permission.
<code>S_IRWXO</code> <sup>1</sup>	00007 others have read, write and execute permission.
<code>S_IROTH</code> <sup>1</sup>	00004 others have read permission.
<code>S_IWOTH</code> <sup>1</sup>	00002 others have write permission.
<code>S_IXOTH</code> <sup>1</sup>	00001 others have execute permission.
<sup>1</sup> L*X only	

## Example

The following call opens a file for writing only and if the file does not exist, it is created:

```
call PXFOPEN( "OPEN.OUT", &  
             8, &  
             IOR( IPXFCNST(O_WRONLY), IPXFCNST(O_CREAT) ), &  
             IOR( IPXFCNST(S_IREAD), IPXFCNST(S_IWRITE) ) )
```

## PXFOPENDIR

**POSIX Subroutine:** *Opens a directory and associates a stream with it.*

---

## Module

`USE IFPOSIX`

## Syntax

`CALL PXFOPENDIR (dirname, lendirname, opendirid, ierror)`

<i>dirname</i>	(Input) Character. The directory name.
<i>lendirname</i>	(Input) INTEGER(4). The length of <i>dirname</i> string.
<i>opendirid</i>	(Output) INTEGER(4). The returned ID for the directory.
<i>ierror</i>	(Output) INTEGER(4). The error status. If successful, <i>ierror</i> is set to zero; otherwise, an error code.

This subroutine opens a directory pointed to by the *dirname* argument and returns the ID of the directory into *opendirid*. After the call, this ID can be used by functions PXFREADDIR, PXFREWINDDIR, PXFCLOSEDIR.

### See Also

PXFCLOSEDIR  
 PXFREADDIR  
 PXFREADDIR

## PXFPATHCONF

**POSIX Subroutine:** Gets the value for a configuration option of an opened file.

### Module

USE IFPOSIX

### Syntax

CALL PXFPATHCONF (*path*,*ilen*,*name*,*ival*,*ierror*)

<i>path</i>	(Input) Character. The path to the opened file.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> .
<i>name</i>	(Input) INTEGER(4). The configurable option.
<i>ival</i>	(Input) INTEGER(4). The value of the configurable option.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFPATHCONF subroutine gets a value for the configuration option named for the opened file with path *path*.

The configuration option, defined in *name*, can be obtained by using PXFCONST or IPXFCONST with one of the following constant names:

Constant	Action
<code>_PC_LINK_MAX</code>	Returns the maximum number of links to the file. If <i>path</i> refers to a directory, then the value applies to the whole directory.
<code>_PC_MAX_CANON<sup>1</sup></code>	Returns the maximum length of a formatted input line; the <i>path</i> must refer to a terminal.
<code>_PC_MAX_INPUT<sup>1</sup></code>	Returns the maximum length of an input line; the <i>path</i> must refer to a terminal.

Constant	Action
<code>_PC_NAME_MAX</code>	Returns the maximum length of a filename in <i>path</i> that the process is allowed to create.
<code>_PC_PATH_MAX</code>	Returns the maximum length of a relative pathname when <i>path</i> is the current working directory.
<code>_PC_PIPE_BUF</code>	Returns the size of the pipe buffer; the <i>path</i> must refer to a FIFO.
<code>_PC_CHOWN_RESTRICTED</code> <sup>1</sup>	Returns nonzero if <code>PXFCCHOWN</code> may not be used on this file. If <i>path</i> refers to a directory, then this applies to all files in that directory.
<code>_PC_NO_TRUNC</code> <sup>1</sup>	Returns nonzero if accessing filenames longer than <code>_POSIX_NAME_MAX</code> will generate an error.
<code>_PC_VDISABLE</code> <sup>1</sup>	Returns nonzero if special character processing can be disabled; the <i>path</i> must refer to a terminal.
<sup>1</sup> <code>L*X, M*X</code>	

On Linux\* and macOS systems, the corresponding macros are defined in `<unistd.h>`. The values for *name* can be obtained by using `PXFCCONST` or `IPXFCCONST` when passing the string names of predefined macros in `<unistd.h>`. The following table shows the corresponding macro names for the above constants:

Constant	Corresponding Macro
<code>_PC_LINK_MAX</code>	<code>_POSIX_LINK_MAX</code>
<code>_PC_MAX_CANON</code>	<code>_POSIX_MAX_CANON</code>
<code>_PC_MAX_INPUT</code>	<code>_POSIX_MAX_INPUT</code>
<code>_PC_NAME_MAX</code>	<code>_POSIX_NAME_MAX</code>
<code>_PC_PATH_MAX</code>	<code>_POSIX_PATH_MAX</code>
<code>_PC_PIPE_BUF</code>	<code>_POSIX_PIPE_BUF</code>
<code>_PC_CHOWN_RESTRICTED</code>	<code>_POSIX_CHOWN_RESTRICTED</code>
<code>_PC_NO_TRUNC</code>	<code>_POSIX_NO_TRUNC</code>
<code>_PC_VDISABLE</code>	<code>_POSIX_VDISABLE</code>

## PXFPAUSE

**POSIX Subroutine:** *Suspends process execution.*

## Module

USE IFPOSIX

## Syntax

```
CALL PXFPAUSE (ierror)
```

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFPAUSE subroutine causes the invoking process (or thread) to sleep until a signal is received that either terminates it or causes it to call a signal-catching function.

## PXFPIPE

**POSIX Subroutine:** *Creates a communications pipe between two processes. This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

## Syntax

```
CALL PXFPIPE (ireadfd,iwritefd,ierror)
```

*ireadfd* (Output) INTEGER(4). The file descriptor for reading.

*iwritefd* (Output) INTEGER(4). The file descriptor for writing.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFPIPE subroutine returns a pair of file descriptors, pointing to a pipe inode, and places them into *ireadfd* for reading and into *iwritefd* for writing.

## PXFPOSIXIO

**POSIX Subroutine:** *Sets the current value of the POSIX I/O flag.*

---

### Module

USE IFPOSIX

## Syntax

```
CALL PXFPOSIXIO (new,old,ierror)
```

*new* (Input) INTEGER(4). The new value for the POSIX I/O flag.

*old* (Output) INTEGER(4). The previous value of the POSIX I/O flag.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

This subroutine sets the current value of the Fortran POSIX I/O flag and returns the previous value of the flag. The initial state of the POSIX I/O flag is unspecified.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is 1, the unit is accessed as if the records are newline delimited, even if the file does not contain records that are delimited by a new line character.

If a file is opened with a Fortran OPEN statement when the value of the POSIX I/O flag is zero, a connection to a file descriptor is not assumed and the records in the file are not required to be accessed as if they are newline delimited.

## PXFPUTC

**POSIX Subroutine:** *Outputs a character to logical unit 6 (stdout).*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFPUTC (*ch*,*ierror*)

*ch* (Input) Character. The character to be written.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code. A possible error code is EEND if the end of the file has been reached.

### See Also

PXFGETC

## PXFREAD

**POSIX Subroutine:** *Reads from a file.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFREAD (*ifildes*,*buf*,*nbyte*,*nread*,*ierror*)

*ifildes* (Input) INTEGER(4). The file descriptor of the file to be read from.

*buf* (Output) Character. The buffer that stores the data read from the file.

*nbyte* (Input) INTEGER(4). The number of bytes to read.

*nread* (Output) INTEGER(4). The number of bytes that were read.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFREAD subroutine reads *nbyte* bytes from the file specified by *ifildes* into memory in *buf*. The subroutine returns the total number of bytes read into *nread*. If no error occurs, the value of *nread* will equal the value of *nbyte*.

### See Also

PXFWRITE

## PXFREADDIR

**POSIX Subroutine:** *Reads the current directory entry.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFREADDIR (*idirid*,*jdirent*,*ierror*)

*idirid* (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.

*jdirent* (Output) INTEGER(4). A handle of structure `dirent`.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFREADDIR subroutine reads the entry of the directory associated with *idirid* into the structure associated with handle *jdirent*.

---

#### NOTE

To get a handle for an instance of the `dirent` structure, use PXFSTRUCTCREATE with the string 'dirent' for the structure name.

---

### See Also

PXFOPENDIR

PXFREWINDDIR

## PXFRENAME

**POSIX Subroutine:** *Changes the name of a file.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFRENAME (*old*,*lenold*,*new*,*lennew*,*ierror*)

*old* (Input) Character. The name of the file to be renamed.

*lenold* (Input) INTEGER(4). The length of *old* string.

*new* (Input) Character. The new file name.

*lennew* (Input) INTEGER(4). The length of *new* string.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFREWINDDIR

**POSIX Subroutine:** *Resets the position of the stream to the beginning of the directory.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFREWINDDIR (*idirid*,*ierror*)

*idirid* (Input) INTEGER(4). The ID of a directory obtained from PXFOPENDIR.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFRMDIR

**POSIX Subroutine:** *Removes a directory.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFRMDIR (*path*,*ilen*,*ierror*)

*path* (Input) Character. The directory to be removed. It must be empty.

*ilen* (Input) INTEGER(4). The length of *path* string.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### See Also

PXFMKDIR

PXFCHDIR

## PXFSETENV

**POSIX Subroutine:** *Adds a new environment variable or sets the value of an environment variable.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFSETENV (*name*,*lenname*,*new*,*lennew*,*ioverwrite*,*ierror*)

*name* (Input) Character. The name of the environment variable.

*lenname* (Input) INTEGER(4). The length of *name*.

<i>new</i>	(Input) Character. The value of the environment variable.
<i>lennew</i>	(Input) INTEGER(4). The length of <i>new</i> .
<i>ioverwrite</i>	(Input) INTEGER(4). A flag indicating whether to change the value of the environment variable if it exists.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

If *name* does not exist, PXFSETENV adds it with value *new*.

If *name* exists, PXFSETENV sets its value to *new* if *ioverwrite* is a nonzero number. If *ioverwrite* is zero, the value of *name* is not changed.

If *lennew* is equal to zero, PXFSETENV sets the value of the environment variable to a string equal to *new* after removing any leading or trailing blanks.

### Example

```

program test2
  use ifposix
  character*10 name, new
  integer lenname, lennew, ioverwrite, ierror
  name = "FOR_NEW"
  lenname = 7
  new = "ON"
  lennew = 2
  ioverwrite = 1

  CALL PXFSETENV (name, lenname, new, lennew, ioverwrite, ierror)
  print *, "name= ", name
  print *, "lenname= ", lenname
  print *, "new= ", lenname
  print *, "lennew= ", lenname
  print *, "ierror= ", ierror
end

```

### See Also

PXFGETENV

### PXFSETGID

**POSIX Subroutine:** Sets the effective group ID of the current process. This routine is only available for Linux and macOS.

### Module

USE IFPOSIX

### Syntax

CALL PXFSETGID (*igid*, *ierror*)

<i>igid</i>	(Input) INTEGER(4). The group ID.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

If the caller is the superuser, the real and saved group ID's are also set. This feature allows a program other than root to drop all of its group privileges, do some un-privileged work, and then re-engage the original effective group ID in a secure manner.

---

**Caution**

If the user is root then special care must be taken. PXFSETGID checks the effective gid of the caller. If it is the superuser, all process-related group ID's are set to gid. After this has occurred, it is impossible for the program to regain root privileges.

---

**See Also**

PXFGETGID

**PXFSETPGID**

**POSIX Subroutine:** *Sets the process group ID. This routine is only available for Linux and macOS.*

---

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFSETPGID (ipid,ipgid,ierror)
```

*ipid* (Input) INTEGER(4). The process group ID to change.

*ipgid* (Input) INTEGER(4). The new process group ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSETPGID subroutine sets the process group ID of the process specified by *ipid* to *ipgid*.

If *ipid* is zero, the process ID of the current process is used. If *ipgid* is zero, the process ID of the process specified by *ipid* is used.

PXFSETPGID can be used to move a process from one process group to another, but both process groups must be part of the same session. In this case, *ipgid* specifies an existing process group to be joined and the session ID of that group must match the session ID of the joining process.

**PXFSETSID**

**POSIX Subroutine:** *Creates a session and sets the process group ID. This routine is only available for Linux and macOS.*

---

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFSETSID (isid,ierror)
```

*isid* (Output) INTEGER(4). The session ID.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSETSID subroutine creates a new session if the calling process is not a process group leader.

The calling process is the leader of the new session and the process group leader for the new process group.

The calling process has no controlling terminal.

The process group ID and session ID of the calling process are set to the PID of the calling process. The calling process will be the only process in this new process group and in this new session.

## PXFSETUID

**POSIX Subroutine:** *Sets the effective user ID of the current process. This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFSETUID (*iuid*,*ierror*)

*iuid* (Output) INTEGER(4). The session ID.

*ierror* (Output) INTEGER(4). The user status.

If successful, *ierror* is set to zero; otherwise, an error code.

If the effective user ID of the caller is root, the real and saved user ID's are also set. This feature allows a program other than root to drop all of its user privileges, do some un-privileged work, and then re-engage the original effective user ID in a secure manner.

---

### Caution

If the user is root then special care must be taken. PXFSETUID checks the effective uid of the caller. If it is the superuser, all process-related user ID's are set to uid. After this has occurred, it is impossible for the program to regain root privileges.

---

## See Also

PXFGETUID

## PXFSIGACTION

**POSIX Subroutine:** *Changes the action associated with a specific signal. It can also be used to examine the action of a signal. This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFSIGACTION (*isig*,*jsigact*,*josigact*,*ierror*)

<i>isig</i>	(Input) INTEGER(4). The signal number whose action should be changed.
<i>jsigact</i>	(Input) INTEGER(4). A handle of structure <i>sigaction</i> . Specifies the new action for signal <i>isig</i> .
<i>josigact</i>	(Output) INTEGER(4). A handle of structure <i>sigaction</i> . Stores the previous action for signal <i>isig</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The signal specified in *isig* can be any valid signal except SIGKILL and SIGSTOP.

If *jsigact* is nonzero, the new action for signal *isig* is installed from the structure associated with handle *jsigact*. If *josigact* is nonzero, the previous action of the specified signal is saved in the structure associated with handle *josigact* where it can be examined.

---

**NOTE**

To get a handle for an instance of the *sigaction* structure, use PXFSTRUCTCREATE with the string 'sigaction' for the structure name.

---

## See Also

PXFSTRUCTCREATE

## PXFSIGADDSET

**POSIX Subroutine:** *Adds a signal to the signal set.*  
*This routine is only available for Linux and macOS.*

---

## Module

USE IFPOSIX

## Syntax

CALL PXFSIGADDSET (*jsigset*,*isigno*,*ierror*)

<i>jsigset</i>	(Input) INTEGER(4). A handle of structure <i>sigset</i> . This is the set to add the signal to.
<i>isigno</i>	(Input) INTEGER(4). The signal number to add to the set.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSIGADDSET subroutine adds signal number *isigno* to the set of signals associated with handle *jsigset*. This set of signals is used by PXFSIGACTION as field *sa\_mask* in structure *sigaction*. It defines the set of signals that will be blocked during execution of the signal handler function (the field *sa\_handler* in structure *sigaction*).

On Windows\* systems, PXFSIGACTION ignores the field *sa\_mask* in structure *sigaction*.

**NOTE**

To get a handle for an instance of the `sigset` structure, use `PXFSTRUCTCREATE` with the string 'sigset' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`  
`PXFSIGDELSET`  
`PXFSIGACTION`

**PXFSIGDELSET**

**POSIX Subroutine:** *Deletes a signal from the signal set. This routine is only available for Linux and macOS.*

---

**Module**

`USE IFPOSIX`

**Syntax**

`CALL PXFSIGDELSET (jsigset, isigno, ierror)`

<code>jsigset</code>	(Input) <code>INTEGER(4)</code> . A handle of structure <code>sigset</code> . This is the set to delete the signal from.
<code>isigno</code>	(Input) <code>INTEGER(4)</code> . The signal number to delete from the set.
<code>ierror</code>	(Output) <code>INTEGER(4)</code> . The error status.

If successful, `ierror` is set to zero; otherwise, an error code.

The `PXFSIGDELSET` subroutine removes signal number `isigno` from the set of signals associated with handle `jsigset`. This set of signals is used by `PXFSIGACTION` as field `sa_mask` in structure `sigaction`. It defines the set of signals that will be blocked during execution of the signal handler function (the field `sa_handler` in structure `sigaction`).

On Windows\* systems, `PXFSIGACTION` ignores the field `sa_mask` in structure `sigaction`.

**NOTE**

To get a handle for an instance of the `sigset` structure, use `PXFSTRUCTCREATE` with the string 'sigset' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`  
`PXFSIGADDSET`  
`PXFSIGACTION`

**PXFSIGEMPTYSET**

**POSIX Subroutine:** *Empties a signal set. This routine is only available for Linux and macOS.*

---

**Module**

`USE IFPOSIX`

## Syntax

```
CALL PXFSIGEMPTYSET (jsigset,ierror)
```

*jsigset* (Input) INTEGER(4). A handle of structure `sigset`. This is the set to empty.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, nonzero.

The PXFSIGEMPTYSET subroutine initializes the signal set associated with handle *jsigset* to empty; all signals are excluded from the set. This set of signals is used by PXFSIGACTION as field `sa_mask` in structure `sigaction`. It defines the set of signals that will be blocked during execution of the signal handler function (the field `sa_handler` in structure `sigaction`).

On Windows\* systems, PXFSIGACTION ignores the field `sa_mask` in structure `sigaction`.

---

### NOTE

To get a handle for an instance of the `sigset` structure, use PXFSTRUCTCREATE with the string 'sigset' for the structure name.

---

## See Also

PXFSTRUCTCREATE

PXFSIGFILLSET

PXFSIGACTION

## PXFSIGFILLSET

**POSIX Subroutine:** *Fills a signal set. This routine is only available for Linux and macOS.*

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFSIGFILLSET (jsigset,ierror)
```

*jsigset* (Input) INTEGER(4). A handle of structure `sigset`. This is the set to fill.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSIGFILLSET subroutine initializes the signal set associated with handle *jsigset* to full; all signals are included into the set. This set of signals is used by PXFSIGACTION as field `sa_mask` in structure `sigaction`. It defines the set of signals that will be blocked during execution of the signal handler function (the field `sa_handler` in structure `sigaction`).

On Windows\* systems, PXFSIGACTION ignores the field `sa_mask` in structure `sigaction`.

**NOTE**

To get a handle for an instance of the `sigset` structure, use `PXFSTRUCTCREATE` with the string 'sigset' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`

`PXFSIGEMPTYSET`

`PXFSIGACTION`

**PXFSIGISMEMBER**

**POSIX Subroutine:** Tests whether a signal is a member of a signal set. This routine is only available for Linux and macOS.

---

**Module**

USE IFPOSIX

**Syntax**

```
CALL PXFSIGISMEMBER (jsignset, isigno, ismember, ierror)
```

<i>jsignset</i>	(Input) INTEGER(4). A handle of structure <code>sigset</code> . This is the set the signal will be tested in.
<i>isigno</i>	(Input) INTEGER(4). The signal number to test for membership.
<i>ismember</i>	(Output) Logical. The returned result.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The `PXFSIGISMEMBER` subroutine tests whether *isigno* is a member of the set associated with handle *jsignset*. If the signal is a member of the set, *ismember* is set to `.TRUE.`; otherwise, `.FALSE.`. This set of signals is used by `PXFSIGACTION` as field `sa_mask` in structure `sigaction`. It defines the set of signals that will be blocked during execution of the signal handler function (the field `sa_handler` in structure `sigaction`).

On Windows\* systems, `PXFSIGACTION` ignores the field `sa_mask` in structure `sigaction`.

**NOTE**

To get a handle for an instance of the `sigset` structure, use `PXFSTRUCTCREATE` with the string 'sigset' for the structure name.

---

**See Also**

`PXFSTRUCTCREATE`

`PXFSIGACTION`

**PXFSIGPENDING**

**POSIX Subroutine:** Examines pending signals. This routine is only available for Linux and macOS.

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFSIGPENDING (jsigset,ierror)
```

*jsigset* (Input) INTEGER(4). A handle of structure `sigaction`. The signals to examine.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSIGPENDING subroutine is used to examine pending signals (ones that have been raised while blocked). The signal mask of the pending signals is stored in the signal set associated with handle *jsigset*.

## PXFSIGPROCMASK

**POSIX Subroutine:** *Changes the list of currently blocked signals. This routine is only available for Linux and macOS.*

---

## Module

USE IFPOSIX

## Syntax

```
CALL PXFSIGPROCMASK (ihow,jsigset,josigset,ierror)
```

*ihow* (Input) INTEGER(4). Defines the action for *jsigset*.

*jsigset* (Input) INTEGER(4). A handle of structure `sigset`. The signals to examine.

*josigset* (Input) INTEGER(4). A handle of structure `sigset`. Stores the previous mask of blocked signals.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The argument *ihow* indicates the way in which the set is to be changed, and consists of one of the following constant names:

---

Constant <sup>1</sup>	Action
SIG_BLOCK	The resulting set of blocked signals will be the union of the current signal set and the <i>jsigset</i> signal set.
SIG_UNBLOCK	The resulting set of blocked signals will be the current set of blocked signals with the signals in <i>jsigset</i> removed. It is legal to attempt to unblock a signal that is not blocked.
SIG_SETMASK	The resulting set of blocked signals will be the <i>jsigset</i> signal set.

---

Constant <sup>1</sup>	Action
<sup>1</sup> These names can be used in PXFCONST or IPXFCONST.	

If *jsigset* is non-zero, the previous value of the signal mask is stored in the structure associated with handle *jsigset*.

## See Also

IPXFCONST

PXFCONST

## PXFSIGSUSPEND

**POSIX Subroutine:** *Suspends the process until a signal is received. This routine is only available for Linux and macOS.*

## Module

USE IFPOSIX

## Syntax

```
CALL PXFSIGSUSPEND (jsigset, ierror)
```

*jsigset* (Input) INTEGER(4). A handle of structure *sigset*. Specifies a set of signals.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFSIGSUSPEND temporarily replaces the signal mask for the process with that given by the structure associated with the *jsigset* handle; it then suspends the process until a signal is received.

## PXFSLEEP

**POSIX Subroutine:** *Forces the process to sleep.*

## Module

USE IFPOSIX

## Syntax

```
CALL PXFSLEEP (iseconds, isecleft, ierror)
```

*iseconds* (Input) INTEGER(4). The number of seconds to sleep.

*isecleft* (Output) INTEGER(4). The number of seconds left to sleep.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSLEEP subroutine forces the current process to sleep until seconds *iseconds* have elapsed or a signal arrives that cannot be ignored.

## PXFSTAT

**POSIX Subroutine:** *Gets a file's status information.*

## Module

USE IFPOSIX

## Syntax

CALL PXFSTAT (*path*,*ilen*,*jstat*,*ierror*)

<i>path</i>	(Input) Character. The path to the file.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>jstat</i>	(Input) INTEGER(4). A handle of structure <i>stat</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFSTAT subroutine puts the status information for the file specified by *path* into the structure associated with handle *jstat*.

---

### NOTE

To get a handle for an instance of the *stat* structure, use PXFSTRUCTCREATE with the string 'stat' for the structure name.

---

## See Also

PXFSTRUCTCREATE

## PXFSTRUCTCOPY

**POSIX Subroutine:** Copies the contents of one structure to another.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFSTRUCTCOPY (*structname*,*jhandle1*,*jhandle2*,*ierror*)

<i>structname</i>	(Input) Character. The name of the structure.
<i>jhandle1</i>	(Input) INTEGER(4). A handle to the structure to be copied.
<i>jhandle2</i>	(Input) INTEGER(4). A handle to the structure that will receive the copy.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## Example

See the example in [PXFSTRUCTCREATE](#)

## PXFSTRUCTCREATE

**POSIX Subroutine:** Creates an instance of the specified structure.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFSTRUCTCREATE (*structname*, *jhandle*, *ierror*)

*structname* (Input) Character. The name of the structure.  
 As for any character string, the name must be specified in single or double quotes; for example, the structure `sigaction` would be specified as 'sigaction'. For more information on available structures, see the table below.

*jhandle* (Output) INTEGER(4). The handle of the newly-created structure.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

If your application passes information to the system, you should call one of the PXF(type)SET subroutines. If your application needs to get information from the structure, you should call one of the PXF(type)GET subroutines.

The following table shows:

- The structures that are available in the Fortran POSIX library
- The fields within each structure
- The subroutines you must use to access the structure fields

Structure Name	Field Names	Subroutines for Access
sigset <sup>1</sup>	Fields are hidden.	PXFSIGEMPTYSET <sup>1</sup> , PXFSIGFILLSET <sup>1</sup> , PXFSIGADDSET <sup>1</sup> , or PXFSIGDELSET <sup>1</sup>
sigaction	sa_handler sa_mask sa_flags	PXFINTGET/PXFINTSET or PXFIN8GET/PXFIN8SET  PXFIN8GET/PXFINTSET or PXFIN8GET/PXFIN8SET  PXFIN8GET/PXFINTSET or PXFIN8GET/PXFIN8SET
utsname	sysname nodename release version machine	For all fields: PXFSTRGET
tms	tms_utime tms_stime tms_cutime tms_cstime	For all fields: PXFIN8GET or PXFIN8SET

Structure Name	Field Names	Subroutines for Access
dirent	d_name	PXFSTRGET
stat	st_mode	For all fields:
	st_ino	PXFINTGET or PXFINT8GET
	st_dev	
	st_nlink	
	st_uid	
	st_gid	
	st_size	
	st_atime	
	st_mtime	
	st_ctime	
utimbuf	actime	For all fields:
	modtime	PXFINTGET or PXFINT8GET
flock <sup>1</sup>	l_type	For all fields:
	l_whence	PXFINTGET or PXFINT8GET
	l_start	
	l_len	
	l_pid	
termios <sup>1</sup>	c_iflag	PXFINTGET/PXFINTSET or PXFINT8GET/PXFINT8SET
	c_oflag	PXFINTGET/PXFINTSET or PXFINT8GET/PXFINT8SET
	c_cflag	PXFINTGET/PXFINTSET or PXFINT8GET/PXFINT8SET
	c_lflag	PXFINTGET/PXFINTSET or PXFINT8GET/PXFINT8SET
	c_cc	PXFINTGET/PXFINTSET or PXFINT8GET/PXFINT8SET
		PXFAINTGET/PXFAINTSET or PXFAINT8GET/PXFAINT8SET
group <sup>1</sup>	gr_name	PXFSTRGET
	gr_gid	PXFINTGET or PXFINT8GET
	gr_nmem	PXFINTGET or PXFINT8GET
	gr_mem	PXFESTRGET
passwd <sup>1</sup>	pw_name	PXFSTRGET
	pw_uid	PXFINTGET or PXFINT8GET
	pw_gid	PXFINTGET or PXFINT8GET
	pw_dir	PXFSTRGET
	pw_shell	PXFSTRGET

Structure Name	Field Names	Subroutines for Access
<sup>1</sup> L*X only		

As for any character string, you must use single or double quotes when specifying a field name in a PXF(type)GET or PXF(type)SET subroutine. For example, field name sysname (in structure utsname) must be specified as 'sysname'.

### Example

```

program test4
  use ifposix
  implicit none
  integer(jhandle_size) jhandle1,jhandle2
  integer(4) ierror,ilen1

  print *, " Create a first instance for structure 'utsname' "
  call PXFSTRUCTCREATE("utsname",jhandle1,ierror)
  if(ierror.NE.0) STOP 'Error: cannot create structure for jhandle1'

  print *, " Create a second instance for structure 'utsname' "
  call PXFSTRUCTCREATE("utsname",jhandle2,ierror)
  if(ierror.NE.0) then
    call PXFSTRUCTFREE(jhandle1,ierror)
    STOP 'test failed - cannot create structure for jhandle2'
  end if

  print *, "Fill the structure associated with jhandle1 with arbitrary data"
  call PXFSTRSET(jhandle1,"sysname","00000000000000",14,ierror)
  if(ierror.NE.0) call Error('Error: can't set component sysname for jhandle1')

  call PXFSTRSET(jhandle1,"Nodename","111111111111",14,ierror)
  if(ierror.NE.0) call Error('Error: can't set component nodename for jhandle1')

  call PXFSTRSET(jhandle1,"RELEASE","222222222222",14,ierror)
  if(ierror.NE.0) call Error('Error: can't set component release for jhandle1')

  call PXFSTRSET(jhandle1,"verSION","333333333333",14,ierror)
  if(ierror.NE.0) call Error('Error: can't set component version for jhandle1')

  call PXFSTRSET(jhandle1,"machine","444444444444",14,ierror)
  if(ierror.NE.0) call Error('Error: can't set component machine for jhandle1')

  print *, "Fill the structure associated with jhandle2 with arbitrary data"
  call PXFSTRSET(jhandle2,"sysname","aaaaaaaa",7,ierror)
  if(ierror.NE.0) call Error('Error: can't set component sysname for jhandle2')

  call PXFSTRSET(jhandle2,"Nodename","BBBBBBBBBB BBB",14,ierror)
  if(ierror.NE.0) call Error('Error: can't set component nodename for jhandle2')

  call PXFSTRSET(jhandle2,"RELEASE","cccc cc-ccnc",12,ierror)
  if(ierror.NE.0) call Error('Error: can't set component release for jhandle2')

  call PXFSTRSET(jhandle2,"verSION","dddd",1,ierror)
  if(ierror.NE.0) call Error('Error: can't set component version for jhandle2')

  call PXFSTRSET(jhandle2,"machine","eeeeee",6,ierror)

```

```
if(ierrone.NE.0) call Error('Error: can't set component machine for jhandle2')

print *, "Print contents of the structure associated with jhandle1"
call PRINT_UTSNAME(jhandle1)

print *, "Print contents of the structure associated with jhandle2"
call PRINT_UTSNAME(jhandle2)

print *, "Get operating system info into structure associated with jhandle1"
call PXFUNAME(jhandle1, ierrone)
if(ierrone.NE.0) call Error('Error: call to PXFUNAME has failed')

print *, "Print contents of the structure associated with jhandle1"
print *, "  returned from PXFUNAME"
call PRINT_UTSNAME(jhandle1)

print *, "Copy the contents of the structure associated with jhandle1"
print *, "  into the structure associated with jhandle2"
call PXFSTRUCTCOPY("utsname", jhandle1, jhandle2, ierrone)
if(ierrone.NE.0) call Error('Error: can't copy jhandle1 contents into jhandle2')

print *, "Print the contents of the structure associated with jhandle2."
print *, "  It should be the same after copying."
call PRINT_UTSNAME(jhandle2)

print *, "Free memory for instance of structure associated with jhandle1"
call PXFSTRUCTFREE(jhandle1, ierrone)
if(ierrone.NE.0) STOP 'Error: can't free instance of structure for jhandle1'

print *, "Free memory for instance of structure associated with jhandle2"
call PXFSTRUCTFREE(jhandle2, ierrone)
if(ierrone.NE.0) STOP 'Error: can't free instance of structure for jhandle2'

print *, "Program terminated normally"
call PXFEXIT(0)
end
```

## See Also

PXFSTRUCTFREE

the example in PXFTIMES

## PXFSTRUCTFREE

**POSIX Subroutine:** *Deletes the instance of a structure.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFSTRUCTFREE (*jhandle*, *ierrone*)

*jhandle* (Input) INTEGER(4). The handle of a structure.

*ierrone* (Output) INTEGER(4). The error status.

If successful, *ierrone* is set to zero; otherwise, an error code.

The `PXFSTRUCTFREE` subroutine deletes the instance of the structure associated with handle *jhandle*.

## Example

See the example in `PXFSTRUCTCREATE`, the example in `PXFTIMES`

## PXFSYSCONF

**POSIX Subroutine:** Gets values for system limits or options.

### Module

USE IFPOSIX

### Syntax

CALL PXFSYSCONF (*name*, *ival*, *ierror*)

*name* (Input) INTEGER(4). The system option you want information about.  
*ival* (Output) INTEGER(4). The returned value.  
*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

PXFSYSCONF lets you determine values for system limits or system options at runtime.

The value for *name* can be any of the following constants:

Constant	Description
<code>_SC_ARG_MAX<sup>1</sup></code>	Indicates the maximum length of the arguments to the <code>PXEXEC</code> family of routines.
<code>_SC_CHILD_MAX<sup>1</sup></code>	Indicates the number of simultaneous processes per user ID.
<code>_SC_CLK_TCK</code>	Indicates the number of clock ticks per second.
<code>_SC_STREAM_MAX<sup>2</sup></code>	Indicates the maximum number of streams that a process can have open at any time.
<code>_SC_TZNAME_MAX</code>	Indicates the maximum number of bytes in a timezone name.
<code>_SC_OPEN_MAX</code>	Indicates the maximum number of files that a process can have open at any time.
<code>_SC_JOB_CONTROL<sup>1</sup></code>	Indicates whether POSIX-style job control is supported.
<code>_SC_SAVED_IDS<sup>1</sup></code>	Indicates whether a process has a saved set-user-ID and a saved set-group-ID.
<code>_SC_VERSION<sup>1</sup></code>	Indicates the year and month the POSIX.1 standard was approved in the format <code>YYYYMML</code> ; the value <code>199009L</code> indicates the most recent revision, 1990.
<code>_SC_BC_BASE_MAX<sup>1</sup></code>	Indicates the maximum obase value accepted by the <code>bc(1)</code> utility.

Constant	Description
<code>_SC_BC_DIM_MAX</code> <sup>1</sup>	Indicates the maximum value of elements that <code>bc(1)</code> permits in an array.
<code>_SC_BC_SCALE_MAX</code> <sup>1</sup>	Indicates the maximum scale value allowed by <code>bc(1)</code> .
<code>_SC_BC_STRING_MAX</code> <sup>1</sup>	Indicates the maximum length of a string accepted by <code>bc(1)</code> .
<code>_SC_COLL_WEIGHTS_MAX</code> <sup>1</sup>	Indicates the maximum numbers of weights that can be assigned to an entry of the <code>LC_COLLATE</code> order keyword in the locale definition file.
<code>_SC_EXPR_NEST_MAX</code> <sup>1,3</sup>	Indicates the maximum number of expressions that can be nested within parentheses by <code>expr(1)</code> .
<code>_SC_LINE_MAX</code> <sup>1</sup>	Indicates the maximum length of a utility's input line length, either from standard input or from a file. This includes the length for a trailing newline.
<code>_SC_RE_DUP_MAX</code> <sup>1</sup>	Indicates the maximum number of repeated occurrences of a regular expression when the interval notation <code>\{m,n\}</code> is used.
<code>_SC_2_VERSION</code> <sup>1</sup>	Indicates the version of the POSIX.2 standard; it is in the format <code>YYYYMML</code> .
<code>_SC_2_DEV</code> <sup>1</sup>	Indicates whether the POSIX.2 C language development facilities are supported.
<code>_SC_2_FORT_DEV</code> <sup>1</sup>	Indicates whether the POSIX.2 FORTRAN language development utilities are supported.
<code>_SC_2_FORT_RUN</code> <sup>1</sup>	Indicates whether the POSIX.2 FORTRAN runtime utilities are supported.
<code>_SC_2_LOCALEDEF</code> <sup>1</sup>	Indicates whether the POSIX.2 creation of locales via <code>localedef(1)</code> is supported.
<code>_SC_2_SW_DEV</code> <sup>1</sup>	Indicates whether the POSIX.2 software development utilities option is supported.
<code>_SC_PAGESIZE</code> (or <code>_SC_PAGE_SIZE</code> )	Indicates the size of a page (in bytes).
<code>_SC_PHYS_PAGES</code> <sup>4</sup>	Indicates the number of pages of physical memory. Note that it is possible for the product of this value and the value of <code>_SC_PAGE_SIZE</code> to overflow.
<code>_SC_AVPHYS_PAGES</code> <sup>4</sup>	Indicates the number of currently available pages of physical memory.

<sup>1</sup>L\*X only

<sup>2</sup>The corresponding POSIX macro is `STREAM_MAX`.

<sup>3</sup>The corresponding POSIX macro is `EXPR_NEST_MAX`.

<sup>4</sup>L\*X, W\*32

The corresponding macros are defined in `<bits/confname.h>` on Linux\* systems; `<unistd.h>` on macOS systems. The values for argument *name* can be obtained by using `PXFCNST` or `IPXFCNST` when passing the string names of predefined macros in the appropriate `.h` file.

## PXFTCDRAIN

**POSIX Subroutine:** *Waits until all output written has been transmitted. This routine is only available for Linux and macOS.*

---

### Module

`USE IFPOSIX`

### Syntax

```
CALL PXFTCDRAIN (ifildes,ierror)
```

*ifildes* (Input) INTEGER(4). The file descriptor associated with the terminal.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFTCFLOW

**POSIX Subroutine:** *Suspends the transmission or reception of data. This routine is only available for Linux and macOS.*

---

### Module

`USE IFPOSIX`

### Syntax

```
CALL PXFTCFLOW (ifildes,iaction,ierror)
```

*ifildes* (Input) INTEGER(4). The file descriptor associated with the terminal.

*iaction* (Input) INTEGER(4). The action to perform.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The `PXFTCFLOW` subroutine suspends or resumes transmission or reception of data from the terminal referred to by *ifildes*. The action performed depends on the value of *iaction*, which must be one of the following constant names:

---

Constant <sup>1</sup>	Action
<code>TCOFF</code>	Output is suspended.
<code>TCOON</code>	Output is resumed.

---

Constant <sup>1</sup>	Action
TCIOFF	A STOP character is transmitted. This should cause the terminal to stop transmitting data to the system.
TCION	A START character is transmitted. This should cause the terminal to resume transmitting data to the system.
<sup>1</sup> These names can be used in PXFCONST or IPXFCONST.	

---

## See Also

IPXFCONST

PXFCONST

## PXFTCFLUSH

**POSIX Subroutine:** Discards terminal input data, output data, or both. This routine is only available for Linux and macOS.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFTCFLUSH (*ifildes*,*iaction*,*ierror*)

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor associated with the terminal.
<i>iaction</i>	(Input) INTEGER(4). The action to perform.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The action performed depends on the value of *iaction*, which must be one of the following constant names:

Constant <sup>1</sup>	Action
TCIFLUSH	Discards all data that has been received but not read.
TCOFLUSH	Discards all data that has been written but not transmitted.
TCIOFLUSH	Discards both data received but not read and data written but not transmitted. (Performs TCIFLUSH and TCOFLUSH actions.)
<sup>1</sup> These names can be used in PXFCONST or IPXFCONST.	

---

PXFCONST

## PXFTCGETATTR

**POSIX Subroutine:** Reads current terminal settings.  
*This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFTCGETATTR (ifildes,jtermios,ierror)
```

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor associated with the terminal.
<i>jtermios</i>	(Output) INTEGER(4). A handle for structure <code>termios</code> . Stores the terminal settings.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

---

#### NOTE

To get a handle for an instance of the `termios` structure, use `PXFSTRUCTCREATE` with the string 'termios' for the structure name.

---

### See Also

PXFSTRUCTCREATE

PXFTCSETATTR

## PXFTCGETPGRP

**POSIX Subroutine:** Gets the foreground process group ID associated with the terminal. *This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFTCGETPGRP (ifildes,ipgid,ierror)
```

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor associated with the terminal.
<i>ipgid</i>	(Output) INTEGER(4). The returned process group ID.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

### See Also

PXFTCSETPGRP

## PXFTCSEENDBREAK

**POSIX Subroutine:** Sends a break to the terminal.  
*This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFTCSEENDBREAK (ifildes, iduration, ierror)
```

*ifildes* (Input) INTEGER(4). The file descriptor associated with the terminal.

*iduration* (Input) INTEGER(4). Indicates how long the break should be.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTCSEENDBREAK subroutine sends a break (a '\0' with a framing error) to the terminal associated with *ifildes*.

## PXFTCSETATTR

**POSIX Subroutine:** Writes new terminal settings.  
*This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

### Syntax

```
CALL PXFTCSETATTR (ifildes, ioptacts, jtermios, ierror)
```

*ifildes* (Input) INTEGER(4). The file descriptor associated with the terminal.

*ioptacts* (Input) INTEGER(4). Specifies when the terminal changes take effect.

*jtermios* (Input) INTEGER(4). A handle for structure `termios`. Contains the new terminal settings.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTCSETATTR subroutine copies all terminal parameters from structure `termios` into the terminal associated with *ifildes*. When the terminal settings will change depends on the value of *ioptacts*, which must be one of the following constant names:

Constant <sup>1</sup>	Action
TCSANOW	The changes occur immediately.
TCSADRAIN	The changes occur after all output written to <i>ifildes</i> has been transmitted.
TCSAFLUSH	The changes occur after all output written to <i>ifildes</i> has been transmitted, and all input that had been received but not read has been discarded.

Constant <sup>1</sup>	Action
<sup>1</sup> These names can be used in PXFCONST or IPXFCONST.	
<b>NOTE</b> To get a handle for an instance of the <code>termios</code> structure, use <code>PXFSTRUCTCREATE</code> with the string 'termios' for the structure name.

PXFSTRUCTCREATE

PXFTCGETATTR

**PXFTCSETPGRP**

**POSIX Subroutine:** Sets the foreground process group ID associated with the terminal. This routine is only available for Linux and macOS.

**Module**

USE IFPOSIX

**Syntax**CALL PXFTCSETPGRP (*ifildes*, *ipgid*, *ierror*)

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor associated with the terminal.
<i>ipgid</i>	(Input) INTEGER(4). The foreground process group ID for <i>ifildes</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

**See Also**

PXFTCGETPGRP

**PXFTIME**

**POSIX Subroutine:** Returns the current system time.

**Module**

USE IFPOSIX

**Syntax**CALL PXFTIME (*itime*, *ierror*)

<i>itime</i>	(Output) INTEGER(4). The returned system time.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTIME subroutine returns the number of seconds since Epoch (00:00:00 UTC, January 1, 1970).

## Example

See the example in [PXFTIMES](#).

## PXFTIMES

**POSIX Subroutine:** *Returns process times.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFTIMES (*jtms*,*itime*,*ierror*)

<i>jtms</i>	(Output) INTEGER(4). A handle of structure <code>tms</code> .
<i>itime</i>	(Output) INTEGER(4). The returned time since system startup.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFTIMES subroutine fills the fields of structure `tms` associated with handle *jtms* with components of time that was spent by the current process. The structure fields are:

- `tms_utime` - User CPU time
- `tms_stime` - System CPU time
- `tms_cutime` - User time of child process
- `tms_cstime` - System time of child process

All members are measured in system clocks. The values can be converted to seconds by dividing by value *ival* returned from the following call:

```
PXFSYSCONF(IPXFCONST('_SC_CLK_TCK'), ival, ierror)
```

User time is the time charged for the execution of user instructions of the calling process. System time is the time charged for execution by the system on behalf of the calling process.

---

### NOTE

To get a handle for an instance of the `tms` structure, use `PXFSTRUCTCREATE` with the string 'tms' for the structure name.

---

## Example

```
program test_uname
  use ifposix
  implicit none
  integer(jhandle_size) jtms1, jtms2
  integer(4) ierror,i
  integer(4),parameter :: n=10000000
  integer(SIZEOF_CLOCK_T) itime,time1,time2, user_time1,user_time2
  integer(SIZEOF_CLOCK_T) system_time1,system_time2
  integer(4) clocks_per_sec, iname
  real(8) s, PI
  real(8) seconds_user, seconds_system

  print *, "Create a first instance for structure 'tms'"
```

```

call PXFSTRUCTCREATE("tms",jtms1,ierror)
if(ierror.NE.0) STOP 'Error: cannot create structure for handle jtms1'
print *, "Create a second instance for structure 'tms'"
call PXFSTRUCTCREATE("tms",jtms2,ierror)
if(ierror.NE.0) then
    call PXFSTRUCTFREE(jtms1,ierror)
    STOP 'Error: cannot create structure for handle jtms2'
end if

print *, 'Do some calculations'
call PXFTIMES(jtms1, itime,ierror)
if(ierror.NE.0) then
    call PXFSTRUCTFREE(jtms1,ierror)
    call PXFSTRUCTFREE(jtms2,ierror)
    STOP 'Error: the first call of PXFTIMES fails'
end if
call PXFTIME(time1, ierror)
if(ierror.NE.0) then
    call PXFSTRUCTFREE(jtms1,ierror)
    call PXFSTRUCTFREE(jtms2,ierror)
    STOP 'Error: the first call of PXFTIME fails'
end if

s = 0._8
PI = atan(1._8)*4
do i=0, n
    s = s + cos(i*PI/n)*sin(i*PI/n)
end do
print *, " s=",s

call PXFTIMES(jtms2, itime,ierror)
if(ierror.NE.0) then
    call PXFSTRUCTFREE(jtms1,ierror)
    call PXFSTRUCTFREE(jtms2,ierror)
    STOP 'Error: the second call of PXFTIMES fails'
end if
call PXFTIME(time2, ierror)
if(ierror.NE.0) then
    call PXFSTRUCTFREE(jtms1,ierror)
    call PXFSTRUCTFREE(jtms2,ierror)
    STOP 'Error: the second call of PXFTIME fails'
end if

    call PXFINTGET(jtms1,"tms_ftime",user_time1,ierror)
    call PXFINTGET(jtms1,"tms_stime",system_time1,ierror)
    call PXFINTGET(jtms2,"tms_ftime",user_time2,ierror)
    call PXFINTGET(jtms2,"tms_stime",system_time2,ierror)
!DIR$ ENDIF

iname = IPXFCONST("_SC_CLK_TCK")
call PXFSYSCONF(iname,clocks_per_sec, ierror)
if(ierror.NE.0) then
    call PXFSTRUCTFREE(jtms1,ierror)

```

```
    call PXFSTRUCTFREE(jtms2,ierror)
    STOP 'Error: the call of PXFSYSCONF fails'
end if

seconds_user = (user_time2 - user_time1)/DBLE(clocks_per_sec)
seconds_system = (system_time2 - system_time1)/DBLE(clocks_per_sec)
print *, " The processor time of calculations:"
print *, " User code execution(in seconds):", seconds_user
print *, " Kernal code execution(in seconds):", seconds_system
print *, " Total processor time(in seconds):", seconds_user + seconds_system
print *, " Elapsed wall clock time(in seconds):", time2 - time1

print *, "Free memory for instance of structure associated with jtms"
call PXFSTRUCTFREE(jtms1,ierror)
call PXFSTRUCTFREE(jtms2,ierror)
end program
```

## See Also

PXFSTRUCTCREATE

## PXFTTYNAME

**POSIX Subroutine:** Gets the terminal pathname.  
*This routine is only available for Linux and macOS.*

---

### Module

USE IFPOSIX

### Syntax

CALL PXFTTYNAME (*ifildes,s,ilen,ierror*)

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor associated with the terminal.
<i>s</i>	(Output) Character. The returned terminal pathname.
<i>ilen</i>	(Output) INTEGER(4). The length of the string stored in <i>s</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFUCOMPARE

**POSIX Subroutine:** Compares two unsigned integers.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFUCOMPARE (*i1,i2,icmpr,idiff*)

<i>i1, i2</i>	(Input) INTEGER(4). The two unsigned integers to compare.
<i>icmpr</i>	(Output) INTEGER(4). The result of the comparison; one of the following values:

---

-1	If $i1 < i2$
0	If $i1 = i2$
1	If $i1 > i2$

---

*idiff* (Output) INTEGER(4). The absolute value of the difference.

The PXFUCOMPARE subroutine compares two unsigned integers and returns the absolute value of their difference into *idiff*.

## PXFUMASK

**POSIX Subroutine:** Sets a new file creation mask and gets the previous one.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFUMASK (*icmask*,*iprevcmask*,*ierror*)

*icmask* (Input) INTEGER(4). The new file creation mask.

*iprevcmask* (Output) INTEGER(4). The previous file creation mask.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFUNAME

**POSIX Subroutine:** Gets the operation system name.

---

### Module

USE IFPOSIX

### Syntax

CALL PXFUNAME (*jutsname*,*ierror*)

*jutsname* (Input) INTEGER(4). A handle of structure `utsname`.

*ierror* (Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFUNAME subroutine provides information about the operation system. The information is stored in the structure associated with handle *jutsname*.

### Example

See the example in [PXFSTRUCTCREATE](#)

## PXFUNLINK

**POSIX Subroutine:** Removes a directory entry.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFUNLINK (*path*,*ilen*,*ierror*)

<i>path</i>	(Input) Character. The name of the directory entry to remove.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

## PXFUTIME

**POSIX Subroutine:** Sets file access and modification times.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFUTIME (*path*,*ilen*,*jutimbuf*,*ierror*)

<i>path</i>	(Input) Character. The path to the file.
<i>ilen</i>	(Input) INTEGER(4). The length of <i>path</i> string.
<i>jutimbuf</i>	(Input) INTEGER(4). A handle of structure <i>utimbuf</i> .
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFUTIME subroutine sets access and modification times for the file pointed to by *path*. The time values are retrieved from structure *utimbuf*.

## PXFWAIT

**POSIX Subroutine:** Waits for a child process. This routine is only available for Linux and macOS.

---

## Module

USE IFPOSIX

## Syntax

CALL PXFWAIT (*istat*,*iretpid*,*ierror*)

<i>istat</i>	(Output) INTEGER(4). The returned status of the child process.
<i>iretpid</i>	(Output) INTEGER(4). The process ID of the stopped child process.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The `PXFWAIT` subroutine suspends execution of the current process until a child has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The subroutine returns in `iretpid` the value of the process ID of the child that exited, or zero if no child was available. The returned value in `istat` can be used in subroutines `IPXFWEXITSTATUS`, `IPXFWSTOPSIG`, `IPXFWTERMSIG`, `PXFWIFEXITED`, `PXFWIFSIGNALED`, and `PXFWIFSTOPPED`.

## Example

```
program t1
use ifposix
integer(4) ipid, istat, ierror, ipid_ret, istat_ret
print *, " the child process will be born"
call PXFFORK(IPID, IERROR)
call PXFGETPID(IPID_RET, IERROR)
if(IPID.EQ.0) then
  print *, " I am a child process"
  print *, " My child's pid is", IPID_RET
  call PXFGETPPID(IPID_RET, IERROR)
  print *, " The pid of my parent is", IPID_RET
  print *, " Now I have exited with code 0xABCD"
  call PXFEXIT(Z'ABCD')
else
  print *, " I am a parent process"
  print *, " My parent pid is ", IPID_RET
  print *, " I am creating the process with pid", IPID
  print *, " Now I am waiting for the end of the child process"
  call PXFWAIT(ISTAT, IPID_RET, IERROR)
  print *, " The child with pid ", IPID_RET, " has exited"
  if( PXFWIFEXITED(ISTAT) ) then
    print *, " The child exited normally"
    istat_ret = IPXFWEXITSTATUS(ISTAT)
    print 10, " The low byte of the child exit code is", istat_ret
  end if
end if
10 FORMAT (A,Z)
end program
```

[PXFWIFSTOPPED](#)

## PXFWAITPID

**POSIX Subroutine:** *Waits for a specific PID. This routine is only available for Linux and macOS.*

## Module

USE IFPOSIX

## Syntax

CALL PXFWAITPID (*ipid*,*istat*,*ioptions*,*iretpid*,*ierror*)

*ipid*

(Input) INTEGER(4). The PID to wait for. One of the following values:

Value	Action
< -1	Specifies to wait for any child process whose process group ID is equal to the absolute value of <i>ipid</i> .
-1	Specifies to wait for any child process; this is the same behavior as PXFWAIT.
0	Specifies to wait for any child process whose process group ID is equal to that of the calling process.
> 0	Specifies to wait for the child whose process ID is equal to the value of <i>ipid</i> .

*istat*

(Output) INTEGER(4). The returned status of the child process.

*ioptions*

(Input) INTEGER(4). One or more of the following constant values (which can be passed to PXFCONST or IPXFCONST):

Value	Action
WNOHANG	Specifies to return immediately if no child process has exited.
WUNTRACED	Specifies to return for child processes that have stopped, and whose status has not been reported.

*iretpid*

(Output) INTEGER(4). The PID of the stopped child process.

*ierror*

(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFWAITPID subroutine suspends execution of the current process until the child specified by *ipid* has exited, or until a signal is delivered whose action terminates the current process or calls a signal handling routine. If the child specified by *ipid* has already exited by the time of the call (a "zombie" process), a return is immediately made. Any system resources used by the child are freed.

The returned value in *istat* can be used in subroutines IPXFWEXITSTATUS, IPXFWSTOPSIG, IPXFWTERMSIG, PXFWIFEXITED, PXFWIFSIGNALED, and PXFWIFSTOPPED.

## PXFWIFEXITED

**POSIX Function:** *Determines if a child process has exited. This routine is only available for Linux and macOS.*

### Module

USE IFPOSIX

### Syntax

```
result = PXFWIFEXITED (istat)
```

*istat* (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

### Results

The result type is logical. The result value is .TRUE. if the child process has exited normally; otherwise, .FALSE..

### Example

```
program t1
  use ifposix
  integer(4) ipid, istat, ierror, ipid_ret, istat_ret
  print *, " the child process will be born"
  call PXFFORK(IPID, IERROR)
  call PXFGETPID(IPID_RET, IERROR)
  if(IPID.EQ.0) then
    print *, " I am a child process"
    print *, " My child's pid is", IPID_RET
    call PXFGETPPID(IPID_RET, IERROR)
    print *, " The pid of my parent is", IPID_RET
    print *, " Now I have exited with code 0xABCD"
    call PXFEXIT(Z'ABCD')
  else
    print *, " I am a parent process"
    print *, " My parent pid is ", IPID_RET
    print *, " I am creating the process with pid", IPID
    print *, " Now I am waiting for the end of the child process"
    call PXFWAIT(ISTAT, IPID_RET, IERROR)
    print *, " The child with pid ", IPID_RET, " has exited"
    if( PXFWIFEXITED(ISTAT) ) then
      print *, " The child exited normally"
      istat_ret = IPXFWEXITSTATUS(ISTAT)
      print 10, " The low byte of the child exit code is", istat_ret
    end if
  end if
  10 FORMAT (A,Z)
end program
```

### See Also

PXFWIFSIGNALED

## PXFWIFSTOPPED

### PXFWIFSIGNALLED

**POSIX Function:** *Determines if a child process has exited because of a signal. This routine is only available for Linux and macOS.*

---

#### Module

USE IFPOSIX

#### Syntax

```
result = PXFWIFSIGNALLED (istat)
```

*istat* (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

#### Results

The result type is logical. The result value is .TRUE. if the child process has exited because of a signal that was not caught; otherwise, .FALSE..

#### See Also

PXFWIFEXITED

PXFWIFSTOPPED

### PXFWIFSTOPPED

**POSIX Function:** *Determines if a child process has stopped. This routine is only available for Linux and macOS.*

---

#### Module

USE IFPOSIX

#### Syntax

```
result = PXFWIFSTOPPED (istat)
```

*istat* (Output) INTEGER(4). The status of the child process (obtained from PXFWAIT or PXFWAITPID).

#### Results

The result type is logical. The result value is .TRUE. if the child process has stopped; otherwise, .FALSE..

#### See Also

PXFWIFEXITED

PXFWIFSIGNALLED

### PXFWRITE

**POSIX Subroutine:** *Writes to a file.*

---

#### Module

USE IFPOSIX

## Syntax

```
CALL PXFWRITE (ifildes,buf,nbyte,nwritten,ierror)
```

<i>ifildes</i>	(Input) INTEGER(4). The file descriptor for the file to be written to.
<i>buf</i>	(Input) Character. The buffer that contains the data to write into the file.
<i>nbyte</i>	(Input) INTEGER(4). The number of bytes to write.
<i>nwritten</i>	(Output) INTEGER(4). The returned number of bytes written.
<i>ierror</i>	(Output) INTEGER(4). The error status.

If successful, *ierror* is set to zero; otherwise, an error code.

The PXFWRITE subroutine writes *nbyte* bytes from the storage *buf* into a file specified by file descriptor *ifildes*. The subroutine returns the total number of bytes read into *nwritten*. If no error occurs, the value of *nwritten* will equal the value of *nbyte*.

# Automation Server and Component Object Model Library Routines

---

This section contains descriptions of the Automation Server (AUTO) and Component Object Model (COM) library routines, which are restricted to Windows\* systems. They are listed in alphabetical order.

To access the appropriate library when using AUTO routines, you must specify a USE IFAUTO statement in your program.

To access the appropriate library when using COM routines, you must specify a USE IFCOM statement in your program.

Some routines also require the USE IFWINTY module. If a procedure requires USE IFWINTY, it is shown in the routine description.

---

### NOTE

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

---

## AUTOAddArg

**AUTO Subroutine:** *Passes an argument name and value and adds the argument to the argument list data structure. This routine is only available for Windows.*

---

## Module

USE IFAUTO

USE IFWINTY

## Syntax

```
CALL AUTOAddArg (invoke_args,name,value[,intent_arg][,type])
```

<i>invoke_args</i>	The argument list data structure. Must be of type <code>INTEGER(INT_PTR_KIND())</code> .
<i>name</i>	The argument's name of type <code>CHARACTER*(*)</code> .
<i>value</i>	The argument's value. Must be of type <code>INTEGER(1)</code> , <code>INTEGER(2)</code> , <code>INTEGER(4)</code> , <code>REAL(4)</code> , <code>REAL(8)</code> , <code>LOGICAL(2)</code> , <code>CHARACTER*(*)</code> , or a single dimension array of one of these types. Can also be of type <code>VARIANT</code> , which is defined in the <code>IFWINTY</code> module.
<i>intent_arg</i>	<p>Indicates the intended use of the argument by the called method. Must be one of the following constants defined in the <code>IFAUTO</code> module:</p> <ul style="list-style-type: none"> <li><code>AUTO_ARG_IN</code>: The argument's value is read by the called method, but not written. This is the default value if <i>intent_arg</i> is not specified.</li> <li><code>AUTO_ARG_OUT</code>: The argument's value is written by the called method, but not read.</li> <li><code>AUTO_ARG_INOUT</code>: The argument's value is read and written by the called method.</li> </ul> <p>When the value of <i>intent_arg</i> is <code>AUTO_ARG_OUT</code> or <code>AUTO_ARG_INOUT</code>, the variable used in the <i>value</i> argument should be declared using the <code>VOLATILE</code> attribute. This is because the value of the variable will be changed by the subsequent call to <code>AUTOInvoke</code>. The compiler's global optimizations need to know that the value can change unexpectedly.</p>
<i>type</i>	The variant type of the argument. Must be one of the following constants defined in the <code>IFWINTY</code> module:

VARIANT Type	Value Type
<code>VT_I1</code>	<code>INTEGER(1)</code>
<code>VT_I2</code>	<code>INTEGER(2)</code>
<code>VT_I4</code>	<code>INTEGER(4)</code>
<code>VT_R4</code>	<code>REAL(4)</code>
<code>VT_R8</code>	<code>REAL(8)</code>
<code>VT_CY</code>	<code>REAL(8)</code>
<code>VT_DATE</code>	<code>REAL(8)</code>
<code>VT_BSTR</code>	<code>CHARACTER*(*)</code>
<code>VT_DISPATCH</code>	<code>INTEGER(4)</code>
<code>VT_ERROR</code>	<code>INTEGER(4)</code>
<code>VT_BOOL</code>	<code>LOGICAL(2)</code>
<code>VT_VARIANT</code>	<code>TYPE(VARIANT)</code>
<code>VT_UNKNOWN</code>	<code>INTEGER(4)</code>

## Example

See the example in [COMInitialize](#).

## AUTOAllocateInvokeArgs

**AUTO Function:** *Allocates an argument list data structure that holds the arguments to be passed to AUTOInvoke. This routine is only available for Windows.*

---

### Module

USE IFAUTO

### Syntax

```
result = AUTOAllocateInvokeArgs( )
```

### Results

The value returned is an argument list data structure of type INTEGER(INT\_PTR\_KIND()).

## Example

See the example in [COMInitialize](#).

## AUTODeallocateInvokeArgs

**AUTO Subroutine:** *Deallocates an argument list data structure. This routine is only available for Windows.*

---

### Module

USE IFAUTO

### Syntax

```
CALL AUTODeallocateInvokeArgs (invoke_args)
```

<i>invoke_args</i>	The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).
--------------------	--

## Example

See the example in [COMInitialize](#).

## AUTOGetExceptInfo

**AUTO Subroutine:** *Retrieves the exception information when a method has returned an exception status. This routine is only available for Windows.*

---

### Module

USE IFAUTO

### Syntax

```
CALL AUTOGetExceptInfo (invoke_args, code, source, description, h_file, h_context, scode)
```

<i>invoke_args</i>	The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).
--------------------	--

<i>code</i>	An output argument that returns the error code. Must be of type INTEGER(2).
<i>source</i>	An output argument that returns a human-readable name of the source of the exception. Must be of type CHARACTER*(*).
<i>description</i>	An output argument that returns a human-readable description of the error. Must be of type CHARACTER*(*).
<i>h_file</i>	An output argument that returns the fully qualified path of a Help file with more information about the error. Must be of type CHARACTER*(*).
<i>h_context</i>	An output argument that returns the Help context of the topic within the Help file. Must be of type INTEGER(4).
<i>scode</i>	An output argument that returns an SCODE describing the error. Must be of type INTEGER(4).

## AUTOGetProperty

**AUTO Function:** *Passes the name or identifier of the property and gets the value of the automation object's property. This routine is only available for Windows.*

---

### Module

USE IFAUTO

USE IFWINTY

### Syntax

```
result = AUTOGetProperty (idispatch,id,value[,type])
```

<i>idispatch</i>	The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
<i>id</i>	The argument's name of type CHARACTER*(*), or its member ID of type INTEGER(4).
<i>value</i>	An output argument that returns the argument's value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER*(*), or a single dimension array of one of these types.
<i>type</i>	The variant type of the requested argument. Must be one of the following constants defined in the IFWINTY module:

---

VARIANT Type	Value Type
VT_I2	INTEGER(2)
VT_I4	INTEGER(4)
VT_R4	REAL(4)
VT_R8	REAL(8)
VT_CY	REAL(8)

VARIANT Type	Value Type
VT_DATE	REAL(8)
VT_BSTR	CHARACTER*(*)
VT_DISPATCH	INTEGER(4)
VT_ERROR	INTEGER(4)
VT_BOOL	LOGICAL(2)
VT_UNKNOWN	INTEGER(4)

## Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

## AUTOGetPropertyByID

**AUTO Function:** Passes the member ID of the property and gets the value of the automation object's property into the argument list's first argument. This routine is only available for Windows.

## Module

USE IFAUTO

## Syntax

```
result = AUTOGetPropertyByID (idispatch, memid, invoke_args)
```

<i>idispatch</i>	The object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
<i>memid</i>	Member ID of the property. Must be of type INTEGER(4).
<i>invoke_args</i>	The argument list data structure. Must be of type INTEGER(INT_PTR_KIND()).

## Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

## AUTOGetPropertyInvokeArgs

**AUTO Function:** Passes an argument list data structure and gets the value of the automation object's property specified in the argument list's first argument. This routine is only available for Windows.

## Module

USE IFAUTO

## Syntax

```
result = AUTOGetPropertyInvokeArgs (idispatch, invoke_args)
```

<code>idispatch</code>	The object's IDispatch interface pointer. Must be of type <code>INTEGER(INT_PTR_KIND())</code> .
<code>invoke_args</code>	The argument list data structure. Must be of type <code>INTEGER(INT_PTR_KIND())</code> .

## Results

Returns an HRESULT describing the status of the operation. Must be of type `INTEGER(INT_PTR_KIND())`.

## AUTOInvoke

**AUTO Function:** *Passes the name or identifier of an object's method and an argument list data structure and invokes the method with the passed arguments. This routine is only available for Windows.*

---

### Module

USE IFAUTO

### Syntax

```
result = AUTOInvoke (idispatch,id,invoke_args)
```

<code>idispatch</code>	The object's IDispatch interface pointer. Must be of type <code>INTEGER(INT_PTR_KIND())</code> .
<code>id</code>	The argument's name of type <code>CHARACTER*(*)</code> , or its member ID of type <code>INTEGER(4)</code> .
<code>invoke_args</code>	The argument list data structure. Must be of type <code>INTEGER(INT_PTR_KIND())</code> .

## Results

Returns an HRESULT describing the status of the operation. Must be of type `INTEGER(4)`.

## Example

See the example in [COMInitialize](#).

## AUTOSetProperty

**AUTO Function:** *Passes the name or identifier of the property and a value, and sets the value of the automation object's property. This routine is only available for Windows.*

---

### Module

USE IFAUTO

USE IFWINTY

### Syntax

```
result = AUTOSetProperty (idispatch,id,value[,type])
```

<code>idispatch</code>	The object's IDispatch interface pointer. Must be of type <code>INTEGER(INT_PTR_KIND())</code> .
------------------------	--

<i>id</i>	The argument's name of type CHARACTER(*), or its member ID of type INTEGER(4).
<i>value</i>	The argument's value. Must be of type INTEGER(2), INTEGER(4), REAL(4), REAL(8), LOGICAL(2), LOGICAL(4), CHARACTER(*), or a single dimension array of one of these types.
<i>type</i>	The variant type of the argument. Must be one of the following constants defined in the IFWINTY module:

VARIANT Type	Value Type
VT_I2	INTEGER(2)
VT_I4	INTEGER(4)
VT_R4	REAL(4)
VT_R8	REAL(8)
VT_CY	REAL(8)
VT_DATE	REAL(8)
VT_BSTR	CHARACTER(*)
VT_DISPATCH	INTEGER(4)
VT_ERROR	INTEGER(4)
VT_BOOL	LOGICAL(2)
VT_UNKNOWN	INTEGER(4)

## Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

## AUTOSetPropertyByID

**AUTO Function:** Passes the member ID of the property and sets the value of the automation object's property into the argument list's first argument. This routine is only available for Windows.

## Module

USE IFAUTO

## Syntax

```
result = AUTOSetPropertyByID (idispatch, memid, invoke_args)
```

*idispatch* The object's IDispatch interface pointer. Must be of type INTEGER(INT\_PTR\_KIND()).

*memid* Member ID of the property. Must be of type INTEGER(4).

*invoke\_args* The argument list data structure. Must be of type INTEGER(INT\_PTR\_KIND()).

## Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

## AUTOSetPropertyInvokeArgs

**AUTO Function:** *Passes an argument list data structure and sets the value of the automation object's property specified in the argument list's first argument. This routine is only available for Windows.*

---

## Module

USE IFAUTO

## Syntax

```
result = AUTOSetPropertyInvokeArgs (idispatch, invoke_args)
```

*idispatch*                                      The object's IDispatch interface pointer. Must be of type INTEGER(INT\_PTR\_KIND()).

*invoke\_args*                                      The argument list data structure. Must be of type INTEGER(INT\_PTR\_KIND()).

## Results

Returns an HRESULT describing the status of the operation. Must be of type INTEGER(4).

## COMAddObjectReference

**COM Function:** *Adds a reference to an object's interface. This routine is only available for Windows.*

---

## Module

USE IFCOM

## Syntax

```
result = COMAddObjectReference (iunknown)
```

*iunknown*                                      An IUnknown interface pointer. Must be of type INTEGER(INT\_PTR\_KIND()).

## Results

The result type is INTEGER(4). It is the object's current reference count.

## See Also

IUnknown::AddRef in the Microsoft® Platform SDK

## COMCLSIDFromProgID

**COM Subroutine:** *Passes a programmatic identifier and returns the corresponding class identifier. This routine is only available for Windows.*

---

## Module

USE IFCOM

## USE IFWINTY

### Syntax

```
CALL COMCLSIDFromProgID (prog_id, clsid, status)
```

<i>prog_id</i>	The programmatic identifier of type CHARACTER*(*).
<i>clsid</i>	The class identifier corresponding to the programmatic identifier. Must be of type GUID, which is defined in the IFWINTY module.
<i>status</i>	The status of the operation. It can be any status returned by CLSIDFromProgID. Must be of type INTEGER(4).

### See Also

CLSIDFromProgID in the Microsoft\* Platform SDK

## COMCLSIDFromString

**COM Subroutine:** *Passes a class identifier string and returns the corresponding class identifier. This routine is only available for Windows.*

---

### Module

USE IFCOM

USE IFWINTY

### Syntax

```
CALL COMCLSIDFromString (string, clsid, status)
```

<i>string</i>	The class identifier string of type CHARACTER*(*).
<i>clsid</i>	The class identifier corresponding to the identifier string. Must be of type GUID, which is defined in the IFWINTY module.
<i>status</i>	The status of the operation. It can be any status returned by CLSIDFromString. Must be of type INTEGER(4).

### See Also

CLSIDFromString in the Microsoft\* Platform SDK

## COMCreateObject

**COM Subroutine:** *A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID. This routine is only available for Windows.*

---

### Module

USE IFCOM

USE IFWINTY

### Description

Your application obtains its first pointer to an object's interface by calling `COMCreateObject`. It creates a new instance of an object class and returns a pointer to it.

## See Also

COMCreateObjectByGUID

COMCreateObjectByProgID

## COMCreateObjectByGUID

**COM Subroutine:** *Passes a class identifier, creates an instance of an object, and returns a pointer to the object's interface. This routine is only available for Windows.*

---

### Module

USE IFCOM

USE IFWINTY

### Syntax

CALL COMCreateObjectByGUID (*clsid, clsctx, iid, interface, status*)

<i>clsid</i>	The class identifier of the class of object to be created. Must be of type GUID, which is defined in the IFWINTY module.
<i>clsctx</i>	Lets you restrict the types of servers used for the object. Must be of type INTEGER(4). Must be one of the CLSCTX_* constants defined in the IFWINTY module.
<i>iid</i>	The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.
<i>interface</i>	An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
<i>status</i>	The status of the operation. It can be any status returned by CoCreateInstance. Must be of type INTEGER(4).

## See Also

CoCreateInstance in the Microsoft\* Platform SDK

## COMCreateObjectByProgID

**COM Subroutine:** *Passes a programmatic identifier, creates an instance of an object, and returns a pointer to the object's IDispatch interface. This routine is only available for Windows.*

---

### Module

USE IFCOM

### Syntax

CALL COMCreateObjectByProgID (*prog\_id, idispatch, status*)

<i>prog_id</i>	The programmatic identifier of type CHARACTER*(*).
<i>idispatch</i>	An output argument that returns the object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

*status* The status of the operation. It can be any status returned by CLSIDFromProgID or CoCreateInstance. Must be of type INTEGER(4).

## See Also

COMCLSIDFromProgID

CoCreateInstance in the OLE section of the Microsoft\* Platform SDK

## COMGetActiveObjectByGUID

**COM Subroutine:** *Passes a class identifier and returns a pointer to the interface of a currently active object. This routine is only available for Windows.*

---

### Module

USE IFCOM

USE IFWINTY

### Syntax

```
CALL COMGetActiveObjectByGUID (clsid,iid,interface,status)
```

<i>clsid</i>	The class identifier of the class of object to be found. Must be of type GUID, which is defined in the IFWINTY module.
<i>iid</i>	The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.
<i>interface</i>	An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
<i>status</i>	The status of the operation. It can be any status returned by GetActiveObject. Must be of type INTEGER(4).

## See Also

GetActiveObject in the Microsoft\* Platform SDK

## COMGetActiveObjectByProgID

**COM Subroutine:** *Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object. This routine is only available for Windows.*

---

### Module

USE IFCOM

### Syntax

```
CALL COMGetActiveObjectByProgID (prog_id,idispatch,status)
```

<i>prog_id</i>	The programmatic identifier of type CHARACTER*(*).
<i>idispatch</i>	An output argument that returns the object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).

*status* The status of the operation. It can be any status returned by CLSIDFromProgID or GetActiveObject. Must be of type INTEGER(4).

## Example

See the example in [COMInitialize](#).

## See Also

CLSIDFromProgID and GetActiveObject in the Microsoft\* Platform SDK

## COMGetFileObject

**COM Subroutine:** *Passes a file name and returns a pointer to the IDispatch interface of an automation object that can manipulate the file. This routine is only available for Windows.*

---

## Module

USE IFCOM

## Syntax

`CALL COMGetFileObject (filename, idispatch, status)`

<i>filename</i>	The path of the file of type CHARACTER*(*).
<i>idispatch</i>	An output argument that returns the object's IDispatch interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
<i>status</i>	The status of the operation. It can be any status returned by the CreateBindCtx or MkParseDisplayName routines, or the IMoniker::BindToObject method. Must be of type INTEGER(4).

## See Also

CreateBindCtx, MkParseDisplayName, and IMoniker::BindToObject in the Microsoft\* Platform SDK

## COMInitialize

**COM Subroutine:** *Initializes the COM library. This routine is only available for Windows.*

---

## Module

USE IFCOM

## Syntax

`CALL COMInitialize (status)`

<i>status</i>	The status of the operation. It can be any status returned by OleInitialize. Must be of type INTEGER(4).
---------------	--

You must use this routine to initialize the COM library before calling any other COM or AUTO routine.

## Example

Consider the following:

```
program COMInitExample
  use ifwin
```

```

use ifcom
use ifauto

    implicit none

    ! Variables
    integer(4) word_app
    integer(4) status
    integer(INT_PTR_KIND()) invoke_args

    call COMInitialize(status)

    ! Call GetActiveObject to get a reference to a running MS WORD application
    call COMGetActiveObjectByProgID("Word.Application", word_app, status)
    if (status >= 0) then
        ! Print the active document
        invoke_args = AutoAllocateInvokeArgs()
        call AutoAddArg(invoke_args, "Copies", 2)
        status = AutoInvoke(word_app, "PrintOut", invoke_args)
        call AutoDeallocateInvokeArgs(invoke_args)
        ! Release the reference
        status = COMReleaseObject(word_app)
    end if

    call COMUninitialize()

end program

```

## See Also

OleInitialize in the Microsoft\* Platform SDK

## COMIsEqualGUID

**COM Function:** *Determines whether two globally unique identifiers (GUIDs) are the same. This routine is only available for Windows.*

### Module

USE IFCOM

USE IFWINTY

### Syntax

```
result = COMIsEqualGUID (guid1, guid2)
```

*guid1*

The first GUID. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).

*guid2*

The second GUID, which will be compared to *guid1*. It must be the same type of GUID as *guid1*. For example, if *guid1* is a CLSID, *guid2* must also be a CLSID.

### Results

The result type is LOGICAL(4). The result is .TRUE. if the two GUIDs are the same; otherwise, .FALSE.

## See Also

IsEqualGUID in the Microsoft\* Platform SDK

## COMQueryInterface

**COM Subroutine:** *Passes an interface identifier and returns a pointer to an object's interface. This routine is only available for Windows.*

---

### Module

USE IFCOM

USE IFWINTY

### Syntax

```
CALL COMQueryInterface (iunknown,iid,interface,status)
```

<i>iunknown</i>	An IUnknown interface pointer. Must be of type INTEGER(4).
<i>iid</i>	The interface identifier of the interface being requested. Must be of type GUID, which is defined in the IFWINTY module.
<i>interface</i>	An output argument that returns the object's interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
<i>status</i>	The status of the operation. It can be any status returned by the IUnknown method QueryInterface. Must be of type INTEGER(4).

## See Also

IUnknown::QueryInterface in the Microsoft\* Platform SDK

## COMReleaseObject

**COM Function:** *Indicates that the program is done with a reference to an object's interface. This routine is only available for Windows.*

---

### Module

USE IFCOM

### Syntax

```
result = COMReleaseObject (iunknown)
```

<i>iunknown</i>	An IUnknown interface pointer. Must be of type INTEGER(INT_PTR_KIND()).
-----------------	---

### Results

The result type is INTEGER(4). It is the object's current reference count.

### Example

See the example in [COMInitialize](#).

## COMStringFromGUID

**COM Subroutine:** *Passes a globally unique identifier (GUID) and returns a string of printable characters. This routine is only available for Windows.*

---

### Module

USE IFCOM

USE IFWINTY

### Syntax

CALL COMStringFromGUID (*guid*, *string*, *status*)

<i>guid</i>	The GUID to be converted. Must be of type GUID, which is defined in the IFWINTY module. It can be any type of GUID, including a class identifier (CLSID), or an interface identifier (IID).
<i>string</i>	A character variable of type CHARACTER*(*) that receives the string representation of the GUID. The length of the character variable should be at least 38.
<i>status</i>	The status of the operation. If the string is too small to contain the string representation of the GUID, the value is zero. Otherwise, the value is the number of characters in the string representation of the GUID. Must be of type INTEGER(4).

The string representation of a GUID has a format like that of the following:

[c200e360-38c5-11ce-ae62-08002b2b79ef]

where the successive fields break the GUID into the form DWORD-WORD-WORD-WORD-WORD.DWORD covering the 128-bit GUID. The string includes enclosing braces, which are an OLE convention.

### See Also

StringFromGUID2 in the Microsoft\* Platform SDK

## COMUninitialize

**COM Subroutine:** *Uninitializes the COM library. This routine is only available for Windows.*

---

### Module

USE IFCOM

### Syntax

CALL COMUninitialize( )

When using COM routines, this must be the last routine called.

### Example

See the example in [COMInitialize](#).

## National Language Support Library Routines

---

This section contains descriptions of the National Language Support (NLS) library routines, which are restricted to Windows\* systems. They are listed in alphabetical order.

To access these library routines, you must specify a USE IFNLS statement in your program.

---

**NOTE**

Routine names are shown in mixed case to make the names easier to understand. When writing your applications, you can use any case.

---

## MBCharLen

**NLS Function:** Returns the length, in bytes, of the first character in a multibyte-character string. This routine is only available for Windows.

---

### Module

USE IFNLS

### Syntax

```
result = MBCharLen (string)
```

*string* (Input) Character\*(\*). Is a string containing the character whose length is to be determined. It can contain multibyte characters.

### Results

The result type is INTEGER(4). The result is the number of bytes in the first character contained in *string*. The function returns 0 if *string* has no characters (is length 0).

MBCharLen does not test for multibyte character validity.

### See Also

MBCurMax

MBLead

MBLen

MBLen\_Trim

## MBConvertMBToUnicode

**NLS Function:** Converts a multibyte-character string from the current codepage to a Unicode string. This routine is only available for Windows.

---

### Module

USE IFNLS

### Syntax

```
result = MBConvertMBToUnicode (mbstr, unicodestr[, flags])
```

*mbstr* (Input) Character\*(\*). Is a multibyte codepage string to be converted.

*unicodestr* (Output) INTEGER(2). Is an array of integers that is the translation of the input string into Unicode.

*flags* (Input; optional) INTEGER(4). If specified, modifies the string conversion. If *flags* is omitted, the value NLS\$Precomposed is used. Available values (defined in IFNLS.F90) are:

- NLS\$Precomposed - Use precomposed characters always. (default)
- NLS\$Composite - Use composite wide characters always.
- NLS\$UseGlyphChars - Use glyph characters instead of control characters.
- NLS\$ErrorOnInvalidChars - Returns -1 if an invalid input character is encountered.

The flags NLS\$Precomposed and NLS\$Composite are mutually exclusive. You can combine NLS\$UseGlyphChars with either NLS\$Precomposed or NLS\$Composite using an inclusive OR (IOR or OR).

## Results

The result type is INTEGER(4). If no error occurs, the result is the number of bytes written to *unicodestr* (bytes are counted, not characters), or the number of bytes required to hold the output string if *unicodestr* has zero size.

If the *unicodestr* array is bigger than needed to hold the translation, the extra elements are set to space characters. If *unicodestr* has zero size, the function returns the number of bytes required to hold the translation and nothing is written to *unicodestr*.

If an error occurs, one of the following negative values is returned:

- NLS\$ErrorInsufficientBuffer - The *unicodestr* argument is too small, but not zero size so that the needed number of bytes would be returned.
- NLS\$ErrorInvalidFlags - The *flags* argument has an illegal value.
- NLS\$ErrorInvalidCharacter - A character with no Unicode translation was encountered in *mbstr*. This error can occur only if the NLS\$InvalidCharsError flag was used in *flags*.

---

### NOTE

By default, or if *flags* is set to NLS\$Precomposed, the function MBConvertMBToUnicode attempts to translate the multibyte codepage string to a precomposed Unicode string. If a precomposed form does not exist, the function attempts to translate the codepage string to a composite form.

---

## See Also

MBConvertUnicodeToMB

## MBConvertUnicodeToMB

**NLS Function:** *Converts a Unicode string to a multibyte-character string from the current codepage. This routine is only available for Windows.*

---

## Module

USE IFNLS

## Syntax

```
result = MBConvertUnicodeToMB (unicodestr,mbstr[,flags])
```

*unicodestr* (Input) INTEGER(2). Is an array of integers holding the Unicode string to be translated.

*mbstr* (Output) Character\*(\*). Is a translation of Unicode string into multibyte character string from the current codepage.

*flags*

(Input; optional) INTEGER(4). If specified, is an argument to modify the string conversion. If *flags* is omitted, no extra checking of the conversion takes place. Available values (defined in IFNLS.F90) are:

- NLS\$CompositeCheck - Convert composite characters to precomposed.
- NLS\$SepChars - Generate separate characters.
- NLS\$DiscardDns - Discard nonspacing characters.
- NLS\$DefaultChars - Replace exceptions with default character.

The last three flags (NLS\$SepChars, NLS\$DiscardDns, and NLS\$DefaultChars) are mutually exclusive and can be used only if NLS\$CompositeCheck is set, in which case one (and only one) of them is combined with NLS\$CompositeCheck using an inclusive OR (IOR or OR).

These last three flags determine what translation to make when there is no precomposed mapping for a base character/nonspacing character combination in the Unicode wide character string. The default (IOR(NLS\$CompositeCheck, NLS\$SepChars)) is to generate separate characters.

## Results

The result type is INTEGER(4). If no error occurs, it returns the number of bytes written to *mbstr* (bytes are counted, not characters), or the number of bytes required to hold the output string if *mbstr* has zero length. If *mbstr* is longer than the translation, it is blank-padded.

If *mbstr* is zero length, the function returns the number of bytes required to hold the translation and nothing is written to *mbstr*.

If an error occurs, one of the following negative values is returned:

- NLS\$ErrorInsufficientBuffer - The *mbstr* argument is too small, but not zero length so the needed number of bytes is returned.
- NLS\$ErrorInvalidFlags - The *flags* argument has an illegal value.

## See Also

MBConvertMBToUnicode

## MBCurMax

**NLS Function:** Returns the longest possible multibyte character length, in bytes, for the current codepage.

*This routine is only available for Windows.*

---

## Module

USE IFNLS

## Syntax

```
result = MBCurMax( )
```

## Results

The result type is INTEGER(4). The result is the longest possible multibyte character, in bytes, for the current codepage.

The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

## See Also

MBCharLen

## MBINCHARQQ

**NLS Function:** Performs the same function as *INCHARQQ* except that it can read a single multibyte character at once, and it returns the number of bytes read as well as the character. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = MBINCHARQQ (string)
```

*string*

(Output) CHARACTER(MBLenMax). Is a string containing the read characters, padded with blanks up to the length MBLenMax. The MBLenMax parameter, defined in the module IFNLS.F90, is the longest length, in bytes, of any character in any codepage installed on the system.

## Results

The result type is INTEGER(4). The result is the number of characters read.

## See Also

INCHARQQ

MBCurMax

MBCharLen

MBLead

## MBINDEX

**NLS Function:** Performs the same function as *INDEX* except that the strings manipulated can contain multibyte characters. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = MBINDEX (string, substring[,back])
```

*string*

(Input) CHARACTER\*(\*). Is a string to be searched for the presence of *substring*. Can contain multibyte characters.

*substring*

(Input) CHARACTER\*(\*). Is a substring whose position within *string* is to be determined. Can contain multibyte characters.

*back*

(Input; optional) LOGICAL(4). If specified, determines direction of the search. If *back* is .FALSE. or is omitted, the search starts at the beginning of *string* and moves toward the end. If *back* is .TRUE., the search starts end of *string* and moves toward the beginning.

## Results

The result type is INTEGER(4). If *back* is omitted or is .FALSE., it returns the leftmost position in *string* that contains the start of *substring*. If *back* is .TRUE., it returns the rightmost position in *string* that contains the start of *substring*.

If *string* does not contain *substring*, it returns 0. If *substring* occurs more than once, it returns the starting position of the first occurrence ("first" is determined by the presence and value of *back*).

The position returned is a byte index, not a character index, because of the confounding case of multibyte characters. For example, if a substring that is a single multibyte character matches the second multibyte character in a string consisting of two two-byte multi-byte characters the position is 3, not 2.

INDEX

MBSCAN

MBVERIFY

## MBJISToJMS, MBJMSToJIS

**NLS Functions:** *Converts Japan Industry Standard (JIS) characters to Microsoft Kanji (JMS) characters, or converts JMS characters to JIS characters. These routines are only available for Windows.*

---

## Module

USE IFNLS

## Syntax

```
result = MBJISToJMS (char)
```

```
result = MBJMSToJIS (char)
```

*char*

(Input) CHARACTER(2). Is a JIS or JMS character to be converted.

A JIS character is converted only if the lead and trail bytes are in the hexadecimal range 21 through 7E.

A JMS character is converted only if the lead byte is in the hexadecimal range 81 through 9F or E0 through FC, and the trail byte is in the hexadecimal range 40 through 7E or 80 through FC.

## Results

The result type is character with length 2. MBJISToJMS returns a Microsoft Kanji (Shift JIS or JMS) character. MBJMSToJIS returns a Japan Industry Standard (JIS) character.

Only computers with Japanese installed as one of the available languages can use the MBJISToJMS and MBJMSToJIS conversion functions.

[NLSSetLocale](#)

## MBLead

**NLS Function:** *Determines whether a given character is the lead (first) byte of a multibyte character sequence. This routine is only available for Windows.*

---

### Module

USE IFNLS

### Syntax

```
result = MBLead (char)
```

*char* (Input) CHARACTER(1). Is a character to be tested for lead status.

### Results

The result type is LOGICAL(4). The result is .TRUE. if *char* is the first character of a multibyte character sequence; otherwise, .FALSE..

MBLead only works when stepping forward through a whole multibyte character string. For example:

```
DO i = 1, LEN(str) ! LEN returns the number of bytes, not the
                  ! number of characters in str
  WRITE(*, 100) MBLead (str(i:i))
END DO
100  FORMAT (L2, \)
```

MBLead is passed only one character at a time and must start on a lead byte and step through a string to establish context for the character. MBLead does not correctly identify a nonlead byte if it is passed only the second byte of a multibyte character because the status of lead byte or trail byte depends on context.

The function MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context. So, MBStrLead can be much slower than MBLead (up to *n* times slower, where *n* is the length of the string).

### See Also

[MBStrLead](#)

[MBCharLen](#)

## MBLen

**NLS Function:** *Returns the number of characters in a multibyte-character string, including trailing blanks. This routine is only available for Windows.*

---

### Module

USE IFNLS

### Syntax

```
result = MBLen (string)
```

*string* (Input) CHARACTER\*(\*). Is the string whose characters are to be counted. It can contain multibyte characters.

## Results

The result type is INTEGER(4). The result is the number of characters in *string*.

MBLen recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

## See Also

MBLen\_Trim

MBStrLead

## MBLen\_Trim

**NLS Function:** Returns the number of characters in a multibyte-character string, not including trailing blanks. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = MBLen_Trim (string)
```

*string* (Input) Character\*(\*). Is the string whose characters are to be counted. It can contain multibyte characters.

## Results

The result type is INTEGER(4). The result is the number of characters in *string* minus any trailing blanks (blanks are bytes containing character 32 (hex 20) in the ASCII collating sequence).

MBLen\_Trim recognizes multibyte-character sequences according to the multibyte codepage currently in use. It does not test for multibyte-character validity.

## See Also

MBLen

MBStrLead

## MBLGE, MBLGT, MBLLE, MBLLT, MBLEQ, MBLNE

**NLS Functions:** Perform the same functions as LGE, LGT, LLE, LLT and the logical operators .EQ. and .NE. except that the strings being compared can include multibyte characters, and optional flags can modify the comparison. These routines are only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = MBLGE (string_a, string_b, [ flags])
```

```
result = MBLGT (string_a, string_b, [ flags])
```

```
result = MBLLE (string_a, string_b, [ flags])
```

```
result = MBLLT (string_a, string_b, [ flags])
```

```
result = MBLEQ (string_a,string_b, [ flags])
```

```
result = MBLNE (string_a,string_b, [ flags])
```

*string\_a, string\_b* (Input) Character\*(\*). Are the strings to be compared. It can contain multibyte characters.

*flags* (Input; optional) INTEGER(4). If specified, determines which character traits to use or ignore when comparing strings. You can combine several flags using an inclusive OR (IOR or OR). There are no illegal combinations of flags, and the functions may be used without flags, in which case all flag options are turned off.

The available values (defined in IFNLS.F90) are:

- NLS\$MB\_IgnoreCase - Ignore case.
- NLS\$MB\_IgnoreNonspace - Ignore nonspacing characters (this flag removes Japanese accent characters if they exist).
- NLS\$MB\_IgnoreSymbols - Ignore symbols.
- NLS\$MB\_IgnoreKanaType - Do not differentiate between Japanese Hiragana and Katakana characters (corresponding Hiragana and Katakana characters will compare as equal).
- NLS\$MB\_IgnoreWidth - Do not differentiate between a single-byte character and the same character as a double byte.
- NLS\$MB\_StringSort - Sort all symbols at the beginning, including the apostrophe and hyphen (see the NOTE below).

## Results

The result type is LOGICAL(4). Comparisons are made using the current locale, not the current codepage. The codepage used is the default for the language/country combination of the current locale.

The results of these functions are as follows:

- MBLGE returns .TRUE. if the strings are equal or *string\_a* comes last in the collating sequence; otherwise, .FALSE..
- MBLGT returns .TRUE. if *string\_a* comes last in the collating sequence; otherwise, .FALSE..
- MBLLE returns .TRUE. if the strings are equal or *string\_a* comes first in the collating sequence; otherwise, .FALSE..
- MBLLT returns .TRUE. if *string\_a* comes first in the collating sequence; otherwise, .FALSE..
- MBLEQ returns .TRUE. if the strings are equal in the collating sequence; otherwise, .FALSE..
- MBLNE returns .TRUE. if the strings are not equal in the collating sequence; otherwise, .FALSE..

If the two strings are of different lengths, they are compared up to the length of the shortest one. If they are equal to that point, then the return value indicates that the longer string is greater.

If *flags* is invalid, the functions return .FALSE..

If the strings supplied contain Arabic Kashidas, the Kashidas are ignored during the comparison. Therefore, if the two strings are identical except for Kashidas within the strings, the functions return a value indicating they are "equal" in the collation sense, though not necessarily identical.

---

### NOTE

When not using the NLS\$MB\_StringSort flag, the hyphen and apostrophe are special symbols and are treated differently than others. This is to ensure that words like coop and co-op stay together within a list. All symbols, except the hyphen and apostrophe, sort before any other alphanumeric character. If you specify the NLS\$MB\_StringSort flag, hyphen and apostrophe sort at the beginning also.

## MBNext

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately following the given position in a multibyte-character string. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = MBNext (string,position)
```

<i>string</i>	(Input) Character*(*). Is the string to be searched for the first lead byte or single-byte character after the current position. It can contain multibyte characters.
<i>position</i>	(Input) INTEGER(4). Is the position in <i>string</i> to search from. It must be the position of a lead byte or a single-byte character. Cannot be the position of a trail (second) byte of a multibyte character.

## Results

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in *string* immediately following the position given in *position*, or 0 if no following first byte is found in *string*.

## See Also

MBPrev

## MBPrev

**NLS Function:** Returns the position of the first lead byte or single-byte character immediately preceding the given string position in a multibyte-character string. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = MBPrev (string,position)
```

<i>string</i>	(Input) Character*(*). Is a string to be searched for the first lead byte or single-byte character before the current position. It can contain multibyte characters.
<i>position</i>	(Input) INTEGER(4). The position in <i>string</i> to search from. It must be the position of a lead byte or single-byte character. Cannot be the position of the trail (second) byte of a multibyte character.

## Results

The result type is INTEGER(4). The result is the position of the first lead byte or single-byte character in *string* immediately preceding the position given in *position*, or 0 if no preceding first byte is found in *string*.

## See Also

MBNext

## MBSCAN

**NLS Function:** *Performs the same function as SCAN except that the strings manipulated can contain multibyte characters. This routine is only available for Windows.*

---

## Module

USE IFNLS

## Syntax

```
result = MBSCAN (string, set[, back])
```

*string* (Input) Character\*(\*). Is the string to be searched for the presence of any character in *set*.

*set* (Input) Character\*(\*). Are the characters to search for.

*back* (Input; optional) LOGICAL(4). If specified, determines direction of the search.

If *back* is .FALSE. or is omitted, the search starts at the beginning of *string* and moves toward the end. If *back* is .TRUE., the search starts end of *string* and moves toward the beginning.

## Results

The result type is INTEGER(4). If *back* is .FALSE. or is omitted, it returns the position of the leftmost character in *string* that is in *set*. If *back* is .TRUE., it returns the rightmost character in *string* that is in *set*. If no characters in *string* are in *set*, it returns 0.

SCAN

MBINDEX

MBVERIFY

## MBStrLead

**NLS Function:** *Performs a context-sensitive test to determine whether a given character byte in a string is a multibyte-character lead byte. This routine is only available for Windows.*

---

## Module

USE IFNLS

## Syntax

```
result = MBStrLead (string, position)
```

<i>string</i>	(Input) Character*(*). Is a string containing the character byte to be tested for lead status.
<i>position</i>	(Input) INTEGER(4). Is the position in <i>string</i> of the character byte in the string to be tested.

## Results

The result type is LOGICAL(4). The result is .TRUE. if the character byte in *position* of *string* is a lead byte; otherwise, .FALSE..

MBStrLead is passed a whole string and can identify any byte within the string as a lead or trail byte because it performs a context-sensitive test, scanning all the way back to the beginning of a string if necessary to establish context.

MBLead is passed only one character at a time and must start on a lead byte and step through a string one character at a time to establish context for the character. So, MBStrLead can be much slower than MBLead (up to *n* times slower, where *n* is the length of the string).

MBLead

## MBVERIFY

**NLS Function:** *Performs the same function as VERIFY except that the strings manipulated can contain multibyte characters. This routine is only available for Windows.*

---

## Module

USE IFNLS

## Syntax

```
result = MBVERIFY (string,set[,back])
```

<i>string</i>	(Input) Character*(*). Is the string to be searched for presence of any character not in <i>set</i> .
<i>set</i>	(Input) Character*(*). Is a set of characters tested to verify that it includes all the characters in <i>string</i> .
<i>back</i>	(Input; optional) LOGICAL(4). If specified, determines the direction of the search. If <i>back</i> is .FALSE. or is omitted, the search starts at the beginning of <i>string</i> and moves toward the end. If <i>back</i> is .TRUE., the search starts end of <i>string</i> and moves toward the beginning.

## Results

The result type is INTEGER(4). If *back* is .FALSE. or is omitted, it returns the position of the leftmost character in *string* that is not in *set*. If *back* is .TRUE., it returns the rightmost character in *string* that is not in *set*. If all the characters in *string* are in *set*, it returns 0.

## NLSEnumCodepages

**NLS Function:** Returns an array containing the codepages supported by the system, with each array element describing one valid codepage. This routine is only available for Windows.

---

### Module

USE IFNLS

### Syntax

```
ptr=> NLSEnumCodepages ( )
```

### Results

The result is a pointer to an array of codepages, with each element describing one supported codepage.

---

#### NOTE

After use, the pointer returned by NLSEnumCodepages should be deallocated with the DEALLOCATE statement.

---

### See Also

NLSEnumLocales

DEALLOCATE

## NLSEnumLocales

**NLS Function:** Returns an array containing the language and country combinations supported by the system, in which each array element describes one valid combination. This routine is only available for Windows.

---

### Module

USE IFNLS

### Syntax

```
ptr=> NLSEnumLocales ( )
```

### Results

The result is a pointer to an array of locales, in which each array element describes one supported language and country combination. Each element has the following structure:

```
TYPE NLS$EnumLocale
  CHARACTER* (NLS$MaxLanguageLen)  Language
  CHARACTER* (NLS$MaxCountryLen)    Country
  INTEGER(4)                        DefaultWindowsCodepage
  INTEGER(4)                        DefaultConsoleCodepage
END TYPE
```

If the application is a Windows or QuickWin application, NLS\$DefaultWindowsCodepage is the codepage used by default for the given language and country combination. If the application is a console application, NLS\$DefaultConsoleCodepage is the codepage used by default for the given language and country combination.

**NOTE**

After use, the pointer returned by `NLSEnumLocales` should be deallocated with the `DEALLOCATE` statement.

**NLSFormatCurrency**

**NLS Function:** *Returns a correctly formatted currency string for the current locale. This routine is only available for Windows.*

---

**Module**

USE IFNLS

**Syntax**

```
result = NLSFormatCurrency (outstr,instr[,flags])
```

<i>outstr</i>	(Output) Character*(*). Is a string containing the correctly formatted currency for the current locale. If <i>outstr</i> is longer than the formatted currency, it is blank-padded.
<i>instr</i>	(Input) Character*(*). Is the number string to be formatted. It can contain only the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.
<i>flags</i>	(Input; optional) INTEGER(4). If specified, modifies the currency conversion. If you omit <i>flags</i> , the flag <code>NLS\$Normal</code> is used. Available values (defined in <code>IFNLS.F90</code> ) are: <ul style="list-style-type: none"><li>• <code>NLS\$Normal</code> - No special formatting</li><li>• <code>NLS\$NoUserOverride</code> - Do not use user overrides</li></ul>

**Results**

The result type is `INTEGER(4)`. The result is the number of characters written to *outstr* (bytes are counted, not multibyte characters).

If an error occurs, the result is one of the following negative values:

- `NLS$ErrorInsufficientBuffer` - *outstr* buffer is too small
- `NLS$ErrorInvalidFlags` - *flags* has an illegal value
- `NLS$ErrorInvalidInput` - *instr* has an illegal value

**Example**

```
USE IFNLS
CHARACTER(40) str
INTEGER(4) i
i = NLSFormatCurrency(str, "1.23")
print *, str                      ! prints $1.23
i = NLSFormatCurrency(str, "1000000.99")
print *, str                      ! prints $1,000,000.99
```

```
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatCurrency(str, "1.23")
print *, str                ! prints 1 Pts
i = NLSFormatCurrency(str, "1000000.99")
print *, str                ! prints 1.000.001 Pts
```

## NLSFormatDate

**NLS Function:** *Returns a correctly formatted string containing the date for the current locale. This routine is only available for Windows.*

## Module

USE IFNLS

## Syntax

```
result = NLSFormatDate (outstr [, intime] [, flags])
```

<i>outstr</i>	(Output) Character(*). Is a string containing the correctly formatted date for the current locale. If <i>outstr</i> is longer than the formatted date, it is blank-padded.
<i>intime</i>	(Input; optional) INTEGER(4). If specified, the date to be formatted for the current locale. It must be an integer date such as the packed time created with PACKTIMEQQ. If you omit <i>intime</i> , the current system date is formatted and returned in <i>outstr</i> .
<i>flags</i>	(Input; optional) INTEGER(4). If specified, modifies the date conversion. If you omit <i>flags</i> , the flag NLS\$Normal is used. Available values (defined in IFNLS.F90) are: <ul style="list-style-type: none"> <li>• NLS\$Normal - No special formatting</li> <li>• NLS\$NoUserOverride - Do not use user overrides</li> <li>• NLS\$UseAltCalendar - Use the locale's alternate calendar</li> <li>• NLS\$LongDate - Use local long date format</li> <li>• NLS\$ShortDate - Use local short date format</li> </ul>

## Results

The result type is INTEGER(4). The result is the number of characters written to *outstr* (bytes are counted, not multibyte characters).

If an error occurs, the result is one of the following negative values:

- NLS\$ErrorInsufficientBuffer - *outstr* buffer is too small
- NLS\$ErrorInvalidFlags - *flags* has an illegal value
- NLS\$ErrorInvalidInput - *intime* has an illegal value

## Example

```
USE IFNLS
INTEGER(4) i
CHARACTER(40) str
```

```
i = NLSFORMATDATE(str, FLAGS=NLS$NORMAL)           ! 8/1/10
i = NLSFORMATDATE(str, FLAGS=NLS$USEALTCALENDAR)    ! 8/1/10
i = NLSFORMATDATE(str, FLAGS=NLS$LONGDATE)         ! Sunday, August 1, 2010
i = NLSFORMATDATE(str, FLAGS=NLS$SHORTDATE)        ! 8/1/10
END
```

## NLSFormatNumber

**NLS Function:** Returns a correctly formatted number string for the current locale. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = NLSFormatNumber (outstr, instr [, flags])
```

<i>outstr</i>	(Output) Character*(*). Is a string containing the correctly formatted number for the current locale. If <i>outstr</i> is longer than the formatted number, it is padded with blanks.
<i>instr</i>	(Input) Character*(*). Is a number string to be formatted. It can only contain the characters '0' through '9', one decimal point (a period) if a floating-point value, and a minus sign in the first position if negative. All other characters are invalid and cause the function to return an error.
<i>flags</i>	(Input; optional) INTEGER(4). If specified, modifies the number conversion. If you omit <i>flags</i> , the flag NLS\$Normal is used. Available values (defined in IFNLS.F90) are: <ul style="list-style-type: none"><li>• NLS\$Normal - No special formatting</li><li>• NLS\$NoUserOverride - Do not use user overrides</li></ul>

## Results

The result type is INTEGER(4). The result is the number of characters written to *outstr* (bytes are counted, not multibyte characters).

If an error occurs, the result is one of the following negative values:

- NLS\$ErrorInsufficientBuffer - *outstr* buffer is too small
- NLS\$ErrorInvalidFlags - *flags* has an illegal value
- NLS\$ErrorInvalidInput - *instr* has an illegal value

## Example

```
USE IFNLS
CHARACTER(40) str
INTEGER(4) i
i = NLSFormatNumber(str, "1.23")
print *, str           ! prints 1.23
```

```

i = NLSFormatNumber(str, "1000000.99")
print *, str                      ! prints 1,000,000.99
i = NLSSetLocale("Spanish", "Spain")
i = NLSFormatNumber(str, "1.23")
print *, str                      ! prints 1,23
i = NLSFormatNumber(str, "1000000.99")
print *, str                      ! prints 1.000.000,99
END

```

## NLSFormatTime

**NLS Function:** Returns a correctly formatted string containing the time for the current locale. This routine is only available for Windows.

## Module

USE IFNLS

## Syntax

```
result = NLSFormatTime (outstr [, intime] [, flags])
```

<i>outstr</i>	(Output) Character*(*). Is a string containing the correctly formatted time for the current locale. If <i>outstr</i> is longer than the formatted time, it is blank-padded.
<i>intime</i>	(Input; optional) INTEGER(4). If specified, the time to be formatted for the current locale. Must be an integer time such as the packed time created with PACKTIMEQQ. If you omit <i>intime</i> , the current system time is formatted and returned in <i>outstr</i> .
<i>flags</i>	(Input; optional) INTEGER(4). If specified, modifies the time conversion. If you omit <i>flags</i> , the flag NLS\$Normal is used. Available values (defined in IFNLS.F90) are: <ul style="list-style-type: none"> <li>• NLS\$Normal - No special formatting</li> <li>• NLS\$NoUserOverride - Do not use user overrides</li> <li>• NLS\$NoMinutesOrSeconds - Do not return minutes or seconds</li> <li>• NLS\$NoSeconds - Do not return seconds</li> <li>• NLS\$NoTimeMarker - Do not add a time marker string</li> <li>• NLS\$Force24HourFormat - Return string in 24 hour format</li> </ul>

## Results

The result type is INTEGER(4). The result is the number of characters written to *outstr* (bytes are counted, not multibyte characters).

If an error occurs, the result is one of the following negative values:

- NLS\$ErrorInsufficientBuffer - *outstr* buffer is too small
- NLS\$ErrorInvalidFlags - *flags* has an illegal value
- NLS\$ErrorInvalidInput - *intime* has an illegal value

## Example

```
USE IFNLS
INTEGER(4) i
CHARACTER(20) str
i = NLSFORMATTIME(str, FLAGS=NLS$NORMAL)           ! 11:38:28 PM
i = NLSFORMATTIME(str, FLAGS=NLS$NOMINUTESORSECONDS) ! 11 PM
i = NLSFORMATTIME(str, FLAGS=NLS$NOTIMEMARKER)       ! 11:38:28 PM
i = NLSFORMATTIME(str, FLAGS=IOR(NLS$FORCE24HOURFORMAT, &
& NLS$NOSECONDS)) ! 23:38 PM
END
```

## NLSGetEnvironmentCodepage

**NLS Function:** Returns the codepage number for the system (Window) codepage or the console codepage. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

result = NLSGetEnvironmentCodepage (flags)

flags

(Input) INTEGER(4). Tells the function which codepage number to return. Available values (defined in IFNLS.F90) are:

- NLS\$ConsoleEnvironmentCodepage - Gets the codepage for the console.
- NLS\$WindowsEnvironmentCodepage - Gets the current Windows codepage.

## Results

The result type is INTEGER(4).

The result is zero if successful; otherwise, it returns one of the following error codes:

- NLS\$ErrorInvalidFlags - flags has an illegal value.
- NLS\$ErrorNoConsole - There is no console associated with the given application. So, operations with the console codepage are not possible.

## See Also

[NLSSetEnvironmentCodepage](#)

## NLSGetLocale

**NLS Subroutine:** Returns the current language, country, or codepage. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
CALL NLSGetLocale ([language] [,country] [,codepage])
```

*language* (Output; optional) Character\*(\*). Is the current language.

*country* (Output; optional) Character\*(\*). Is the current country.

*codepage* (Output; optional) INTEGER(4). Is the current codepage.

NLSGetLocale returns a valid codepage in *codepage*.

## Example

```
USE IFNLS
CHARACTER(50) cntry, lang
INTEGER(4)    code
CALL NLSGetLocale (lang, cntry, code)    ! get all three
CALL NLSGetLocale (CODEPAGE = code)      ! get the codepage
CALL NLSGetLocale (COUNTRY = cntry, CODEPAGE =code) ! get country
                                                ! and codepage
```

## See Also

NLSSetLocale

## NLSGetLocaleInfo

**NLS Function:** *Returns information about the current locale. This routine is only available for Windows.*

## Module

USE IFNLS

## Syntax

```
result = NLSGetLocaleInfo (type,outstr)
```

*type* (Input) INTEGER(4). Is the NLS parameter requested. A list of parameter names is provided in [NLS LocaleInfo Parameters](#).

*outstr* (Output) Character\*(\*). Is the parameter setting for the current locale. All parameter settings placed in *outstr* are character strings, even numbers. If a parameter setting is numeric, the ASCII representation of the number is used.

If the requested parameter is a date or time string, an explanation of how to interpret the format in *outstr* is provided in [NLS Date and Time Format](#).

## Results

The result type is INTEGER(4). The result is the number of characters written to *outstr* if successful, or if *outstr* has 0 length, the number of characters required to hold the requested information.

Otherwise, the result is one of the following error codes (defined in IFNLS.F90):

- NLS\$ErrorInvalidInput - *type* has an illegal value.
- NLS\$ErrorInsufficientBuffer - The *outstr* buffer was too small, but was not 0 (so that the needed size would be returned).

The NLS\$LI parameters are used for the argument *type* and select the locale information returned by NLSGetLocaleInfo in *outstr*. You can perform an inclusive OR with NLS\$NoUserOverride and any NLS\$LI parameter. This causes NLSGetLocaleInfo to bypass any user overrides and always return the system default value.

The following table lists and describes the NLS\$LI parameters in alphabetical order.

#### NLS LocaleInfo Parameters

Parameter	Description
NLS\$LI_ICALENDARTYPE	Specifies which type of calendar is currently being used: 1 - Gregorian (as in United States) 2 - Gregorian (English strings always) 3 - Era: Year of the Emperor (Japan) 4 - Era: Year of the Republic of China 5 - Tangun Era (Korea)
NLS\$LI_ICENTURY	Specifies whether to use full 4-digit century for the short date only: 0 - Two-digit year 1 - Full century
NLS\$LI_ICOUNTRY	Is the country code, based on international phone codes, also referred to as IBM country codes.
NLS\$LI_ICURRDIGITS	Is the number of decimal digits for the local monetary format.
NLS\$LI_ICURRENCY	Determines how positive currency is represented: 0 - Puts currency symbol in front with no separation: \$1.1 1 - Puts currency symbol in back with no separation: 1.1\$ 2 - Puts currency symbol in front with single space after: \$ 1.1 3 - Puts currency symbol in back with single space before: 1.1 \$
NLS\$LI_IDATE	Short Date format ordering: 0 - Month-Day-Year 1 - Day-Month-Year 2 - Year-Month-Day
NLS\$LI_IDAYLZERO	Specifies whether to use leading zeros in day fields for the short date only: 0 - Use no leading zeros 1 - Use leading zeros
NLS\$LI_IDEFAULTANSICODEPAGE	Is the ANSI code page associated with this locale.
NLS\$LI_IDEFAULTCOUNTRY	Is the country code for the principal country in this locale. This is provided so that partially specified locales can be completed with default values.

Parameter	Description
NLS\$LI_IDEFAULTLANGUAGE	Is the language ID for the principal language spoken in this locale. This is provided so that partially specified locales can be completed with default values.
NLS\$LI_IDEFAULTOEMCODEPAGE	Is the OEM code page associated with the locale.
NLS\$LI_IDIGITS	Is the number of decimal digits.
NLS\$LI_IFIRSTDAYOFWEEK	Specifies which day is considered first in a week: 0 - SDAYNAME1 1 - SDAYNAME2 2 - SDAYNAME3 3 - SDAYNAME4 4 - SDAYNAME5 5 - SDAYNAME6 6 - SDAYNAME7
NLS\$LI_IFIRSTWEEKOFYEAR	Specifies which week of the year is considered first: 0 - Week containing 1/1 1 - First full week following 1/1 2 - First week containing at least 4 days
NLS\$LI_IINTLCURRDIGITS	Is the number of decimal digits for the international monetary format.
NLS\$LI_ILANGUAGE	Is an ID indicating the language.
NLS\$LI_ILDATE	Long Date format ordering: 0 - Month-Day-Year 1 - Day-Month-Year 2 - Year-Month-Day
NLS\$LI_ILZERO	Determines whether to use leading zeros in decimal fields: 0 - Use no leading zeros 1 - Use leading zeros
NLS\$LI_IMEASURE	This value is 0 if the metric system (S.I.) is used and 1 for the U.S. system of measurements.
NLS\$LI_IMONLZERO	Specifies whether to use leading zeros in month fields for the short date only: 0 - Use no leading zeros 1 - Use leading zeros
NLS\$LI_INEGCURR	Determines how negative currency is represented: 0 (\$1.1) 1 -\$1.1

Parameter	Description
	<p>2 \$-1.1</p> <p>3 \$1.1-</p> <p>4 (1.1\$)</p> <p>5 -1.1\$</p> <p>6 1.1-\$</p> <p>7 1.1\$-</p> <p>8 -1.1 \$ (space before \$)</p> <p>9 -\$ 1.1 (space after \$)</p> <p>10 1.1 \$- (space before \$)</p> <p>11 \$ 1.1- (space after \$)</p> <p>12 \$ -1.1 (space after \$)</p> <p>13 1.1- \$ (space before \$)</p> <p>14 (\$ 1.1) (space after \$)</p> <p>15 (1.1 \$) (space before \$)</p>
NLS\$LI_INEGNUMBER	<p>Determines how negative numbers are represented:</p> <p>0 - Puts negative numbers in parentheses: (1.1)</p> <p>1 - Puts a minus sign in front: -1.1</p> <p>2 - Puts a minus sign followed by a space in front: - 1.1</p> <p>3 - Puts a minus sign after: 1.1-</p> <p>4 - Puts a space then a minus sign after: 1.1 -</p>
NLS\$LI_INEGSEPBYSYSPACE	1 if the monetary symbol is separated by a space from a negative amount; otherwise, 0.
NLS\$LI_INEGSIGNPOSN	Determines the formatting index for negative values. Same values as for NLS\$LI_IPOSSIGNPOSN.
NLS\$LI_INEGSYMPRECEDES	1 if the monetary symbol precedes, 0 if it follows a negative amount.
NLS\$LI_IOPTIONALCALENDAR	<p>Specifies which additional calendar types are valid and available for this locale. This can be a null separated list of all valid optional calendars:</p> <p>0 - No additional types valid</p> <p>1 - Gregorian (localized)</p> <p>2 - Gregorian (English strings always)</p> <p>3 - Era: Year of the Emperor (Japan)</p> <p>4 - Era: Year of the Republic of China</p> <p>5 - Tangun Era (Korea)</p>
NLS\$LI_IPOSSEPBYSYSPACE	1 if the monetary symbol is separated by a space from a positive amount; otherwise, 0.

Parameter	Description
NLS\$LI_IPOSSIGNPOSN	Determines the formatting index for positive values: 0 - Parenthesis surround the amount and the monetary symbol 1 - The sign string precedes the amount and the monetary symbol 2 - The sign string follows the amount and the monetary symbol 3 - The sign string immediately precedes the monetary symbol 4 - The sign string immediately follows the monetary symbol
NLS\$LI_IPOSSYMPRECEDES	1 if the monetary symbol precedes, 0 if it follows a positive amount.
NLS\$LI_ETIME	Time format: 0 - Use 12-hour format 1 - Use 24-hour format
NLS\$LI_ITLZERO	Determines whether to use leading zeros in time fields: 0 - Use no leading zeros 1 - Use leading zeros for hours
NLS\$LI_S1159	Is the string for the AM designator.
NLS\$LI_S2359	Is the string for the PM designator.
NLS\$LI_SABBREVCTRYNAME	Is the abbreviated name of the country as per ISO Standard 3166.
NLS\$LI_SABBREVDAYNAME1 - NLS\$LI_SABBREVDAYNAME7	Is the native abbreviated name for each day of the week. 1 = Mon, 2 = Tue, etc.
NLS\$LI_SABBREVLANGNAME	Is the abbreviated name of the language, created by taking the 2-letter language abbreviation as found in ISO Standard 639 and adding a third letter as appropriate to indicate the sublanguage.
NLS\$LI_SABBREVMONTHNAME1 - NLS\$LI_SABBREVMONTHNAME13	Is the native abbreviated name for each month. 1 = Jan, 2 = Feb, etc. 13 = the 13th month, if it exists in the locale.
NLS\$LI_SCOUNTRY	Is the full localized name of the country.
NLS\$LI_SCURRENCY	Is the string used as the local monetary symbol. Cannot be set to digits 0-9.
NLS\$LI_SDATE	Is the character(s) for the date separator. Cannot be set to digits 0-9.
NLS\$LI_SDAYNAME1 - NLS\$LI_SDAYNAME7	Is the native name for each day of the week. 1 = Monday, 2 = Tuesday, etc.
NLS\$LI_SDECIMAL	Is the character(s) used as decimal separator. This is restricted such that it cannot be set to digits 0 - 9.

Parameter	Description
NLS\$LI_SENGCOUNTRY	Is the full English name of the country. This will always be restricted to characters that map into the ASCII 127 character subset.
NLS\$LI_SENGLANGUAGE	Is the full English name of the language from the ISO Standard 639. This will always be restricted to characters that map into the ASCII 127 character subset.
NLS\$LI_SGROUPING	Are the sizes for each group of digits to the left of the decimal. An explicit size is needed for each group; sizes are separated by semicolons. If the last value is 0 the preceding value is repeated. To group thousands, specify "3;0".
NLS\$LI_SINTLSYMBOL	Three characters of the International monetary symbol specified in ISO 4217 "Codes for the Representation of Currencies and Funds", followed by the character separating this string from the amount.
NLS\$LI_SLANGUAGE	Is the full localized name of the language.
NLS\$LI_SLIST	Is the character(s) used to separate list items, for example, comma in many locales.
NLS\$LI_SLONGDATE	Long Date formatting string for this locale. The string returned may contain a string within single quotes ( ' '). Any characters within single quotes should be left as is. The d, M and y should have the day, month, and year substituted, respectively.
NLS\$LI_SMONDECIMALSEP	Is the character(s) used as monetary decimal separator. This is restricted such that it cannot be set to digits 0-9.
NLS\$LI_SMONGROUPING	Are the sizes for each group of monetary digits to the left of the decimal. If the last value is 0, the preceding value is repeated. To group thousands, specify "3;0".
NLS\$LI_SMONTHNAME1 - NLS\$LI_SMONTHNAME13	Is the native name for each month. 1 = January, 2 = February, etc. 13 = the 13th month, if it exists in the locale.
NLS\$LI_SMONTHOUSANDSEP	Is the character(s) used as monetary separator between groups of digits left of the decimal. Cannot be set to digits 0-9.
NLS\$LI_SNATIVECTRYNAME	Is the native name of the country.
NLS\$LI_SNATIVEDIGITS	The ten characters that are the native equivalent to the ASCII 0-9.
NLS\$LI_SNATIVELANGNAME	Is the native name of the language.
NLS\$LI_SNEGATIVESIGN	String value for the negative sign. Cannot be set to digits 0-9.
NLS\$LI_SPOSITIVESIGN	String value for the positive sign. Cannot be set to digits 0-9.
NLS\$LI_SSHORTDATE	Short Date formatting string for this locale. The d, M and y should have the day, month, and year substituted, respectively. See <a href="#">NLS Date and Time Format</a> for explanations of the valid strings.

Parameter	Description
NLS\$LI_STHOUSAND	Is the character(s) used as separator between groups of digits left of the decimal. This is restricted such that it cannot be set to digits 0 - 9.
NLS\$LI_STIME	Character(s) for the time separator. Cannot be set to digits 0-9.
NLS\$LI_STIMEFORMAT	Time formatting string. See <a href="#">NLS Date and Time Format</a> for explanations of the valid strings.

When `NLSGetLocaleInfo ( type, outstr)` returns information about the date and time formats of the current locale, the value returned in *outstr* can be interpreted according to the following tables.

Any text returned within a date and time string that is enclosed within single quotes should be left in the string in its exact form; that is, do not change the text or the location within the string.

#### Day

The day can be displayed in one of four formats using the letter "d". The following table shows the four variations:

d	Day of the month as digits without leading zeros for single-digit days
dd	Day of the month as digits with leading zeros for single-digit days
ddd	Day of the week as a three-letter abbreviation (SABBREVDAYNAME)
dddd	Day of the week as its full name (SDAYNAME)

#### Month

The month can be displayed in one of four formats using the letter "M". The uppercase "M" distinguishes months from minutes. The following table shows the four variations:

M	Month as digits without leading zeros for single-digit months
MM	Month as digits with leading zeros for single-digit months
MMM	Month as a three-letter abbreviation (SABBREVMONTHNAME)
MMMM	Month as its full name (SMONTHNAME)

#### Year

The year can be displayed in one of three formats using the letter "y". The following table shows the three variations:

y	Year represented by only the last digit
yy	Year represented by only the last two digits
yyyy	Year represented by the full 4 digits

#### Period/Era

The period/era string is displayed in a single format using the letters "gg".

gg	Period/Era string
----	-------------------

#### Time

The time can be displayed in one of many formats using the letter "h" or "H" to denote hours, the letter "m" to denote minutes, the letter "s" to denote seconds and the letter "t" to denote the time marker.

The following table shows the numerous variations of the time format. Lowercase "h" denotes the 12 hour clock and uppercase "H" denotes the 24 hour clock. The lowercase "m" distinguishes minutes from months.

---

h	Hours without leading zeros for single-digit hours (12 hour clock)
hh	Hours with leading zeros for single-digit hours (12 hour clock)
H	Hours without leading zeros for single-digit hours (24 hour clock)
HH	Hours with leading zeros for single-digit hours (24 hour clock)
m	Minutes without leading zeros for single-digit minutes
mm	Minutes with leading zeros for single-digit minutes
s	Seconds without leading zeros for single-digit seconds
ss	Seconds with leading zeros for single-digit seconds
t	One-character time marker string
tt	Multicharacter time marker string

---

## Example

```
USE IFNLS
INTEGER(4) strlen
CHARACTER(40) str
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME1, str)
print *, str      ! prints Monday if language is English
strlen = NLSGetLocaleInfo(NLS$LI_SDAYNAME2, str)
print *, str      ! prints Tuesday if language is English
```

[NLSSetLocale](#)

## NLSSetEnvironmentCodepage

**NLS Function:** Sets the codepage for the current console. The specified codepage affects the current console program and any other programs launched from the same console. It does not affect other open consoles or any consoles opened later. This routine is only available for Windows.

---

## Module

USE IFNLS

## Syntax

```
result = NLSSetEnvironmentCodepage (codepage, flags)
```

<i>codepage</i>	(Input) INTEGER(4). Is the number of the codepage to set as the console codepage.
<i>flags</i>	(Input) INTEGER(4). Must be set to NLS \$ConsoleEnvironmentCodepage.

## Results

The result type is INTEGER(4). The result is zero if successful.

Otherwise, it returns one of the following error codes defined in IFNLS.F90:

- NLS\$ErrorInvalidCodepage - *codepage* is invalid or not installed on the system
- NLS\$ErrorInvalidFlags - *flags* is not valid
- NLS\$ErrorNoConsole - There is no console associated with the given applicatio. So operations, with the console codepage are not possible

The *flags* argument must be a NLS\$ConsoleEnvironmentCodepage. It cannot be a NLS \$WindowsEnvironmentCodepage. NLS\$SetEnvironmentCodepage does not affect the Windows\* codepage.

## See Also

NLS\$GetEnvironmentCodepage

## NLS\$SetLocale

**NLS Function:** *Sets the current language, country, or codepage. This routine is only available for Windows.*

## Module

USE IFNLS

## Syntax

```
result = NLS$SetLocale (language[,country] [,codepage])
```

<i>language</i>	(Input) Character*(*). Is one of the languages installed on the current system. It can be the English name of the language (for example, "German") or the native name of the language (for example, "Deutsch"), or the abbreviated language-country code (for example, "de-DE" or "en-US"). If the language-country code is specified, the country argument should be omitted.
<i>country</i>	(Input; optional) Character*(*). If specified, is the name of a country. It can be the English name (for example, "Germany") or the native name (for example, "Deutschland"). If it is the native name, it must have any special characters in that name. The native country name may be used with the English language name and vice-versa. If omitted, the first installed locale with the specified language name will be selected.
<i>codepage</i>	(Input; optional) INTEGER(4). This argument is ignored.

## Results

The result type is INTEGER(4). The result is zero if successful.

Otherwise, one of the following error codes (defined in IFNLS.F90) may be returned:

- NLS\$ErrorInvalidLanguage - *language* is invalid or not supported

- NLS\$ErrorInvalidCountry - *country* is invalid or is not valid with the language specified

---

**NOTE**

NLSSetLocale works on installed locales only. Many locales are supported, but they must be installed through the system Control Panel/International menu.

---

Calling NLSSetLocale has no effect on the locale used by C programs. The locale set with C's setlocale( ) routine is independent of NLSSetLocale.

NLSGetLocale

---

## QuickWin Library Routines

---

This section contains descriptions of the Quickwin library routines, which are restricted to Windows\* systems. They are listed in alphabetical order.

To access these library routines, you must specify a USE IFQWIN statement in your program.

---

**NOTE**

QuickWin applications are only supported for ifort.

---

### ABOUTBOXQQ

**QuickWin Function:** *Specifies the information displayed in the message box that appears when the user selects the About command from a QuickWin application's Help menu. This routine is only available for Windows.*

---

**Module**

USE IFQWIN

**Syntax**

```
result=ABOUTBOXQQ(cstring)
```

*cstring* (Input; output) Character\*(\*). Null-terminated C string.

**Results**

The value of the result is INTEGER(4). It is zero if successful; otherwise, nonzero.

If your program does not call ABOUTBOXQQ, the QuickWin run-time library supplies a default string.

**Example**

```
USE IFQWIN
INTEGER(4) dummy
! Set the About box message
dummy = ABOUTBOXQQ ('Matrix Multiplier\r      Version 1.0'C)
```

## APPENDMENUQQ

**QuickWin Function:** Appends a menu item to the end of a menu and registers its callback subroutine. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = APPENDMENUQQ (menuID, flags, text, routine)
```

<i>menuID</i>	(Input) INTEGER(4). Identifies the menu to which the item is appended, starting with 1 as the leftmost menu.
<i>flags</i>	<p>(Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:</p> <ul style="list-style-type: none"><li>• \$MENUGRAYED - Disables and grays out the menu item.</li><li>• \$MENUDISABLED - Disables but does not gray out the menu item.</li><li>• \$MENUENABLED - Enables the menu item.</li><li>• \$MENUSEPARATOR - Draws a separator bar.</li><li>• \$MENUCHECKED - Puts a check by the menu item.</li><li>• \$MENUUNCHECKED - Removes the check by the menu item.</li></ul>
<i>text</i>	(Input) Character*(*). Menu item name. Must be a null-terminated C string, for example, 'WORDS OF TEXT'C.
<i>routine</i>	<p>(Input) EXTERNAL. Callback subroutine that is called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:</p> <ul style="list-style-type: none"><li>• WINPRINT - Prints the program.</li><li>• WINSAVE - Saves the program.</li><li>• WINEXIT - Terminates the program.</li><li>• WINSELECTTEXT - Selects text from the current window.</li><li>• WINSELECTGRAPHICS - Selects graphics from the current window.</li><li>• WINSELECTALL - Selects the entire contents of the current window.</li><li>• WININPUT - Brings to the top the child window requesting input and makes it the current window.</li><li>• WINCOPY - Copies the selected text and/or graphics from the current window to the Clipboard.</li><li>• WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.</li><li>• WINCLEARPASTE - Clears the paste buffer.</li><li>• WINSIZETOFIT - Sizes output to fit window.</li><li>• WINFULLSCREEN - Displays output in full screen.</li><li>• WINSTATE - Toggles between pause and resume states of text output.</li><li>• WINCASCADE - Cascades active windows.</li><li>• WINTILE - Tiles active windows.</li><li>• WINARRANGE - Arranges icons.</li><li>• WINSTATUS - Enables a status bar.</li></ul>

- WININDEX - Displays the index for QuickWin help.
- WINUSING - Displays information on how to use Help.
- WINABOUT - Displays information about the current QuickWin application.
- NUL - No callback routine.

## Results

The result type is logical. It is `.TRUE.` if successful; otherwise, `.FALSE.`.

You do not need to specify a menu item number, because `APPENDMENUQQ` always adds the new item to the bottom of the menu list. If there is no item yet for a menu, your appended item is treated as the top-level menu item (shown on the menu bar), and *text* becomes the menu title. `APPENDMENUQQ` ignores the callback routine for a top-level menu item if there are any other menu items in the menu. In this case, you can set *routine* to `NUL`.

If you want to insert a menu item into a menu rather than append to the bottom of the menu list, use `INSERTMENUQQ`.

The constants available for flags can be combined with an inclusive `OR` where reasonable, for example `$MENUCHECKED .OR. $MENUENABLED`. Some combinations do not make sense, such as `$MENUENABLED` and `$MENUDISABLED`, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to `APPENDMENUQQ` as *text* by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the *r* underlined, *text* should be `"P&rint"`. Quick-access keys allow users of your program to activate that menu item with the key combination `ALT+QUICK-ACCESS-KEY` (`ALT+R` in the example) as an alternative to selecting the item with the mouse.

## Example

```
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
...
! Append two items to the bottom of the first (FILE) menu
str    = '&Add to File Menu'C ! 'A' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
str    = 'Menu Item &2b'C ! '2' is a quick-access key
result = APPENDMENUQQ(1, $MENUENABLED, str, WINCASCADE)
! Append an item to the bottom of the second (EDIT) menu
str    = 'Add to Second &Menu'C ! 'M' is a quick-access key
result = APPENDMENUQQ(2, $MENUENABLED, str, WINTILE)
```

## CLICKMENUQQ

**QuickWin Function:** *Simulates the effect of clicking or selecting a menu command. The QuickWin application responds as though the user had clicked or selected the command. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

```
result = CLICKMENUQQ (item)
```

*item*

(Input) INTEGER(4). Constant that represents the command selected from the Window menu. Must be one of the following symbolic constants (defined in IFQWIN.F90):

- QWIN\$STATUS - Status command
- QWIN\$TILE - Tile command
- QWIN\$CASCADE - Cascade command
- QWIN\$ARRANGE - Arrange Icons command

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

## See Also

REGISTERMOUSEEVENT

UNREGISTERMOUSEEVENT

WAITONMOUSEEVENT

## DELETEMENUQQ

**QuickWin Function:** *Deletes a menu item from a QuickWin menu. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

```
result = DELETEMENUQQ (menuID, itemID)
```

*menuID*

(Input) INTEGER(4). Identifies the menu that contains the menu item to be deleted, starting with 1 as the leftmost menu.

*itemID*

(Input) INTEGER(4). Identifies the menu item to be deleted, starting with 0 as the top menu item.

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

## Example

```
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
str = 'Add to EDIT Menu'C    ! Append to 2nd menu
result = APPENDMENUQQ(2, $MENUENABLED, str, WINSTATUS)
! Delete third item (EXIT) from menu 1 (FILE)
result = DELETEMENUQQ(1, 3)
```

```
! Delete entire fifth menu (WINDOW)
result = DELETEMENUQQ(5,0)
END
```

## FOCUSQQ

**QuickWin Function:** Sets focus to the window with the specified unit number. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = FOCUSQQ (iunit)
```

*iunit* (Input) INTEGER(4). Unit number of the window to which the focus is set. Unit numbers 0, 5, and 6 refer to the default startup window.

### Results

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

Units 0, 5, and 6 refer to the default window only if the program does not specifically open them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

Unlike SETACTIVEQQ, FOCUSQQ brings the specified unit to the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```

By default IOFOCUS=.TRUE., except for child windows opened with as unit \*. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

## See Also

[SETACTIVEQQ](#)

[INQFOCUSQQ](#)

## GETACTIVEQQ

**QuickWin Function:** Returns the unit number of the currently active child window. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

```
result = GETACTIVEQQ( )
```

### Results

The result type is INTEGER(4). The result is the unit number of the currently active window. If no child window is active, it returns the parameter QWIN\$NOACTIVEWINDOW (defined in IFQWIN.F90).

### See Also

SETACTIVEQQ

GETHWNDQQ

## GETEXITQQ

**QuickWin Function:** Returns the setting for a QuickWin application's exit behavior. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

```
result = GETEXITQQ( )
```

### Results

The result type is INTEGER(4). The result is exit mode with one of the following constants (defined in IFQWIN.F90):

- QWIN\$EXITPROMPT - Displays a message box that reads "Program exited with exit status *n*. Exit Window?", where *n* is the exit status from the program.

If you choose Yes, the application closes the window and terminates. If you choose No, the dialog box disappears and you can manipulate the window as usual. You must then close the window manually.

- QWIN\$EXITNOPERSIST - Terminates the application without displaying a message box.
- QWIN\$EXITPERSIST - Leaves the application open without displaying a message box.

The default for both QuickWin and Console Graphics applications is QWIN\$EXITPROMPT.

### Example

```
! Program to demonstrate GETEXITQQ
USE IFQWIN
INTEGER i
i = GETEXITQQ()
SELECT CASE (i)
CASE (QWIN$EXITPROMPT)
    WRITE(*, *) "Prompt on exit."
CASE (QWIN$EXITNOPERSIST)
```

```
WRITE(*,*) "Exit and close."
CASE (QWIN$EXITPERSIST)
  WRITE(*,*) "Exit and leave open."
END SELECT
END
```

## See Also

SETEXITQQ

## GETHWNDQQ

**QuickWin Function:** *Converts a window unit number into a Windows\* handle. This routine is only available for Windows.*

---

### Module

USE IFQWIN

### Syntax

```
result = GETHWNDQQ (unit)
```

*unit* (Input) INTEGER(4). The window unit number. If *unit* is set to QWIN\$FRAMEWINDOW (defined in IFQWIN.F90), the handle of the frame window is returned.

### Results

The result type is INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The result is a true Windows handle to the window. If *unit* is not open, it returns -1 .

## See Also

GETACTIVEQQ

GETUNITQQ

SETACTIVEQQ

## GETUNITQQ

**QuickWin Function:** *Returns the unit number corresponding to the specified Windows\* handle. This routine is only available for Windows.*

---

### Module

USE IFQWIN

### Syntax

```
result = GETUNITQQ (whandle)
```

*whandle* (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. The Windows handle to the window; this is a unique ID.

### Results

The result type is INTEGER(4). The result is the unit number corresponding to the specified Windows handle. If *whandle* does not exist, it returns -1 .

This routine is the inverse of GETHWNDQQ.

**See Also**

GETHWNDQQ

**GETWINDOWCONFIG**

**QuickWin Function:** Returns the properties of the current window. This routine is only available for Windows.

**Module**

USE IFQWIN

**Syntax**

```
result = GETWINDOWCONFIG (wc)
```

wc

(Output) Derived type windowconfig. Contains window properties. The windowconfig derived type is defined in IFQWIN.F90 as follows:

```
TYPE windowconfig
  INTEGER(2) numxpixels      ! Number of pixels on x-
axis
  INTEGER(2) numypixels      ! Number of pixels on y-
axis
  INTEGER(2) numtextcols     ! Number of text columns
available
  INTEGER(2) numtextrows     ! Number of text rows
available
  INTEGER(2) numcolors       ! Number of color indexes
  INTEGER(4) fontsize        ! Size of default font. Set to
                             ! QWIN$EXTENDFONT when
specifying
                             ! extended attributes, in
which
                             ! case extendfontsize sets
the
                             ! font size
  CHARACTER(80) title        ! The window title
  INTEGER(2) bitsperpixel     ! The number of bits per
pixel
  INTEGER(2) numvideopages    ! Unused
  INTEGER(2) mode             ! Controls scrolling mode
  INTEGER(2) adapter          ! Unused
  INTEGER(2) monitor          ! Unused
  INTEGER(2) memory           ! Unused
  INTEGER(2) environment      ! Unused
!
! The next three parameters provide extended font attributes.
!
  CHARACTER(32) extendfontname ! The name of the desired
font
  INTEGER(4) extendfontsize     ! Takes the same values
as fontsize,
                             ! when fontsize is set
to
                             ! QWIN$EXTENDFONT
  INTEGER(4) extendfontattributes ! Font attributes such as
```

```
bold
! and italic
END TYPE windowconfig
```

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE. (for example, if there is no active child window).

GETWINDOWCONFIG returns information about the active child window. If you have not set the window properties with SETWINDOWCONFIG, GETWINDOWCONFIG returns default window values.

A typical set of values would be 1024 x pixels, 768 y pixels, 128 text columns, 48 text rows, and a font size of 8x16 pixels. The resolution of the display and the assumed font size of 8x16 pixels generates the number of text rows and text columns. The resolution (in this case, 1024 x pixels by 768 y pixels) is the size of the *virtual* window.

To get the size of the *physical* window visible on the screen, use GETWSIZEQQ. In this case, GETWSIZEQQ returned the following values: (0,0) for the x and y position of the physical window, 25 for the height or number of rows, and 71 for the width or number of columns.

The number of colors returned depends on the video drive. The window title defaults to "Graphic1" for the default window. All of these values can be changed with SETWINDOWCONFIG.

Note that the bitsperpixel field in the windowconfig derived type is an output field only, while the other fields return output values to GETWINDOWCONFIG and accept input values from SETWINDOWCONFIG.

## Example

```
!Build as QuickWin or Standard Graphics App.
USE IFQWIN
LOGICAL(4) status
TYPE (windowconfig) wc
status = GETWINDOWCONFIG(wc)
IF(wc%numtextrows .LT. 10) THEN
  wc%numtextrows = 10
  status = SETWINDOWCONFIG(wc)
  IF(.NOT. status ) THEN ! if setwindowconfig error
    status = SETWINDOWCONFIG(wc) ! reset
    ! setwindowconfig with corrected values
    status = GETWINDOWCONFIG(wc)
    IF(wc%numtextrows .NE. 10) THEN
      WRITE(*,*) 'Error: Cannot increase text rows to 10'
    END IF
  END IF
END IF
END IF
END
```

## See Also

[GETWSIZEQQ](#)  
[SETWINDOWCONFIG](#)  
[SETACTIVEQQ](#)

## GETWSIZEQQ

**QuickWin Function:** Returns the size and position of a window. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = GETWSIZEQQ (unit, ireq, winfo)
```

<i>unit</i>	(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5 and 6 refer to the default startup window only if you have not explicitly opened them with the OPEN statement. To access information about the frame window (as opposed to a child window), set <i>unit</i> to the symbolic constant QWIN\$FRAMEWINDOW, defined in IFQWIN.F90.
<i>ireq</i>	(Input) INTEGER(4). Specifies what information is obtained. The following symbolic constants, defined in IFQWIN.F90, are available: <ul style="list-style-type: none"> <li>• QWIN\$SIZEMAX - Gets information about the maximum window size.</li> <li>• QWIN\$SIZECURR - Gets information about the current window size.</li> </ul>
<i>winfo</i>	(Output) Derived type <code>qwinfo</code> . Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type <code>qwinfo</code> is defined in IFQWIN.F90 as follows:

```

TYPE QWINFO
  INTEGER(2) TYPE ! request type (controls
                  !   SETWSIZEQQ)
  INTEGER(2) X    ! x coordinate for upper left
  INTEGER(2) Y    ! y coordinate for upper left
  INTEGER(2) H    ! window height
  INTEGER(2) W    ! window width
END TYPE QWINFO

```

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width returned for a frame window reflects the size in pixels of the client area *excluding* any borders, menus, and status bar at the bottom of the frame window. You should adjust the values used in SETWSIZEQQ to take this into account.

The client area is the area actually available to place child windows.

## See Also

GETWINDOWCONFIG

SETWSIZEQQ

## INCHARQQ

**QuickWin Function:** Reads a single character input from the keyboard and returns the ASCII value of that character without any buffering. This routine is only available for Windows.

## Module

### USE IFQWIN

## Syntax

```
result = INCHARQQ( )
```

## Results

The result type is INTEGER(2). The result is the ASCII key code.

The keystroke is read from the child window that currently has the focus. You must call INCHARQQ before the keystroke is made (INCHARQQ does not read the keyboard buffer). This function does not echo its input. For function keys, INCHARQQ returns 0xE0 as the upper 8 bits, and the ASCII code as the lower 8 bits.

For direction keys, INCHARQQ returns 0xF0 as the upper 8 bits, and the ASCII code as the lower 8 bits. To allow direction keys to be read, you must use the [PASSDIRKEYSQQ](#) function. The escape characters (the upper 8 bits) are different from those of [GETCHARQQ](#). Note that console applications do not need, and cannot use PASSDIRKEYSQQ.

## Example

```
use IFQWIN
integer*4 res
integer*2 exchar
character*1 ch, chl

Print *, "Type X to exit, S to scroll, D to pass Direction keys"

123 continue
exchar = incharqq()
! check for escapes
! 0xE0 0x?? is a function key
! 0xF0 0x?? is a direction key

ch = char(rshift(exchar,8) .and. Z'00FF')
chl= char(exchar .and. Z'00FF')

if (ichar(ch) .eq. 224) then
  print *, "function key = ", ichar(ch), " ", ichar(chl), " ", chl
  goto 123
endif

if (ichar(ch) .eq. 240) then
  print *, "direction key = ", ichar(ch), " ", ichar(chl), " ", chl
  goto 123
endif

print *, "other key = ", ichar(ch), " ", ichar(chl), " ", chl

if(chl .eq. 'S') then
  res = passdirkeysqq(.false.)
  print *, "Entering Scroll mode"
endif

if(chl .eq. 'D') then
  res = passdirkeysqq(.true.)
  print *, "Entering Direction keys mode"
endif
```

```
if(ch1 .ne. 'X') go to 123
end
```

## INITIALSETTINGS

**QuickWin Function:** *Initializes QuickWin. This routine is only available for Windows.*

---

### Module

USE IFQWIN

### Syntax

```
result = INITIALSETTINGS( )
```

### Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can change the initial appearance of an application's default frame window and menus by defining an INITIALSETTINGS function. Do not use INITIALSETTINGS to open or change the properties of child windows.

If no user-defined INITIALSETTINGS function is supplied, QuickWin calls a predefined INITIALSETTINGS routine to control the default frame window and menu appearance. You do not need to call INITIALSETTINGS if you define it, since it will be called automatically during initialization.

## INQFOCUSQQ

**QuickWin Function:** *Determines which window has the focus. This routine is only available for Windows.*

---

### Module

USE IFQWIN

### Syntax

```
result = INQFOCUSQQ (unit)
```

*unit*

(Output) INTEGER(4). Unit number of the window that has the I/O focus.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero. The function fails if the window with the focus is associated with a closed unit.

Unit numbers 0, 5, and 6 refer to the default window only if the program has not specifically opened them. If these units have been opened and connected to windows, they are automatically reconnected to the console once they are closed.

The window with focus is always in the foreground. Note that the window with the focus is not necessarily the active window (the one that receives graphical output). A window can be made active without getting the focus by calling SETACTIVEQQ.

A window has focus when it is given the focus by FOCUSQQ, when it is selected by a mouse click, or when an I/O operation other than a graphics operation is performed on it, unless the window was opened with IOFOCUS=.FALSE.. The IOFOCUS specifier determines whether a window receives focus when an I/O statement is executed on that unit. For example:

```
OPEN (UNIT = 10, FILE = 'USER', IOFOCUS = .TRUE.)
```

By default IOFOCUS=.TRUE., except for child windows opened with as unit \*. If IOFOCUS=.TRUE., the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

FOCUSQQ

## INSERTMENUQQ

**QuickWin Function:** *Inserts a menu item into a QuickWin menu and registers its callback routine. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

```
result = INSERTMENUQQ (menuID,itemID,flag,text,routine)
```

<i>menuID</i>	(Input) INTEGER(4). Identifies the menu in which the item is inserted, starting with 1 as the leftmost menu.
<i>itemID</i>	(Input) INTEGER(4). Identifies the position in the menu where the item is inserted, starting with 0 as the top menu item.
<i>flag</i>	(Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see Results section below). The following constants are available: <ul style="list-style-type: none"><li>• \$MENUGRAYED - Disables and grays out the menu item.</li><li>• \$MENUDISABLED - Disables but does not gray out the menu item.</li><li>• \$MENUENABLED - Enables the menu item.</li><li>• \$MENUSEPARATOR - Draws a separator bar.</li><li>• \$MENUCHECKED - Puts a check by the menu item.</li><li>• \$MENUUNCHECKED - Removes the check by the menu item.</li></ul>
<i>text</i>	(Input) Character*(*). Menu item name. Must be a null-terminated C string, for example, words of text'C.

*routine*

(Input) EXTERNAL. Callback subroutine that is called if the menu item is selected. You can assign the following predefined routines to menus:

- WINPRINT - Prints the program.
- WINSAVE - Saves the program.
- WINEXIT - Terminates the program.
- WINSELECTTEXT - Selects text from the current window.
- WINSELECTGRAPHICS - Selects graphics from the current window.
- WINSELECTALL - Selects the entire contents of the current window.
- WININPUT - Brings to the top the child window requesting input and makes it the current window.
- WINCOPY - Copies the selected text and/or graphics from current window to the Clipboard.
- WNPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
- WNCLEARPASTE - Clears the paste buffer.
- WINSIZETOFIT - Sizes output to fit window.
- WINFULLSCREEN - Displays output in full screen.
- WINSTATE - Toggles between pause and resume states of text output.
- WINCASCADE - Cascades active windows.
- WINTILE - Tiles active windows.
- WINARRANGE - Arranges icons.
- WINSTATUS - Enables a status bar.
- WININDEX - Displays the index for QuickWin help.
- WINUSING - Displays information on how to use Help.
- WINABOUT - Displays information about the current QuickWin application.
- NUL - No callback routine.

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE.

Menus and menu items must be defined in order from left to right and top to bottom. For example, INSERTMENUQQ fails if you try to insert menu item 7 when 5 and 6 are not defined yet. For a top-level menu item, the callback routine is ignored if there are subitems under it.

The constants available for flags can be combined with an inclusive OR where reasonable, for example \$MENUCHECKED .OR. \$MENUENABLED. Some combinations do not make sense, such as \$MENUENABLED and \$MENUDISABLED, and lead to undefined behavior.

You can create quick-access keys in the text strings you pass to INSERTMENUQQ as *text* by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the *r* underlined, *text* should be "P&rint". Quick-access keys allow users of your program to activate that menu item with the key combination ALT+QUICK-ACCESS-KEY(ALT+R in the example) as an alternative to selecting the item with the mouse.

## Example

```
USE IFQWIN
LOGICAL(4)      :: status
CHARACTER (80) :: text_input

! insert new item into Menu 5 (Window)
status= INSERTMENUQQ(5, 5, $MENUCHECKED, 'New Item:Status 5_5'C, WINSTATUS)
! insert new menu in position 2
```

```
status= INSERTMENUQQ(2, 0, $MENUENABLED, 'New Menu:2_0'C, NUL)
! insert new menu in position 3, and mark it disabled & grayed
status= INSERTMENUQQ(3, 0, IOR($MENUGRAYED,$MENUDISABLED), 'New Disabled Menu:3_0'C, NUL)
! insert new item under the new menu 2 in position 1
status= INSERTMENUQQ(2, 1, $MENUENABLED, 'New Item:Print'C, WINPRINT)
! insert separator bar under the new menu 2 in position 2
status= INSERTMENUQQ(2, 2, $MENUSEPARATOR, 'New Separator'C, NUL)
! insert new item under the new menu 2 in position 3
status= INSERTMENUQQ(2, 3, IOR($MENUCHECKED,$MENUENABLED), 'New Item:Select Text'C, &
    WINSELECTTEXT)
! insert new item under the new menu 2 in position 5
status= INSERTMENUQQ(2, 4, $MENUENABLED, 'New Item:Copy Selected Text'C, WINCOPY)
! insert new item under the new menu 2 in position 6
status= INSERTMENUQQ(2, 5, $MENUENABLED, 'New Item:Paste Selected Text'C, WINPASTE)

write(*,('Enter (or cut and paste) a text value: '),advance='no')
read (*,"(A)") text_input
write(*,('You just entered: ", A1, A, A1)') " ",trim(text_input),"")

END
```

## INTEGERTORGB

**QuickWin Subroutine:** *Converts an RGB color value into its red, green, and blue components. This routine is only available for Windows.*

---

### Module

USE IFQWIN

### Syntax

CALL INTEGERTORGB (*rgb, red, green, blue*)

<i>rgb</i>	(Input) INTEGER(4). RGB color value whose red, green, and blue components are to be returned.
<i>red</i>	(Output) INTEGER(4). Intensity of the red component of the RGB color value.
<i>green</i>	(Output) INTEGER(4). Intensity of the green component of the RGB color value.
<i>blue</i>	(Output) INTEGER(4). Intensity of the blue component of the RGB color value.

INTEGERTORGB separates the four-byte RGB color value into the three components as follows:

### Example

```
! build as a QuickWin App.
USE IFQWIN
INTEGER(4) r, g, b
CALL INTEGERTORGB(2456, r, g, b)
write(*,*) r, g, b
END
```

### See Also

## MESSAGEBOXQQ

**QuickWin Function:** *Displays a message box in a QuickWin window. This routine is only available for Windows.*

### Module

USE IFQWIN

### Syntax

```
result = MESSAGEBOXQQ (msg,caption,mtype)
```

<i>msg</i>	(Input) Character*(*). Null-terminated C string. Message the box displays.
<i>caption</i>	(Input) Character*(*). Null-terminated C string. Caption that appears in the title bar.
<i>mtype</i>	<p>(Input) INTEGER(4). Symbolic constant that determines the objects (buttons and icons) and properties of the message box. You can combine several constants (defined in <code>IFQWIN.F90</code>) using an inclusive OR (IOR or OR). The symbolic constants and their associated objects or properties are as follows:</p> <ul style="list-style-type: none"> <li>• MB\$ABORTRETRYIGNORE - The Abort, Retry, and Ignore buttons.</li> <li>• MB\$DEFBUTTON1 - The first button is the default.</li> <li>• MB\$DEFBUTTON2 - The second button is the default.</li> <li>• MB\$DEFBUTTON3 - The third button is the default.</li> <li>• MB\$ICONASTERISK, MB\$ICONINFORMATION - Lowercase <i>i</i> in blue circle icon.</li> <li>• MB\$ICONEXCLAMATION - The exclamation-mark icon.</li> <li>• MB\$ICONHAND, MB\$ICONSTOP - The stop-sign icon.</li> <li>• MB\$ICONQUESTION - The question-mark icon.</li> </ul>

- MB\$OK - The OK button.
- MB\$OKCANCEL - The OK and Cancel buttons.
- MB\$RETRYCANCEL - The Retry and Cancel buttons.
- MB\$SYSTEMMODAL - Box is system-modal: all applications are suspended until the user responds.
- MB\$YESNO - The Yes and No buttons.
- MB\$YESNOCANCEL - The Yes, No, and Cancel buttons.

## Results

The result type is INTEGER(4). The result is zero if memory is not sufficient for displaying the message box. Otherwise, the result is one of the following values, indicating the user's response to the message box:

- MB\$IDABORT - The Abort button was pressed.
- MB\$IDCANCEL - The Cancel button was pressed.
- MB\$IDIGNORE - The Ignore button was pressed.
- MB\$IDNO - The No button was pressed.
- MB\$IDOK - The OK button was pressed.
- MB\$IDRETRY - The Retry button was pressed.
- MB\$IDYES - The Yes button was pressed.

## Example

```
! Build as QuickWin app
USE IFQWIN
message = MESSAGEBOXQQ('Do you want to continue?'C,    &
    'Matrix'C,    &
    MB$ICONQUESTION.OR.MB$YESNO.OR.MB$DEFBUTTON1)
END
```

## MODIFYMENUFLAGSQQ

**QuickWin Function:** *Modifies a menu item's state.*  
*This routine is only available for Windows.*

---

### Module

USE IFQWIN

### Syntax

```
result = MODIFYMENUFLAGSQQ (menuID, itemID, flag)
```

*menuID* (Input) INTEGER(4). Identifies the menu containing the item whose state is to be modified, starting with 1 as the leftmost menu.

*itemID* (Input) INTEGER(4). Identifies the menu item whose state is to be modified, starting with 0 as the top item.

*flags* (Input) INTEGER(4). Constant indicating the menu state. Flags can be combined with an inclusive OR (see the Results section below). The following constants are available:

- \$MENUGRAYED - Disables and grays out the menu item.

- \$MENUDISABLED - Disables but does not gray out the menu item.
- \$MENUENABLED - Enables the menu item.
- \$MENUSEPARATOR - Draws a separator bar.
- \$MENUCHECKED - Puts a check by the menu item.
- \$MENUUNCHECKED - Removes the check by the menu item.

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The constants available for flags can be combined with an inclusive OR where reasonable, for example \$MENUCHECKED .OR. \$MENUENABLED. Some combinations do not make sense, such as \$MENUENABLED and \$MENUDISABLED, and lead to undefined behavior.

## Example

```
USE IFQWIN
LOGICAL(4)    result
CHARACTER(20) str
! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu'C
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
! Gray out and disable the first two menu items in the
! first (FILE) menu
result = MODIFYMENUFLAGSQQ (1, 1, $MENUGRAYED)
result = MODIFYMENUFLAGSQQ (1, 2, $MENUGRAYED)
END
```

## MODIFYMENUROUTINEQQ

**QuickWin Function:** *Changes a menu item's callback routine. This routine is only available for Windows.*

### Module

USE IFQWIN

### Syntax

```
result = MODIFYMENUROUTINEQQ (menuID, itemID, routine)
```

*menuID* (Input) INTEGER(4). Identifies the menu that contains the item whose callback routine is to be changed, starting with 1 as the leftmost menu.

*itemID* (Input) INTEGER(4). Identifies the menu item whose callback routine is to be changed, starting with 0 as the top item.

*routine* (Input) EXTERNAL. Callback subroutine called if the menu item is selected. All routines take a single LOGICAL parameter that indicates whether the menu item is checked or not. You can assign the following predefined routines to menus:

- WINPRINT - Prints the program.
- WINSAVE - Saves the program.
- WINEXIT - Terminates the program.
- WINSELECTTEXT - Selects text from the current window.
- WINSELECTGRAPHICS - Selects graphics from the current window.
- WINSELECTALL - Selects the entire contents of the current window.
- WININPUT - Brings to the top the child window requesting input and makes it the current window.
- WINCOPY - Copies the selected text and/or graphics from the current window to the Clipboard.
- WINPASTE - Allows the user to paste Clipboard contents (text only) to the current text window of the active window during a READ.
- WINCLEARPASTE - Clears the paste buffer.
- WINSIZETO FIT - Sizes output to fit window.
- WINFULLSCREEN - Displays output in full screen.
- WINSTATE - Toggles between pause and resume states of text output.
- WINCASCADE - Cascades active windows.
- WINTILE - Tiles active windows.
- WINARRANGE - Arranges icons.
- WINSTATUS - Enables a status bar.
- WININDEX - Displays the index for QuickWin help.
- WINUSING - Displays information on how to use Help.
- WINABOUT - Displays information about the current QuickWin application.
- NUL - No callback routine.

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

## See Also

APPENDMENUQQ  
DELETEMENUQQ

MODIFYMENUFLAGSQQ  
MODIFYMENUSTRINGQQ

## MODIFYMENUSTRINGQQ

**QuickWin Function:** *Changes a menu item's text string. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

`result = MODIFYMENUSTRINGQQ (menuID, itemID, text)`

*menuID*

(Input) INTEGER(4). Identifies the menu containing the item whose text string is to be changed, starting with 1 as the leftmost item.

<i>itemID</i>	(Input) INTEGER(4). Identifies the menu item whose text string is to be changed, starting with 0 as the top menu item.
<i>text</i>	(Input) Character*(*). Menu item name. Must be a null-terminated C string. For example, words of text'C.

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

You can add access keys in your text strings by placing an ampersand (&) before the letter you want underlined. For example, to add a Print menu item with the r underlined, use "P&rint"C as *text*.

## Example

```
USE IFQWIN
LOGICAL(4) result
CHARACTER(25) str
! Append item to the bottom of the first (FILE) menu
str = '&Add to File Menu'C
result = APPENDMENUQQ(1, $MENUENABLED, str, WINSTATUS)
! Change the name of the first item in the first menu
str = '&Browse'C
result = MODIFYMENUSTRINGQQ (1, 1, str)
END
```

## See Also

[SETMESSAGEQQ](#)

[MODIFYMENUFLAGSQQ](#)

[MODIFYMENUROUTINEQQ](#)

## PASSDIRKEYSQQ

**QuickWin Function:** *Determines the behavior of direction and page keys in a QuickWin application.*

*This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

```
result = PASSDIRKEYSQQ (val)
```

*val* (Input) INTEGER(4) or LOGICAL(4).

A value of .TRUE. causes direction and page keys to be input as normal characters (the PassDirKeys flag is turned on). A value of .FALSE. causes direction and page keys to be used for scrolling.

The following constants, defined in IFQWIN.F90, can be used as integer arguments:

- PASS\_DIR\_FALSE - Turns off any special handling of direction keys. They are not passed to the program by GETCHARQQ.

- **PASS\_DIR\_TRUE** - Turns on special handling of direction keys. That is, they are passed to the program by GETCHARQQ.
- **PASS\_DIR\_INSDEL** - INSERT and DELETE are also passed to the program by GETCHARQQ
- **PASS\_DIR\_CNTRLC** - Only needed for a QuickWin application, but harmless if used with a Standard Graphics application that already passes CTRL+C.

This value allows CTRL+C to be passed to a QuickWin program by GETCHARQQ if the following is true: the program must have removed the File menu EXIT item by using DELETEMENUQQ.

This value also passes direction keys and INSERT and DELETE.

## Results

The return value indicates the previous setting of the PassDirKeys flag.

The return data type is the same as the data type of *val*; that is, either INTEGER(4) or LOGICAL(4).

When the PassDirKeys flag is turned on, the mouse must be used for scrolling since the direction and page keys are treated as normal input characters.

The PASSDIRKEYSQQ function is meant to be used primarily with the GETCHARQQ and INCHARQQ functions. Do not use normal input statements (such as READ) with the PassDirKeys flag turned on, unless your program is prepared to interpret direction and page keys.

## Example

```

use IFQWIN

logical*4 res
character*1 ch, chl

Print *, "Type X to exit, S to scroll, D to pass Direction keys"

123 continue
ch = getcharqq( )
! check for escapes
! 0x00 0x?? is a function key
! 0xE0 0x?? is a direction key
if (ichar(ch) .eq. 0) then
  chl = getcharqq()
  print *, "function key follows escape = ", ichar(ch), " ", ichar(chl), " ", chl
  goto 123
else if (ichar(ch) .eq. 224) then
  chl = getcharqq()
  print *, "direction key follows escape = ", ichar(ch), " ", ichar(chl), " ", chl
  goto 123
else
  print *, ichar(ch), " ", ch

  if(ch .eq. 'S') then
    res = passdirkeysqq(.false.)
    print *, "Entering Scroll mode ", res
  endif

  if(ch .eq. 'D') then
    res = passdirkeysqq(.true.)
  endif

```

```

    print *, "Entering Direction keys mode ",res
endif

    if(ch .ne. 'X') go to 123

endif
end

```

The following example uses an integer constant as an argument to PASSDIRKEYSQQ:

```

## REGISTERMOUSEEVENT

**QuickWin Function:** Registers the application-supplied callback routine to be called when a specified mouse event occurs in a specified window. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = REGISTERMOUSEEVENT (unit,mouseevents,callbackroutine)
```

*unit* (Input) INTEGER(4). Unit number of the window whose callback routine on mouse events is to be registered.

*mouseevents* (Input) INTEGER(4). One or more mouse events to be handled by the callback routine to be registered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:

- MOUSE\$LBUTTONDOWN - Left mouse button down
- MOUSE\$LBUTTONUP - Left mouse button up
- MOUSE\$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE\$RBUTTONDOWN - Right mouse button down

- MOUSE\$RBUTTONUP - Right mouse button up
- MOUSE\$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE\$MOVE - Mouse moved

*callbackroutine*

(Input) Routine to be called on the specified mouse event in the specified window. It must be declared EXTERNAL.

## Results

The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:

- MOUSE\$BADUNIT - The unit specified is not open, or is not associated with a QuickWin window.
- MOUSE\$BADEVENT - The event specified is not supported.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system's CONTROL PANEL/MOUSE.

## Example

The following example registers the routine CALCULATE, to be called when the user double-clicks the left mouse button while the mouse cursor is in the child window opened as unit 4:

```
USE IFQWIN
INTEGER(4) result
OPEN (4, FILE= 'USER')
...
result = REGISTERMOUSEEVENT (4, MOUSE$LBUTTONDBLCLK, CALCULATE)
```

## See Also

UNREGISTERMOUSEEVENT

WAITONMOUSEEVENT

## RGBTOINTEGER

**QuickWin Function:** *Converts three integers specifying red, green, and blue color intensities into a four-byte RGB integer for use with RGB functions and subroutines. This routine is only available for Windows.*

## Module

USE IFQWIN

## Syntax

```
result = RGBTOINTEGER (red, green, blue)
```

*red*

(Input) INTEGER(4). Intensity of the red component of the RGB color value. Only the lower 8 bits of *red* are used.

*green*

(Input) INTEGER(4). Intensity of the green component of the RGB color value. Only the lower 8 bits of *green* are used.

*blue*

(Input) INTEGER(4). Intensity of the blue component of the RGB color value. Only the lower 8 bits of *blue* are used.

## Results

The result type is INTEGER(4). The result is the combined RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value returned with RGBTOINTEGER, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

## Example

```
! Build as a QuickWin App.
USE IFQWIN
INTEGER r, g, b, rgb, result
INTEGER(2) status
r = Z'F0'
g = Z'F0'
b = 0
rgb = RGBTOINTEGER(r, g, b)
result = SETCOLORRGB(rgb)
status = ELLIPSE($GFILLINTERIOR,INT2(40), INT2(55), &
                INT2(90), INT2(85))
END
```

## SETACTIVEQQ

**QuickWin Function:** *Makes a child window active, but does not give it focus. This routine is only available for Windows.*

## Module

USE IFQWIN

## Syntax

```
result = SETACTIVEQQ (unit)
```

*unit* (Input) INTEGER(4). Unit number of the child window to be made active.

## Results

The result type is INTEGER(4). The result is 1 if successful; otherwise, 0.

When a window is made active, it receives graphics output (from ARC, LINETO and OUTGTEXT, for example) but is not brought to the foreground and does not have the focus. If a window needs to be brought to the foreground, it must be given the focus. A window is given focus with FOCUSQQ, by clicking it with the mouse, or by performing I/O other than graphics on it, unless the window was opened with IOFOCUS='.FALSE.'. By default, IOFOCUS='.TRUE.', except for child windows opened as unit '\*'.

The window that has the focus is always on top, and all other windows have their title bars grayed out. A window can have the focus and yet not be active and not have graphics output directed to it. Graphical output is independent of focus.

If IOFOCUS='.TRUE.', the child window receives focus prior to each READ, WRITE, PRINT, or OUTTEXT. Calls to graphics functions (such as OUTGTEXT and ARC) do not cause the focus to shift.

GETACTIVEQQ

FOCUSQQ

INQFOCUSQQ

## SETEXITQQ

**QuickWin Function:** Sets a QuickWin application's exit behavior. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = SETEXITQQ (exitmode)
```

*exitmode* (Input) INTEGER(4). Determines the program exit behavior. The following exit parameters are defined in IFQWIN.F90:

- QWIN\$EXITPROMPT - Displays the following message box:  
"Program exited with exit status X. Exit Window?"  
where X is the exit status from the program.  
If Yes is entered, the application closes the window and terminates. If No is entered, the dialog box disappears and you can manipulate the windows as usual. You must then close the window manually.
- QWIN\$EXITNOPERSIST - Terminates the application without displaying a message box.
- QWIN\$EXITPERSIST - Leaves the application open without displaying a message box.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The default for both QuickWin and Standard Graphics applications is QWIN\$EXITPROMPT.

## Example

```
! Build as QuickWin Ap
USE IFQWIN
INTEGER(4) exmode, result

WRITE(*,'(1X,A,/)' ) 'Please enter the exit mode 1, 2   &
                        or 3 '

READ(*,*) exmode
SELECT CASE (exmode)
  CASE (1)
    result = SETEXITQQ(QWIN$EXITPROMPT)
  CASE (2)
    result = SETEXITQQ(QWIN$EXITNOPERSIST)
  CASE (3)
    result = SETEXITQQ(QWIN$EXITPERSIST)
  CASE DEFAULT
    WRITE(*,*) 'Invalid option - checking for bad   &
              return'
    IF(EXITQQ( exmode ) .NE. -1) THEN
      WRITE(*,*) 'Error not returned'
    ELSE
      WRITE(*,*) 'Error code returned'
    ENDIF
  END SELECT
END
```

GETEXITQQ

## SETMESSAGEQQ

**QuickWin Subroutine:** Changes QuickWin status messages, state messages, and dialog box messages. *This routine is only available for Windows.*

## Module

USE IFQWIN

## Syntax

CALL SETMESSAGEQQ (msg,id)

*msg*

(Input) Character\*(\*). Message to be displayed. Must be a regular Fortran string, not a C string. Can include multibyte characters.

*id*

(Input) INTEGER(4). Identifier of the message to be changed. The following table shows the messages that can be changed and their identifiers:

Id	Message
QWIN\$MSG_TERM	"Program terminated with exit code"
QWIN\$MSG_EXITQ	"Exit Window"
QWIN\$MSG_FINISHED	"Finished"

Id	Message
QWIN\$MSG_PAUSED	"Paused"
QWIN\$MSG_RUNNING	"Running"
QWIN\$MSG_FILEOPENDLG	"Text Files(*.txt), *.txt; Data Files(*.dat), *.dat; All Files(*.*), *.*;"
QWIN\$MSG_BMPSAVEDLG	"Bitmap Files(*.bmp), *.bmp; All Files(*.*), *.*;"
QWIN\$MSG_INPUTPEND	"Input pending in"
QWIN\$MSG_PASTEINPUTPEND	"Paste input pending"
QWIN\$MSG_MOUSEINPUTPEND	"Mouse input pending in"
QWIN\$MSG_SELECTTEXT	"Select Text in"
QWIN\$MSG_SELECTGRAPHICS	"Select Graphics in"
QWIN\$MSG_PRINTABORT	"Error! Printing Aborted."
QWIN\$MSG_PRINTLOAD	"Error loading printer driver"
QWIN\$MSG_PRINTNODEFAULT	"No Default Printer."
QWIN\$MSG_PRINTDRIVER	"No Printer Driver."
QWIN\$MSG_PRINTINGERROR	"Print: Printing Error."
QWIN\$MSG_PRINTING	"Printing"
QWIN\$MSG_PRINTCANCEL	"Cancel"
QWIN\$MSG_PRINTINPROGRESS	"Printing in progress..."
QWIN\$MSG_HELPNOTAVAIL	"Help Not Available for Menu Item"
QWIN\$MSG_TITLETEXT	"Graphic"

QWIN\$MSG\_FILEOPENDLG and QWIN\$MSG\_BMPSAVEDLG control the text in file choosing dialog boxes and have the following syntax:

"file description, file designation"

You can change any string produced by QuickWin by calling SETMESSAGEQQ with the appropriate *id*. This includes status messages displayed at the bottom of a QuickWin application, state messages (such as "Paused"), and dialog box messages. These messages can include multibyte characters. To change menu messages, use MODIFYMENUSTRINGQQ.

### Example

```
USE IFQWIN
print*, "Hello"
CALL SETMESSAGEQQ('Changed exit text', QWIN$MSG_EXITQ)
```

### See Also

[MODIFYMENUSTRINGQQ](#)

## SETMOUSECURSOR

**Quickwin Function:** Sets the shape of the mouse cursor for the window in focus. This routine is only available for Windows.

### Module

USE IFQWIN

USE IFWIN

### Syntax

```
oldcursor = SETMOUSECURSOR (newcursor)
```

*newcursor* (Input) INTEGER(4). A Windows HCURSOR value. For many predefined shapes, LoadCursor(0, shape) is a convenient way to get a legitimate value. See the list of predefined shapes [below](#).

A value of zero prevents the cursor from being displayed.

### Results

The result type is INTEGER(4). This is also an HCURSOR Value. The result is the previous cursor value.

The window in focus at the time SETMOUSECURSOR is called has its cursor changed to the specified value. Once changed, the cursor retains its shape until another call to SETMOUSECURSOR.

In Standard Graphics applications, units 5 and 6 (the default screen input and output units) are always considered to be in focus.

The following predefined values for cursor shapes are available:

Predefined Value	Cursor Shape
IDC_APPSTARTING	Standard arrow and small hourglass
IDC_ARROW	Standard arrow
IDC_CROSS	Crosshair
IDC_IBEAM	Text I-beam
IDC_ICON	Obsolete value
IDC_NO	Slashed circle
IDC_SIZE	Obsolete value; use IDC_SIZEALL
IDC_SIZEALL	Four-pointed arrow
IDC_SIZENESW	Double-pointed arrow pointing northeast and southwest
IDC_SIZENS	Double-pointed arrow pointing north and south
IDC_SIZENWSE	Double-pointed arrow pointing northwest and southeast
IDC_SIZEWE	Double-pointed arrow pointing west and east
IDC_UPARROW	Vertical arrow

Predefined Value	Cursor Shape
IDC_WAIT	Hour glass

A LoadCursor must be done on these values before they can be used by SETMOUSECURSOR.

### Example

```
! Build as Standard Graphics or QuickWin
  use ifqwin
  use ifwin

  integer*4  cursor, oldcursor
  write(6,*) 'The cursor will now be changed to an hour glass shape'
  write(6,*) 'Hit <return> to see the next change'
  cursor = LoadCursor(0, IDC_WAIT)
  oldcursor = SetMouseCursor(cursor)
  read(5,*)

  write(6,*) 'The cursor will now be changed to a cross-hair shape'
  write(6,*) 'Hit <return> to see the next change'
  cursor = LoadCursor(0, IDC_CROSS)
  oldcursor = SetMouseCursor(cursor)
  read(5,*)

  write(6,*) 'The cursor will now be turned off'
  write(6,*) 'Hit <return> to see the next change'
  oldcursor = SetMouseCursor(0)
  read(5,*)

  write(6,*) 'The cursor will now be turned on'
  write(6,*) 'Hit <return> to see the next change'
  oldcursor = SetMouseCursor(oldcursor)
  read(5,*)

stop
end
```

## SETWINDOWCONFIG

**QuickWin Function:** Sets the properties of a child window. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

```
result = SETWINDOWCONFIG (wc)
```

wc

(Input) Derived type windowconfig. Contains window properties. The windowconfig derived type is defined in IFQWIN.F90 as follows:

```
TYPE windowconfig
  INTEGER(2) numxpixels      ! Number of pixels on x-axis.
  INTEGER(2) numypixels      ! Number of pixels on y-axis.
  INTEGER(2) numtextcols     ! Number of text columns
available.
```

```

    INTEGER(2) numtextrows      ! Number of text rows
available.
    INTEGER(2) numcolors       ! Number of color indexes.
    INTEGER(4) fontsize        ! Size of default font. Set to
                                ! QWIN$EXTENDFONT when
specifying
                                ! extended attributes, in
which
                                ! case extendfontsize sets
the
                                ! font size.
    CHARACTER(80) title        ! The window title.
    INTEGER(2) bitsperpixel    ! The number of bits per
pixel.
    INTEGER(2) numvideopages   ! Unused.
    INTEGER(2) mode            ! Controls scrolling mode.
    INTEGER(2) adapter         ! Unused.
    INTEGER(2) monitor         ! Unused.
    INTEGER(2) memory          ! Unused.
    INTEGER(2) environment     ! Unused.
! The next three parameters provide extended font
! attributes.
    CHARACTER(32) extendfontname ! The name of the desired
font.
    INTEGER(4) extendfontsize    ! Takes the same values as
fontsize,
                                ! when fontsize is set to
                                ! QWIN$EXTENDFONT.
    INTEGER(4) extendfontattributes ! Font attributes such as
bold
                                ! and italic.
END TYPE windowconfig

```

## Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The following value can be used to configure a QuickWin window so that it will show the last line written and the text cursor (if it is on):

```
wc%mode = QWIN$SCROLLDOWN
```

Note that if you scroll the window to another position, you will have to scroll back to the last line to see your input.

The following values can be used with SETWINDOWCONFIG extended fonts:

### Style:

QWIN\$EXTENDFONT_NORMAL	No underline, no italic, and a font weight of 400 out of 1000.
QWIN\$EXTENDFONT_UNDERLINE	Underlined characters.
QWIN\$EXTENDFONT_BOLD	A font weight of 700 out of 1000.
QWIN\$EXTENDFONT_ITALIC	Italic characters.

### Pitch:

QWIN\$EXTENDFONT_FIXED_PITCH	QuickWin default. Equal character widths.
------------------------------	---

---

QWIN\$EXTENDFONT_VARIABLE_PITCH	Variable character widths.
---------------------------------	----------------------------

---

**Font Families:**

QWIN\$EXTENDFONT_FF_ROMAN	Variable stroke width, serified. Times Roman, Century Schoolbook, etc.
QWIN\$EXTENDFONT_FF_SWISS	Variable stroke width, sans-serified. Helvetica, Swiss, etc.
QWIN\$EXTENDFONT_FF_MODERN	QuickWin default. Constant stroke width, serified or sans-serified. Pica, Elite, Courier, etc.
QWIN\$EXTENDFONT_FF_SCRIPT	Cursive, etc.
QWIN\$EXTENDFONT_FF_DECORATIVE	Old English, etc.

---

**Character Sets:**

QWIN\$EXTENDFONT_ANSI_CHARSET	QuickWin default.
QWIN\$EXTENDFONT_OEM_CHARSET	Use this to get Microsoft* LineDraw.

---

Using QWIN\$EXTENDFONT\_OEM\_CHARSET with the font name 'MS LineDraw'C will get the old DOS-style character set with symbols that can be used to draw lines and boxes. The pitch and font family items can be specified to help guide the font matching algorithms used by CreateFontIndirect, the Windows\* API used by SETWINDOWCONFIG.

If you use SETWINDOWCONFIG to set the variables in `windowconfig` to -1, the function sets the highest resolution possible for your system, given the other fields you specify, if any. You can set the actual size of the window by specifying parameters that influence the window size: the number of x and y pixels, the number of rows and columns, and the font size. If you do not call SETWINDOWCONFIG, the window defaults to the best possible resolution and a font size of 8x16. The number of colors available depends on the video driver used.

If you use SETWINDOWCONFIG, you should specify a value for each field (-1 or your own value for the numeric fields and a C string for the title, for example, "words of text"C). Using SETWINDOWCONFIG with only some fields specified can result in useless values for the unspecified fields.

If you request a configuration that cannot be set, SETWINDOWCONFIG returns .FALSE. and calculates parameter values that will work and are as close as possible to the requested configuration. A second call to SETWINDOWCONFIG establishes the adjusted values; for example:

```
status = SETWINDOWCONFIG(wc)
if (.NOT.status) status = SETWINDOWCONFIG(wc)
```

If you specify values for all four of the size parameters, *numxpixels*, *numypixel*, *numtextcols*, and *numtextrows*, the font size is calculated by dividing these values. The default font is Courier New and the default font size is 8x16. There is no restriction on font size, except that the window must be large enough to hold it.

Under Standard Graphics, the application attempts to start in Full Screen mode with no window decoration (window decoration includes scroll bars, menu bar, title bar, and message bar) so that the maximum resolution can be fully used. Otherwise, the application starts in a window. You can use ALT+ENTER at any time to toggle between the two modes.

If you are in Full Screen mode and the resolution of the window does not match the resolution of the video driver, graphics output will be slow compared to drawing in a window.

**NOTE**

You must call `DISPLAYCURSOR($GCURSORON)` to make the cursor visible after calling `SETWINDOWCONFIG`.

---

**Example**

```
USE IFQWIN
TYPE (windowconfig) wc
LOGICAL status /.FALSE./
! Set the x & y pixels to 800X600 and font size to 8x12
wc%numxpixels = 800
wc%numypixels = 600
wc%numtextcols = -1
wc%numtextrows = -1
wc%numcolors = -1
wc%title= "This is a test"C
wc%fontsize = Z'0008000C'
status = SETWINDOWCONFIG(wc) ! attempt to set configuration with above values
! if attempt fails, set with system estimated values
if (.NOT.status) status = SETWINDOWCONFIG(wc)
```

**See Also**

`DISPLAYCURSOR`

`GETWINDOWCONFIG`

**SETWINDOWMENUQQ**

**QuickWin Function:** Sets a top-level menu as the menu to which a list of current child window names is appended. This routine is only available for Windows.

---

**Module**

`USE IFQWIN`

**Syntax**

```
result = SETWINDOWMENUQQ (menuID)
```

*menuID* (Input) INTEGER(4). Identifies the menu to hold the child window names, starting with 1 as the leftmost menu.

**Results**

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, .FALSE..

The list of current child window names can appear in only one menu at a time. If the list of windows is currently in a menu, it is removed from that menu. By default, the list of child windows appears at the end of the Window menu.

**Example**

```
USE IFQWIN
TYPE (windowconfig) wc
LOGICAL(4) result, status /.FALSE./
! Set title for child window
wc%numxpixels = -1
wc%numypixels = -1
wc%numtextcols = -1
```

```

wc%numtextrows = -1
wc%numcolors   = -1
wc%fontsize    = -1
wc%title= "I am child window name"C
if (.NOT.status) status = SETWINDOWCONFIG(wc)

! put child window list under menu 3 (View)
result = SETWINDOWMENUQQ(3)
END

```

## See Also

APPENDMENUQQ

## SETWSIZEQQ

**QuickWin Function:** *Sets the size and position of a window. This routine is only available for Windows.*

### Module

USE IFQWIN

### Syntax

```
result = SETWSIZEQQ (unit, winfo)
```

*unit*

(Input) INTEGER(4). Specifies the window unit. Unit numbers 0, 5, and 6 refer to the default startup window only if the program does not explicitly open them with the OPEN statement. To set the size of the frame window (as opposed to a child window), set *unit* to the symbolic constant QWIN\$FRAMEWINDOW (defined in IFQWIN.F90).

When called from INITIALSETTINGS, SETWSIZEQQ behaves slightly differently than when called from a user routine after initialization. See below under [Results](#).

*winfo*

(Input) Derived type `qwinfo`. Physical coordinates of the window's upper-left corner, and the current or maximum height and width of the window's client area (the area within the frame). The derived type `qwinfo` is defined in IFQWIN.F90 as follows:

```

TYPE QWINFO
  INTEGER(2) TYPE ! request type
  INTEGER(2) X    ! x coordinate for upper left
  INTEGER(2) Y    ! y coordinate for upper left
  INTEGER(2) H    ! window height
  INTEGER(2) W    ! window width
END TYPE QWINFO

```

This function's behavior depends on the value of `QWINFO%TYPE`, which can be any of the following:

- QWIN\$MIN - Minimizes the window.
- QWIN\$MAX - Maximizes the window.
- QWIN\$RESTORE - Restores the minimized window to its previous size.
- QWIN\$SET - Sets the window's position and size according to the other values in `qwinfo`.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, nonzero (unless called from INITIALSETTINGS). If called from INITIALSETTINGS, the following occurs:

- SETWSIZEQQ always returns -1.
- Only QWIN\$SET will work.

The position and dimensions of child windows are expressed in units of character height and width. The position and dimensions of the frame window are expressed in screen pixels.

The height and width specified for a frame window reflects the actual size in pixels of the frame window *including* any borders, menus, and status bar at the bottom.

## Example

```
USE IFQWIN
INTEGER(4)      result
INTEGER(2)      numfonts, fontnum
TYPE (qwinfo)   winfo
TYPE (xycoord)  pos
! Maximize frame window
winfo%TYPE = QWIN$MAX
result = SETWSIZEQQ(QWIN$FRAMEWINDOW, winfo)
! Maximize child window
result = SETWSIZEQQ(0, winfo)
numfonts = INITIALIZEFONTS( )
fontnum = SETFONT ('t'Arial'h50w34i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT("BIG Window")
END
```

## See Also

GETWSIZEQQ

INITIALSETTINGS

## UNREGISTERMOUSEEVENT

**QuickWin Function:** Removes the callback routine registered for a specified window by an earlier call to REGISTERMOUSEEVENT. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = UNREGISTERMOUSEEVENT (unit,mouseevents)
```

*unit* (Input) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. Unit number of the window whose callback routine on mouse events is to be unregistered.

*mouseevents* (Input) INTEGER(4). One or more mouse events handled by the callback routine to be unregistered. Symbolic constants (defined in IFQWIN.F90) for the possible mouse events are:

- MOUSE\$LBUTTONDOWN - Left mouse button down

- MOUSE\$LBUTTONUP - Left mouse button up
- MOUSE\$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE\$RBUTTONDOWN - Right mouse button down
- MOUSE\$RBUTTONUP - Right mouse button up
- MOUSE\$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE\$MOVE - Mouse moved

## Results

The result type is INTEGER(4). The result is zero or a positive integer if successful; otherwise, a negative integer that can be one of the following:

- MOUSE\$BADUNIT - The unit specified is not open, or is not associated with a QuickWin window.
- MOUSE\$BADEVENT - The event specified is not supported.

Once you call UNREGISTERMOUSEEVENT, QuickWin no longer calls the callback routine specified earlier for the window when mouse events occur. Calling UNREGISTERMOUSEEVENT when no callback routine is registered for the window has no effect.

## See Also

REGISTERMOUSEEVENT

WAITONMOUSEEVENT

## WAITONMOUSEEVENT

**QuickWin Function:** *Waits for the specified mouse input from the user. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

```
result = WAITONMOUSEEVENT (mouseevents, keystate, x, y)
```

*mouseevents* (Input) INTEGER(4). One or more mouse events that must occur before the function returns. Symbolic constants for the possible mouse events are:

- MOUSE\$LBUTTONDOWN - Left mouse button down
- MOUSE\$LBUTTONUP - Left mouse button up
- MOUSE\$LBUTTONDBLCLK - Left mouse button double-click
- MOUSE\$RBUTTONDOWN - Right mouse button down
- MOUSE\$RBUTTONUP - Right mouse button up
- MOUSE\$RBUTTONDBLCLK - Right mouse button double-click
- MOUSE\$MOVE - Mouse moved

*keystate* (Output) INTEGER(4). Bitwise inclusive OR of the state of the mouse during the event. The value returned in *keystate* can be any or all of the following symbolic constants:

- MOUSE\$KS\_LBUTTON - Left mouse button down during event
- MOUSE\$KS\_RBUTTON - Right mouse button down during event
- MOUSE\$KS\_SHIFT - SHIFTkey held down during event
- MOUSE\$KS\_CONTROL - CTRLkey held down during event

x	(Output) INTEGER(4). X position of the mouse when the event occurred.
y	(Output) INTEGER(4). Y position of the mouse when the event occurred.

## Results

The result type is INTEGER(4). The result is the symbolic constant associated with the mouse event that occurred if successful. If the function fails, it returns the constant MOUSE\$BADEVENT, meaning the event specified is not supported.

WAITONMOUSEEVENT does not return until the specified mouse input is received from the user. While waiting for a mouse event to occur, the status bar changes to read "Mouse input pending in XXX", where XXX is the name of the window. When a mouse event occurs, the status bar returns to its previous value.

A mouse event must happen in the window that had focus when WAITONMOUSEEVENT was initially called. Mouse events in other windows will not end the wait. Mouse events in other windows cause callbacks to be called for the other windows, if callbacks were previously registered for those windows.

For every BUTTONDOWN or BUTTONDBLCLK event there is an associated BUTTONUP event. When the user double clicks, four events happen: BUTTONDOWN and BUTTONUP for the first click, and BUTTONDBLCLK and BUTTONUP for the second click. The difference between getting BUTTONDBLCLK and BUTTONDOWN for the second click depends on whether the second click occurs in the double click interval, set in the system's CONTROL PANEL/MOUSE.

## Example

```
USE IFQWIN
INTEGER(4) mouseevent, keystate, x, y, result
...
mouseevent = IOR(MOUSE$RBUTTONDOWN,MOUSE$LBUTTONDOWN)
result = WAITONMOUSEEVENT (mouseevent, keystate, x , y)
!
! Wait until right or left mouse button is clicked, then check the keystate
! with the following:
!
  if (IAND(MOUSE$KS_SHIFT,keystate) == MOUSE$KS_SHIFT)      &
& write (*,*) 'Shift key was down'
  if (IAND(MOUSE$KS_CONTROL,keystate) == MOUSE$KS_CONTROL)  &
& write (*,*) 'Ctrl key was down'
```

## Graphics Library Routines

---

This section contains descriptions of the Graphics library routines, which are restricted to Windows\* systems. They are listed in alphabetical order.

To access these library routines, you must specify a USE IFQWIN statement in your program.

### ARC, ARC\_W

**Graphics Functions:** Draw elliptical arcs using the current graphics color. These routines are only available for Windows.

---

### Module

USE IFQWIN

## Syntax

```
result = ARC (x1,y1,x2,y2,x3,y3,x4,y4)
```

```
result = ARC_W (wx1,wy1,wx2,wy2,wx3,wy3,wx4,wy4)
```

<code>x1, y1</code>	(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
<code>x2, y2</code>	(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
<code>x3, y3</code>	(Input) INTEGER(2). Viewport coordinates of start vector.
<code>x4, y4</code>	(Input) INTEGER(2). Viewport coordinates of end vector.
<code>wx1, wy1</code>	(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
<code>wx2, wy2</code>	(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.
<code>wx3, wy3</code>	(Input) REAL(8). Window coordinates of start vector.
<code>wx4, wy4</code>	(Input) REAL(8). Window coordinates of end vector.

## Results

The result type is INTEGER(2). It is nonzero if successful; otherwise, 0. If the arc is clipped or partially out of bounds, the arc is considered successfully drawn and the return is 1. If the arc is drawn completely out of bounds, the return is 0.

The center of the arc is the center of the bounding rectangle defined by the points (`x1, y1`) and (`x2, y2`) for ARC and (`wx1, wy1`) and (`wx2, wy2`) for ARC\_W.

The arc starts where it intersects an imaginary line extending from the center of the arc through (`x3, y3`) for ARC and (`wx3, wy3`) for ARC\_W. It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through (`x4, y4`) for ARC and (`wx4, wy4`) for ARC\_W.

ARC uses the view-coordinate system. ARC\_W uses the window-coordinate system. In each case, the arc is drawn using the current color.

### NOTE

The ARC routine described here is a QuickWin graphics routine. If you are trying to use the Microsoft\* Platform SDK version of the Arc routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$Arc.

## Example

This program draws the arc shown below.

```
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4

x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 75
```

```
x4 = 90; y4 = 180
status = ARC( x1, y1, x2, y2, x3, y3, x4, y4 )
END
```

## CLEARSCREEN

**Graphics Subroutine:** Erases the target area and fills it with the current background color. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
CALL CLEARSCREEN (area)
```

*area*

(Input) INTEGER(4). Identifies the target area. Must be one of the following symbolic constants (defined in IFQWIN.F90):

- \$GCLEARSCREEN - Clears the entire screen.
- \$GVIEWPORT - Clears only the current viewport.
- \$GWINDOW - Clears only the current text window (set with SETTEXTWINDOW).

All pixels in the target area are set to the color specified with SETBKCOLORRGB. The default color is black.

### Example

```
USE IFQWIN
CALL CLEARSCREEN($GCLEARSCREEN)
```

### See Also

GETBKCOLORRGB  
SETBKCOLORRGB  
SETTEXTWINDOW  
SETVIEWPORT

## DISPLAYCURSOR

**Graphics Function:** Controls cursor visibility. This routine is only available for Windows.

---

### Module

USE IFQWIN

## Syntax

```
result = DISPLAYCURSOR (toggle)
```

*toggle*

(Input) INTEGER(2). Constant that defines the cursor state. Has two possible values:

- \$GCURSOROFF - Makes the cursor invisible regardless of its current shape and mode.
- \$GCURSORON - Makes the cursor always visible in graphics mode.

## Results

The result type is INTEGER(2). The result is the previous value of *toggle*.

Cursor settings hold only for the currently active child window. You need to call DISPLAYCURSOR for each window in which you want the cursor to be visible.

A call to SETWINDOWCONFIG turns off the cursor.

SETTEXTCURSOR

SETWINDOWCONFIG

## ELLIPSE, ELLIPSE\_W

**Graphics Functions:** Draw a circle or an ellipse using the current graphics color. These routines are only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = ELLIPSE (control,x1,y1,x2,y2)
```

```
result = ELLIPSE_W (control,wx1,wy1,wx2,wy2)
```

*control*

(Input) INTEGER(2). Fill flag. Can be one of the following symbolic constants:

- \$GFILLINTERIOR - Fills the figure using the current color and fill mask.
- \$GBORDER - Does not fill the figure.

*x1, y1*

(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.

*x2, y2*

(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.

*wx1, wy1*

(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.

*wx2, wy2*

(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.

## Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the ellipse is clipped or partially out of bounds, the ellipse is considered successfully drawn, and the return is 1. If the ellipse is drawn completely out of bounds, the return is 0.

The border is drawn in the current color and line style.

When you use ELLIPSE, the center of the ellipse is the center of the bounding rectangle defined by the viewport-coordinate points ( *x1*, *y1*) and ( *x2*, *y2*). When you use ELLIPSE\_W, the center of the ellipse is the center of the bounding rectangle defined by the window-coordinate points ( *wx1*, *wy1*) and ( *wx2*, *wy2*). If the bounding-rectangle arguments define a point or a vertical or horizontal line, no figure is drawn.

The control option given by \$GFILLINTERIOR is equivalent to a subsequent call to the FLOODFILLRGB function using the center of the ellipse as the start point and the current color (set by SETCOLORRGB) as the boundary color.

---

### NOTE

The ELLIPSE routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the Ellipse routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$Ellipse.

---

## Example

The following program draws the shape shown below.

```
! compile as QuickWin or Standard Graphics application
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80;  y1 = 50
x2 = 240; y2 = 150
dummy = ELLIPSE( $GFILLINTERIOR, x1, y1, x2, y2 )
END
```

## FLOODFILL, FLOODFILL\_W

**Graphics Functions:** Fill an area using the current color index and fill mask. These routines are only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = FLOODFILL (x,y,bcolor)
```

```
result = FLOODFILL_W (wx,wy,bcolor)
```

*x, y* (Input) INTEGER(2). Viewport coordinates for fill starting point.

*bcolor* (Input) INTEGER(2). Color index of the boundary color.

*wx, wy* (Input) REAL(8). Window coordinates for fill starting point.

### Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color *bcolor*, or if the starting point lies outside the clipping region).

FLOODFILL begins filling at the viewport-coordinate point ( *x, y*). FLOODFILL\_W begins filling at the window-coordinate point ( *wx, wy*). The fill color used by FLOODFILL and FLOODFILL\_W is set by SETCOLOR. You can obtain the current fill color index by calling GETCOLOR. These functions allow access only to the colors in the palette (256 or less). To access all available colors on a VGA (262,144 colors) or a true color system, use the RGB functions FLOODFILLRGB and FLOODFILLRGB\_W.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current graphics color index set by SETCOLOR. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color *bcolor*.

---

#### NOTE

The FLOODFILL routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the FloodFill routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$FloodFill.

---

### Example

```
USE IFQWIN
INTEGER(2) status, bcolor, red, blue
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
x1 = 80; y1 = 50
x2 = 240; y2 = 150
red = 4
blue = 1
status = SETCOLOR(red)
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLOR()
status = SETCOLOR (blue)
```

```
xinterior = 160; yinterior = 100
status = FLOODFILL (xinterior, yinterior, bcolor)
END
```

## FLOODFILLRGB, FLOODFILLRGB\_W

**Graphics Functions:** Fill an area using the current Red-Green-Blue (RGB) color and fill mask. These routines are only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = FLOODFILLRGB (x,y,color)
```

```
result = FLOODFILLRGB_W (wx,wy,color)
```

*x, y* (Input) INTEGER(2). Viewport coordinates for fill starting point.

*color* (Input) INTEGER(4). RGB value of the boundary color.

*wx, wy* (Input) REAL(8). Window coordinates for fill starting point.

## Results

The result type is INTEGER(4). The result is a nonzero value if successful; otherwise, 0 (occurs if the fill could not be completed, or if the starting point lies on a pixel with the boundary color *color*, or if the starting point lies outside the clipping region).

FLOODFILLRGB begins filling at the viewport-coordinate point ( *x*, *y*). FLOODFILLRGB\_W begins filling at the window-coordinate point ( *wx*, *wy*). The fill color used by FLOODFILLRGB and FLOODFILLRGB\_W is set by SETCOLORRGB. You can obtain the current fill color by calling GETCOLORRGB.

If the starting point lies inside a figure, the interior is filled; if it lies outside a figure, the background is filled. In both cases, the fill color is the current color set by SETCOLORRGB. The starting point must be inside or outside the figure, not on the figure boundary itself. Filling occurs in all directions, stopping at pixels of the boundary color *color*.

## Example

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) status
INTEGER(4) result, bcolor
INTEGER(2) x1, y1, x2, y2, xinterior, yinterior
```

```

x1 = 80; y1 = 50
x2 = 240; y2 = 150
result = SETCOLORRGB(Z'008080') ! red
status = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
bcolor = GETCOLORRGB( )
result = SETCOLORRGB (Z'FF0000') ! blue
xinterior = 160; yinterior = 100
result = FLOODFILLRGB (xinterior, yinterior, bcolor)
END

```

## GETARCINFO

**Graphics Function:** *Determines the endpoints (in viewport coordinates) of the most recently drawn arc or pie. This routine is only available for Windows.*

## Module

USE IFQWIN

## Syntax

```
result = GETARCINFO (lpstart, lpend, lppaint)
```

<i>lpstart</i>	(Output) Derived type <code>xycoord</code> . Viewport coordinates of the starting point of the arc.
<i>lpend</i>	(Output) Derived type <code>xycoord</code> . Viewport coordinates of the end point of the arc.
<i>lppaint</i>	(Output) Derived type <code>xycoord</code> . Viewport coordinates of the point at which the fill begins.

## Results

The result type is `INTEGER(2)`. The result is nonzero if successful. The result is zero if neither the ARC nor the PIE function has been successfully called since the last time `CLEARSCREEN` or `SETWINDOWCONFIG` was successfully called, or since a new viewport was selected.

`GETARCINFO` updates the *lpstart* and *lpend*`xycoord` derived types to contain the endpoints (in viewport coordinates) of the arc drawn by the most recent call to the ARC or PIE functions. The `xycoord` derived type, defined in `IFQWIN.F90`, is:

```

TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord

```

The returned value in *lppaint* specifies a point from which a pie can be filled. You can use this to fill a pie in a color different from the border color. After a call to GETARCINFO, change colors using SETCOLORRGB. Use the new color, along with the coordinates in *lppaint*, as arguments for the FLOODFILLRGB function.

### Example

```
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2, x3, y3, x4, y4
TYPE (xycoord) xystart, xyend, xyfillpt
x1 = 80; y1 = 50
x2 = 240; y2 = 150
x3 = 120; y3 = 80
x4 = 90; y4 = 180
status = ARC(x1, y1, x2, y2, x3, y3, x4, y4)
status = GETARCINFO(xystart, xyend, xyfillpt)
END
```

### GETBKCOLOR

**Graphics Function:** Returns the current background color index for both text and graphics output. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = GETBKCOLOR( )
```

### Results

The result type is INTEGER(4). The result is the current background color index.

GETBKCOLOR returns the current background color index for both text and graphics, as set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background index is 0, which is associated with black unless the user remaps the palette with REMAPPALETTERGB.

**NOTE**

The GETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the GetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$GetBkColor.

**Example**

```
USE IFQWIN
INTEGER(4) bcindex
bcindex = GETBKCOLOR()
```

**See Also**

SETBKCOLOR

GETCOLOR

GETTEXTCOLOR

REMAPALLPALETTEGB, REMAPPALETTEGB

**GETBKCOLORRGB**

**Graphics Function:** Returns the current background Red-Green-Blue (RGB) color value for both text and graphics. This routine is only available for Windows.

**Module**

USE IFQWIN

**Syntax**

```
result = GETBKCOLORRGB( )
```

**Results**

The result type is INTEGER(4). The result is the RGB value of the current background color for both text and graphics.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB and returned with GETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB and returned with GETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETBKCOLOR, SETCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes,

you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

### Example

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) back, fore, oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETCOLORRGB(Z'FF') ! red
! reverse the screen
back = GETBKCOLORRGB()
fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore)
oldcolor = SETCOLORRGB(back)
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END
```

### GETCOLOR

**Graphics Function:** *Returns the current graphics color index. This routine is only available for Windows.*

### Module

USE IFQWIN

### Syntax

```
result = GETCOLOR( )
```

### Results

The result type is INTEGER(2). The result is the current color index, if successful; otherwise, -1.

GETCOLOR returns the current color index used for graphics over the background color as set with SETCOLOR. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR and returned with GETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

### Example

```
! Program to demonstrate GETCOLOR
PROGRAM COLORS
USE IFQWIN
INTEGER(2) loop, loop1, status, color
LOGICAL(4) winstat
REAL rnd1, rnd2, xnum, ynum
```

```

type (windowconfig) wc
status = SETCOLOR(INT2(0))
! Color random pixels with 15 different colors
DO loop1 = 1, 15
  color = INT2(MOD(GETCOLOR() +1, 16))
  status = SETCOLOR (color) ! Set to next color
  DO loop = 1, 75
! Set color of random spot, normalized to be on screen
    CALL RANDOM(rnd1)
    CALL RANDOM(rnd2)
    winstat = GETWINDOWCONFIG(wc)
    xnum = wc%numxpixels
    ynum = wc%numypixels
    status = &
    SETPIXEL(INT2(rnd1*xnum+1),INT2(rnd2*ynum))
    status = &
    SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum+1))
    status = &
    SETPIXEL(INT2(rnd1*xnum-1),INT2(rnd2*ynum))
    status = &
    SETPIXEL(INT2(rnd1*xnum),INT2(rnd2*ynum-1))
  END DO
END DO
END

```

**See Also**

[GETCOLORRGB](#)  
[GETBKCOLOR](#)

[SETCOLOR](#)

**GETCOLORRGB**

**Graphics Function:** Returns the current graphics color Red-Green-Blue (RGB) value (used by graphics functions such as *ARC*, *ELLIPSE*, and *FLOODFILLRGB*). This routine is only available for Windows.

**Module**

USE IFQWIN

**Syntax**

```
result = GETCOLORRGB( )
```

**Results**

The result type is `INTEGER(4)`. The result is the RGB value of the current graphics color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with `GETCOLORRGB`, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

<b>Bit</b>	31 (MSB)	24	23	16	15	8	7	0																								
<b>RGB</b>	0	0	0	0	0	0	0	0	B	B	B	B	B	B	B	B	G	G	G	G	G	G	G	G	R	R	R	R	R	R	R	R

Larger numbers correspond to stronger color intensity with binary 1111111 (hex FF) the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETCOLORRGB returns the RGB color value of graphics over the background color (used by graphics functions such as ARC, ELLIPSE, and FLOODFILLRGB), set with SETCOLORRGB. GETBKCOLORRGB returns the RGB color value of the current background for both text and graphics, set with SETBKCOLORRGB. GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB.

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

## Example

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
INTEGER(4) fore, oldcolor
numfonts = INITIALIZEFONTS ( )
oldcolor = SETCOLORRGB(Z'FF')      ! set graphics
                                   !  color to red

fore = GETCOLORRGB()
oldcolor = SETBKCOLORRGB(fore)    ! set background
                                   !  to graphics color

CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB (Z'FF0000') ! set graphics
                                   !  color to blue

CALL OUTGTEXT("hello, world")
END
```

## GETCURRENTPOSITION, GETCURRENTPOSITION\_W

**Graphics Subroutines:** Return the coordinates of the current graphics position. These routines are only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
CALL GETCURRENTPOSITION (s)
CALL GETCURRENTPOSITION_W (s)
```

S

(Output) Derived type `xycoord`. Viewport coordinates of current graphics position. The derived type `xycoord` is defined in `IFQWIN.F90` as follows:

```
TYPE xycoord
  INTEGER(2) xcoord    ! x-coordinate
  INTEGER(2) ycoord    ! y-coordinate
END TYPE xycoord
```

`LINETO`, `MOVETO`, and `OUTGTEXT` all change the current graphics position. It is in the center of the screen when a window is created.

Graphics output starts at the current graphics position returned by `GETCURRENTPOSITION` or `GETCURRENTPOSITION_W`. This position is not related to normal text output (from `OUTTEXT` or `WRITE`, for example), which begins at the current text position (see `SETTEXTPOSITION`). It does, however, affect graphics text output from `OUTGTEXT`.

### Example

```
! Program to demonstrate GETCURRENTPOSITION
USE IFQWIN
TYPE (xycoord) position
INTEGER(2)      result
result = LINETO(INT2(300), INT2(200))
CALL GETCURRENTPOSITION( position )
IF (position%xcoord .GT. 50) THEN
  CALL MOVETO(INT2(50), position%ycoord, position)
  WRITE(*,*) "Text unaffected by graphics position"
END IF
result = LINETO(INT2(300), INT2(200))
END
```

### See Also

`LINETO`  
`MOVETO`  
`OUTGTEXT`  
`SETTEXTPOSITION`  
`GETTEXTPOSITION`

### GETFILLMASK

**Graphics Subroutine:** Returns the current pattern used to fill shapes. This routine is only available for Windows.

### Module

`USE IFQWIN`

### Syntax

```
CALL GETFILLMASK (mask)
```

*mask*

(Output) `INTEGER(1)`. One-dimensional array of length 8.

There are 8 bytes in *mask*, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of *mask* becomes the top 8 bits of the pattern, and the eighth element (byte) of *mask* becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of 0 are unchanged. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

### Example

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1) style(8). array(8)
INTEGER(2) i
style = 0
style(1) = Z'F'
style(3) = Z'F'
style(5) = Z'F'
style(7) = Z'F'
CALL SETFILLMASK (style)
...
CALL GETFILLMASK (array)
WRITE (*, *) 'Fill mask in bits: '
DO i = 1, 8
  WRITE (*, '(B8)') array(i)
END DO
END
```

### GETFONTINFO

**Graphics Function:** Returns the current font characteristics. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

result = GETFONTINFO (font)

font

(Output) Derived type FONTINFO. Set of characteristics of the current font. The FONTINFO derived type is defined in IFQWIN.F90 as follows:

```
TYPE FONTINFO
  INTEGER(4) type           ! 1 = truetype, 0 = bit map
  INTEGER(4) ascent         ! Pixel distance from top to
                           ! baseline
  INTEGER(4) pixwidth       ! Character width in pixels,
```

```

                                ! 0=proportional
INTEGER(4) pixheight           ! Character height in pixels
INTEGER(4) avgwidth            ! Average character width in
                                ! pixels
CHARACTER(81) filename         ! File name including path
CHARACTER(32) facename         ! Font name
LOGICAL(1) italic              ! .TRUE. if current font
                                ! formatted italic
LOGICAL(1) emphasized          ! .TRUE. if current font
                                ! formatted bold
LOGICAL(1) underline           ! .TRUE. if current font
                                ! formatted underlined
END TYPE FONTINFO

```

## Results

The result type is INTEGER(2). The result is zero if successful; otherwise, -1.

You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETFONTINFO.

## Example

```

! Build as QuickWin or Standard Graphics
USE IFQWIN
TYPE (FONTINFO) info
INTEGER(2)      numfonts, return, line_spacing
numfonts = INITIALIZEFONTS ( )
return = GETFONTINFO(info)
line_spacing = info%pixheight + 2
END

```

[SETFONT](#)

## GETGTEXTTEXTENT

**Graphics Function:** Returns the width in pixels that would be required to print a given string of text (including any trailing blanks) with OUTGTEXT using the current font. This routine is only available for Windows.

## Module

USE IFQWIN

## Syntax

```
result = GETGTEXTTEXTENT (text)
```

*text* (Input) Character\*(\*). Text to be analyzed.

## Results

The result type is INTEGER(2). The result is the width of *text* in pixels if successful; otherwise, -1 (for example, if fonts have not been initialized with INITIALIZEFONTS).

This function is useful for determining the size of text that uses proportionally spaced fonts. You must initialize fonts with INITIALIZEFONTS before calling any font-related function, including GETGTEXTTEXTENT.

## Example

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status, pwidth
CHARACTER(80) text
status= INITIALIZEFONTS( )
status= SETFONT('t' 'Arial' 'h22w10')
pwidth= GETGTEXTTEXTENT('How many pixels wide is this?')
WRITE(*,*) pwidth
END
```

OUTGTEXT

SETFONT

INITIALIZEFONTS

GETGTEXTROTATION

## GETGTEXTROTATION

**Graphics Function:** Returns the current orientation of the font text output by OUTGTEXT. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = GETGTEXTROTATION( )
```

## Results

The result type is INTEGER(4). It is the current orientation of the font text output in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 tenths of degrees (90°) is straight up, 1800 tenths of degrees (180°) is upside-down and left, 2700 tenths of degrees (270°) is straight down, and so forth.

The orientation for text output with OUTGTEXT is set with SETGTEXTROTATION.

## Example

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER ang
REAL rang
ang = GETGTEXTROTATION( )
rang = FLOAT(ang)/10.0
WRITE(*,*) "Text tilt in degrees is: ", rang
END
```

**Syntax**

CALL GETIMAGE (x1,y1,x2,y2,image)

CALL GETIMAGE\_W (wx1,wy1,wx2,wy2,image)

x1, y1	(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
x2, y2	(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
wx1, wy1	(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
wx2, wy2	(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.
image	(Output) INTEGER(1). Array of single-byte integers. Stored image buffer.

GETIMAGE defines the bounding rectangle in viewport-coordinate points ( x1, y1) and ( x2, y2).

GETIMAGE\_W defines the bounding rectangle in window-coordinate points ( wx1, wy1) and ( wx2, wy2).

The buffer used to store the image must be large enough to hold it. You can determine the image size by calling IMAGESIZE at run time, or by using the formula described under IMAGESIZE. After you have determined the image size, you can dimension the buffer accordingly.

**Example**

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(1), ALLOCATABLE:: buffer (:)
INTEGER(2) status, x, y, error
INTEGER(4) imsize
x = 50
y = 30
status = ELLIPSE ($GFILLINTERIOR, INT2(x-15), &
                 INT2(y-15), INT2( x+15), INT2(y+15))
imsize = IMAGESIZE (INT2(x-16), INT2(y-16), &
                   INT2( x+16), INT2(y+16))
ALLOCATE(buffer (imsize), STAT = error)
IF (error .NE. 0) THEN
  STOP 'ERROR: Insufficient memory'
END IF
```

```
CALL GETIMAGE (INT2(x-16), INT2(y-16), &  
              INT2( x+16), INT2(y+16), buffer)  
END
```

## GETLINESTYLE

**Graphics Function:** Returns the current graphics line style. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = GETLINESTYLE( )
```

## Results

The result type is INTEGER(2). The result is the current line style.

GETLINESTYLE retrieves the mask (line style) used for line drawing. The mask is a 16-bit number, where each bit represents a pixel in the line being drawn.

If a bit is 1, the corresponding pixel is colored according to the current graphics color and logical write mode; if a bit is 0, the corresponding pixel is left unchanged. The mask is repeated for the entire length of the line. The default mask is Z'FFFF' (a solid line). A dashed line can be represented by Z'FF00' (long dashes) or Z'F0F0' (short dashes).

The line style is set with SETLINESTYLE. The current graphics color is set with SETCOLORRRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

The line style retrieved by GETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE or PIE.

## Example

```
! Build as Graphics  
  USE IFQWIN  
  INTEGER(2) lstyle  
  lstyle = GETLINESTYLE()  
  WRITE (*, 100) lstyle, lstyle  
100  FORMAT (1X, 'Line mask in Hex ', Z4, ' and binary ', B16)  
END
```

## GETLINEWIDTHQQ

**Graphics Function:** Gets the current line width or the line width set by the last call to SETLINEWIDTHQQ.

*This routine is only available for Windows.*

### Module

USE IFQWIN

### Syntax

```
result = GETLINEWIDTHQQ( )
```

### Results

The result is of type INTEGER(4). It contains the current width of the line in pixels.

If there is no call to SETLINEWIDTHQQ in the program (or on that particular graphics window), it returns 1. (The default width of a line drawn by any graphics routine is 1 pixel.)

### See Also

SETLINEWIDTHQQ (W\*S)

## GETPHYSCOORD

**Graphics Subroutine:** Translates viewport coordinates to physical coordinates. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

```
CALL GETPHYSCOORD (x,y,s)
```

*x,y*

(Input) INTEGER(2). Viewport coordinates to be translated to physical coordinates.

*s*

(Output) Derived type `xycoord`. Physical coordinates of the input viewport position. The `xycoord` derived type is defined in `IFQWIN.F90` as follows:

```
TYPE xycoord
  INTEGER(2) xcoord  ! x-coordinate
  INTEGER(2) ycoord  ! y-coordinate
END TYPE xycoord
```

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with SETVIEWPORT. Both take integer coordinate values. Window coordinates refer to a window sized with SETWINDOW or SETWSIZEQQ. Window coordinates are floating-point values and allow easy scaling of data to the window area.

### Example

```
! Program to demonstrate GETPHYSCOORD, GETVIEWCOORD,
! and GETWINDOWCOORD. Build as QuickWin or Standard
! Graphics
```

```
USE IFQWIN
TYPE (xycoord)  viewxy, physxy
TYPE (wxycoord) windy
CALL SETVIEWPORT(INT2(80), INT2(50), &
                 INT2(240), INT2(150))

! Get viewport equivalent of point (100, 90)
CALL GETVIEWCOORD (INT2(100), INT2(90), viewxy)

! Get physical equivalent of viewport coordinates
CALL GETPHYSCOORD (viewxy%xcoord, viewxy%ycoord, &
                  physxy)

! Get physical equivalent of viewport coordinates
CALL GETWINDOWCOORD (viewxy%xcoord, viewxy%ycoord, &
                    windy)

! Write viewport coordinates
WRITE (*,*) viewxy%xcoord, viewxy%ycoord
! Write physical coordinates
WRITE (*,*) physxy%xcoord, physxy%ycoord
! Write window coordinates
WRITE (*,*) windy%wx, windy%wy
END
```

## GETPIXEL, GETPIXEL\_W

**Graphics Functions:** Return the color index of the pixel at a specified location. These routines are only available for Windows.

---

## Module

USE IFQWIN

## Syntax

result = GETPIXEL (x, y)

result = GETPIXEL\_W (wx, wy)

x, y (Input) INTEGER(2). Viewport coordinates for pixel position.

wx, wy (Input) REAL(8). Window coordinates for pixel position.

## Results

The result type is INTEGER(2). The result is the pixel color index if successful; otherwise, -1 (if the pixel lies outside the clipping region, for example).

Color routines without the RGB suffix, such as GETPIXEL, use color indexes, not true color values, and limit you to colors in the palette, at most 256. To access all system colors, use SETPIXELRGB to specify an explicit Red-Green-Blue value and retrieve the value with GETPIXELRGB.

**NOTE**

The GETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the GetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$GetPixel.

**See Also**

GETPIXELRGB

GRSTATUS

REMAPALLPALETTE, REMAPPALETTE

SETCOLOR

GETPIXELS

SETPIXEL

**GETPIXELRGB, GETPIXELRGB\_W**

**Graphics Functions:** Return the Red-Green-Blue (RGB) color value of the pixel at a specified location. These routines are only available for Windows.

**Module**

USE IFQWIN

**Syntax**

```
result = GETPIXELRGB (x,y)
```

```
result = GETPIXELRGB_W (wx,wy)
```

*x, y* (Input) INTEGER(2). Viewport coordinates for pixel position.

*wx, wy* (Input) REAL(8). Window coordinates for pixel position.

**Results**

The result type is INTEGER(4). The result is the pixel's current RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETPIXELRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELRGB returns the true color value of the pixel, set with SETPIXELRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixel's position and the current configuration of the screen.

SETPIXELRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256.

Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function.

### Example

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) pixcolor, rseed
INTEGER(2) status
REAL rnd1, rnd2
LOGICAL(4) winstat
TYPE (windowconfig) wc
CALL GETTIM (status, status, status, INT2(rseed))
CALL SEED (rseed)
CALL RANDOM (rnd1)
CALL RANDOM (rnd2)
! Get the color index of a random pixel, normalized to
! be in the window. Then set current color to that
! pixel color.
winstat = GETWINDOWCONFIG(wc)
xnum = wc%numxpixels
ynum = wc%numypixels
pixcolor = GETPIXELRGB( INT2( rnd1*xnum ), INT2( rnd2*ynum ))
status = SETCOLORRGB (pixcolor)
END
```

## GETPIXELS

**Graphics Subroutine:** Returns the color indexes of multiple pixels. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

CALL GETPIXELS (n,x,y,color)

<i>n</i>	(Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other arguments.
<i>x, y</i>	(Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to get.
<i>color</i>	(Output) INTEGER(2). Array to be filled with the color indexes of the pixels at x and y.

GETPIXELS fills in the array *color* with color indexes of the pixels specified by the two input arrays *x* and *y*. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If the pixel is outside the clipping region, the value placed in the `color` array is undefined. Calls to GETPIXELS with `n` less than 1 are ignored. GETPIXELS is a much faster way to acquire multiple pixel color indexes than individual calls to GETPIXEL.

The range of possible pixel color index values is determined by the current video mode and palette, at most 256 colors. To access all system colors you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function such as SETPIXELSRGB and retrieve the value with GETPIXELSRGB, rather than a palette index with a non-RGB color function.

### See Also

GETPIXELSRGB

SETPIXELSRGB

GETPIXEL

SETPIXELS

## GETPIXELSRGB

**Graphics Subroutine:** Returns the Red-Green-Blue (RGB) color values of multiple pixels. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

```
CALL GETPIXELSRGB (n,x,y,color)
```

<code>n</code>	(Input) INTEGER(4). Number of pixels to get. Sets the number of elements in the other argument arrays.
<code>x, y</code>	(Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels.
<code>color</code>	(Output) INTEGER(4). Array to be filled with RGB color values of the pixels at <code>x</code> and <code>y</code> .

GETPIXELS fills in the array `color` with the RGB color values of the pixels specified by the two input arrays `x` and `y`. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the values you retrieve with GETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 11111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETPIXELSRGB is a much faster way to acquire multiple pixel RGB colors than individual calls to GETPIXELRGB. GETPIXELSRGB returns an array of true color values of multiple pixels, set with SETPIXELSRGB, SETCOLORRGB, SETBKCOLORRGB, or SETTEXTCOLORRGB, depending on the pixels' positions and the current configuration of the screen.

SETPIXELSRGB (and the other RGB color selection functions SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB) sets colors to a color value chosen from the entire available range. The non-RGB color functions (SETPIXELS, SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

### Example

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) color(50), result
INTEGER(2) x(50), y(50), status
TYPE (xycoord) pos
result = SETCOLORRGB(Z'FF')
CALL MOVETO(INT2(0), INT2(0), pos)
status = LINETO(INT2(100), INT2(200))
! Get 50 pixels at line 30 in viewport
DO i = 1, 50
  x(i) = i-1
  y(i) = 30
END DO
CALL GETPIXELSRGB(300, x, y, color)
! Move down 30 pixels and redisplay pixels
DO i = 1, 50
  y(i) = y(i) + 30
END DO
CALL SETPIXELSRGB (50, x, y, color)
END
```

## GETTEXTCOLOR

**Graphics Function:** Returns the current text color index. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = GETTEXTCOLOR( )
```

### Results

The result type is INTEGER(2). It is the current text color index.

GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT. The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.

The default text color index is 15, which is associated with white unless the user remaps the palette.

#### NOTE

The GETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the GetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$GetTextColor.

#### See Also

OUTTEXT  
REMAPPALETTE

SETTEXTCOLOR

### GETTEXTCOLORRGB

**Graphics Function:** Returns the Red-Green-Blue (RGB) value of the current text color (used with OUTTEXT, WRITE and PRINT). This routine is only available for Windows.

#### Module

USE IFQWIN

#### Syntax

```
result = GETTEXTCOLORRGB( )
```

#### Results

The result type is INTEGER(4). It is the RGB value of the current text color.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you retrieve with GETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

GETTEXTCOLORRGB returns the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT), set with SETTEXTCOLORRGB. The RGB color value used for graphics is set and returned with SETCOLORRGB and GETCOLORRGB. SETCOLORRGB controls the color used by the graphics function OUTGTEXT, while SETTEXTCOLORRGB controls the color used by all other text output functions. The RGB background color value for both text and graphics is set and returned with SETBKCOLORRGB and GETBKCOLORRGB.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and SETCOLORRGB) sets the color to a color value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters

(SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

## Example

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(4) oldtextc, oldbackc, temp
TYPE (rccoord) curpos
! Save color settings
oldtextc = GETTEXTCOLORRGB()
oldbackc = GETBKCOLORRGB()
CALL CLEARSCREEN( $GCLEARSCREEN )
! Reset colors
temp = SETTEXTCOLORRGB(Z'00FFFF') ! full red + full green
! = full yellow text
temp = SETBKCOLORRGB(Z'FF0000') ! blue background
CALL SETTEXTPOSITION( INT2(4), INT2(15), curpos)
CALL OUTTEXT( 'Hello, world')
! Restore colors
temp = SETTEXTCOLORRGB(oldtextc)
temp = SETBKCOLORRGB(oldbackc)
END
```

## See Also

SETTEXTCOLORRGB

GETBKCOLORRGB

GETCOLORRGB

GETTEXTCOLOR

## GETTEXTPOSITION

**Graphics Subroutine:** Returns the current text position. This routine is only available for Windows.

## Module

USE IFQWIN

## Syntax

CALL GETTEXTPOSITION (s)

s

(Output) Derived type `rccoord`. Current text position. The derived type `rccoord` is defined in `IFQWIN.F90` as follows:

```
TYPE rccoord
  INTEGER(2) row ! Row coordinate
  INTEGER(2) col ! Column coordinate
END TYPE rccoord
```

The text position given by coordinates (1, 1) is defined as the upper-left corner of the text window. Text output from the `OUTTEXT` function (and `WRITE` and `PRINT` statements) begins at the current text position. Font text is not affected by the current text position. Graphics output, including `OUTGTEXT` output, begins at the current graphics output position, which is a separate position returned by `GETCURRENTPOSITION`.

## Example

```
! Build as QuickWin or Standard Graphics
  USE IFQWIN
  TYPE (rccoord) textpos
  CALL GETTEXTPOSITION (textpos)
  END
```

## See Also

## GETTEXTWINDOW

**Graphics Subroutine:** *Finds the boundaries of the current text window. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

CALL GETTEXTWINDOW (*r1,c1,r2,c2*)

*r1, c1* (Output) INTEGER(2). Row and column coordinates for upper-left corner of the text window.

*r2, c2* (Output) INTEGER(2). Row and column coordinates for lower-right corner of the text window.

Output from OUTTEXT and WRITE is limited to the text window. By default, this is the entire window, unless the text window is redefined by SETTEXTWINDOW.

The window defined by SETTEXTWINDOW has no effect on output from OUTGTEXT.

## Example

```
! Build as QuickWin or Standard Graphics
  USE IFQWIN
  INTEGER(2) top, left, bottom, right
  DO i = 1, 10
    WRITE(*,*) "Hello, world"
  END DO
  ! Save text window position
  CALL GETTEXTWINDOW (top, left, bottom, right)
  ! Scroll text window down seven lines
  CALL SCROLLTEXTWINDOW (INT2(-7))
  ! Restore text window
  CALL SETTEXTWINDOW (top, left, bottom, right)
  WRITE(*,*) "At beginning again"
  END
```

## GETVIEWCOORD, GETVIEWCOORD\_W

**Graphics Subroutines:** Translate physical coordinates or window coordinates to viewport coordinates. These routines are only available for Windows.

---

### Module

USE IFQWIN

### Syntax

CALL GETVIEWCOORD (x, y, s)

CALL GETVIEWCOORD\_W (wx, wy, s)

x, y	(Input) INTEGER(2). Physical coordinates to be converted to viewport coordinates.
wx, wy	(Input) REAL(8). Window coordinates to be converted to viewport coordinates.
s	(Output) Derived type <code>xycoord</code> . Viewport coordinates. The <code>xycoord</code> derived type is defined in <code>IFQWIN.F90</code> as follows:

```
TYPE xycoord
  INTEGER(2) xcoord    ! x-coordinate
  INTEGER(2) ycoord    ! y-coordinate
END TYPE xycoord
```

Viewport coordinates refer to an area of the screen defined as the viewport with `SETVIEWPORT`. Physical coordinates refer to the whole screen. Both take integer coordinate values. Window coordinates refer to a window sized with `SETWINDOW` or `SETWSIZEQQ`. Window coordinates are floating-point values and allow easy scaling of data to the window area.

### Example

See the example program in [GETPHYSCOORD](#).

### See Also

[GETPHYSCOORD](#)  
[GETWINDOWCOORD](#)

## GETWINDOWCOORD

**Graphics Subroutine:** Converts viewport coordinates to window coordinates. This routine is only available for Windows.

---

### Module

USE IFQWIN

## Syntax

CALL GETWINDOWCOORD (*x*, *y*, *s*)

*x*, *y*

(Input) INTEGER(2). Viewport coordinates to be converted to window coordinates.

*s*

(Output) Derived type `wxycoord`. Window coordinates. The `wxycoord` derived type is defined in `IFQWIN.F90` as follows:

```
TYPE wxycoord
  REAL(8) wx    ! x-coordinate
  REAL(8) wy    ! y-coordinate
END TYPE wxycoord
```

Physical coordinates refer to the physical screen. Viewport coordinates refer to an area of the screen defined as the viewport with `SETVIEWPORT`. Both take integer coordinate values. Window coordinates refer to a window sized with `SETWINDOW` or `SETWSIZEQQ`. Window coordinates are floating-point values and allow easy scaling of data to the window area.

## Example

## GETWRITEMODE

**Graphics Function:** Returns the current logical write mode, which is used when drawing lines with the `LINE`, `POLYGON`, and `RECTANGLE` functions. This routine is only available for Windows.

## Module

USE IFQWIN

## Syntax

result = GETWRITEMODE( )

## Results

The result type is INTEGER(2). The result is the current write mode. Possible return values are:

- `$GPSET` - Causes lines to be drawn in the current graphics color. (default)
- `$GAND` - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- `$GOR` - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- `$GPRESET` - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
- `$GXOR` - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

The default value is \$GPSET. These constants are defined in IFQWIN.F90.

The write mode is set with SETWRITEMODE.

### Example

```
! Build as QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) mode
mode = GETWRITEMODE()
END
```

GRSTATUS

## GRSTATUS

**Graphics Function:** Returns the status of the most recently used graphics routine. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = GRSTATUS( )
```

### Results

The result type is INTEGER(2). The result is the status of the most recently used graphics function.

Use GRSTATUS immediately following a call to a graphics routine to determine if errors or warnings were generated. Return values less than 0 are errors, and values greater than 0 are warnings.

The following symbolic constants are defined in the IFQWIN.F90 module file for use with GRSTATUS:

---

Constant	Meaning
\$GRFILEWRITEERROR	Error writing bitmap file
\$GRFILEOPENERROR	Error opening bitmap file
\$GRIMAGEREADERROR	Error reading image
\$GRBITMAPDISPLAYERROR	Error displaying bitmap
\$GRBITMAPTOOLARGE	Bitmap too large
\$GRIMPROPERBITMAPFORMAT	Improper format for bitmap file

---

Constant	Meaning
\$GRFILEREADERROR	Error reading file
\$GRNOBITMAPFILE	No bitmap file
\$GRINVALIDIMAGEBUFFER	Image buffer data inconsistent
\$GRINSUFFICIENTMEMORY	Not enough memory to allocate buffer or to complete a fill operation
\$GRINVALIDPARAMETER	One or more parameters invalid
\$GRMODENOTSUPPORTED	Requested video mode not supported
\$GRERROR	Graphics error
\$GROK	Success
\$GRNOOUTPUT	No action taken
\$GRCLIPPED	Output was clipped to viewport
\$GRPARAMETERALTERED	One or more input parameters was altered to be within range, or pairs of parameters were interchanged to be in the proper order

After a graphics call, compare the return value of GRSTATUS to \$GROK. to determine if an error has occurred. For example:

```
IF ( GRSTATUS .LT. $GROK ) THEN
```

```
! Code to handle graphics error goes here
```

```
ENDIF
```

The following routines cannot give errors, and they all set GRSTATUS to \$GROK:

DISPLAYCURSOR	GETCOLORRGB	GETTEXTWINDOW
GETBKCOLOR	GETTEXTCOLOR	OUTTEXT
GETBKCOLORRGB	GETTEXTCOLORRGB	WRAPON
GETCOLOR	GETTEXTPOSITION	

The following table lists some other routines with the error or warning messages they produce for GRSTATUS:

Function	Possible GRSTATUS error codes	Possible GRSTATUS warning codes
ARC, ARC_W	\$GRINVALIDPARAMETER	\$GRNOOUTPUT
CLEARSCREEN	\$GRINVALIDPARAMETER	
ELLIPSE, ELLIPSE_W	\$GRINVALIDPARAMETER, \$GRINSUFFICIENTMEMORY	\$GRNOOUTPUT
FLOODFILLRGB	\$GRINVALIDPARAMETER, \$GRINSUFFICIENTMEMORY	\$GRNOOUTPUT

Function	Possible GRSTATUS error codes	Possible GRSTATUS warning codes
GETARCINFO	\$GRERROR	
GETFILLMASK	\$GRERROR, \$GRINVALIDPARAMETER	
GETFONTINFO	\$GRERROR	
GETGTEXTTEXTENT	\$GRERROR

**IMAGESIZE, IMAGESIZE\_W**

**Graphics Functions:** Return the number of bytes needed to store the image inside the specified bounding rectangle. *IMAGESIZE* is useful for determining how much memory is needed for a call to *GETIMAGE*. These routines are only available for Windows.

**Module**

USE IFQWIN

**Syntax**

```
result = IMAGESIZE (x1,y1,x2,y2)
```

```
result = IMAGESIZE_W (wx1,wy1,wx2,wy2)
```

<code>x1, y1</code>	(Input) INTEGER(2). Viewport coordinates for upper-left corner of image.
<code>x2, y2</code>	(Input) INTEGER(2). Viewport coordinates for lower-right corner of image.
<code>wx1, wy1</code>	(Input) REAL(8). Window coordinates for upper-left corner of image.
<code>wx2, wy2</code>	(Input) REAL(8). Window coordinates for lower-right corner of image.

## Results

The result type is INTEGER(4). The result is the storage size of an image in bytes.

IMAGESIZE defines the bounding rectangle in viewport-coordinate points ( `x1, y1`) and ( `x2, y2`).

IMAGESIZE\_W defines the bounding rectangle in window-coordinate points ( `wx1, wy1`) and ( `wx2, wy2`).

IMAGESIZE\_W defines the bounding rectangle in terms of window-coordinate points ( `wx1, wy1`) and ( `wx2, wy2`).

## Example

See the example in [GETIMAGE](#).

## INITIALIZEFONTS

**Graphics Function:** *Initializes Windows\* fonts. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

```
result = INITIALIZEFONTS( )
```

## Results

The result type is INTEGER(2). The result is the number of fonts initialized.

All fonts on Windows systems become available after a call to INITIALIZEFONTS. Fonts must be initialized with INITIALIZEFONTS before any other font-related library function (such as GETFONTINFO, GETGTEXTTEXT, SETFONT, OUTGTEXT) can be used.

The font functions affect the output of OUTGTEXT only. They do not affect other Fortran I/O functions (such as WRITE) or graphics output functions (such as OUTTEXT).

For each window you open, you must call INITIALIZEFONTS before calling SETFONT. INITIALIZEFONTS needs to be executed after each new child window is opened in order for a subsequent SETFONT call to be successful.

## Example

```
! build as a QuickWin or Standard Graphics App.  
USE IFQWIN  
INTEGER(2) numfonts
```

```
numfonts = INITIALIZEFONTS()
WRITE (*,*) numfonts
END
```

OUTGTEXT

## LINETO, LINETO\_W

**Graphics Function:** *Draws a line from the current graphics position up to and including the end point. These routines are only available for Windows.*

### Module

USE IFQWIN

### Syntax

```
result = LINETO (x,y)
```

```
result = LINETO_W (wx, wy)
```

*x, y* (Input) INTEGER(2). Viewport coordinates of end point.

*wx, wy* (Input) REAL(8). Window coordinates of end point.

### Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, 0.

The line is drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

If no error occurs, LINETO sets the current graphics position to the viewport point (*x, y*), and LINETO\_W sets the current graphics position to the window point (*wx, wy*).

If you use FLOODFILLRGB to fill in a closed figure drawn with LINETO, the figure must be drawn with a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

### NOTE

The LINETO routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the LineTo routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$LineTo.

### Example

This program draws the figure shown below.

```
! Build as QuickWin or Standard Graphics
USE IFQWIN
INTEGER(2) status
TYPE (xycoord) xy

CALL MOVETO(INT2(80), INT2(50), xy)
status = LINETO(INT2(240), INT2(150))
status = LINETO(INT2(240), INT2(50))
END
```

### See Also

SETWRITEMODE

## LINETOAR

**Graphics Function:** Draws a line between each *x,y* point in the *from*-array to each corresponding *x,y* point in the *to*-array. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

```
result = LINETOAR (loc(fx), loc(fy), loc(tx) loc(ty), cnt)
```

<i>fx</i>	(Input) INTEGER(2). From x viewport coordinate array.
<i>fy</i>	(Input) INTEGER(2). From y viewport coordinate array.
<i>tx</i>	(Input) INTEGER(2). To x viewport coordinate array.
<i>ty</i>	(Input) INTEGER(2). To y viewport coordinate array.
<i>cnt</i>	(Input) INTEGER(4). Length of each coordinate array; all should be the same size.

### Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with SETCOLORRGB, the write mode with SETWRITEMODE, and the line style with SETLINESTYLE.

### Example

```
! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3),fy(3),tx(3),ty(3),result
integer(4) cnt, i
! load the points
```

```

do i = 1,3
  !from here
  fx(i) =20*i
  fy(i) =10
  !to there
  tx(i) =20*i
  ty(i) =60
end do
! draw the lines all at once
! 3 white vertical lines in upper left corner
result = LINETOAR(loc(fx),loc(fy),loc(tx),loc(ty), 3)
end

```

## See Also

SETWRITEMODE

## LINETOAREX

**Graphics Function:** *Draws a line between each x,y point in the from-array to each corresponding x,y point in the to-array. Each line is drawn with the specified graphics color and line style. This routine is only available for Windows.*

## Module

USE IFQWIN

## Syntax

```
result = LINETOAREX (loc(fx), loc(fy), loc(tx) loc(ty), loc(C), loc(S), cnt)
```

<i>fx</i>	(Input) INTEGER(2). From x viewport coordinate array.
<i>fy</i>	(Input) INTEGER(2). From y viewport coordinate array.
<i>tx</i>	(Input) INTEGER(2). To x viewport coordinate array.
<i>ty</i>	(Input) INTEGER(2). To y viewport coordinate array.
<i>C</i>	(Input) INTEGER(4). Color array.
<i>S</i>	(Input) INTEGER(4). Style array.
<i>cnt</i>	(Input) INTEGER(4). Length of each coordinate array; also the length of the color array and style array. All of the arrays should be the same size.

## Results

The result type is INTEGER(2). The result is a nonzero value if successful; otherwise, zero.

The lines are drawn using the specified graphics colors and line styles, and with the current write mode. The current write mode is set with SETWRITEMODE.

If the color has the Z'80000000' bit set, the color is an RGB color; otherwise, the color is a palette color.

The styles are as follows from `wingdi.h`:

```
SOLID          0
DASH           1      /* ----- */
DOT            2      /* ..... */
DASHDOT        3      /* -.-.-.- */
DASHDOTDOT     4      /* -.-.-.- */
NULL           5
```

## Example

```
! Build for QuickWin or Standard Graphics
USE IFQWIN
integer(2) fx(3),fy(3),tx(3),ty(3),result
integer(4) C(3),S(3),cnt,i,color

color = #000000FF

! load the points
do i = 1,3
  S(i) = 0 ! all lines solid
  C(i) = IOR(Z'80000000',color)
  color = color*256 ! pick another of RGB
  if(IAND(color,Z'00FFFFFF').eq.0) color = Z'000000FF'
  !from here
  fx(i) =20*i
  fy(i) =10
  !to there
  tx(i) =20*i
  ty(i) =60
end do
! draw the lines all at once
! 3 vertical lines in upper left corner, Red, Green, and Blue
result = LINETOAREX(loc(fx),loc(fy),loc(tx),loc(ty),loc(C),loc(S),3)
end
```

## LOADIMAGE, LOADIMAGE\_W

**Graphics Functions:** Read an image from a Windows bitmap file and display it at a specified location. These routines are only available for Windows.

### Module

`USE IFQWIN`

### Syntax

```
result = LOADIMAGE (filename,xcoord,ycoord)
```

```
result = LOADIMAGE_W (filename,wxcoord,wycoord)
```

<i>filename</i>	(Input) Character*(*). Path of the bitmap file.
<i>xcoord, ycoord</i>	(Input) INTEGER(4). Viewport coordinates for upper-left corner of image display.
<i>wxcoord, wycoord</i>	(Input) REAL(8). Window coordinates for upper-left corner of image display.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The image is displayed with the colors in the bitmap file. If the color palette in the bitmap file is different from the current system palette, the current palette is discarded and the bitmap's palette is loaded.

LOADIMAGE specifies the screen placement of the image in viewport coordinates. LOADIMAGE\_W specifies the screen placement of the image in window coordinates.

## See Also

SAVEIMAGE, SAVEIMAGE\_W

## MOVETO, MOVETO\_W

**Graphics Subroutines:** Move the current graphics position to a specified point. No drawing occurs. These routines are only available for Windows.

## Module

USE IFQWIN

## Syntax

```
CALL MOVETO (x,y,s)
```

```
CALL MOVETO_W (wx,wy,ws)
```

<i>x, y</i>	(Input) INTEGER(2). Viewport coordinates of the new graphics position.
<i>s</i>	(Output) Derived type <i>xycoord</i> . Viewport coordinates of the previous graphics position. The derived type <i>xycoord</i> is defined in IFQWIN.F90 as follows:
<pre> TYPE xycoord   INTEGER(2) xcoord ! x coordinate   INTEGER(2) ycoord ! y coordinate END TYPE xycoord </pre>	
<i>wx, wy</i>	(Input) REAL(8). Window coordinates of the new graphics position.
<i>ws</i>	(Output) Derived type <i>wxycoord</i> . Viewport coordinates of the previous graphics position. The derived type <i>wxycoord</i> is defined in IFQWIN.F90 as follows:

```

TYPE wxycoord
  DOUBLE PRECISION WX,WY
  STRUCTURE/WXYCOORD/
  DOUBLE PRECISION WX

```

```
DOUBLE PRECISION WY
END STRUCTURE
END TYPE wxycoord
```

MOVETO sets the current graphics position to the viewport coordinate ( *x*, *y*). MOVETO\_W sets the current graphics position to the window coordinate ( *wx*, *wy*).

MOVETO and MOVETO\_W assign the coordinates of the previous position to *s*.

### Example

```
! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
INTEGER(4) result
TYPE (xycoord) xy
RESULT = SETCOLORRGB(Z'FF0000') ! blue
x = 60
! Draw a series of lines DO y = 50, 92, 3
  CALL MOVETO(x, y, xy)
  status = LINETO(INT2(x + 20), y)
END DO
END
```

### See Also

GETCURRENTPOSITION

LINETO

OUTGTEXT

## OUTGTEXT

**Graphics Subroutine:** *In graphics mode, sends a string of text to the screen, including any trailing blanks. This routine is only available for Windows.*

---

### Module

USE IFQWIN

### Syntax

```
CALL OUTGTEXT (text)
```

*text* (Input) Character\*(\*). String to be displayed.

Text output begins at the current graphics position, using the current font set with SETFONT and the current color set with SETCOLORRGB or SETCOLOR. No formatting is provided. After it outputs the text, OUTGTEXT updates the current graphics position.

Before you call OUTGTEXT, you must call the INITIALIZEFONTS function.

Because OUTGTEXT is a graphics function, the color of text is affected by the SETCOLORRGB function, not by SETTEXTCOLORRGB.

### Example

```
! build as a QuickWin App.
USE IFQWIN
INTEGER(2) result
INTEGER(4) i
TYPE (xycoord) xys
```

```

result = INITIALIZEFONTS()
result = SETFONT('t'Arial'h18w10pvib')
do i=1,6
  CALL MOVETO(INT2(0),INT2(30*(i-1)),xys)
  grstat=SETCOLOR(INT2(i))
  CALL OUTGTEXT('This should be ')
  SELECT CASE (i)
    CASE (1)
      CALL OUTGTEXT('Blue')
    CASE (2)
      CALL OUTGTEXT('Green')
    CASE (3)
      CALL OUTGTEXT('Cyan')
    CASE (4)
      CALL OUTGTEXT('Red')
    CASE (5)
      CALL OUTGTEXT('Magenta')
    CASE (6)
      CALL OUTGTEXT('Orange')
  END SELECT
end do
END

```

**OUTTEXT**

**Graphics Subroutine:** *In text or graphics mode, sends a string of text to the screen, including any trailing blanks. This routine is only available for Windows.*

---

**Module**

[USE IFQWIN](#)

**Syntax**

```
CALL OUTTEXT (text)
```

*text* (Input) Character\*(\*). String to be displayed.

Text output begins at the current text position in the color set with SETTEXTCOLORRRGB or SETTEXTCOLOR. No formatting is provided. After it outputs the text, OUTTEXT updates the current text position.

To output text using special fonts, you must use the OUTGTEXT subroutine.

## Example

```
USE IFQWIN
INTEGER(2) oldcolor
TYPE (rccoord) rc

CALL CLEARSCREEN($GCLEARSCREEN)
CALL SETTEXTPOSITION (INT2(1), INT2(5), rc)
oldcolor = SETTEXTCOLOR(INT2(4))
CALL OUTTEXT ('Hello, everyone')
END
```

## PIE, PIE\_W

**Graphics Functions:** Draw a pie-shaped wedge in the current graphics color. These routines are only available for Windows.

---

## Module

USE IFQWIN

## Syntax

result = PIE (i, x1, y1, x2, y2, x3, y3, x4, y4)

result = PIE\_W (i, wx1, wy1, wx2, wy2, wx3, y3, wx4, wy4)

i	(Input) INTEGER(2). Fill flag. One of the following symbolic constants defined in IFQWIN.F90: <ul style="list-style-type: none"><li>• \$GFILLINTERIOR - Fills the figure using the current color and fill mask.</li><li>• \$GBORDER - Does not fill the figure.</li></ul>
x1, y1	(Input) INTEGER(2). Viewport coordinates for upper-left corner of bounding rectangle.
x2, y2	(Input) INTEGER(2). Viewport coordinates for lower-right corner of bounding rectangle.
x3, y3	(Input) INTEGER(2). Viewport coordinates of start vector.
x4, y4	(Input) INTEGER(2). Viewport coordinates of end vector.
wx1, wy1	(Input) REAL(8). Window coordinates for upper-left corner of bounding rectangle.
wx2, wy2	(Input) REAL(8). Window coordinates for lower-right corner of bounding rectangle.
wx3, wy3	(Input) REAL(8). Window coordinates of start vector.

*wx4*, *wy4*

(Input) REAL(8). Window coordinates of end vector.

## Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0. If the pie is clipped or partially out of bounds, the pie is considered successfully drawn and the return is 1. If the pie is drawn completely out of bounds, the return is 0.

The border of the pie wedge is drawn in the current color set by SETCOLORRGB.

The PIE function uses the viewport-coordinate system. The center of the arc is the center of the bounding rectangle, which is specified by the viewport-coordinate points (*x1*, *y1*) and (*x2*, *y2*). The arc starts where it intersects an imaginary line extending from the center of the arc through (*x3*, *y3*). It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through (*x4*, *y4*).

The PIE\_W function uses the window-coordinate system. The center of the arc is the center of the bounding rectangle specified by the window-coordinate points (*wx1*, *wy1*) and (*wx2*, *wy2*). The arc starts where it intersects an imaginary line extending from the center of the arc through (*wx3*, *wy3*). It is drawn counterclockwise about the center of the arc, ending where it intersects an imaginary line extending from the center of the arc through (*wx4*, *wy4*).

The fill flag option \$GFILLINTERIOR is equivalent to a subsequent call to FLOODFILLRGB using the center of the pie as the starting point and the current graphics color (set by SETCOLORRGB) as the fill color. If you want a fill color different from the boundary color, you cannot use the \$GFILLINTERIOR option. Instead, after you have drawn the pie wedge, change the current color with SETCOLORRGB and then call FLOODFILLRGB. You must supply FLOODFILLRGB with an interior point in the figure you want to fill. You can get this point for the last drawn pie or arc by calling GETARCINFO.

If you fill the pie with FLOODFILLRGB, the pie must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

## NOTE

The PIE routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the Pie routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$Pie.

## Example

```
! build as Graphics App.
USE IFQWIN
INTEGER(2) status, dummy
INTEGER(2) x1, y1, x2, y2, x3, y3, x4, y4
x1 = 80; y1 = 50
x2 = 180; y2 = 150
x3 = 110; y3 = 80
x4 = 90; y4 = 180

status = SETCOLOR(INT2(4))
dummy = PIE( $GFILLINTERIOR, x1, y1, x2, y2, &
            x3, y3, x4, y4)
END
```

This figure shows the coordinates used to define PIE and PIE\_W:

**POLYBEZIER, POLYBEZIER\_W**

**Graphics Functions:** Draw one or more Bezier curves. These routines are only available for Windows.

**Module**

USE IFQWIN

**Syntax**

```
result = POLYBEZIER (lppoints, cpoints)
```

```
result = POLYBEZIER_W (lppoints, cpoints)
```

*lppoints*

(Input) Derived type `xycoord`. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type `xycoord` is defined in `IFQWIN.F90` as follows:

```

TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord

```

*cpoints*

(Input) `INTEGER(2)`. Number of points in *lppoints*.

**Results**

The result type is `INTEGER(2)`. The result is nonzero if anything is drawn; otherwise, 0.

A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point must be given for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, *cpoints* should contain 4 for one curve, 7 for 2 curves, 10 for 3 curves, and so forth.

POLYBEZIER does not use or change the current graphics position.

### Example

```

### Module

USE IFQWIN

### Syntax

```
result = POLYBEZIERTO (lppoints, cpoints)
```

```
result = POLYBEZIERTO_W (lppoints, cpoints)
```

*lppoints* (Input) Derived type `xycoord`. Array of derived types defining the endpoints and the control points for each Bezier curve. The derived type `xycoord` is defined in `IFQWIN.F90` as follows:

```
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

*cpoints* (Input) `INTEGER(2)`. Number of points in *ppoints* or *lppoints*.

### Results

The result type is `INTEGER(2)`. The result is nonzero if anything is drawn; otherwise, 0.

A Bezier curve is based on fitting a cubic curve to four points. The first point is the starting point, the next two points are control points, and last point is the ending point. The starting point is the current graphics position as set by `MOVETO` for the first curve; subsequent curves use the ending point of the previous curve as their starting point. So, *cpoints* should contain 3 for one curve, 6 for 2 curves, 9 for 3 curves, and so forth.

`POLYBEZIERTO` moves the current graphics position to the ending point of the last curve drawn.

### Example

See the example in `POLYBEZIER, POLYBEZIER_W (W*S)`.

`MOVETO, MOVETO_W`

## POLYGON, POLYGON\_W

**Graphics Functions:** Draw a polygon using the current graphics color, logical write mode, and line style. These routines are only available for Windows.

### Module

USE IFQWIN

### Syntax

```
result = POLYGON (control, lppoints, cpoints)
```

```
result = POLYGON_W (control, lppoints, cpoints)
```

*control*

(Input) INTEGER(2). Fill flag. One of the following symbolic constants defined in `IFQWIN.F90`:

- `$GFILLINTERIOR` - Draws a solid polygon using the current color and fill mask.
- `$GBORDER` - Draws the border of a polygon using the current color and line style.

*lppoints*

(Input) Derived type `xycoord`. Array of derived types defining the polygon vertices in viewport coordinates. The derived type `xycoord` is defined in `IFQWIN.F90` as follows:

```
TYPE xycoord
  INTEGER(2) xcoord
  INTEGER(2) ycoord
END TYPE xycoord
```

*cpoints*

(Input) INTEGER(2). Number of polygon vertices.

## Results

The result type is INTEGER(2). The result is nonzero if anything is drawn; otherwise, 0.

The border of the polygon is drawn in the current graphics color, logical write mode, and line style, set with `SETCOLORRGB`, `SETWRITEMODE`, and `SETLINESTYLE`, respectively. The `POLYGON` routine uses the viewport-coordinate system (expressed in `xycoord` derived types), and the `POLYGON_W` routine uses real-valued window coordinates (expressed in `xycoord` types).

The argument *lppoints* is an array whose elements are `xycoord` derived types. Each element specifies one of the polygon's vertices. The argument *cpoints* is the number of elements (the number of vertices) in the *lppoints* array.

Note that `POLYGON` draws between the vertices in their order in the array. Therefore, when drawing outlines, skeletal figures, or any other figure that is not filled, you need to be careful about the order of the vertices. If you don't want lines between some vertices, you may need to repeat vertices to make the drawing backtrack and go to another vertex to avoid drawing across your figure. Also, `POLYGON` draws a line from the last specified vertex back to the first vertex.

If you fill the polygon using `FLOODFILLRGB`, the polygon must be bordered by a solid line style. Line style is solid by default and can be changed with `SETLINESTYLE`.

---

### NOTE

The `POLYGON` routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the Polygon routine by including the `IFWIN` module, you need to specify the routine name as `MSFWIN$Polygon`.

---

## Example

```
! Build as a Graphics App.

! Draw a skeletal box
  USE IFQWIN
  INTEGER(2) status
  TYPE (xycoord) poly(12)

! Set up box vertices in order they will be drawn, &
!   repeating some to avoid unwanted lines across box
```

```

poly(1)%xcoord = 50
poly(1)%ycoord = 80
poly(2)%xcoord = 85
poly(2)%ycoord = 35
poly(3)%xcoord = 185
poly(3)%ycoord = 35
poly(4)%xcoord = 150
poly(4)%ycoord = 80
poly(5)%xcoord = 50
poly(5)%ycoord = 80
poly(6)%xcoord = 50
poly(6)%ycoord = 180
poly(7)%xcoord = 150
poly(7)%ycoord = 180
poly(8)%xcoord = 185
poly(8)%ycoord = 135
poly(9)%xcoord = 185
poly(9)%ycoord = 35
poly(10)%xcoord = 150
poly(10)%ycoord = 80
poly(11)%xcoord = 150
poly(11)%ycoord = 180
poly(12)%xcoord = 150
poly(12)%ycoord = 80

status = SETCOLORRGB(Z'0000FF')
status = POLYGON($GBORDER, poly, INT2(12))
END

```

**POLYLINEQQ**

**Graphics Function:** *Draws a line between each successive x, y point in a given array. This routine is only available for Windows.*

**Module**

[USE IFQWIN](#)

**Syntax**

```
result = POLYLINEQQ (points,cnt)
```

*points*

(Input) An array of `DF_POINT` objects. The derived type `DF_POINT` is defined in `IFQWIN.F90` as:

```
type DF_POINT
  sequence
  integer(4) x
  integer(4) y
end type DF_POINT
```

*cnt*

(Input) `INTEGER(4)`. Number of elements in the *points* array.

## Results

The result type is `INTEGER(4)`. The result is a nonzero value if successful; otherwise, zero.

`POLYLINEQQ` uses the viewport-coordinate system.

The lines are drawn using the current graphics color, logical write mode, and line style. The graphics color is set with `SETCOLORRGB`, the write mode with `SETWRITEMODE`, and the line style with `SETLINESTYLE`.

The current graphics position is not used or changed as it is in the `LINETO` function.

## Example

```
! Build for QuickWin or Standard Graphics
USE IFQWIN
TYPE(DF_POINT) points(12)
integer(4) result
integer(4) cnt, i

! load the points
do i = 1,12,2
  points(i).x =20*i
  points(i).y =10
  points(i+1).x =20*i
  points(i+1).y =60
end do

! A sawtooth pattern will appear in the upper left corner
result = POLYLINEQQ(points, 12)
end
```

## PUTIMAGE, PUTIMAGE\_W

**Graphics Subroutines:** *Transfer the image stored in memory to the screen. These routines are only available for Windows.*

---

## Module

`USE IFQWIN`

## Syntax

`CALL PUTIMAGE (x,y,image,action)`

`CALL PUTIMAGE_W (wx,wy,image,action)`

<code>x, y</code>	(Input) INTEGER(2). Viewport coordinates for upper-left corner of the image when placed on the screen.
<code>wx, wy</code>	(Input) REAL(8). Window coordinates for upper-left corner of the image when placed on the screen.
<code>image</code>	(Input) INTEGER(1). Array of single-byte integers. Stored image buffer.
<code>action</code>	<p>(Input) INTEGER(2). Interaction of the stored image with the existing screen image. One of the following symbolic constants defined in <code>IFQWIN.F90</code>:</p> <ul style="list-style-type: none"> <li>• <code>\$GAND</code> - Forms a new screen display as the logical AND of the stored image and the existing screen display. Points that have the same color in both the existing screen image and the stored image remain the same color, while points that have different colors are joined by a logical AND.</li> <li>• <code>\$GOR</code> - Superimposes the stored image onto the existing screen display. The resulting image is the logical OR of the image.</li> <li>• <code>\$GPRESET</code> - Transfers the data point-by-point onto the screen. Each point has the inverse of the color attribute it had when it was taken from the screen by <code>GETIMAGE</code>, producing a negative image.</li> <li>• <code>\$GPSET</code> - Transfers the data point-by-point onto the screen. Each point has the exact color attribute it had when it was taken from the screen by <code>GETIMAGE</code>.</li> <li>• <code>\$GXOR</code> - Causes points in the existing screen image to be inverted wherever a point exists in the stored image. This behavior is like that of a cursor. If you perform an exclusive OR of an image with the background twice, the background is restored unchanged. This allows you to move an object around without erasing the background. The <code>\$GXOR</code> constant is a special mode often used for animation.</li> <li>• In addition, the following ternary raster operation constants can be used (described in the online documentation for the Windows* API <code>BitBlt</code>): <ul style="list-style-type: none"> <li>• <code>\$GSRCCOPY</code> (same as <code>\$GPSET</code>)</li> <li>• <code>\$GSRCPAINT</code> (same as <code>\$GOR</code>)</li> <li>• <code>\$GSRCAND</code> (same as <code>\$GAND</code>)</li> <li>• <code>\$GSRCINVERT</code> (same as <code>\$GXOR</code>)</li> <li>• <code>\$GSRCERASE</code></li> <li>• <code>\$GNOTSRCCOPY</code> (same as <code>\$GPRESET</code>)</li> <li>• <code>\$GNOTSRCERASE</code></li> <li>• <code>\$GMERGECOPY</code></li> <li>• <code>\$GMERGEPAINT</code></li> <li>• <code>\$GPATCOPY</code></li> <li>• <code>\$GPATPAINT</code></li> <li>• <code>\$GPATINVERT</code></li> <li>• <code>\$GDSTINVERT</code></li> <li>• <code>\$GBLACKNESS</code></li> </ul> </li> </ul>

- \$GWHITENESS

PUTIMAGE places the upper-left corner of the image at the viewport coordinates (x, y). PUTIMAGE\_W places the upper-left corner of the image at the window coordinates (wx, wy).

### Example

```
! Build as a Graphics App.
USE IFQWIN
INTEGER(1), ALLOCATABLE :: buffer(:)
INTEGER(2) status, x
INTEGER(4) imsize

status = SETCOLOR(INT2(4))

! draw a circle
status = ELLIPSE($GFILLINTERIOR, INT2(40), INT2(55),      &
                INT2(70), INT2(85))
imsize = IMAGESIZE (INT2(39), INT2(54), INT2(71), &
                  INT2(86))
ALLOCATE (buffer(imsize))
CALL GETIMAGE (INT2(39), INT2(54), INT2(71), INT2(86),      &
              buffer)

! copy a row of circles beneath it
DO x = 5 , 395, 35
  CALL PUTIMAGE(x, INT2(90), buffer, $GPSET)
END DO
DEALLOCATE(buffer)
END
```

## RECTANGLE, RECTANGLE\_W

**Graphics Functions:** Draw a rectangle using the current graphics color, logical write mode, and line style. These routines are only available for Windows.

---

### Module

USE IFQWIN

### Syntax

result = RECTANGLE (control, x1, y1, x2, y2)

result = RECTANGLE\_W (control, wx1, wy1, wx2, wy2)

control

(Input) INTEGER(2). Fill flag. One of the following symbolic constants defined in IFQWIN.F90:

- \$GFILLINTERIOR - Draws a solid figure using the current color and fill mask.
- \$GBORDER - Draws the border of a rectangle using the current color and line style.

<code>x1, y1</code>	(Input) INTEGER(2). Viewport coordinates for upper-left corner of rectangle.
<code>x2, y2</code>	(Input) INTEGER(2). Viewport coordinates for lower-right corner of rectangle.
<code>wx1, wy1</code>	(Input) REAL(8). Window coordinates for upper-left corner of rectangle.
<code>wx2, wy2</code>	(Input) REAL(8). Window coordinates for lower-right corner of rectangle.

## Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0.

The RECTANGLE function uses the viewport-coordinate system. The viewport coordinates (`x1, y1`) and (`x2, y2`) are the diagonally opposed corners of the rectangle.

The RECTANGLE\_W function uses the window-coordinate system. The window coordinates (`wx1, wy1`) and (`wx2, wy2`) are the diagonally opposed corners of the rectangle.

SETCOLORRGB sets the current graphics color. SETFILLMASK sets the current fill mask. By default, filled graphic shapes are filled solid with the current color.

If you fill the rectangle using FLOODFILLRGB, the rectangle must be bordered by a solid line style. Line style is solid by default and can be changed with SETLINESTYLE.

### NOTE

The RECTANGLE routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the Rectangle routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$Rectangle.

## Example

This program draws the rectangle shown below.

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) dummy, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
dummy = RECTANGLE( $GBORDER, x1, y1, x2, y2 )
END
```

## REMAPALLPALETTERGB, REMAPPALETTERGB

**Graphics Functions:** *REMAPALLPALETTERGB* remaps a set of Red-Green-Blue (RGB) color values to indexes recognized by the video hardware.

*REMAPPALETTERGB* remaps one color index to an RGB color value. These routines are only available for Windows.

---

### Module

USE IFQWIN

### Syntax

`result = REMAPALLPALETTERGB (colors)`

`result = REMAPPALETTERGB (index, colors)`

*colors* (Input) INTEGER(4). Ordered array of RGB color values to be mapped in order to indexes. Must hold 0-255 elements.

*index* (Input) INTEGER(4). Color index to be reassigned an RGB color.

*color* (Input) INTEGER(4). RGB color value to assign to a color index.

### Results

The result type is INTEGER(4). REMAPALLPALETTERGB returns 0 if successful; otherwise, -1.

REMAPPALETTERGB returns the previous color assigned to the index.

The REMAPALLPALETTERGB function remaps all of the available color indexes simultaneously (up to 236; 20 indexes are reserved by the operating system). The *colors* argument points to an array of RGB color values. The default mapping between the first 16 indexes and color values is shown in the following table. The 16 default colors are provided with symbolic constants in IFQWIN.F90.

Index	Color	Index	Color
0	\$BLACK	8	\$GRAY
1	\$BLUE	9	\$LIGHTBLUE
2	\$GREEN	10	\$LIGHTGREEN
3	\$CYAN	11	\$LIGHTCYAN
4	\$RED	12	\$LIGHTRED
5	\$MAGENTA	13	\$LIGHTMAGENTA
6	\$BROWN	14	\$YELLOW
7	\$WHITE	15	\$BRIGHTWHITE

The number of colors mapped can be fewer than 236 if the number of colors supported by the current video mode is fewer, but at most 236 colors can be mapped by REMAPALLPALETTERGB. Most Windows\* graphics drivers support a palette of 256K colors or more, of which only a few can be mapped into the 236 palette indexes at a time. To access and use all colors on the system, bypass the palette and use direct RGB color functions such as SETCOLORRGB and SETPIXELSRGB.

Any RGB colors can be mapped into the 236 palette indexes. Thus, you could specify a palette with 236 shades of red.

In each RGB color value, each of the three colors, red, green and blue, is represented by an eight-bit value (2 hex digits). In the values you specify with REMAPALLPALETTERGB or REMAPPALETTERGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 11111111 (hex FF) the maximum for each of the three components. For example, Z'008080' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

### Example

```
! Build as QuickWin or Standard Graphics App.

USE IFQWIN
INTEGER(4) colors(3)
INTEGER(2) status
colors(1) = Z'00FFFF' ! yellow
colors(2) = Z'FFFFFF' ! bright white
colors(3) = 0         ! black

status = REMAPALLPALETTERGB(colors)
status = REMAPPALETTERGB(INT2(47), Z'45A315')
END
```

SETCOLOR

## SAVEIMAGE, SAVEIMAGE\_W

**Graphics Functions:** Save an image from a specified portion of the screen into a Windows bitmap file. These routines are only available for Windows.

### Module

USE IFQWIN

### Syntax

```
result = SAVEIMAGE (filename,ulxcoord,ulycoord, lrxcoord,lrycoord)
result = SAVEIMAGE_W (filename,ulwxcoord,ulwycoord, lrxwcoord,lrwycoord)

filename (Input) Character*(*). Path of the bitmap file.
```

<code>ulxcoord, ulycoord</code>	(Input) INTEGER(4). Viewport coordinates for upper-left corner of the screen image to be captured.
<code>lrxcoord, lrycoord</code>	(Input) INTEGER(4). Viewport coordinates for lower-right corner of the screen image to be captured.
<code>ulwxcoord, ulwycoord</code>	(Input) REAL(8). Window coordinates for upper-left corner of the screen image to be captured.
<code>lrwxcoord, lrwycoord</code>	(Input) REAL(8). Window coordinates for lower-right corner of the screen image to be captured.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a negative value.

The SAVEIMAGE function captures the screen image within a rectangle defined by the upper-left and lower-right screen coordinates and stores the image as a Windows bitmap file specified by *filename*. The image is stored with a palette containing the colors displayed on the screen.

SAVEIMAGE defines the bounding rectangle in viewport coordinates. SAVEIMAGE\_W defines the bounding rectangle in window coordinates.

## SCROLLTEXTWINDOW

**Graphics Subroutine:** *Scrolls the contents of a text window. This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

CALL SCROLLTEXTWINDOW (*rows*)

*rows* (Input) INTEGER(2). Number of rows to scroll.

The SCROLLTEXTWINDOW subroutine scrolls the text in a text window (previously defined by SETTEXTWINDOW). The default text window is the entire window.

The *rows* argument specifies the number of lines to scroll. A positive value for *rows* scrolls the window up (the usual direction); a negative value scrolls the window down. Specifying a number larger than the height of the current text window is equivalent to calling CLEARSCREEN (\$GWINDOW). A value of 0 for *rows* has no effect.

## Example

```
! Build as QuickWin or Standard Graphics app.
USE IFQWIN INTEGER(2) row, istat
CHARACTER(18) string
TYPE (rccoord) oldpos

CALL SETTEXTWINDOW (INT2(1), INT2(0), &
                    INT2(25), INT2(80))
```

```

CALL CLEARSCREEN ( $GCLEARSCREEN )
CALL SETTEXTPOSITION (INT2(1), INT2(1), oldpos)
DO row = 1, 6
  string = 'Hello, World # '
  CALL SETTEXTPOSITION( row, INT2(1), oldpos )
  WRITE(string(15:16), '(I2)') row
  CALL OUTTEXT( string )
END DO
istat = displaycursor($G_CURSORON)
WRITE(*, '(1x,A\') 'Hit ENTER'
READ (*,*)
! wait for ENTER
! Scroll window down 4 lines

CALL SCROLLTEXTWINDOW(INT2( -4) )
CALL SETTEXTPOSITION (INT2(10), INT2(18), oldpos)
WRITE(*, '(2X,A\') "Hit ENTER"
READ( *,* ) ! wait for ENTER
! Scroll window up 5 lines
CALL SCROLLTEXTWINDOW( INT2(5) )
END

```

**SETBKCOLOR**

**Graphics Function:** *Sets the current background color index for both text and graphics. This routine is only available for Windows.*

**Module**

[USE IFQWIN](#)

**Syntax**

```
result = SETBKCOLOR (color)
```

*color* (Input) INTEGER(4). Color index to set the background color to.

**Results**

The result type is INTEGER(4). The result is the previous background color index.

SETBKCOLOR changes the background color index for both text and graphics. The color index of text over the background color is set with SETTEXTCOLOR. The color index of graphics over the background color (used by drawing functions such as FLOODFILL and ELLIPSE) is set with SETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETBKCOLORRGB, SETCOLORRGB, and SETTEXTCOLORRGB.

Changing the background color index does not change the screen immediately. The change becomes effective when CLEARSCREEN is executed or when doing text input or output, such as with READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

Generally, INTEGER(4) color arguments refer to color values and INTEGER(2) color arguments refer to color indexes. The two exceptions are GETBKCOLOR and SETBKCOLOR. The default background color index is 0, which is associated with black unless the user remaps the palette with REMAPPALETTERGB.

---

**NOTE**

The SETBKCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the SetBkColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$SetBkColor.

---

### Example

```
USE IFQWIN
INTEGER(4) i
i = SETBKCOLOR(14)
```

### See Also

GETBKCOLOR

REMAPALLPALETTERGB, REMAPPALETTERGB

SETCOLOR

SETTEXTCOLOR

### SETBKCOLORRGB

**Graphics Function:** Sets the current background color to the given Red-Green-Blue (RGB) value. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

result = SETBKCOLORRGB (color)

color (Input) INTEGER(4). RGB color value to set the background color to. Range and result depend on the system's display adapter.

### Results

The result type is INTEGER(4). The result is the previous background RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETBKCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

The default background color is value 0, which is black. Changing the background color value does not change the screen immediately, but becomes effective when CLEARSCREEN is executed or when doing text input or output such as READ, WRITE, or OUTTEXT. The graphics output function OUTGTEXT does not affect the color of the background.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. The RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT) is set with SETTEXTCOLORRGB. The RGB color value of graphics over the background color (used by graphics functions such as ARC, OUTGTEXT, and FLOODFILLRGB) is set with SETCOLORRGB.

SETBKCOLORRGB (and the other RGB color selection functions SETCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

## Example

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(4) oldcolor
INTEGER(2) status, x1, y1, x2, y2
x1 = 80; y1 = 50
x2 = 240; y2 = 150
oldcolor = SETBKCOLORRGB(Z'FF0000') !blue
oldcolor = SETCOLORRGB(Z'FF') ! red
CALL CLEARSCREEN ($GCLEARSCREEN)
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END
```

## See Also

GETBKCOLORRGB

SETCOLORRGB

SETTEXTCOLORRGB

SETPIXELRGB

SETPIXELSRGB

SETBKCOLOR

## SETCLIPRGN

**Graphics Subroutine:** Limits graphics output to part of the screen. This routine is only available for Windows.

## Module

USE IFQWIN

## Syntax

```
CALL SETCLIPRGN (x1,y1,x2,y2)
```

<code>x1, y1</code>	(Input) INTEGER(2). Physical coordinates for upper-left corner of clipping region.
<code>x2, y2</code>	(Input) INTEGER(2). Physical coordinates for lower-right corner of clipping region.

The SETCLIPRGN function limits the display of subsequent graphics output and font text output to that which fits within a designated area of the screen (the "clipping region"). The physical coordinates (`x1, y1`) and (`x2, y2`) are the upper-left and lower-right corners of the rectangle that defines the clipping region. The SETCLIPRGN function does not change the viewport-coordinate system; it merely masks graphics output to the screen.

SETCLIPRGN affects graphics and font text output only, such as OUTGTEXT. To mask the screen for text output using OUTTEXT, use SETTEXTWINDOW.

### Example

This program draws an ellipse lying partly within a clipping region, as shown below.

```
! Build as QuickWin or Standard Graphics ap.
USE IFQWIN
INTEGER(2) status, x1, y1, x2, y2
INTEGER(4) oldcolor
x1 = 10; y1 = 50
x2 = 170; y2 = 150
! Draw full ellipse in white
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
oldcolor = SETCOLORRGB(Z'FF0000') !blue
WRITE(*,*) "Hit enter"
READ(*,*)
CALL CLEARSCREEN($GCLEARSCREEN) ! clear screen
CALL SETCLIPRGN( INT2(0), INT2(0), &
                INT2(150), INT2(125))
! only part of ellipse inside clip region drawn now
status = ELLIPSE($GBORDER, x1, y1, x2, y2)
END
```

The following shows the output of this program.

## SETVIEWPORT SETWINDOW

## SETCOLOR

**Graphics Function:** Sets the current graphics color index. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = SETCOLOR (color)
```

*color* (Input) INTEGER(2). Color index to set the current graphics color to.

### Results

The result type is INTEGER(2). The result is the previous color index if successful; otherwise, -1.

The SETCOLOR function sets the current graphics color index, which is used by graphics functions such as ELLIPSE. The background color index is set with SETBKCOLOR. The color index of text over the background color is set with SETTEXTCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. For access to all system colors, use SETCOLORRGB, SETBKCOLORRGB, and SETTEXTCOLORRGB.

### Example

```
USE IFQWIN
INTEGER(2) color, oldcolor
LOGICAL status
TYPE (windowconfig) wc

status = GETWINDOWCONFIG(wc)
color = wc%numcolors - 1
oldcolor = SETCOLOR(color)
END
```

## SETCOLORRGB

**Graphics Function:** Sets the current graphics color to the specified Red-Green-Blue (RGB) value. This routine is only available for Windows.

---

### Module

USE IFQWIN

## Syntax

```
result = SETCOLORRGB (color)
```

*color*

(Input) INTEGER(4). RGB color value to set the current graphics color to. Range and result depend on the system's display adapter.

## Results

The result type is INTEGER(4). The result is the previous RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

SETCOLORRGB sets the RGB color value of graphics over the background color, used by the following graphics functions: ARC, ELLIPSE, FLOODFILL, LINETO, OUTGTEXT, PIE, POLYGON, RECTANGLE, and SETPIXEL. SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. SETTEXTCOLORRGB sets the RGB color value of text over the background color (used by text functions such as OUTTEXT, WRITE, and PRINT).

SETCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB, and SETTEXTCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETCOLOR, SETBKCOLOR, and SETTEXTCOLOR) use color indexes rather than true color values. If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

## Example

```
! Build as a QuickWin or Standard Graphics App.
USE IFQWIN
INTEGER(2) numfonts
INTEGER(4) oldcolor
TYPE (xycoord) xy
numfonts = INITIALIZEFONTS( )
oldcolor = SETCOLORRGB(Z'0000FF') ! red
oldcolor = SETBKCOLORRGB(Z'00FF00') ! green
CALL MOVETO(INT2(200), INT2(100), xy)
CALL OUTGTEXT("hello, world")
END
```

## SETFILLMASK

**Graphics Subroutine:** Sets the current fill mask to a new pattern. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

CALL SETFILLMASK (*mask*)

*mask* (Input) INTEGER(1). One-dimensional array of length 8.

There are 8 bytes in *mask*, and each of the 8 bits in each byte represents a pixel, creating an 8x8 pattern. The first element (byte) of *mask* becomes the top 8 bits of the pattern, and the eighth element (byte) of *mask* becomes the bottom 8 bits.

During a fill operation, pixels with a bit value of 1 are set to the current graphics color, while pixels with a bit value of zero are set to the current background color. The current graphics color is set with SETCOLORRGB or SETCOLOR. The 8-byte mask is replicated over the entire fill area. If no fill mask is set (with SETFILLMASK), or if the mask is all ones, solid current color is used in fill operations.

The fill mask controls the fill pattern for graphics routines (FLOODFILLRGB, PIE, ELLIPSE, POLYGON, and RECTANGLE).

To change the current fill mask, determine the array of bytes that corresponds to the desired bit pattern and set the pattern with SETFILLMASK, as in the following example.

Bit pattern								Value In mask
●	○	○	●	○	○	●	●	mask(1) = Z'93'
●	●	○	○	●	○	○	●	mask(2) = Z'C9'
○	●	●	○	○	●	○	○	mask(3) = Z'64'
●	○	●	●	○	○	●	○	mask(4) = Z'B2'
○	●	○	●	●	○	○	●	mask(5) = Z'59'
○	○	●	○	●	●	○	○	mask(6) = Z'2C'
●	○	○	●	○	●	●	○	mask(7) = Z'96'
○	●	○	○	●	○	●	●	mask(8) = Z'4B'
bit	7	6	5	4	3	2	1	0

## Example

This program draws six rectangles, each with a different fill mask, as shown below.

```
! Build as QuickWin or Standard Graphics Ap.
USE IFQWIN

INTEGER(1), TARGET :: style1(8) &
  /Z'18',Z'18',Z'18',Z'18',Z'18',Z'18',Z'18',Z'18'/
INTEGER(1), TARGET :: style2(8) &
  /Z'08',Z'08',Z'08',Z'08',Z'08',Z'08',Z'08',Z'08'/
INTEGER(1), TARGET :: style3(8) &
  /Z'18',Z'00',Z'18',Z'18',Z'18',Z'00',Z'18',Z'18'/
INTEGER(1), TARGET :: style4(8) &
  /Z'00',Z'08',Z'00',Z'08',Z'08',Z'08',Z'08',Z'08'/
INTEGER(1), TARGET :: style5(8) &
  /Z'18',Z'18',Z'00',Z'18',Z'18',Z'00',Z'18',Z'18'/
INTEGER(1), TARGET :: style6(8) &
  /Z'08',Z'00',Z'08',Z'00',Z'08',Z'00',Z'08',Z'00'/
INTEGER(1) oldstyle(8) ! Placeholder for old style
INTEGER loop
INTEGER(1), POINTER :: ptr(:)

CALL GETFILLMASK( oldstyle )
! Make 6 rectangles, each with a different fill
DO loop = 1, 6
  SELECT CASE (loop)
    CASE (1)
      ptr => style1
    CASE (2)
      ptr => style2
    CASE (3)
      ptr => style3
    CASE (4)
      ptr => style4
    CASE (5)
      ptr => style5
    CASE (6)
      ptr => style6
  END SELECT
  CALL SETFILLMASK( ptr)
  status = RECTANGLE($GFILLINTERIOR,INT2(loop*40+5), &
    INT2(90),INT2((loop+1)*40), INT2(110))
END DO

CALL SETFILLMASK( oldstyle ) ! Restore old style
READ (*,*)                  ! Wait for ENTER to be
                             ! pressed
END
```

The following shows the output of this program.

## SETFONT

**Graphics Function:** Finds a single font that matches a specified set of characteristics and makes it the current font used by the OUTGTEXT function. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = SETFONT (options)
```

*options* (Input) Character\*(\*). String describing font characteristics (see below for details).

### Results

The result type is INTEGER(2). The result is the index number (*x* as used in the *nx* option) of the font if successful; otherwise, -1.

The SETFONT function searches the list of available fonts for a font matching the characteristics specified in *options*. If a font matching the characteristics is found, it becomes the current font. The current font is used in all subsequent calls to the OUTGTEXT function. There can be only one current font.

The *options* argument consists of letter codes, as follows, that describe the desired font. The argument is neither case sensitive nor position sensitive.

---

<i>t</i> ' <i>fontname</i> '	Name of the desired typeface. It can be any installed font.
<i>hy</i>	Character height, where <i>y</i> is the number of pixels.
<i>wX</i>	Select character width, where <i>x</i> is the number of pixels.
<i>f</i>	Select only a fixed-space font (do not use with the <i>p</i> characteristic).
<i>p</i>	Select only a proportional-space font (do not use with the <i>f</i> characteristic).
<i>v</i>	Select only a vector-mapped font (do not use with the <i>r</i> characteristic). Roman, Modern, and Script are examples of vector-mapped fonts, also called plotter fonts. True Type fonts (for example, Arial, Symbol, and Times New Roman) are not vector-mapped.

<code>r</code>	Select only a raster-mapped (bitmapped) font (do not use with the <code>v</code> characteristic). Courier, Helvetica, and Palatino are examples of raster-mapped fonts, also called screen fonts. True Type fonts are not raster-mapped.
<code>e</code>	Select the bold text format. This parameter is ignored if the font does not allow the bold format.
<code>u</code>	Select the underline text format. This parameter is ignored if the font does not allow underlining.
<code>i</code>	Select the italic text format. This parameter is ignored if the font does not allow italics.
<code>b</code>	Select the font that best fits the other parameters specified.
<code>nx</code>	Select font number <i>x</i> , where <i>x</i> is less than or equal to the value returned by the INITIALIZEFONTS function.

---

You can specify as many options as you want, except with `nx`, which should be used alone. If you specify options that are mutually exclusive (such as the pairs `f/p` or `r/v`), the SETFONT function ignores them. There is no error detection for incompatible parameters used with `nx`.

If the `b` option is specified and at least one font is initialized, SETFONT sets a font and returns 0 to indicate success.

In selecting a font, the SETFONT routine uses the following criteria, rated from highest precedence to lowest:

1. Pixel height
2. Typeface
3. Pixel width
4. Fixed or proportional font

You can also specify a pixel width and height for fonts. If you choose a nonexistent value for either and specify the `b` option, SETFONT chooses the closest match.

A smaller font size has precedence over a larger size. If you request Arial 12 with best fit, and only Arial 10 and Arial 14 are available, SETFONT selects Arial 10.

If you choose a nonexistent value for pixel height and width, the SETFONT function applies a magnification factor to a vector-mapped font to obtain a suitable font size. This automatic magnification does not apply if you specify the `r` option (raster-mapped font), or if you request a specific typeface and do not specify the `b` option (best-fit).

If you specify the `nx` parameter, SETFONT ignores any other specified options and supplies only the font number corresponding to *x*.

If a height is given, but not a width, SETFONT computes the width to preserve the correct font proportions.

If a width is given, but not a height, SETFONT uses a default height, which may vary from font type to font type. This may lead to characters that appear distorted, particularly when a very wide width is specified. This behavior is the same as that of the Windows\* API CreateFontIndirect. A [sample program](#) is provided below showing you how to calculate the correct height for a given width.

The font functions affect only OUTGTEXT and the current graphics position; no other Fortran Graphics Library output functions are affected by font usage.

For each window you open, you must call `INITIALIZEFONTS` before calling `SETFONT`. `INITIALIZEFONTS` needs to be executed after each new child window is opened in order for a subsequent `SETFONT` call to be successful.

### Example

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
! Set typeface to Arial, character height to 18,
! character width to 10, and italic
fontnum = SETFONT ('t'Arial'h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Demo text')
END
```

Another example follows:

```
! The following program shows you how to compute
! an appropriate font height for a given font width
!
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
TYPE (xycoord) pos
TYPE (rccoord) rcc
TYPE (FONTINFO) info
CHARACTER*11 str, str1
CHARACTER*22 str2
real rh
integer h, inw
str = "t'Arial'bih"
str1= " "
numfonts = INITIALIZEFONTS ( )
! Default both height and width. This seems to work
! properly. From this setting get the ratio between
! height and width.
fontnum = SETFONT ("t'Arial'")
ireturn = GETFONTINFO(info)
rh = real(info%pixheight)/real(info%avgwidth)

! Now calculate the height for a width of 40
write(*,*) 'Input desired width:'
read(*,*) inw
h =int(inw*rh)
write(str1,'(I3.3)') h
str2 = str//str1
print *,str2
fontnum = SETFONT (str2)
CALL MOVETO (INT2(10), INT2(50), pos)
CALL OUTGTEXT('ABCDEFGHabcdefgh12345!@#$$%')
CALL MOVETO (INT2(10), INT2(50+10+h), pos)
CALL OUTGTEXT('123456789012345678901234')
ireturn = GETFONTINFO(info)
```

```
call settextposition(4,1, rcc)
print *, info%avgwidth, info%pixheight
END
```

## See Also

SETGTEXTROTATION

## SETGTEXTROTATION

**Graphics Subroutine:** Sets the orientation angle of the font text output in degrees. The current orientation is used in calls to OUTGTEXT. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

CALL SETGTEXTROTATION (degree-tenths)

*degree-tenths* (Input) INTEGER(4). Angle of orientation, in tenths of degrees, of the font text output.

The orientation of the font text output is set in tenths of degrees. Horizontal is 0°, and angles increase counterclockwise so that 900 (90°) is straight up, 1800 (180°) is upside down and left, 2700 (270°) is straight down, and so forth. If the user specifies a value greater than 3600 (360°), the subroutine takes a value equal to:

```
MODULO (user-specified tenths of degrees, 3600)
```

Although SETGTEXTROTATION accepts arguments in tenths of degrees, only increments of one full degree differ visually from each other on the screen.

Bitmap fonts cannot be rotated; TruType fonts should be used instead.

## Example

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) fontnum, numfonts
INTEGER(4) oldcolor, deg
TYPE (xycoord) pos
numfonts = INITIALIZEFONTS ( )
fontnum = SETFONT ('t'Arial'h18w10i')
CALL MOVETO (INT2(10), INT2(30), pos)
CALL OUTGTEXT('Straight text')
deg = -1370
CALL SETGTEXTROTATION(deg)
oldcolor = SETCOLORRGB(Z'008080')
CALL OUTGTEXT('Slanted text')
END
```

GETGTEXTROTATION

**SETLINESTYLE**

**Graphics Subroutine:** Sets the current line style to a new line style. This routine is only available for Windows.

**Module**

USE IFQWIN

**Syntax**CALL SETLINESTYLE (*mask*)

*mask* (Input) INTEGER(2). Desired Quickwin line-style mask. (See the table below.)

The mask is mapped to the style that most closely equivalences the percentage of the bits in the mask that are set. The style produces lines that cover a certain percentage of the pixels in that line.

SETLINESTYLE sets the style used in drawing a line. You can choose from the following styles:

QuickWin Mask	Internal Windows* Style	Selection Criteria	Appearance
0xFFFF	PS_SOLID	16 bits on	_____
0xEEEE	PS_DASH	11 to 15 bits on	-----
0xECEC	PS_DASHDOT	10 bits on	-.-.-.-.-.
0xECCC	PS_DASHDOTDOT	9 bits on	-.-.-.-.-.
0xAAAA	PS_DOT	1 to 8 bits on	.....
0x0000	PS_NULL	0 bits on	

SETLINESTYLE affects the drawing of straight lines as in LINETO, POLYGON, and RECTANGLE, but not the drawing of curved lines as in ARC, ELLIPSE, or PIE.

The current graphics color is set with SETCOLORRGB or SETCOLOR. SETWRITEMODE affects how the line is displayed.

**Example**

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2)    status, style
TYPE (xycoord) xy

style = Z'FFFF'
CALL SETLINESTYLE(style)
CALL MOVE TO (INT2(50), INT2(50), xy )
status = LINETO(INT2(300), INT2(300))
END
```

**See Also**

POLYGON  
RECTANGLE  
SETCOLOR  
SETWRITEMODE

## SETLINEWIDTHQQ

**Graphics Subroutine:** Sets the width of a solid line drawn using any of the supported graphics functions. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
CALL SETLINEWIDTHQQ (x)
```

x (Input) INTEGER(4). It can be any non-negative integer.

This subroutine sets the line width in pixels using the value that is passed as the argument.

SETLINEWIDTHQQ affects the drawing of straight lines using functions such as LINETO, POLYGON, LINETOAR, LINETOAREX, RECTANGLE, and it affects the drawing of curved lines using functions such as ARC, ELLIPSE, or PIE.

---

#### NOTE

The nWidth argument in the Windows\* API CreatePen() is the width used to draw the lines or borders of a closed shape. A cosmetic pen can only have a width of 1 pixel. If you specify a higher width, it is ignored. A geometric pen can have a width of 1 or more pixels, but the line can only be solid or null.

This means that if you specify the style as PS\_DASH, PS\_DOT, PS\_DASHDOT, or PS\_DASHDOTDOT, but set a width higher than 1 pixel, the line is drawn as PS\_SOLID.

---

### See Also

GETLINEWIDTHQQ (W\*S)

Windows\* API CreatePen in the Microsoft\* MSDN documentation

## SETPIXEL, SETPIXEL\_W

**Graphics Functions:** Set a pixel at a specified location to the current graphics color index. These routines are only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = SETPIXEL (x,y)
```

```
result = SETPIXEL_W (wx, wy)
```

x, y (Input) INTEGER(2). Viewport coordinates for target pixel.

`wx, wy`

(Input) REAL(8). Window coordinates for target pixel.

## Results

The result type is INTEGER(2). The result is the previous color index of the target pixel if successful; otherwise, -1 (for example, if the pixel lies outside the clipping region).

SETPIXEL sets the specified pixel to the current graphics color index. The current graphics color index is set with SETCOLOR and retrieved with GETCOLOR. The non-RGB color functions (such as SETCOLOR and SETPIXELS) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit Red-Green-Blue (RGB) value with an RGB color function, rather than a palette index with a non-RGB color function. SETPIXELRGB and SETPIXELRGB\_W give access to the full color capacity of the system by using direct color values rather than indexes to a palette.

### NOTE

The SETPIXEL routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the SetPixel routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$SetPixel.

## Example

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) status, x, y
status = SETCOLOR(INT2(2))
x = 10
! Draw pixels.
DO y = 50, 389, 3
  status = SETPIXEL( x, y )
  x = x + 2
END DO
READ (*,*) ! Wait for ENTER to be pressed
END
```

## See Also

[SETPIXELRGB](#)[GETPIXEL](#)[SETPIXELS](#)[GETPIXELS](#)[GETCOLOR](#)[SETCOLOR](#)

## SETPIXELRGB, SETPIXELRGB\_W

**Graphics Functions:** Set a pixel at a specified location to the specified Red-Green-Blue (RGB) color value. These routines are only available for Windows.

## Module

[USE IFQWIN](#)

## Syntax

```
result = SETPIXELRGB (x,y,color)
```

```
result = SETPIXELRGB_W (x,y,color)
```

*x, y* (Input) INTEGER(2). Viewport coordinates for target pixel.

*wx, wy* (Input) REAL(8). Window coordinates for target pixel.

*color* (Input) INTEGER(4). RGB color value to set the pixel to. Range and result depend on the system's display adapter.

## Results

The result type is INTEGER(4). The result is the previous RGB color value of the pixel.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETPIXELRGB or SETPIXELRGB\_W, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

If any of the pixels are outside the clipping region, those pixels are ignored.

SETPIXELRGB (and the other RGB color selection functions such as SETPIXELSRGB, SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

## Example

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) x, y
INTEGER(4) color
DO i = 10, 30, 10
  SELECT CASE (i)
    CASE(10)
      color = Z'0000FF'
    CASE(20)
      color = Z'00FF00'
    CASE (30)
      color = Z'FF0000'
  END SELECT
! Draw pixels.
DO y = 50, 180, 2
  status = SETPIXELRGB( x, y, color )
  x      = x + 2
END DO
```

```

END DO
READ (*,*) ! Wait for ENTER to be pressed
END

```

## SETPIXELS

**Graphics Subroutine:** *Sets the color indexes of multiple pixels. This routine is only available for Windows.*

### Module

USE IFQWIN

### Syntax

```
CALL SETPIXELS (n, x, y, color)
```

<i>n</i>	(Input) INTEGER(4). Number of pixels to set. Sets the number of elements in the other arguments.
<i>x, y</i>	(Input) INTEGER(2). Parallel arrays containing viewport coordinates of pixels to set.
<i>color</i>	(Input) INTEGER(2). Array containing color indexes to set the pixels to.

SETPIXELS sets the pixels specified in the arrays *x* and *y* to the color indexes in *color*. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELS with *n* less than 1 are also ignored. SETPIXELS is a much faster way to set multiple pixel color indexes than individual calls to SETPIXEL.

Unlike SETPIXELS, SETPIXELSRGB gives access to the full color capacity of the system by using direct color values rather than indexes to a palette. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

### Example

```

! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) color(9)
INTEGER(2) x(9), y(9), i
DO i = 1, 9
  x(i) = 20 * i
  y(i) = 10 * i
  color(i) = INT2(i)

```

```

END DO
CALL SETPIXELS(9, x, y, color)
END

```

## See Also

GETPIXELS

SETPIXEL

SETPIXELSRGB

## SETPIXELSRGB

**Graphics Subroutine:** Sets multiple pixels to the given Red-Green-Blue (RGB) color. This routine is only available for Windows.

### Module

USE IFQWIN

### Syntax

```
CALL SETPIXELSRGB (n,x,y,color)
```

<i>n</i>	(Input) INTEGER(4). Number of pixels to be changed. Determines the number of elements in arrays <i>x</i> and <i>y</i> .
<i>x</i> , <i>y</i>	(Input) INTEGER(2). Parallel arrays containing viewport coordinates of the pixels to set.
<i>color</i>	(Input) INTEGER(4). Array containing the RGB color values to set the pixels to. Range and result depend on the system's display adapter.

SETPIXELSRGB sets the pixels specified in the arrays *x* and *y* to the RGB color values in *color*. These arrays are parallel: the first element in each of the three arrays refers to a single pixel, the second element refers to the next pixel, and so on.

In each RGB color value, each of the three color values, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you set with SETPIXELSRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

A good use for SETPIXELSRGB is as a buffering form of SETPIXELRGB, which can improve performance substantially. The example code shows how to do this.

If any of the pixels are outside the clipping region, those pixels are ignored. Calls to SETPIXELSRGB with *n* less than 1 are also ignored.

SETPIXELSRGB (and the other RGB color selection functions such as SETPIXELRGB and SETCOLORRGB) sets colors to values chosen from the entire available range. The non-RGB color functions (such as SETPIXELS and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

## Example

```
! Buffering replacement for SetPixelRGB and
! SetPixelRGB_W. This can improve performance by
! doing batches of pixels together.

USE IFQWIN
PARAMETER (I$SIZE = 200)
INTEGER(4) bn, bc(I$SIZE), status
INTEGER(2) bx(I$SIZE), by(I$SIZE)

bn = 0
DO i = 1, I$SIZE
  bn = bn + 1
  bx(bn) = i
  by(bn) = i
  bc(bn) = GETCOLORRGB()
  status = SETCOLORRGB(bc(bn)+1)
END DO
CALL SETPIXELSRGB(bn,bx,by,bc)
END
```

## See Also

SETPIXELS

## SETTEXTCOLOR

**Graphics Function:** *Sets the current text color index.*  
*This routine is only available for Windows.*

## Module

USE IFQWIN

## Syntax

```
result = SETTEXTCOLOR (index)
```

*index* (Input) INTEGER(2). Color index to set the text color to.

## Results

The result type is INTEGER(2). The result is the previous text color index.

SETTEXTCOLOR sets the current text color index. The default value is 15, which is associated with white unless the user remaps the palette. GETTEXTCOLOR returns the text color index set by SETTEXTCOLOR. SETTEXTCOLOR affects text output with OUTTEXT, WRITE, and PRINT.

The background color index is set with SETBKCOLOR and returned with GETBKCOLOR. The color index of graphics over the background color is set with SETCOLOR and returned with GETCOLOR. These non-RGB color functions use color indexes, not true color values, and limit the user to colors in the palette, at most 256. To access all system colors, use SETTEXTCOLORRGB, SETBKCOLORRGB, and SETCOLORRGB.

**NOTE**

The SETTEXTCOLOR routine described here is a QuickWin routine. If you are trying to use the Microsoft\* Platform SDK version of the SetTextColor routine by including the IFWIN module, you need to specify the routine name as MSFWIN\$SetTextColor.

**Example**

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) oldtc
oldtc = SETTEXTCOLOR(INT2(2)) ! green
WRITE(*,*) "hello, world"
END
```

**See Also**

GETTEXTCOLOR

REMAPPALETTEGB

SETCOLOR

SETTEXTCOLORRGB

**SETTEXTCOLORRGB**

**Graphics Function:** Sets the current text color to the specified Red-Green-Blue (RGB) value. This routine is only available for Windows.

**Module**

USE IFQWIN

**Syntax**

```
result = SETTEXTCOLORRGB (color)
```

*color* (Input) INTEGER(4). RGB color value to set the text color to. Range and result depend on the system's display adapter.

**Results**

The result type is INTEGER(4). The result is the previous text RGB color value.

In each RGB color value, each of the three colors, red, green, and blue, is represented by an eight-bit value (2 hex digits). In the value you specify with SETTEXTCOLORRGB, red is the rightmost byte, followed by green and blue. The RGB value's internal structure is as follows:

Larger numbers correspond to stronger color intensity with binary 1111111 (hex Z'FF') the maximum for each of the three components. For example, Z'0000FF' yields full-intensity red, Z'00FF00' full-intensity green, Z'FF0000' full-intensity blue, and Z'FFFFFF' full-intensity for all three, resulting in bright white.

SETTEXTCOLORRGB sets the current text RGB color. The default value is Z'00FFFFFF', which is full-intensity white. SETTEXTCOLORRGB sets the color used by OUTTEXT, WRITE, and PRINT. It does not affect the color of text output with the OUTGTEXT font routine. Use SETCOLORRGB to change the color of font output.

SETBKCOLORRGB sets the RGB color value of the current background for both text and graphics. SETCOLORRGB sets the RGB color value of graphics over the background color, used by the graphics functions such as ARC, FLOODFILLRGB, and OUTGTEXT.

SETTEXTCOLORRGB (and the other RGB color selection functions SETBKCOLORRGB and SETCOLORRGB) sets the color to a value chosen from the entire available range. The non-RGB color functions (SETTEXTCOLOR, SETBKCOLOR, and SETCOLOR) use color indexes rather than true color values.

If you use color indexes, you are restricted to the colors available in the palette, at most 256. Some display adapters (SVGA and true color) are capable of creating 262,144 (256K) colors or more. To access any available color, you need to specify an explicit RGB value with an RGB color function, rather than a palette index with a non-RGB color function.

## Example

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(4) oldtc

oldtc = SETTEXTCOLORRGB(Z'000000FF')
WRITE(*,*) 'I am red'
oldtc = SETTEXTCOLORRGB(Z'0000FF00')
CALL OUTTEXT ('I am green'//CHAR(13)//CHAR(10))
oldtc = SETTEXTCOLORRGB(Z'00FF0000')
PRINT *, 'I am blue'
END
```

## See Also

## SETTEXTCURSOR

**Graphics Function:** Sets the height and width of the text cursor (the caret) for the window in focus. This routine is only available for Windows.

## Module

USE IFQWIN

## Syntax

```
result = SETTEXTCURSOR (newcursor)
```

*newcursor*

(Input) INTEGER(2). The leftmost 8 bits specify the width of the cursor, and the rightmost 8 bits specify the height of the cursor. These dimensions can range from 1 to 8, and represent a fraction of the current character cell size. For example:

- Z'0808' - Specifies the full character cell; this is the default size.
- Z'0108' - Specifies 1/8th of the character cell width, and 8/8th (or all) of the character cell height.

If either of these dimensions is outside the range 1 to 8, it is forced to 8.

## Results

The result type is INTEGER(2); it is the previous text cursor value in the same format as *newcursor*.

---

### NOTE

After calling SETTEXTCURSOR, you must call DISPLAYCURSOR(\$GCURSORON) to actually see the cursor.

---

## Example

```
use IFQWIN
integer(2) oldcur
integer(2) istat
type(rccoord) rc
open(10,file='user')
istat = displaycursor($GCURSORON)
write(10,*) 'Text cursor is now character cell size, the default.'
read(10,*)
write(10,*) 'Setting text cursor to wide and low.'
oldcur = settextcursor(Z'0801')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to high and narrow.'
oldcur = settextcursor(Z'0108')
istat = displaycursor($GCURSORON)
read(10,*)
write(10,*) 'Setting text cursor to a dot.'
oldcur = settextcursor(Z'0101')
istat = displaycursor($GCURSORON)
read(10,*)
end
```

## See Also

DISPLAYCURSOR

## SETTEXTPOSITION

**Graphics Subroutine:** Sets the current text position to a specified position relative to the current text window. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

CALL SETTEXTPOSITION (*row*, *column*, *t*)

*row* (Input) INTEGER(2). New text row position.

*column* (Input) INTEGER(2). New text column position.

*t* (Output) Derived type `rccoord`. Previous text position. The derived type `rccoord` is defined in `IFQWIN.F90` as follows:

```
TYPE rccoord
  INTEGER(2) row ! Row coordinate
  INTEGER(2) col ! Column coordinate
END TYPE rccoord
```

Subsequent text output with the `OUTTEXT` function (as well as standard console I/O statements, such as `PRINT` and `WRITE`) begins at the point (*row*, *column*).

### Example

```
USE IFQWIN
TYPE (rccoord) curpos

WRITE(*,*) "Original text position"
CALL SETTEXTPOSITION (INT2(6), INT2(5), curpos)
WRITE (*,*) 'New text position'
END
```

## SETTEXTWINDOW

**Graphics Subroutine:** *Sets the current text window.*  
*This routine is only available for Windows.*

### Module

`USE IFQWIN`

### Syntax

```
CALL SETTEXTWINDOW (r1, c1, r2, c2)
```

*r1*, *c1* (Input) `INTEGER(2)`. Row and column coordinates for upper-left corner of the text window.

*r2*, *c2* (Input) `INTEGER(2)`. Row and column coordinates for lower-right corner of the text window.

`SETTEXTWINDOW` specifies a window in row and column coordinates where text output to the screen using `OUTTEXT`, `WRITE`, or `PRINT` will be displayed. You set the text location within this window with `SETTEXTPOSITION`.

Text is output from the top of the window down. When the window is full, successive lines overwrite the last line.

`SETTEXTWINDOW` does not affect the output of the graphics text routine `OUTGTEXT`. Use the `SETVIEWPORT` function to control the display area for graphics output.

## Example

```
USE IFQWIN
TYPE (rccoord) curpos

CALL SETTEXTWINDOW(INT2(5), INT2(1), INT2(7), &
                   INT2(40))
CALL SETTEXTPOSITION (INT2(5), INT2(5), curpos)
WRITE(*,*) "Only two lines in this text window"
WRITE(*,*) "so this line will be overwritten"
WRITE(*,*) "by this line"
END
```

## SETVIEWORG

**Graphics Subroutine:** Moves the viewport-coordinate origin (0, 0) to the specified physical point. *This routine is only available for Windows.*

---

## Module

USE IFQWIN

## Syntax

```
CALL SETVIEWORG (x,y,s)
```

x, y

(Input) INTEGER(2). Physical coordinates of new viewport origin.

s

(Output) Derived type `xycoord`. Physical coordinates of the previous viewport origin. The derived type `xycoord` is defined in `IFQWIN.F90` as follows:

```
TYPE xycoord
  INTEGER(2) xcoord ! x-coordinate
  INTEGER(2) ycoord ! y-coordinate
END TYPE xycoord
```

The `xycoord` type variable `s`, defined in `IFQWIN.F90`, returns the physical coordinates of the previous viewport origin.

## Example

```
USE IFQWIN
TYPE ( xycoord ) xy

CALL SETVIEWORG(INT2(30), INT2(30), xy)
```

**See Also**

GETPHYSCOORD  
GETVIEWCOORD  
GETWINDOWCOORD  
GRSTATUS  
SETCLIPRGN  
SETVIEWPORT

**SETVIEWPORT**

**Graphics Subroutine:** *Redefines the graphics viewport by defining a clipping region in the same manner as SETCLIPRGN and then setting the viewport-coordinate origin to the upper-left corner of the region. This routine is only available for Windows.*

**Module**

USE IFQWIN

**Syntax**

```
CALL SETVIEWPORT (x1,y1,x2,y2)
```

*x1, y1* (Input) INTEGER(2). Physical coordinates for upper-left corner of viewport.

*x2, y2* (Input) INTEGER(2). Physical coordinates for lower-right corner of viewport.

The physical coordinates (*x1, y1*) and (*x2, y2*) are the upper-left and lower-right corners of the rectangular clipping region. Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

**Example**

```
USE IFQWIN
INTEGER(2) upx, upy
INTEGER(2) downx, downy

upx = 0
upy = 30
downx= 250
downy = 100
CALL SETVIEWPORT(upx, upy, downx, downy)
```

GETPHYSCOORD  
GRSTATUS  
SETCLIPRGN  
SETVIEWORG  
SETWINDOW

## SETWINDOW

**Graphics Function:** Defines a window bound by the specified coordinates. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = SETWINDOW (finvert, wx1, wy1, wx2, wy2)
```

<i>finvert</i>	(Input) LOGICAL(2). Direction of increase of the y-axis. If <i>finvert</i> is .TRUE., the y-axis increases from the window bottom to the window top (as Cartesian coordinates). If <i>finvert</i> is .FALSE., the y-axis increases from the window top to the window bottom (as pixel coordinates).
<i>wx1, wy1</i>	(Input) REAL(8). Window coordinates for upper-left corner of window.
<i>wx2, wy2</i>	(Input) REAL(8). Window coordinates for lower-right corner of window.

### Results

The result type is INTEGER(2). The result is nonzero if successful; otherwise, 0 (for example, if the program that calls SETWINDOW is not in a graphics mode).

The SETWINDOW function determines the coordinate system used by all window-relative graphics routines. Any graphics routines that end in \_W (such as ARC\_W, RECTANGLE\_W, and LINETO\_W) use the coordinate system set by SETWINDOW.

Any window transformation done with the SETWINDOW function is relative to the viewport, not the entire screen.

An arc drawn using inverted window coordinates is not an upside-down version of an arc drawn with the same parameters in a noninverted window. The arc is still drawn counterclockwise, but the points that define where the arc begins and ends are inverted.

If *wx1* equals *wx2* or *wy1* equals *wy2*, SETWINDOW fails.

### Example

```
USE IFQWIN
INTEGER(2) status
LOGICAL(2) invert /.TRUE./
REAL(8) upx /0.0/, upy /0.0/
REAL(8) downx /1000.0/, downy /1000.0/
status = SETWINDOW(invert, upx, upy, downx, downy)
```

## SETWRITEMODE

**Graphics Function:** Sets the current logical write mode, which is used when drawing lines with the LINETO, POLYGON, and RECTANGLE functions. This routine is only available for Windows.

---

### Module

USE IFQWIN

### Syntax

```
result = SETWRITEMODE (wmode)
```

wmode

(Input) INTEGER(2). Write mode to be set. One of the following symbolic constants (defined in IFQWIN.F90):

- \$GPSET - Causes lines to be drawn in the current graphics color. (Default)
- \$GAND - Causes lines to be drawn in the color that is the logical AND of the current graphics color and the current background color.
- \$GOR - Causes lines to be drawn in the color that is the logical OR of the current graphics color and the current background color.
- \$GPRESET - Causes lines to be drawn in the color that is the logical NOT of the current graphics color.
- \$GXOR - Causes lines to be drawn in the color that is the logical exclusive OR (XOR) of the current graphics color and the current background color.

In addition, one of the following binary raster operation constants can be used (described in the online documentation for the Windows\* API SetROP2):

- \$GR2\_BLACK
- \$GR2\_NOTMERGEPEN
- \$GR2\_MASKNOTPEN
- \$GR2\_NOTCOPYPEN (same as \$GPRESET)
- \$GR2\_MASKPENNOT
- \$GR2\_NOT
- \$GR2\_XORPEN (same as \$GXOR)
- \$GR2\_NOTMASKPEN
- \$GR2\_MASKPEN (same as \$GAND)
- \$GR2\_NOTXORPEN
- \$GR2\_NOP
- \$GR2\_MERGENOTPEN
- \$GR2\_COPYPEN (same as \$GPSET)
- \$GR2\_MERGEENNOT
- \$GR2\_MERGEEN (same as \$GOR)
- \$GR2\_WHITE

## Results

The result type is INTEGER(2). The result is the previous write mode if successful; otherwise, -1.

The current graphics color is set with SETCOLORRGB (or SETCOLOR) and the current background color is set with SETBKCOLORRGB (or SETBKCOLOR). As an example, suppose you set the background color to yellow (Z'00FFFF') and the graphics color to purple (Z'FF00FF') with the following commands:

```
oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
```

If you then set the write mode with the \$GAND option, lines are drawn in red (Z'0000FF'); with the \$GOR option, lines are drawn in white (Z'FFFFFF'); with the \$GXOR option, lines are drawn in turquoise (Z'FFFF00'); and with the \$GPRESET option, lines are drawn in green (Z'00FF00'). Setting the write mode to \$GPSET causes lines to be drawn in the graphics color.

## Example

```
! Build as a Graphics ap.
USE IFQWIN
INTEGER(2) result, oldmode
INTEGER(4) oldcolor
TYPE (xycoord) xy

oldcolor = SETBKCOLORRGB(Z'00FFFF')
CALL CLEARSCREEN ($GCLEARSCREEN)
oldcolor = SETCOLORRGB(Z'FF00FF')
CALL MOVETO(INT2(0), INT2(0), xy)
result = LINETO(INT2(200), INT2(200)) ! purple

oldmode = SETWRITEMODE( $GAND)
CALL MOVETO(INT2(50), INT2(0), xy)
result = LINETO(INT2(250), INT2(200)) ! red
END
```

## WRAPON

**Graphics Function:** Controls whether text output is wrapped. This routine is only available for Windows.

---

## Module

USE IFQWIN

## Syntax

```
result = WRAPON (option)
```

*option*

(Input) INTEGER(2). Wrap mode. One of the following symbolic constants:

- \$GWRAPOFF - Truncates lines at right edge of window border.
- \$GWRAPON - Wraps lines at window border, scrolling if necessary.

## Results

The result type is INTEGER(2). The result is the previous value of *option*.

WRAPON controls whether text output with the OUTTEXT function wraps to a new line or is truncated when the text output reaches the edge of the defined text window.

WRAPON does not affect font routines such as OUTGTEXT.

## Example

```
USE IFQWIN
INTEGER(2) row, status2
INTEGER(4) status4
TYPE ( rccoord ) curpos
TYPE ( windowconfig ) wc
LOGICAL status

status = GETWINDOWCONFIG( wc )
wc%numtextcols = 80
wc%numxpixels = -1
wc%numypixels = -1
wc%numtextrows = -1
wc%numcolors = -1
wc%fontsize = -1
wc%title = "This is a test"C
wc%bitsperpixel = -1
status = SETWINDOWCONFIG( wc )
status4= SETBKCOLORRGB( #FF0000 )
CALL CLEARSCREEN( $GCLEARSCREEN )

! Display wrapped and unwrapped text in text windows.
CALL SETTEXTWINDOW( INT2(1),INT2(1),INT2(5),INT2(25))
CALL SETTEXTPOSITION(INT2(1),INT2(1), curpos )
status2 = WRAPON( $GWRAPON )
status4 = SETTEXTCOLORRGB( #00FF00 )
DO i = 1, 5
  CALL OUTTEXT( 'Here text does wrap. ' )
END DO
CALL SETTEXTWINDOW( INT2(7),INT2(10),INT2(11),INT2(40))
CALL SETTEXTPOSITION( INT2(1),INT2(1), curpos )
status2 = WRAPON( $GWRAPOFF )
status4 = SETTEXTCOLORRGB( #008080 )
DO row = 1, 5
  CALL SETTEXTPOSITION( INT2(row), INT2(1), curpos )
  CALL OUTTEXT( 'Here text does not wrap. ' )
  CALL OUTTEXT( 'Here text does not wrap.' )
END DO
READ (*,*) ! Wait for ENTER to be pressed
END
```

## Serial Port I/O Library Routines

---

This section contains descriptions of the Serial Port I/O library routines, which are restricted to Windows\* systems. They are listed in alphabetical order.

To access these library routines, you must specify a USE IFPORT statement in your program.

You may also need to add a USE IFWINTY statement to your program because some Windows\* constants may be required that are typically defined in the IFWINTY module.

### SPORT\_CANCEL\_IO

**Serial Port I/O Function:** *Cancels any I/O in progress to the specified port. This routine is only available for Windows.*

---

#### Module

USE IFPORT

#### Syntax

```
result = SPORT_CANCEL_IO (port)
```

*port* (Input) Integer. The port number.

#### Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

---

#### NOTE

This call also kills the thread that keeps an outstanding read operation to the serial port. This call *must* be done before any of the port characteristics are modified.

---

#### Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CANCEL_IO( 2 )
END
```

#### See Also

Communications and Communications Functions in the Microsoft\* Platform SDK

### SPORT\_CONNECT

**Serial Port I/O Function:** *Establishes the connection to a serial port and defines certain usage parameters. This routine is only available for Windows.*

---

#### Module

USE IFPORT

## Syntax

```
result = SPORT_CONNECT (port [,options])
```

*port* (Input) Integer. The port number of connection. The routine will open COM *n*, where *n* is the port number specified.

*options* (Input; optional) Integer. Defines the connection options. These options define how the *nnn\_LINE* routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

Option	Description
DL_TOSS_CR	Removes carriage return (CR) characters on input.
DL_TOSS_LF	Removes linefeed (LF) characters on input.
DL_OUT_CR	Causes SPORT_WRITE_LINE to add a CR to each record written.
DL_OUT_LF	Causes SPORT_WRITE_LINE to add a LF to each record written.
DL_TERM_CR	Causes SPORT_READ_LINE to terminate READ when a CR is encountered.
DL_TERM_LF	Causes SPORT_READ_LINE to terminate READ when a LF is encountered.
DL_TERM_CRLF	Causes SPORT_READ_LINE to terminate READ when CR+LF is encountered.

If *options* is not specified, the following occurs by default:

```
(DL_OUT_CR .OR. DL_TERM_CR .OR. DL_TOSS_CR .OR. DL_TOSS_LF)
```

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

## Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_CONNECT( 2 )
END
```

## See Also

[SPORT\\_RELEASE](#)

Communications and Communications Functions in the Microsoft\* Platform SDK

## SPORT\_CONNECT\_EX

**Serial Port I/O Function:** Establishes the connection to a serial port, defines certain usage parameters, and defines the size of the internal buffer for data reception. This routine is only available for Windows.

### Module

USE IFPORT

### Syntax

```
result = SPORT_CONNECT_EX (port [,options] [,BufferSize])
```

*port* (Input) Integer. The port number of connection. The routine will open COM *n*, where *n* is the port number specified.

*options* (Input; optional) Integer. Defines the connection options. These options define how the *nnn\_LINE* routines will work and also effect the data that is passed to the user. If more than one option is specified, the operator .OR. should be used between each option. Options are as follows:

Option	Description
DL_TOSS_CR	Removes carriage return (CR) characters on input.
DL_TOSS_LF	Removes linefeed (LF) characters on input.
DL_OUT_CR	Causes SPORT_WRITE_LINE to add a CR to each record written.
DL_OUT_LF	Causes SPORT_WRITE_LINE to add a LF to each record written.
DL_TERM_CR	Causes SPORT_READ_LINE to terminate READ when a CR is encountered.
DL_TERM_LF	Causes SPORT_READ_LINE to terminate READ when a LF is encountered.
DL_TERM_CRLF	Causes SPORT_READ_LINE to terminate READ when CR+LF is encountered.

If *options* is not specified, the following occurs by default:

```
(DL_OUT_CR .OR. DL_TERM_CR .OR. DL_TOSS_CR .OR. DL_TOSS_LF)
```

This specifies to remove carriage returns and linefeeds on input, to follow output lines with a carriage return, and to return input lines when a carriage return is encountered.

*BufferSize* (Input; optional) Integer. Size of the internal buffer for data reception. If *BufferSize* is not specified, the size of the buffer is 16384 bytes (the default).

The size of the buffer must be 4096 bytes or larger. If you try to specify a size smaller than 4096 bytes, your specification will be ignored and the buffer size will be set to 4096 bytes.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

## Example

```
USE IFPORT
INTEGER(4) irestult
irestult = SPORT_CONNECT_EX( 2, BufferSize = 8196 )
END
```

## SPORT\_GET\_HANDLE

**Serial Port I/O Function:** Returns the Windows\* handle associated with the communications port. This is the handle that was returned by the Windows API *CreateFile*. This routine is only available for Windows.

## Module

USE IFPORT

## Syntax

```
result = SPORT_GET_HANDLE (port,handle)
```

*port* (Input) Integer. The port number.

*handle* (Output) INTEGER(4) on IA-32 architecture; INTEGER(8) on Intel® 64 architecture. This is the Windows handle that was returned from *CreatFile*( ) on the serial port.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

## Example

```
USE IFPORT
INTEGER(4) irestult
INTEGER(KIND=INT_PTR_KIND( )) handle
irestult = SPORT_GET_HANDLE( 2, handle )
END
```

## SPORT\_GET\_STATE

**Serial Port I/O Function:** Returns the baud rate, parity, data bits setting, and stop bits setting of the communications port. This routine is only available for Windows.

---

### Module

USE IFPORT

### Syntax

```
result = SPORT_GET_STATE (port [,baud] [,parity] [,dbits] [,sbits])
```

<i>port</i>	(Input) Integer. The port number.
<i>baud</i>	(Output; optional) Integer. The baud rate of the port.
<i>parity</i>	(Output; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
<i>dbits</i>	(Output; optional) Integer. The data bits for the port.
<i>sbits</i>	(Output; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

### Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

### Example

```
USE IFPORT
INTEGER(4) irestult
INTEGER    baud
INTEGER    parity
INTEGER    dbits
INTEGER    sbits

irestult = SPORT_GET_STATE( 2, baud, parity, dbits, sbits )
END
```

### See Also

## SPORT\_GET\_STATE\_EX

**Serial Port I/O Function:** Returns the baud rate, parity, data bits setting, stop bits, and other settings of the communications port. This routine is only available for Windows.

---

### Module

USE IFPORT

## Syntax

```
result = SPORT_GET_STATE_EX (port[,baud] [,parity] [,dbits] [,sbits] [,Binmode]
[,DTRcntrl]
    [,RTScntrl] [,OutCTSFlow] [,OutDSRFlow] [,DSRSense] [,OutXonOff] [,InXonOff] [,XonLim]
    [,XoffLim] [,TXContOnXoff] [,ErrAbort] [,ErrCharEnbl] [,NullStrip] [,XonChar]
[,XoffChar]
    [,ErrChar] [,EofChar] [,EvtChar])
```

<i>port</i>	(Input) Integer. The port number.
<i>baud</i>	(Input; optional) Integer. The baud rate of the port.
<i>parity</i>	(Output; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
<i>dbits</i>	(Output; optional) Integer. The data bits for the port.
<i>sbits</i>	(Output; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).
<i>Binmode</i>	(Output; optional) Integer. 1 if binary mode is enabled; otherwise, 0. Currently, the value of this parameter is always 1.
<i>DTRcntrl</i>	(Output; optional) Integer. 1 if DTR (data-terminal-ready) flow control is used; otherwise, 0.
<i>RTScntrl</i>	(Output; optional) Integer. 1 if RTS (request-to-send) flow control is used; otherwise, 0.
<i>OutCTSFlow</i>	(Output; optional) Integer. 1 if the CTS (clear-to-send) signal is monitored for output flow control; otherwise, 0.
<i>OutDSRFlow</i>	(Output; optional) Integer. 1 if the DSR (data-set-ready) signal is monitored for output flow control; otherwise, 0.
<i>DSRSense</i>	(Output; optional) Integer. 1 if the communications driver is sensitive to the state of the DSR signal; otherwise, 0.
<i>OutXonOff</i>	(Output; optional) Integer. 1 if XON/XOFF flow control is used during transmission; otherwise, 0.
<i>InXonOff</i>	(Output; optional) Integer. 1 if XON/XOFF flow control is used during reception; otherwise, 0.
<i>XonLim</i>	(Output; optional) Integer. The minimum number of bytes accepted in the input buffer before the XON character is set.
<i>XoffLim</i>	(Output; optional) Integer. The maximum number of bytes accepted in the input buffer before the XOFF character is set.
<i>TXContOnXoff</i>	(Output; optional) Integer. 1 if transmission stops when the input buffer is full and the driver has transmitted the <i>XoffChar</i> character; otherwise, 0.
<i>ErrAbort</i>	(Output; optional) Integer. 1 if read and write operations are terminated when an error occurs; otherwise, 0.

<i>ErrCharEnbl</i>	(Output; optional) Integer. 1 if bytes received with parity errors are replaced with the <i>ErrChar</i> character; otherwise, 0.
<i>NullStrip</i>	(Output; optional) Integer. 1 if null bytes are discarded; otherwise, 0.
<i>XonChar</i>	(Output; optional) Character. The value of the XON character that is used for both transmission and reception.
<i>XoffChar</i>	(Output; optional) Character. The value of the XOFF character that is used for both transmission and reception.
<i>ErrChar</i>	(Output; optional) Character. The value of the character that is used to replace bytes received with parity errors.
<i>EofChar</i>	(Output; optional) Character. The value of the character that is used to signal the end of data.
<i>EvtChar</i>	Output; optional) Character. The value of the character that is used to signal an event.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

## Example

```
USE IFPORT
INTEGER(4) iresult
INTEGER(4) port, baud, parity, dbits, sbits
INTEGER(4) OutXonOff, InXonOff, OutDSRFlow
INTEGER(4) OutCTSFlow, DTRcntrl, RTScntrl
INTEGER(4) DSRSense, XonLim, XoffLim
CHARACTER(1) XonChar, XoffChar
iresult = SPORT_GET_STATE_EX(port, baud, parity, dbits, sbits, &
                             OutXonOff=OutXonOff, InXonOff=InXonOff, OutDSRFlow=OutDSRFlow, &
                             OutCTSFlow=OutCTSFlow, DTRcntrl=DTRcntrl, RTScntrl=RTScntrl, &
                             DSRSense = DSRSense, XonChar = XonChar, XoffChar = XoffChar, &
                             XonLim=XonLim, XoffLim=XoffLim)
END
```

## SPORT\_GET\_TIMEOUTS

**Serial Port I/O Function:** Returns the user selectable timeouts for the serial port. This routine is only available for Windows.

---

## Module

USE IFPORT

## Syntax

```
result = SPORT_GET_TIMEOUTS (port [,rx_int] [,tx_tot_mult] [,tx_tot_const])
```

<code>port</code>	(Input) Integer. The port number.
<code>rx_int</code>	(Output; optional) INTEGER(4). The receive interval timeout value.
<code>tx_tot_mult</code>	(Output; optional) INTEGER(4). The transmit multiplier part of the timeout value.
<code>tx_tot_const</code>	(Output; optional) INTEGER(4). The transmit constant part of the timeout value.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

## Example

```
USE IFPORT
INTEGER(4) iresult
INTEGER*4 rx_int
INTEGER*4 tx_tot_mult
INTEGER*4 tx_tot_const

iresult = SPORT_GET_TIMEOUTS( 2, rx_int, tx_tot_mult, tx_tot_const )
END
```

## See Also

## SPORT\_PEEK\_DATA

**Serial Port I/O Function:** Returns information about the availability of input data. This routine is only available for Windows.

---

## Module

USE IFPORT

## Syntax

```
result = SPORT_PEEK_DATA (port [,present] [,count])
```

<code>port</code>	(Input) Integer. The port number.
<code>present</code>	(Output; optional) Integer. 1 if data is present, 0 if no data has been read.
<code>count</code>	(Output; optional) Integer. The count of characters that will be returned by SPORT_READ_DATA.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

---

### NOTE

CR and LF characters may not be returned depending on the mode specified in the SPORT\_CONNECT( ) call.

---

## Example

```
USE IFPORT
INTEGER(4) ireresult
INTEGER    present
INTEGER    count

ireresult = SPORT_PEEK_DATA( 2, present, count )
END
```

## See Also

## SPORT\_PEEK\_LINE

**Serial Port I/O Function:** Returns information about the availability of input records. This routine is only available for Windows.

---

## Module

USE IFPORT

## Syntax

```
result = SPORT_PEEK_LINE (port [,present] [,count])
```

*port* (Input) Integer. The port number.

*present* (Output; optional) Integer. 1 if data is present, 0 if no data has been read.

*count* (Output; optional) Integer. The count of characters that will be returned by SPORT\_READ\_DATA.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT\_CONNECT( ) call.

---

### NOTE

CR and LF characters may not be returned depending on the mode specified in the SPORT\_CONNECT( ) call.

---

## Example

```
USE IFPORT
INTEGER(4) ireresult
INTEGER    present
INTEGER    count

ireresult = SPORT_PEEK_LINE( 2, present, count )
END
```

## SPORT\_PURGE

**Serial Port I/O Function:** *Executes the Windows\* API communications function PurgeComm on the specified port. This routine is only available for Windows.*

---

### Module

USE IFPORT

### Syntax

```
result = SPORT_PURGE (port,function)
```

*port* (Input) Integer. The port number.

*function* (Input) INTEGER(4). The function for PurgeComm (see the Windows\* documentation).

### Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows error value.

### Example

```
USE IFWINTY
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_PURGE( 2, (PURGE_TXABORT .or. PURGE_RXABORT) )
END
```

## See Also

Communications and Communications Functions in the Microsoft\* Platform SDK

## SPORT\_READ\_DATA

**Serial Port I/O Function:** *Reads available data from the specified port. This routine stalls until at least one character has been read. This routine is only available for Windows.*

---

### Module

USE IFPORT

### Syntax

```
result = SPORT_READ_DATA (port,buffer[,count])
```

*port* (Input) Integer. The port number.

*buffer* (Output) Character\*(\*). The data that was read.

*count* (Output; optional) Integer. The count of bytes read.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

---

### NOTE

CR and LF characters may not be returned depending on the mode specified in the SPORT\_CONNECT( ) call.

---

## Example

```
USE IFPORT
INTEGER(4)      irect
INTEGER         ount
CHARACTER*1024  rbuff

irect = SPORT_READ_DATA( 2, rbuff, ount )
END
```

## See Also

## SPORT\_READ\_LINE

**Serial Port I/O Function:** Reads a record from the specified port. This routine stalls until at least one record has been read. This routine is only available for Windows.

---

## Module

USE IFPORT

## Syntax

*result* = SPORT\_READ\_LINE (*port*,*buffer*[, *count*])

*port* (Input) Integer. The port number.

*buffer* (Output) Character\*(\*). The data that was read.

*count* (Output; optional) Integer. The count of bytes read.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

This routine will only return when a line terminator has been seen - as defined by the mode specified in the SPORT\_CONNECT( ) call.

**NOTE**

CR and LF characters may not be returned depending on the mode specified in the `SPORT_CONNECT( )` call.

**Example**

```
USE IFPORT
INTEGER(4)    iresult
INTEGER       count
CHARACTER*1024 rbuff

iresult = SPORT_READ_LINE( 2, rbuff, count )
END
```

**SPORT\_RELEASE**

**Serial Port I/O Function:** Releases a serial port that was previously connected when `SPORT_CONNECT` was specified. This routine is only available for Windows.

**Module**

USE IFPORT

**Syntax**

```
result = SPORT_RELEASE (port)
```

*port* (Input) Integer. The port number.

**Results**

The result type is `INTEGER(4)`. The result is zero if successful; otherwise, a Windows\* error value.

**Example**

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_RELEASE( 2 )
END
```

**See Also**

[SPORT\\_CONNECT](#)

Communications and Communications Functions in the Microsoft\* Platform SDK

## SPORT\_SET\_STATE

**Serial Port I/O Function:** Sets the baud rate, parity, data bits setting, and stop bits setting of the communications port. This routine is only available for Windows.

---

### Module

USE IFPORT

### Syntax

```
result = SPORT_SET_STATE (port [,baud] [,parity] [,dbits] [,sbits])
```

<i>port</i>	(Input) Integer. The port number.
<i>baud</i>	(Input; optional) Integer. The baud rate of the port.
<i>parity</i>	(Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
<i>dbits</i>	(Input; optional) Integer. The data bits for the port.
<i>sbits</i>	(Input; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).

### Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

The following restrictions apply:

- The number of data bits must be 5 to 8 bits.
- The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.

---

#### NOTE

This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call `SPORT_CANCEL_IO` before port parameters can be changed.

---

### Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SET_STATE( 2, 9600, 0, 7, 0 )
END
```

### See Also

[SPORT\\_CANCEL\\_IO](#)

## SPORT\_SET\_STATE\_EX

**Serial Port I/O Function:** Sets the baud rate, parity, data bits setting, stop bits, and other settings of the communications port. This routine is only available for Windows.

### Module

USE IFPORT

### Syntax

```
result = SPORT_SET_STATE_EX (port [,baud] [,parity] [,dbits] [,sbits] [,Binmode]
[,DTRcntrl]
    [,RTScntrl] [,OutCTSFlow] [,OutDSRFlow] [,DSRSense] [,OutXonOff] [,InXonOff] [,XonLim]
    [,XoffLim] [,TXContOnXoff] [,ErrAbort] [,ErrCharEnbl] [,NullStrip] [,XonChar]
[,XoffChar]
    [,ErrChar] [,EofChar] [,EvtChar] [,fZeroDCB])
```

<i>port</i>	(Input) Integer. The port number.
<i>baud</i>	(Input; optional) Integer. The baud rate of the port.
<i>parity</i>	(Input; optional) Integer. The parity setting of the port (0-4 = no, odd, even, mark, space).
<i>dbits</i>	(Input; optional) Integer. The data bits for the port.
<i>sbits</i>	(Input; optional) Integer. The stop bits for the port (0, 1, 2 = 1, 1.5, 2).
<i>Binmode</i>	(Input; optional) Integer. 1 if binary mode should be enabled; otherwise, 0. Currently, if this parameter is used, the value must be 1.
<i>DTRcntrl</i>	(Input; optional) Integer. 1 if DTR (data-terminal-ready) flow control should be used; otherwise, 0.
<i>RTScntrl</i>	(Input; optional) Integer. 1 if RTS (request-to-send) flow control should be used; otherwise, 0.
<i>OutCTSFlow</i>	(Input; optional) Integer. 1 if the CTS (clear-to-send) signal should be monitored for output flow control; otherwise, 0.
<i>OutDSRFlow</i>	(Input; optional) Integer. 1 if the DSR (data-set-ready) signal should be monitored for output flow control; otherwise, 0.
<i>DSRSense</i>	(Input; optional) Integer. 1 if the communications driver should be sensitive to the state of the DSR signal; otherwise, 0.
<i>OutXonOff</i>	(Input; optional) Integer. 1 if XON/XOFF flow control should be used during transmission; otherwise, 0.
<i>InXonOff</i>	(Input; optional) Integer. 1 if XON/XOFF flow control should be used during reception; otherwise, 0.
<i>XonLim</i>	(Input; optional) Integer. The minimum number of bytes that should be accepted in the input buffer before the XON character is set.

<i>XoffLim</i>	(Input; optional) Integer. The maximum number of bytes that should be accepted in the input buffer before the XOFF character is set.
<i>TXContOnXoff</i>	(Input; optional) Integer. 1 if transmission should be stopped when the input buffer is full and the driver has transmitted the <i>XoffChar</i> character; otherwise, 0.
<i>ErrAbort</i>	(Input; optional) Integer. 1 if read and write operations should be terminated when an error occurs; otherwise, 0.
<i>ErrCharEnbl</i>	(Input; optional) Integer. 1 if bytes received with parity errors should be replaced with the <i>ErrChar</i> character; otherwise, 0.
<i>NullStrip</i>	(Input; optional) Integer. 1 if null bytes should be discarded; otherwise, 0.
<i>XonChar</i>	(Input; optional) Character. The value of the XON character that should be used for both transmission and reception.
<i>XoffChar</i>	(Input; optional) Character. The value of the XOFF character that should be used for both transmission and reception.
<i>ErrChar</i>	(Input; optional) Character. The value of the character that should be used to replace bytes received with parity errors.
<i>EofChar</i>	(Input; optional) Character. The value of the character that should be used to signal the end of data.
<i>EvtChar</i>	(Input; optional) Character. The value of the character that should be used to signal an event.
<i>fZeroDCB</i>	(Input; optional) Integer. 1 if all settings of the communications port should be set to zero before parameters are set; otherwise, 0.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

The following restrictions apply:

- The number of data bits must be 5 to 8 bits.
- The use of 5 data bits with 2 stop bits is an invalid combination, as is 6, 7, or 8 data bits with 1.5 stop bits.

---

### NOTE

This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call `SPORT_CANCEL_IO` before port parameters can be changed.

---

## Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SET_STATE_EX( 2, 9600, 0, 7, 1, OutXonOff=1, InXonOff=1, &
                             XonLim=1024, XoffLim=512, XonChar=CHAR(17), XoffChar=CHAR(19), &
                             fZeroDCB=1) )
END
```

**See Also**

**SPORT\_SET\_TIMEOUTS**

**Serial Port I/O Function:** Sets the user selectable timeouts for the serial port. This routine is only available for Windows.

---

**Module**

USE IFPORT

**Syntax**

```
result = SPORT_SET_TIMEOUTS (port [,rx_int] [,tx_tot_mult] [,tx_tot_const])
```

<code>port</code>	(Input) Integer. The port number.
<code>rx_int</code>	(Input; optional) INTEGER(4). The receive interval timeout value.
<code>tx_tot_mult</code>	(Input; optional) INTEGER(4). The transmit multiplier part of the timeout value.
<code>tx_tot_const</code>	(Input; optional) INTEGER(4). The transmit constant part of the timeout value.

**Results**

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

**NOTE**

This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call SPORT\_CANCEL\_IO before port parameters can be changed.

---

**Example**

```
USE IFPORT
INTEGER(4) ireresult
ireresult = SPORT_SET_TIMEOUTS( 2, 100, 0, 1000 )
END
```

**See Also**

SPORT\_CANCEL\_IO  
SPORT\_GET\_TIMEOUTS

**SPORT\_SHOW\_STATE**

**Serial Port I/O Function:** Displays the state of a port to standard output. This routine is only available for Windows.

---

## Module

USE IFPORT

## Syntax

```
result = SPORT_SHOW_STATE (port, level)
```

*port* (Input) Integer. The port number.

*level* (Input) Integer. Controls the level of detail displayed as follows:

---

0	Basic one line display
1	Basic information
2	Add modem signal control flow information
3	Add XON/XOFF information
4	Add event character information
11	Add timeout information
901	Add debug information

---

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

---

### NOTE

This routine must not be used when any I/O is pending. Since a read operation is always pending after any I/O has been started, you must first call `SPORT_CANCEL_IO` before port parameters can be changed.

---

## Example

```
USE IFPORT
INTEGER(4) ireresult
ireresult = SPORT_SHOW_STATE( 2, 0 )
END
```

## See Also

[SPORT\\_CANCEL\\_IO](#)

Communications and Communications Functions in the Microsoft\* Platform SDK

## SPORT\_SPECIAL\_FUNC

**Serial Port I/O Function:** Executes the Windows\* API communications function *EscapeCommFunction* on the specified port. This routine is only available for Windows.

---

## Module

USE IFPORT

## Syntax

```
result = SPORT_SPECIAL_FUNC (port,function)
```

*port* (Input) Integer. The port number.

*function* (Input) INTEGER(4). The function to perform.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, the result is a Windows\* error value.

## Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_SPECIAL_FUNC( 2, ? )
END
```

## See Also

Communications and Communications Functions in the Microsoft\* Platform SDK

## SPORT\_WRITE\_DATA

**Serial Port I/O Function:** *Outputs data to the specified port. This routine is only available for Windows.*

---

## Module

USE IFPORT

## Syntax

```
result = SPORT_WRITE_DATA (port,data[,count])
```

*port* (Input) Integer. The port number.

*data* (Input) Character\*(\*). The data to be output.

*count* (Input; optional) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

---

### NOTE

When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT\_WRITE\_DATA and SPORT\_WRITE\_LINE can write less bytes than required. When this occurs, the functions return the code ERROR\_IO\_INCOMPLETE, and the return value of parameter *count* contains the number of bytes that were really written.

---

## Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_DATA( 2, 'ATZ'//CHAR(13), 0 )
END
```

## See Also

[SPORT\\_WRITE\\_LINE](#)

[SPORT\\_READ\\_DATA](#)

Communications and Communications Functions in the Microsoft\* Platform SDK

## SPORT\_WRITE\_LINE

**Serial Port I/O Function:** *Outputs data, followed by a record terminator, to the specified port. This routine is only available for Windows.*

---

## Module

USE IFPORT

## Syntax

```
result = SPORT_WRITE_LINE (port,data[,count])
```

*port* (Input) Integer. The port number.

*data* (Input) Character\*(\*). The data to be output.

*count* (Input; optional) Integer. The count of bytes to write. If the value is zero, this number is computed by scanning the data backwards looking for a non-blank character.

## Results

The result type is INTEGER(4). The result is zero if successful; otherwise, a Windows\* error value.

After the data is output, a line terminator character is added based on the mode used during the SPORT\_CONNECT( ) call.

---

### NOTE

When hardware (DTR, RTS, etc.) or software (XON/XOFF) flow controls are used, the functions SPORT\_WRITE\_DATA and SPORT\_WRITE\_LINE can write less bytes than required. When this occurs, the functions return the code ERROR\_IO\_INCOMPLETE, and the return value of parameter *count* contains the number of bytes that were really written.

---

## Example

```
USE IFPORT
INTEGER(4) iresult
iresult = SPORT_WRITE_LINE( 2, 'ATZ', 0 )
END
```

## Dialog Library Routines

This section contains descriptions of the Dialog library routines, which are restricted to Windows\* systems. They are listed in alphabetical order.

To access these library routines, you must specify a USE IFLOGM statement in your program.

### DLGEXIT

**Dialog Subroutine:** *Closes an open dialog box. This routine is only available for Windows.*

#### Module

USE IFLOGM

#### Syntax

```
CALL DLGEXIT (dlg)
```

*dlg* (Input) Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the `PRIVATE` attribute, and cannot be changed or individually accessed by the user.

If you want to exit a dialog box on a condition other than the user selecting the OK or Cancel button, you need to include a call to `DLGEXIT` from within your callback routine. `DLGEXIT` saves the data associated with the dialog box controls and then closes the dialog box. The dialog box is exited after `DLGEXIT` has returned control back to the dialog manager, not immediately after the call to `DLGEXIT`.

#### Example

```
SUBROUTINE EXITSUB (dlg, exit_button_id, callbacktype)
USE IFLOGM
TYPE (DIALOG) dlg
INTEGER exit_button_id, callbacktype
...
CALL DLGEXIT (dlg)
```

#### See Also

[DLGSETRETURN](#)

[DLGINIT](#)

[DLGMODAL](#)

[DLGMODELESS](#)

### DLGFLUSH

**Dialog Subroutine:** *Updates the display of a dialog box. This routine is only available for Windows.*

#### Module

USE IFLOGM

#### Syntax

```
CALL DLGFLUSH (dlg[,flushall])
```

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
<i>flushall</i>	(Input; optional) Logical. If <code>.FALSE.</code> (the default), then only the controls that the dialog routines have marked as changed are updated. If <code>.TRUE.</code> , all controls are updated with the state of the controls as known by the dialog routines. Normally, you would not set <i>flushall</i> to <code>.TRUE.</code> .

When your application calls `DLGSET` to change a property of a control in a dialog box, the change is not immediately reflected in the displayed dialog box. Changes are applied when the dialog box is first displayed, and then after every dialog callback to the user's code.

This design expects that, after a call to `DLGMODAL` or `DLGMODELESS`, every call to `DLGSET` will be made from within a callback routine, and that the callback routine finishes quickly. This is true most of the time.

However, there may be cases where you want to change a control outside of a dialog callback, or from within a loop in a dialog callback.

In these cases, `DLGFLUSH` is required, but is not always sufficient, to update the dialog display. `DLGFLUSH` sends pending Windows\* system messages to the dialog box and the controls that it contains. However, many display changes do not appear until after the program reads and processes these messages. A loop that processes the pending messages may be required; for example:

```
use IFWINTY
use USER32
use IFLOGM
logical lNotQuit, lret
integer iret
TYPE (T_MSG) mesg
lNotQuit = .TRUE.
do while (lNotQuit .AND. (PeekMessage(mesg, 0, 0, 0, PM_NOREMOVE) <> 0))
  lNotQuit = GetMessage(mesg, NULL, 0, 0)
  if (lNotQuit) then
    if (DLGISDLGMESSEGE(mesg) .EQV. .FALSE) then
      lret = TranslateMessage(mesg)
      iret = DispatchMessage(mesg)
    end if
  end if
end do
```

## DLGGET, DLGGETINT, DLGGETLOG, DLGGETCHAR

**Dialog Functions:** *Return the state of the dialog control variable. These routines are only available for Windows.*

---

## Module

`USE IFLOGM`

## Syntax

```
result = DLGGET (dlg,controlid,value[,index])
```

```
result = DLGGETINT (dlg,controlid,value[,index])
```

```
result = DLGGETLOG (dlg,controlid,value[,index])
```

```
result = DLGGETCHAR (dlg,controlid,value[,index])
```

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
<i>controlid</i>	(Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension <code>.FD</code> ).
<i>value</i>	(Output) Integer, logical, or character. The value of the control's variable.
<i>index</i>	(Input; optional) Integer. Specifies the control variable whose value is retrieved. Necessary if the control has more than one variable of the same data type and you do not want to get the value of the default for that type.

## Results

The result type is `LOGICAL(4)`. The result is `.TRUE.` if successful; otherwise, the result is `.FALSE..`

Use the `DLGGET` functions to retrieve the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variable associated with it, but not necessarily all. For information about the location of a document that contains lists of index variables for each control type, see [Additional Documentation: Creating Fortran Applications that Use Windows\\* Features](#).

You can use `DLGGET` to retrieve the value of any variable. You can also use `DLGGETINT` to retrieve an integer value, or `DLGGETLOG` and `DLGGETCHAR` to retrieve logical and character values, respectively. If you use `DLGGET`, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to retrieve a variable type that is not available, the `DLGGET` functions return `.FALSE..`

If two or more controls have the same *controlid*, you cannot use these controls in a `DLGGET` operation. In this case the function returns `.FALSE..`

The dialog box does not need to be open to access its control variables.

## Example

```
USE IFLOGM
INCLUDE "THISDLG.FD"
TYPE (DIALOG)  dlg
INTEGER        val
LOGICAL        retlog, is_checked
CHARACTER(256) text
...
retlog = DLGGET (dlg, IDC_CHECKBOX1, is_checked, dlg_status)
retlog = DLGGET (dlg, IDC_SCROLLBAR2, val, dlg_range)
retlog = DLGGET (dlg, IDC_STATIC_TEXT1, text, dlg_title)
...
```

## DLGINIT, DLGINITWITHRESOURCEHANDLE

**Dialog Functions:** Initialize a dialog box. These routines are only available for Windows.

---

### Module

USE IFLOGM

### Syntax

```
result = DLGINIT (id,dlg)
```

```
result = DLGINITWITHRESOURCEHANDLE (id,hinst,dlg)
```

*id* (Input) INTEGER(4). Dialog identifier. Can be either the symbolic name for the dialog or the identifier number, both listed in the Include file (with extension .FD).

*dlg* (Output) Derived type dialog. Contains dialog box parameters.

*hinst* (Input) INTEGER(HANDLE). Handle of the module instance in which the dialog resource can be found. INTEGER(HANDLE) is INTEGER(4) on IA-32 architecture and INTEGER(8) on Intel® 64 architecture.

### Results

The result type is LOGICAL(4). The result is .TRUE. if successful; otherwise, the result is .FALSE..

DLGINIT must be called to initialize a dialog box before it can be used with DLGMODAL, DLGMODELESS, or any other dialog function.

DLGINIT will only search for the dialog box resource in the main application. For example, it will not find a dialog box resource that has been built into a dynamic link library.

DLGINITWITHRESOURCEHANDLE can be used when the dialog resource is not in the main application. If the dialog resource is in a dynamic link library (DLL), *hinst* must be the value passed as the first argument to the DLLMAIN procedure.

Dialogs can be used from any application, including console, QuickWin, and Windows\* applications.

### Example

```
USE IFLOGM
INCLUDE 'DLG1.FD'
LOGICAL retlog
TYPE (DIALOG) thisdlg
...
retlog = DLGINIT (IDD_DL3, thisdlg)
IF (.not. retlog) THEN
  WRITE (*,*) 'ERROR: dialog not found'
ELSE
  ...
```

### See Also

DLGEXIT

## DLGMODELESS DLGUNINIT

### DLGISDLGMESSAGE, DLGISDLGMESSAGEWITHDLG

**Dialog Functions:** Determine whether the specified message is intended for one of the currently displayed modeless dialog boxes, or a specific dialog box. These routines are only available for Windows.

#### Module

USE IFLOGM

#### Syntax

```
result = DLGISDLGMESSAGE (mesg)
```

```
result = DLGISDLGMESSAGEWITHDLG (mesg, dlg)
```

*mesg* (Input) Derived type T\_MSG. Contains a Windows message.

*dlg* (Input) Derived type dialog. Contains dialog box parameters. The components of the type dialog are defined with the PRIVATE attribute, and cannot be changed or individually accessed by the user.

#### Results

The result type is LOGICAL(4). The result is .TRUE. if the message is processed by the dialog box. Otherwise, the result is .FALSE. and the message should be further processed.

DLGISDLGMESSAGE must be called in the message loop of Windows applications that display a modeless dialog box using DLGMODELESS. DLGISDLGMESSAGE determines whether the message is intended for one of the currently displayed modeless dialog boxes. If it is, it passes the message to the dialog box to be processed.

DLGISDLGMESSAGEWITHDLG specifies a particular dialog box to check. Use DLGISDLGMESSAGEWITHDLG when the message loop is in a main application and the currently active modeless dialog box was created by a DLL.

#### Example

```
use IFLOGM
include 'resource.fd'
type (DIALOG) dlg
type (T_MSG) mesg
integer*4 ret
logical*4 lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) /= 0 )
    ! Note that DlgIsDlgMessage must be called in order to give
    ! the dialog box first chance at the message.
    if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
        lret = TranslateMessage( mesg )
```

```
        ret = DispatchMessage( msg )
    end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = msg%wParam
return
```

## See Also

DLGMODELESS

## DLGMODAL, DLGMODALWITHPARENT

**Dialog Functions:** *Display a dialog box and process user control selections made within the box. This routine is only available for Windows.*

---

### Module

USE IFLOGM

### Syntax

result = DLGMODAL (dlg)

result = DLGMODAL (dlg, hwndParent)

*dlg* (Input) Derived type dialog. Contains dialog box parameters. The components of the type `dialog` are defined with the `PRIVATE` attribute, and cannot be changed or individually accessed by the user.

*hwndParent* (Input) Integer. Specifies the parent window for the dialog box. If omitted, the value is determined in this order:

1. If `DLGMODAL` is called from the callback of a modal or modeless dialog box, then that dialog box is the parent window.
2. If it is a QuickWin or Standard Graphics application, then the frame window is the parent window.
3. The Windows\* desktop window is the parent window.

### Results

The result type is `INTEGER(4)`. By default, if successful, it returns the identifier of the control that caused the dialog to exit; otherwise, it returns -1. The return value can be changed with the `DLGSETRETURN` subroutine.

During execution, `DLGMODAL` displays a dialog box and then waits for user control selections. When a control selection is made, the callback routine, if any, of the selected control (set with `DLGSETSUB`) is called.

The dialog remains active until an exit control is executed: either the default exit associated with the OK and Cancel buttons, or `DLGEXIT` within your own control callbacks. `DLGMODAL` does not return a value until the dialog box is exited.

The default return value for `DLGMODAL` is the identifier of the control that caused it to exit (for example, `IDOK` for the OK button and `IDCANCEL` for the Cancel button). You can specify your own return value with `DLGSETRETURN` from within one of your dialog control callback routines. You should not specify -1 as your return value, because this is the error value `DLGMODAL` returns if it cannot open the dialog.

Use `DLGMODALWITHPARENT` when you want the parent window to be other than the default value (see argument *hwndParent* above). In particular, in an SDI or MDI Windows application, you may want the parent window to be the main application window. The parent window is disabled for user input while the modal dialog box is displayed.

## Example

```
USE IFLOGM
INCLUDE "MYDLG.FD"
INTEGER return
TYPE (DIALOG) mydialog
...
return = DLGMODAL (mydialog)
...
```

## See Also

DLGSETRETURN

DLGSETSUB

## DLGMODELESS

**Dialog Function:** *Displays a modeless dialog box.*  
*This routine is only available for Windows.*

## Module

USE IFLOGM

## Syntax

```
result = DLGMODELESS (dlg[,nCmdShow,hwndParent])
```

*dlg*

(Input) Derived type `dialog`. Contains dialog box parameters. The components of the type `dialog` are defined with the `PRIVATE` attribute, and cannot be changed or individually accessed by the user. The variable passed to this function must remain in memory for the duration of the dialog box, that is from the `DLGINIT` call through the `DLGUNINIT` call.

The variable can be declared as global data in a module, as a variable with the `STATIC` attribute, or in a calling procedure that is active for the duration of the dialog box. It must not be an `AUTOMATIC` variable in the procedure that calls `DLGMODELESS`.

*nCmdShow*

(Input) Integer. Specifies how the dialog box is to be shown. It must be one of the following values:

Value	Description
SW_HIDE	Hides the dialog box.
SW_MINIMIZE	Minimizes the dialog box.
SW_RESTORE	Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows system restores it to its original size and position.

Value	Description
SW_SHOW	Activates the dialog box and displays it in its current size and position.
SW_SHOWMAXIMIZED	Activates the dialog box and displays it as a maximized window.
SW_SHOWMINIMIZED	Activates the dialog box and displays it as an icon.
SW_SHOWMINNOACTIVE	Displays the dialog box as an icon. The window that is currently active remains active.
SW_SHOWNA	Displays the dialog box in its current state. The window that is currently active remains active.
SW_SHOWNOACTIVATE	Displays the dialog box in its most recent size and position. The window that is currently active remains active.
SW_SHOWNORMAL	Activates and displays the dialog box. If the dialog box is minimized or maximized, the Windows* system restores it to its original size and position.

The default value is SW\_SHOWNORMAL.

*hwndParent*

(Input) Integer. Specifies the parent window for the dialog box. The default value is determined in this order:

1. If DLGMODELESS is called from a callback of a modeless dialog box, then that dialog box is the parent window.
2. The Windows desktop window is the parent window.

## Results

The result type is LOGICAL(4). The value is .TRUE. if the function successfully displays the dialog box. Otherwise the result is .FALSE..

During execution, DLGMODELESS displays a modeless dialog box and returns control to the calling application. The dialog box remains active until DLGEXIT is called, either explicitly or as the result of the invocation of a default button callback.

DLGMODELESS is typically used in a Windows application. The application must contain a message loop that processes Windows messages. The message loop must call DLGISDLGMESSAGE for each message. See the example below in the Example section. Multiple modeless dialog boxes can be displayed at the same time. A modal dialog box can be displayed from a modeless dialog box by calling DLGMODAL from a modeless dialog callback. However, DLGMODELESS cannot be called from a modal dialog box callback.

DLGMODELESS also can be used in a Console, DLL, or LIB project. However, the requirements remain that the application must contain a message loop and must call DLGISDLGMESSAGE for each message. For an example of calling DLGMODELESS in a DLL project, see the Dllprgrs sample in the ... \SAMPLES \DIALOG folder.

Use the DLG\_INIT callback with DLGSETSUB to perform processing immediately after the dialog box is created and before it is displayed, and to perform processing immediately before the dialog box is destroyed.

## Example

```

use IFLOGM
include 'resource.fd'
type (DIALOG)   dlg
type (T_MSG)    mesg
integer*4      ret
logical*4      lret
...
! Create the main dialog box and set up the controls and callbacks
lret = DlgInit(IDD_THERM_DIALOG, dlg)
lret = DlgSetSub(dlg, IDD_THERM_DIALOG, ThermSub)
...
lret = DlgModeless(dlg, nCmdShow)
...
! Read and process messages
do while( GetMessage (mesg, NULL, 0, 0) )
  ! Note that DlgIsDlgMessage must be called in order to give
  ! the dialog box first chance at the message.
  if ( DlgIsDlgMessage(mesg) .EQV. .FALSE. ) then
    lret = TranslateMessage( mesg )
    ret  = DispatchMessage( mesg )
  end if
end do
! Cleanup dialog box memory and exit the application
call DlgUninit(dlg)
WinMain = mesg%wParam
return

```

## DLGSENDCTRLMESSAGE

**Dialog Function:** Sends a Windows message to a dialog box control. This routine is only available for Windows.

## Module

USE IFLOGM

## Syntax

```
result = DLGSENDCTRLMESSAGE (dlg, controlid, msg, wparam, lparam)
```

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
<i>controlid</i>	(Input) Integer. Specifies the identifier of the control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension <code>.FD</code> ).
<i>msg</i>	(Input) Integer. Derived type <code>T_MSG</code> . Specifies the message to be sent.
<i>wparam</i>	(Input) Integer. Specifies additional message specific information.
<i>lparam</i>	(Input) Integer. Specifies additional message specific information.

## Results

The result type is `INTEGER(4)`. The value specifies the result of the message processing and depends upon the message sent.

The dialog box must be currently active by a call to `DLGMODAL` or `DLGMODELESS`. This function does not return until the message has been processed by the control.

## Example

```
use IFLOGM
include 'resource.fd'
type (dialog)    dlg
integer          callbacktype
integer          cref
integer          ired

if (callbacktype == dlg_init) then
    ! Change the color of the Progress bar to red
    ! NOTE:  The following message succeeds only if Internet Explorer 4.0
    !         or higher is installed
    cref = Z'FF'    ! Red
    ired = DlgSendCtrlMessage(dlg, IDC_PROGRESS1, PBM_SETBARCOLOR, 0, cref)
endif
```

## DLGSET, DLGSETINT, DLGSETLOG, DLGSETCHAR

**Dialog Functions:** Set the values of dialog control variables. These routines are only available for Windows.

---

## Module

`USE IFLOGM`

## Syntax

```
result = DLGSET (dlg, controlid, value[, index])
```

```

result = DLGSETINT (dlg,controlid,value[,index])
result = DLGSETLOG (dlg,controlid,value[,index])
result = DLGSETCHAR (dlg,controlid,value[,index])

```

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
<i>controlid</i>	(Input) Integer. Specifies the identifier of a control within the dialog box. Can be either the symbolic name for the control or the identifier number, both listed in the Include file (with extension <code>.FD</code> ).
<i>value</i>	(Input) Integer, logical, or character. The value of the control's variable.
<i>index</i>	(Input; optional) Integer. Specifies the control variable whose value is set. Necessary if the control has more than one variable of the same data type and you do not want to set the value of the default for that type.

## Results

The result type is `LOGICAL(4)`. The result is `.TRUE.` if successful; otherwise, the result is `.FALSE.`.

Use the `DLGSET` functions to set the values of variables associated with your dialog box controls. Each control has at least one of the integer, logical, or character variables associated with it, but not necessarily all. For information about the location of a document that contains lists of index variables for each control type, see [Additional Documentation: Creating Fortran Applications that Use Windows\\* OS Features](#).

You can use `DLGSET` to set any control variable. You can also use `DLGSETINT` to set an integer variable, or `DLGSETLOG` and `DLGSETCHAR` to set logical and character values, respectively. If you use `DLGSET`, you do not have to worry about matching the function to the variable type. If you use the wrong function type for a variable or try to set a variable type that is not available, the `DLGSET` functions return `.FALSE.`.

Calling `DLGSET` does not cause a callback routine to be called for the changing value of a control. In particular, when inside a callback, performing a `DLGSET` on a control does not cause the associated callback for that control to be called. Callbacks are invoked automatically only by user action on the controls in the dialog box. If the callback routine needs to be called, you can call it manually after the `DLGSET` is executed.

If two or more controls have the same *controlid*, you cannot use these controls in a `DLGSET` operation. In this case the function returns `.FALSE.`.

## Example

```

USE IFLOGM
INCLUDE "DLGRADAR.FD"
TYPE (DIALOG)  dlg
LOGICAL        retlog
...
retlog = DLGSET (dlg, IDC_SCROLLBAR1, 400, dlg_range)
retlog = DLGSET (dlg, IDC_CHECKBOX1, .FALSE., dlg_status)
retlog = DLGSET (dlg, IDC_RADIOBUTTON1, "Hot Button", dlg_title)
...

```

## DLGSETCTRLEVENTHANDLER

**Dialog Subroutine:** Lets you assign your own event handlers to ActiveX controls in a dialog box. This routine is only available for Windows.

---

### Module

**Dialog Function:** Assigns user-written event handlers to ActiveX controls in a dialog box.

USE IFLOGM

### Syntax

```
result = DLGSETCTRLEVENTHANDLER (dlg,controlid,handler,dispid[,iid])
```

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
<i>controlid</i>	(Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension <code>.FD</code> ) file.
<i>handler</i>	(Input) Name of the routine to be called when the event occurs. It must be declared <code>EXTERNAL</code> .
<i>dispid</i>	(Input) Integer. Specifies the member id of the method in the event interface that identifies the event.
<i>iid</i>	(Input; optional) Derived type <code>GUID</code> , which is defined in the <code>IFWINTY</code> module. Specifies the interface identifier of the source (event) interface. If omitted, the default source interface of the ActiveX control is used.

### Results

The result type is `INTEGER(4)`. The result is an `HRESULT` describing the status of the operation.

When the ActiveX control event occurs, the handler associated with the event is called. You call `DLGSETCTRLEVENTHANDLER` to specify the handler to be called.

The events supported by an ActiveX control and the interfaces of the handlers are determined by the ActiveX control.

You can find this information in one of the following ways:

- By reading the documentation of the ActiveX control.
- By using a tool that lets you examine the type information of the ActiveX control;, such as the OLE-COM Object Viewer.
- By using the Fortran Module Wizard to generate a module that contains Fortran interfaces to the ActiveX control, and examining the generated module.

The handler that you define in your application must have the interface that the ActiveX control expects, including calling convention and parameter passing mechanisms. Otherwise, your application will likely crash in unexpected ways because of the application's stack getting corrupted.

Note that an object is always the first parameter in an event handler. This object value is a pointer to the control's source (event) interface, *not* the `IDispatch` pointer of the control. You can use `DLGGET` with the `DLG_IDISPATCH` index to retrieve the control's `IDispatch` pointer.

## Example

```
USE IFLOGM
ret = DlgSetCtrlEventHandler(      &
    dlg,                          &
    IDC_ACTIVEMOVIECONTROL1,      & ! Identifies the control
    ReadyStateChange,             & ! Name of the event handling routine
    -609,                         & ! Member id of the ActiveMovie's
                                & ! control ReadyStateChange event.
    IID_DActiveMovieEvents2 )     ! Identifier of the source (event)
                                ! interface.
```

## DLGSETRETURN

**Dialog Subroutine:** Sets the return value for the *DLGMODAL* function from within a callback subroutine. This routine is only available for Windows.

## Module

USE IFLOGM

## Syntax

```
CALL DLGSETRETURN (dlg,retval)
```

<i>dlg</i>	(Input) Derived type <i>dialog</i> . Contains dialog box parameters. The components of the type <i>dialog</i> are defined with the <i>PRIVATE</i> attribute, and cannot be changed or individually accessed by the user.
<i>retval</i>	(Input) Integer. Specifies the return value for <i>DLGMODAL</i> upon exiting.

*DLGSETRETURN* overrides the default return value with *retval*. You can set your own value as a means of determining the condition under which the dialog box was closed. The default return value for an error condition is -1, so you should not use -1 as your return value.

*DLGSETRETURN* should be called from within a callback routine, and is generally used with *DLGEXIT*, which causes the dialog box to be exited from a control callback rather than the user selecting the OK or Cancel button.

## Example

```
SUBROUTINE SETRETSUB (dlg, button_id, callbacktype)
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) dlg
LOGICAL      is_checked, retlog
INTEGER      return, button_id, callbacktype
...
retlog = DLGGET(dlg, IDC_CHECKBOX4, is_checked, dlg_state)
IF (is_checked) THEN
    return = 999
```

```
ELSE
    return = -999
END IF
CALL DLGSETRETURN (dlg, return)
CALL DLGEXIT (dlg)
END SUBROUTINE SETRETSUB
```

## See Also

DLGEXIT

DLGMODAL

## DLGSETSUB

**Dialog Function:** *Assigns your own callback subroutines to dialog controls and to the dialog box. This routine is only available for Windows.*

---

## Module

USE IFLOGM

## Syntax

```
result = DLGSETSUB (dlg, controlid, value[, index])
```

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
<i>controlid</i>	(Input) Integer. Specifies the identifier of a control within the dialog box. Can be the symbolic name for the control or the identifier number, both listed in the include (with extension <code>.FD</code> ) file, or it can be the identifier of the dialog box.
<i>value</i>	(Input) <code>EXTERNAL</code> . Name of the routine to be called when the callback event occurs.
<i>index</i>	(Input; optional) Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

## Results

The result type is `LOGICAL(4)`. The result is `.TRUE.` if successful; otherwise, `.FALSE.`

When a callback event occurs (for example, when you select a check box), the callback routine associated with that callback event is called. You use `DLGSETSUB` to specify the subroutine to be called. All callback routines should have the following interface:

```
SUBROUTINE callbackname( dlg, control_id, callbacktype)
```

```
!DIR$ ATTRIBUTES DEFAULT :: callbackname
```

<i>callbackname</i>	Is the name of the callback routine.
<i>dlg</i>	Refers to the dialog box and allows the callback to change values of the dialog controls.
<i>control_id</i>	Is the name of the control that caused the callback.

*callbacktype* (Input; optional) Integer. Specifies which callback routine is executed when the callback event occurs. Necessary if the control has more than one callback routine.

The *control\_id* and *callbacktype* parameters let you write a single subroutine that can be used with multiple callbacks from more than one control. Typically, you do this for controls comprising a logical group. You can also associate more than one callback routine with the same control, but you must use then use *index* parameter to indicate which callback routine to use.

The *control\_id* can also be the identifier of the dialog box. The dialog box supports two *callbacktypes*, DLG\_INIT and DLG\_SIZECHANGE. The DLG\_INIT callback is executed immediately after the dialog box is created with *callbacktype* DLG\_INIT, and immediately before the dialog box is destroyed with *callbacktype* DLG\_DESTROY. DLG\_SIZECHANGE is called when the size of a dialog is changed.

Callback routines for a control are called after the value of the control has been updated based on the user's action.

If two or more controls have the same *controlid*, you cannot use these controls in a DLGSETSUB operation. In this case, the function returns .FALSE..

## Example

```
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (dialog) mydialog
LOGICAL retlog
INTEGER return
EXTERNAL RADIOSUB
retlog = DLGINIT(IDD_mydlg, mydialog)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON1, RADIOSUB)
retlog = DLGSETSUB (mydialog, IDC_RADIO_BUTTON2, RADIOSUB)
return = DLGMODAL(mydialog)
END
SUBROUTINE RADIOSUB( dlg, id, callbacktype )
!DIR$ ATTRIBUTES DEFAULT :: radiosub
  USE IFLOGM
  TYPE (dialog) dlg
  INTEGER id, callbacktype
  INCLUDE 'MYDLG.FD'
  CHARACTER(256) text
  LOGICAL retlog
  SELECT CASE (id)
    CASE (IDC_RADIO_BUTTON1)
      ! Radio button 1 selected by user so
      ! change text accordingly
      text = 'Statistics Package A'
      retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
    CASE (IDC_RADIO_BUTTON2)
      ! Radio button 2 selected by user so
      ! change text accordingly
      text = 'Statistics Package B'
      retlog = DLGSET( dlg, IDC_STATICTEXT1, text )
  END SELECT
END SUBROUTINE RADIOSUB
```

## See Also

DLGSET

DLGGET

## DLGSETTITLE

**Dialog Subroutine:** Sets the title of a dialog box.  
*This routine is only available for Windows.*

---

### Module

USE IFLOGM

### Syntax

CALL DLGSETTITLE (*dlg*,*title*)

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
<i>title</i>	(Input) Character*(*). Specifies text to be the title of the dialog box.

Use this routine when you want to specify the title for a dialog box.

### Example

```
USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG) mydialog
LOGICAL retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGSETTITLE(mydialog, "New Title")
...
```

### See Also

DLGINIT

DLGMODAL

DLGMODELESS

## DLGUNINIT

**Dialog Subroutine:** Deallocates memory associated with an initialized dialog. *This routine is only available for Windows.*

---

### Module

USE IFLOGM

### Syntax

CALL DLGUNINIT (*dlg*)

<i>dlg</i>	(Input) Derived type <code>dialog</code> . Contains dialog box parameters. The components of the type <code>dialog</code> are defined with the <code>PRIVATE</code> attribute, and cannot be changed or individually accessed by the user.
------------	--

You should call DLGUNINIT when a dialog that was successfully initialized by DLGINIT is no longer needed. DLGUNINIT should only be called on a dialog initialized with DLGINIT. If it is called on an uninitialized dialog or one that has already been deallocated with DLGUNINIT, the result is undefined.

## Example

```

USE IFLOGM
INCLUDE "MYDLG.FD"
TYPE (DIALOG)  mydialog
LOGICAL       retlog
...
retlog = DLGINIT(IDD_mydlg, mydialog)
...
CALL DLGUNINIT (mydialog)
END

```

# Glossary

This section contains abbreviated definitions of some commonly used terms in this manual.

## Glossary A

absolute pathname	A directory path specified in fixed relationship to the root directory. On Windows* systems, the first character is a backslash (\). On Linux* and macOS systems, the first character is a slash (/).
abstract interface	A named set of procedure characteristics that can be referenced in PROCEDURE declarations.
abstract type	A derived type, declared with the ABSTRACT keyword, which can be extended to declare an object. An abstract type cannot be used directly to declare an object.
active image	An image that is not a failed image and has neither initiated normal or error termination.
active screen buffer	The screen buffer that is currently displayed in a console's window.
active team	A team that becomes the current team by execution of a CHANGE TEAM statement is active until the execution of the corresponding END TEAM statement. The current team, and all ancestor teams are active teams. The initial team is always an active team until the program terminates.
active window	A top-level window of the application with which the user is working. The Windows system identifies the active window by highlighting its title bar and border.
actual argument	A value (a variable, expression, or procedure) passed from a calling program unit to a subprogram (function or subroutine). See also <a href="#">dummy argument</a> .
adjustable array	An explicit-shape array that is a dummy argument to a subprogram. The term is from FORTRAN 77. See also <a href="#">explicit-shape array</a> .

aggregate reference	A reference to a record structure field.
allocatable array	A named array that has the <a href="#">ALLOCATABLE</a> attribute. The array's rank is specified at compile time, but its bounds are determined at run time. Once space has been allocated for this type of array, the array has a shape and can be defined (and redefined) or referenced. It is an error to allocate an allocatable array that is currently allocated.
allocation status	Indicates whether an allocatable array or pointer is allocated. An allocation status is one of: allocated, deallocated, or undefined. An undefined allocation status means an array can no longer be referenced, defined, allocated, or deallocated. See also <i>association status</i> .
alphanumeric	Pertaining to letters and digits.
alternate return	A subroutine argument that permits control to branch immediately to some position other than the statement following the call. The actual argument in an alternate return is the statement label to which control should be transferred. (An alternate return is an obsolescent feature in Standard Fortran.)
ancestor team	A team that is the parent team of the current team, or the parent team of the parent team of the current team, etc. The initial team is always an ancestor of the current team if the current team is not the initial team.
ANSI	The American National Standards Institute. An organization through which accredited organizations create and maintain voluntary industry standards.
argument	<p>Can be either of the following:</p> <ul style="list-style-type: none"><li>• An actual argument--A variable, expression, or procedure passed from a calling program unit to a subprogram. See also <i>actual argument</i>.</li><li>• A dummy argument--A variable whose name appears in the parenthesized list following the procedure name in a <a href="#">FUNCTION</a> statement, a <a href="#">SUBROUTINE</a> statement, an ENTRY statement, or a <a href="#">statement function</a> statement. See also <a href="#">dummy argument</a>.</li></ul>
argument association	The relationship (or "matching up") between an actual argument and dummy argument during the execution of a procedure reference.
argument keyword	<p>The name of a dummy (formal) argument. The name is used in a subprogram definition. Argument keywords can be used when the subprogram is invoked to associate dummy arguments with actual arguments, so that the subprogram arguments can appear in any order.</p> <p>Argument keywords are supplied for many of the intrinsic procedures.</p>
array	<p>A set of scalar data that all have the same type and kind type parameters. An array can be referenced by element (using a subscript), by section (using a section subscript list), or as a whole. An array has a rank (up to <a href="#">31</a>), bounds, size, and a shape.</p> <p>An individual array element is a scalar object. An array section, which is itself an array, is a subset of the entire array. Contrast with <a href="#">scalar</a>. See also <a href="#">bounds</a>, <a href="#">conformable</a>, <a href="#">shape</a>, <a href="#">size</a>, <a href="#">whole array</a>, and <a href="#">zero-sized array</a>.</p>
array constructor	A mechanism used to specify a sequence of scalar values that produce a rank-one array.

	To construct an array of rank greater than one, you must apply the <a href="#">RESHAPE</a> intrinsic function to the array constructor.
array element	A scalar (individual) item in an array. An array element is identified by the array name followed by one or more subscripts in parentheses, indicating the element's position in the array. For example, B(3) or A(2,5).
array pointer	A pointer to an array. See also <i>array</i> and <a href="#">pointer</a> .
array section	A subobject (or portion) of an array. It consists of the set of array elements or substrings of this set. The set (or section subscript list) is specified by subscripts, subscript triplets, or vector subscripts. If the set does not contain at least one subscript triplet or vector subscript, the reference indicates an array element, not an array.
array specification	A program statement specifying an array name and the number of dimensions the array contains (its rank). An array specification can appear in a <a href="#">DIMENSION</a> or <a href="#">COMMON</a> statement, or in a <a href="#">type declaration statement</a> .
ASCII	The American Standard Code for Information Interchange. A 7-bit character encoding scheme associating an integer from 0 through 127 with 128 characters.
assignment statement	Usually, a statement that assigns (stores) the value of an expression on the right of an equal sign to the storage location of the variable to the left of the equal sign. In the case of Fortran pointers, the storage location is assigned, not the pointer itself.
associate name	The name of a construct entity associated with a selector of an ASSOCIATE or SELECT TYPE construct.
association	The relationship that allows an entity to be referenced by different names in one scoping unit or by the same or different names in more than one scoping unit. The principal kinds of association are argument, host, pointer, storage, and use association. See also <i>argument association</i> , <a href="#">host association</a> , <a href="#">pointer association</a> , <a href="#">storage association</a> , and <a href="#">use association</a> .
association status	Indicates whether or not a pointer is associated with a target. An association status is one of: undefined, associated, or disassociated. An undefined association status means a pointer can no longer be referenced, defined, or deallocated. An undefined pointer can, however, be allocated, nullified, or pointer assigned to a new target. See also <i>allocation status</i> .
assumed-length character argument	A dummy argument that assumes the length attribute of the corresponding actual argument. An asterisk (*) specifies the length of the dummy character argument.
assumed-shape array	A dummy argument array that assumes the shape of its associated actual argument array. The rank of the array is the number of colons (:) specified in parentheses.
assumed-size array	A dummy array whose size (only) is assumed from its associated actual argument. The upper bound of its last dimension is specified by an asterisk (*). All other extents (if any) must be specified.
atomic subroutine	An intrinsic subroutine that performs an action on a variable (its ATOM argument) indivisibly.

attribute	<p>A property of a data object that can be specified in a type declaration statement. These properties determine how the data object can be used in a program.</p> <p>Most attributes can be alternatively specified in statements. For example, the <a href="#">DIMENSION</a> statement has the same meaning as the DIMENSION attribute appearing in a <a href="#">type declaration</a> statement.</p>
automatic array	<p>An explicit-shape array that is a local variable in a subprogram. It is not a dummy argument, and has bounds that are nonconstant specification expressions. The bounds (and shape) are determined at entry to the procedure by evaluating the bounds expressions. <i>See also automatic object.</i></p>
automatic object	<p>A local data object that is created upon entry to a subprogram and disappears when the execution of the subprogram is completed. There are two kinds of automatic objects: arrays (of any data type) and objects of type CHARACTER. Automatic objects cannot be saved or initialized.</p> <p>An automatic object is not a dummy argument, but is declared with a specification expression that is not a constant expression. The specification expression can be the bounds of the array or the length of the character object.</p>

---

## Glossary B

---

background process	<p>On Linux* systems, a process for which the command interpreter is not waiting. Its process group differs from that of its controlling terminal, so it is blocked from most terminal access. Contrast with <a href="#">foreground process</a>.</p>
background window	<p>Any window created by a thread other than the foreground thread.</p>
big endian	<p>A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the highest addressed byte. Contrast with <a href="#">little endian</a>.</p>
binary constant	<p>A constant that is a string of binary (base 2) digits (0 or 1) enclosed by apostrophes or quotation marks and preceded by the letter B.</p>
binary operator	<p>An operator that acts on a pair of operands. The exponentiation, multiplication, division, and concatenation operators are binary operators.</p>
bit constant	<p>A constant that is a binary, octal, or hexadecimal number.</p>
bit field	<p>A contiguous group of bits within a binary pattern; they are specified by a starting bit position and length. Some intrinsic functions (for example, <a href="#">IBSET</a> and <a href="#">BTEST</a>) and the intrinsic subroutine <a href="#">MVBITS</a> operate on bit fields.</p>
bitmap	<p>An array of bits that contains data that describes the colors found in a rectangular region on the screen (or the rectangular region found on a page of printer paper).</p>
blank common	<p>A common block (one or more contiguous areas of storage) without a name. Common blocks are defined by a <a href="#">COMMON</a> statement.</p>
block	<p>In general, a group of related items treated as a physical unit. For example, a block can be a group of constructs or statements that perform a task; the task can be executed once, repeatedly, or not at all.</p>

block data program unit	A program unit, containing a <a href="#">BLOCK DATA</a> statement and its associated specification statements, that establishes common blocks and assigns initial values to the variables in named common blocks. In FORTRAN 77, this was called a block data subprogram.
bounds	The range of subscript values for elements of an array. The lower bound is the smallest subscript value in a dimension, and the upper bound is the largest subscript value in that dimension. Array bounds can be positive, zero, or negative. These bounds are specified in an array specification. See also <a href="#">array specification</a> .
breakpoint	A critical point in a program, at which execution is stopped so that you can see if the program variables contain the correct values. Breakpoints are often used to debug programs.
brush	A bitmap that is used to fill the interior of closed shapes, polygons, ellipses, and paths.
brush origin	A coordinate that specifies the location of one of the pixels in a brush's bitmap. The Windows system maps this pixel to the upper left corner of the window that contains the object to be painted. See also <i>bitmap</i> .
built-in procedure	See <a href="#">intrinsic procedure</a> .
byte	A group of 8 contiguous bits (binary digits) starting on an addressable boundary.
byte-order mark	A special Unicode character (0xFEFF) that is placed at the beginning of Unicode text files to indicate that the text is in Unicode format.

## Glossary C

---

carriage-control character	A character in the first position of a printed record that determines the vertical spacing of the output line.
character constant	A constant that is a string of printable ASCII characters enclosed by apostrophes (') or quotation marks (").
character expression	A character constant, variable, function value, or another constant expression, separated by a concatenation operator (//); for example, DAY// ' FIRST'.
character storage unit	The unit of storage for holding a scalar value of default character type (and character length one) that is not a pointer. One character storage unit corresponds to one byte of memory.
character string	A sequence of contiguous characters; a character data value. See also <i>character constant</i> , which appears above.
character substring	One or more contiguous characters in a character string.
child process	A process initiated by another process (the parent). The child process can operate independently from the parent process. Also, the parent process can suspend or terminate without affecting the child process. See also <a href="#">parent process</a> .
child team	A team created by the execution of a FORM TEAM statement is a child of the team that executes the FORM TEAM statement.
child window	A window that has the WS_CHILD style. A child window always appears within the client area of its parent window. See also <a href="#">parent window</a> .

column-major order	See <a href="#">order of subscript progression</a> .
coarray	A data entity that has nonzero corank. A Fortran program containing coarrays is interpreted as if it were replicated a fixed number of times and all copies were executed asynchronously. Its corank, cobounds, and coextents are given by the data in square brackets in its declaration or allocation.
cobound	A bound (limit) of a codimension. The values of each lower cobound and upper cobound determine the cobounds of the coarray along a particular codimension.
codimension	A dimension of the pattern formed by a set of corresponding coarrays.
comment	<p>Text that documents or explains a program. In free source form, a comment begins with an exclamation point (!), unless it appears in a Hollerith or character constant.</p> <p>In fixed and tab source form, a comment begins with a letter C or an asterisk (*) in column 1. A comment can also begin with an exclamation point anywhere in a source line (except in a Hollerith or character constant) or in column 6 of a fixed-format line. The comment extends from the exclamation point to the end of the line.</p> <p>The compiler does not process comments, but shows them in program listings. See also the definition for <i>compiler directive</i>, which appears below.</p>
common block	A physical storage area shared by one or more program units. This storage area is defined by a <a href="#">COMMON</a> statement. If the common block is given a name, it is a named common block; if it is not given a name, it is a blank common. See also <a href="#">blank common</a> and <a href="#">named common block</a> .
compilation unit	The source or files that are compiled together to form a single object file, possibly using interprocedural optimization across source files.
compiler directive	A structured comment that tells the compiler to perform certain tasks when it compiles a source program unit. Compiler directives are usually compiler-specific. (Some Fortran compilers call these directives "metacommands".)
compiler option	An option (or flag) that can be used on the compiler command line to override the default behavior of the Intel® Fortran Compiler.
complex constant	A constant that is a pair of real or integer constants representing a complex number; the pair is separated by a comma and enclosed in parentheses. The first constant represents the real part of the number; the second constant represents the imaginary part. The following types of complex constants are available on all systems: COMPLEX(KIND=4), COMPLEX(KIND=8), and COMPLEX(KIND=16).
complex type	A data type that represents the values of complex numbers. The value is expressed as a complex constant. See also <a href="#">data type</a> .
component	Part of a derived-type definition. There must be at least one component (intrinsic or derived type) in every derived-type definition.
component order	The ordering of the components of a derived type that is used for intrinsic formatted input/output and for structure constructors.

concatenate	The combination of two items into one by placing one of the items after the other. In Standard Fortran, the concatenation operator (//) is used to combine character items. See also <i>character expression</i> , which appears above.
conformable	Pertains to dimensionality. Two arrays are conformable if they have the same shape. A scalar is conformable with any array.
conformance	See <a href="#">shape conformance</a> .
conservative automatic inlining	The inline expansion of small procedures, with conservative heuristics to limit extra code.
console	An interface that provides input and output to character-mode applications.
constant	A data object whose value does not change during the execution of a program; the value is defined at the time of compilation. A constant can be named (using the <a href="#">PARAMETER</a> attribute or statement) or unnamed. An unnamed constant is called a literal constant. The value of a constant can be numeric or logical, or it can be a character string. Contrast with <a href="#">variable</a> .
constant expression	An expression that you can use as a kind type parameter, a named constant, or to specify an initial value for an entity. It is evaluated when a program is compiled.
construct	A series of statements starting with a statement denoting the kind of construct, such as <a href="#">DO</a> , <a href="#">SELECT CASE</a> , <a href="#">IF</a> , <a href="#">FORALL</a> , or <a href="#">WHERE</a> , and ending with the appropriate termination statement.
construct association	The association between a selector and an associate name in an <a href="#">ASSOCIATE</a> or <a href="#">SELECT TYPE</a> construct.
contiguous	Pertaining to entities that are adjacent (next to one another) without intervening blanks (spaces); for example, contiguous characters or contiguous areas of storage.
control edit descriptor	A format descriptor that directly displays text or affects the conversions performed by subsequent data edit descriptors. Except for the slash descriptor, control edit descriptors are nonrepeatable.
control statement	A statement that alters the normal order of execution by transferring control to another part of a program unit or a subprogram. A control statement can be conditional (such as the <a href="#">IF</a> construct or <a href="#">computed GO TO</a> statement) or unconditional (such as the <a href="#">STOP</a> or <a href="#">GO TO</a> statement).
corank	The number of codimensions of a coarray.
critical section	An object used to synchronize the threads of a single process. Only one thread at a time can own a critical-section object.
current team	The current team is the initial team at program startup. The team described by the team variable specified in a <a href="#">CHANGE TEAM</a> statement becomes the current team during execution of a change team construct. The team that was current immediately before the <a href="#">CHANGE TEAM</a> statement becomes the current team when the corresponding <a href="#">END TEAM</a> statement is executed.

## Glossary D

---

data abstraction	A style of programming in which you define types to represent objects in your program, define a set of operations for objects of each type, and restrict the operations to only this set, making the types abstract. The Standard Fortran modules, derived types, and defined operators, support this programming paradigm.
data edit descriptor	A repeatable format descriptor that causes the transfer or conversion of data to or from its internal representation. In FORTRAN 77, this term was called a field descriptor.
data entity	A data object that has a data type. It is the result of the evaluation of an expression, or the result of the execution of a function reference (the function result).
data item	A unit of data (or value) to be processed. Includes constants, variables, arrays, character substrings, or records.
data object	A constant, variable, or subobject (part) of a constant or variable. Its type may be specified implicitly or explicitly.
data type	The properties and internal representation that characterize data and functions. Each intrinsic and user-defined data type has a name, a set of operators, a set of values, and a way to show these values in a program. The basic intrinsic data types are integer, real, complex, logical, and character. The data value of an intrinsic data type depends on the value of the type parameter. See also <a href="#">type parameter</a> .
data type declaration	See <a href="#">type declaration statement</a> .
data type length specifier	The form <code>*n</code> appended to Intel® Fortran-specific data type names. For example, in <code>REAL*4</code> , the <code>*4</code> is the data type length specifier.
deadlock	A bug where the execution of thread A is blocked indefinitely waiting for thread B to perform some action, while thread B is blocked waiting for thread A. For example, two threads on opposite ends of a named pipe can become deadlocked if each thread waits to read data written by the other thread. A single thread can also deadlock itself. See also <a href="#">thread</a> .
declaration	See <a href="#">specification statement</a> .
declared type	The type that a data entity is declared to have. For polymorphic data entities, it may differ from the type during execution (the dynamic type) .
decorated name	An internal representation of a procedure name or variable name that contains information about where it is declared; for procedures, the information includes how it is called. Decorated names are mainly of interest in mixed-language programming, when calling Fortran routines from other languages.
default character	The kind for character constants if no kind type parameter is specified. Currently, the only kind type parameter for character constants is <code>CHARACTER(1)</code> , the default character kind.
default complex	The kind for complex constants if no kind type parameter is specified. The default complex kind is affected by compiler options specifying double size. If no compiler option is specified, default complex is <code>COMPLEX(4)</code> ( <code>COMPLEX*8</code> ). See also <i>default real</i> .

default integer	<p>The kind for integer constants if no kind type parameter is specified. The default integer kind is affected by the <code>INTEGER</code> directive, the <code>OPTIONS</code> statement, and by compiler options specifying integer size. If none of these are specified, default integer is <code>INTEGER(4)</code> (<code>INTEGER*4</code>).</p> <p>If a command line option affecting integer size has been specified, the integer has the kind specified, unless it is outside the range of the kind specified by the option. In this case, the kind type of the integer is the smallest integer kind which can hold the integer.</p>
default logical	<p>The kind for logical constants if no kind type parameter is specified. The default logical kind is affected by the <code>INTEGER</code> directive, the <code>OPTIONS</code> statement, and by compiler options specifying integer size. If none of these are specified, default logical is <code>LOGICAL(4)</code> (<code>LOGICAL*4</code>). See also <i>default integer</i>.</p>
default real	<p>The kind for real constants if no kind type parameter is specified. The default real kind is affected by compiler options specifying real size and by the <code>REAL</code> directive. If neither of these is specified, default real is <code>REAL(4)</code> (<code>REAL*4</code>).</p> <p>If a real constant is encountered that is outside the range for the default, an error occurs.</p>
deferred-shape array	<p>An array pointer (an array with the <a href="#">POINTER</a> attribute) or an allocatable array (an array with the <a href="#">ALLOCATABLE</a> attribute). The size in each dimension is determined by pointer assignment or when the array is allocated.</p> <p>The array specification contains a colon (:) for each dimension of the array. No bounds are specified.</p>
definable	<p>A property of variables. A variable is definable if its value can be changed by the appearance of its name or designator on the left of an assignment statement. An example of a variable that is not definable is an allocatable array that has not been allocated.</p>
defined	<p>For a data object, the property of having or being given a valid value.</p>
defined assignment	<p>An assignment statement that is not intrinsic, but is defined by a subroutine and an <code>ASSIGNMENT(=)</code> interface block. See also <i>derived type</i> and <a href="#">interface block</a>.</p>
defined operation	<p>An operation that is not intrinsic, but is defined by a function subprogram containing a generic interface block with the specifier <code>OPERATOR</code>. See also <i>derived type</i> and <a href="#">interface block</a>.</p>
denormalized number	<p>A computational floating-point result smaller than the lowest value in the normal range of a data type (the smallest representable normalized number). You cannot write a constant for a subnormal number. Older floating-point standard documents used the term <i>denormal</i>; newer standards call such numbers <i>subnormal</i>.</p>
dependent task	<p>A task that cannot be executed until its preceding task completes; this is due to a task dependence. See also <a href="#">preceding task</a> and <a href="#">task dependence</a>.</p>
derived type	<p>A data type that is user-defined and not intrinsic. It requires a type definition to name the type and specify its components (which can be intrinsic or user-defined types). A structure constructor can be used to specify a value of derived type. A component of a structure is referenced using a percent sign (%).</p>

Operations on objects of derived types (structures) must be defined by a function with an OPERATOR interface. Assignment for derived types can be defined intrinsically, or be redefined by a subroutine with an ASSIGNMENT(=) interface. Structures can be used as procedure arguments and function results, and can appear in input and output lists. Also called a user-defined type. See also [record](#), the first definition.

designator	A name that references a subobject (part of a data object) that can be defined and referenced separately from other parts of the data object. A designator is the name of the object followed by a selector that selects the subobject. For example, B(3) is a designator for an array element. Also called a subobject designator. See also <a href="#">selector</a> and <a href="#">subobject</a> .
dimension	A range of values for one subscript or index of an array. An array can have from 1 to 7 dimensions. The number of dimensions is the rank of the array.
dimension bounds	See <a href="#">bounds</a> .
direct access	A method for retrieving or storing data in which the data (record) is identified by the record number, or the position of the record in the file. The record is accessed directly (nonsequentially); therefore, all information is equally accessible. Also called random access. Contrast with <a href="#">sequential access</a> .
DLL	See <i>Dynamic Link Library</i> .
double-byte character set (DBCS)	A mapping of characters to their identifying numeric values, in which each value is 2 bytes wide. Double-byte character sets are sometimes used for languages that have more than 256 characters.
double-precision constant	A processor approximation to the value of a real number that occupies 8 bytes of memory and can assume a positive, negative, or zero value. The precision is greater than a constant of real (single-precision) type. For the precise ranges of the double-precision constants, see Data Representation Overview in the <i>Compiler Reference</i> . See also <i>denormalized number</i> .
driver program	A program that is the user interface to the language compiler. It accepts command line options and file names and causes one or more language utilities or system programs to process each file.
dummy aliasing	The sharing of memory locations between dummy (formal) arguments and other dummy arguments or <a href="#">COMMON</a> variables that are assigned.
dummy argument	A variable whose name appears in the parenthesized list following the procedure name in a <a href="#">FUNCTION</a> statement, a <a href="#">SUBROUTINE</a> statement, an <a href="#">ENTRY</a> statement, or a <a href="#">statement function</a> statement. A dummy argument takes the value of the corresponding actual argument in the calling program unit (through argument association). Also called a formal argument.
dummy array	A dummy argument that is an array.
dummy pointer	A dummy argument that is a pointer.
dummy procedure	A dummy argument that is specified as a procedure or appears in a procedure reference. The corresponding actual argument must be a procedure.

Dynamic Link Library (DLL)	A separate source module compiled and linked independently of the applications that use it. Applications access the DLL through procedure calls. The code for a DLL is not included in the user's executable image, but the compiler automatically modifies the executable image to point to DLL procedures at run time.
dynamic type	The type of a data entity during execution of a program. The dynamic type of a data entity that is not polymorphic is the same as its declared type.

## Glossary E

---

edit descriptor	A descriptor in a format specification. It can be a data edit descriptor, control edit descriptor, or string edit descriptor. See also <a href="#">control edit descriptor</a> , <a href="#">data edit descriptor</a> , and <a href="#">string edit descriptor</a> .
element	See <a href="#">array element</a> .
elemental	Pertains to an intrinsic operation, intrinsic procedure, or assignment statement that is independently applied to either of the following: <ul style="list-style-type: none"><li>• The elements of an array</li><li>• Corresponding elements of a set of conformable arrays and scalars</li></ul>
end-of-file	The condition that exists when all records in a file open for sequential access have been read.
entity	A general term referring to any Standard Fortran concept; for example, a constant, a variable, a program unit, a statement label, a common block, a construct, an I/O unit and so forth.
environment variable	A symbolic variable that represents some element of the operating system, such as a path, a filename, or other literal data.
error number	An integer value denoting an I/O error condition, obtained by using the <a href="#">IOSTAT</a> keyword in an I/O statement.
error termination	<p>When error termination is initiated on an image, all images terminate execution. If an error condition occurs, error termination is initiated unless the error occurs in one of the following ways:</p> <ul style="list-style-type: none"><li>• During the execution of a statement that specifies a STAT= specifier</li><li>• During the execution of an I/O statement that specifies a STAT= or ERR= specifier</li><li>• During the execution of an intrinsic procedure with a present STAT argument.</li></ul> <p>In these cases, the STAT argument of the intrinsic procedure, or the <i>stat-variable</i> of the STAT= specifier becomes defined with a positive integer value and the program execution continues. See also <a href="#">normal termination</a>.</p>
established coarray	An established coarray is a coarray that is accessible using an image selector.
exceptional values	For floating-point numbers, values outside the range of normalized numbers, including subnormal numbers, infinity, Not-a-Number (NaN) values, zero, and other architecture-defined numbers.
executable construct	A <a href="#">CASE</a> , <a href="#">DO</a> , <a href="#">IF</a> , <a href="#">WHERE</a> , or <a href="#">FORALL</a> construct.
executable program	A set of program units that include only one main program.

executable statement	A statement that specifies an action to be performed or controls one or more computational instructions.
explicit interface	<p>A procedure interface whose properties are known within the scope of the calling program, and do not have to be assumed. These properties are the names of the procedure and its dummy arguments, the attributes of a procedure (if it is a function), and the attributes and order of the dummy arguments.</p> <p>The following have explicit interfaces:</p> <ul style="list-style-type: none"><li>• Internal and module procedures (explicit by definition)</li><li>• Intrinsic procedures</li><li>• External procedures that have an interface block</li><li>• External procedures that are defined by the scoping unit and are recursive</li><li>• Dummy procedures that have an interface block</li></ul>
explicit-shape array	An array whose rank and bounds are specified when the array is declared.
expression	A data reference or a computation formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values.
extended type	An extensible type that is an extension of another type. A type that is declared with the EXTENDS attribute.
extensible type	A type from which new types may be derived using the EXTENDS attribute. A nonsequence type that does not have the BIND attribute.
extent	The size of (number of elements in) one dimension of an array.
external file	A sequence of records that exists in a medium external to the executing program.
external procedure	A procedure that is contained in an external subprogram. External procedures can be used to share information (such as source files, common blocks, and public data in modules) and can be used independently of other procedures and program units. Also called an external routine.
external subprogram	A subroutine or function that is not contained in a main program, module, or another subprogram. A module is not a subprogram.

---

## Glossary F

---

failed image	An image that has not initiated normal or error termination but has stopped participating in program execution due to having executed a FAIL IMAGE statement or for some other reason.
field	<p>Can be either of the following:</p> <ul style="list-style-type: none"><li>• A set of contiguous characters, considered as a single item, in a record or line.</li><li>• A substructure of a <a href="#">STRUCTURE</a> declaration.</li></ul>
field descriptor	See <a href="#">data edit descriptor</a> .
field separator	The comma (,) or slash (/) that separates edit descriptors in a format specification.

field width	The total number of characters in the field. See also <i>field</i> , the first definition.
file	A collection of logically related records. If the file is in internal storage, it is an internal file; if the file is on an input/output device, it is an external file.
file access	The way records are accessed (and stored) in a file. The standard Fortran file access modes are sequential and direct.
file handle	A unique identifier that the system assigns to a file when the file is opened or created. A file handle is valid until the file is closed.
file organization	The way records in a file are physically arranged on a storage device. Standard Fortran files can have sequential or relative organization.
final subroutine	A subroutine whose name appears in a FINAL statement in a type definition. It can be automatically invoked by the processor when an object of that type is finalized.
final task	A task that forces all of its descendant tasks to become included tasks.
fixed-length record type	A file format in which all the records are the same length.
floating-point environment	A collection of registers that control the behavior of floating-point (FP) machine instructions and indicate the current FP status. The floating-point environment may include rounding mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.
focus window	The window to which keyboard input is directed.
foreground process	On Linux* systems, a process for which the command interpreter is waiting. Its process group is the same as that of its controlling terminal, so the process is allowed to read from or write to the terminal. Contrast with <a href="#">background process</a> .
foreground window	The window the user is currently working with. The system assigns a slightly higher priority to the thread that created the foreground window than it does to other threads.
foreign file	An unformatted file that contains data from a foreign platform, such as data from a CRAY*, IBM*, or big endian IEEE* machine.
format	A specific arrangement of data. A <a href="#">FORMAT</a> statement specifies how data is to be read or written.
format specification	The part of a <a href="#">FORMAT</a> statement that specifies explicit data arrangement. It is a list within parentheses that can include edit descriptors and field separators. A character expression can also specify format; the expression must evaluate to a valid format specification.
formatted data	Data written to a file by using formatted I/O statements. Such data contains ASCII representations of binary values.
formatted I/O statement	An I/O statement specifying a format for data transfer. The format specified can be explicit (specified in a format specification) or implicit (specified using list-directed or namelist formatting). Contrast with <a href="#">unformatted I/O statement</a> . See also <a href="#">list-directed I/O statement</a> and <a href="#">namelist I/O statement</a> .
frame window	The outermost <a href="#">parent window</a> in QuickWin.

function	<p>A series of statements that perform some operation and return a single value (through the function or result name) to the calling program unit. A function is invoked by a function reference in a main program unit or a subprogram unit.</p> <p>In Standard Fortran, a function can be used to define a new operator or extend the meaning of an intrinsic operator symbol. The function is invoked by the appearance of the new or extended operator in the expression (along with the appropriate operands). For example, the symbol * can be defined for logical operands, extending its intrinsic definition for numeric operands. See also <i>function subprogram</i>, <i>statement function</i>, and <i>subroutine</i>.</p>
function reference	<p>Used in an expression to invoke a function, it consists of the function name and its actual arguments. A function reference returns a value (through the function or result name) that is used to evaluate the calling expression.</p>
function result	<p>The result value associated with a particular execution or call to a function. This result can be of any data type (including derived type) and can be array-valued. In a <b>FUNCTION</b> statement, the <b>RESULT</b> option can be used to give the result a name different from the function name. This option is required for a recursive function that directly calls itself.</p>
function subprogram	<p>A sequence of statements beginning with a <b>FUNCTION</b> (or optional <b>OPTIONS</b>) statement that is not in an interface block and ending with the corresponding END statement. See also <i>function</i>.</p>

---

## Glossary G

generic identifier	<p>A generic name, operator, or assignment specified in an <b>INTERFACE</b> statement that is associated with all of the procedures within the interface block. Also called a generic specification.</p>
global entity	<p>An entity (a program unit, common block, or external procedure) that can be used with the same meaning throughout the executable program. A global entity has global scope; it is accessible throughout an executable program. See also <i>local entity</i>.</p>
global section	<p>A data structure (for example, global <b>COMMON</b>) or shareable image section potentially available to all processes in the system.</p>

---

## Glossary H

handle	<p>A value (often, but not always, a 32-bit integer) that identifies some operating system resource, for example, a window or a process. The handle value is returned from an operating system call when the resource is created; your program then passes that value as an argument to subsequent operating system routines to identify which resource is being accessed.</p> <p>Your program should consider the handle value a "private" type and not try to interpret it as having any specific meaning (for example, an address).</p>
hexadecimal constant	<p>A constant that is a string of hexadecimal (base 16) digits (range 0 to 9, or an uppercase or lowercase letter in the range A to F) enclosed by apostrophes or quotation marks and preceded by the letter Z.</p>

Hollerith constant	A constant that is a string of printable ASCII characters preceded by $nH$ , where $n$ is the number of characters in the string (including blanks and tabs).
host	Either the main program or subprogram that contains an internal procedure, or the module that contains a module procedure. The data environment of the host is available to the (internal or module) procedure.
host association	The process by which a module procedure, internal procedure, or derived-type definition accesses the entities of its host.

## Glossary I

---

image	An instance of a Fortran program.
image index	An integer value that identifies an image.
image control statement	A statement that affects the execution ordering between images.
implicit interface	A procedure interface whose properties (the collection of names, attributes, and arguments of the procedure) are not known within the scope of the calling program, and have to be assumed. The information is assumed by the calling program from the properties of the procedure name and actual arguments in the procedure call.
implicit typing	The mechanism by which the data type for a variable is determined by the beginning letter of the variable name.
import library	A .LIB file that contains information about one or more dynamic-link libraries (DLLs), but does not contain the DLL's executable code. To provide the information needed to resolve the external references to DLL functions, the linker uses an import library when building an executable module of a process.
included task	A task for which execution is sequentially included in the generating task region; that is, the task is undeferred and executed immediately by the encountering thread.
index	Can be either of the following: <ul style="list-style-type: none"><li>• The variable used as a loop counter in a DO statement.</li><li>• An intrinsic function specifying the starting position of a substring inside a string.</li></ul>
inheritance association	The relationship between the inherited components and the parent component in an extended type.
initial team	The team existing when the program begins execution, consisting of all images. It is the only team that has no parent team, and that has a negative team number (-1).
initialize	The assignment of an initial value to a variable.
inlining	An optimization that replaces a subprogram reference ( <a href="#">CALL</a> statement or <a href="#">function invocation</a> ) with the replicated code of the subprogram.
input/output (I/O)	The data that a program reads or writes. Also, devices to read and write data.
inquiry function	An intrinsic function whose result depends on properties of the principal argument, not the value of the argument.

integer constant	A constant that is a whole number with no decimal point. It can have a leading sign and is interpreted as a decimal number.
intent	An <a href="#">attribute</a> of a dummy argument that is not a procedure or a pointer. It indicates whether the argument is used to transfer data into the procedure, out of the procedure, or both.
interactive process	A process that must periodically get user input to do its work. Contrast with <a href="#">background process</a> .
interface	See <a href="#">procedure interface</a> .
interface block	The sequence of statements starting with an <a href="#">INTERFACE</a> statement and ending with the corresponding END INTERFACE statement.
interface body	The sequence of statements in an interface block starting with a <a href="#">FUNCTION</a> or <a href="#">SUBROUTINE</a> statement and ending with the corresponding END statement. Also called a procedure interface body.
internal file	The designated internal storage space (or variable buffer) that is manipulated during input and output. An internal file can be a character variable, character array, character array element, or character substring. In general, an internal file contains one record. However, an internal file that is a character array has one record for each array element.
internal procedure	A procedure (other than a statement function) that is contained within an internal subprogram. The program unit containing an internal procedure is called the host of the internal procedure. The internal procedure (which appears between a CONTAINS and END statement) is local to its host and inherits the host's environment through host association.
internal subprogram	A subprogram contained in a main program or another subprogram.
intrinsic	Describes entities defined by the Fortran language (such as data types and procedures). Intrinsic entities can be used freely in any scoping unit.
intrinsic procedure	A subprogram supplied as part of the Fortran library that performs array, mathematical, numeric, character, bit manipulation, and other miscellaneous functions. Intrinsic procedures are automatically available to any Fortran program unit (unless specifically overridden by an <a href="#">EXTERNAL</a> statement or a procedure interface block). Also called a built-in or library procedure.
invoke	To call upon; used especially with reference to subprograms. For example, to invoke a function is to execute the function.
iteration count	The number of executions of the DO range, which is determined as follows: $[(\text{terminal value} - \text{initial value} + \text{increment value}) / \text{increment value}]$

---

## Glossary K

---

keyword	See <a href="#">argument keyword</a> and <a href="#">statement keyword</a> .
kind type parameter	Indicates the range of an intrinsic data type; for example: INTEGER(KIND=2). For real and complex types, it also indicates precision. If a specific kind parameter is not specified, the kind is the

default for that type (for example, default integer). See also [default character](#), [default complex](#), [default integer](#), [default logical](#), and [default real](#).

## Glossary L

label	An integer, from 1 to 5 digits long, that precedes a statement and identifies it. For example, labels can be used to refer to a <code>FORMAT</code> statement or branch target statement.
language extension	An Intel® Fortran language element or interpretation that is not part of the Fortran 2018 standard.
lexical token	A sequence of one or more characters that have an indivisible interpretation. A lexical token is the smallest meaningful unit (a basic language element) of a Fortran statement; for example, constants, and statement keywords.
library routines	Files that contain functions, subroutines, and data that can be used by Fortran programs.  For example: one library contains routines that handle the various differences between Fortran and C in argument passing and data types; another contains run-time functions and subroutines for Windows* graphics and QuickWin* applications.  Some library routines are intrinsic (automatically available) to Fortran; others may require a specific <a href="#">USE statement</a> to access the module defining the routines. See also <a href="#">intrinsic procedure</a> .
line	A source form record consisting of 0 or more characters. A standard Fortran line is limited to a maximum of 132 characters.
linker	A system program that creates an executable program from one or more object files produced by a language compiler or assembler. The linker resolves external references, acquires referenced library routines, and performs other processing required to create Linux* and Windows* executable files.
list-directed I/O statement	An implicit, formatted I/O statement that uses an asterisk (*) specifier rather than an explicit format specification. See also <a href="#">formatted I/O statement</a> and <a href="#">namelist I/O statement</a> .
listing	A printed copy of a program.
literal constant	A constant without a name; its value is directly specified in a program. See also <a href="#">named constant</a> .
little endian	A method of data storage in which the least significant bit of a numeric value spanning multiple bytes is in the lowest addressed byte. This is the method used on Intel® systems. Contrast with <a href="#">big endian</a> .
local entity	An entity that can be used only within the context of a subprogram (its scoping unit); for example, a statement label. A local entity has local scope. See also <a href="#">global entity</a> .
local optimization	A level of optimization enabling optimizations within the source program unit and recognition of common expressions. See also <a href="#">optimization</a> .
local symbol	A name defined in a program unit that is not accessible outside of that program unit.

logical constant	A constant that specifies the value <code>.TRUE.</code> or <code>.FALSE.</code> .
logical expression	An integer or logical constant, variable, function value, or another constant expression, joined by a relational or logical operator. The logical expression is evaluated to a value of either true or false. For example, <code>.NOT. 6.5 + (B .GT. D)</code> .
logical operator	A symbol that represents an operation on logical expressions. The logical operators are <code>.AND.</code> , <code>.OR.</code> , <code>.NEQV.</code> , <code>.XOR.</code> , <code>.EQV.</code> , and <code>.NOT.</code> .
logical unit	A channel in memory through which data transfer occurs between the program and the device or file. See also <a href="#">unit identifier</a> .
longword	Four contiguous bytes (32 bits) starting on any addressable byte boundary. Bits are numbered 0 to 31. The address of the longword is the address of the byte containing bit 0. When the longword is interpreted as a signed integer, bit 31 is the sign bit. The value of signed integers is in the range $-2^{31}$ to $2^{31}-1$ . The value of unsigned integers is in the range 0 to $2^{32}-1$ .
loop	A group of statements that are executed repeatedly until an ending condition is reached.
loosely structured block	A group of Fortran statements that do not begin with a Fortran BLOCK statement. See also <a href="#">strictly structured block</a> .
lower bounds	See <a href="#">bounds</a> .

## Glossary M

---

main program	The first program unit to receive control when a program is run; it exercises control over subprograms. The main program usually contains a <a href="#">PROGRAM</a> statement (or does not contain a SUBROUTINE, FUNCTION, or BLOCK DATA statement). Contrast with <a href="#">subprogram</a> .
makefile	<p>On Linux* and macOS systems, an argument to the make command containing a sequence of entries that specify dependencies. On Windows* systems, a file passed to the NMAKE utility containing a sequence of entries that specify dependencies. The contents of a makefile override the system built-in rules for maintaining, updating, and regenerating groups of programs.</p> <p>For more information on makefiles on Linux* and macOS systems, see <code>make(1)</code>. For more information on using makefiles, see <i>Using Makefiles to Compile Your Application in Compiler Setup</i>.</p>
many-one array section	An array section with a vector subscript having two or more elements with the same value.
master thread	This is a deprecated term. In an OpenMP* Fortran program, the thread that creates a team of threads when a parallel region ( <a href="#">PARALLEL construct</a> ) is encountered. The statements in the parallel region are then executed in parallel by each thread in the team. At the end of the parallel region, the team threads synchronize and only the master thread continues execution. See also <a href="#">thread</a> and <a href="#">primary thread</a> .
merged task	A task whose data environment, inclusive of internal control variables, is the same as the data environment of its generating task region. Internal control variables (ICVs) are discussed in the latest OpenMP* specifications.

message file	A Linux* and macOS catalog that contains the diagnostic message text of errors that can occur during program execution (runtime).
metacommand	See <a href="#">compiler directive</a> .
misaligned data	Data not aligned on a natural boundary. See also <a href="#">natural boundary</a> .
module	A program unit that contains specifications and definitions that other program units can access (unless the module entities are declared <a href="#">PRIVATE</a> ). <a href="#">Modules</a> are referenced in <a href="#">USE</a> statements.
module procedure	A subroutine or function that is not an internal procedure and is contained in a module. The <a href="#">module procedure</a> appears between a CONTAINS and END statement in its host module, and inherits the host module's environment through host association. A module procedure can be declared PRIVATE to the module; it is public by default.
multibyte character set	A character set in which each character is identified by using more than one byte. Although Unicode characters are 2 bytes wide, the Unicode character set is not referred to by this term.
multitasking	The ability of an operating system to execute several programs (tasks) at once.
multithreading	The ability of an operating system to execute different parts of a program, called <a href="#">threads</a> , simultaneously. If the system supports parallel processing, multiple processors may be used to execute the threads.

## Glossary N

---

name	<p>Identifies an entity within a Fortran program unit (such as a variable, function result, common block, named constant, procedure, program unit, namelist group, or dummy argument).</p> <p>A name can contain letters, digits, underscores ( <code>_</code> ), and the dollar sign ( <code>\$</code> ) special character. The first character must be a letter or a dollar sign. In earlier versions of Fortran, this term was called a symbolic name.</p>
name association	Pertains to argument, host, or use association. See also <a href="#">argument association</a> , <a href="#">host association</a> , and <a href="#">use association</a> .
named common block	A common block (one or more contiguous areas of storage) with a name. Common blocks are defined by a <a href="#">COMMON</a> statement.
named constant	A constant that has a name. In earlier versions of Fortran, this term was called a symbolic constant.
namelist I/O statement	An implicit, formatted I/O statement that uses a namelist group specifier rather than an explicit format specifier. See also <a href="#">formatted I/O statement</a> and <a href="#">list-directed I/O statement</a> .
NaN	Not-a-Number. The condition that results from a floating-point operation that has no mathematical meaning; for example, zero divided by zero.
natural boundary	The virtual address of a data item that is the multiple of the size of its data type. For example, a REAL(8) (REAL*8) data item aligned on natural boundaries has an address that is a multiple of eight.

naturally aligned record	A record that is aligned on a hardware-specific natural boundary; each field is naturally aligned. Contrast with <a href="#">packed record</a> .
nesting	The placing of one entity (such as a construct, subprogram, format specification, or loop) inside another entity of the same kind. For example, nesting a loop within another loop (a nested loop), or nesting a subroutine within another subroutine (a nested subroutine).
nonexecutable statement	A Fortran statement that describes program attributes, but does not cause any action to be taken when the program is executed.
nonsignaled	The state of an object used for synchronization in one of the wait functions is either signaled or nonsignaled. A nonsignaled state can prevent the wait function from returning. See also <a href="#">wait function</a> .
normal termination	<p>Normal termination of an image is initiated when the image executes a STOP statement or an END [PROGRAM] statement. The image becomes a stopped image. Its coarrays remain accessible to other active images and may be defined or referenced by them.</p> <p>When the last active image initiates normal termination, all images terminate execution. See also <a href="#">error termination</a>.</p>
numeric expression	A numeric constant, variable, or function value, or combination of these, joined by numeric operators and parentheses, so that the entire expression can be evaluated to produce a single numeric value. For example, -L or X+(Y-4.5*Z).
numeric operator	A symbol designating an arithmetic operation. In Standard Fortran, the symbols +, -, *, /, and ** are used to designate addition, subtraction, multiplication, division, and exponentiation, respectively.
numeric storage unit	The unit of storage for holding a non-pointer scalar value of type default real, default integer, or default logical. One numeric storage unit corresponds to 4 bytes of memory.
numeric type	Integer, real, or complex type.

---

## Glossary O

---

object	See <a href="#">data object</a> .
object file	The binary output of a language processor (such as an assembler or compiler), which can either be executed or used as input to the linker.
obsolescent feature	A feature of earlier versions of Fortran that is considered to be redundant in Fortran 2018. These features are still in frequent use.
octal constant	A constant that is a string of octal (base 8) digits (range of 0 to 7) enclosed by apostrophes or quotation marks and preceded by the letter O.
operand	The passive element in an expression on which an operation is performed. Every expression must have at least one operand. For example, in I .NE. J, I and J are operands. Contrast with <i>operator</i> .
operation	A computation involving one or two operands.
operator	The active element in an expression that performs an operation. An expression can have zero or more operators. Intrinsic operators are arithmetic (+, -, *, /, and **) or logical (.AND., .NOT., and so on). For example, in I .NE. J, .NE. is the operator.

	Executable programs can define operators which are not intrinsic.
optimization	The process of producing efficient object or executing code that takes advantage of the hardware architecture to produce more efficient execution.
optional argument	A dummy argument that has the <a href="#">OPTIONAL</a> attribute (or is included in an <a href="#">OPTIONAL</a> statement in the procedure definition). This kind of argument does not have to be associated with an actual argument when its procedure is invoked.
order of subscript progression	A characteristic of a multidimensional array in which the leftmost subscripts vary most rapidly. Also called column-major order.
overflow	An error condition occurring when an arithmetic operation yields a result that is larger than the maximum value in the range of a data type.

## Glossary P

---

packed record	A record that starts on an arbitrary byte boundary; each field starts in the next unused byte. Contrast with <a href="#">naturally aligned record</a> .
pad	The filling of unused positions in a field or character string with dummy data (such as zeros or blanks).
parallel processing	The simultaneous use of more than one processor (CPU) to execute a program.
parameter	Can be either of the following: <ul style="list-style-type: none"><li>• In general, any quantity of interest in a given situation; often used in place of the term "argument".</li><li>• A Fortran named constant.</li></ul>
parent component	The component of an entity of extended type that corresponds to its inherited portion.
parent process	A process that initiates and controls another process (child). The parent process defines the environment for the child process. Also, the parent process can suspend or terminate without affecting the child process. See also <a href="#">child process</a> .
parent team	The team that executes a <code>FORM TEAM</code> statement is the parent team of the teams formed by execution of the <code>FORM TEAM</code> statement.
parent window	A window that has one or more child windows. See also <a href="#">child window</a> .
parent type	The extensible type from which an extended type is derived.
passed-object dummy argument	The dummy argument of a type-bound procedure or procedure pointer component that becomes associated with the object through which the procedure was invoked.
pathname	The path from the root directory to a subdirectory or file. See also <a href="#">root</a> .
pipe	A connection that allows one program to get its input directly from the output of another program.
platform	A combination of operating system and hardware that provides a distinct environment in which to use a software product (for example, Microsoft* Windows* on processors using Intel® 64 architecture).

pointer	<p>A pointer is either a data pointer or a procedure pointer. A data pointer is a data entity that has the <code>POINTER</code> attribute. A procedure pointer is a procedure entity that has the <code>POINTER</code> attribute.</p> <p>A pointer is associated with a target by pointer assignment. A data pointer can also be associated with a target by allocation. A pointer that is not associated must not be referenced or defined.</p> <p>A disassociated pointer is not associated with a target. A pointer is disassociated following one of these events:</p> <ul style="list-style-type: none"><li>• Execution of a <code>NULLIFY</code> statement</li><li>• Pointer assignment with a disassociated pointer</li><li>• Default initialization</li><li>• Explicit initialization</li></ul> <p>A data pointer can also be disassociated by execution of a <code>DEALLOCATE</code> statement.</p> <p>If a data pointer is an array, the rank is declared, but the extents are determined when the pointer is associated with a target.</p> <p>A data pointer is one of the following:</p> <ul style="list-style-type: none"><li>• <a href="#">A Fortran pointer</a> A data object that has the <code>POINTER</code> attribute. To be referenced or defined, it must be "pointer-associated" with a target (have storage space associated with it). If the pointer is an array, it must be pointer-associated to have a shape. See also <i>pointer association</i>.</li><li>• <a href="#">An integer pointer</a> A data object that contains the address of its paired variable. This is also called a Cray* pointer.</li></ul>
pointer assignment	The association of a pointer with a target by the execution of a pointer assignment statement or the execution of an assignment statement for a data object of derived type having the pointer as a subobject.
pointer association	The association of storage space to a Fortran pointer by means of a target. A pointer is associated with a target after pointer assignment or the valid execution of an <a href="#">ALLOCATE</a> statement.
polymorphic object	An object that can have different types during program execution. An object declared with the <code>CLASS</code> keyword is polymorphic.
potential subobject component	For a derived type or a structure, a nonpointer component or a potential subobject component of a nonpointer component.
preceding task	A task that must complete execution prior to execution of its dependent task(s). See also <a href="#">dependent task</a> and <a href="#">task dependence</a> .
precision	The number of significant digits in a real number. See also <a href="#">double-precision constant</a> , <a href="#">kind type parameter</a> , and <a href="#">single-precision constant</a> .
primary	<p>The simplest form of an expression. A primary can be any of the following data objects:</p> <ul style="list-style-type: none"><li>• A constant</li><li>• A constant subobject (parent is a constant)</li><li>• A variable (scalar, structure, array, or pointer; an array cannot be assumed size)</li><li>• An array constructor</li><li>• A structure constructor</li></ul>

- A function reference
- An expression in parentheses

primary thread	In an OpenMP* Fortran program, the thread that creates a team of threads when a parallel region ( <a href="#">PARALLEL construct</a> ) is encountered. The statements in the parallel region are then executed in parallel by each thread in the team. At the end of the parallel region, the team threads synchronize and only the primary thread continues execution. See also <a href="#">thread</a> .
procedure	A computation that can be invoked during program execution. It can be a subroutine or function, an internal, external, dummy or module procedure, or a statement function. A subprogram can define more than one procedure if it contains an ENTRY statement. See also <a href="#">subprogram</a> .
procedure interface	<p>The statements that specify the name and characteristics of a procedure, the name and characteristics of each dummy argument, and the generic identifier (if any) by which the procedure can be referenced. The characteristics of a procedure are fixed, but the remainder of the interface can change in different scoping units.</p> <p>If these properties are all known within the scope of the calling program, the procedure interface is explicit; otherwise it is implicit (deduced from its reference and declaration).</p>
process object	A virtual address space, security profile, a set of threads that execute in the address space of the process, and a set of resources visible to all threads executing in the process. Several thread objects can be associated with a single process.
program	A set of instructions that can be compiled and executed by itself. Program blocks contain a declaration and an executable section.
program section	A particular common block or local data area for a particular routine containing equivalence groups.
program unit	The fundamental component of an executable program. A sequence of statements and comment lines. It can be a main program, a module, an external subprogram, or a block data program unit.

## Glossary Q

---

quadword	Four contiguous words (64 bits) starting on any addressable byte boundary. Bits are numbered 0 to 63. (Bit 63 is used as the sign bit.) A quadword is identified by the address of the word containing the low-order bit (bit 0). The value of a signed quadword integer is in the range $-2^{63}$ to $2^{63}-1$ .
----------	--

## Glossary R

---

random access	See <a href="#">direct access</a> .
rank	The number of dimensions of an array. A scalar has a rank of zero.
rank-one object	A data structure comprising scalar elements with the same data type and organized as a simple linear sequence. See also <a href="#">scalar</a> .

real constant	A constant that is a number written with a decimal point, exponent, or both. It can have single precision (REAL(KIND=4)), double precision (REAL(KIND=8)), or quad precision (REAL(KIND=16)).
record	<p>Can be either of the following:</p> <ul style="list-style-type: none"><li>• A set of logically related data items (in a file) that is treated as a unit; such a record contains one or more fields. This definition applies to I/O records and items that are declared in a record structure.</li><li>• One or more data items that are grouped in a structure declaration and specified in a <a href="#">RECORD</a> statement.</li></ul>
record access	The method used to store and retrieve records in a file.
record structure declaration	A block of statements that define the fields in a record. The block begins with a <a href="#">STRUCTURE</a> statement and ends with END STRUCTURE. The name of the structure must be specified in a RECORD statement.
record type	The property that determines whether records in a file are all the same length, of varying length, or use other conventions to define where one record ends and another begins.
recursion	Pertains to a subroutine or function that directly or indirectly references itself.
reduction scoping clause	OpenMP* directive clauses that define the region in which a reduction is computed by tasks or Single Instruction Multiple Data (SIMD) instructions.
reference	<p>Can be any of the following:</p> <ul style="list-style-type: none"><li>• For a data object, the appearance of its name, designator, or associated pointer where the value of the object is required. When an object is referenced, it must be defined.</li><li>• For a procedure, the appearance of its name, operator symbol, or assignment symbol that causes the procedure to be executed. Procedure reference is also called "calling" or "invoking" a procedure.</li><li>• For a module, the appearance of its name in a <a href="#">USE</a> statement.</li></ul>
relational expression	An expression containing one relational operator and two operands of numeric or character type. The result is a value that is true or false. For example, A-C .GE. B+2 or DAY .EQ. 'MONDAY'.
relational operator	The symbols used to express a relational condition or expression. The relational operators are (.EQ., .NE., .LT., .LE., .GT., and .GE.).
relative file organization	A file organization that consists of a series of component positions, called cells, numbered consecutively from 1 to n. Intel Fortran uses these numbered, fixed-length cells to calculate the component's physical position in the file.
relative pathname	A directory path expressed in relation to any directory other than the root directory. Contrast with <a href="#">absolute pathname</a> .
root	<p>On Windows* systems, the top-level directory on a disk drive; it is represented by a backslash (\). For example, C:\ is the root directory for drive C.</p> <p>On Linux* systems, the top-level directory in the file system; it is represented by a slash (/).</p>
routine	A subprogram; a function or procedure. See also <a href="#">function</a> , <a href="#">subroutine</a> , and <a href="#">procedure</a> .

run time	The time during which a computer executes the statements of a program.
----------	--

## Glossary S

saved object	A variable that retains its association status, allocation status, definition status, and value after execution of a RETURN or END statement in the scoping unit containing the declaration.
scalar	Pertaining to data items with a rank of zero. A single data object of any intrinsic or derived data type. Contrast with <a href="#">array</a> . See also <a href="#">rank-one object</a> .
scalar memory reference	A reference to a scalar variable, scalar record field, or array element that resolves into a single data item (having a data type) and can be assigned a value with an assignment statement. It is similar to a scalar reference, but it excludes constants, character substrings, and expressions.
scalar reference	A reference to a scalar variable, scalar record field, derived-type component, array element, constant, character substring, or expression that resolves into a single data item having a data type.
scalar variable	A variable name specifying one storage location.
scale factor	A number indicating the location of the decimal point in a real number and, if there is no exponent, the size of the number on input.
scope	The portion of a program in which a declaration or a particular name has meaning. Scope can be global (throughout an executable program), scoping unit (local to the scoping unit), or statement (within a statement, or part of a statement).
scoping unit	<p>The part of the program in which a name has meaning. It is one of the following:</p> <ul style="list-style-type: none"> <li>• A program unit or subprogram</li> <li>• A derived-type definition</li> <li>• A procedure interface body</li> </ul> <p>Scoping units cannot overlap, though one scoping unit can contain another scoping unit. The outer scoping unit is called the host scoping unit.</p>
screen coordinates	Coordinates relative to the upper left corner of the screen.
section subscript	A subscript list (enclosed in parentheses and appended to the array name) indicating a portion (section) of an array. At least one of the subscripts in the list must be a subscript triplet or vector subscript. The number of section subscripts is the rank of the array. See also <a href="#">array section</a> , <a href="#">vector subscript</a> , and <i>subscript</i> and <i>subscript triplet</i> , which appear below.
seed	<p>A value (which can be assigned to a variable) that is required in order to properly determine the result of a calculation; for example, the argument <i>k</i> in the random number generator (RAN) function syntax:</p> <pre>y = RAN (k)</pre>
selector	<p>A mechanism for designating the following:</p> <ul style="list-style-type: none"> <li>• Part of a data object (an array element or section, a substring, a derived type, or a structure component)</li> <li>• The set of values for which a <a href="#">CASE</a> block is executed</li> </ul>

sequence	A set ordered by a one-to-one correspondence with the numbers 1 through $n$ , where $n$ is the total number of elements in the sequence. A sequence can be empty (contain no elements).
sequential access	A method for retrieving or storing data in which the data (record) is read from, written to, or removed from a file based on the logical order (sequence) of the record in the file. (The record cannot be accessed directly.) Contrast with <a href="#">direct access</a> .
sequential file organization	A file organization in which records are stored one after the other, in the order in which they were written to the file.
shape	The rank and extents of an array. Shape can be represented by a rank-one array (vector) whose elements are the extents in each dimension.
shape conformance	Pertains to the rule concerning operands of binary intrinsic operations in expressions: to be in shape conformance, the two operands must both be arrays of the same shape, or one or both of the operands must be scalars.
short field termination	The use of a comma (,) to terminate the field of a numeric data edit descriptor. This technique overrides the field width (w) specification in the data edit descriptor and therefore avoids padding of the input field. The comma can only terminate fields less than w characters long. See also <a href="#">data edit descriptor</a> .
sibling team	Two teams are sibling teams if they were created by execution of the same FORM TEAM statement.
signal	The software mechanism used to indicate that an exception condition (abnormal event) has been detected. For example, a signal can be generated by a program or hardware error, or by request of another program.
single-precision constant	A processor approximation of the value of a real number that occupies 4 bytes of memory and can assume a positive, negative, or zero value. The precision is less than a constant of double-precision type. For the precise ranges of the single-precision constants, see Data Representation Overview in the <i>Compiler Reference</i> . See also <i>subnormal number</i> , which appears below.
size	The total number of elements in an array (the product of the extents).
source file	A program or portion of a program library, such as an object file, or image file.
specification expression	A restricted expression that is of type integer and has a scalar value. This type of expression appears only in the declaration of array bounds and character lengths.
specification statement	A nonexecutable statement that provides information about the data used in the source program. Such a statement can be used to allocate and initialize variables, arrays, records, and structures, and define other characteristics of names used in a program.
statement	<p>An instruction in a programming language that represents a step in a sequence of actions or a set of declarations. In Standard Fortran, an ampersand can be used to continue a statement from one line to another, and a semicolon can be used to separate several statements on one line.</p> <p>There are two main classes of statements: executable and nonexecutable.</p>

statement function	A computing procedure defined by a single statement in the same program unit in which the procedure is referenced.
statement function definition	<p>A statement that defines a statement function. Its form is the statement function name (followed by its optional dummy arguments in parentheses), followed by an equal sign (=), followed by a numeric, logical, or character expression.</p> <p>A statement function definition must precede all executable statements and follow all specification statements.</p>
statement keyword	A word that begins the syntax of a statement. All program statements (except assignment statements and statement function definitions) begin with a statement keyword. Examples are INTEGER, DO, IF, and WRITE.
statement label	See <a href="#">label</a> .
static variable	A variable whose storage is allocated for the entire execution of a program.
stopped image	An image that has begun normal termination, either by execution of a STOP statement, or by execution of an END statement or END PROGRAM statement terminating the main program.
storage association	The relationship between two storage sequences when the storage unit of one is the same as the storage unit of the other. Storage association is provided by the <a href="#">COMMON</a> and <a href="#">EQUIVALENCE</a> statements. For modules, pointers, allocatable arrays, and automatic data objects, the <a href="#">SEQUENCE</a> statement defines a storage order for structures.
storage location	An addressable unit of main memory.
storage sequence	A sequence of any number of consecutive storage units. The size of a storage sequence is the number of storage units in the storage sequence. A sequence of storage sequences forms a composite storage sequence. See also <i>storage association</i> and <i>storage unit</i> .
storage unit	In a storage sequence, the number of storage units needed to represent one real, integer, logical, or character value. See also <a href="#">character storage unit</a> , <a href="#">numeric storage unit</a> , and <i>storage sequence</i> .
strictly structured block	A Fortran BLOCK construct. See also <a href="#">loosely structured block</a> .
stride	The increment between subscript values that can optionally be specified in a subscript triplet. If it is omitted, it is assumed to be one.
string edit descriptor	A format descriptor that transfers characters to an output record.
structure	<p>Can be either of the following:</p> <ul style="list-style-type: none"><li>• A scalar data object of derived (user-defined) type.</li><li>• An aggregate entity containing one or more fields or components.</li></ul>
structure component	<p>Can be either of the following:</p> <ul style="list-style-type: none"><li>• One of the components of a structure.</li><li>• An array whose elements are components of the elements of an array of derived type.</li></ul>
structure constructor	<p>A mechanism that is used to specify a scalar value of a derived type. A structure constructor is the name of the type followed by a parenthesized list of values for the components of the type.</p>

subnormal number	A computational floating-point result smaller than the lowest value in the normal range of a data type (the smallest representable normalized number). You cannot write a constant for a subnormal number. Older floating-point standard documents used the term <i>denormal</i> ; newer standards call such numbers <i>subnormal</i> .
subobject	Part of a data object (parent object) that can be referenced and defined separately from other parts of the data object. A subobject can be an array element, an array section, a substring, a derived type, or a structure component. Subobjects are referenced by designators and can be considered to be data objects themselves. See also <a href="#">designator</a> .
subobject designator	See <a href="#">designator</a> .
subprogram	A function or subroutine subprogram that can be invoked from another program unit to perform a specific task. A subprogram can define more than one procedure if it contains an ENTRY statement. Contrast with <a href="#">main program</a> . See also <a href="#">procedure</a> .
subroutine	<p>A procedure that can return many values, a single value, or no value to the calling program unit (through arguments). A subroutine is invoked by a <a href="#">CALL</a> statement in another program unit.</p> <p>In recent versions of Fortran, a subroutine can also be used to specify a defined assignment. Such assignments are invoked with an ASSIGNMENT(=) interface block rather than the CALL statement. See also <a href="#">function</a>, <i>statement function</i>, and <i>subroutine subprogram</i>.</p>
subroutine subprogram	A sequence of statements starting with a <a href="#">SUBROUTINE</a> (or optional <a href="#">OPTIONS</a> ) statement and ending with the corresponding END statement. See also <i>subroutine</i> .
subscript	A scalar integer expression (enclosed in parentheses and appended to the array name) indicating the position of an array element. The number of subscripts is the rank of the array. See also <a href="#">array element</a> .
subscript triplet	An item in a section subscript list specifying a range of values for the array section. A subscript triplet contains at least one colon and has three optional parts: a lower bound, an upper bound, and a stride. Contrast with <a href="#">vector subscript</a> . See also <a href="#">array section</a> and <i>section subscript</i> .
substring	A contiguous portion of a scalar character string. Do not confuse this with the substring selector in an array section, where the result is another array section, not a substring.
symbolic name	See <a href="#">name</a> .
syntax	The formal structure of a statement or command string.

---

## Glossary T

---

target	The named data object associated with a pointer (in the form pointer-object => target). A target is declared in a type declaration statement that contains the <a href="#">TARGET</a> attribute. See also <a href="#">pointer</a> and <a href="#">pointer association</a> .
task dependence	An ordering between two sibling tasks; one is the dependent task and the other is the preceding task. The dependence is satisfied upon completion of the preceding task. See also <a href="#">dependent task</a> and <a href="#">preceding task</a> .

team	An ordered set of images, either the initial team, or created by execution of a FORM TEAM statement.
team number	A positive integer value that identifies a team created by a FORM TEAM statement. It is assigned to the team during the execution of a FORM TEAM statement. Only the initial team has a team number which is negative (-1).
team variable	Is a scalar variable of type TEAM_TYPE defined in the intrinsic module ISO_FORTRAN_ENV. The values of the team variables on all images of the team fully describe the team. Each image on the team has a unique copy of the team variable. A team variable for an active team may not be defined or become undefined during the execution of the CHANGE TEAM construct that made that team an active team.
thread	Part of a program that can run at the same time as other parts, usually with some form of communication and/or synchronization among the threads. See also <a href="#">multithreading</a> .
transformational function	An intrinsic function that is not an elemental or inquiry function. A transformational function usually changes an array actual argument into a scalar result or another array, rather than applying the argument element by element.
truncation	Can be either of the following: <ul style="list-style-type: none"><li>• A technique that approximates a numeric value by dropping its fractional value and using only the integer portion.</li><li>• The process of removing one or more characters from the left or right of a number or string.</li></ul>
type declaration statement	A nonexecutable statement specifying the data type of one or more variables: an INTEGER, REAL, DOUBLE PRECISION, COMPLEX, DOUBLE COMPLEX, CHARACTER, LOGICAL, or TYPE statement. A type declaration statement may also specify attributes for the variables. Also called a type declaration or type specification.
type parameter	Defines an intrinsic data type. The type parameters are kind and length. The kind type parameter (KIND=) specifies the range for the integer data type, the precision and range for real and complex data types, and the machine representation method for the character and logical data types. The length type parameter (LEN=) specifies the length of a character string. See also <a href="#">kind type parameter</a> .
type-bound procedure	A procedure that is bound to a derived type and referenced by means of an object of that type.

---

## Glossary U

---

ultimate component	For a derived type or a structure, a component that is of intrinsic type or has the <a href="#">ALLOCATABLE</a> or <a href="#">POINTER</a> attribute, or an ultimate component of a component that is a derived type and does not have the ALLOCATABLE or POINTER attribute.
unary operator	An operator that operates on one operand. For example, the minus sign in -A and the .NOT. operator in .NOT. (J .GT. K).
underrun task	A task for which execution is not deferred with respect to its generating task region; that is, its generating task region is suspended until execution of the underrun task has finished.
undefined	For a data object, the property of not having a determinate value.

underflow	An error condition occurring when the result of an arithmetic operation yields a result that is smaller than the minimum value in the range of a data type. For example, in unsigned arithmetic, underflow occurs when a result is negative. See also <a href="#">subnormal number</a> .
unformatted data	Data written to a file by using unformatted I/O statements; for example, binary numbers.
unformatted I/O statement	An I/O statement that does not contain format specifiers and therefore does not translate the data being transferred. Contrast with <a href="#">formatted I/O statement</a> .
unformatted record	A record that is transmitted in internal format between internal and external storage.
unit identifier	<p>The identifier that specifies an external unit or internal file. The identifier can be any one of the following:</p> <ul style="list-style-type: none"><li>• An integer expression whose value must be zero or positive</li><li>• An asterisk (*) that corresponds to the default (or implicit) I/O unit</li><li>• The name of a character scalar memory reference or character array name reference for an internal file</li></ul> <p>Also called a device code, or logical unit number.</p>
unspecified storage unit	A unit of storage for holding a pointer or a scalar that is not a pointer and is of type other than default integer, default character, or default real.
upper bounds	See <a href="#">bounds</a> .
use association	The process by which the entities in a module are made accessible to other scoping units (through a <a href="#">USE</a> statement in the scoping unit).
user-defined assignment	See <a href="#">defined assignment</a> .
user-defined operator	See <a href="#">defined operation</a> .
user-defined type	See <a href="#">derived type</a> .

## Glossary V

---

variable	A data object (stored in a memory location) whose value can change during program execution. A variable can be a named data object, an array element, an array section, a structure component, or a substring. In FORTRAN 77, a variable was always scalar and named. Contrast with <a href="#">constant</a> .
variable format expression	A numeric expression enclosed in angle brackets (< >) that can be used in a <a href="#">FORMAT</a> statement. If necessary, it is converted to integer type before use.
variable-length record type	A file format in which records may be of different lengths.
vector subscript	A rank-one array of integer values used as a section subscript to select elements from a parent array. Unlike a subscript triplet, a vector subscript specifies values (within the declared bounds for the dimension) in an arbitrary order. Contrast with <a href="#">subscript triplet</a> . See also <a href="#">array section</a> and <a href="#">section subscript</a> .

## Glossary W

---

wait function	A function that blocks the execution of a calling thread until a specified set of conditions has been satisfied.
whole array	An array reference (for example, in a type declaration statement) that consists of the array name alone, without subscript notation. Whole array operations affect every element in the array. See also <a href="#">array</a> .

## Glossary Z

---

zero-sized array	An array with at least one dimension that has at least one extent of zero. A zero-sized array has a size of zero and contains no elements. See also <a href="#">array</a> .
------------------	---

# Compilation

This section contains information about features that can affect compilation, such as environment variables, and using configuration files.

## Supported Environment Variables

You can customize your system environment by specifying paths where the compiler searches for certain files such as libraries, include files, configuration files, and certain settings.

### Compiler Compile-Time Environment Variables

The following table shows the compile-time environment variables that affect the compiler:

Compile-Time Environment Variable	Description
IFORTCFG	<p>Specifies a configuration file that the compiler should use instead of the default configuration file.</p> <p>By default, the compiler uses the default configuration file (ifort.cfg) from the same directory where the compiler executable resides.</p> <hr/> <p><b>NOTE</b> On Windows, this environment variable cannot be set from Visual Studio*.</p>
INTEL_LICENSE_FILE	<p>Specifies the location for the Intel license file.</p> <hr/> <p><b>NOTE</b> On Windows, this environment variable cannot be set from Visual Studio.</p>
__INTEL_PRE_FFLAGS __INTEL_POST_FFLAGS	<p>Specifies a set of compiler options to add to the compile line.</p> <p>This is an extension to the facility already provided in the compiler configuration file ifort.cfg.</p> <hr/> <p><b>NOTE</b> By default, a configuration file named ifort.cfg is used. This file is in the same directory as the compiler executable. To use another configuration file in another location, you can use the IFORTCFG environment variable to assign the directory and file name for the configuration file.</p> <hr/> <p>You can insert command line options in the prefix position using __INTEL_PRE_FFLAGS , or in the suffix position using __INTEL_POST_FFLAGS. The command line is built as follows:</p>

Compile-Time Environment Variable	Description
	<p><b>Syntax:</b> <code>ifort &lt;PRE flags&gt; &lt;flags from configuration file&gt; &lt;flags from the compiler invocation&gt; &lt;POST flags&gt;</code></p> <hr/> <p><b>NOTE</b> The driver issues a warning that the compiler is overriding an option because of an environment variable, but only when you include the option <code>/W5</code> (Windows) or <code>-w3</code> (Linux and macOS).</p> <hr/>
INTEL_TARGET_ARCH_IA32 (Linux and Windows)	<p>Set this environment variable to target 32-bit compilations for all associated tools (this includes the compiler and Intel-specific linker tools). Without this environment variable, you will be required to use the explicit command line options, <code>/Qm32</code> on Windows and <code>-m32</code> on Linux, for each compiler invocation.</p> <hr/> <p><b>NOTE</b> IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release.</p> <hr/>
PATH	<p>Specifies the directories the system searches for binary executable files.</p> <hr/> <p><b>NOTE</b> On Windows, this also affects the search for Dynamic Link Libraries (DLLs).</p> <hr/>
TMP TMPDIR TEMP	<p>Specifies the location for temporary files. If none of these are specified, or writeable, or found, the compiler stores temporary files in <code>/tmp</code> (Linux, macOS) or the current directory (Windows).</p> <p>The compiler searches for these variables in the following order: <code>TMP</code>, <code>TMPDIR</code>, and <code>TEMP</code>.</p> <hr/> <p><b>NOTE</b> On Windows, these environment variables cannot be set from Visual Studio.</p> <hr/>
LD_LIBRARY_PATH (Linux)	<p>Specifies the location for shared objects (.so files).</p>
DYLD_LIBRARY_PATH (macOS)	<p>Specifies the path for dynamic libraries.</p>
INCLUDE (Windows)	<p>Specifies the directory path for the include files (files included by <code>INCLUDE</code> statements, <code>#include</code> files, <code>RC INCLUDE</code> files<sup>1</sup>, and module files referenced by <code>USE</code> statements).</p> <p><sup>1</sup> Files from the Resource Compiler, used to create dialog boxes and other Windows-GUI interfaces.</p>
LIB (Windows)	<p>Specifies the directories for all libraries used by the compiler and linker.</p>
<b>GNU Environment Variables and Extensions</b>	

Compile-Time Environment Variable	Description
CPATH (Linux and macOS)	Specifies the path for include and module files.
LIBRARY_PATH (Linux and macOS)	Specifies the path for libraries to be used during the link phase.

**NOTE** INTEL\_ROOT is an environment variable that is reserved for the Intel® Compiler. Its use is not supported.

## Compiler Runtime Environment Variables

The Intel® Fortran Compiler runtime system recognizes a number of environment variables. These variables can be used to customize runtime diagnostic error reporting, allow program continuation under certain conditions, disable the display of certain dialog boxes under certain conditions, and allow just-in-time debugging.

Environment variables relating to file I/O are interpreted when the file is opened. Other variables are read when the program starts.

The order of precedence for runtime environment variables is:

1. OPEN keyword
2. Environment variable(s)
3. Command line option

For Fortran runtime environment variables that are boolean (either enabled or disabled), the following tables describe values you can use to enable or disable them. These rules do not apply to environment variables for OpenMP\* (OMP\_) and their extensions (KMP\_), or PGO.

Setting a Runtime Environment Variable to ON or OFF	Examples
An integer composed entirely of digits other than 0 enables the environment variable.	1 4938493848
A string starting with <b>t</b> or <b>T</b> , <b>y</b> or <b>Y</b> , enables the environment variable.	T t
Because you cannot include quotes, or spaces preceding the string, " <b>T</b> " and ' <b>YES</b> ' do not work, because both spaces and quotation marks are considered letters.	TRUE TFALSE Y y yes yeti
Anything that doesn't enable the environment variable disables it.	0 -1

Setting a Runtime Environment Variable to ON or OFF	Examples
	+1
	<no value set>

The following table summarizes compiler environment variables that are recognized at runtime.

Runtime Environment Variable	Description
F_UFMTENDIAN	<p>This variable specifies the numbers of the units to be used for little-endian-to-big-endian conversion purposes. See <a href="#">Environment Variable F_UFMTENDIAN Method</a>.</p> <p>The variable is retrieved once when the first unit is opened, and then checked for every open.</p>
FOR_COARRAY_CONFIG_FILE (Windows and Linux)	<p>This variable specifies the coarray configuration file and path to be used at execution time. The variable overrides the value specified by the [Q]coarray-config-file=<i>value</i> qualifier at runtime.</p>
FOR_COARRAY_DEBUG_STARTUP (Windows and Linux)	<p>Boolean.</p> <p>When set to TRUE, this variable tells the Fortran runtime library to display the Message Passing Interface (MPI) launcher command that begins the underlying parallel support for coarrays.</p>
FOR_COARRAY_MPI_VERBOSE (Windows and Linux)	<p>Boolean.</p> <p>When set to TRUE, this variable tells the Fortran runtime library to pass the '-verbose' qualifier to the MPI support underlying the coarray implementation so that MPI will issue status and activity messages.</p>
FOR_COARRAY_NUM_IMAGES (Windows and Linux)	<p>This variable specifies the number of images created for coarrays. The value overrides the value specified by the [Q]coarray-num-images=<i>value</i> qualifier at runtime. If neither is specified, the number of logical processors is used.</p>
FOR_DUMP_CORE_FILE	<p>Boolean.</p> <p>This variable must be lowercase for Linux.</p> <p>When set to TRUE, a core dump will be taken when any severe Intel® Fortran runtime error occurs.</p> <p><b>Default:</b> FALSE</p> <p>decfort_dump_flag is an alternate spelling for FOR_DUMP_CORE_FILE</p>
FOR_FASTMEM_NO_RETRY	<p>Boolean.</p> <p>When set to TRUE, this variable specifies that if an allocation from FASTMEM fails because either the libmemkind library is not linked into the executable</p>

Runtime Environment Variable	Description
FOR_FASTMEM_RETRY	<p>or HBW memory is not available on the node then the runtime will report the failure to the user via STAT= or ERRMSG= or aborting the program with the appropriate error message.</p> <p>The variable is retrieved once at program initialization, and checked for each FASTMEM memory allocation.</p> <p><b>Default:</b> TRUE</p> <p>Boolean.</p> <p>When set to TRUE, this variable specifies that if an allocation from FASTMEM fails because either the libmemkind library is not linked into the executable or HBW memory is not available on the node then memory will be allocated from the default memory allocator for that platform.</p> <p>The variable is retrieved once at program initialization, and checked for each FASTMEM memory allocation.</p> <p><b>Default:</b> FALSE</p>
FOR_FASTMEM_RETRY_WARN	<p>Boolean.</p> <p>When set to TRUE, this variable specifies that if an allocation from FASTMEM fails because either the libmemkind library is not linked into the executable or HBW memory is not available on the node then a warning message will be issued to stdout and memory will be allocated from the default memory allocator for that platform.</p> <p>The variable is retrieved once at program initialization, and checked for each FASTMEM memory allocation.</p> <p><b>Default:</b> FALSE</p>
FOR_FMT_TERMINATOR	<p>This variable specifies the numbers of the units to have a specific record terminator. See <a href="#">Record Types</a>.</p> <p>The variable is retrieved once when the first unit is opened, and then checked for every open.</p>
FORT_FMT_NO_WRAP_MARGIN	<p>Boolean.</p> <p>When set to TRUE, disables column wrapping in Fortran list-directed output when the record being written is longer than 80 characters.</p>

Runtime Environment Variable	Description
	<hr/> <p><b>NOTE</b></p> <p>There is no environment variable to set a value for the right margin, this only disables wrapping. The RECL= open specifier can be used to set the right margin when the unit is opened.</p> <hr/> <p><b>Default:</b> FALSE (Wrap margin)</p>
FOR_ACCEPT	<p>The ACCEPT statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the FOR_ACCEPT environment variable. If FOR_ACCEPT is <i>not</i> defined, the code ACCEPT f,iolist reads from standard input. If FOR_ACCEPT is defined (as a file name optionally containing a path), the specified file would be read.</p>
FOR_DEBUGGER_IS_PRESENT	<p>Boolean.</p> <p>When set to TRUE, this variable tells the Fortran runtime library that your program is executing under a debugger, and generates debug exceptions whenever severe or continuable errors are detected.</p> <p>Under normal conditions, this variable can be extracted from the operating system for Windows.</p> <hr/> <p><b>User-convenience feature</b></p> <p>If the user sets this environment variable to a TRUE value (such as 1) on Windows and the user's program executes an ERROR STOP statement, the Windows system function <code>__debugbreak</code> will be called and will bring up the Windows debugger (if it is really present).</p> <p>The user can use the debugger to look at the state of the application, and any step or continue command will continue the ERROR STOP process and terminate the application.</p> <hr/> <p>On Linux and macOS, this variable must be set for debug exceptions. Setting this variable to TRUE when a program is <i>not</i> executing under a debugger causes unpredictable behavior.</p> <p><b>Default:</b> FALSE</p>
FOR_DEFAULT_PRINT_DEVICE (Windows)	<p>This variable lets you specify the print device other than the default print device PRN (LPT1) for files closed (CLOSE statement) with the DISPOSE='PRINT' specifier. To specify a different</p>

Runtime Environment Variable	Description
<code>FOR_DIAGNOSTIC_LOG_FILE</code>	<p>print device for the file associated with the CLOSE statement <code>DISPOSE='PRINT'</code> specifier, set <code>FOR_DEFAULT_PRINT_DEVICE</code> to any legal spooled print device before executing the program.</p> <p>It can also be used for the PRINT settings in the OPEN: <code>DISPOSE</code> specifier.</p> <p>If this variable is set to the name of a file, diagnostic output is written to the specified file.</p> <p>The Fortran runtime system attempts to open that file (append output) and write the error information (ASCII text) to the file.</p> <p>Because the setting of <code>FOR_DIAGNOSTIC_LOG_FILE</code> is independent of <code>FOR_DISABLE_DIAGNOSTIC_DISPLAY</code>, you can disable the screen display of information but still capture the error information in a file. Because the text string you assign for the file name is used literally, you must specify the full name. If the file open fails, no error is reported and the runtime system continues diagnostic processing.</p> <p>See also <a href="#">Locating Runtime Errors</a> and <a href="#">Traceback</a>.</p>
<code>FOR_DISABLE_DIAGNOSTIC_DISPLAY</code>	<p>Boolean.</p> <p>When set to TRUE, this variable disables the display of all error information. This variable is helpful if you just want to test the error status of your program and do not want the Fortran runtime system to display any information about an abnormal program termination.</p> <p>See also <a href="#">Traceback</a>.</p>
<code>FOR_DISABLE_KMP_MALLOC</code>	<p>Boolean.</p> <p>When set to TRUE, this variable forces Fortran allocate statements to resolve to glibc malloc.</p> <p><b>Default:</b> FALSE</p>
<code>FOR_FORCE_STACK_TRACE</code>	<p>Boolean.</p> <p>When set to TRUE, this variable forces a traceback to follow any runtime diagnostic message.</p> <p>If <code>FOR_DISABLE_STACK_TRACE</code> is also set, <code>FOR_FORCE_STACK_TRACE</code> takes precedence over <code>FOR_DISABLE_STACK_TRACE</code>.</p> <p><b>Default:</b> FALSE</p>
<code>FOR_DISABLE_STACK_TRACE</code>	<p>Boolean.</p>

Runtime Environment Variable	Description
FOR_IGNORE_EXCEPTIONS	<p>When set to TRUE, this variable disables the call stack trace information that typically follows the displayed severe error message text.</p> <p>The Fortran runtime error message is displayed regardless of whether <code>FOR_DISABLE_STACK_TRACE</code> is set to TRUE. If the program is executing under a debugger, the automatic output of the stack trace information by the Fortran library will be disabled to reduce noise. Use the debugger's stack trace facility to view the stack trace.</p> <p><b>Default:</b> FALSE</p> <p>See also <a href="#">Locating Runtime Errors</a> and <a href="#">Traceback</a>.</p> <p>Boolean.</p> <p>When set to TRUE, this variable disables default runtime exception handling to allow, for example, just-in-time debugging. The runtime system exception handler returns <code>EXCEPTION_CONTINUE_SEARCH</code> to the operating system, which looks for other handlers to service the exception.</p> <p><b>Default:</b> FALSE</p>
FOR_NOERROR_DIALOGS	<p>Boolean.</p> <p>When set to TRUE, this variable disables the display of dialog boxes when certain exceptions or errors occur. This is useful when running many test programs in batch mode to prevent a failure from stopping execution of the entire test stream.</p> <p><b>Default:</b> FALSE</p>
FOR_PRINT	<p>Neither the PRINT statement nor a WRITE statement with an asterisk (*) in place of a unit number includes an explicit logical unit number. Instead, both use an implicit internal logical unit number and the <code>FOR_PRINT</code> environment variable. If <code>FOR_PRINT</code> is <i>not</i> defined, the code <code>PRINT f,iolist</code> or <code>WRITE (*,f) iolist</code> writes to standard output. If <code>FOR_PRINT</code> is defined (as a file name optionally containing a path), the specified file would be written to.</p>
FOR_READ	<p>A READ statement that uses an asterisk (*) in place of a unit number does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the <code>FOR_READ</code> environment variable. If <code>FOR_READ</code> is <i>not</i> defined, the code <code>READ (*,f) iolist</code> or <code>READ f,iolist</code> reads from</p>

Runtime Environment Variable	Description
<code>FOR_TYPE</code>	<p>standard input. If <code>FOR_READ</code> is defined (as a file name optionally containing a path), the specified file would be read.</p> <p>The <code>TYPE</code> statement does not include an explicit logical unit number. Instead, it uses an implicit internal logical unit number and the <code>FOR_TYPE</code> environment variable. If <code>FOR_TYPE</code> is <i>not</i> defined, the code <code>TYPE f,iolist</code> writes to standard output. If <code>FOR_TYPE</code> is defined (as a file name optionally containing a path), the specified file would be written to.</p>
<code>FORT_BLOCKSIZE</code>	<p>Specifies the default <code>BLOCKSIZE</code> value to be used when <code>BLOCKSIZE=</code> is omitted on the <code>OPEN</code> statement. Valid values are 0 to 2147467264. Sizes are rounded up to the next 512-byte boundary.</p> <p>This variable applies to all Fortran I/O units except <code>stderr</code>, which is never buffered.</p> <p>The variable is retrieved once at program initialization, and checked for each unit open.</p>
<code>FORT_BUFFERCOUNT</code>	<p>Specifies the default <code>BUFFERCOUNT</code> value to be used when <code>BUFFERCOUNT=</code> is omitted on the <code>OPEN</code> statement. Valid values are 0 to 127. If set to 0, the default value of 1 is used.</p> <p>This variable applies to all Fortran I/O units except <code>stdout</code> (units <code>*</code> and <b>6</b>) and <code>stderr</code>.</p> <p>The variable is retrieved once at program initialization, and checked for each unit open.</p>
<code>FORT_BUFFERED</code>	<p>Boolean.</p> <p>When set to <code>TRUE</code>, this variable specifies that buffered I/O should be used at runtime for input and output on all Fortran I/O units, except <code>stdout</code> (units <code>*</code> and <b>6</b>). Output to <code>stderr</code> is never buffered.</p> <p><b>Default:</b> <code>FALSE</code></p>
<code>FORT_BUFFERING_THRESHOLD=n</code>	<p>Specifies dynamic buffering for unformatted sequential <code>READ</code> operations:</p> <ul style="list-style-type: none"> <li>I/O list items with a size <math>\leq n</math> are buffered and are moved one at a time from the buffer to the I/O list item.</li> <li>I/O list items with a size <math>&gt; n</math> are not buffered and are moved one at a time from the file to the I/O list item.</li> </ul>
<code>FORT_CONVERTn</code>	<p>Specifies the data format for an unformatted file associated with a particular unit number (<i>n</i>), as described in <a href="#">Specify the Data Format</a>.</p>

Runtime Environment Variable	Description
<code>FORT_CONVERT.ext</code> and <code>FORT_CONVERT_ext</code>	Specifies the data format for unformatted files with a particular file extension suffix ( <code>.ext</code> ), as described in <a href="#">Specify the Data Format</a> .
<code>FORT_FMT_RECL</code>	<p>Specifies the default record length (normally 132 bytes) for formatted files.</p> <p>The variable is retrieved once at program initialization, and checked for each unit open.</p>
<code>FORT_UFMT_RECL</code>	<p>Specifies the default record length (normally 2040 bytes) for unformatted files.</p> <p>The variable is retrieved once at program initialization, and checked for each unit open.</p>
<code>FORTn</code>	Specifies the file name for a particular unit number <i>n</i> , when a file name is not specified in the OPEN statement or an implicit OPEN is used, and the compiler option <code>fpscomp</code> with option keyword <code>filesfromcmd</code> was not specified. Preconnected files attached to units 0, 5, and 6 are associated with system standard I/O files by default.
<code>INTEL_CHKP_REPORT_MODE</code> (Linux)	Changes the pointer checker reporting mode at runtime.
<code>INTEL_ISA_DISABLE</code>	Causes named features (in a comma-separated list) not to be visible on the host even if the CPUID reports that it has them onboard.
<code>NLSPATH</code> (Linux and macOS)	Specifies the path for the Intel® Fortran runtime error message catalog.
<code>TBK_ENABLE_VERBOSE_STACK_TRACE</code>	<p>Boolean.</p> <p>When set to TRUE, traceback output displays more detailed call stack information in the event of an error.</p> <p>The default brief output is usually sufficient to determine where an error occurred. Brief output includes up to twenty stack frames, reported one line per stack frame. For each frame, the image name containing the PC, routine name, line number, and source file are given.</p> <p>The verbose output, if selected, will provide the exception context record (in addition to the information in brief output) if the error was a machine exception (machine register dump), and for each frame, the return address, frame pointer and stack pointer and possible parameters to the routine. This output can be quite long (limited to 16K bytes) and use of the environment variable <code>FOR_DIAGNOSTIC_LOG_FILE</code> is recommended if</p>

Runtime Environment Variable	Description
	<p>you want to capture the output accurately. Most situations should not require the use of verbose output.</p> <p><b>Default:</b> FALSE</p> <p>See also <a href="#">Locating Runtime Errors</a> and <a href="#">Traceback</a>.</p>
TBK_FULL_SRC_FILE_SPEC	<p>Boolean.</p> <p>When set to TRUE, traceback output displays complete file name information including the path. By default, the traceback output displays only the file name and extension in the source file field.</p> <p><b>Default:</b> FALSE</p> <p>See also <a href="#">Locating Runtime Errors</a> and <a href="#">Traceback</a>.</p>
FORT_TMPDIR	
TMP	
TMPDIR	Specifies an alternate working directory where scratch files are created.
TEMP	
<b>GNU extensions (recognized by the Intel OpenMP* compatibility library)</b>	
GOMP_CPU_AFFINITY (Linux)	<p>GNU extension recognized by the Intel OpenMP compatibility library. Specifies a list of OS processor IDs.</p> <p>You must set this environment variable before the first parallel region or before certain API calls including <code>omp_get_max_threads()</code>, <code>omp_get_num_procs()</code> and any affinity API calls. For detailed information on this environment variable, see <i>Thread Affinity Interface</i>.</p> <p><b>Default:</b> Affinity is disabled</p>
GOMP_STACKSIZE (Linux)	<p>GNU extension recognized by the Intel OpenMP compatibility library. Same as <code>OMP_STACKSIZE.KMP_STACKSIZE</code> overrides <code>GOMP_STACKSIZE</code>, which overrides <code>OMP_STACKSIZE</code>.</p> <p><b>Default:</b> See the description for <code>OMP_STACKSIZE</code>.</p>
<b>OpenMP Environment Variables (OMP_) and Extensions (KMP_)</b>	
OMP_CANCELLATION	<p>Activates cancellation of the innermost enclosing region of the type specified. If set to TRUE, the effects of the cancel construct and of cancellation points are enabled and cancellation is activated. If set to FALSE, cancellation is disabled and the cancel construct and cancellation points are effectively ignored.</p>

Runtime Environment Variable	Description
	<p><b>NOTE</b></p> <p>Internal barrier code will work differently depending on whether the cancellation is enabled. Barrier code should repeatedly check the global flag to figure out if the cancellation had been triggered. If a thread observes the cancellation it should leave the barrier prematurely with the return value 1 (may wake up other threads). Otherwise, it should leave the barrier with the return value 0.</p>
OMP_CANCELLATION	<p>Enables (TRUE) or disables (FALSE) cancellation of the innermost enclosing region of the type specified.</p> <p><b>Default:</b> FALSE</p> <p><b>Example:</b> OMP_CANCELLATION=TRUE</p>
OMP_DISPLAY_ENV	<p>Enables (TRUE) or disables (FALSE) the printing to stderr of the OpenMP version number and the values associated with the OpenMP environment variable.</p> <p>Possible values are: TRUE, FALSE, or VERBOSE.</p> <p><b>Default:</b> FALSE</p> <p><b>Example:</b> OMP_DISPLAY_ENV=TRUE</p>
OMP_DEFAULT_DEVICE	<p>Sets the device that will be used in a target region. The OpenMP routine <code>omp_set_default_device</code> or a <code>device</code> clause in a target directive can override this variable.</p> <p>If no device with the specified device number exists, the code is executed on the host. If this environment variable is not set, device number 0 is used.</p>
OMP_DYNAMIC	<p>Enables (TRUE) or disables (FALSE) the dynamic adjustment of the number of threads.</p> <p><b>Default:</b> FALSE</p> <p><b>Example:</b> OMP_DYNAMIC=TRUE</p>
OMP_MAX_ACTIVE_LEVELS	<p>The maximum number of levels of parallel nesting for the program.</p> <p>Possible values: Non-negative integer.</p> <p><b>Default:</b> 1</p>
OMP_NESTED	<p>Deprecated; use OMP_MAX_ACTIVE_LEVELS instead.</p>

Runtime Environment Variable	Description
OMP_NUM_THREADS	<p>Sets the maximum number of threads to use for OpenMP parallel regions if no other value is specified in the application.</p> <p>The value can be a single integer, in which case it specifies the number of threads for all parallel regions. The value can also be a comma-separated list of integers, in which case each integer specifies the number of threads for a parallel region at a nesting level.</p> <p>The first position in the list represents the outer-most parallel nesting level, the second position represents the next-inner parallel nesting level, and so on. At any level, the integer can be left out of the list. If the first integer in a list is left out, it implies the normal default value for threads is used at the outer-most level. If the integer is left out of any other level, the number of threads for that level is inherited from the previous level.</p> <p>This environment variable applies to the options <code>Qopenmp (Windows)</code> or <code>qopenmp (Linux and macOS)</code>, and <code>Qparallel (Windows)</code> or <code>parallel (Linux and macOS)</code>.</p> <p><b>Default:</b> The number of processors visible to the operating system on which the program is executed.</p> <p><b>Syntax:</b> <code>OMP_NUM_THREADS=value[,value]*</code></p>
OMP_PLACES	<p>Specifies an explicit ordered list of places, either as an abstract name describing a set of places or as an explicit list of places described by nonnegative numbers. An exclusion operator "!" can also be used to exclude the number or place immediately following the operator.</p> <p>For <b>explicit lists</b>, the meaning of the numbers and how the numbering is done for a list of nonnegative numbers are implementation defined. Generally, the numbers represent the smallest unit of execution exposed by the execution environment, typically a hardware thread.</p> <p>Intervals can be specified using the <code>&lt;lower-bound&gt; : &lt;length&gt; : &lt;stride&gt;</code> notation to represent the following list of numbers:</p> <pre>"&lt;lower-bound&gt;, &lt;lower-bound&gt; + &lt;stride&gt;, ..., &lt;lower-bound&gt; +(&lt;length&gt;-1)*&lt;stride&gt;."</pre>

Runtime Environment Variable	Description
	<p>When <code>&lt;stride&gt;</code> is omitted, a unit stride is assumed. Intervals can specify numbers within a place as well as sequences of places.</p> <pre data-bbox="826 388 1440 531"># EXPLICIT LIST EXAMPLE setenv OMP_PLACES "{0,1,2,3},{4,5,6,7}, {8,9,10,11},{12,13,14,15}" setenv OMP_PLACES "{0:4},{4:4},{8:4},{12:4}" setenv OMP_PLACES "{0:4}:4:4"</pre> <p>The <b>abstract names</b> listed below should be understood by the execution and runtime environment:</p> <ul style="list-style-type: none"> <li>• <code>threads</code>: Each place corresponds to a single hardware thread on the target machine.</li> <li>• <code>cores</code>: Each place corresponds to a single core (having one or more hardware threads) on the target machine.</li> <li>• <code>ll_caches</code>: Each place corresponds to a set of cores that share the last level cache on the device.</li> <li>• <code>numa_domains</code>: Each place corresponds to a set of cores for which their closest memory on the device is 1) the same memory and 2) at a similar distance from the cores.</li> <li>• <code>sockets</code>: Each place corresponds to a single socket (consisting of one or more cores) on the target machine.</li> </ul> <p>When requesting fewer places or more resources than available on the system, the determination of which resources of type <code>abstract_name</code> are to be included in the place list is implementation-defined. The precise definitions of the abstract names are implementation defined. An implementation may also add abstract names as appropriate for the target platform. The abstract name may be appended by a positive number in parentheses to denote the length of the place list to be created, that is <code>abstract_name(num-places)</code>.</p> <pre data-bbox="826 1539 1219 1623"># ABSTRACT NAMES EXAMPLE setenv OMP_PLACES threads setenv OMP_PLACES threads(4)</pre> <p><b>NOTE</b></p> <p>If any numerical values cannot be mapped to a processor on the target platform the behavior is implementation-defined. The behavior is also implementation-defined when the <code>OMP_PLACES</code> environment variable is defined using an abstract name.</p>

Runtime Environment Variable	Description
OMP_PROC_BIND (Windows, Linux)	<p>Sets the thread affinity policy to be used for parallel regions at the corresponding nested level. Enables (TRUE) or disables (FALSE) the binding of threads to processor contexts. If enabled, this is the same as specifying KMP_AFFINITY=scatter. If disabled, this is the same as specifying KMP_AFFINITY=none.</p> <p><b>Acceptable values:</b> TRUE, FALSE, or a comma separated list, each element of which is one of the following values: PRIMARY, MASTER (deprecated), CLOSE, SPREAD.</p> <p><b>Default:</b> FALSE</p> <p>If set to FALSE, the execution environment may move OpenMP threads between OpenMP places, thread affinity is disabled, and proc_bind clauses on parallel constructs are ignored. Otherwise, the execution environment should not move OpenMP threads between OpenMP places, thread affinity is enabled, and the initial thread is bound to the first place in the OpenMP place list.</p> <p>If set to PRIMARY, all threads are bound to the same place as the primary thread. If set to CLOSE, threads are bound to successive places, close to where the primary thread is bound. If set to SPREAD, the primary thread's partition is subdivided and threads are bound to single place successive sub-partitions.</p> <hr/> <p><b>NOTE</b> KMP_AFFINITY takes precedence over GOMP_CPU_AFFINITY and OMP_PROC_BIND. GOMP_CPU_AFFINITY takes precedence over OMP_PROC_BIND.</p> <hr/>
OMP_SCHEDULE	<p>Sets the runtime schedule type and an optional chunk size.</p> <p><b>Default:</b> static, no chunk size specified</p> <p><b>Example syntax:</b> OMP_SCHEDULE="[modifier:]kind[,chunk_size]" where</p> <ul style="list-style-type: none"> <li>• modifier is one of monotonic or nonmonotonic</li> <li>• kind is one of static, dynamic, guided, or auto</li> <li>• chunk_size is a positive integer</li> </ul>

Runtime Environment Variable	Description
OMP_STACKSIZE	<p><b>NOTE</b></p> <p>Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.</p>
	<p>Sets the number of bytes to allocate for each OpenMP thread to use as the private stack for the thread. Recommended size is 16M.</p> <p>Use the optional suffixes to specify byte units: <b>B</b> (bytes), <b>K</b> (Kilobytes), <b>M</b> (Megabytes), <b>G</b> (Gigabytes), or <b>T</b> (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be <b>K</b> (Kilobytes).</p> <p>This variable does not affect the native operating system threads created by the user program, or the thread executing the sequential part of an OpenMP program or parallel programs created using the option <code>qparallel (Windows)</code> or <code>parallel (Linux and macOS)</code>.</p> <p>The <code>kmp_{set,get}_stacksize_s()</code> routines set/retrieve the value. The <code>kmp_set_stacksize_s()</code> routine must be called from sequential part, before first parallel region is created. Otherwise, calling <code>kmp_set_stacksize_s()</code> has no effect.</p> <p><b>Default (IA-32 architecture):</b> 2M</p> <p><b>Default (Intel® 64 architecture):</b> 4M</p> <p><b>NOTE</b> IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release.</p> <p><b>Related environment variables:</b></p> <p><code>KMP_STACKSIZE</code> (overrides <code>OMP_STACKSIZE</code>).</p> <p><b>Syntax:</b> <code>OMP_STACKSIZE=value</code></p>
OMP_THREAD_LIMIT	<p>Limits the number of simultaneously-executing threads in an OpenMP program.</p> <p>If this limit is reached and another native operating system thread encounters OpenMP API calls or constructs, the program can abort with an error message. If this limit is reached when an OpenMP parallel region begins, a one-time warning message</p>

Runtime Environment Variable	Description
	<p>might be generated indicating that the number of threads in the team was reduced, but the program will continue.</p> <p>This environment variable is only used for programs compiled with the following options: <code>Qopenmp (Windows)</code> or <code>qopenmp (Linux and macOS)</code>, or <code>Qparallel (Windows)</code> or <code>parallel (Linux and macOS)</code>.</p> <p>The <code>omp_get_thread_limit()</code> routine returns the value of the limit.</p> <p><b>Default:</b> No enforced limit</p> <p><b>Related environment variable:</b>  <code>KMP_ALL_THREADS</code> (overrides <code>OMP_THREAD_LIMIT</code>).</p> <p><b>Example syntax:</b> <code>OMP_THREAD_LIMIT=value</code></p>
<code>OMP_WAIT_POLICY</code>	<p>Decides whether threads spin (active) or yield (passive) while they are waiting.</p> <p><code>OMP_WAIT_POLICY=ACTIVE</code> is an alias for <code>KMP_LIBRARY=turnaround</code>, and <code>OMP_WAIT_POLICY=PASSIVE</code> is an alias for <code>KMP_LIBRARY=throughput</code>.</p> <p><b>Default:</b> Passive</p> <p><b>Syntax:</b> <code>OMP_WAIT_POLICY=value</code></p>
<code>OMP_DISPLAY_AFFINITY</code>	<p>Instructs the runtime to display formatted affinity information for all OpenMP threads in the parallel region upon entering the first parallel region and when any change occurs in the information accessible by the format specifiers listed in the <code>OMP_AFFINITY_FORMAT</code> entry.</p> <p>Possible values: <code>TRUE</code> or <code>FALSE</code></p> <p><b>Default:</b> <code>FALSE</code></p>
<code>OMP_AFFINITY_FORMAT</code>	<p>Defines the format when displaying OpenMP thread affinity information. Possible values are any string with the following format field available:</p> <ul style="list-style-type: none"> <li><code>%t</code> or <code>%{team_num}</code>: Value returned by <code>omp_get_team_num()</code></li> <li><code>%T</code> or <code>%{num_teams}</code>: Value returned by <code>omp_get_num_teams()</code></li> <li><code>%L</code> or <code>%{nesting_level}</code>: Value returned by <code>omp_get_level()</code></li> <li><code>%n</code> or <code>%{thread_num}</code>: Value returned by <code>omp_get_thread_num()</code></li> </ul>

Runtime Environment Variable	Description
	<ul style="list-style-type: none"> <li>• <code>%a</code> or <code>%{ancestor_tnum}</code>: Value returned by <code>omp_get_ancestor_thread_num(omp_get_level() - 1)</code></li> <li>• <code>%H</code> or <code>%{host}</code>: Name of host device</li> <li>• <code>%P</code> or <code>%{process_id}</code>: Process ID</li> <li>• <code>%i</code> or <code>%{native_thread_id}</code>: Native thread ID on the platform</li> <li>• <code>%A</code> or <code>%{thread_affinity}</code>: List of processor ID on which a thread may execute</li> </ul> <p><b>Default:</b> 'OMP: pid %P tid %i thread %n bound to OS proc set {%A}'</p>
OMP_MAX_TASK_PRIORITY	<p>Controls the use of task priorities by setting the initial value.</p> <p>Possible values: Non-negative integer.</p> <p><b>Default:</b> 0</p>
OMP_TOOL	<p>Controls whether the OpenMP runtime will try to register a first party tool that uses OMPT interface.</p> <p>Possible values: <code>ENABLED</code> or <code>DISABLED</code>.</p> <p><b>Default:</b> <code>ENABLED</code></p> <hr/> <p><b>NOTE</b> Only the host OpenMP runtime is supported.</p>
OMP_TOOL_LIBRARIES	<p>Sets a list of first-party tool locations that use the OMPT interface. The list enumerates names of dynamically-loadable libraries with OS-specific path separator.</p> <p><b>Default:</b> Empty</p> <hr/> <p><b>NOTE</b> Only the host OpenMP runtime is supported.</p>
OMP_TOOL_VERBOSE_INIT	<p>Controls whether the OpenMP runtime will verbosely log the registration of a tool that uses the OMPT interface.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>• <code>DISABLED</code>: Do not log the registration.</li> <li>• <code>STDOUT</code>: Log the registration to stdout.</li> <li>• <code>STDERR</code>: Log the registration to stderr.</li> <li>• <code>File_Name</code>: Log the registration to the location specified by <code>File_Name</code>.</li> </ul> <p><b>Default:</b> <code>DISABLED</code></p>

Runtime Environment Variable	Description
OMP_DEBUG	<hr/> <b>NOTE</b> Only the host OpenMP runtime is supported. <hr/>
	<p>Controls whether the OpenMP runtime collects information that an OMPD library may need to support a tool.</p> <p>Possible values: ENABLED or DISABLED.</p> <p><b>Default:</b> DISABLED</p> <hr/> <b>NOTE</b> Only the host OpenMP runtime is supported. <hr/>
OMP_ALLOCATOR	<p>Specifies the default allocator for allocation calls, directives, and clauses that do not specify an allocator.</p> <p><b>Default:</b> omp_default_mem_alloc</p> <p><b>Syntax:</b> &lt;PredefinedMemAllocator&gt;   &lt;PredefinedMemSpace&gt;   &lt;PredefinedMemSpace&gt;:&lt;Traits&gt;</p> <p>Currently supported values for &lt;PredefinedMemAllocator&gt; and &lt;PredefinedMemSpace&gt; :</p> <ul style="list-style-type: none"> <li>omp_default_mem_alloc and omp_default_mem_space</li> </ul> <p>Additional values are supported if libmemkind is available and there is system support for it:</p> <ul style="list-style-type: none"> <li>omp_high_bw_mem_alloc and omp_high_bw_mem_space</li> <li>omp_large_cap_mem_alloc and omp_large_cap_mem_space</li> </ul> <p>Refer to the <a href="#">OpenMP specification</a> for more information.</p>
OMP_NUM_TEAMS	<p>Sets the maximum number of teams created by a teams construct by setting nteams-var ICV.</p> <p>Possible values: Positive integer.</p> <p><b>Default:</b> 1</p>
OMP_TEAMS_THREAD_LIMIT	<p>Sets the maximum number of OpenMP threads to use in each team created by a teams construct.</p> <p>Possible values: Positive integer.</p> <p><b>Default:</b> &lt;NumberOfProcessors&gt; / &lt;ntteams-var ICV&gt;</p>

Runtime Environment Variable	Description
KMP_AFFINITY (Linux, Windows)	<p>Enables runtime library to bind threads to physical processing units.</p> <p>You must set this environment variable before the first parallel region, or certain API calls including <code>omp_get_max_threads()</code>, <code>omp_get_num_procs()</code> and any affinity API calls. For detailed information on this environment variable, see <i>Thread Affinity Interface</i>.</p> <p><b>Default:</b>  <code>noverbose,warnings,noreset,respect,granularity=core,none</code></p> <p>Default (Windows with multiple processor groups):  <code>noverbose,warnings,noreset,norespect,granularity=group,compact,0,0</code></p> <hr/> <p><b>NOTE</b> On Windows with multiple processor groups, the <code>norespect</code> affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows). Otherwise, the <code>respect</code> affinity modifier is used.</p> <hr/>
KMP_ALL_THREADS	<p>Limits the number of simultaneously-executing threads in an OpenMP program. If this limit is reached and another native operating system thread encounters OpenMP API calls or constructs, then the program may abort with an error message. If this limit is reached at the time an OpenMP parallel region begins, a one-time warning message may be generated indicating that the number of threads in the team was reduced, but the program will continue execution.</p> <p>This environment variable is only used for programs compiled with the <code>Qopenmp(Windows)</code> or <code>qopenmp(Linux and macOS)</code> option.</p> <p><b>Default:</b> No enforced limit.</p>
KMP_BLOCKTIME	<p>Sets the time, in milliseconds, that a thread should wait, after completing the execution of a parallel region, before sleeping.</p> <p>Use the optional character suffixes: <code>s</code> (seconds), <code>m</code> (minutes), <code>h</code> (hours), or <code>d</code> (days) to specify the units.</p> <p>Specify <code>infinite</code> for an unlimited wait time.</p> <p><b>Default:</b> 200 milliseconds</p> <p><b>Related Environment Variable:</b> <code>KMP_LIBRARY</code> environment variable.</p>

Runtime Environment Variable	Description
KMP_CPUINFO_FILE	<p>Specifies an alternate file name for a file containing the machine topology description. The file must be in the same format as <code>/proc/cpuinfo</code>.</p> <p><b>Default:</b> None</p>
KMP_DETERMINISTIC_REDUCTION	<p>Enables (TRUE) or disables (FALSE) the use of a specific ordering of the reduction operations for implementing the reduction clause for an OpenMP parallel region. This has the effect that, for a given number of threads, in a given parallel region, for a given data set and reduction operation, a floating point reduction done for an OpenMP reduction clause has a consistent floating point result from run to run, since round-off errors are identical.</p> <hr/> <p><b>NOTE</b> When compiling, you must set the following flag to ensure correct behavior:</p> <ul style="list-style-type: none"> <li>• <code>-fp-model precise</code> (Linux)</li> <li>• <code>-fp:precise</code> (Windows)</li> </ul> <hr/> <p><b>Default:</b> FALSE</p>
KMP_DYNAMIC_MODE	<p>Selects the method used to determine the number of threads to use for a parallel region when <code>OMP_DYNAMIC=TRUE</code>. Possible values: (<code>asat</code>   <code>load_balance</code>   <code>thread_limit</code>), where,</p> <ul style="list-style-type: none"> <li>• <code>asat</code>: estimates number of threads based on parallel start time;</li> </ul> <hr/> <p><b>NOTE</b> Support for <code>asat</code> (automatic self-allocating threads) is now deprecated and will be removed in a future release.</p> <hr/> <ul style="list-style-type: none"> <li>• <code>load_balance</code>: tries to avoid using more threads than available execution units on the machine;</li> <li>• <code>thread_limit</code>: tries to avoid using more threads than total execution units on the machine.</li> </ul> <p><b>Default (IA-32 architecture):</b> <code>load_balance</code> (on all supported OSes)</p> <p><b>Default (Intel® 64 architecture):</b> <code>load_balance</code> (on all supported OSes)</p>

Runtime Environment Variable	Description
	<p><b>NOTE</b> IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release.</p>
KMP_HOT_TEAMS_MAX_LEVEL	<p>Sets the maximum nested level to which teams of threads will be hot.</p> <p><b>NOTE</b> A <i>hot</i> team is a team of threads optimized for faster reuse by subsequent parallel regions. In a hot team, threads are kept ready for execution of the next parallel region, in contrast to the cold team, which is freed after each parallel region, with its threads going into a common pool of threads.</p> <p>For values of 2 and above, nested parallelism should be enabled.</p> <p><b>Default: 1</b></p> <p>Specifies the runtime behavior when the number of threads in a hot team is reduced.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>0: Extra threads are freed and put into a common pool of threads.</li> <li>1: Extra threads are kept in the team in reserve, for faster reuse in subsequent parallel regions.</li> </ul> <p><b>Default: 0</b></p>
KMP_HOT_TEAMS_MODE	
KMP_HW_SUBSET	<p>Specifies the subset of available hardware resources for the hardware topology hierarchy. The subset is specified in terms of number of units per upper layer unit starting from top layer downwards. For example, it can specify the number of sockets (top layer units), cores per socket, and the threads per core, to use with an OpenMP application. It is a convenient alternative to writing complicated explicit affinity settings or a limiting process affinity mask. You can also specify an offset value to set which resources to use. When available, you can specify attributes to select different subsets of resources.</p> <p>An extended syntax is available when <code>KMP_TOPOLOGY_METHOD=hwloc</code>. Depending on what resources are detected, you may be able to specify additional resources, such as NUMA nodes and groups of hardware resources that share certain cache levels.</p>

Runtime Environment Variable	Description
	<p><b>Basic syntax:</b></p> <pre>[num_units]ID[@offset][:attribute] [, [num_units]ID[@offset][:attribute]...]</pre> <p>where</p> <ul style="list-style-type: none"> <li>num_units is either a positive integer, which requests an exact number of resources, or an asterisk (*), which means using all available resources at that layer (for example, using all cores per socket). If num_units is not specified, the asterisk (*) semantics are assumed.</li> <li>ID is a supported ID: <ul style="list-style-type: none"> <li><i>S - socket</i> num_units specifies the requested number of sockets.</li> <li><i>D - die</i> num_units specifies the requested number of dies per socket.</li> <li><i>C - core</i> num_units specifies the requested number of cores per die - if any - otherwise, per socket.</li> <li><i>T - thread</i> num_units specifies the requested number of HW threads per core.</li> </ul> </li> </ul> <p>Supported unit IDs are not case-sensitive.</p> <ul style="list-style-type: none"> <li>offset is the number of units to skip (optional).</li> <li>attribute is an attribute differentiating resources at a particular layer (optional).</li> </ul> <p>This is only available for the core layer on machines with Intel® Hybrid Technology. The attributes available to users are:</p> <ul style="list-style-type: none"> <li>Core type: Either <i>intel_atom</i> or <i>intel_core</i></li> <li>Core efficiency: Specified as <i>effnum</i> where <i>num</i> is a number from 0 to the number of core efficiencies detected in the machine topology minus one. For example: <i>eff0</i>. The greater the efficiency number, the more performant the core. There may be more core efficiencies than core types, which can be viewed by setting <code>KMP_AFFINITY=verbose</code>.</li> </ul> <hr/> <p><b>NOTE</b> The hardware cache can be specified as a unit, for example L2 for L2 cache, or LL for last level cache.</p> <hr/> <p><b>Extended syntax when</b>  <b>KMP_TOPOLOGY_METHOD=hwloc:</b></p>

Runtime Environment Variable	Description
	<p>Additional IDs can be specified if detected. For example:</p> <p><i>N</i> - <i>numa</i>      <i>num_units</i> specifies the requested number of NUMA nodes per upper layer unit, e.g. per socket.</p> <p><i>TI</i> - <i>tile</i>      <i>num_units</i> specifies the requested number of tiles to use per upper layer unit, e.g. per NUMA node.</p> <p>When any <i>numa</i> or <i>tile</i> units are specified in <code>KMP_HW_SUBSET</code>, the <code>KMP_TOPOLOGY_METHOD</code> will be automatically set to <code>hwloc</code>, so there is no need to set it explicitly.</p> <p>If you don't specify one or more types of resource, such as socket or thread, all available resources of that type are used.</p> <p>The runtime library prints a warning, and the setting of <code>KMP_HW_SUBSET</code> is ignored if:</p> <ul style="list-style-type: none"> <li>• a resource is specified, but detection of that resource is not supported by the chosen topology detection method and/or</li> <li>• a resource is specified twice. An exception to this condition is if attributes differentiate the resource.</li> <li>• attributes are used when unavailable, not detected in the machine topology, or conflict with each other.</li> </ul> <p>This variable does not work if the OpenMP affinity is set to <code>disabled</code>.</p> <p><b>Default:</b> If omitted, the default value is to use all the available hardware resources.</p> <p><b>Examples:</b></p> <ul style="list-style-type: none"> <li>• <code>2s,4c,2t</code>: Use the first 2 sockets (<code>s0</code> and <code>s1</code>), the first 4 cores on each socket (<code>c0</code> - <code>c3</code>), and 2 threads per core.</li> <li>• <code>2s@2,4c@8,2t</code>: Skip the first 2 sockets (<code>s0</code> and <code>s1</code>) and use 2 sockets (<code>s2</code>-<code>s3</code>), skip the first 8 cores (<code>c0</code>-<code>c7</code>) and use 4 cores on each socket (<code>c8</code>-<code>c11</code>), and use 2 threads per core.</li> <li>• <code>5C@1,3T</code>: Use all available sockets, skip the first core and use 5 cores, and use 3 threads per core.</li> <li>• <code>1T</code>: Use all cores on all sockets, 1 thread per core.</li> <li>• <code>1s, 1d, 1n, 1c, 1t</code>: Use 1 socket, 1 die, 1 NUMA node, 1 core, 1 thread - use HW thread as a result.</li> </ul>

Runtime Environment Variable	Description
	<ul style="list-style-type: none"> <li>4c:intel_atom,5c:intel_core: Use all available sockets and use 4 Intel Atom® processor cores and 5 Intel® Core™ processor cores per socket.</li> <li>2c:eff0,3c:eff1: Use all available sockets and use 2 cores with efficiency 0 and 3 cores with efficiency 1 per socket.</li> <li>1s, 1c, 1t: Use 1 socket, 1 core, 1 thread. This may result in using single thread on a 3-layer topology architecture, or multiple threads on 4-layer or 5-layer architecture. Result may even be different on the same architecture, depending on KMP_TOPOLOGY_METHOD specified, as hwloc can often detect more topology layers than default method used by the OpenMP runtime library.</li> </ul> <p>To see the result of the setting, you can specify the <code>verbose</code> modifier in for the <code>KMP_AFFINITY</code> environment variable. The OpenMP runtime library will output to <code>stderr</code> stream the information about discovered HW topology before and after the <code>KMP_HW_SUBSET</code> setting was applied. For example, on Intel® Xeon Phi™ 7210 CPU in SNC-4 Clustering Mode, the setting <code>KMP_AFFINITY=verbose KMP_HW_SUBSET=1N,1L2,1L1,1T</code> outputs various verbose information to <code>stderr</code>, including the following lines about discovered HW topology before and after <code>KMP_HW_SUBSET</code> was applied:</p> <ul style="list-style-type: none"> <li>Info #191: <code>KMP_AFFINITY</code>: 1 socket x 4 NUMA domains/socket x 8 tiles/NUMA domain x 2 cores/tile x 4 threads/core. (64 total cores)</li> <li>Info #191: <code>KMP_HW_SUBSET</code> 1 socket x 1 NUMA domain/socket x 1 tile/NUMA domain x 1 core/tile x 1 thread/core (1 total cores)</li> </ul>
KMP_INHERIT_FP_CONTROL	<p>Enables (TRUE) or disables (FALSE) the copying of the floating-point control settings of the primary thread to the floating-point control settings of the OpenMP worker threads at the start of each parallel region.</p> <p><b>Default:</b> TRUE</p>
KMP_LIBRARY	<p>Selects the OpenMP runtime library execution mode. The values for this variable are <code>serial</code>, <code>turnaround</code>, or <code>throughput</code>.</p> <p><b>Default:</b> throughput</p>
KMP_PLACE_THREADS	<p>Deprecated; use <code>KMP_HW_SUBSET</code> instead.</p>

Runtime Environment Variable	Description
KMP_SETTINGS	<p>Enables (TRUE) or disables (FALSE) the printing of OpenMP runtime library environment variables during program execution. Two lists of variables are printed: user-defined environment variables settings and effective values of variables used by OpenMP runtime library.</p> <p><b>Default:</b> FALSE</p>
KMP_STACKSIZE	<p>Sets the number of bytes to allocate for each OpenMP thread to use as its private stack.</p> <p>Recommended size is 16m.</p> <p>Use the optional suffixes to specify byte units: <b>B</b> (bytes), <b>K</b> (Kilobytes), <b>M</b> (Megabytes), <b>G</b> (Gigabytes), or <b>T</b> (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be <b>K</b> (Kilobytes).</p> <p>This variable does not affect the native operating system threads created by the user program nor the thread executing the sequential part of an OpenMP program or parallel programs created using the option <a href="#">qparallel (Windows)</a> or <a href="#">parallel (Linux and macOS)</a> .</p> <p>KMP_STACKSIZE overrides GOMP_STACKSIZE, which overrides OMP_STACKSIZE.</p> <p><b>Default (IA-32 architecture):</b> 2m</p> <p><b>Default (Intel® 64 architecture):</b> 4m</p> <hr/> <p><b>NOTE</b> IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release.</p> <hr/>
KMP_TOPOLOGY_METHOD	<p>Forces OpenMP to use a particular machine topology modeling method.</p> <p>Possible values are:</p> <ul style="list-style-type: none"> <li>• <b>all:</b> Lets OpenMP choose which topology method is most appropriate based on the platform and possibly other environment variable settings.</li> <li>• <b>cpuid_leaf11:</b> Decodes the APIC identifiers as specified by leaf 11 of the <i>cpuid</i> instruction.</li> <li>• <b>cpuid_leaf4:</b> Decodes the APIC identifiers as specified in leaf 4 of the <i>cpuid</i> instruction.</li> </ul>

Runtime Environment Variable	Description
	<ul style="list-style-type: none"> <li><b>cpuinfo:</b> If <code>KMP_CPUINFO_FILE</code> is not specified, forces OpenMP to parse <code>/proc/cpuinfo</code> to determine the topology (Linux only). If <code>KMP_CPUINFO_FILE</code> is specified as described above, uses it (Windows or Linux).</li> <li><b>group:</b> Models the machine as a 2-level map, with level 0 specifying the different processors in a group, and level 1 specifying the different groups (Windows 64-bit only) .</li> </ul> <hr/> <p><b>NOTE</b> Support for <code>group</code> is now deprecated and will be removed in a future release. Use <code>all</code> instead.</p> <hr/> <ul style="list-style-type: none"> <li><b>flat:</b> Models the machine as a flat (linear) list of processors.</li> <li><b>hwloc:</b> Models the machine as the Portable Hardware Locality* (hwloc) library does. This model is the most detailed and includes, but is not limited to: numa nodes, packages, cores, hardware threads, caches, and Windows processor groups.</li> </ul> <p><b>Default:</b> <code>all</code></p>
<code>KMP_USER_LEVEL_MWAIT</code>	<p>Enables (<code>TRUE</code>) or disables (<code>FALSE</code>) the use of user-level <code>mwait</code> as alternative to putting waiting threads to sleep, if available, either from <code>ring3</code> or <code>WAITPKG</code>.</p> <p><b>Default:</b> <code>FALSE</code></p>
<code>KMP_VERSION</code>	<p>Enables (<code>TRUE</code>) or disables (<code>FALSE</code>) the printing of OpenMP runtime library version information during program execution.</p> <p><b>Default:</b> <code>FALSE</code></p>
<code>KMP_WARNINGS</code>	<p>Enables (<code>TRUE</code>) or disables (<code>FALSE</code>) displaying warnings from the OpenMP runtime library during program execution.</p> <p><b>Default:</b> <code>TRUE</code></p>
<b>OpenMP Offload Environment Variables (<code>OMP_</code>, <code>LIBOMPTARGET</code>)</b>	
This feature is only available for <code>ifx</code> .	
<code>OMP_TARGET_OFFLOAD</code>	<p>Controls the program behavior when offloading a target region.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li><b>MANDATORY:</b> Program execution is terminated if a device construct or device memory routine is encountered and the device is not available or is not supported.</li> </ul>

Runtime Environment Variable	Description
LIBOMPTARGET_DEBUG	<ul style="list-style-type: none"> <li><b>DISABLED:</b> Disables target offloading to devices and execution occurs on the host.</li> <li><b>DEFAULT:</b> Target offloading is enabled if the device is available and supported.</li> </ul> <p><b>Default:</b> DEFAULT</p> <p>Controls whether debugging information will be displayed from the offload runtime.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>0: Disabled.</li> <li>1: Displays basic debug information from the plugin actions such as device detection, kernel compilation, memory copy operations, kernel invocations, and other plugin-dependent actions.</li> <li>2: Displays which GPU runtime API functions are invoked with which arguments and parameters in addition to the information displayed with value 1.</li> </ul> <p><b>Default:</b> 0</p>
LIBOMPTARGET_INFO	<p>Controls whether basic offloading information will be displayed from the offload runtime.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>0: Disabled.</li> <li>1: Prints all data arguments upon entering an OpenMP device kernel.</li> <li>2: Indicates when a mapped address already exists in the device mapping table.</li> <li>4: Dump the contents of the device pointer map if target offloading fails.</li> <li>8: Indicates when an entry is changed in the device mapping table.</li> <li>32: Indicates when data is copied to and from the device.</li> </ul> <p><b>Default:</b> 0</p>
LIBOMPTARGET_PLUGIN	<p>Specifies which offload plugin is used when offloading a target region.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>LEVEL_ZERO   LEVEL0   level_zero   level0: Uses Intel® oneAPI Level Zero (Level Zero) offload plugin.</li> <li>OPENCL   opencl: Uses OpenCL offload plugin.</li> <li>X86_64   x86_64: Uses X86_64 plugin.</li> </ul> <p><b>Default:</b> LEVEL_ZERO</p>
LIBOMPTARGET_DEVICE_TYPE	<p>Selects device type to which a target region is offloaded.</p>

Runtime Environment Variable	Description
	<p>Possible values:</p> <ul style="list-style-type: none"> <li>GPU   <code>gpu</code>: GPU device is used.</li> <li>CPU   <code>cpu</code>: CPU device is used.</li> </ul> <p>Offload plugin support for device type:</p> <ul style="list-style-type: none"> <li>Level Zero offload plugin only supports GPU type.</li> <li>OpenCL offload plugin supports both GPU and CPU types.</li> <li>X86_64 offload plugin ignores this variable.</li> </ul> <p><b>Default:</b> GPU</p>
LIBOMPTARGET_PLUGIN_PROFILE	<p>Enables basic plugin profiling and displays the result when program finishes.</p> <p><b>Default:</b> Disabled</p> <p><b>Syntax:</b> &lt;Value&gt;[,usec], where &lt;Value&gt;=1   T   t</p> <p>The unit of reported time is microsecond if “,usec” is appended, millisecond otherwise.</p>
LIBOMPTARGET_DYNAMIC_MEMORY_SIZE	<p>Sets the size of preallocated memory in MB to service malloc calls on the device.</p> <p>Currently, calls to free memory on the device do not release memory. All the allocated memory is released only when the program exits.</p> <p>Possible values: Non-negative integer.</p> <p><b>Default:</b> 0</p>
<b>OpenMP Offload Environment Variables for Level Zero Offload Plugin</b>	
This feature is only available for ifx.	
LIBOMPTARGET_LEVEL0_COMPILATION_OPTIONS	<p>Passes extra build options when building native target program binaries.</p> <p>Possible values: Valid <a href="#">Level Zero build options</a>.</p>
LIBOMPTARGET_DEVICES	<p>Controls how subdevices or sub-subdevices are exposed to users if device supports subdevices.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>DEVICE   <code>device</code>: Only top-level devices are reported as OpenMP devices and <code>subdevice</code> clause is supported.</li> <li>SUBDEVICE   <code>subdevice</code>: Only first-level subdevices are reported as OpenMP devices and <code>subdevice</code> clause is ignored.</li> <li>SUBSUBDEVICE   <code>subsubdevice</code>: Only second-level subdevices are reported as OpenMP devices and <code>subdevice</code> clause is ignored.</li> </ul>

Runtime Environment Variable	Description
LIBOMPTARGET_LEVEL0_MEMORY_POOL	<ul style="list-style-type: none"> <li>ALL   all: All devices and subdevices are reported as OpenMP devices and subdevice clause is ignored.</li> </ul> <p><b>Default:</b> DEVICE</p> <p>Controls memory pool configuration.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>0 : Disables using memory pool.</li> <li>&lt;PoolInfoList&gt;=&lt;PoolInfo&gt;[,&lt;PoolInfoList&gt;]</li> </ul> <p>&lt;PoolInfo&gt;=&lt;MemType&gt;[,&lt;AllocMax&gt;[,&lt;Capacity&gt;[,&lt;PoolSize&gt;]]]</p> <p>&lt;MemType&gt;=all   device   host   shared</p> <p>&lt;AllocMax&gt; is a positive integer or empty</p> <p>&lt;Capacity&gt; is a positive integer or empty</p> <p>&lt;PoolSize&gt; is a positive integer or empty</p> <p>&lt;AllocMax&gt; means maximum allocation size in MB supported by the pool, &lt;Capacity&gt; means number of allocations supported by a single memory block allocated from the Level Zero runtime, and &lt;PoolSize&gt; means maximum size of the total pool size in MB.</p> <p><b>Examples:</b></p> <ul style="list-style-type: none"> <li>all,2,8,1024: Enables memory pool for all memory types which can allocate up to eight 2MB blocks from a single block allocated from Level Zero with 1GB total pool size allowed.</li> <li>device,1,4,512: Enables memory pool only for device memory type which can allocate up to four 1MB blocks from a single block allocated from Level Zero with 512MB total pool size allowed.</li> </ul> <p><b>Default:</b> all,1,4,256</p>
LIBOMPTARGET_LEVEL0_USE_COPY_ENGINE	<p>Disables use of copy engine for memory transfers.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>0   F   f: Disables use of copy engine.</li> </ul> <p><b>Default:</b> Enabled</p>
LIBOMPTARGET_LEVEL0_DEFAULT_TARGET_MEM	<p>Selects memory type returned by the <code>omp_target_alloc</code> routine.</p> <p>Possible values:</p>

Runtime Environment Variable	Description
	<ul style="list-style-type: none"> <li>• <code>DEVICE</code>   <code>device</code>: Returned memory type is <code>device</code> type. Device owns the memory and data movement is explicit.</li> <li>• <code>SHARED</code>   <code>shared</code>: Returned memory type is <code>shared</code> type. Ownership of the memory is shared between host and device, and data movement is implicit.</li> <li>• <code>HOST</code>   <code>host</code>: Returned memory type is <code>host</code> type. Host owns the memory and data movement is implicit.</li> </ul> <p><b>Default:</b> <code>DEVICE</code></p>
<code>LIBOMPTARGET_LEVEL0_STAGING_BUFFER_SIZE</code>	<p>Sets the staging buffer size in KB that is used in data transfer between host and device.</p> <p>Possible values: Non-negative integers where 0 disables use of staging buffer.</p> <p><b>Default:</b> 4</p>
<b>OpenMP Offload Environment Variables for OpenCL Offload Plugin</b>	
This feature is only available for ifx.	
<code>LIBOMPTARGET_OPENCL_COMPILATION_OPTIONS</code>	<p>Passes extra compilation options when compiling target programs from SPIRV target images.</p> <p>Possible values: Valid <a href="#">OpenCL compilation options</a>.</p>
<code>LIBOMPTARGET_OPENCL_LINKING_OPTIONS</code>	<p>Passes extra linking options when linking target programs.</p> <p>Possible values: Valid <a href="#">OpenCL linking options</a>.</p>
<code>LIBOMPTARGET_OPENCL_USE_SVM</code>	<p>Enables or disables using OpenCL SVM memory for default target memory type.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>• 1   T   t: Enables using OpenCL SVM memory.</li> <li>• 0   F   f: Disables using OpenCL SVM memory.</li> </ul> <p><b>Default:</b> Disabled</p>
<code>LIBOMPTARGET_OPENCL_DATA_TRANSFER_METHOD</code>	<p>Selects memory transfer method to use. This is only effective when OpenCL SVM memory is enabled by setting <code>LIBOMPTARGET_OPENCL_USE_SVM</code>.</p> <p>Possible values:</p> <ul style="list-style-type: none"> <li>• 0: Uses <code>clEnqueueRead and WriteBuffer</code> API on a temporary OpenCL buffer.</li> <li>• 1: Uses <code>clEnqueueSVMMMap and Unmap</code> API.</li> <li>• 2: Uses <code>clEnqueueSVMMemcpy</code> API.</li> </ul> <p><b>Default:</b> 1</p>
<b>Profile Guided Optimization (PGO_) Environment Variables</b>	

Runtime Environment Variable	Description
INTEL_PROF_DUMP_CUMULATIVE	<p>When using interval profile dumping (initiated by INTEL_PROF_DUMP_INTERVAL or the function <code>_PGOPTI_Set_Interval_Prof_Dump</code>) during the execution of an instrumented user application, allows creation of a single <code>.dyn</code> file to contain profiling information instead of multiple <code>.dyn</code> files. If not set, executing an instrumented user application creates a new <code>.dyn</code> file for each interval.</p> <p>Setting this environment variable is useful for applications that do not terminate or those that terminate abnormally (bypass the normal exit code).</p>
INTEL_PROF_DUMP_INTERVAL	<p>Initiates interval profile dumping in an instrumented user application. This environment variable may be used to initiate Interval Profile Dumping in an instrumented application.</p>
INTEL_PROF_DYN_PREFIX	<p>Specifies the prefix to be used for the <code>.dyn</code> filename to distinguish it from the other <code>.dyn</code> files dumped by other PGO runs. Executing the instrumented application generates a <code>.dyn</code> filename as follows: <code>&lt;prefix&gt;_&lt;timestamp&gt;_&lt;pid&gt;.dyn</code>, where <code>&lt;prefix&gt;</code> is the identifier that you have specified.</p> <hr/> <p><b>NOTE</b></p> <p>The value specified in this environment variable must not contain <code>&lt; &gt; : " / \   ? * </code> characters. The default naming scheme is used if an invalid prefix is specified.</p> <hr/>
PROF_DIR	<p>Specifies the directory where profiling files (files with extensions <code>.dyn</code>, <code>.dpi</code>, <code>.spi</code> and so on) are stored. The default is to store the <code>.dyn</code> files in the source directory of the file containing the first executed instrumented routine in the binary compiled with <code>[Q]prof-gen</code> option.</p> <p>This variable applies to all three phases of the profiling process:</p> <ul style="list-style-type: none"> <li>• Instrumentation compilation and linking</li> <li>• Instrumented execution</li> <li>• Feedback compilation</li> </ul>
PROF_DPI	<p>Name for the <code>.dpi</code> file.</p> <p><b>Default:</b> <code>pgopti.dpi</code></p>
PROF_DUMP_INTERVAL	<p>Deprecated; use INTEL_PROF_DUMP_INTERVAL instead.</p>

Runtime Environment Variable	Description
PROF_NO_CLOBBER	<p>Alters the feedback compilation phase slightly. By default, during the feedback compilation phase, the compiler merges data from all dynamic information files and creates a new <code>pgopti.dpi</code> file if the <code>.dyn</code> files are newer than an existing <code>pgopti.dpi</code> file.</p> <p>When this variable is set, the compiler does not overwrite the existing <code>pgopti.dpi</code> file. Instead, the compiler issues a warning. You must remove the <code>pgopti.dpi</code> file if you want to use additional dynamic information files.</p>

The following table summarizes CPU environment variables that are recognized at runtime.

Runtime configuration	Default value	Description
CL_CONFIG_CPU_FORCE_PRIVATE_MEM_SIZE	32KB	<p>Forces <code>CL_DEVICE_PRIVATE_MEM_SIZE</code> for the CPU device to be the given value. The value must include the unit; for example: 8MB, 8192KB, 8388608B.</p> <hr/> <p><b>NOTE</b> You must compile your host application with sufficient stack size.</p>
CL_CONFIG_CPU_FORCE_LOCAL_MEM_SIZE	32KB	<p>Forces <code>CL_DEVICE_LOCAL_MEM_SIZE</code> for CPU device to be the given value. The value needs to be set with size including units, examples: 8MB, 8192KB, 8388608B.</p> <hr/> <p><b>NOTE</b> You must compile your host application with sufficient stack size. Our recommendation is to set the stack size equal to twice the local memory size to cover possible application and OpenCL Runtime overheads.</p>
CL_CONFIG_CPU_EXPENSIVE_MEMORY_OPT	0	<p>A bitmap indicating enabled expensive memory optimizations. These optimizations may lead to more JIT compilation time, but give some performance benefit.</p>

Runtime configuration	Default value	Description
CL_CONFIG_CPU_STREAMING_AL WAYS	False	<p><b>NOTE</b> Currently, only the least significant bit is available.</p> <p>Available bits:</p> <ul style="list-style-type: none"> <li>0: OpenCL address space alias analysis</li> </ul>
		Controls whether non-temporal instructions are used.

## Use Other Methods to Set Environment Variables

**All Operating Systems**

From within a program: Call the `SETENVQQ` routine to set environment variables. For example:

```
USE IFPORT
LOGICAL success
success = SETENVQQ("FORT9=C:\mydir\test.dat")
```

Depending on your operating system, there are additional ways to set environment variables.

**Linux\* and macOS**

Within the Bourne\*/Bourne\* Again shell (`sh/bash`), or the Korn shell (`ksh`), use the `export` command and assignment command to set an environment variable:

```
export FORT9
FORT9=/usr/users/smith/test.dat
```

To remove the association of an environment variable and its value within the Bourne\*, Korn shell, or bash shells, use the `unset` command:

```
unset FORT9
```

Within the C shell (`csh`), use the `setenv` command to set an environment variable:

```
setenv FORT9 /usr/users/smith/test.dat
```

To remove the association of an environment variable and its value within the C shell, use the `unsetenv` command.

```
unsetenv FORT9
```

## Windows\*

Environment variables in a command prompt session can be set using the `SET` command. Changes here will affect programs run from that command prompt only. For example:

```
set FORT9=C:\mydir\test.dat
```

To remove an environment variable, omit the value. For example:

```
set FORT9=
```

To display the current value, use the `ECHO` command and enclose the environment variable name in the percent signs as shown below:

```
echo %FORT9%
```

To display the values of all variables whose names begin with a string, use `SET` and omit the equal sign as shown below:

```
set FORT
```

In Microsoft Visual Studio you can specify environment variables that will be set when a program is run. In the project properties, edit the Configuration Properties > Debugging > Environment property and set the field to a series of name=value pairs separated by semicolons. For example:

```
FORT9=C:\mydir\test.dat;FOR_FORCE_STACK_TRACE=TRUE
```

A default set of environment variables is established per user and at the system level. These can be specified through Control Panel > System > Advanced System Settings > Environment Variables.

---

### NOTE

Changing system-wide environment variables affects command line builds (those done without IDE involvement), but not builds done through the IDE. IDE builds are managed in the IDE using **Tools > Options**. An exception to this is an IDE build (`devenv`) done from the command line that specifies the `useenv` option. In this case, the IDE uses the `PATH`, `INCLUDE`, and `LIB` environment variables defined for that command line.

# Files Associated with Intel® Fortran Applications on Windows

There are a number of files associated with Intel® Fortran Compiler applications. The following table shows common files used by the Intel® Fortran Compiler and lists their contents.

File Extension	Type	Contents
.asm	Intermediate	Assembly file, passed to the assembler
.exe	Output	Executable, dynamic- link library, or library files
.dll		
.lib		
.fi	Source	Header files
.fd		
.for	Source	Fortran source files (fixed format)
.f		
.fpp		
.f90	Source	Fortran source file (free format)
.def	Source	Linker
.idl	Source	Microsoft IDL (non-Fortran)
.ilk	Intermediate	Incremental link file
.map	Output	Map file; output from the linker
.mod	Intermediate	Module file; created if a source file defines a Fortran module
.obj	Intermediate	Object file; passed to the linker
.pdb	Output (Debug)	Program debug database file
.tbl	Output (MIDL)	Type library; passed to Resource
.rc	Resource	Resource file (non-Fortran)
.res	Intermediate	Resource file; passed to the linker
.sln	Solution	Visual Studio* solution file and solution options file
.suo		
.vfproj	Project	Intel® Fortran, Intel® C++, and Microsoft Visual C++* project files
.icproj		
.vcproj		

You can specify additional Fortran file extensions to be recognized by Visual Studio\*. For more information, see [Specifying Fortran File Extensions](#).

# Compile and Link Multithreaded Programs

---

When building a multithreaded application, be sure to link against the thread-safe version of the Fortran runtime libraries and to enable thread safety. This is specified by the `threads` and `reentrancy:threaded` compiler options. The Visual Studio\* integrated development environment (IDE), described later in this topic, can also be used on Windows\*.

You must also link with the correct library files. Some libraries, such as those for OpenMP\* or coarrays, are always linked dynamically.

## Linux\* and macOS

To create statically-linked, multithreaded programs, link with the static library named `libifcoremt.a`.

To use shared libraries, link your application with `libifcoremt.so` (Linux\*) or `libifcoremt.dylib` (macOS).

### To compile and link your multithreaded program from the command line:

1. Make sure the `IA32ROOT` environment variable points to the directory containing your library files.
2. Compile and link the program with the `-threads` option. For example:

```
ifort -threads mythread.f90
```

---

#### NOTE

To ensure that a threadsafe and/or reentrant runtime library is linked and correctly initialized, option `threads` should also be used for the link step and for the compilation of the main routine.

---

## Windows\*

To create statically linked multithreaded programs, link with the re-entrant support library

`LIBIFCOREMT.LIB`.

To use shared libraries, use the shared `LIBIFCOREMD.DLL` library, which is also re-entrant, and is referenced by linking your application with the `LIBIFCOREMD.LIB` import library.

Programs built with `LIBIFCOREMT.LIB` do not share Fortran runtime library code or data with any dynamic-link libraries they call. You must link with `LIBIFCOREMD.LIB` if you plan to call a DLL.

### Additional Notes:

- The `/threads` option is automatically set when a multithreaded application is specified in the IDE.
- Specify the compiler options `/libs=dll` and `/threads` if you are using both multithreaded code and DLLs.
- You can use the `/libs=dll` and `/threads` options only with Fortran Console projects, not QuickWin applications.

**To compile and link your multithreaded program using Visual Studio\***

1. Create a new project by clicking **File > New > Project**.
2. Select the Intel® Visual Fortran project type from **Intel® Visual Fortran Projects** in the left pane.
3. Add the file containing the source code to the project.

From the **Project** menu, select **Properties**. The **Property Pages** dialog box appears.

4. Choose the **Fortran** folder, **Libraries** category, and set the Runtime Library to **Multithreaded** or **Multithread DLL** (or their debug equivalents).
5. Create the executable file by choosing **Build Solution** from the **Build** menu.

**To compile and link your multithreaded program from the command line:**

1. Make sure your *LIB* environment variable points to the directory containing your library files.
2. Compile and link the program with the `/threads` option. For example:

```
ifort /threads mythread.f90
```

**NOTE**

To ensure that a threadsafe and/or reentrant runtime library is linked and correctly initialized, option `threads` should also be used for the link step and for the compilation of the main routine.

# Linking Tools and Options

This topic describes how to use the Intel® linking tools, `xild` (Linux\* and macOS) and `xilink` (Windows\*).

The Intel® linking tools behave differently on different platforms. The following sections summarize the primary differences between linking behavior.

## Linux\* and macOS Linking Behavior Summary

The linking tool invokes the Intel® Fortran Compiler to perform IPO if objects containing `IR` (intermediate representation) are found. These are mock objects. The tool invokes GNU `ld` to link the application.

The command-line syntax for `xild` is the same as that of the GNU linker: where:

- `[<options>]`: One or more options supported only by `xild` (optional).
- `<normal command-line>`: Linker command line containing a set of valid arguments for `ld`.

To create the file `app` using IPO, use the option `o[filename]` as shown in the following example:

The linking tool calls the compiler to perform IPO for objects containing `IR` and creates a new list of object(s) to be linked. The linker then calls `ld` to link the object files that are specified in the new list and produce the application with the name specified by the `o` option. The linker supports the `ipo[n]` option and `ipo-separate` option.

To display a list of the supported link options from `xild`, use the following command:

## Windows\* Linking Behavior Summary

The linking tool invokes the Intel® Fortran Compiler to perform multi-file IPO if objects containing `IR` (intermediate representation) is found. These are mock objects. It invokes the Microsoft linker `link.exe` to link the application.

**Windows\* Linking Behavior Summary**

The command-line syntax for the Intel® linker is the same as that of the Microsoft linker: where:

- [`<options>`]: One or more options supported only by `xilink` (optional).
- `<normal command-line>`: Linker command line containing a set of valid arguments for the Microsoft linker.

To place the multifile IPO executable in `ipo_file.exe`, use the linker option `out:[filename]`, for example:

The linker calls the compiler to perform IPO for objects containing `IR` and creates a new list of object(s) to be linked. The linker calls Microsoft `link.exe` to link the object files that are specified in the new list and produce the application with the name specified by the `out:[filename]` linker option.

To display a list of support link options from `xilink`, use the following command:

`xilink.exe` accepts all the options of `link.exe` and will pass them on to `link.exe` at the final linking stage.

**Using the Linking Tools**

You must use the Intel® linking tools to link your application if the following conditions apply:

- Your source files were compiled with multi-file IPO enabled. Multi-file IPO is enabled by specifying compiler option `[Q] ipo`.
- You would normally invoke the GNU linker (`ld`) to link your application.
- You would normally invoke the Microsoft linker (`link.exe`) to link your application.

**Linker Options**

The following table provides information on linking options.

Linking Tools Option	Description
<code>qdiag-[type]=[diag-list]</code>	<p>Controls the display of diagnostic information.</p> <p>The <i>type</i> is an action to perform on diagnostics. Possible values are:</p> <ul style="list-style-type: none"> <li>• <b>Enable:</b> Enables a diagnostic message or a group of messages.</li> <li>• <b>Disable:</b> Disables a diagnostic message or a group of messages.</li> </ul> <p>The <i>diag-list</i> is a diagnostic group or ID value. Possible values are:</p> <ul style="list-style-type: none"> <li>• <b>thread:</b> Specifies diagnostic messages that help in thread-enabling a program.</li> <li>• <b>vec:</b> Specifies diagnostic messages issued by the vectorizer.</li> <li>• <b>par:</b> Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).</li> <li>• <b>openmp:</b> Specifies diagnostic messages issued by the OpenMP* parallelizer.</li> <li>• <b>warn:</b> Specifies diagnostic messages that have a "warning" severity level.</li> <li>• <b>error:</b> Specifies diagnostic messages that have an "error" severity level.</li> <li>• <b>remark:</b> Specifies diagnostic messages that are remarks or comments.</li> <li>• <b>cpu-dispatch:</b> Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default.</li> <li>• <b>id[id,...]:</b> Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each "id".</li> </ul>

Linking Tools Option	Description
	<ul style="list-style-type: none"> <li><b>tag[,tag,...]:</b> Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each "tag".</li> </ul> <hr/> <p><b>NOTE</b> Diagnostic messages generated by this option can be affected by other options, such as <code>/arch</code> (Windows), <code>-m</code> (Linux and macOS), or <code>[Q]x</code>.</p> <hr/>
m32 (Linux* only), m64 (Linux* and macOS)	<p><code>[Q]m32</code> generates code for IA-32 architecture. Option <code>-m32</code> is only available on Linux* systems.</p> <p><code>[Q]m64</code> generates code for Intel® 64 architecture.</p>
Qm32, Qm64 (Windows*)	<p>For example, when your compilation environment is configured for Intel® 64 architecture, and you use <code>[Q]m32</code> with the compiler, you also need to use <code>qm32</code> on the linker command line to make sure the proper compilation target is set up for any IPO compilations or the final link.</p>

[Using IPO](#) from the command line

## Use Configuration Files

You can decrease the time you spend entering command-line options by using the configuration file to automate command-line entries. Configuration files are automatically processed every time you run the Intel® Fortran Compiler. You can insert any valid command-line options into the configuration file. The compiler processes options in the configuration file in the order in which they appear, followed by the specified command-line options when the compiler is invoked.

### NOTE

Options in the configuration file are executed every time you run the compiler. If you have varying option requirements for different projects, use [Using Response Files](#).

### Sample Configuration Files

The default configuration file `ifort.cfg` is located in the same directory as the compiler executable file. If you want to use a different configuration file than the default, you can use the `IFORTCFG` environment variable to specify the location of another configuration file.

### NOTE

Anytime you instruct the compiler to use a different configuration file, the default configuration file(s) are ignored.

The following examples illustrate basic configuration files.

## Linux

```
## Sample ifort.cfg file
## Define preprocessor macro MY_PROJECT.
-DMY_PROJECT

## Set extended-length source lines.
-extend_source

## Set maximum floating-point significand precision.
-pc80
```

## Windows

```
## Sample ifort.cfg file
## Define preprocessor macro MY_PROJECT
/DMY_PROJECT

## Set extended-length source lines.
/extend_source

## Additional directories to be searched for include
## files, before the default.
/Ic:\project\include

## Use the static, multithreaded runtime library.
/MT
```

In the Windows examples, the compiler reads the configuration file and invokes the `/I` option every time you run the compiler, along with any options specified on the command line.

## See Also

[Supported Environment Variables](#)

[Using Response Files](#)

---

# Use Response Files

---

You can use response files to:

- Specify options used during particular compilations or projects.
- Save this information in individual files.

Response files are invoked as options on the command line. Options in response files are inserted in the command line at the point where the response file is invoked. Unlike configuration files, which are automatically processed every time you run the compiler, response files must be invoked as an option on the command line. If you create a response file without specifying it on the command line, it will not be invoked.

Use response files to decrease the time spent entering command-line options and to ensure consistency by automating command-line entries. Use individual response files to maintain options for specific projects.

Any number of options or file names can be placed on a line in a response file. Several response files can be referenced in the same command line. The following example shows how to specify a response file on the command line:

```
ifort @ [responsefile2 ... ]
```

**NOTE**

An "at" sign (@) must precede the name of the response file on the command line.

---

**See Also**

[Using Configuration Files](#)

---

## Create Fortran Executables

---

The simplest way to build an application is to compile all of your Fortran source files, then link the resulting object files into a single executable. You can build single-file executables using the `ifort` command. You can also use the Visual Studio\* IDE on Windows\*.

The executable file you build with this method contains all of the code needed to execute the program, including the runtime library. Because the program resides in a single file, it is easy to copy or install. The project contains all of the source and object files for the routines used to build the application. To use these routines in other projects, all source and object files must be relinked.

Exceptions to this are as follows:

- If you are using shared libraries, all code will not be contained in the executable file.
- On macOS, the object files contain debug information and would need to be copied along with the executable.

---

## Link Debug Information

---

**Linux**

Use option `-g` at compile time to tell the compiler to generate symbolic debugging information in the object file.

Use option `-gsplit-dwarf` to create a separate object file containing DWARF debug information. Because the DWARF object file is not used by the linker, this reduces the amount of debug information the linker must process and it results in a smaller executable file. See [gsplit-dwarf](#) for detailed information.

**macOS**

You can link the DWARF debug information from the object files for an executable using `dsymutil`, a utility included with Xcode\*. By linking the debug information in an executable, you eliminate the need to retain object files specifically for debugging purposes.

The utility runs automatically in the following cases:

- When you use the Intel® Fortran Compiler to compile directly from source to executable using the command line with option `-g`. For example:

Example
<pre>ifort -g myprogram.f90</pre>

- When you compile using Xcode\*.

In other cases, you must explicitly run `dsymutil`, such as when you compile using a make file that builds `.o` files and subsequently links the program.

**NOTE** Xcode\* integration capabilities within our Intel® Fortran Compiler bundle have been removed. The command-line interface remains fully functional for macOS\*. Keep in mind that installation of Xcode is still recommended because command-line tools from Xcode are required by the command-line compiler. However, you can install just the Xcode Command Line Tools with this command from a terminal window:

```
xcode-select --install
```

---

## Windows

Use option `z7` at compile time or option `debug` at link time to tell the compiler to generate symbolic debugging information in the object file. Alternately, use option `zi` at link time to generate executables with debug information in the `.pdb` file.

# Debugging

---

Depending on your operating system and architecture platform, several debuggers may be available to you. You can use the debugger provided by your operating system:

- On Linux\* and macOS, this debugger is `gdb`.
- On Windows\*, the debugger is the Microsoft Visual Studio\* debugger.

On Windows\* systems, you can use your local (host) system to debug an application running on a remote system. For more information, see [Using Remote Debugging](#).

## See Also

[Using Remote Debugging](#)

## Prepare Your Program for Debugging

---

This section describes preparing your program for debugging.

### Prepare for Debugging using the Command Line

**To prepare your program for debugging when using the command line (ifort command):**

1. Correct any compilation and linker errors.
2. In a command window, such as the Fortran command window available from the Intel® Fortran program folder, compile and link the program with full debug information and no optimization:

```
// (Linux* OS and macOS)
ifort -g file.f90
```

```
// (Windows* OS)
ifort /debug:full file.f90
```

On Linux\* OS and on macOS, specify the `g` compiler option to create unoptimized code and provide the symbol table and traceback information needed for symbolic debugging. The `notraceback` option cancels the traceback information.

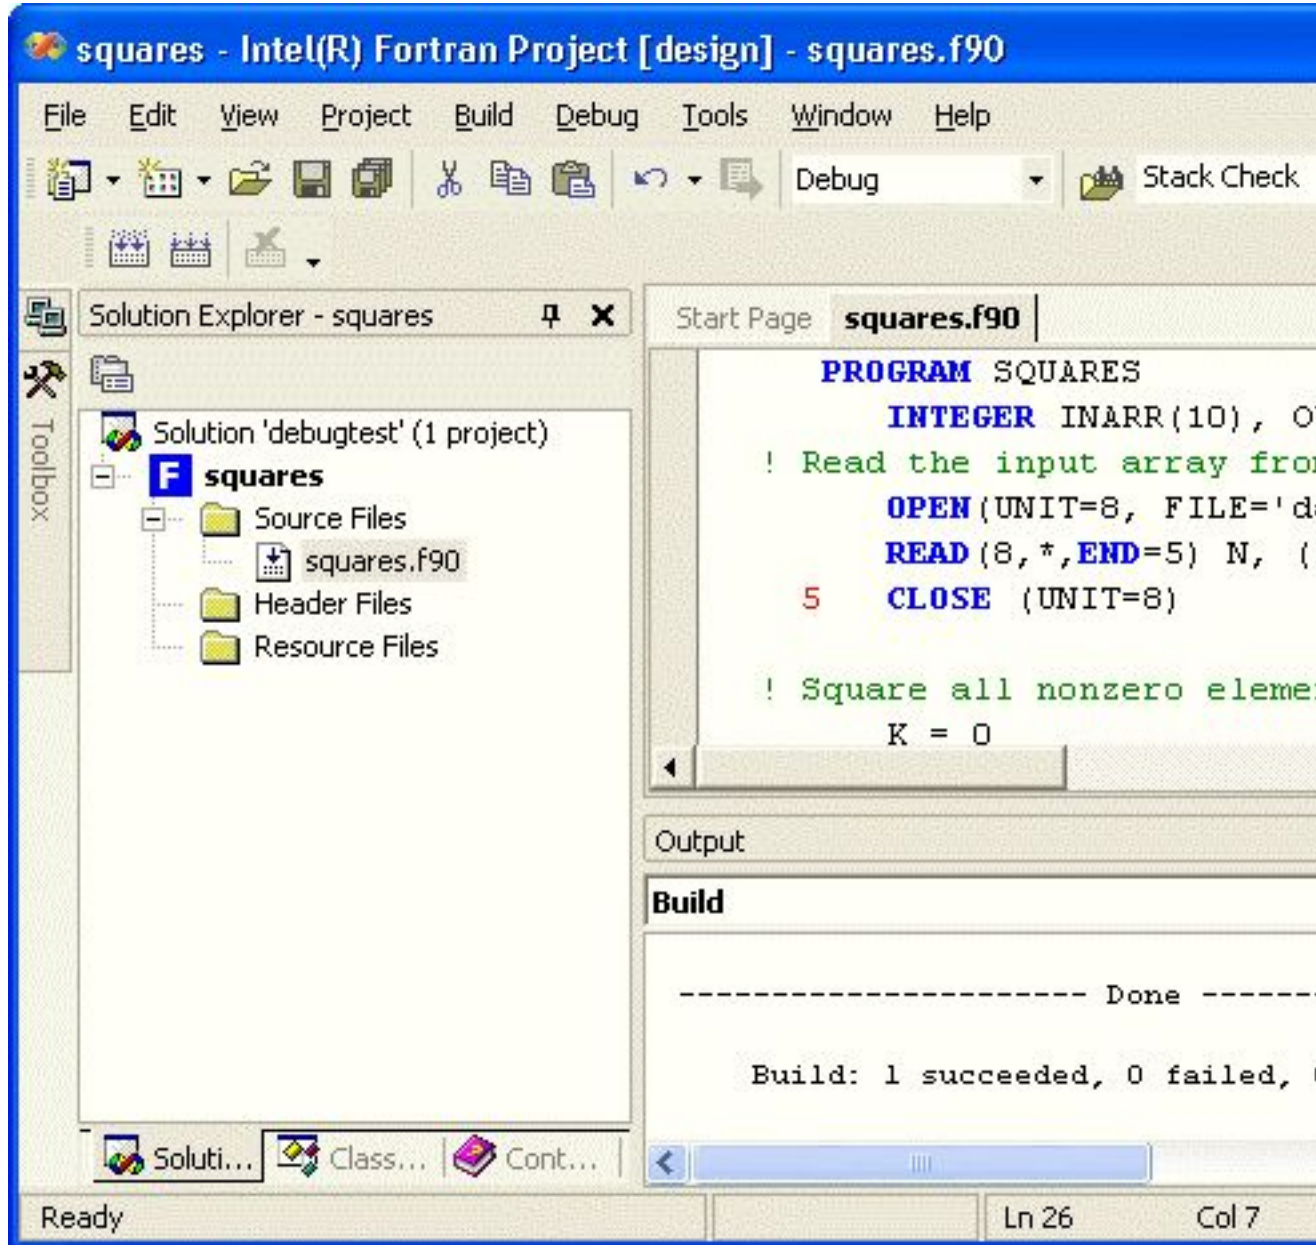

On Windows\* OS, specify the `debug` compiler option with keyword `full` to produce full debugging information. It produces symbol table information needed for full symbolic debugging of unoptimized code and global symbol information needed for linking.

## Prepare for Debugging using Visual Studio\*

The following applies to Windows\* operating systems only.

### To prepare your program for debugging when using the integrated development environment (IDE):

1. Start the IDE (select the appropriate version of Visual Studio\* in the program folder).
2. Open the appropriate solution (using the Solution menu, either **Open Solution** or **Recent Projects**).
3. Open the **Solution Explorer** View.
4. To view the source file to be debugged, double-click on the file name. The screen resembles the following:

5. In the **Build** menu, select **Configuration Manager** and select the **Debug** configuration.

6. To check your project settings for compiling and linking, select the project name in **Solution Explorer** . Now, in the **Project** menu, select **Properties** , then click the Fortran folder in the left pane. Similarly, to check the debug options set for your project (such as command arguments or working directory), click the Debugging folder in the **Property Pages** dialog box.
7. To build your application, select **Build > Build Solution**.
8. Eliminate any compiler diagnostic messages using the text editor to resolve problems detected in the source code and recompile if needed.
9. Set breakpoints in the source file and debug the program. For more information, see [Debugging the Squares Example Program](#).

---

**NOTE** You must set a breakpoint before starting the program, otherwise the program will run to completion, and exit.

---

[Debugging the Squares Example Program](#)

## Use Breakpoints in the Debugger

---

This topic applies to Fortran applications for Windows only.

This topic describes how to use the Microsoft Visual Studio\* debugger to set file and data breakpoints. Information is organized as follows:

- [Viewing All Current Breakpoints](#)
- [Working with File Breakpoints](#)
- [Adding Conditions to File Breakpoints](#)
- [Working with Data Breakpoints](#)

In addition to file and data breakpoints, the Visual Studio\* debugger supports the following:

- Address breakpoints
- Function breakpoints
- Tracepoints

For information on these additional features, see the Microsoft documentation for your version of Visual Studio\*.

## View All Current Breakpoints

You can view all currently set breakpoints in the **Breakpoints** window. To view all set breakpoints using the Breakpoints window:

1. In the **Debug** menu, select **Windows > Breakpoints**.
2. Scroll up or down in the Breakpoints list to view the breakpoints. Enabled breakpoints have a check mark in the check box and disabled breakpoints have an empty check box. The window displays all types of breakpoints.

## Use File Breakpoints

Use a file breakpoint to interrupt program execution when the program reaches a specified location within a file. Several symbols are used to show the status of file breakpoints; these appear in the left margin of the **Source** window:

**Enabled** file breakpoints are identified as a red circle.

**Disabled** file breakpoints are identified as a hollow circle in the left margin.

During debugging, a **currently active** breakpoint appears as a red circle containing a yellow arrow in the left margin of the **Source** window.

For a walk-through of a sample debugging session using file breakpoints, see [Debugging the Squares Example Program](#).

#### To set (enable) a file breakpoint:

1. Open the desired source file in the solution.
2. In the **Source** window, click the line at which you want to enable a file breakpoint.
3. Do one of the following:
  - Click in the left margin of the line or press the F9 key. When you set a breakpoint, it is enabled by default.
  - Right click on the desired line and select **Insert Breakpoint** from the pop-up menu.

#### To disable a file breakpoint:

1. In the **Source** window, click the line containing the file breakpoint you want to disable.
2. Do one of the following:
  - Right click on that line, and select **Disable Breakpoint** from the pop-up menu.
  - In the **Debug** menu, select **Windows > Breakpoints**, which opens the **Breakpoints** window. Select the check box for that breakpoint so it is unchecked (disabled).

#### To remove a file breakpoint:

1. In the **Source** window, click the line containing the file breakpoint you want to remove.
2. Do one of the following:
  - Click in the left margin of the line or press the F9 key. If the breakpoint was originally disabled, press F9 again to remove it.
  - Right click on that line, and select **Delete Breakpoint** from the pop-up menu.
  - In the **Debug** menu, select **Windows > Breakpoints**. In the **Breakpoints** window, select the breakpoint in the Name column and click the **Delete** button (which looks like an "X").

#### To view the source code where a file breakpoint is set:

1. In the **Debug** menu, select **Windows > Breakpoints**.
2. In the Breakpoints window, click a file breakpoint.
3. Click the **Go To Source Code** button.

This action takes you to the source code for a breakpoint set at a line number or function (or subroutine) name. In the case of function (or subroutine) names, the debugger must be running for this to work.

#### To remove all breakpoints (including data breakpoints):

In the **Debug** menu, select **Delete All Breakpoints**.

### Add Conditions to File Breakpoints

When you associate a condition with a file breakpoint, the program executes until that location is reached *and* the specified condition is met, such as when the value of an array element is greater than 1.

To add a condition to a breakpoint:

1. Set a file breakpoint.

## 2. Right-click in the associated line and select **Breakpoint > Condition....**

The **Breakpoint Condition** dialog box appears.

The condition that you specify in the **Breakpoint Condition** dialog box must relate to a local variable within the breakpoint's scoping unit, or to a global variable. You must apply proper Fortran syntax in the **Condition** field in order for the specified condition to be properly detected. Consider the following examples:

To break when the local variable `RecNum` reaches a value of 7520, enter the following condition:

```
RecNum == 7520
```

You can also specify joint conditions. To break when `RecNum` reaches at least 7520 and the variable `Var2` is equal to 90, enter the following condition:

```
RecNum >= 7520 .and. Var2 == 90
```

You can also specify an `or` condition. For example:

```
Var1 == 3.14 .or. Var2 < 500.0
```

If the condition that you specify occurs at the chosen location when the program is run, a message box appears. If the breakpoint is set in part of a loop, continuing execution proceeds until the debugger detects another specified condition. If no such condition is detected, the debugger continues to the next breakpoint or, if no more breakpoints are set, until the end of the loop.

To disable, enable, or remove a file breakpoint with a defined condition, follow the general procedures for a file breakpoint. Use the checkbox for the **Condition** field to enable or disable the condition setting.

## Use Data Breakpoints

Use a data breakpoint to interrupt program execution when the value of a certain variable changes. A data breakpoint displays a message box when the value of a variable changes, or, if a condition has been defined, when a condition is met. Unlike a file breakpoint, data breakpoints are not associated with a specific source location.

## Use Visual C++ Data Breakpoint Support

The Visual Studio\* IDE does not provide data breakpoint support specifically for Fortran, but you can still use data breakpoints in a Fortran program; they are handled using the existing mechanism provided by Microsoft Visual C++\*. This means that you must use Visual C++\* syntax; you cannot enter the variable name or condition using Fortran syntax. The following guidelines apply:

- For scalar variables, enter the variable name in upper case. This allows Visual C++\* to find the variable in the debug information and apply the correct breakpoint.
- For arrays and types, use the Fortran LOC intrinsic function in a **Watch** window or the **Immediate** window to obtain the address of the variable. Use this address in the variable name edit box.

For example, to prepare to set a data breakpoint at an array element `a(5)`, do the following:

1. Select **Debug > Windows > Immediate**.
2. Enter `loc(a(5))` in the immediate window and press Enter.

The result displayed is the address of the array element. The address may be displayed as a decimal number or a hexadecimal number, depending upon your current display mode. For a decimal number, you will enter it in the **Address:** field. For a hexadecimal number, you will use the Visual C++\* hexadecimal syntax (`0xxxxxxxx`) rather than the Fortran syntax (`#xxxxxxxx`) in the fields.

The following procedure applies to debugging the current routine (current scope).

### To set a data breakpoint:

1. Start debugging.

2. In the **Debug** menu, select **New Breakpoint > New Data Breakpoint...**
3. Enter the desired address. Also enter the Byte Count and Language (specify C++).

If you want to associate a condition with this breakpoint, right-click on the breakpoint in the **Breakpoints** window and choose **Condition...**

**To disable, enable, or remove a data breakpoint:**

1. In the **Debug** menu, select **Windows > Breakpoints**.
2. To disable or enable the data breakpoint, use the check box to the left of the data breakpoint (check indicates enabled).
3. To remove a data breakpoint, select the data breakpoint and click the **Delete** button.

Under certain conditions, the debugger may disable a data breakpoint. In this case, you should either try to enable it or remove and set it again.

**To remove all breakpoints (including file breakpoints):**

In the **Debug** menu, select **Delete All Breakpoints**.

**See Also**

[Debugging the Squares Example Program](#)

## Debug the Squares Example Program

This topic applies to Fortran applications for Windows only.

The example below shows a program called `SQUARES` that requires debugging. The program was compiled and linked without diagnostic messages from either the compiler or the linker, however, this program contains a logic error in an arithmetic expression.

```

PROGRAM SQUARES
  INTEGER INARR(10), OUTARR(10), I, K
! Read the input array from the data file.
  OPEN(UNIT=8, FILE='datafile.dat', STATUS='OLD')
  READ(8,*,END=5) N, (INARR(I), I=1,N)
5  CLOSE (UNIT=8)

! Square all nonzero elements and store in OUTARR.
  K = 0
  DO I = 1, N
    IF (INARR(I) .NE. 0) THEN
      OUTARR(K) = INARR(I)**2
    ENDIF
  END DO

! Print the squared output values. Then stop.
  PRINT 20, N
20  FORMAT (' Total number of elements read is',I4)
  PRINT 30, K
30  FORMAT (' Number of nonzero elements is',I4)
  DO I=1,K
    PRINT 40, I, OUTARR(K)
40  FORMAT(' Element', I4, 'Has value',I6)
  END DO
END PROGRAM SQUARES

```

The program `SQUARES` performs the following functions:

- Reads a sequence of integer numbers from a data file and saves these numbers in the array `INARR`. The file `datafile.dat` contains one record with the integer values 4, 3, 2, 5, and 2. The first number indicates the number of data items that follow.
- Enters a loop in which it copies the square of each nonzero integer into another array `OUTARR`.
- Prints the number of nonzero elements in the original sequence and the square of each such element.

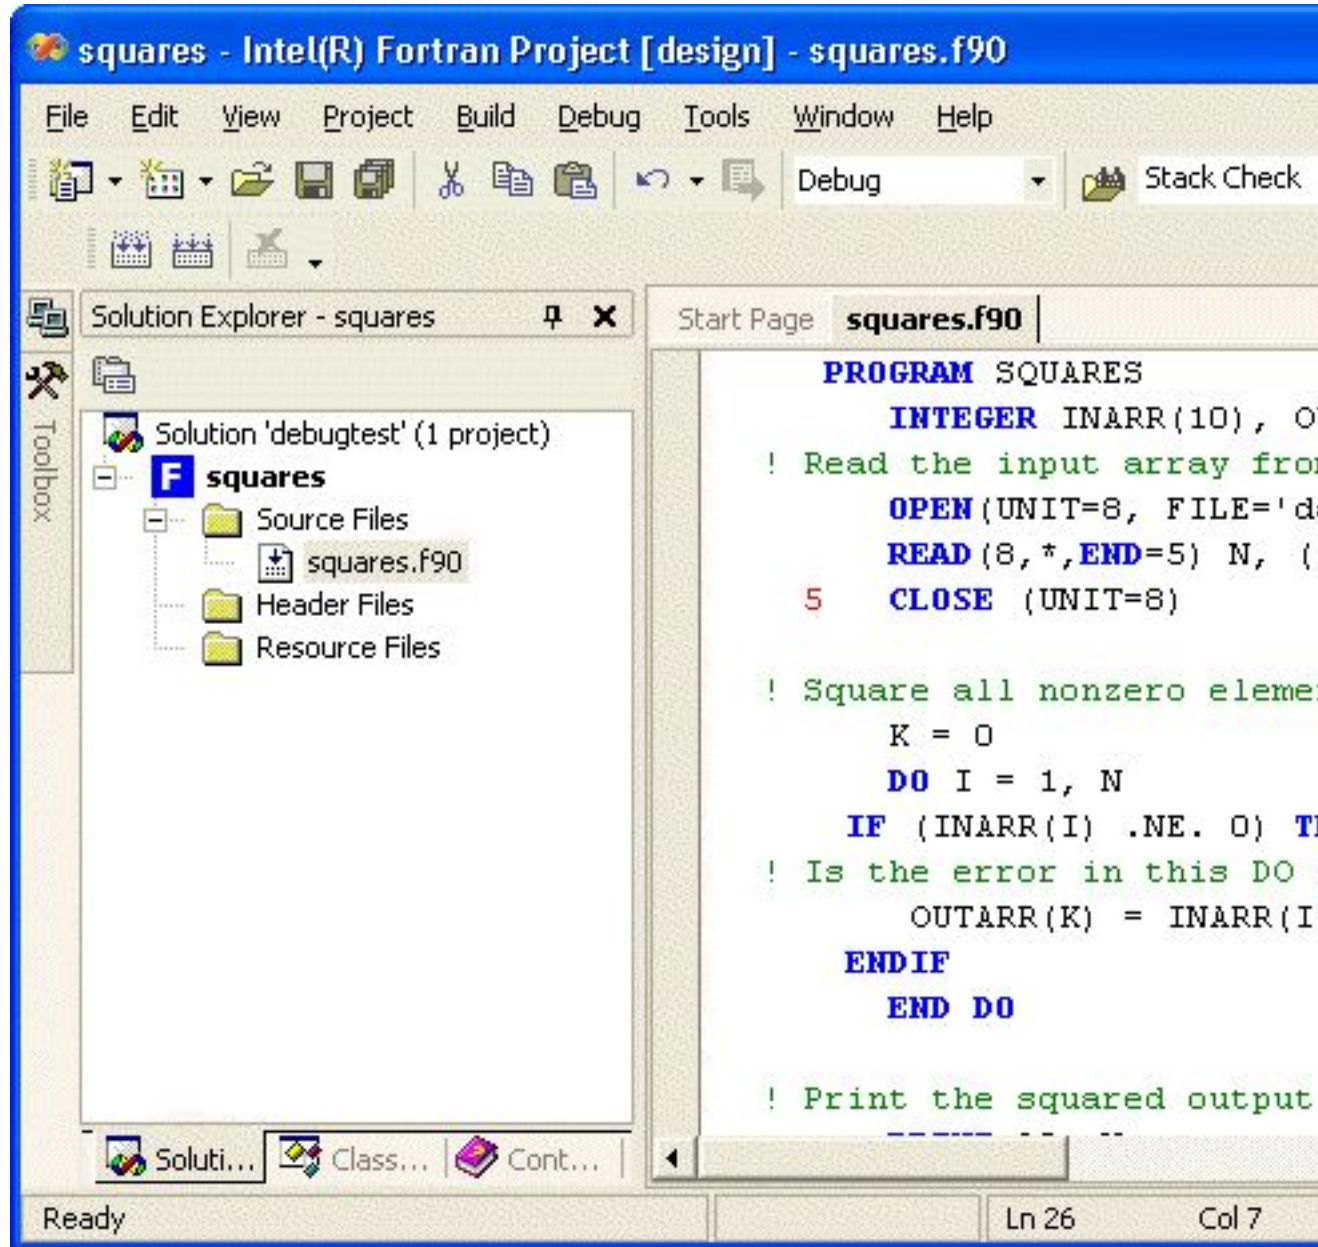

In the program, the logic error occurs because variable `K`, which keeps track of the current index into `OUTARR`, is not incremented in the loop on lines 9 through 13. The statement `K = K + 1` should be inserted just before line 11.

This example assumes that the program was executed without array bounds checking (set by specifying `nobounds` for the `check` command-line option). When executed with array bounds checking, a runtime error message appears.

**Debugging Example:** The following shows how to debug a Windows\* OS based program using the Microsoft integrated debugger within the integrated development environment (see [Preparing Your Program for Debugging](#) and [Using Breakpoints in the Debugger](#)). This example assumes a solution already exists.

**To debug this program:**

1. Start Visual Studio\*.
2. In the **File** menu, select **Open Solution**. Open the solution containing the file.
3. Edit the file `squares.f90`: double-click the file name in the **Solution Explorer** View. The screen appears as follows:

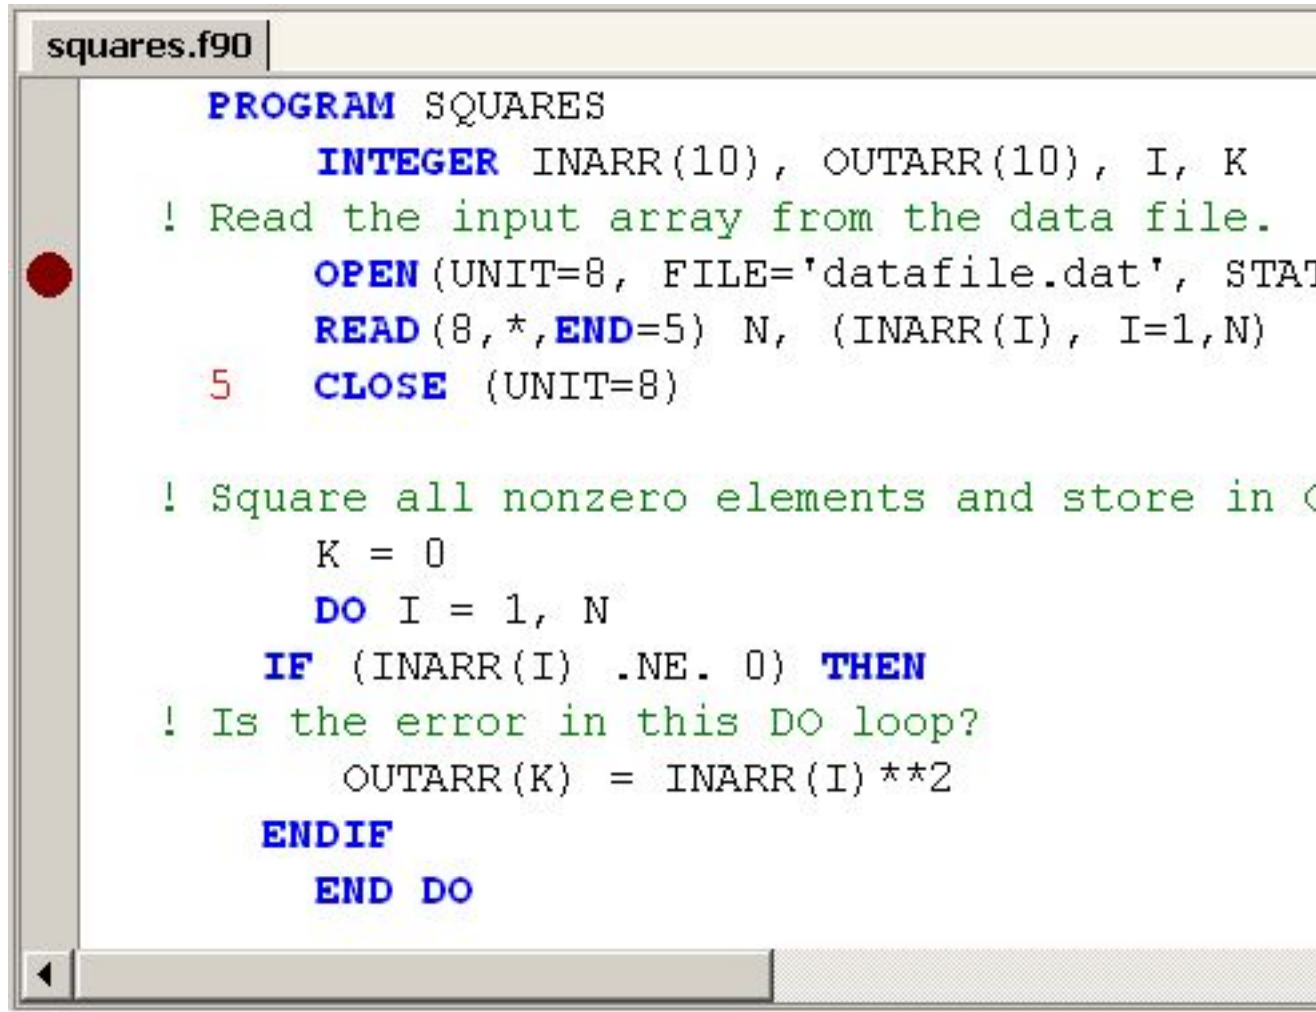

The following toolbars are shown: **Build** toolbar, **Standard** toolbar.

4. To change the displayed toolbars, select **View > Toolbars**. To display the debug toolbar, select **Debug**.
5. Click the first executable line to set the cursor position. In this case, click the beginning of the `OPEN` statement line:

```
OPEN(UNIT=8, FILE='datafile.dat', STATUS='OLD')
```

6. Click in the left margin of the first executable line to set a breakpoint. The red circle in the left margin of the text editor/debugger window shows where a breakpoint is set:

```

squares.f90
PROGRAM SQUARES
    INTEGER INARR(10), OUTARR(10), I, K
    ! Read the input array from the data file.
    OPEN (UNIT=8, FILE='datafile.dat', STAT
    READ (8, *, END=5) N, (INARR(I), I=1,N)
5    CLOSE (UNIT=8)

    ! Square all nonzero elements and store in C
    K = 0
    DO I = 1, N
        IF (INARR(I) .NE. 0) THEN
            ! Is the error in this DO loop?
            OUTARR(K) = INARR(I) **2
        ENDIF
    END DO

```

7. This example assumes you have previously built your application (see [Preparing Your Program for Debugging](#)).  
In the **Debug** menu, select **Start Debugging**.  
The debugger is now active. The current position is marked by a yellow arrow at the first executable line (the initial breakpoint).
8. If needed, you can set another breakpoint. Position the cursor at the line where you want to add a breakpoint, right click, and select **Breakpoint > Insert Breakpoint**.
9. Step through the lines of source code. You can do this with **Debug > Step Over** or with the **Step Over** button on the **Debug** toolbar.
10. Repeat the **Step Over** action and follow program execution into the `DO` loop and unto the end of the program. Position the cursor over the variable `K` to view its value in a **Data Tip** box:

```
squares.f90
      OUTARR(K) = INARR(I)**2
      ENDIF
    END DO

! Print the squared output values. Then stop
PRINT 20, N
20  FORMAT (' Total number of elements read is ', I0)
PRINT 30, K
30  FORMAT (' Number of nonzero elements is ', I0)
DO, I=1,K
  PRINT 40, I, OUTARR(I)
```

The error seems related to the value of variable `K`.

11. In the **Text Editor**, add the line `K = K + 1` as follows:

```
! Square all nonzero elements and store in OUTARR.
K = 0
DO I = 1, N
  IF (INARR(I) .NE. 0) THEN
    K = K + 1      ! add this line
    OUTARR(K) = INARR(I)**2
  ENDIF
END DO
```

12. Since you have modified the source, you need to rebuild the application:

- In the **Debug** menu, select **Stop Debugging**
- In the **Build** menu, select **Build debugtest.**
- In the **Debug** menu, select **Start Debugging.**

The output screen appears as follows:

```
Total number of elements read is  4
Number of nonzero elements is  4
Element  1 has value  9
Element  2 has value  4
Element  3 has value 25
Element  4 has value  4
```

13. The program now generates better results. You can examine the values of both the input array `INARR` (read from the file) and the output array `OUTARR` that the program calculates. In the **Text Editor** window, the previously set breakpoint remains set.

In the **Debug** menu, select **Start Debugging.**

14. To view the values of certain variables as the program executes, display the Locals window. In the **Debug** menu, select **Windows > Locals**.
15. You can view the values of the local variables in the Locals window. Click the plus sign to view array values.

I	1
⊕ OUTARR	{...}
⊕ INARR	{...}

The **Locals** window does not let you display module variables or other non-local variables. To display non-local variables, display one of the **Watch** windows.

16. Although this example does not use module variables or non-local variables, you can drag a variable name into the **Watch** window so the variable can be displayed. The **Watch** window allows you to display expressions.

In the **Text Editor** window, select the variable name `INARR` (without its subscript syntax), drag it, and drop it into the **Watch** window, Name column:

17. Also drag the `OUTARR` array name to the **Watch** window. Click the Plus sign (+) to the left of the `OUTARR` variable's name to display the values of its array elements.
18. Execute lines of the program by using the **Step Over** button on the **Debug** toolbar. As the program executes, you can view the values of scalar variables with the data tips feature and view the values of arrays (or other variables) in the **Watch** window.

If a **Disassembly** window (shows disassembled code with source-code symbols) unintentionally appears, click the **Step Out** button on the debugger toolbar (or select **Step Out** in the **Debug** menu) as needed to dismiss the **Disassembly** window.

[Using Breakpoints in the Debugger](#)

## View Fortran Data Types in the Microsoft Debugger

This topic applies to Fortran applications for Windows only.

The following general suggestions apply to different types of Fortran data:

- For scalar (nonarray) data, use the data tips (leave pointer on a variable name) feature or use the **Locals** window or a **Watch** window. Intel® Fortran does not support the **Autos** window.
- For single-dimension array data, derived-type data, record structure data, and COMPLEX data, use the **Locals** window or a **Watch** window.
- For common blocks exported from a DLL, enter the name of the common block in a **Watch** window. You will be able to view the common block variables like any other structure.
- By default, values of named constants (parameters) are not visible in the debugger. To make these visible, add the `/debug-parameters:used` option or `/debug-parameters:all` option when compiling the sources.

For information on using Data Tips, the **Locals** window, or a **Watch** window, see [Debugging the Squares Example Program](#).

The following sections apply to using a **Watch** window:

- [Specifying Array Sections](#)
- [Specifying Module Variables](#)
- [Specifying Format Specifiers](#)

To display a **Watch** window:

1. In the **Debug** menu, select **Windows > Watch**.
2. In the submenu, click Watch 1, 2, 3, or 4.

## Specify Array Sections

You can specify array sections in a **Watch** window. For example, consider an array declared as:

```
integer foo(10)
```

You can specify the following statement in a **Watch** window to see the 2nd, 5th, and 8th elements:

```
foo(2:10:3)
```

When working with character arrays, this syntax may be combined with a substring specification. Consider the following array declaration:

```
character*8 chr_arr(10)
```

You can specify the following statement in a **Watch** window to display the substring made up of character 3 through 8 of array elements 2 through 5:

```
chr_arr(2:5)(3:8)
```

This support is available for arrays of any type, including array pointers, assumed-shape, allocatable, and assumed-size arrays.

Any valid integer expression can be used when specifying lower bound, upper bound, or stride. If the lower bound is omitted, the array lower bound is used. If the upper bound is omitted, the array upper bound is used. For example, consider the following declaration:

```
integer foo(10)
```

To display:

- Elements 1 through 8, specify `foo(:8)`
- Elements 5 through 10, specify `foo(5:)`
- All 10 elements, specify `foo(:)`

## Specify Module Variables

To view a module variable in a Watch window, specify the module name, followed by "::", followed by the variable name.

For example, to watch variable "bar" of module "foo", specify the following expression:

```
foo::bar
```

## Specify Format Specifiers

You can use format specifiers in **Watch** windows to display variables in different data formats.

For example, given a REAL variable 'foo' in a program, it is now possible to see 'foo' in different floating point notation (by typing "foo,f" "foo,g" or "foo,e" in a **Watch** window) or as an integer ("foo,i" or "foo,d"), a hexadecimal value ("foo,x"), an an octal value ("foo,o"), and so on.

You can change the display format of variables in a **Watch** window using the formatting symbols in the following table:

Symbol	Format	Value	Displays
d,i	<i>signed</i> decimal integer	0xF000F065	-268373915
o	<i>unsigned</i> octal integer	0xF065	0170145
x,X	Hexadecimal integer	61541 (decimal)	#0000F065
f	<i>signed</i> floating-point	3./2.	1.5000000

Symbol	Format	Value	Displays
e	<i>signed</i> scientific notation	3./2.	0.1500000E+01
g	<i>signed</i> floating-point or <i>signed</i> scientific notation, whichever is shorter	3./2.	1.500000
c	Single character	0x0065	'e'
s	String	0x0012fde8	"Hello world"

To use a formatting symbol, type the variable name, followed by a comma and the appropriate symbol. For example, if `var` has a value of `0x0065`, and you want to see the value in character form, type `var,c` in the **Name** column on the tab of the **Watch** window. When you press ENTER, the character-format value appears:

```
var,c = 'e'
```

You can use the formatting symbols shown in the following table to format the contents of memory locations:

Symbol	Format	Displays
ma	64 ASCII characters	0x0012ffac .4...0..."OW&.....1W&.0.:W..1...."..1.J O&.1.2.."..1...0y....1
m	16 bytes in hexadecimal, followed by 16 ASCII characters	0x0012ffac B3 34 CB 00 84 30 94 80 FF 22 8A 30 57 26 00 00 .4...0..."OW&..
mb	16 bytes in hexadecimal, followed by 16 ASCII characters	0x0012ffac B3 34 CB 00 84 30 94 80 FF 22 8A 30 57 26 00 00 .4...0..."OW&..
mw	8 words	0x0012ffac 34B3 00CB 3084 8094 22FF 308A 2657 0000
md	4 doublewords	0x0012ffac 00CB34B3 80943084 308A22FF 00002657

With the memory location formatting symbols, you can type any value or expression that evaluates to a location.

A formatting character can also follow an expression:

```
rep+1,x  
xloc,g  
count,d
```

#### NOTE

You can apply formatting symbols to structures, arrays, pointers, and objects as unexpanded variables only. If you expand the variable, the specified formatting affects all members. You cannot apply formatting symbols to individual members.

## View the Call Stack in the Microsoft Debugger

In most cases, your program will automatically stop at the point where the exception occurs, allowing you to view the source code and values of variables. If the error is related to an I/O statement, you may want to view the call stack.

If you want to view where your program is currently executing in the hierarchy of routines, you can display the **Call Stack** window in the debugger. For example, you may want to display this window to determine where in your program an exception occurs.

To view the call stack:

1. Start the debugger and stop at a breakpoint.
2. Select **Debug > Windows > Call Stack**.

A severe unhandled I/O programming error (such as an End-of-File condition) can occur while the program is executing in the debugger. When this occurs, the Fortran runtime system will raise a debug event automatically to stop program execution, allowing display of the **Call Stack**.

When the severe unhandled I/O error occurs in the debugger:

- An information box is displayed that contains:

```
User breakpoint called from code at 0xnnnnnnnn
```

- A window appears with your cursor in NTDLL disassembly code

Click **OK** to dismiss the information box.

Scanning down the **Call Stack** display, there will be a few frames from NTDLL and the Fortran runtime system displayed, then the actual Fortran routine with the I/O statement that caused the error. In the call stack, select the Fortran routine to display the Fortran code and the variables using the **Locals** window. The green arrow points to the I/O statement that caused the error.

This action all occurs after the error message and traceback information has been displayed. The error message and traceback information is available in the program output window. To view the program output window, either iconize (minimize) the integrated development environment (IDE) or click the icon for the output window in the task bar. You should not need the stack dump because you have the **Call Stack** window in the IDE, but the error message with the file name might be useful to see.

[Locating Runtime Errors](#)

[Traceback](#)

## Locate Unaligned Data

Unaligned data can slow program execution. You should determine the cause of the unaligned data, fix the source code (if necessary), and recompile and relink the program.

If your program encounters unaligned data at runtime, to make it easier to debug the program, you should recompile and relink with the `-g` (Linux\* OS and macOS) or `/debug:full` (Windows\* OS) option to generate sufficient table information and debug unoptimized code.

## Debug a Program that Encounters a Signal or Exception

If your program encounters a signal (exception) at runtime, you may want to recompile and relink with certain command-line options before debugging the cause. The following will make it easier to debug the program:

- Use the `fpe[:]n` option to control the handling of floating point exceptions.
- To generate sufficient symbol table information and debug unoptimized code, as with other debugging tasks, use the `-g` (Linux\* and macOS) or `/debug:full` (Windows\*) compiler option.

## Debug an Exception in the Microsoft Debugger

You can request that the program always stop when a certain type of exception occurs. Because certain exceptions are caught by default by the Intel® Fortran runtime library, your program stops in the runtime library code. In most cases, you want the program to stop in your program's source code instead.

### To change how an exception is handled in the Microsoft debugger:

1. In the **Debug** menu, select **Exceptions**.
2. View the displayed exceptions.
3. Select **Windows Exceptions**. Select each type of exception to be changed and change its handling using the radio buttons.
4. Start program execution using **Start** in the **Debug** menu.
5. When the exception occurs, you can now view the source line being executed, examine current variable values, execute the next instruction, and so on, to help you better understand that part of your program.
6. After you locate the error and correct the program, consider whether you want to reset the appropriate type of exception to **"Use Parent Setting"** before you debug the program again.

For machine exceptions, you can use the just-in-time debugging feature to debug your programs as they run outside of the visual development environment. To do this, set the following items:

- In **Tools > Options**, select **Native** in the **Debugging Just-In Time** category.
- Set the `FOR_IGNORE_EXCEPTIONS`, as listed in [Supported Environment Variables](#), to `TRUE`.

### See Also

[Supported Environment Variables](#)

---

## Debugging and Optimizations

This topic describes the relationship between various command-line options that control debugging and optimizing.

Whenever you enable debugging with the `-g` option (Linux\* and macOS) or `/debug:full` option (Windows\*), you disable optimizations. You can override this behavior by explicitly specifying compiler options for optimizations on the command line.

The following summarizes commonly used options for debugging and for optimization.

---

<code>-O0</code> (Linux* and macOS)	Disables optimizations so you can debug your program before any optimization is attempted. This is the default behavior when debugging.
<code>/Od</code> (Windows*)	

---

### NOTE

On Linux\* and macOS, `-fno-omit-frame-pointer` is set if either option `-O0` or `-g` is specified.

---

For more information, see the following topics:

- `-O0` (Linux\* and macOS) compiler option
- `/Od` (Windows\*) compiler option

`O1`, `O2`, or `O3`  
(Linux\* and macOS)

Specifies the code optimization level for applications. If you use any of these options, it is recommended that you use `-debug extended` when debugging.

For more information, see the following topics:

`O` (Windows\*)

- `-O1`, `-O2`, `-O3` (Linux\* and macOS) compiler options
- `/O` (Windows\*) compiler option

<code>-g</code> (Linux* and macOS) <code>/debug:full</code> (Windows*)	<p>Generates symbolic debugging information and line numbers in the object code for use by the source-level debuggers. Turns off <code>O2</code> and makes <code>-O0</code> (Linux* and macOS) or <code>/Od</code> (Windows*) the default. The exception to this is if options <code>O1</code>, <code>O2</code>, or <code>O3</code> are explicitly specified in the command line.</p> <p>For more information, see the following topics:</p> <ul style="list-style-type: none"><li>• <code>-g</code> (Linux* and macOS)</li><li>• <code>/debug:full</code> (Windows*) compiler option</li></ul>
<code>-debug extended</code> (Linux* and macOS)	<p>Specifies settings that enhance debugging.</p> <p>For more information, see the following topic:</p> <ul style="list-style-type: none"><li>• <code>-debug extended</code> (Linux* and macOS)</li></ul>
<code>-fip</code> (Linux* OS and macOS) <code>/Oy</code> (Windows*) (IA-32 architecture only)	<p>Disables the <code>ebp</code> register in optimizations and sets the <code>ebp</code> register to be used as the frame pointer.</p> <p>For more information, see the following compiler option topics:</p> <ul style="list-style-type: none"><li>• <code>-fip</code> (Linux* and macOS)</li><li>• <code>/Oy</code> (Windows*)</li></ul>
<code>traceback</code>	<p>Causes the compiler to generate extra information in the object file, which allows a symbolic stack traceback.</p> <p>For more information, see the following topic:</p> <ul style="list-style-type: none"><li>• <code>traceback</code> compiler option</li></ul>

---

## Combine Optimization and Debugging

The compiler lets you generate code to support symbolic debugging when `O1`, `O2`, or `O3` optimization options are specified on the command line along with `-g` (Linux\* and macOS) or `/debug:full` (Windows\*); this produces symbolic debug information in the object file.

---

### NOTE

Note that if you specify an `O1`, `O2`, or `O3` option with the `-g` (Linux\* and macOS) or `/debug:full` (Windows\*) option, some of the debugging information returned may be inaccurate as a side-effect of optimization.

To counter this on Linux\* OS and macOS, you should also specify the `-debug extended` option.

---

It is best to make your optimization and/or debugging choices explicit:

- If you need to debug your program excluding any optimization effect, use the `-O0` (Linux\* and macOS) or `/Od` (Windows\*) option, which turns off all the optimizations.
- If you need to debug your program with optimizations enabled, then you can specify the `O1`, `O2`, or `O3` option on the command line along with `debug extended`.

---

### NOTE

When no optimization level is specified, the `-g` or `/debug:full` option slows program execution; this is because this option turns on `-O0` or `/Od`, which causes the slowdown. However, if both `O2` and `-g` (Linux\* and macOS) or `/debug:full` (Windows\*) are specified, for example, the code should not experience much of a slowdown.

---

Refer to the table below for the summary of the effects of using the `-g` or `/debug:full` option with the optimization options.

These options	Produce these results
<code>-g</code> (Linux* and macOS) <code>/debug:full</code> (Windows*)	Debugging information produced, <code>-O0</code> (Linux* and macOS) or <code>/Od</code> (Windows*) enabled (meaning optimizations are disabled).  For Linux* and macOS, <code>-fp</code> is also enabled for compilations targeted for IA-32 architecture.
<code>-g-O1</code> (Linux* and macOS) <code>/debug:full /O1</code> (Windows*)	Debugging information produced, <code>O1</code> optimizations enabled.
<code>-g-O2</code> (Linux* and macOS) <code>/debug:full /O2</code> (Windows*)	Debugging information produced, <code>O2</code> optimizations enabled.
<code>-g-O2</code> (Linux* and macOS) <code>/debug:full /O2 /Oy-</code> (Windows*)	Debugging information produced, <code>O2</code> optimizations enabled. For Windows* using IA-32 architecture, <code>/Oy</code> disabled.
<code>-g -O3 -fp</code> (Linux* and macOS) <code>/debug:full /O3</code> (Windows*)	Debugging information produced, <code>O3</code> optimizations enabled. For Linux*, <code>-fp</code> enabled for compilations targeted for IA-32 architecture.

#### NOTE

Even the use of option `debug extended` with optimized programs may not allow you to examine all variables or to set breaks at all lines, due to code movement or removal during the optimization process.

## Debug Mixed-Language Programs

The Visual Studio debugger let you debug mixed-language programs. Program flow of control across subprograms written in different languages is transparent.

The debugger uses debug information associated with the program to automatically identify the language of the current subprogram or code segment.

For example, if program execution is suspended in a subprogram in Fortran, the current language is seen as Fortran. If the debugger stops the program in a C function, the current language becomes C.

## Debug Multithreaded Programs

The debugging of multithreaded programs discussed in this topic applies to both the OpenMP\* Fortran API and the Intel® Fortran parallel compiler directives. When a program uses parallel decomposition directives, you must take into consideration that the bug might be caused either by an incorrect program statement or it might be caused by an incorrect parallel decomposition directive. In either case, the program to be debugged can be executed by multiple threads simultaneously.

To determine the correctness of and debug multithreaded programs, you can use the following:

- Linux\* and macOS systems: `gdb`.
- Windows\* operating systems: Microsoft Visual Studio\* Debugger.
- Intel® Fortran Compiler debugging options and methods; in particular, `debug` and `traceback` options.

## Use Remote Debugging

The following applies to Microsoft\* Visual Studio\* 2013 and 2015.

Remote debugging lets you use your local (host) system to debug an application running on a remote system.

### Remote Debugging using Microsoft\* Visual Studio\*

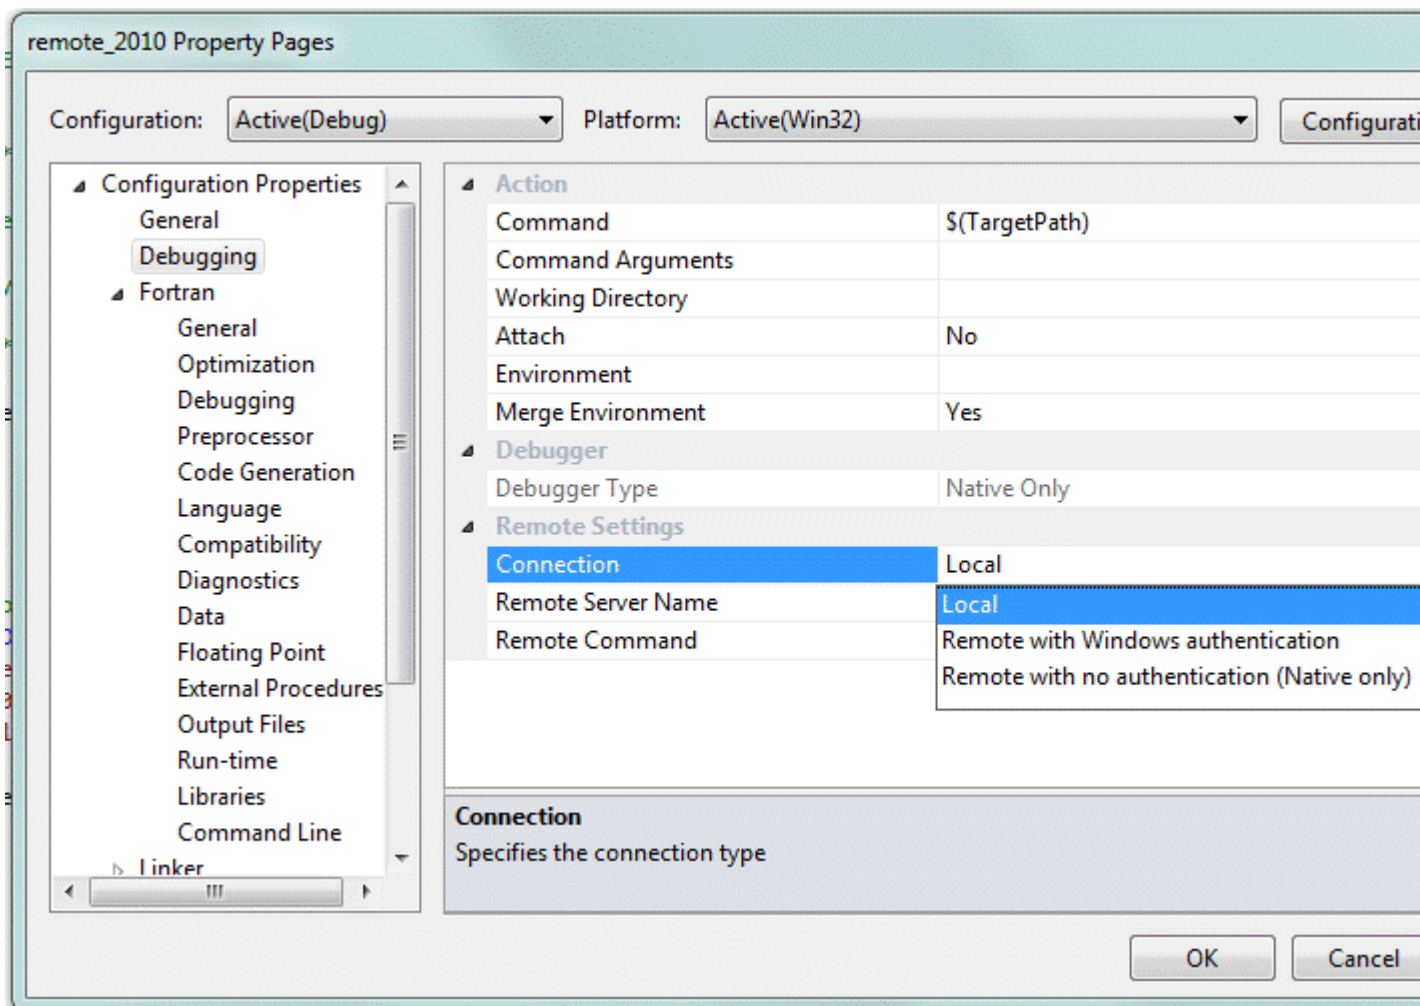

There are two remote connection types available: DCOM ("Remote with Windows authentication") and TCP/IP ("Remote with no authentication"). For more information on initial setup for remote debugging, refer to the Microsoft\* Visual Studio\* remote debugging setup topics in the Microsoft\* MSDN documentation.

Remote debugging typically requires use of the debugging monitor (`msvsmon.exe`). Run the monitor in the correct mode for the remote system's architecture. To do this, on the remote system, select the program group **Microsoft Visual Studio 2013** (or applicable version year), then choose **Visual Studio Tools** and select the correct **Remote Debugger Folder**.

Remote debugging also requires proper set up of the IDE Debugging property page on the host machine.

To set up remote debugging using the IDE property pages:

1. On the host machine, choose **Project** > **Properties** > **Configuration Properties** > **Debugging**. Your screen should resemble this image:

2. Specify the following:

**Connection:** Use the drop-down box to select the type of connection.

**Remote Server Name:** Use the drop-down box to select the name of the remote system.

**Remote Command:** Type the command you want to issue on the remote machine. Typically, this is a pathname to an executable file (.exe) on the remote machine; for example: d:\remote\myapp.exe

3. Optionally, set **Attach** to **Yes** to attach to an application that is already running on the remote machine.

To start remote debugging:

1. Make sure you have the necessary remote debugging permissions on the remote machine. For example, you need Administrator privileges if you want to debug a process running on a remote machine under another account name.
2. Run the Remote Debugging Monitor on the remote machine.
3. Launch Microsoft® Visual Studio® on the host machine and use it to attach to a program you want to debug on the remote machine, or launch a program you want to debug on the remote machine.

## Remote Debugging Scenario

This topic applies to Fortran applications for Windows only.

The remote debugging scenario described here includes the cross-platform and cross-compilation remote debugging features. The following parameters apply:

---

Host platform:	IA-32
Remote platform:	Intel® 64
Name of host machine:	<i>HOST_MACHINE</i> (domain name of host machine)
Name of remote machine:	<i>REMOTE_SERVER</i> (domain name of remote machine)
Host OS:	Windows* 10 - 32 Bit
Remote OS:	Windows 10 - 64 Bit
Executable for debugging:	Win64 (x64)
Type of executable:	Console application
Microsoft Visual Studio*:	Microsoft Visual Studio 2017 or 2019

---

**NOTE** Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

---

Connection types:	Remote with/without Windows authentication
Sessions:	Remote debugging, remote execution, attach to process on a remote machine

---

### 1. *HOST\_MACHINE*

Start Microsoft Visual Studio 2019 on the host machine (*HOST\_MACHINE*).

2. Create a new console application; for this example, use remote\_2019.
3. Add the following lines to the remote\_2019.f90 file:

```
REAL, DIMENSION(1) :: xxx = 0
PRINT *, 'Type one number: '
READ (*, '(F10.3)') xxx
```

4. Open **Project > Properties** and create a new platform configuration for x64 using the **Configuration Manager**.
5. Make sure, that current (target) configuration is **Debug|x64** and build the solution (**Build > Build Solution**). This invokes the cross-compiler and causes the 64-bit executable file remote\_2019.exe to be built.

6. Run the `remote_2019.exe` application to make sure that it is 64-bit code. An error should result, explaining that it is not a valid Win32 application.
7. Run the Remote Desktop Connection program (`%SystemRoot%\System32\mstsc.exe`) and connect to the remote machine (*REMOTE\_SERVER*).
8. Create `C:\remote_dir` on *REMOTE\_SERVER* and copy `remote_2019.exe` from *HOST\_MACHINE* to *REMOTE\_SERVER*.
9. On the *HOST\_MACHINE* open the `remote_2019.f90` source file in the Visual Studio editor.
10. Set a breakpoint at line 27.
11. Open **Project > Properties** and select **Debugging**. In the Remote Settings section, set the following properties:
  - Connection:** Remote with Windows authentication
  - Remote Machine:** *REMOTE\_SERVER*
  - Remote Command:** `C:\remote_dir\remote_2019.exe`
12. Press F5 to start debugging.
 

If there is a firewall you will get an Unable to start debugging error message. In this case go to *REMOTE\_SERVER*, locate, and run the Remote Debugger application (64-bit mode). Find `msvsmon.exe` in the location where it was installed, or open the Start menu and search for **Remote Debugger**. Go back to *LOCAL\_SERVER* and press F5 to start debugging.
13. Go to *REMOTE\_SERVER* and make sure that the `remote_2019` application is started.
14. Type 5 and press Enter. Go back to *HOST\_MACHINE*.
15. Verify that the Debugger reaches the breakpoint at the line 27.
16. Open the Locals window and make sure that value `xxx` is 64-bit.
17. Press Shift+F5 to stop debugging and terminate the application on the remote server.
18. Open the project properties again, select **Debugging**, and set **Attach** to **Yes**.
19. Press Ctrl+F5 (remote execution).
20. Press F5 for attaching to a process.
21. Repeat steps 12-17 to check that the attach to process works correctly.
22. Open **Project > Properties** and set **Attach** to **No**.
23. Open **Project > Properties** and set **Connection** to **Remote with no authentication (Native only)**.
24. Go to *REMOTE\_SERVER* and switch debugging monitor to No Authentication mode using the **Tools > Options** menu.
25. Repeat steps 12-22 to check that Remote with no authentication (Native only) mode works correctly.

### Results of Remote Debugging Exercise

The results of this remote debugging exercise for Microsoft Visual Studio 2019 are summarized in the table below.

Connection Type	Session	Result	Debugging Monitor status
Remote with Windows authentication	Debug (F5)	Works	Monitor should be run in Windows Authentication mode.
	Execute (Ctrl+F5)	Works	
	Attach to Process	Works	
Remote with no authentication (Native only)	Debug (F5)	Works	Monitor should be run in No Authentication mode.
	Execute (Ctrl+F5)	Works	
	Attach to Process	Works	

**Part****V  
I**

## ***Program Structure***

---

This section contains some information about Fortran program structure.

### ***Use Module Files***

---

A way to reduce potential confusion when you use the same source code in several projects is to organize the routines into modules and submodules.

A module is a type of program unit that contains specifications of such entities as data objects, parameters, structures, procedures, and operators. These precompiled specifications and definitions can be used by one or more program units.

Partial or complete access to the module entities is provided by the program's USE statement. Typical applications of modules are the specification of global data or the specification of a derived type and its associated operations.

You can set up separate modules for:

- Commonly used routines
- Data definitions specific to certain operating systems
- System-dependent language extensions

Submodules let you separate the interface of procedures from their implementation, making it easier to build applications and perform maintenance.

To use a module, its source must first be compiled into a `.mod` file. The name of the `.mod` file is the module name, not the source file name. Similarly, submodules are compiled into `.smod` files; their parent modules or submodules must be compiled first. Compiling a module or submodule also creates an object file (`.o` or `.obj`) that must be included when linking the application.

When compiling a source that has a USE statement containing a module, the compiler looks for the corresponding `.mod` file in the same place it looks for include files. Submodule `.smod` files are used only when a child submodule is compiled.

Some programs require modules that are located in multiple directories. You can use compiler option `-x` when you compile the program to specify the location of the `.mod` and `.smod` files that should be included in the program.

Intrinsic modules, defined by the Fortran standard, are supplied in a system directory alongside the compiler binaries and libraries. These have a `.modintr` file type that is searched only when the Fortran source includes USE, INTRINSIC.

You can use compiler option `module path` to specify the directory in which to create the module files. If you do not use this option, module files are created in the current directory.

When the compiler is looking for `.mod` and `.smod` files, directories are searched in this order:

1. In the directory of the source file that contains the USE statement

2. In the directories specified by compiler option `module path`
3. In the current working directory
4. In the directories specified by compiler options `-I`*dir* (Linux\* and macOS) or `/include` (Windows\*)
5. In the directories specified with environment variables `CPATH` or `INCLUDE`
6. In the standard system directories

If you are building your program as part of a Microsoft Visual Studio\* project that has dependent projects, the Fortran build system automatically searches the dependent projects for compiled `.mod` files.

---

#### NOTE

You must make sure that the module files are created before they are referenced by another program or subprogram. If the module and its `USE` statement are in the same source file, the module must appear first.

---

You can specify compiler option `gen-dep` to create a list of compiled module files that a source file depends upon. This list can be used with build utilities such as `make` to specify dependencies and to ensure that files that use a module are recompiled when the module is modified and recompiled.

## Compile Programs with Modules

If a file being compiled has one or more modules defined in it, the compiler generates one or more `.mod` or `.smod` files, along with object files.

For example, consider that file `a.f90` contains modules defined as follows:

```
module test
integer:: a
contains
  subroutine f()
  end subroutine
end module test
module payroll
...
end module payroll
```

When the following command is specified:

```
ifort -ca.f90
```

It generates the following files:

- `test.mod`
- `payroll.mod`
- `a.o` (Linux\* and macOS)
- `a.obj` (Windows\*)

The `.mod` files contain the necessary information about the modules that have been defined in the program `a.f90`.

The following example uses the program `mod_def.f90`, which contains a module defined as follows:

```
file: mod_def.f90
module definedmod
...
end module
```

When you compile the program as follows:

```
ifort -c mod_def.f90
```

It produces the object files `mod_def.o` (Linux\* and macOS) or `mod_def.obj` (Windows\*) and also the `.mod` file `definedmod.mod` - all in the current directory.

```
file: use_mod_def.f90
program usemod
  use definedmod
  ...
end program
```

To compile the above program, use compiler option `I` or `module` to specify the path to search and locate the `definedmod.mod` file.

### Example

Consider that the current directory contains the files `mod_def.f90` and `use_mod_def.f90`, and it also contains the subdirectory `my_modules`.

If you execute the following command on Linux\* or macOS, it creates the file `definedmod.mod` in the subdirectory `my_modules`, and it creates the file `mod_def.o` in the current directory:

```
ifort -c -module ./my_modules mod_def.f90
```

If you then execute either of the following commands, it creates the executable file `./a.out`:

```
ifort -c -module ./my_modules use_mod_def.f90 mod_def.o
```

```
ifort -c -I ./my_modules use_mod_def.f90 mod_def.o
```

[module](#) compiler option

[SUBMODULE](#) statement

[USE](#) statement

---

## Use Include Files

Include files are brought into a program with the `#include` preprocessor directive or a Fortran `INCLUDE` statement.

Directories are searched for include files in this order:

1. In the directory of the source file that contains the include
2. In the current working directory
3. In the directories specified by compiler option `I`.
4. In the directory specified by compiler option `-isystem` (Linux\* and macOS only)
5. In the directories specified with environment variables `CPATH` (Linux\* and macOS) or `INCLUDE` (Windows\*)
6. In the standard system directories

The locations of directories to be searched are known as the include file path. More than one directory can be specified in the include file path.

### Specify and Remove an Include File Path

You can use compiler option `I` to indicate the location of include files (and also module files).

To prevent the compiler from searching the default path specified by the `CPATH` or the `INCLUDE` environment variable, use compiler option `-X` or `/noinclude`.

You can specify these options in the configuration file, `ifort.cfg`, or on the command line.

For example, to direct the compiler to search a specified path instead of the default path, use the following command:

#### Linux

```
ifort -X -I/alt/include newmain.f
```

#### Windows

```
ifort /noinclude /IC:\Project2\include newmain.f
```

## Advantages of Internal Procedures

---

Functions or subroutines that are used in only one program can be organized as internal procedures, following the `CONTAINS` statement of a program or module.

Internal procedures have the advantage of host association, that is, variables declared and used in the main program are also available to any internal procedure it may contain. For more information on procedures and host association, see [Program Units and Procedures](#).

Internal procedures, like modules, provide a means of encapsulation. Modules can be used to store routines commonly used by many programs; internal procedures separate functions and subroutines whose use is limited or temporary.

## Implications for Array Copies

---

Fortran language semantics sometimes require the compiler to make a temporary copy of an array or array slice. Situations where this can occur include:

- Passing a non-contiguous array to a procedure that does not declare it as assumed-shape
- Array expressions, especially those involving intrinsic functions `RESHAPE`, `PACK`, and `MERGE`
- Assignments of arrays where the array appears on both the left and right-hand sides of the assignment
- Assignments of `POINTER` arrays

By default, these temporary values are created on the stack and, if large, may result in a stack overflow error at runtime. The size of the stack can be increased, but with limitations dependent on the operating system. If you use compiler option `heap-arrays`, it tells the compiler to use heap allocation, rather than the stack, for such temporary copies. Heap allocation adds a small amount of overhead when creating and removing the temporary values, but this is usually inconsequential in comparison to the rest of the code.

Performance can be further improved by entirely eliminating the need for a temporary copy. For the first case in the above list, passing a non-contiguous array to a procedure expecting a contiguous array, enabling compiler option `check:arg_temp_created` will produce a runtime informational message when the compiler

determines that the argument being passed is not contiguous. A runtime test is performed and if the argument is contiguous, no copy is made. However, this option will not issue a diagnostic message for other uses of temporary copies.

One way to avoid temporary copies for array arguments is to change the called procedure to declare the array as assumed-shape, with the `DIMENSION(:)` attribute. Such procedures require an explicit interface to be visible to the caller. This is best provided by placing the called procedure in a module or a `CONTAINS` section. As an alternative, an `INTERFACE` block can be declared.

Use of `POINTER` arrays makes it difficult for the compiler to know if a temporary value can be avoided. Where possible, replace `POINTER` with `ALLOCATABLE`, especially as components of derived types. The language definition directs the compiler to assume that `ALLOCATABLE` arrays are contiguous and that they do not overlap other variables, unlike `POINTERS`.

Another situation where the temporary values can be created is for automatic arrays, where an array's bounds are dependent on a routine argument, use or host associated variable, or `COMMON` variable, and the array is a local variable in the procedure. As above, these automatic arrays are created on the stack by default; compiler option `heap-arrays` creates them on the heap. Consider making such arrays `ALLOCATABLE` instead; local `ALLOCATABLE` variables that do not have the `SAVE` attribute are automatically deallocated when the routine exits. For example, replace:

```
SUBROUTINE SUB (N)
  INTEGER, INTENT(IN) :: N
  REAL :: A(N)
```

with:

```
SUBROUTINE SUB(N)
  INTEGER, INTENT(IN) :: N
  REAL, ALLOCATABLE :: A(:)
  ALLOCATE (A(N))
```

# ***Optimization and Programming***

This section contains information about features related to code optimization and program performance improvement.

## ***OpenMP\* Support***

The Intel® Fortran Compiler Classic and Intel® Fortran Compiler fully support the OpenMP\* Application Programming Interface 5.0 Version TR4, and the Intel® Fortran Compiler supports some of the features of OpenMP Version 5.1. For the complete OpenMP specification, read the specifications available from the OpenMP web site (<http://www.openmp.org>; see OpenMP Specifications on that site). The descriptions of OpenMP language characteristics in this documentation often use terms defined in that specification.

The OpenMP API provides symmetric multiprocessing (SMP) with the following major features:

- Relieves you from implementing the low-level details of iteration space partitioning, data sharing, thread creation, scheduling, or synchronization.
- Provides the benefit of performance available from shared memory multiprocessor and multi-core processor systems on all supported Intel architectures, including those processors with Intel® Hyper-Threading Technology (Intel® HT Technology).

The compiler performs transformations to generate multithreaded code based on your placement of OpenMP directives in the source program, making it simple to add threading to existing software. The compiler compiles parallel programs and supports the industry-standard OpenMP directives.

The compiler provides Intel®-specific extensions to the OpenMP specification including [runtime library routines](#) and [environment variables](#). A summary of the compiler options appear in the [OpenMP Options Quick Reference](#).

### **Parallel Processing with OpenMP**

To compile with the OpenMP API, add the directives in the form of the Fortran program comments to your code. The compiler processes the code and internally produces a multithreaded version which is then compiled into an executable with the parallelism implemented by threads that execute parallel regions or constructs.

### **Using Other Compilers**

The OpenMP specification does not define interoperability of multiple implementations, so the OpenMP implementation supported by other compilers and OpenMP support in the Intel Fortran Compiler Classic and Intel Fortran Compiler might not be interoperable. Even if you compile and build the entire application with one compiler, be aware that different compilers might not provide OpenMP source compatibility that enable you to compile and link the same set of application sources with a different compiler and get the expected parallel execution results.

## Add OpenMP\* Support

To add OpenMP\* support to your application, do the following:

1. Add the appropriate OpenMP directives to your source code.
2. Compile the application with the `/Qopenmp` (Windows\*) or `-qopenmp` (Linux\* and macOS) option.
3. For applications with large local or temporary arrays, you may need to increase the stack space available at runtime. In addition, you may need to increase the stack allocated to individual threads by using the `OMP_STACKSIZE` environment variable or by setting the corresponding [library routines](#).

You can set other environment variables to control multi-threaded code execution.

### OpenMP Directive Syntax

To add OpenMP support to your application, first add appropriate OpenMP directives to your source code.

OpenMP directives use a specific format and syntax. [Intel Extension Routines to OpenMP](#) describes the OpenMP extensions to the specification that have been added to the Intel® Fortran Compiler.

To use directives in your source, use this syntax:

```
<prefix> <directive> [<clause>[,<clause>...]]
```

where:

- `<prefix>` - Required for all OpenMP directives. For free form source input, the prefix is `!$OMP` only; for fixed form source input, the prefix is `!$OMP` or `C$OMP`.
- `<directive>` - A valid OpenMP directive. Must immediately follow the prefix; for example: `!$OMP PARALLEL`.
- `[<clause>]` - Optional. Clauses can be in any order and repeated as necessary, unless otherwise restricted.
- `<newline>` - A required component of directive syntax. It precedes the structured block that is enclosed by this directive.
- `[,]`: Optional. Commas between more than one `<clause>` are optional.

The directives are interpreted as comments if you omit the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option.

The OpenMP constructs defining a parallel region have one of the following syntax forms:

```
!$OMP <directive>
  <structured block of code>
!$OMP END <directive>
      # OR
!$OMP <directive>
  <structured block of code>
      # OR
!$OMP <directive>
```

The following example demonstrates one way of using an OpenMP directive to parallelize a loop:

```
subroutine simple_omp(a, N)
  use omp_lib
  integer :: N, a(N)
!$OMP PARALLEL DO
  do i = 1, N
    a(i) = i*2
  end do
end subroutine simple_omp
```

## Compile the Application

The `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option enables the parallelizer to generate multi-threaded code based on the OpenMP directives in the source. The code can be executed in parallel on single processor, multi-processor, or multi-core processor systems.

The `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option works with both `-O0` (Linux and macOS) and `/Od` (Windows\*) and with any optimization level of `O1`, `O2` and `O3`.

Specifying `-O0` (Linux and macOS) or `/Od` (Windows) with the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option helps to debug OpenMP applications.

Compile your application using a command similar to one of the following:

### Linux

```
ifort -qopenmp source_file
```

### macOS

```
ifort -qopenmp source_file
```

### Windows

```
ifort /Qopenmp source_file
```

For example, to compile the previous code example without generating an executable, use the `c` option:

### Linux

```
ifort -qopenmp -c parallel.f90
```

### macOS

```
ifort -qopenmp -c parallel.f90
```

### Windows

```
ifort /Qopenmp /c parallel.f90
```

To build your application with target offload support (introduced since OpenMP 4.0) use compiler options to specify the target for which the regions marked with OpenMP "target" directives must be compiled. For example:

### Linux

```
ifx -qopenmp -fopenmp-targets=spir64 offload.f90
```

### macOS

```
ifx -qopenmp -fopenmp-targets=spir64 offload.f90
```

### Windows

```
ifx /Qopenmp /Qopenmp-targets:spir64 offload.f90
```

Refer to [Get Started with OpenMP\\* Offload to GPU for the Intel® oneAPI DPC/C++ Compiler and Intel® Fortran Compiler](#) for more information.

## Configure the OpenMP Environment

Before you run the multi-threaded code, you can set the number of desired threads using the OpenMP environment variable, `OMP_NUM_THREADS`.

## Parallel Processing Model

A program containing OpenMP\* directives begins execution as a single thread, called the initial thread of execution. The initial thread executes sequentially until the first parallel construct is encountered.

The `PARALLEL` and `END PARALLEL` directives define the extent of the parallel construct. When the initial thread encounters a parallel construct, it creates a team of threads, with the initial thread becoming the primary thread of the team. All program statements enclosed by the parallel construct are executed in parallel by each thread in the team, including all routines called from within the enclosed statements.

The statements enclosed lexically within a construct define the static extent of the construct. The dynamic extent includes all statements encountered during the execution of a construct by a thread, including all called routines.

When a thread encounters the end of a structured block enclosed by a parallel construct, the thread waits until all threads in the team have arrived. When that happens the team is dissolved, and only the primary thread continues execution of the code following the parallel construct. The other threads in the team enter a wait state until they are needed to form another team. You can specify any number of parallel constructs in a single program. As a result, thread teams can be created and dissolved many times during program execution.

The following example illustrates, from a high level, the execution model for the OpenMP constructs. The comments in the code explain the structure of each construct or section.

```
PROGRAM MAIN                ! Begin serial execution.
...                          ! Only the initial thread executes.
!$OMP PARALLEL              ! Begin a Parallel construct, form a team.
...                          ! This code is executed by each team member.
!$OMP SECTIONS              ! Begin a worksharing construct.
!$OMP SECTION              ! One unit of work.
...                          !
!$OMP SECTION              ! Another unit of work.
...                          !
!$OMP END SECTIONS         ! Wait until both units of work complete.
...                          ! More Replicated Code.
!$OMP DO                   ! Begin a worksharing construct,
DO                          !   each iteration is a unit of work.
...                          ! Work is distributed among the team.
END DO                      !
!$OMP END DO NOWAIT        ! End of worksharing construct, NOWAIT
                           !   is specified (threads need not wait).
                           ! This code is executed by each team member.
!$OMP CRITICAL              ! Begin critical construct.
...                          ! One thread executes at a time.
!$OMP END CRITICAL         ! End the critical construct.
...                          ! This code is executed by each team member.
!$OMP BARRIER              ! Wait for all team members to arrive.
...                          ! This code is executed by each team member.
!$OMP END PARALLEL         ! End of parallel construct, disband team
                           !   and continue with serial execution.
...                          ! Possibly more parallel constructs.
END PROGRAM MAIN           ! End serial execution.
```

### Use Orphaned Directives

In routines called from within parallel constructs, you can also use directives. Directives that are not in the static extent of the parallel construct, but are in the dynamic extent, are called orphaned directives. Orphaned directives allow you to execute portions of your program in parallel with only minimal changes to

the sequential version of the program. Using this functionality, you can code parallel constructs at the top levels of your program call tree and use directives to control execution in any of the called routines. For example:

```
subroutine F
...
!$OMP PARALLEL...
  call G
...
subroutine G
!$OMP DO... ! This is an orphaned directive.
...
```

This is an orphaned DO directive since the parallel region is not lexically present in subroutine G .

## Data Environment

You can control the data environment of OpenMP constructs by using data environment clauses supported by the construct. You can also privatize named global-lifetime objects by using the THREADPRIVATE directive.

Refer to the OpenMP specification for the full list of data environment clauses. Some commonly used ones include:

- DEFAULT
- SHARED
- PRIVATE
- FIRSTPRIVATE
- LASTPRIVATE
- REDUCTION
- LINEAR

You can use several directive clauses to control the data scope attributes of variables for the duration of the construct in which you specify them; however, if you do not specify a data scope attribute clause on a directive, the behavior for the variable is determined by the default scoping rules, which are described in the OpenMP specification, for the variables affected by the directive.

## Determine How Many Threads to Use

For applications where the workload depends on application input that can vary widely, delay the decision about the number of threads to employ until runtime when the input sizes can be examined. Examples of workload input parameters that affect the thread count include things like matrix size, database size, image/video size and resolution, depth/breadth/bushiness of tree-based structures, and size of list-based structures. Similarly, for applications designed to run on systems where the processor count can vary widely, defer choosing the number of threads to employ until application runtime when the machine size can be examined.

For applications where the amount of work is unpredictable from the input data, consider using a calibration step to understand the workload and system characteristics to aid in choosing an appropriate number of threads. If the calibration step is expensive, the calibration results can be made persistent by storing the results in a permanent place like the file system.

Avoid simultaneously using more threads than the number of processing units on the system. This situation causes the operating system to multiplex threads on the processors and typically yields sub-optimal performance.

When developing a library as opposed to an entire application, provide a mechanism whereby the user of the library can conveniently select the number of threads used by the library, because it is possible that the user has outer-level parallelism that renders the parallelism in the library unnecessary or even disruptive.

Use the `NUM_THREADS` clause on parallel regions to control the number of threads employed and use the `IF` clause on parallel regions to decide whether to employ multiple threads at all. The `OMP_SET_NUM_THREADS()` routine can also be used, but it also affects parallel regions created by the calling thread. The `NUM_THREADS` clause is local in its effect, so it does not impact other parallel regions. The disadvantages of explicitly setting the number of threads are:

1. In a system with a large number of processors, your application will use some but not all of the processors.
2. In a system with a small number of processors, your application may force over subscription that results in poor performance.

The Intel OpenMP runtime will create the same number of threads as the available number of logical processors unless you use the `OMP_SET_NUM_THREADS()` routine. To determine the actual limits, use `OMP_GET_THREAD_LIMIT()` and `OMP_GET_MAX_ACTIVE_LEVELS()`. Developers should carefully consider their thread usage and nesting of parallelism to avoid overloading the system. The `OMP_THREAD_LIMIT` environment variable limits the number of OpenMP threads to use for the whole OpenMP program. The `OMP_MAX_ACTIVE_LEVELS` environment variable limits the number of active nested parallel regions.

## Binding Sets and Binding Regions

The binding task set for an OpenMP construct is the set of tasks that are affected by, or provide the context for, the execution of its region. It can be all tasks, the current team tasks, all tasks of the current team that are generated in the region, the binding implicit task, or the generating task.

The binding thread set for an OpenMP construct is the set of threads that are affected by, or provide the context for, the execution of its region. It can be all threads on a device, all threads in a contention group, all primary threads executing an enclosing teams region, the current team, or the encountering thread.

The binding region for an OpenMP construct is the enclosing region that determines the execution context and the scope of the effects of the directive:

- The binding region for an `ORDERED` construct is the innermost enclosing `DO` loop region.
- The binding region for a `TASKWAIT` construct is the innermost enclosing `TASK` region.
- For all other constructs for which the binding thread set is the current team or the binding task set is the current team tasks, the binding region is the innermost enclosing `PARALLEL` region.
- For constructs for which the binding task set is the generating task, the binding region is the region of the generating task.
- A `PARALLEL` construct need not be active to be a binding region.
- A `TASK` construct need not be explicit to be a binding region.
- A region never binds to any region outside of the innermost enclosing parallel region.

## Control Thread Allocation

---

The `KMP_HW_SUBSET` and `KMP_AFFINITY` environment variables allow you to control how the OpenMP\* runtime uses the hardware threads on the processors. These environment variables allow you to try different thread distributions on the cores of the processors and determine how these threads are bound to the cores. You can use the environment variables to work out what is optimal for your application.

The `KMP_HW_SUBSET` variable controls the allocation of hardware resources and the `KMP_AFFINITY` variable controls how the OpenMP threads are bound to those resources.

### Control Thread Distribution

The `KMP_HW_SUBSET` variable controls the hardware resources that will be used by the program. This variable often specifies three layers of machine topology: the number of sockets to use, how many cores to use per socket, and how many threads to use per core. For example, `KMP_HW_SUBSET=2s,12c,2t` means to use two sockets, 12 cores per socket, and two threads per core, giving a total of 48 available hardware threads.

When more layers exist (NUMA domain, tile, etc.) in the machine topology, you can specify those layers as well. For example, `KMP_HW_SUBSET=2s,2n,8c,2t` means to use two sockets, two NUMA domains per socket, eight cores per NUMA domain, and two threads per core, giving a total of 64 available hardware threads. For historical reasons, when a layer is not explicitly specified in `KMP_HW_SUBSET`, it is assumed you want all the resources in that unspecified layer. You can use `KMP_AFFINITY=verbose` to see all the different detected layers in the machine. For example, `KMP_HW_SUBSET=2s,2t` is interpreted to mean use two sockets, all cores per socket (and possibly all resources of other detected layers as well), and two threads per layer.

When available, you can specify core attributes to choose different sets of cores. The core attributes are appended to the regular core layer specification with a colon (:) and attribute. There are two attributes to help filter types of cores:

1. Core type, specified as `intel_core`, or `intel_atom`.
2. Core efficiency, specified as `effnum` where *num* is a non-negative integer from zero to the number of core efficiencies detected minus one. The larger the efficiency the more performant the core. For example, `KMP_HW_SUBSET=4c:eff0,5c:eff1` will select all sockets, four cores of efficiency 0, five cores of efficiency 1, and all threads per those cores.

There is also a special syntax to explicitly request all resources at a specific layer. Instead of specifying a positive integer, you can use an optional asterisk (\*). For example, `KMP_HW_SUBSET='*c:eff0'` or `KMP_HW_SUBSET=c:eff0` will request all the cores of efficiency 0.

Consider a system with 24 cores and four hardware threads per core. While specifying two threads per core often yields better performance than one thread per core, specifying three or four threads per core may or may not improve the performance. This variable enables you to conveniently measure the performance of up to four threads per core.

For example, you can determine the effects of assigning 24, 48, 72, or the maximum 96 OpenMP threads in a system with 24 cores by specifying the following variable settings:

To Assign This Number of Threads ...	... Use This Setting
24	<code>KMP_HW_SUBSET=24c,1t</code>
48	<code>KMP_HW_SUBSET=24c,2t</code>
72	<code>KMP_HW_SUBSET=24c,3t</code>
96	<code>KMP_HW_SUBSET=24c,4t</code>

### Caution

Take care when using the `OMP_NUM_THREADS` variable along with this variable. Using the `OMP_NUM_THREADS` variable can result in over or under subscription.

### NOTE

If you use `KMP_HW_SUBSET` to specify more resources than the system has, the runtime will issue a warning and ignore the setting. For example, setting `KMP_HW_SUBSET=24c,5t` will be ignored on a system where each core has four hardware threads.

## Control Thread Bindings

The `KMP_AFFINITY` variable controls how the OpenMP threads are bound to the hardware resources allocated by the `KMP_HW_SUBSET` variable. While this variable can be set to several binding or affinity types, the following are the recommended affinity types to use to run your OpenMP threads on the processor:

- *compact*: Distribute the threads sequentially among the cores.
- *scatter*: Distribute the threads among the cores in a round robin manner. Distribution is one thread per core initially, followed by repeat distribution among the cores.

The following table shows how the threads are bound to the cores when you want to use three threads per core on two cores by specifying `KMP_HW_SUBSET=2c,3t`:

Affinity	OpenMP Threads on Core 0	OpenMP Threads on Core 1
<code>KMP_AFFINITY=compact</code>	0, 1, 2	3, 4, 5
<code>KMP_AFFINITY=scatter</code>	0, 2, 4	1, 3, 5

## Determine the Best Setting

To determine the best thread distribution and bindings using these variables, use the following:

1. Ensure that your OpenMP code is working properly before using these environment variables.
2. Establish a baseline with your current OpenMP code to compare to the performance when you allocate the threads to a processor.
3. Measure the performance of distributing one, two, three, or four threads per core by use the `KMP_HW_SUBSET` variable.
4. Measure the performance of binding the threads to the cores by using the `KMP_AFFINITY` variable.

## OpenMP\* Directives

This is a summary of the OpenMP\* directives supported in the Intel® Fortran Compiler. For detailed information about the OpenMP API, see the *OpenMP Application Program Interface Version 5.1* specification, which is available from the OpenMP web site.

In the directive lists below, an OpenMP directive is qualified with the word **Directive** when the name of the directive is also used for one or more elements besides the directive. For example: `FLUSH` refers to a directive, a statement, and a subroutine.

### PARALLEL Directive

Use this directive to form a team of threads and execute those threads in parallel.

Directive	Description
<a href="#">PARALLEL Directive (OpenMP)</a>	Defines a parallel region.

### TASKING Directives

Use these directives for deferring execution.

Directive	Description
<code>TASK</code>	Defines a task region.
<code>TASKLOOP</code>	Specifies that the iterations of one or more associated DO loops should be executed using OpenMP tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed in parallel by the current team.

## WORKSHARING Directives

Use these directives to share work among a team of threads.

Directive	Description
<code>DO Directive</code>	Identifies an iterative worksharing construct in which the iterations of the associated loop should be divided among threads in a team.
<code>LOOP Directive (ifx)</code>	Specifies that the iterations of the associated DO loops can execute in any order or concurrently. This feature is only available for ifx.
<code>SECTIONS</code>	Specifies that the enclosed <code>SECTION</code> directives define blocks of code to be divided among threads in a team. Each section is executed once by a thread in the team.
<code>SCOPE (ifx)</code>	Specifies a block of code to be executed by all threads of the team. This feature is only available for ifx.
<code>SINGLE</code>	Specifies that a block of code is to be executed by only one thread in the team.
<code>WORKSHARE</code>	Divides the work of executing a block of statements or constructs into separate units. It also distributes the work of executing the units to threads of the team so each unit is only executed once.

## SYNCHRONIZATION Directives

Use these directives to synchronize between threads.

Directive	Description
<code>ATOMIC</code>	Ensures that a specific memory location is updated atomically; this prevents the possibility of multiple, simultaneous reading and writing of threads.
<code>BARRIER</code>	Synchronizes all the threads in a team. It causes each thread to wait until all of the other threads in the team have reached the barrier.
<code>CRITICAL Directive</code>	Restricts access to a block of code to only one thread at a time.
<code>FLUSH Directive</code>	Identifies synchronization points at which the threads in a team must provide a consistent view of memory.
<code>MASKED</code>	Specifies a structured block that is executed by a subset of the threads of the current team. This feature is only available for ifx.
<code>MASTER (deprecated, see MASKED)</code>	Specifies a block of code to be executed by the primary thread of the team.

Directive	Description
<a href="#">ORDERED</a>	Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations.
<a href="#">TASKGROUP</a>	Specifies a wait for the completion of all child tasks of the current task and all of their descendant tasks.
<a href="#">TASKWAIT</a>	Specifies a wait on the completion of child tasks generated since the beginning of the current task.
<a href="#">TASKYIELD</a>	Specifies that the current task can be suspended at this point in favor of execution of a different task.

### Data Environment Directive

Use these directives to affect the data environment.

Directive	Description
<a href="#">DECLARE MAPPER</a> (ifx)	Declares a user-defined data mapper for derived types and variables that can subsequently be used in MAP clauses. This feature is only available for ifx.
<a href="#">DEPOBJ</a> (ifx)	Initializes, updates, or uninitializes an OpenMP depend object. This feature is only available for ifx.
<a href="#">PREFETCH</a> (ifx)	Suggests to the compiler to preload data into cache. Preloading data in cache minimizes the effects of memory latency. This is an Intel® language extension. This feature is only available for ifx.
<a href="#">THREADPRIVATE</a>	Specifies named common blocks to be private (local) to each thread; they are global within the thread.

### Offload Target Control Directives

Use these directives to control execution on one or more offload targets.

Directive	Description
<a href="#">DECLARE TARGET</a> (ifx)	Specifies named routines and variables that are created or mapped to a device. This feature is only available for ifx.
<a href="#">DECLARE VARIANT</a> (ifx)	Identifies a variant of a base procedure and specifies the context in which this variant is used. This feature is only available for ifx.
<a href="#">DISPATCH</a> (ifx)	Determines if a procedure variant is called for a given subroutine or function call. This feature is only available for ifx.
<a href="#">DISTRIBUTE</a>	Specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct.
<a href="#">INTEROP</a> (ifx)	Identifies a foreign runtime context and identifies runtime characteristics of that context, enabling interoperability with it. This feature is only available for ifx.
<a href="#">REQUIRES</a> (ifx)	Lists the features that an implementation must support so that the program compiles and runs correctly. This feature is only available for ifx.

Directive	Description
<a href="#">TARGET Directive</a> (ifx)	Creates a device data environment and executes the construct on that device. This feature is only available for ifx.
<a href="#">TARGET DATA</a> (ifx)	Maps variables to a device data environment for the extent of the region. This feature is only available for ifx.
<a href="#">TARGET ENTER DATA</a> (ifx)	Specifies that variables are mapped to a device data environment. This feature is only available for ifx.
<a href="#">TARGET EXIT DATA</a> (ifx)	Specifies that variables are unmapped from a device data environment. This feature is only available for ifx.
<a href="#">TEAMS</a> (ifx)	Creates a league of thread teams inside a target region to execute a structured block in the primary thread of each team. This feature is only available for ifx.
<a href="#">TARGET UPDATE</a> (ifx)	Makes the list items in the device data environment consistent with their corresponding original list items. This feature is only available for ifx.

### Vectorization Directives

Use these directives to control execution on vector hardware.

Directive	Description
<a href="#">SCAN</a>	Specifies a scan computation that updates each list item in each iteration of an enclosing SIMD loop nest.
<a href="#">SIMD Directive (OpenMP*)</a>	Transforms the loop into a loop that will be executed concurrently using SIMD instructions.
<a href="#">DECLARE SIMD</a>	Generates a SIMD procedure.

### Loop Transformation Directive

Use this directive to transform or restructure loops.

Directive	Description
<a href="#">UNROLL</a> (ifx)	Partially or fully unrolls a DO loop. This feature is only available for ifx.

### Cancellation Constructs

Directive	Description
<a href="#">CANCEL</a>	Requests cancellation of the innermost enclosing region of the construct specified, and causes the encountering task to proceed to the end of the cancelled construct.
<a href="#">CANCELLATION POINT</a>	Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified.

## Memory Space Allocation Directive

Use this declarative directive to allocate memory space. This feature is only available for ifx.

Directive	Description
<code>ALLOCATE</code> (ifx)	Specifies memory allocators to use for object allocation and deallocation. This feature is only available for ifx.

## Combined and Composite Directives

Use these directives as shortcuts for multiple directives in sequence. A combined construct is a shortcut for specifying one construct immediately nested inside another construct. A combined construct is semantically identical to that of explicitly specifying the first construct containing one instance of the second construct and no other statements.

A composite construct is composed of two constructs but does not have identical semantics to specifying one of the constructs immediately nested inside the other. A composite construct either adds semantics not included in the constructs from which it is composed or the nesting of the one construct inside the other is not conforming.

Directive	Description
<code>DISTRIBUTE PARALLEL DO</code> <sup>1</sup>	Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
<code>DISTRIBUTE PARALLEL DO SIMD</code> <sup>1</sup>	Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.
<code>DISTRIBUTE SIMD</code> <sup>1</sup>	Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions
<code>DO SIMD</code> <sup>1</sup>	Specifies a loop that can be executed concurrently using SIMD instructions.
<code>MASKED TASKLOOP</code>	Provides an abbreviated way to specify a TASKLOOP construct inside a MASKED construct. This feature is only available for ifx.
<code>MASKED TASKLOOP SIMD</code>	Provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASKED construct. This feature is only available for ifx.
<code>MASTER TASKLOOP</code>	Deprecated; provides an abbreviated way to specify a TASKLOOP construct inside a MASTER construct. This feature is only available for ifx.
<code>MASTER TASKLOOP SIMD</code>	Deprecated; provides an abbreviated way to specify a TASKLOOP SIMD construct inside a MASTER construct. This feature is only available for ifx.
<code>PARALLEL DO</code>	Provides an abbreviated way to specify a parallel region containing a single DO directive.
<code>PARALLEL DO SIMD</code>	Specifies a loop that can be executed concurrently using SIMD instructions. It provides a shortcut for specifying a PARALLEL construct containing one SIMD loop construct and no other statement.
<code>PARALLEL LOOP</code>	Provides an abbreviated way to specify a parallel region containing a single LOOP construct. This feature is only available for ifx.

Directive	Description
PARALLEL MASKED	Provides an abbreviated way to specify a MASKED construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASKED TASKLOOP	Provides an abbreviated way to specify a MASKED TASKLOOP construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASKED TASKLOOP SIMD	Provides an abbreviated way to specify a MASKED TASKLOOP SIMD construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER	Deprecated; provides an abbreviated way to specify a MASTER construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER TASKLOOP	Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL MASTER TASKLOOP SIMD	Deprecated; provides an abbreviated way to specify a MASTER TASKLOOP SIMD construct inside a PARALLEL construct. This feature is only available for ifx.
PARALLEL SECTIONS	Provides an abbreviated way to specify a parallel region containing a single SECTIONS directive. The semantics are identical to explicitly specifying a PARALLEL directive immediately followed by a SECTIONS directive.
PARALLEL WORKSHARE	Provides an abbreviated way to specify a parallel region containing a single WORKSHARE directive.
TARGET PARALLEL	Creates a device data environment in a parallel region and executes the construct on that device.
TARGET PARALLEL DO	Provides an abbreviated way to specify a TARGET construct that contains a PARALLEL DO construct and no other statement between them.
TARGET PARALLEL DO SIMD	Specifies a TARGET construct that contains a PARALLEL DO SIMD construct and no other statement between them.
TARGET PARALLEL LOOP	Provides an abbreviated way to specify a TARGET region that contains a single PARALLEL LOOP construct and no other statements. This feature is only available for ifx.
TARGET SIMD	Specifies a TARGET construct that contains a SIMD construct and no other statement between them.
TARGET TEAMS	Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block
TARGET TEAMS DISTRIBUTE	Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a TEAMS construct.

Directive	Description
<b>TARGET TEAMS DISTRIBUTE PARALLEL DO</b>	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct.
<b>TARGET TEAMS DISTRIBUTE PARALLEL DO SIMD</b>	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a TEAMS construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions.
<b>TARGET TEAMS DISTRIBUTE SIMD</b>	Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions.
<b>TARGET TEAMS LOOP</b>	Provides an abbreviated way to specify a TARGET region that contains a single TEAMS LOOP construct with no other statements. This feature is only available for ifx.
<b>TASKLOOP SIMD</b> <sup>1</sup>	Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP tasks.
<b>TEAMS DISTRIBUTE</b>	Creates a league of thread teams to execute the structured block in the primary thread of each team. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a TEAMS construct.
<b>TEAMS DISTRIBUTE PARALLEL DO</b>	Creates a league of thread teams and specifies that the associated loop can be executed in parallel by multiple threads that are members of multiple teams.
<b>TEAMS DISTRIBUTE PARALLEL DO SIMD</b>	Creates a league of thread teams to execute a structured block in the primary thread of each team. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams. The loop will be distributed across the primary threads of the teams region, which will be executed concurrently using SIMD instructions.
<b>TEAMS DISTRIBUTE SIMD</b>	Creates a league of thread teams to execute the structured block in the primary thread of each team. It also specifies a loop that will be distributed across the primary threads of the teams.
<b>TEAMS LOOP</b>	Provides an abbreviated way to specify a TEAMS region that contains a single LOOP construct with no other statements. This feature is only available for ifx.

**Footnotes:**<sup>1</sup> This directive specifies a composite construct.

## OpenMP\* Library Support

---

This section provides information about OpenMP\* runtime library routines, Intel® compiler extension routines to OpenMP, OpenMP support libraries and how to use them, and the thread affinity interface. It also provides information about OpenMP memory spaces and allocators.

### OpenMP\* Runtime Library Routines

OpenMP\* provides runtime library routines to help you manage your program in parallel mode. Many of these runtime library routines have corresponding environment variables that can be set as defaults. The runtime library routines let you dynamically change these factors to assist in controlling your program. In all cases, a call to a runtime library routine overrides any corresponding environment variable. These routines are all external procedures.

---

**Caution**

Running OpenMP runtime library routines may initialize the OpenMP runtime environment, which might cause a situation where subsequent programmatic setting of OpenMP environment variables has no effect. To avoid this situation, you can use the Intel extension routine `kmp_set_defaults()` to set OpenMP environment variables.

---

The compiler supports all the OpenMP runtime library routines. Refer to the OpenMP API specification for detailed information about using these routines.

Include the appropriate declarations of the routines in the program unit containing the routine by adding a statement similar to the following:

```
use omp_lib
```

The compiler provides module files in the `../include` (Linux\* and macOS) or `..\include` (Windows\*) directory of your compiler installation.

The integer parameter `openmp_version` in `omp_lib.mod` (and `omp_lib.h`, an `INCLUDE` version of `omp_lib.mod`) has the decimal value `yyyymm` where `yyyy` and `mm` are the year and month of the version of the OpenMP API supported by the current version of the compiler and libraries. See the predefined preprocessor symbol `_OPENMP` for more information.

**NOTE**

The following table lists the keys that specify the data types of the dummy arguments for each of the listed routines:

Key	OMP_LIB Kind	BIND(C) Kind	KIND=
INTEGER ( <i>int</i> )	OMP_INTEGER_KIND	C_INT	4
LOGICAL ( <i>log</i> )	OMP_LOGICAL_KIND		4
REAL ( <i>dp</i> )	DOUBLE PRECISION	C_DOUBLE	8
INTEGER(OMP_LOCK_KIND)		C_INTPTR_T	intptr_t <<1>>
INTEGER(OMP_NEST_LOCK_KIND)		C_INTPTR_T	intptr_t <<1>>
INTEGER (OMP_SCHED_KIND)	OMP_INTEGER_KIND	C_INT	4
INTEGER(OMP_PROC_BIND_KIND)	OMP_INTEGER_KIND	C_INT	4
INTEGER(OMP_SYNC_HINT_KIND)		C_INTPTR_T	intptr_t <<1>>

`intptr_t` is an integer that is large enough to hold a pointer (address). With the Intel® Fortran Compiler, this is INTEGER(4) when building a 32-bit application and INTEGER(8) when building a 64-bit application. It is the value returned by the Intel Fortran intrinsic `INT_PTR_KIND()`.

## Thread Team Routines

Routines that affect and monitor thread teams in the current contention group.

Routine	Description
<pre>SUBROUTINE OMP_SET_NUM_THREADS(num_threads) INTEGER(int) num_threads</pre>	Sets the number of threads to use for subsequent parallel regions created by the calling thread.
<pre>INTEGER(int) FUNCTION OMP_GET_NUM_THREADS()</pre>	<p>Returns the number of threads that are being used in the current parallel region.</p> <p>This function does not necessarily return the value inherited by the calling thread from the <code>OMP_SET_NUM_THREADS()</code> function.</p>
<pre>INTEGER(int) FUNCTION OMP_GET_MAX_THREADS()</pre>	Returns the number of threads available to subsequent parallel regions created by the calling thread.
<pre>INTEGER(int) FUNCTION OMP_GET_THREAD_NUM()</pre>	Returns the thread number of the calling thread, within the context of the current parallel region.

Routine	Description
LOGICAL( <i>log</i> ) FUNCTION OMP_IN_PARALLEL()	Returns <code>.TRUE.</code> if called within the dynamic extent of a parallel region executing in parallel; otherwise returns <code>.FALSE.</code> .
SUBROUTINE OMP_SET_DYNAMIC( <i>dynamic_threads</i> ) LOGICAL <i>dynamic_threads</i>	Enables or disables dynamic adjustment of the number of threads used to execute a parallel region. If <i>dynamic_threads</i> is <code>.TRUE.</code> , dynamic threads are enabled. If <i>dynamic_threads</i> is <code>.FALSE.</code> , dynamic threads are disabled. Dynamic threads are disabled by default.
LOGICAL( <i>log</i> ) FUNCTION OMP_GET_DYNAMIC()	Returns <code>.TRUE.</code> if dynamic thread adjustment is enabled, otherwise returns <code>.FALSE.</code> .
LOGICAL( <i>log</i> ) FUNCTION OMP_GET_CANCELLATION()	Returns <code>.TRUE.</code> if cancellation is enabled, otherwise returns <code>.FALSE.</code> . This routine can be affected by the setting for environment variable <code>OMP_CANCELLATION</code> .
SUBROUTINE OMP_SET_NESTED( <i>nested</i> ) LOGICAL( <i>log</i> ) <i>nested</i>	Enables or disables nested parallelism. If <i>nested</i> is <code>.TRUE.</code> , nested parallelism is enabled. If <i>nested</i> is <code>.FALSE.</code> , nested parallelism is disabled. Nested parallelism is disabled by default.
<b>NOTE</b> This has been deprecated.	
LOGICAL FUNCTION OMP_GET_NESTED()	Returns <code>.TRUE.</code> if nested parallelism is enabled, otherwise returns <code>.FALSE.</code> .
<b>NOTE</b> This has been deprecated.	
SUBROUTINE OMP_SET_SCHEDULE( <i>kind</i> , <i>chunk_size</i> ) INTEGER(KIND=omp_sched_kind) <i>kind</i> INTEGER( <i>int</i> ) <i>chunk_size</i>	Determines the schedule of a worksharing loop that is applied when 'runtime' is used as the schedule kind.
SUBROUTINE OMP_GET_SCHEDULE( <i>kind</i> , <i>chunk_size</i> ) INTEGER(KIND=omp_sched_chunk_size) <i>kind</i> INTEGER( <i>int</i> ) <i>chunk_size</i>	Returns the schedule of a worksharing loop that is applied when the 'runtime' schedule is used.
INTEGER FUNCTION OMP_GET_THREAD_LIMIT()	Returns the maximum number of simultaneously executing threads in an OpenMP program.
INTEGER FUNCTION OMP_GET_SUPPORTED_ACTIVE_LEVELS()	Returns the number of active levels of parallelism supported by the implementation.

Routine	Description
SUBROUTINE OMP_SET_MAX_ACTIVE_LEVELS(max_active_levels) INTEGER max_active_levels  INTEGER FUNCTION OMP_GET_MAX_ACTIVE_LEVELS()  INTEGER FUNCTION OMP_GET_LEVEL()  INTEGER FUNCTION OMP_GET_ANCESTOR_THREAD_NUM(level) INTEGER level  INTEGER FUNCTION OMP_GET_TEAM_SIZE(level) INTEGER level  INTEGER FUNCTION OMP_GET_ACTIVE_LEVEL()	<p>Limits the number of nested active parallel regions. The call is ignored if negative max_active_levels are specified.</p> <p>Returns the maximum number of nested active parallel regions.</p> <p>Returns the number of nested parallel regions (whether active or inactive) enclosing the task that contains the call, not including the implicit parallel region.</p> <p>Returns the thread number of the ancestor at a given nest level of the current thread.</p> <p>Returns the size of the thread team to which the ancestor or the current thread belongs for the specified nested level of the current thread.</p> <p>Returns the number of nested, active parallel regions enclosing the task that contains the call.</p>

The following parameter constants are defined in OMP\_LIB.MOD and can be set or returned in the `KIND` dummy argument in `OMP_SET_SCHEDULE` and `OMP_GET_SCHEDULE`:

```
integer(omp_sched_kind), parameter :: omp_sched_static = 1
integer(omp_sched_kind), parameter :: omp_sched_dynamic = 2
integer(omp_sched_kind), parameter :: omp_sched_guided = 3
integer(omp_sched_kind), parameter :: omp_sched_auto = 4
```

## Thread Affinity Routines

Routines that affect and access thread affinity policies that are in effect.

Function	Description
INTEGER(KIND=OMP_PROC_BIND_KIND) OMP_GET_PROC_BIND()	<p>Returns the currently active thread affinity policy, which can be initialized by the environment variable <code>OMP_PROC_BIND</code>.</p> <p>This policy is used for subsequent nested parallel regions.</p>
INTEGER(int) FUNCTION OMP_GET_NUM_PLACES()	<p>Returns the number of places available to the execution environment in the place list of the initial task, usually threads, cores, or sockets.</p>
INTEGER(int) FUNCTION OMP_GET_PLACE_NUM_PROCS(place_num) INTEGER(int) place_num	<p>Returns the number of processors associated with the place numbered <code>place_num</code>. The routine returns zero when <code>place_num</code> is negative or is greater than or equal to <code>OMP_GET_NUM_PLACES()</code>.</p>

Function	Description
<pre> SUBROUTINE OMP_GET_PLACE_PROC_IDS(place_num,ids) INTEGER(int) place_num INTEGER(int) ids(*) </pre>	<p>Returns the numerical identifiers of each processor associated with the place numbered <code>place_num</code>. The numerical identifiers are non-negative and their meaning is implementation defined. The numerical identifiers are returned in the array <code>ids</code> and their order in the array is implementation defined. <code>ids</code> must have at least</p> <pre>OMP_GET_PLACE_NUM_PROCS(place_num)</pre> <p>elements. The routine has no effect when <code>place_num</code> is negative or greater than or equal to <code>OMP_GET_NUM_PLACES()</code>.</p>
<pre> INTEGER(int) FUNCTION OMP_GET_PLACE_NUM() </pre>	<p>Returns the place number of the place to which the encountering thread is bound. The returned value is between 0 and <code>OMP_GET_NUM_PLACES() - 1</code>, inclusive. When the encountering thread is not bound to a place, the routine returns -1.</p>
<pre> INTEGER FUNCTION OMP_GET_PARTITION_NUM_PLACES() </pre>	<p>Returns the number of places in the place partition of the innermost implicit task.</p>
<pre> SUBROUTINE OMP_GET_PARTITION_PLACE_NUMS(place_nums) INTEGER(int) place_nums(*) </pre>	<p>Returns the list of place numbers corresponding to the places in the place-partition-var ICV of the innermost implicit task. The array <code>place_nums</code> must be sufficiently large to contain <code>OMP_GET_PARTITION_NUM_PLACES()</code> elements.</p>
<pre> SUBROUTINE OMP_SET_AFFINITY_FORMAT(format) CHARACTER(LEN=*),INTENT(IN) :: format </pre>	<p>Sets the affinity format to be used on the device by setting the value of the affinity-format-var ICV.</p>
<pre> INTEGER FUNCTION OMP_GET_AFFINITY_FORMAT(buffer) CHARACTER(LEN=*),INTENT(OUT) :: buffer </pre>	<p>Returns the value of the affinity-format-var ICV on the device.</p>
<pre> SUBROUTINE OMP_DISPLAY_AFFINITY(format) CHARACTER(LEN=*),INTENT(IN) :: format </pre>	<p>Prints the OpenMP thread affinity information using the format specification provided.</p>
<pre> INTEGER FUNCTION OMP_CAPTURE_AFFINITY(buffer, format) CHARACTER(LEN=*),INTENT(OUT) :: buffer CHARACTER(LEN=*),INTENT(IN) :: format </pre>	<p>Prints the OpenMP thread affinity information into a buffer using the format specification provided.</p>

The following parameter constants are defined in `OMP_LIB.MOD` and represent values returned by `OMP_GET_PROC_BIND`:

```

integer (omp_proc_bind_kind), parameter :: omp_proc_bind_false = 0
integer (omp_proc_bind_kind), parameter :: omp_proc_bind_true = 1
integer (omp_proc_bind_kind), parameter :: omp_proc_bind_master = 2
integer (omp_proc_bind_kind), parameter :: omp_proc_bind_close = 3
integer (omp_proc_bind_kind), parameter :: omp_proc_bind_spread = 4

```

## Teams Region Routines

Routines that affect and monitor the league of teams that may execute a TEAMS region.

Function	Description
INTEGER( <i>int</i> ) FUNCTION OMP_GET_NUM_TEAMS()	Returns the number of initial teams in the current TEAMS region.
INTEGER( <i>int</i> ) FUNCTION OMP_GET_TEAM_NUM()	Returns the team number of the calling thread.
SUBROUTINE OMP_SET_NUM_TEAMS( <i>num_teams</i> ) INTEGER <i>num_teams</i>	Affects the number of threads to be used for subsequent TEAMS regions that do not specify a NUM_TEAMS clause.
INTEGER FUNCTION OMP_GET_MAX_TEAMS()	Returns an upper bound on the number of teams that could be created by a TEAMS construct without a NUM_TEAMS clause that is encountered after execution returns from this routine.
SUBROUTINE OMP_SET_TEAMS_THREAD_LIMIT( <i>thread_limit</i> ) INTEGER <i>thread_limit</i>	Defines the maximum number of OpenMP threads that can participate in each contention group created by a TEAMS construct.
INTEGER FUNCTION OMP_GET_TEAMS_THREAD_LIMIT()	Returns the maximum number of OpenMP threads available to participate in each contention group created by a TEAMS construct.

## Tasking Routines

Routines that pertain to OpenMP explicit tasks.

Function	Description
INTEGER( <i>int</i> ) FUNCTION OMP_GET_MAX_TASK_PRIORITY()	Returns the maximum value that can be specified in the PRIORITY clause.
LOGICAL( <i>log</i> ) FUNCTION OMP_IN_EXPLICIT_TASK()	Returns <code>.TRUE.</code> if called within an explicit task region; otherwise returns <code>.FALSE.</code> .
LOGICAL( <i>log</i> ) FUNCTION OMP_IN_FINAL()	Returns <code>.TRUE.</code> if called within a final task region; otherwise returns <code>.FALSE.</code> .

## Resource Relinquishing Routines

Routines that relinquish resources used by the OpenMP runtime. These routines are only effective on the host device.

Function	Description
INTEGER FUNCTION OMP_PAUSE_RESOURCE( <i>kind</i> , <i>device_num</i> ) INTEGER (OMP_PAUSE_RESOURCE_KIND) <i>kind</i> INTEGER <i>device_num</i>	Allows the runtime to relinquish resources used by OpenMP on the specified device. The routine returns zero in case of success, and non-zero otherwise.

Function	Description
<pre> INTEGER FUNCTION OMP_PAUSE_RESOURCE_ALL(kind)  INTEGER (OMP_PAUSE_RESOURCE_KIND) kind </pre>	Allows the runtime to relinquish resources used by OpenMP on all devices. The routine returns zero in case of success, and non-zero otherwise.

## Device Information Routines

Routines that pertain to the set of devices that are accessible to an OpenMP program.

Function	Description
<pre> INTEGER(int) FUNCTION OMP_GET_NUM_PROCS()  SUBROUTINE OMP_SET_DEFAULT_DEVICE(device_number) INTEGER(int) device_number  INTEGER(int) FUNCTION OMP_GET_DEFAULT_DEVICE()  INTEGER(int) FUNCTION OMP_GET_NUM_DEVICES()  INTEGER FUNCTION OMP_GET_DEVICE_NUM()  LOGICAL(log) FUNCTION OMP_IS_INITIAL_DEVICE()  INTEGER(int) FUNCTION OMP_GET_INITIAL_DEVICE() </pre>	<p>Returns the number of processors available to the program.</p> <p>Sets the default device number.</p> <p>Returns the default device number.</p> <p>Returns the number of target devices.</p> <p>Returns the device number of the device on which the calling thread is executing.</p> <p>Returns <code>.TRUE.</code> if the current task is running on the host device; otherwise, <code>.FALSE.</code></p> <p>Returns the device number of the host device. The value of the device number is implementation defined. If it is between 0 and <code>OMP_GET_NUM_DEVICES() - 1</code>, then it is valid in all device constructs and routines; if it is outside that range, then it is only valid in the device memory routines and not in the <code>DEVICE</code> clause.</p>

## Device Memory Routines

This feature is only available for ifx.

Function	Description
<pre> TYPE(c_ptr) FUNCTION omp_target_alloc (size, device_num)  USE, INTRINSIC :: ISO_C_BINDING  INTEGER(c_size_t) :: size  INTEGER(c_int) :: device_num  SUBROUTINE omp_target_free (device_ptr, device_num)  USE, INTRINISIC :: ISO_C_BINDING </pre>	<p>Returns the device address of a storage location that is <code>size</code> bytes in length. If the allocation request cannot be satisfied, a null address is returned. The allocation occurs on the device specified by <code>device_num</code>.</p> <p>Deallocates the previously allocated memory allocation pointed to by <code>device_ptr</code> on the device specified by <code>device_num</code>.</p>

Function	Description
<pre>TYPE (c_ptr) :: device_ptr INTEGER(c_int) :: device_num</pre>	

## Lock Routines

Use these routines to affect OpenMP locks.

Function	Description
<pre>SUBROUTINE OMP_INIT_LOCK(svar) INTEGER (KIND=OMP_LOCK_KIND) svar</pre>	Initializes the lock to the unlocked state.
<pre>SUBROUTINE OMP_INIT_NEST_LOCK(nvar) INTEGER (KIND=OMP_NEST_LOCK_KIND) nvar</pre>	Initializes the nested lock to the unlocked state. The nesting count for the nested lock is set to zero.
<pre>SUBROUTINE OMP_INIT_LOCK_WITH_HINT(svar, hint) INTEGER (KIND=OMP_LOCK_KIND) svar INTEGER (KIND=OMP_SYNC_HINT_KIND) hint</pre>	Initializes the lock to the unlocked state, optionally choosing a specific lock implementation based on <code>hint</code> .
<pre>SUBROUTINE OMP_INIT_NEST_LOCK_WITH_HINT(nvar, hint) INTEGER (KIND=OMP_NEST_LOCK_KIND) nvar INTEGER (KIND=OMP_SYNC_HINT_KIND) hint</pre>	Initializes the nested lock to the unlocked state, optionally choosing a specific lock implementation based on <code>hint</code> . The nesting count for the nested lock is set to zero.
<pre>SUBROUTINE OMP_DESTROY_LOCK(svar) INTEGER (KIND=OMP_LOCK_KIND) svar</pre>	Changes the state of the lock to uninitialized.
<pre>SUBROUTINE OMP_DESTROY_NEST_LOCK(nvar) INTEGER (KIND=OMP_NEST_LOCK_KIND) nvar</pre>	Changes the state of the nested lock to uninitialized.
<pre>SUBROUTINE OMP_SET_LOCK(svar) INTEGER (KIND=OMP_LOCK_KIND) svar</pre>	Forces the executing thread to wait until the lock is available. The thread is granted ownership of the lock when it becomes available. The lock must be initialized.
<pre>SUBROUTINE OMP_SET_NEST_LOCK(nvar) INTEGER (KIND=OMP_NEST_LOCK_KIND) nvar</pre>	Forces the executing thread to wait until the nested lock is available. If the thread already owns the lock, then the lock nesting count is incremented. The lock must be initialized.
<pre>SUBROUTINE OMP_UNSET_LOCK(svar) INTEGER (KIND=OMP_LOCK_KIND) svar</pre>	Releases the executing thread from ownership of the lock. The behavior is undefined if the executing thread does not own the lock.
<pre>SUBROUTINE OMP_UNSET_NEST_LOCK(nvar) INTEGER (KIND=OMP_NEST_LOCK_KIND) nvar</pre>	Decrements the nesting count for the nested lock and releases the executing thread from ownership of the nested lock if the resulting nesting count is zero. Behavior is undefined if the executing thread does not own the nested lock.
<pre>LOGICAL(log) OMP_TEST_LOCK(svar) INTEGER (KIND=OMP_LOCK_KIND) svar</pre>	Attempts to set the lock. If successful, returns <code>.TRUE.</code> , otherwise returns <code>.FALSE.</code> . The lock must be initialized.

Function	Description
<pre>INTEGER(int) OMP_TEST_NEST_LOCK(nvar) INTEGER(KIND=OMP_NEST_LOCK_KIND) nvar</pre>	Attempts to set the nested lock. If successful, returns the nesting count, otherwise returns zero.

The following parameter constants are defined in `OMP_LIB.MOD` and can be set in the `HINT` dummy argument in `OMP_INIT_LOCK_WITH_HINT` and `OMP_INIT_NEST_LOCK_WITH_HINT`:

```
integer (omp_sync_hint_kind), parameter :: omp_sync_hint_none      = 0
integer (omp_sync_hint_kind), parameter :: omp_sync_hint_uncontended = 1
integer (omp_sync_hint_kind), parameter :: omp_sync_hint_contended   = 2
integer (omp_sync_hint_kind), parameter :: omp_sync_hint_nonspeculative = 4
integer (omp_sync_hint_kind), parameter :: omp_sync_hint_speculative   = 8
```

The hints can be combined by using the `+` operator in Fortran. The effect of the combined hint is implementation defined. Combining `omp_sync_hint_none` with any other hint is equivalent to specifying the other hint. The following restrictions apply to combined hints:

- Hints `omp_sync_hint_uncontended` and `omp_sync_hint_contended` cannot be combined.
- Hints `omp_sync_hint_nonspeculative` and `omp_sync_hint_speculative` cannot be combined.

## Timing Routines

Function	Description
<pre>REAL (dp) FUNCTION OMP_GET_WTIME()</pre>	Returns a double precision value equal to the elapsed wall clock time (in seconds) relative to an arbitrary reference time. The reference time does not change during program execution.
<pre>REAL (dp) FUNCTION OMP_GET_WTICK()</pre>	Returns a double precision value equal to the number of seconds between successive clock ticks.

## Event Routines

Function	Description
<pre>SUBROUTINE OMP_FULFILL_EVENT(event) INTEGER(OMP_EVENT_HANDLE_KIND) event</pre>	Fulfills the event associated with the event handle <code>event</code> and destroys the event.

## Memory Management Routines

This feature is only available for ifx.

Function	Description
<pre>FUNCTION omp_init_allocator(memspace, ntraits, traits) INTEGER (KIND=omp_allocator_handle_kind) omp_init_allocator INTEGER (KIND=omp_memspace_handle_kind), INTENT(IN) ) :: memspace INTEGER, INTENT(IN) :: ntraits</pre>	Initialize an allocator and associate it with a memory space, returning an allocator handle. The <code>memspace</code> argument must be one of the predefined memory spaces defined in <a href="#">OpenMP Memory Space Allocators</a> . The <code>ntraits</code> argument specifies the number of traits in the traits array argument. If there are fewer traits than specified by <code>ntraits</code> , the behavior is undefined. A <code>REQUIRES</code> directive

Function	Description
<pre> TYPE(omp_alloctrait), INTENT(IN) :: traits(*)  SUBROUTINE omp_destroy_allocator (allocator)  INTEGER(KIND=omp_allocator_handle_kind), I NTENT(IN) :: allocator  SUBROUTINE omp_set_default_allocator (allocator)  INTEGER(KIND=omp_allocator_handle_kind) : : allocator  FUNCTION omp_get_default_allocator ()  INTEGER(KIND=omp_allocator_handle_kind) : : omp_get_default_allocator  TYPE(c_ptr) FUNCTION omp_alloc (size, allocator) bind (c)  USE, INTRINSIC ISO_C_BINDING INTEGER(c_size_t) VALUE :: size INTEGER(omp_allocator_handle_kind), value :: allocator </pre>	<p>specifying <code>dynamic_allocators</code> must appear in the same compilation unit of a target region that calls this function.</p> <p>Releases all resources used by the allocator handle argument. The allocator argument must not be a handle for a predefined allocator. A <code>REQUIRES</code> directive specifying <code>dynamic_allocators</code> must appear in the same compilation unit of a target region that calls this function.</p> <p>Sets the default memory allocator used for memory allocations resulting from <code>ALLOCATE</code> clauses and directives that do not specify an allocator. The allocator argument must be a valid allocator.</p> <p>Returns the allocator handle of the allocator to be used for allocations resulting from <code>ALLOCATE</code> clauses and directives that do not specify an allocator.</p> <p>Requests a memory allocation of <code>size</code> bytes from the specified memory allocator.</p> <p>The <code>allocator</code> argument must be an integer constant expression that evaluates to the value of one of the predefined memory allocator values. Allocated memory is byte aligned to at least the maximum of the alignment required by <code>malloc</code> and the alignment trait of the allocator.</p> <p>Calls to <code>omp_alloc</code> that appear in target regions may not pass <code>OMP_NULL_ALLOCATOR</code> as the allocator argument, unless a <code>REQUIRES</code> directive specifying <code>DYNAMIC_ALLOCATORS</code> appears in the same compilation unit.</p>
<pre> TYPE(c_ptr) FUNCTION omp_aligned_alloc (alignment, size, allocator) bind (c)  USE, INTRINSIC ISO_C_BINDING INTEGER(c_size_t) VALUE :: alignment, size </pre>	<p>Requests a memory allocation of <code>size</code> bytes from the specified memory allocator. <code>alignment</code> must be a power of two, and <code>size</code> must be a multiple of alignment.</p> <p>The <code>allocator</code> argument must be an integer constant expression that evaluates to the value of one of the predefined memory allocator values. If</p>

Function	Description
<pre> INTEGER(omp_allocator_handle_kind), value :: allocator </pre>	<p><code>allocator</code> is <code>OMP_NULL_ALLOCATOR</code>, the allocator used is the allocator specified by the ICV <code>def-allocator-var</code> of the binding implicit task.</p> <p>A pointer to the first word allocated is returned if the allocation is successful; otherwise, the behavior is that specified for the fallback trait of the allocator. If <code>size</code> is zero, <code>C_NULL_PTR</code> (Fortran) or <code>NULL</code> (C) is returned. Allocated memory is byte aligned to at least the maximum of the alignment required by <code>malloc</code>, the alignment trait of the allocator, and the value specified for the alignment argument.</p> <p>Calls to <code>omp_alloc</code> that appear in target regions may not pass <code>OMP_NULL_ALLOCATOR</code> as the allocator argument, unless a <code>REQUIRES</code> directive specifying <code>DYNAMIC_ALLOCATORS</code> appears in the same compilation unit.</p>
<pre> TYPE(c_ptr) FUNCTION omp_calloc (nmemb, size, allocator) bind (c)  USE, INTRINSIC :: ISO_C_BINDING  INTEGER(c_size_t) value :: nmemb, size  INTEGER(omp_allocator_handle_t), value :: allocator </pre>	<p>Requests a zero initialized memory allocation of <code>size</code> bytes from the specified memory allocator.</p> <p>The <code>allocator</code> argument must be an integer constant expression whose value is one of the predefined memory allocators. If <code>omp_calloc</code> is called from a <code>TARGET</code> region, the value of <code>allocator</code> must not be <code>OMP_NULL_ALLOCATOR</code> unless <code>DYNAMIC_ALLOCATORS</code> appears in a <code>REQUIRES</code> directive in the same compilation unit as the call. If <code>OMP_NULL_ALLOCATOR</code> is specified, the allocator used is the allocator specified by the <code>def-allocator-var</code> ICV of the binding implicit task.</p> <p>The allocation is an array of <code>nmemb</code> elements; each element is <code>size</code> bytes. <code>allocator</code> specifies the memory allocator to use. The allocated memory is initialized to zero. If the request is unsuccessful, the behavior is that specified by the <code>FALLBACK</code> trait of the allocator. The allocation is aligned to at least the maximum of the alignment required by <code>malloc</code> and the alignment trait of the allocator.</p> <p>If either <code>nmemb</code> or <code>size</code> has the value 0, the value <code>NULL</code> (C) or <code>C_NULL_PTR</code> (Fortran) is returned.</p>

The derived type `omp_allocator` is defined in `OMP_LIB.MOD` and is used as the type of the `traits` argument to the `omp_init_allocator` function.

```

type omp_alloctrail
  integer(kind=omp_alloctrail_key_kind) :: key
  integer(kind=omp_alloctrail_val_kind) :: value
end type omp_alloctrail

```

The following parameter constants are defined in `OMP_LIB.MOD` and can be used to specify allocator trait keys in a derived type of type `omp_alloctrail`.

```
integer(omp_alloctrail_key_kind), parameter :: omp_atk_sync_hint = 1
integer(omp_alloctrail_key_kind), parameter :: omp_atk_alignment = 2
integer(omp_alloctrail_key_kind), parameter :: omp_atk_access = 3
integer(omp_alloctrail_key_kind), parameter :: omp_atk_pool_size = 4
integer(omp_alloctrail_key_kind), parameter :: omp_atk_fallback = 5
integer(omp_alloctrail_key_kind), parameter :: omp_atk_fb_data = 6
integer(omp_alloctrail_key_kind), parameter :: omp_atk_atk_pinned = 7
integer(omp_alloctrail_key_kind), parameter :: omp_atk_partition = 8
```

The following parameter constants are defined in `OMP_LIB.MOD` and can be used to set allocator trait values in a derived type of type `omp_alloctrail`.

```
integer(omp_alloctrail_val_kind), parameter :: omp_atv_false = 0
integer(omp_alloctrail_val_kind), parameter :: omp_atv_true = 1
integer(omp_alloctrail_val_kind), parameter :: omp_atv_default = 2
integer(omp_alloctrail_val_kind), parameter :: omp_atv_contended = 3
integer(omp_alloctrail_val_kind), parameter :: omp_atv_uncontended = 4
integer(omp_alloctrail_val_kind), parameter :: omp_atv_sequential = 5
integer(omp_alloctrail_val_kind), parameter :: omp_atv_private = 6
integer(omp_alloctrail_val_kind), parameter :: omp_atv_all = 7
integer(omp_alloctrail_val_kind), parameter :: omp_atv_thread = 8
integer(omp_alloctrail_val_kind), parameter :: omp_atv_pteam = 9
integer(omp_alloctrail_val_kind), parameter :: omp_atv_cgroup = 10

```

## Tool Control Routines

Function	Description
INTEGER FUNCTION <code>OMP_CONTROL_TOOL(command, modifier)</code>  INTEGER (kind=omp_control_tool_kind) <code>command</code>  INTEGER <code>modifier</code>	Enables a program to pass commands to an active tool.

## Environment Display Routines

Function	Description
SUBROUTINE <code>OMP_DISPLAY_ENV(verbose)</code>  LOGICAL, INTENT(IN) :: <code>verbose</code>	Displays the OpenMP version number and the initial values of ICVs associated with the environment variables.

Intel Extension Routines to OpenMP\*  
 Predefined Preprocessor Symbols

## Intel® Compiler Extension Routines to OpenMP\*

The Intel® compiler implements the following group of routines as extensions to the OpenMP\* runtime library:

- Get and set the execution environment
- Get and set the stack size for parallel threads
- Memory allocation
- Get and set the thread sleep time for the throughput execution mode
- Target memory allocation

The Intel® extension routines described in this section can be used for low-level tuning to verify that the library code and application are functioning as intended. These routines are generally not recognized by other OpenMP-compliant compilers, which may cause the link stage to fail in the other compiler. To execute these OpenMP routines, use the `/Qopenmp-stubs` (Windows\*) or `-qopenmp-stubs` (Linux\* and macOS) option.

In most cases, environment variables can be used in place of the extension library routines. For example, the stack size of the parallel threads may be set using the `OMP_STACKSIZE` environment variable rather than the `KMP_SET_STACKSIZE_S()` library routine.

### NOTE

A runtime call to an Intel extension routine takes precedence over the corresponding environment variable setting.

## Execution Environment

Function	Description
SUBROUTINE KMP_SET_DEFAULTS (STRING) CHARACTER* (*) STRING	Sets OpenMP environment variables defined as a list of variables separated by " " in the argument.
SUBROUTINE KMP_SET_LIBRARY_THROUGHPUT()	Sets execution mode to throughput, which is the default. Allows the application to determine the runtime environment. Use in multi-user environments.
SUBROUTINE KMP_SET_LIBRARY_TURNAROUND()	Sets execution mode to turnaround. Use in dedicated parallel (single user) environments.
SUBROUTINE KMP_SET_LIBRARY_SERIAL()	Sets execution mode to serial.
SUBROUTINE KMP_SET_LIBRARY (LIBNUM) INTEGER (KIND=OMP_INTEGER_KIND) LIBNUM	Sets execution mode indicated by the value passed to the function. Valid values are: <ul style="list-style-type: none"> <li>• <b>1</b> - serial mode</li> <li>• <b>2</b> - turnaround mode</li> <li>• <b>3</b> - throughput mode</li> </ul> Call this routine before the first parallel region is executed.
FUNCTION KMP_GET_LIBRARY() INTEGER (KIND=OMP_INTEGER_KIND) KMP_GET_LIBRARY	Returns a value corresponding to the current execution mode: <ul style="list-style-type: none"> <li>• <b>1</b> - serial</li> <li>• <b>2</b> - turnaround</li> </ul>

Function	Description
	<ul style="list-style-type: none"> <li>• <b>3</b> - throughput</li> </ul>

## Stack Size

Function	Description
<pre>FUNCTION KMP_GET_STACKSIZE_S() INTEGER(KIND=KMP_SIZE_T_KIND) &amp; KMP_GET_STACKSIZE_S</pre>	Returns the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can be changed with <code>KMP_SET_STACKSIZE_S()</code> routine, prior to the first parallel region or via the <code>KMP_STACKSIZE</code> environment variable.
<pre>FUNCTION KMP_GET_STACKSIZE() INTEGER KMP_GET_STACKSIZE</pre>	Provided for backwards compatibility only. Use <code>KMP_GET_STACKSIZE_S()</code> routine for compatibility across different families of Intel processors.
<pre>SUBROUTINE KMP_SET_STACKSIZE_S(size) INTEGER (KIND=KMP_SIZE_T_KIND) size</pre>	Sets to <i>size</i> the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can also be set via the <code>KMP_STACKSIZE</code> environment variable. In order for <code>KMP_SET_STACKSIZE_S()</code> to have an effect, it must be called before the beginning of the first (dynamically executed) parallel region in the program.
<pre>SUBROUTINE KMP_SET_STACKSIZE_S(size) INTEGER size</pre>	Provided for backward compatibility only. Use <code>KMP_SET_STACKSIZE_S(size)</code> for compatibility across different families of Intel® processors.

## Memory Allocation

The Intel® compiler implements a group of memory allocation routines as an extension to the OpenMP runtime library to enable threads to allocate memory from a heap local to each thread. These routines are: `KMP_MALLOC()`, `KMP_CALLOC()`, and `KMP_REALLOC()`.

The memory allocated by these routines must also be freed by the `KMP_FREE()` routine. While you can allocate memory in one thread and then free that memory in a different thread, this mode of operation incurs a slight performance penalty.

Working with the local heap might lead to improved application performance because synchronization is not required.

Function	Description
<pre>FUNCTION KMP_MALLOC(size) INTEGER(KIND=KMP_POINTER_KIND) KMP_MALLOC INTEGER(KIND=KMP_SIZE_T_KIND) size</pre>	Allocate memory block of <i>size</i> bytes from thread-local heap.
<pre>FUNCTION KMP_CALLOC(nelem, elsize) INTEGER(KIND=KMP_POINTER_KIND) KMP_CALLOC INTEGER(KIND=KMP_SIZE_T_KIND) nelem INTEGER(KIND=KMP_SIZE_T_KIND) elsize</pre>	Allocate array of <i>nelem</i> elements of size <i>elsize</i> from thread-local heap.

Function	Description
<pre> FUNCTION KMP_REALLOC(<i>ptr</i>, <i>size</i>) INTEGER(KIND=KMP_POINTER_KIND) KMP_REALLOC INTEGER(KIND=KMP_POINTER_KIND) <i>ptr</i> INTEGER(KIND=KMP_SIZE_T_KIND) <i>size</i> </pre>	Reallocate memory block at address <i>ptr</i> and <i>size</i> bytes from thread-local heap.
<pre> SUBROUTINE KMP_FREE(<i>ptr</i>) INTEGER (KIND=KMP_POINTER_KIND) <i>ptr</i> </pre>	Free memory block at address <i>ptr</i> from thread-local heap.  Memory must have been previously allocated with <code>KMP_MALLOC()</code> , <code>KMP_CALLOC()</code> , or <code>KMP_REALLOC()</code> .

## Thread Sleep Time

In the throughput [OpenMP\\* Support Libraries](#), threads wait for new parallel work at the ends of parallel regions, and then sleep, after a specified period of time. This time interval can be set by the `KMP_BLOCKTIME` environment variable or by the `KMP_SET_BLOCKTIME()` function.

Function	Description
<pre> FUNCTION KMP_GET_BLOCKTIME ( INTEGER KMP_GET_BLOCKTIME </pre>	Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping, as set either by the <code>KMP_BLOCKTIME</code> environment variable or by <code>KMP_SET_BLOCKTIME()</code> .
<pre> FUNCTION KMP_SET_BLOCKTIME(<i>msec</i>) INTEGER <i>msec</i> </pre>	Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping. This routine affects the block time setting for the calling thread and any OpenMP team threads formed by the calling thread. The routine does not affect the block time for any other threads.

## Target Memory Allocation

This feature is only available for ifx.

Function	Description
<pre> TYPE(c_ptr) FUNCTION omp_target_alloc_host (size, device_num) USE, INTRINSIC :: ISO_C_BINDING INTEGER(c_size_t) :: size INTEGER(c_int) :: device_num </pre>	Returns the address of a storage location that is <i>size</i> bytes in length allocated in host memory. The same pointer may be used to access the memory on the host and all supported devices. If the allocation request fails, a null pointer is returned.
<pre> TYPE(c_ptr) FUNCTION omp_target_alloc_device (size, device_num) USE, INTRINSIC :: ISO_C_BINDING INTEGER(c_size_t) :: size INTEGER(c_int) :: device_num </pre>	Returns the address of a storage allocation that is <i>size</i> bytes in length. Device allocations are owned by the device specified by <i>device_num</i> device memory if present. Generally, the allocation can be accessed only by the device, but may be copied to

Function	Description
<pre> TYPE(c_ptr) FUNCTION omp_target_alloc_shared (size, device_num) USE, INTRINSIC :: ISO_C_BINDING INTEGER(c_size_t) :: size INTEGER(c_int) :: device_num </pre>	<p>other device or host allocated memory. A null pointer return value indicates the allocation was not successful.</p> <p>Returns the address of a storage allocation that is <code>size</code> bytes in length. The same pointer may be used to access the memory on the host and the specified device. Shared allocations are shared by the host and the specified device, and are intended to migrate between the host and the device. A null pointer is returned if the allocation is unsuccessful.</p>

## OpenMP\* Support Libraries

The Intel® Fortran Compiler provides support libraries for OpenMP\*. There are several kinds of libraries:

- **Performance:** supports parallel OpenMP execution.
- **Stubs:** supports serial execution of OpenMP applications.

Each kind of library is available for both dynamic and static linking on Linux\* and macOS operating systems. Only dynamic linking is supported on Windows\* operating systems.

### Performance Libraries

To use these libraries, specify the `/Qopenmp` (Windows\*) or `-qopenmp` (Linux\* and macOS) option.

Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the `SINGLE` construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Operating System	Dynamic Link	Static Link
Linux	libiomp5.so	libiomp5.a
macOS	libiomp5.dylib	libiomp5.a
Windows	libiomp5md.lib libiomp5md.dll	None

Many routines in the OpenMP support libraries are more optimized for Intel® microprocessors than for non-Intel microprocessors.

### Stubs Libraries

To use these libraries, specify `/Qopenmp-stubs` (Windows\*) or `-qopenmp-stubs` (Linux\* and macOS) option. These allow you to compile OpenMP applications in serial mode and provide stubs for OpenMP routines and extended Intel-specific routines.

Operating System	Dynamic Link	Static Link
Linux	libiompstubs5.so	libiompstubs5.a
macOS	libiompstubs5.dylib	libiompstubs5.a
Windows	libiompstubs5md.lib libiompstubs5md.dll	None

## Execution Modes

The compiler enables you to run an application under different execution modes specified at runtime; the libraries support the turnaround, throughput, and serial modes. Use the `KMP_LIBRARY` environment variable to select the modes at runtime.

Mode	Description
<b>throughput</b> (default)	<p>The throughput mode allows the program to yield to other running programs and adjust resource usage to produce efficient execution in a dynamic environment.</p> <p>In a multi-user environment where the load on the parallel machine is not constant or where the job stream is not predictable, it may be better to design and tune for throughput. This minimizes the total time to run multiple jobs simultaneously. In this mode, the worker threads yield to other threads while waiting for more parallel work.</p> <p>After completing the execution of a parallel region, threads wait for new parallel work to become available. After a certain period of time has elapsed, they stop waiting and sleep. Until more parallel work becomes available, sleeping allows processor and resources to be used for other work by non-OpenMP threaded code that may execute between parallel regions, or by other applications.</p> <p>The amount of time to wait before sleeping is set either by the <code>KMP_BLOCKTIME</code> environment variable or by the <code>KMP_SET_BLOCKTIME()</code> function. A small blocktime value may offer better overall performance if your application contains non-OpenMP threaded code that executes between parallel regions. A larger blocktime value may be more appropriate if threads are to be reserved solely for use for OpenMP execution, but may penalize other concurrently-running OpenMP or threaded applications.</p>
<b>turnaround</b>	<p>The turnaround mode is designed to keep active all processors involved in the parallel computation, which minimizes execution time of a single job. In this mode, the worker threads actively wait for more parallel work, without yielding to other threads (although they are still subject to <code>KMP_BLOCKTIME</code> control). In a dedicated (batch or single user) parallel environment where all processors are exclusively allocated to the program for its entire run, it is most important to effectively use all processors all of the time.</p> <hr/> <p><b>NOTE</b></p> <p>Avoid over-allocating system resources. The condition can occur if either too many threads have been specified, or if too few processors are available at runtime. If system resources are over-allocated, this mode will cause poor performance. The throughput mode should be used instead if this occurs.</p>

Mode	Description
<b>serial</b>	The serial mode forces parallel applications to run as a single thread.

## Use the OpenMP Libraries

This section describes the steps needed to set up and use the OpenMP Libraries from the command line. On Windows systems, you can also build applications compiled with the OpenMP libraries in the Microsoft Visual Studio development environment.

For a list of the options and libraries used by the OpenMP libraries, see [OpenMP Support Libraries](#).

### Set Up Environment

Set up your environment for access to the compiler to ensure that the appropriate OpenMP library is available during linking.

#### Linux and macOS

On Linux and macOS systems you can source the appropriate script file (`setvars` file).

#### Windows

On Windows systems you can either execute the appropriate batch (`.bat`) file or use the command-line window supplied in the compiler program folder that already has the environment set up.

To use the `gfortran` compiler with the Intel® OpenMP library along with the OpenMP API functions:

1. Use the `use omp_lib` statement to compile the `omp_lib.f90` source file, which is in the `include` directory.
2. Add the `-I` option to the compile command line with appropriate path to the directory containing the resulting module file.

During compilation, ensure that the version of `omp_lib.h` or `omp_lib.mod` used when compiling is the version provided by that compiler.

---

#### Caution

Be aware that when using the GCC or Microsoft Compiler, you may inadvertently use inappropriate header or module files. To avoid this, copy the header or module file(s) to a separate directory and put it in the appropriate `include` path using the `-I` option.

---

If a program uses data structures or classes that contain members with data types defined in the `omp_lib.h` file, then source files that use those data structures should all be compiled with the same `omp_lib.h` file.

### Linux Examples

This section shows several examples of using OpenMP with the Intel Fortran Compiler Classic and Intel Fortran Compiler from the command line on Linux.

The command for the Intel® Fortran Compiler Classic is `ifort`. The command for the Intel® Fortran Compiler is `ifx`. In all Windows and Linux examples that follow, the command `ifx` can be substituted for the command `ifort`. macOS is only supported for `ifort`.

#### Compile and Link OpenMP Libraries

You can compile an application and link the Intel OpenMP libraries with a single command using the `-qopenmp` option. For example:

```
ifx -qopenmp hello.f90
```

By default, the Intel Fortran Compiler Classic and Intel Fortran Compiler performs a dynamic link of the OpenMP libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP libraries on Linux and macOS systems (default is `-qopenmp-link=dynamic`). See [OpenMP Support Libraries](#) for more information about dynamic and static OpenMP libraries.

### Link OpenMP Object Files Compiled with GCC or Intel Fortran Compiler Classic and Intel Fortran Compiler

You can use the `ifort/ifx` compilers with the `gcc/g++` compilers to compile parts of an application and create object files that can then be linked (object-level interoperability).

When using `gcc` or the `g++` compiler to link the application with the Intel Fortran Compiler Classic and Intel Fortran Compiler OpenMP compatibility library, you need to specify the following:

- The Intel OpenMP library name using the `-l` option
- The Linux `pthread` library using the `-l` option
- The path to the Intel libraries where the Intel Fortran Compiler Classic and Intel Fortran Compiler is installed using the `-L` option

For example:

1. Compile `foo.c` and `bar.c` with `gcc`, using the `-fopenmp` option to enable OpenMP support:

```
gcc -fopenmp -c foo.c bar.c
```

The `-c` prevents linking at this step.

2. Use the `gcc` compiler to link the application object code with the Intel OpenMP library:

```
gcc foo.o bar.o -liomp5 -lpthread -L<install_dir>/lib
```

where `<install_dir>` is the location of the installed Intel OpenMP library.

Alternately, you can use the Intel Fortran Compiler Classic and Intel Fortran Compiler to link the application so that you don't need to specify the `gcc-l` option, `-L` option, and the `-lpthread` options.

For example:

1. Compile `foo.c` with `gcc`, using the `gcc -fopenmp` option to enable OpenMP:

```
gcc -fopenmp -c foo.c
```

2. Compile `bar.c` with `icx`, using the `-qopenmp` option to enable OpenMP:

```
icx -qopenmp -c bar.c
```

3. Use the `ifort` compiler to link the resulting application object code with the Intel OpenMP library:

```
ifort -qopenmp -nofor-main foo.o bar.o
```

### Link Mixed C/C++ and Fortran Object Files

You can mix C/C++ and Fortran object files and link the Intel OpenMP libraries using GNU, GCC, or Intel Fortran Compiler Classic and Intel Fortran Compiler compilers.

This example shows mixed C and Fortran sources, linked using the Intel Fortran Compiler Classic and Intel Fortran Compiler. Consider the mixed source files `ibar.c`, `gbar.c`, and `foo.f`:

1. Compile `ibar.c` using the `icx` compiler:

```
icx -qopenmp -c ibar.c
```

**2. Compile gbar.c using the gcc compiler:**

```
gcc -fopenmp -c gbar.c
```

**3. Compile foo.f using the ifort compiler:**

```
ifort -qopenmp -c foo.f
```

**4. Use the ifort compiler to link the resulting object files:**

```
ifort -qopenmp foo.o ibar.o gbar.o
```

When using ifort or ifx, if the main program does not exist in a Fortran object file that is compiled by either ifort or ifx, specify the `-nofor-main` option on the command line during linking.

---

**NOTE**

Do not mix objects created by the Intel Fortran Compiler Classic and Intel Fortran Compiler with the GNU Fortran Compiler (`gfortran`); instead, recompile all Fortran sources with either ifort or ifx, or recompile all Fortran sources with the GNU Fortran Compiler. The GNU Fortran Compiler is only available on Linux operating systems.

---

When using the GNU `gfortran` Compiler to link the application with the Intel Fortran Compiler Classic and Intel Fortran Compiler OpenMP compatibility library, you need to specify the following:

- The Intel® OpenMP compatibility library name and the Intel®irc libraries using the `-l` option
- The Linux `pthread` library using the `-l` option
- The path to the Intel® libraries where it is installed using the `-L` option

You do not need to specify the `-fopenmp` option on the link line.

For example, consider the mixed source files `ibar.c`, `gbar.c`, and `foo.f`:

**1. Compile ibar.c using the icx compiler:**

```
icx -qopenmp -c ibar.c
```

**2. Compile gbar.c using the GCC compiler:**

```
gcc -fopenmp -c gbar.c
```

**3. Compile foo.f using the gfortran compiler:**

```
gfortran -fopenmp -c foo.f
```

**4. Use the gfortran compiler to link the application object code with the Intel OpenMP library. You do not need to specify the -fopenmp option in the link command:**

```
gfortran foo.o ibar.o gbar.o -lirc -liomp5 -lpthread -lc -L<install_dir>/lib
```

where `<install_dir>` is the location of the installed Intel OpenMP library.

Alternately, you can use the Intel Fortran Compiler Classic and Intel Fortran Compiler. to link the application object code but need to pass multiple `gfortran` libraries using the `-l` options at the link step.

This example shows mixed C and GNU Fortran sources linked using the icx compiler. Consider the mixed source files `ibar.c` and `foo.f`:

**1. Compile the C source with the icx compiler:**

```
icx -qopenmp -c ibar.c
```

**2. Compile the GNU Fortran source with gfortran:**

```
gfortran -fopenmp -c foo.f
```

**3. Use ifort to link the resulting object files with the -l option to pass the needed gfortran libraries:**

```
ifort -qopenmp -nofor-main foo.o ibar.o -lgfortran
```

## macOS Examples

This section shows several examples of using OpenMP with the Intel Fortran Compiler Classic and Intel Fortran Compiler from the command line on macOS.

macOS is only supported for `ifort`.

### Compile and Link OpenMP Libraries

You can compile an application and link the Intel OpenMP libraries with a single command using the `-qopenmp` option. For example:

```
ifort -qopenmp hello.f90
```

By default, the Intel Fortran Compiler Classic performs a dynamic link of the OpenMP libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP libraries on Linux and macOS systems (default is `-qopenmp-link=dynamic`).

### Link Mixed OpenMP Object Files

You can mix OpenMP object files compiled by the Intel C++ Compiler Classic and Intel Fortran Compiler Classic.

This example shows mixed C and Fortran sources, compiled by the `icc` and `ifort` drivers, linked using the Intel Fortran Compiler Classic. Consider the mixed source files `ibar.c` and `foo.f90`:

1. Compile `ibar.c` using `icc`:

```
icc -qopenmp -c ibar.c
```

The `-c` prevents linking at this step.

2. Compile `foo.f90` using `ifort`:

```
ifort -qopenmp -c foo.f90
```

3. Use `ifort` to link the resulting object files:

```
ifort -qopenmp foo.o ibar.o
```

When using `ifort`, if the main program does not exist in a Fortran object file that is compiled by `ifort`, specify the `-nofor-main` option on the command line during linking.

## Windows Examples

This section shows several examples of using OpenMP with the Intel Fortran Compiler Classic and Intel Fortran Compiler from the command line on Windows.

### Compile and Link OpenMP Libraries

You can compile an application and link the Compatibility libraries with a single command using the `/Qopenmp` option. By default, the Intel Fortran Compiler Classic and Intel Fortran Compiler performs a dynamic link of the OpenMP libraries.

For example, to compile source file `hello.cpp` and link Compatibility libraries using the Intel Fortran Compiler Classic and Intel Fortran Compiler:

```
ifort /MD /Qopenmp hello.f90
```

### Mix OpenMP Object Files Compiled with Visual C++ Compiler or Intel® Fortran Compiler Classic and Intel® Fortran Compiler

You can use the Intel® Fortran Compiler Classic and Intel® Fortran Compiler with the Visual C++ Compiler to compile parts of an application and create object files that can then be linked (object-level interoperability).

For example:

1. Compile `f1.c` and `f2.c` with the Visual C++ Compiler, using the `/openmp` option to enable OpenMP support:

```
cl /MD /openmp /c f1.c f2.c
```

The `/c` prevents linking at this step.

2. Compile `f3.f90` and `f4.f90` with the `ifort` compiler, using the `/Qopenmp` option to enable OpenMP support:

```
ifort /MD /Qopenmp /c f3.f90 f4.f90
```

3. Use the `ifort` compiler to link the resulting application object code with the Intel C++ Compiler OpenMP library:

```
ifort /MD /Qopenmp f1.obj f2.obj f3.obj f4.obj /Feapp /link /nodefaultlib:vcomp
```

The `/Fe` specifies the generated executable file name.

## Thread Affinity Interface

The Intel® runtime library has the ability to bind OpenMP\* threads to physical processing units. The interface is controlled using the `KMP_AFFINITY` environment variable. Depending on the system (machine) topology, application, and operating system, thread affinity can have a dramatic effect on the application speed.

*Thread affinity* restricts execution of certain threads (virtual execution units) to a subset of the physical processing units in a multiprocessor computer. Depending upon the topology of the machine, thread affinity can have a dramatic effect on the execution speed of a program.

Thread affinity is supported on Windows\* systems and versions of Linux\* systems that have kernel support for thread affinity, but is not supported by macOS.

The Intel OpenMP runtime library has the ability to bind OpenMP threads to physical processing units. There are three types of interfaces you can use to specify this binding, which are collectively referred to as the Intel OpenMP Thread Affinity Interface:

- The high-level affinity interface uses an environment variable to determine the machine topology and assigns OpenMP threads to the processors based upon their physical location in the machine. This interface is controlled entirely by [the KMP\\_AFFINITY environment variable](#).
- The [mid-level affinity interface](#) uses an environment variable to explicitly specifies which processors (labeled with integer IDs) are bound to OpenMP threads. This interface provides compatibility with the GCC\* `GOMP_AFFINITY` environment variable, but you can also invoke it by using the `KMP_AFFINITY` environment variable. The `GOMP_AFFINITY` environment variable is supported on Linux systems only, but users on Windows or Linux systems can use the similar functionality provided by the `KMP_AFFINITY` environment variable.
- The [low-level affinity interface](#) uses APIs to enable OpenMP threads to make calls into the OpenMP runtime library to explicitly specify the set of processors on which they are to be run. This interface is similar in nature to `sched_setaffinity` and related functions on Linux systems or to `SetThreadAffinityMask` and related functions on Windows systems. In addition, you can specify certain options of the `KMP_AFFINITY` environment variable to affect the behavior of the low-level API interface. For example, you can set the affinity type `KMP_AFFINITY` to `disabled`, which disables the low-level affinity interface, or you could use the `KMP_AFFINITY` or `GOMP_AFFINITY` environment variables to set the initial affinity mask, and then retrieve the mask with the low-level API interface.

The following terms are used in this section:

- The total number of processing elements on the machine is referred to as the number of *OS thread contexts*.

- Each processing element is referred to as an Operating System processor, or *OS proc*.
- Each OS processor has a unique integer identifier associated with it, called an *OS proc ID*.
- The term *package* refers to a single or multi-core processor chip.
- The term *OpenMP Global Thread ID* (GTID) refers to an integer which uniquely identifies all threads known to the Intel OpenMP runtime library. The thread that first initializes the library is given GTID 0. In the normal case where all other threads are created by the library and when there is no nested parallelism, then  $n\text{-threads-var} - 1$  new threads are created with GTIDs ranging from 1 to  $n\text{-threads-var} - 1$ , and each thread's GTID is equal to the OpenMP thread number returned by function `omp_get_thread_num()`. The high-level and mid-level interfaces rely heavily on this concept. Hence, their usefulness is limited in programs containing nested parallelism. The low-level interface does not make use of the concept of a GTID and can be used by programs containing arbitrarily many levels of parallelism.

Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

## The KMP\_AFFINITY Environment Variable

### NOTE

You must set the `KMP_AFFINITY` environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in [Low Level Affinity API](#), below.

The `KMP_AFFINITY` environment variable uses the following general syntax:

#### Syntax

```
KMP_AFFINITY=[<modifier>,...]<type>[,<permute>][,<offset>]
```

For example, to list a machine topology map, specify `KMP_AFFINITY=verbose,none` to use a *modifier* of `verbose` and a *type* of `none`.

The following table describes the supported specific arguments.

Argument	Default	Description
<code>modifier</code>	noverbose respect granularity=core	Optional. String consisting of keyword and specifier. <ul style="list-style-type: none"> <li>• <code>granularity=&lt;specifier&gt;</code> takes the following specifiers: fine, thread, core, tile, die, node, group, and socket</li> <li>• <code>norespect</code></li> <li>• <code>noverbose</code></li> <li>• <code>nowarnings</code></li> <li>• <code>noreset</code></li> <li>• <code>proclist={&lt;proc-list&gt;}</code></li> <li>• <code>respect</code></li> <li>• <code>verbose</code></li> <li>• <code>warnings</code></li> <li>• <code>reset</code></li> </ul> The syntax for <code>&lt;proc-list&gt;</code> is explained in <a href="#">mid-level affinity interface</a> .

Argument	Default	Description
		<hr/> <b>NOTE</b> On Windows with multiple processor groups, the norespect affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows). Otherwise, the respect affinity modifier is used. <hr/>
<code>type</code>	<code>none</code>	<p>Required string. Indicates the thread affinity to use.</p> <ul style="list-style-type: none"> <li>• <code>balanced</code></li> <li>• <code>compact</code></li> <li>• <code>disabled</code></li> <li>• <code>explicit</code></li> <li>• <code>none</code></li> <li>• <code>scatter</code></li> <li>• <code>logical</code> (deprecated; instead use <code>compact</code>, but omit any <code>permute</code> value)</li> <li>• <code>physical</code> (deprecated; instead use <code>scatter</code>, possibly with an <code>offset</code> value)</li> </ul> <p>The <code>logical</code> and <code>physical</code> types are <a href="#">deprecated</a> but supported for backward compatibility.</p>
<code>permute</code>	<code>0</code>	Optional. Positive integer value. Not valid with type values of <code>explicit</code> , <code>none</code> , or <code>disabled</code> .
<code>offset</code>	<code>0</code>	Optional. Positive integer value. Not valid with type values of <code>explicit</code> , <code>none</code> , or <code>disabled</code> .

## Affinity Types

Type is the only required argument.

### **type = none (default)**

Does not bind OpenMP threads to particular thread contexts; however, if the operating system supports affinity, the compiler still uses the OpenMP thread affinity interface to determine machine topology. Specify `KMP_AFFINITY=verbose,none` to list a machine topology map.

### **type = balanced**

Places threads on separate cores until all cores have at least one thread, similar to the `scatter` type. However, when the runtime must use multiple hardware thread contexts on the same core, the `balanced` type ensures that the OpenMP thread numbers are close to each other, which `scatter` does not do. This affinity type is supported on the CPU only for single socket systems.

**NOTE**

The OpenMP\* environment variable `OMP_PROC_BIND=spread` is similar to `KMP_AFFINITY=balanced` and is available on all platforms, including multi-socket CPU systems.

**type = compact**

Specifying `compact` assigns the OpenMP thread `<n>+1` to a free thread context as close as possible to the thread context where the `<n>` OpenMP thread was placed. For example, in a topology map, the nearer a node is to the root, the more significance the node has when sorting the threads.

**type = disabled**

Specifying `disabled` completely disables the thread affinity interfaces. This forces the OpenMP runtime library to behave as if the affinity interface was not supported by the operating system. This includes the low-level API interfaces such as `kmp_set_affinity` and `kmp_get_affinity`, which have no effect and will return a nonzero error code.

**type = explicit**

Specifying `explicit` assigns OpenMP threads to a list of OS proc IDs that have been explicitly specified by using the `proclist=` modifier, which is required for this affinity type. See [Explicitly Specifying OS Proc IDs \(GOMP\\_CPU\\_AFFINITY\)](#).

**type = scatter**

Specifying `scatter` distributes the threads as evenly as possible across the entire system. `scatter` is the opposite of `compact`; so the leaves of the node are most significant when sorting through the machine topology map.

**Deprecated Types: logical and physical**

Types `logical` and `physical` are deprecated and may become unsupported in a future release. Both are supported for backward compatibility.

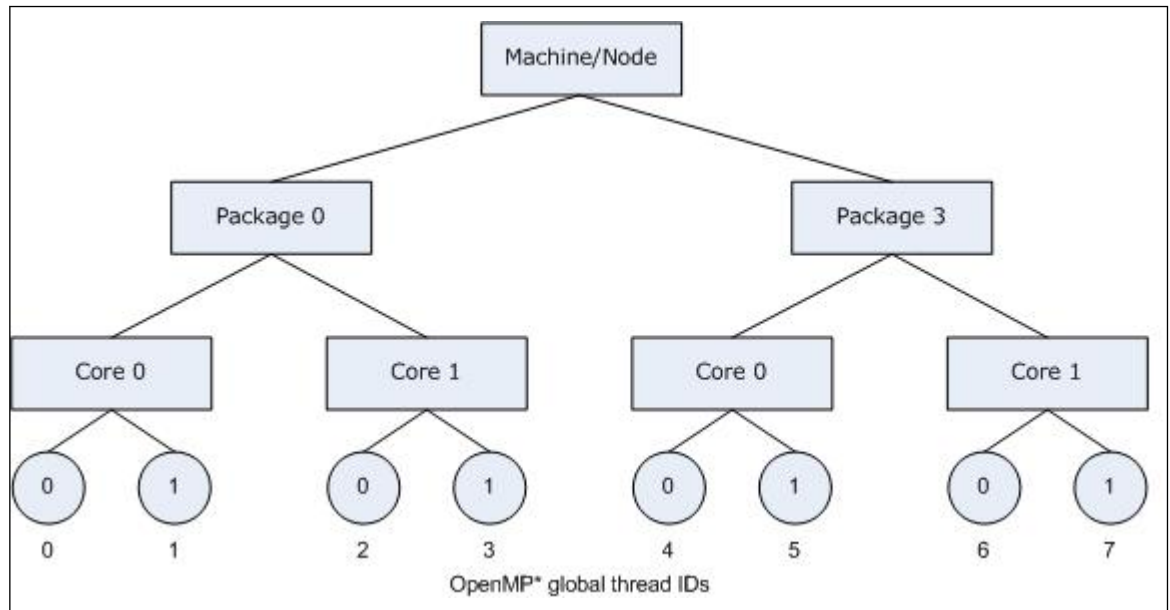

For `logical` and `physical` affinity types, a single trailing integer is interpreted as an `offset` specifier instead of a `permute` specifier. In contrast, with `compact` and `scatter` types, a single trailing integer is interpreted as a `permute` specifier.

- Specifying `logical` assigns OpenMP threads to consecutive logical processors, which are also called hardware thread contexts. The type is equivalent to `compact`, except that the `permute` specifier is not allowed. Thus, `KMP_AFFINITY=logical,n` is equivalent to `KMP_AFFINITY=compact,0,n` (this equivalence is true regardless of the whether or not a `granularity=fine` modifier is present).
- Specifying `physical` assigns threads to consecutive physical processors (cores). For systems where there is only a single thread context per core, the type is equivalent to `logical`. For systems where multiple thread contexts exist per core, `physical` is equivalent to `compact` with a `permute` specifier of 1; that is, `KMP_AFFINITY=physical,n` is equivalent to `KMP_AFFINITY=compact,1,n` (regardless of the whether or not a `granularity=fine` modifier is present). This equivalence means that when the compiler sorts the map it should permute the innermost level of the machine topology map to the outermost, presumably the thread context level. This type does not support the `permute` specifier.

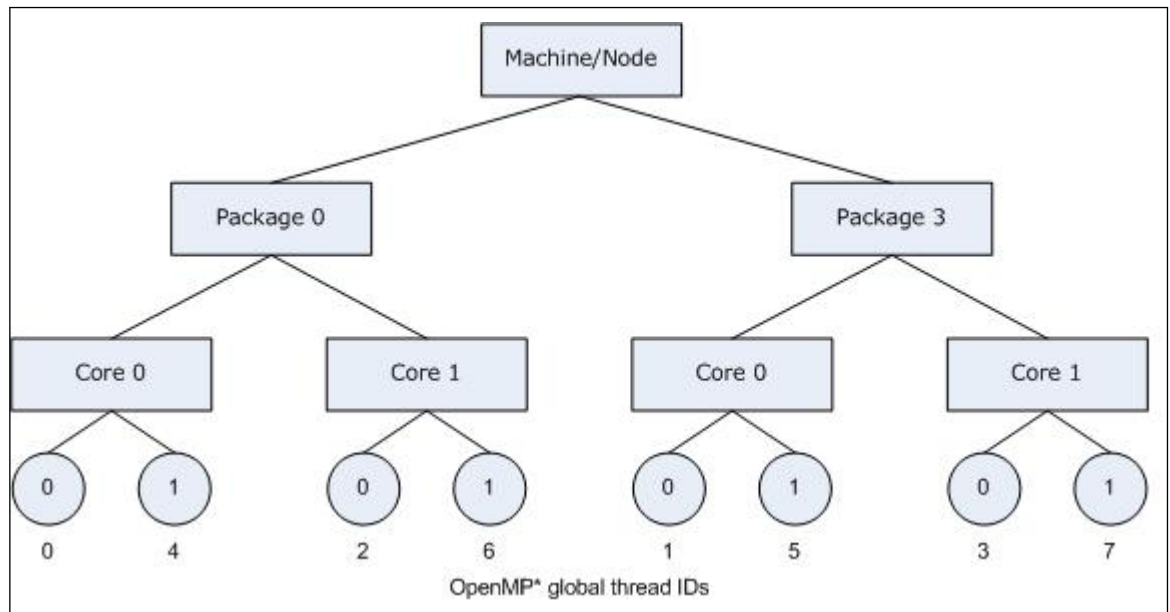

**Examples of Types `compact` and `scatter`**

The following figure illustrates the topology for a machine with two processors, and each processor has two cores; further, each core has Intel® Hyper-Threading Technology (Intel® HT Technology) enabled.

The following figure also illustrates the binding of OpenMP thread to hardware thread contexts when specifying `KMP_AFFINITY=granularity=fine,compact`.

Specifying `scatter` on the same system as shown in the figure above, the OpenMP threads would be assigned the thread contexts as shown in the following figure, which shows the result of specifying `KMP_AFFINITY=granularity=fine,scatter`.

### permute and offset combinations

For both `compact` and `scatter`, `permute` and `offset` are allowed; however, if you specify only one integer, the compiler interprets the value as a permute specifier. Both `permute` and `offset` default to 0.

The `permute` specifier controls which levels are most significant when sorting the machine topology map. A value for `permute` forces the mappings to make the specified number of most significant levels of the sort the least significant, and it inverts the order of significance. The root node of the tree is not considered a separate level for the sort operations.

The `offset` specifier indicates the starting position for thread assignment.

The following figure illustrates the result of specifying `KMP_AFFINITY=granularity=fine,compact,0,5`.

Consider the hardware configuration from the previous example, running an OpenMP application which exhibits data sharing between consecutive iterations of loops. We would therefore like consecutive threads to be bound close together, as is done with `KMP_AFFINITY=compact`, so that communication overhead, cache line invalidation overhead, and page thrashing are minimized. Now, suppose the application also had a number of parallel regions which did not utilize all of the available OpenMP threads. It is desirable to avoid binding multiple threads to the same core and leaving other cores not utilized, since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core. Since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core, you might want to avoid binding multiple threads to the same core while leaving other cores unused. The following figure illustrates this strategy of using

`KMP_AFFINITY=granularity=fine,compact,1,0` as a setting.

The OpenMP thread  $n+1$  is bound to a thread context as close as possible to OpenMP thread  $n$ , but on a different core. Once each core has been assigned one OpenMP thread, the subsequent OpenMP threads are assigned to the available cores in the same order, but they are assigned on different thread contexts.

### Modifier Values for Affinity Types

Modifiers are optional arguments that precede type. If you do not specify a modifier, the `noverbose`, `respect`, and `granularity=core` modifiers are used automatically.

Modifiers are interpreted in order from left to right, and they may conflict. Following conflicting modifier is ignored. For example, specifying `KMP_AFFINITY=verbose,noverbose,scatter` is therefore equivalent to setting `KMP_AFFINITY=verbose,scatter`.

#### **modifier = noverbose (default)**

Does not print verbose messages.

#### **modifier = verbose**

Prints messages concerning the supported affinity. The messages include information about the number of packages, number of cores in each package, number of thread contexts for each core, and OpenMP thread bindings to physical thread contexts.

Information about binding OpenMP threads to physical thread contexts is indirectly shown in the form of the mappings between hardware thread contexts and the operating system (OS) processor (proc) IDs. The affinity mask for each OpenMP thread is printed as a set of OS processor IDs.

For example, specifying `KMP_AFFINITY=verbose,scatter` on a dual core system with two processors, with Intel® Hyper-Threading Technology (Intel® HT Technology) disabled, results in a message listing similar to the following when the program is executed:

#### **Verbose, scatter message**

```
...
KMP_AFFINITY: Initial OS proc set respected: 0,1,2,3
KMP_AFFINITY: affinity capable, using hwloc.
KMP_AFFINITY: 4 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0
KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0
KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0
KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
KMP_AFFINITY: pid 79739 tid 79739 thread 0 bound to OS proc set 0
KMP_AFFINITY: pid 79739 tid 79740 thread 2 bound to OS proc set 2
KMP_AFFINITY: pid 79739 tid 79741 thread 3 bound to OS proc set 3
KMP_AFFINITY: pid 79739 tid 79742 thread 1 bound to OS proc set 1
```

The verbose modifier generates several standard, general messages. The following table summarizes how to read the messages.

Message String	Description
"affinity capable"	Indicates that all components (compiler, operating system, and hardware) support affinity, so thread binding is possible.
"decoding x2APIC ids"	Indicates that the machine topology was discovered by binding a thread to each operating system processor and decoding the output of the <code>cpuid</code> instruction.

Message String	Description
"using hwloc"	Indicates that the Portable Hardware Locality* ( <code>hwloc</code> ) library used to determine machine topology.
"using /proc/cpuinfo"	Linux only. Indicates that <code>cpuinfo</code> is being used to determine machine topology.
"using flat"	Operating system processor ID is assumed to be equivalent to physical package ID. This method of determining machine topology is used if none of the other methods will work, but may not accurately detect the actual machine topology.
"uniform topology"	The machine topology map is a full tree with no missing leaves at any level.

The mapping from the operating system processors to thread context ID is printed next. The binding of OpenMP thread context ID is printed next unless the affinity type is none. For more information, see [Determining Machine Topology](#).

### **modifier = granularity**

Binding OpenMP threads to particular packages and cores will often result in a performance gain on systems with Intel processors with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled; however, it is usually not beneficial to bind each OpenMP thread to a particular thread context on a specific core. Granularity describes the lowest levels that OpenMP threads are allowed to float within a topology map.

This modifier supports the following additional specifiers.

Specifier	Description
<code>core</code>	Default. Allows all the OpenMP threads bound to a core to float between the different thread contexts.
<code>fine</code> or <code>thread</code>	The finest granularity level. Causes each OpenMP thread to be bound to a single thread context. The two specifiers are functionally equivalent.
<code>tile</code> , or <code>die</code> , or <code>node</code> , or <code>group</code> , or <code>socket</code>	Allows all the OpenMP threads bound to a tile, or die, or NUMA node, or group, or socket to float between the different thread contexts of cores the tile, or die, or NUMA node, or group, or socket consists of.

Specifying `KMP_AFFINITY=verbose,granularity=core,compact` on the same dual core system with two processors as in the previous section, but with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, results in a message listing similar to the following when the program is executed:

Verbose, granularity=core,compact message
<pre> KMP_AFFINITY: Initial OS proc set respected: 0-7 KMP_AFFINITY: decoding x2APIC ids. KMP_AFFINITY: 8 available OS procs KMP_AFFINITY: Uniform topology KMP_AFFINITY: 2 sockets x 2 cores/socket x 2 threads/core (4 total cores) KMP_AFFINITY: OS proc to physical thread map: KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0 KMP_AFFINITY: OS proc 4 maps to socket 0 core 0 thread 1 KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0 KMP_AFFINITY: OS proc 6 maps to socket 0 core 1 thread 1 KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0 KMP_AFFINITY: OS proc 5 maps to socket 3 core 0 thread 1 </pre>

**Verbose, granularity=core,compact message**

```

KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to socket 3 core 1 thread 1
KMP_AFFINITY: pid 40880 tid 40880 thread 0 bound to OS proc set 0,4
KMP_AFFINITY: pid 40880 tid 40881 thread 1 bound to OS proc set 0,4
KMP_AFFINITY: pid 40880 tid 40882 thread 2 bound to OS proc set 2,6
KMP_AFFINITY: pid 40880 tid 40883 thread 3 bound to OS proc set 2,6
KMP_AFFINITY: pid 40880 tid 40884 thread 4 bound to OS proc set 1,5
KMP_AFFINITY: pid 40880 tid 40885 thread 5 bound to OS proc set 1,5
KMP_AFFINITY: pid 40880 tid 40886 thread 6 bound to OS proc set 3,7
KMP_AFFINITY: pid 40880 tid 40887 thread 7 bound to OS proc set 3,7

```

The affinity mask for each OpenMP thread is shown in the listing (above) as the set of operating system processor to which the OpenMP thread is bound.

The following figure illustrates the machine topology map, for the above listing, with OpenMP thread bindings.

In contrast, specifying `KMP_AFFINITY=verbose,granularity=fine,compact` or `KMP_AFFINITY=verbose,granularity=thread,compact` binds each OpenMP thread to a single hardware thread context when the program is executed:

**Verbose, granularity=fine,compact message**

```

KMP_AFFINITY: Initial OS proc set respected: 0-7
KMP_AFFINITY: decoding x2APIC ids.
KMP_AFFINITY: 8 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to socket 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to socket 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0

```

**Verbose, granularity=fine,compact message**

```

KMP_AFFINITY: OS proc 5 maps to socket 3 core 0 thread 1
KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to socket 3 core 1 thread 1
KMP_AFFINITY: pid 40895 tid 40895 thread 0 bound to OS proc set 0
KMP_AFFINITY: pid 40895 tid 40896 thread 1 bound to OS proc set 4
KMP_AFFINITY: pid 40895 tid 40897 thread 2 bound to OS proc set 2
KMP_AFFINITY: pid 40895 tid 40898 thread 3 bound to OS proc set 6
KMP_AFFINITY: pid 40895 tid 40899 thread 4 bound to OS proc set 1
KMP_AFFINITY: pid 40895 tid 40900 thread 5 bound to OS proc set 5
KMP_AFFINITY: pid 40895 tid 40901 thread 6 bound to OS proc set 3
KMP_AFFINITY: pid 40895 tid 40902 thread 7 bound to OS proc set 7

```

The OpenMP to hardware context binding for this example was illustrated in the [first example](#).

Specifying `granularity=fine` will always cause each OpenMP thread to be bound to a single OS processor. This is equivalent to `granularity=thread`, currently the finest granularity level.

**modifier = respect (default)**

Respect the process' original affinity mask, or more specifically, the affinity mask in place for the thread that initializes the OpenMP runtime library. The behavior differs between Linux and Windows:

- On Windows: Respect original affinity mask for the process.
- On Linux: Respect the affinity mask for the thread that initializes the OpenMP runtime library.

---

**NOTE** On Windows with multiple processor groups, the `norespect` affinity modifier is the default when the process affinity mask equals a single processor group (which is default on Windows). Otherwise, the `respect` affinity modifier is the default.

---

Specifying `KMP_AFFINITY=verbose,compact` for the same system used in the previous example, with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, and invoking the library with an initial affinity mask of {4,5,6,7} (thread context 1 on every core) causes the compiler to model the machine as a dual core, two-processor system with Intel® HT Technology disabled.

**Verbose,compact message**

```

KMP_AFFINITY: Initial OS proc set respected: 4-7
KMP_AFFINITY: decoding x2APIC ids.
KMP_AFFINITY: 4 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 4 maps to socket 0 core 0 thread 1
KMP_AFFINITY: OS proc 6 maps to socket 0 core 1 thread 1
KMP_AFFINITY: OS proc 5 maps to socket 3 core 0 thread 1
KMP_AFFINITY: OS proc 7 maps to socket 3 core 1 thread 1
KMP_AFFINITY: pid 41032 tid 41032 thread 0 bound to OS proc set 4
KMP_AFFINITY: pid 41032 tid 41033 thread 1 bound to OS proc set 6
KMP_AFFINITY: pid 41032 tid 41034 thread 2 bound to OS proc set 5
KMP_AFFINITY: pid 41032 tid 41035 thread 3 bound to OS proc set 7

```

Because there are four thread contexts accessible on the machine, by default the compiler created four threads for an OpenMP `parallel` construct.

The following figure illustrates the corresponding machine topology map and threads placement in case eight OpenMP threads requested via `OMP_NUM_THREADS=8`

When using the local `cpuid` information to determine the machine topology, it is not always possible to distinguish between a machine that does not support Intel® Hyper-Threading Technology (Intel® HT Technology) and a machine that supports it, but has it disabled. Therefore, the compiler does not include a level in the map if the elements (nodes) at that level had no siblings, with the exception that the package level is always modeled. As mentioned earlier, the package level will always appear in the topology map, even if there only a single package in the machine.

#### **modifier = norespect**

Do not respect original affinity mask for the process. Binds OpenMP threads to all operating system processors.

In early versions of the OpenMP runtime library that supported only the `physical` and `logical` affinity types, `norespect` was the default and was not recognized as a modifier.

The default was changed to `respect` when types `compact` and `scatter` were added; therefore, thread bindings may have changed with the newer compilers in situations where the application specified a partial initial thread affinity mask.

#### **modifier = nowarnings**

Do not print warning messages from the affinity interface.

#### **modifier = warnings (default)**

Print warning messages from the affinity interface (default).

#### **modifier = noreset (default)**

Do not reset the primary thread's affinity after each outermost parallel region is complete. This setting preserves the primary thread's OpenMP affinity setting between parallel regions. For example, if `KMP_AFFINITY=compact,granularity=core`, then the primary thread's affinity is set to the first core for the first parallel region and kept that way for the thread's lifetime, even during serial regions.

#### **modifier = reset**

Reset the primary thread's affinity after each outermost parallel region is complete. This setting will reset the primary thread's affinity back to the initial affinity before OpenMP was initialized after each outermost parallel region is complete.

## Determining Machine Topology

If the package has an APIC (Advanced Programmable Interrupt Controller), the compiler will use the `cpuid` instruction to obtain the `package id`, `core id`, and `thread context id`. Under normal conditions, each thread context on the system is assigned a unique APIC ID at boot time. The compiler obtains other pieces of information obtained by using the `cpuid` instruction, which together with the number of OS thread contexts (total number of processing elements on the machine), determine how to break the APIC ID down into the `package ID`, `core ID`, and `thread context ID`.

There are several ways to specify the APIC ID in the `cpuid` instruction - the legacy method in leaf 4, and the more modern method in leaf 11 and leaf 31. Only 256 unique APIC IDs are available in leaf 4. Leaf 11 and leaf 31 have no such limitation.

Normally, all `core ids` on a package and all `thread context ids` on a core are contiguous; however, numbering assignment gaps are common for `package ids`, as shown in the figure above.

If the compiler cannot determine the machine topology using any other method, but the operating system supports affinity, a warning message is printed, and the topology is assumed to be `flat`. For example, a flat topology assumes the operating system process *N* maps to package *N*, and there exists only one thread context per core and only one core for each package.

If the machine topology cannot be accurately determined as described above, the user can manually copy `/proc/cpuinfo` to a temporary file, correct any errors, and specify the machine topology to the OpenMP runtime library via the environment variable `KMP_CPUINFO_FILE=<temp_filename>`, as described in the section `KMP_CPUINFO_FILE` and `/proc/cpuinfo`.

Regardless of the method used in determining the machine topology, if there is only one thread context per core for every core on the machine, the thread context level will not appear in the topology map. If there is only one core per package for every package in the machine, the core level will not appear in the machine topology map. The topology map need not be a full tree, because different packages may contain a different number of cores, and different cores may support a different number of thread contexts.

The package level will always appear in the topology map, even if there only a single package in the machine.

## KMP\_CPUINFO\_FILE and /proc/cpuinfo

One of the methods the OpenMP runtime library can use to detect the machine topology on Linux systems is to parse the contents of `/proc/cpuinfo`. If the contents of this file (or a device mapped into the Linux file system) are insufficient or erroneous, you can consider copying its contents to a writable temporary file `<temp_file>`, correct it or extend it with the necessary information, and set `KMP_CPUINFO_FILE=<temp_file>`.

If you do this, the OpenMP runtime library will read the `<temp_file>` location pointed to by `KMP_CPUINFO_FILE` instead of the information contained in `/proc/cpuinfo` or attempting to detect the machine topology by decoding the [APIC](#) IDs. That is, the information contained in the `<temp_file>` overrides these other methods. You can use the `KMP_CPUINFO_FILE` interface on Windows systems, where `/proc/cpuinfo` does not exist.

The content of `/proc/cpuinfo` or `<temp_file>` should contain a list of entries for each processing element on the machine. Each processor element contains a list of entries (descriptive name and value on each line). A blank line separates the entries for each processor element. Only the following fields are used to determine the machine topology from each entry, either in `<temp_file>` or `/proc/cpuinfo`:

Field	Description
processor :	Specifies the OS ID for the processing element. The OS ID must be unique. The <code>processor</code> and <code>physical id</code> fields are the only ones that are required to use the interface.
physical id :	Specifies the package ID, which is a physical chip ID. Each package may contain multiple cores. The package level always exists in the compiler's OpenMP runtime library model of the machine topology.
core id :	Specifies the core ID. If it does not exist, it defaults to 0. If every package on the machine contains only a single core, the core level will not exist in the machine topology map (even if some of the core ID fields are non-zero).
apicid :	Specifies the thread ID. If it does not exist, it defaults to 0. If every core on the machine contains only a single thread, the thread level will not exist in the machine topology map (even if some thread ID fields are non-zero).
node_ <i>n</i> id :	This is an extension to the normal contents of <code>/proc/cpuinfo</code> that can be used to specify the nodes at different levels of the memory interconnect on Non-Uniform Memory Access (NUMA) systems. Arbitrarily many levels <i>n</i> are supported. The <code>node_0</code> level is closest to the package level; multiple packages comprise a node at level 0. Multiple nodes at level 0 comprise a node at level 1, and so on.

Each entry must be spelled exactly as shown, in lowercase, followed by optional whitespace, a colon (:), more optional whitespace, then the integer ID. Fields other than those listed are simply ignored.

#### NOTE

It is common for the `thread id` field to be missing from `/proc/cpuinfo` on many Linux variants, and for a field labeled `siblings` to specify the number of threads per node or number of nodes per package. However, the Intel OpenMP runtime library ignores fields labeled `siblings` so it can distinguish between the `thread id` and `siblings` fields. When this situation arises, the warning message `Physical node/pkg/core/thread ids not unique appears` (unless the type specified is `nowarnings`).

## Windows Processor Groups

On a 64-bit Windows operating system, it is possible for multiple processor groups to accommodate more than 64 processors. Each group is limited in size, up to a maximum value of sixty-four (64) processors.

If multiple processor groups are detected, the default is to model the machine as a 2-level tree, where level 0 are for the processors in a group, and level 1 are for the different groups. Threads are assigned to a group until there are as many OpenMP threads bound to the groups as there are processors in the group. Subsequent threads are assigned to the next group, and so on.

By default, threads are allowed to float among all processors in a group, that is to say, granularity equals the group [granularity=group]. You can override this binding and explicitly use another affinity type like compact, scatter, and so on. If you do so, the granularity must be sufficiently fine to prevent a thread from being bound to multiple processors in different groups.

### Using a Specific Machine Topology Modeling Method (KMP\_TOPOLOGY\_METHOD)

You can set the `KMP_TOPOLOGY_METHOD` environment variable to force OpenMP to use a particular machine topology modeling method.

Value	Description
<code>cpuid_leaf11</code>	Decodes the APIC identifiers as specified by leaf 11 of the <i>cpuid</i> instruction.
<code>cpuid_leaf4</code>	Decodes the APIC identifiers as specified in leaf 4 of the <i>cpuid</i> instruction.
<code>cpuinfo</code>	<p>If <code>KMP_CPUINFO_FILE</code> is not specified, forces OpenMP to parse <code>/proc/cpuinfo</code> to determine the topology (Linux only).</p> <p>If <code>KMP_CPUINFO_FILE</code> is specified as described above, uses it (Windows or Linux).</p>
<code>group</code>	Models the machine as a 2-level map, with level 0 specifying the different processors in a group, and level 1 specifying the different groups (Windows 64-bit only) .
<code>flat</code>	Models the machine as a flat (linear) list of processors.
<code>hwloc</code>	Models the machine as the Portable Hardware Locality* (hwloc) library does. This model is the most detailed and includes, but is not limited to: numa nodes, packages, cores, hardware threads, caches, and Windows processor groups.

### Explicitly Specifying OS Processor IDs (GOMP\_CPU\_AFFINITY)

#### NOTE

You must set the `GOMP_CPU_AFFINITY` environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in [Low Level Affinity API](#), below.

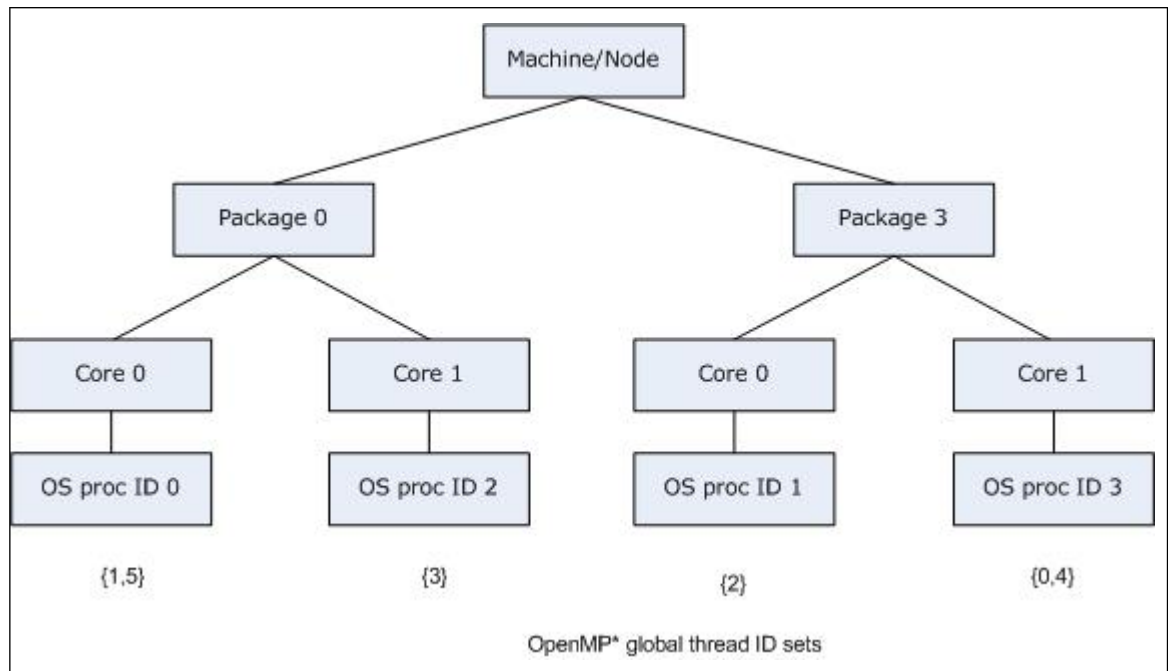

Instead of allowing the library to detect the hardware topology and automatically assign OpenMP threads to processing elements, the user may explicitly specify the assignment by using a list of operating system (OS) processor (proc) IDs. However, this requires knowledge of which processing elements the OS proc IDs represent.

On Linux systems, when using the Intel OpenMP compatibility libraries enabled by the compiler option `-qopenmp-lib compat`, you can use the `GOMP_AFFINITY` environment variable to specify a list of OS processor IDs. Its syntax is identical to that accepted by `libgomp` (assume that `<proc_list>` produces the entire `GOMP_AFFINITY` environment string):

Value	Description
<code>&lt;proc_list&gt; :=</code>	<code>&lt;entry&gt;   &lt;elem&gt; , &lt;list&gt;   &lt;elem&gt;</code> <code>&lt;whitespace&gt; &lt;list&gt;</code>
<code>&lt;elem&gt; :=</code>	<code>&lt;proc_spec&gt;   &lt;range&gt;</code>
<code>&lt;proc_spec&gt; :=</code>	<code>&lt;proc_id&gt;</code>
<code>&lt;range&gt; :=</code>	<code>&lt;proc_id&gt; - &lt;proc_id&gt;   &lt;proc_id&gt; - &lt;proc_id&gt; :</code> <code>&lt;int&gt;</code>
<code>&lt;proc_id&gt; :=</code>	<code>&lt;positive_int&gt;</code>

OS processors specified in this list are then assigned to OpenMP threads, in order of OpenMP Global Thread IDs. If more OpenMP threads are created than there are elements in the list, then the assignment occurs modulo the size of the list. That is, OpenMP Global Thread ID  $n$  is bound to list element  $n \bmod \text{<list\_size>}$ .

Consider the machine previously mentioned: a dual core, dual-package machine without Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, where the OS proc IDs are assigned in the same manner as the example in a previous figure. Suppose that the application creates six OpenMP threads instead of 4 (the default), oversubscribing the machine. If `GOMP_AFFINITY=3,0-2`, then OpenMP threads are bound as shown in the figure below, just as should happen when compiling with `gcc` and linking with `libgomp`:

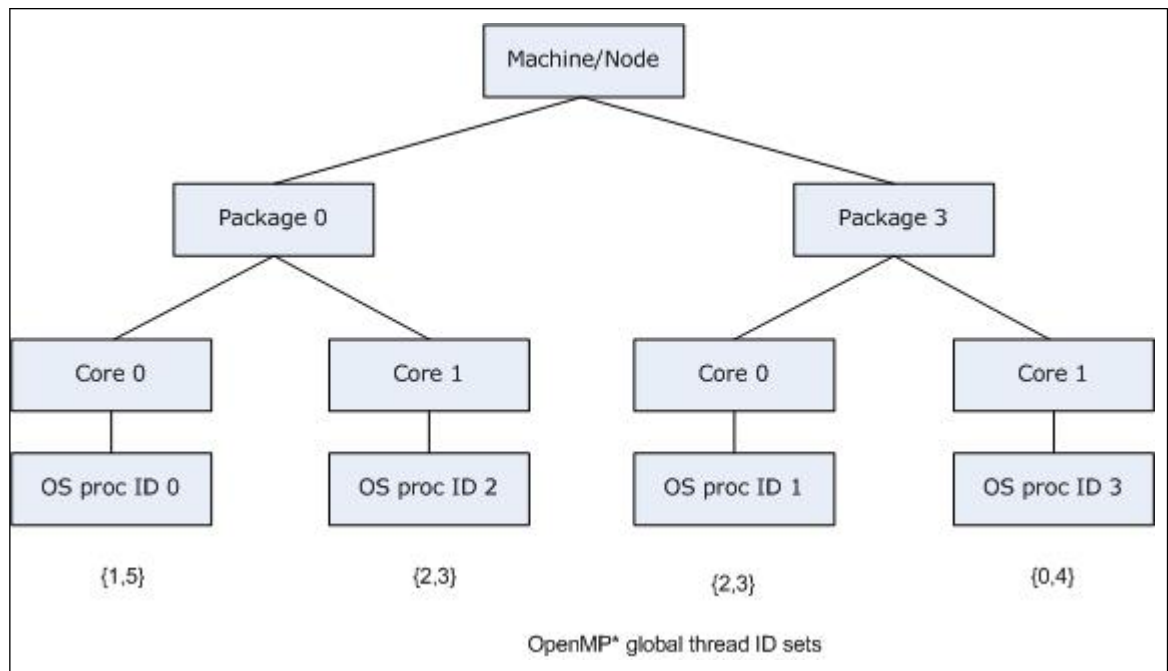

The same syntax can be used to specify the OS proc ID list in the `proclist=[<proc_list>]` modifier in the `KMP_AFFINITY` environment variable string. There is a slight difference: in order to have strictly the same semantics as in the `gcc` OpenMP runtime library `libgomp`: the `GOMP_AFFINITY` environment variable implies `granularity=fine`. If you specify the OS proc list in the `KMP_AFFINITY` environment variable without a

`granularity= specifier`, then the default `granularity` is not changed. That is, OpenMP threads are allowed to float between the different thread contexts on a single core. Thus `GOMP_AFFINITY=<proc_list>` is an alias for `KMP_AFFINITY="granularity=fine,proclist=[<proc_list>],explicit"`.

In the `KMP_AFFINITY` environment variable string, the syntax is extended to handle operating system processor ID sets. The user may specify a set of operating system processor IDs among which an OpenMP thread may execute ("float") enclosed in brackets:

Value	Description
<code>&lt;proc_list&gt; :=</code>	<code>&lt;proc_id&gt;   { &lt;float_list&gt; }</code>
<code>&lt;float_list&gt; :=</code>	<code>&lt;proc_id&gt;   &lt;proc_id&gt; , &lt;float_list&gt;</code>

This allows functionality similarity to the `granularity= specifier`, but it is more flexible. The OS processors on which an OpenMP thread executes may exclude other OS processors nearby in the machine topology, but include other distant OS processors. Building upon the previous example, we may allow OpenMP threads 2 and 3 to "float" between OS processor 1 and OS processor 2 by using `KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"`, as shown in the figure below:

If `verbose` were also specified, the output when the application is executed would include:

**`KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"`**

```

KMP_AFFINITY: Initial OS proc set respected: 0,1,2,3
KMP_AFFINITY: decoding x2APIC ids.
KMP_AFFINITY: 4 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0
KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0
KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0
KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
  
```

```
KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"
```

```
KMP_AFFINITY: pid 41464 tid 41464 thread 0 bound to OS proc set 3
KMP_AFFINITY: pid 41464 tid 41465 thread 1 bound to OS proc set 0
KMP_AFFINITY: pid 41464 tid 41466 thread 2 bound to OS proc set 1,2
KMP_AFFINITY: pid 41464 tid 41467 thread 3 bound to OS proc set 1,2
KMP_AFFINITY: pid 41464 tid 41468 thread 4 bound to OS proc set 3
KMP_AFFINITY: pid 41464 tid 41469 thread 5 bound to OS proc set 0
```

## Low Level Affinity API

Instead of relying on the user to specify the OpenMP thread to OS proc binding by setting an environment variable before program execution starts (or by using the `kmp_settings` interface before the first parallel region is reached), each OpenMP thread can determine the desired set of OS procs on which it is to execute and bind to them with the `kmp_set_affinity` API call.

### Caution

When you use this affinity interface you take complete control of the hardware resources on which your threads run. To do that sensibly you need to understand in detail how the logical CPUs, the enumeration of hardware threads controlled by the OS, map to the physical hardware of the specific machine on which you are running. That mapping can be, and likely is, different on different machines, so you risk binding machine-specific information into your code, which can result in explicitly forcing bad affinities when your code runs on a different machine. And if you are concerned with optimization at this level of detail, your code is probably valuable, and therefore will probably move to another machine.

This interface may also allow you to ignore the resource limitations that were set by the program startup mechanism, such as Message Passing Interface (MPI), specifically to prevent multiple OpenMP processes on the same node from using the same hardware threads. Again, this can result in explicitly forcing affinities that cause bad performance, and the OpenMP runtime will neither prevent this from happening, nor warn you when it does. These are expert interfaces and you must use them with caution.

It is recommended, therefore, to use the higher level affinity settings if you possibly can, because they are more portable and do not require this low level knowledge.

The Fortran API interfaces follow, where the type name `kmp_affinity_mask_kind` is defined in `omp_lib.h` or `omp_lib.mod`:

Syntax	Description
<pre>integer function kmp_set_affinity(mask) integer (kind=kmp_affinity_mask_kind) mask</pre>	<p>Sets the affinity mask for the current OpenMP thread to <code>mask</code>, where <code>mask</code> is a set of OS proc IDs that has been created using the API calls listed below, and the thread will only execute on OS procs in the set. Returns either a zero (0) upon success or a nonzero error code.</p>
<pre>integer function kmp_get_affinity(mask) integer (kind=kmp_affinity_mask_kind) mask</pre>	<p>Retrieves the affinity mask for the current OpenMP thread, and stores it in <code>mask</code>, which must have previously been initialized with a call to <code>kmp_create_affinity_mask()</code>. Returns either a zero (0) upon success or a nonzero error code.</p>

Syntax	Description
<pre>integer function kmp_get_affinity_max_proc()</pre>	Returns the maximum OS proc ID that is on the machine, plus 1. All OS proc IDs are guaranteed to be between 0 (inclusive) and <code>kmp_get_affinity_max_proc()</code> (exclusive).
<pre>subroutine kmp_create_affinity_mask(mask) integer (kind=kmp_affinity_mask_kind) mask</pre>	Allocates a new OpenMP thread affinity mask, and initializes <code>mask</code> to the empty set of OS procs. The implementation is free to use an object of <code>kmp_affinity_mask_t</code> either as the set itself, a pointer to the actual set, or an index into a table describing the set. Do not make any assumption as to what the actual representation is.
<pre>subroutine kmp_destroy_affinity_mask(mask) integer (kind=kmp_affinity_mask_kind) mask</pre>	Deallocates the OpenMP thread affinity mask. For each call to <code>kmp_create_affinity_mask()</code> , there should be a corresponding call to <code>kmp_destroy_affinity_mask()</code> .
<pre>integer function kmp_set_affinity_mask_proc(proc, mask) integer proc integer (kind=kmp_affinity_mask_kind) mask</pre>	Adds the OS proc ID <code>proc</code> to the set <code>mask</code> , if it is not already. Returns either a zero (0) upon success or a nonzero error code.
<pre>integer function kmp_unset_affinity_mask_proc(proc, mask) integer proc integer (kind=kmp_affinity_mask_kind) mask</pre>	If the OS proc ID <code>proc</code> is in the set <code>mask</code> , it removes it. Returns either a zero (0) upon success or a nonzero error code.
<pre>integer function kmp_get_affinity_mask_proc(proc, mask)integer proc integer (kind=kmp_affinity_mask_kind) mask</pre>	Returns 1 if the OS proc ID <code>proc</code> is in the set <code>mask</code> ; if not, it returns 0.

Once an OpenMP thread has set its own affinity mask via a successful call to `kmp_set_affinity()`, then that thread remains bound to the corresponding OS proc set until at least the end of the parallel region, unless reset via a subsequent call to `kmp_set_affinity()`.

Between parallel regions, the affinity mask (and the corresponding OpenMP thread to OS proc bindings) can be considered thread private data objects, and have the same persistence as described in the OpenMP Application Program Interface. For more information, see the OpenMP API specification (<http://www.openmp.org>), some relevant parts of which are provided below:

In order for the affinity mask and thread binding to persist between two consecutive active parallel regions, all three of the following conditions must hold:

- Neither parallel region is nested inside another explicit parallel region.
- The number of threads used to execute both parallel regions is the same.
- The value of the dyn-var internal control variable in the enclosing task region is false at entry to both parallel regions."

Therefore, by creating a parallel region at the start of the program whose sole purpose is to set the affinity mask for each thread, you can mimic the behavior of the `KMP_AFFINITY` environment variable with low-level affinity API calls, if program execution obeys the three aforementioned rules from the OpenMP specification.

The following example shows how these low-level interfaces can be used. This code binds the executing thread to the specified logical CPU:

### Example

```
! Force the executing thread to execute on logical CPU i
! Returns .TRUE. on success, .FALSE. on failure

function forceAffinity (i)
  use omp_lib
  logical forceAffinity
  integer, intent(in) :: i

  integer(kmp_affinity_mask_kind) :: mask

  call kmp_create_affinity_mask(mask)
  forceAffinity = (kmp_set_affinity_mask_proc(i, mask) == 0)
  if (.not. forceAffinity) return
  forceAffinity = (kmp_set_affinity_mask(mask) == 0)
  return
end function forceAffinity
```

This program fragment was written with knowledge about the mapping of the OS proc IDs to the physical processing elements of the target machine. On another machine, or on the same machine with a different OS installed, the program would still run, but the OpenMP thread to physical processing element bindings could differ and you might be explicitly force a bad distribution.

## OpenMP\* Memory Spaces and Allocators

This feature is only available for ifx.

For storage and retrieval variables, OpenMP\* provides memory known as memory spaces. Different memory spaces have different traits. Depending on how a variable is to be used and accessed determines which memory space is appropriate for allocation of the variable.

Each memory space has a unique allocator that is used to allocate and deallocate memory in that space. The allocators allocate variables in contiguous space that does not overlap any other allocation in the memory space. Multiple memory spaces with different traits may map to a single memory resource.

The behavior of the allocator is affected by the allocator traits that you specify. The allocator traits, their possible values, and their default values are shown in the following table:

Allocator Trait	Values That Can Be Specified	Default Value
access	<ul style="list-style-type: none"> <li>all</li> <li>cgroup</li> <li>pteam</li> <li>thread</li> </ul>	All
alignment	A positive integer value that is a power of 2 specifying number of bytes	1 byte
fallback	<ul style="list-style-type: none"> <li>abort_fb</li> <li>allocator_fb</li> </ul>	default_mem_fb

Allocator Trait	Values That Can Be Specified	Default Value
	<ul style="list-style-type: none"> <li>• <code>default_mem_fb</code></li> <li>• <code>null_fb</code></li> </ul>	
<code>fb_data</code>	An allocator handle	None
<code>partition</code>	<ul style="list-style-type: none"> <li>• <code>blocked</code></li> <li>• <code>environment</code></li> <li>• <code>interleaved</code></li> <li>• <code>nearest</code></li> </ul>	<code>environment</code>
<code>pinned</code>	<ul style="list-style-type: none"> <li>• <code>true</code></li> <li>• <code>false</code></li> </ul>	<code>false</code>
<code>pool_size</code>	a positive integer value	Implementation defined
<code>sync_hint</code>	<ul style="list-style-type: none"> <li>• <code>contended</code></li> <li>• <code>uncontended</code></li> <li>• <code>private</code></li> <li>• <code>serialized</code></li> </ul>	<code>contended</code>

The `access` trait specifies the accessibility of the allocated memory. The following are values you can specify for `access`:

- `all`

This value indicates that the allocated memory must be accessible by all threads in the device where the memory allocation occurs.

This is the default setting.

- `cgroup`

This value indicates that the allocated memory must be accessible by all threads of the same contention group as the thread that requested the allocation. Accessing the allocated memory thread that is not part of the same contention group results in undefined behavior.

- `pteam`

This value indicates that the allocated memory is accessible by all threads that bind to the same parallel region as the thread that requests the allocations. Access to the memory by a thread that does not bind to the same parallel region as the thread that allocated the memory results in undefined behavior.

- `thread`

This value indicates that the memory allocated is accessible only by the thread that allocated it. Attempts to allocate the memory by another thread result in undefined behavior.

The `alignment` trait specifies how allocated variables will be aligned. Variables will be byte-aligned to at least the value specified for this trait. The default setting is 1 byte. Alignment can also be affected by directives and OpenMP runtime allocator routines that specify alignment requirements.

The `fallback` trait indicates how an allocator behaves if it is unable to satisfy an allocation request. The following are values you can specify for `fallback`:

- `abort_fb`

This value indicates that the program terminates if the allocation request fails.

- `allocator_fb`

If this value is specified and the allocation request fails, the allocation will be tried by the allocator specified by the `fb_data` trait.

- `default_mem_fb`

This value indicates that a failed allocation request will be retried in the `omp_default_mem_space` memory space. All traits for the `omp_default_mem_space` allocator should be set to the default trait values, except the `fallback` trait should be set to `null_fb`. This is the default setting.

- `null_fb`

This value indicates the allocator returns a zero value when an allocation request fails.

The `fb_data` trait lets you specify a fall back allocator to be used if the requested allocator fails to satisfy the allocation request. The `fallback` trait of the failing allocator must be set to `allocator_fb` in order for the allocator specified by the `fb_data` trait to be used.

The `partition` trait describes the partitioning of allocated memory over the storage resources represented by the memory space of the allocator. The following are values you can specify for `partition`:

- `blocked`

This value indicates the allocated memory is partitioned into blocks of memory of approximately equal size with one block per storage resource.

- `environment`

This value indicates the allocated memory placement is determined by the runtime execution environment. This is the default setting.

- `interleaved`

This value indicates the allocated memory is distributed in a round-robin fashion across the storage resources.

- `nearest`

This value indicates that the allocated memory will be placed in the storage resource nearest to the thread that requested the allocation.

If the `pinned` trait has the value `true`, the allocator ensures each allocation made by the allocator will remain in the storage resource at the same location where it was allocated until it is deallocated. The default setting is `false`.

The value of `pool_size` is the total number of bytes of storage available to an allocator when there have been no allocations. The following affect `pool_size`:

- If the `access` trait has the value `all`, the value of `pool_size` is the limit for all allocations for all threads having access to the allocator.
- If the `access` trait of the allocator has the value `cgroup`, the value of `pool_size` is the limit for allocations made from the threads within the same contention group.
- For allocators with the `access` trait value of `pteam`, the value of `pool_size` is the limit for allocations made within the same parallel team.
- If the `access` trait has the value `thread`, the value of `pool_size` is the limit for allocations made from each thread using the allocator.
- An allocation request for more space than the value of `pool_size` results in the allocator not fulfilling the allocation request.

The `sync_hint` trait describes the way that multiple threads can access an allocator. The following are values you can specify for `sync_hint`:

- `contended` or `uncontended`

Value `contended` indicates that many threads are anticipated to make simultaneous allocation requests while the value `uncontended` indicates that few threads are anticipated to make simultaneous allocation. The default setting is `contended`.

- `private`

This value indicates that all allocation requests will come from the same thread. Specifying `private` when this is not the case and two or more threads make allocation requests by the same allocator results in undefined behavior.

- `serialized`

This value indicates that only one thread will request an allocation at a given time. The behavior is undefined if two threads request an allocation simultaneously by an allocator whose `sync_hint` value is serialized.

There are five predefined memory spaces in OpenMP:

- The system default memory is referred to as `omp_default_mem_space`.
- Large capacity memory is referred to as `omp_large_cap_mem_space`.
- High bandwidth memory is referred to as `omp_high_bw_mem_space`.
- Low latency memory is referred to as `omp_low_lat_mem_space`.
- Memory designed for optimal storage of constant values is referred to as `omp_const_mem_space`.

It can be initialized with compile-time constant expressions or by using a `firstprivate` clause.

Writing to variables in `omp_const_mem_space` results in undefined behavior.

There are three additional predefined memory spaces that are extensions to the OpenMP standard:

- `omp_target_host_mem_space` is host memory that is accessible by the device.
- `omp_target_shared_mem_space` is memory that can migrate between the host and the device.
- `omp_target_device_mem_space` is memory that is accessible to the device.

The following table shows the predefined memory allocators, the memory space they are associated with, and the non-default memory trait values they possess.

Allocator Name	Associated Memory Space	Non-Default Trait Values
<code>omp_default_mem_alloc</code>	<code>omp_default_mem_space</code>	<code>fallback=null_fb</code>
<code>omp_large_cap_mem_alloc</code>	<code>omp_large_cap_mem_space</code>	<code>none</code>
<code>omp_low_lat_mem_alloc</code>	<code>omp_low_lat_mem_space</code>	<code>none</code>
<code>omp_high_bw_mem_alloc</code>	<code>omp_high_bw_mem_space</code>	<code>none</code>
<code>omp_const_mem_alloc</code>	<code>omp_const_mem_space</code>	<code>none</code>
<code>omp_cgroup_mem_alloc</code>	implementation/system defined	<code>access=cgroup</code>
<code>omp_pteam_mem_alloc</code>	implementation/system defined	<code>access=pteam</code>
<code>omp_thread_mem_alloc</code>	implementation/system defined	<code>access=thread</code>
<code>omp_target_host_mem_alloc</code>	<code>omp_target_host_mem_space</code>	<code>none</code>
<code>omp_target_shared_mem_alloc</code>	<code>omp_target_shared_mem_space</code>	<code>none</code>
<code>omp_target_device_mem_alloc</code>	<code>omp_target_device_mem_space</code>	<code>none</code>

## OpenMP\* Advanced Issues

This topic discusses how to use the OpenMP\* library functions and environment variables and discusses some guidelines for enhancing performance with OpenMP.

OpenMP provides specific function calls, and environment variables. See the following topics to refresh your memory about the primary functions and environment variable used in this topic:

- [OpenMP Runtime Library Routines](#)
- [OpenMP Environment Variables](#)

To use the function calls, include the `omp_lib.h` header file or specify `use omp_lib` to use the Fortran90 module file. These files are installed in the `INCLUDE` directory during the compiler installation and compile the application using the `/Qopenmp` (Windows\*) or `-qopenmp` (Linux\* and macOS) option.

The following example demonstrates how to use the OpenMP functions to print the alphabet and illustrates several important concepts:

1. When using functions instead of directives, your code must be rewritten; rewrites can mean extra debugging, testing, and maintenance efforts.
2. It becomes difficult to compile without OpenMP support.
3. It is very easy to introduce simple bugs, as in the loop (shown in example) that fails to print all the letters of the alphabet when the number of threads is not a multiple of 26.
4. You lose the ability to adjust loop scheduling without creating your own work-queue algorithm, which is a lot of extra effort. You are limited by your own scheduling, which is mostly likely static scheduling as shown in the example.

```
include "omp_lib.h"
integer i
integer LettersPerThread, ThisThreadNum, StartLetter, EndLetter

call omp_set_num_threads(4)
!$OMP PARALLEL PRIVATE(i)

! OMP_NUM_THREADS is not a multiple of 26,
! which can be considered a bug in this code.
LettersPerThread = 26 / omp_get_num_threads()
ThisThreadNum = omp_get_thread_num()
StartLetter = 'a'+ThisThreadNum*LettersPerThread
EndLetter = 'a'+ThisThreadNum*LettersPerThread+LettersPerThread

DO i = StartLetter, EndLetter - 1
    write( *,FMT='(A)',ADVANCE='NO') char(i)
END DO

!$OMP END PARALLEL
write(*,*)
end
```

Debugging threaded applications is a complex process because debuggers change the runtime performance, which can mask race conditions. Even print statements can mask issues, because they use synchronization and operating system functions. OpenMP itself also adds some complications, because it introduces additional structure by distinguishing private variables and shared variables and inserts additional code. A debugger that supports OpenMP can help you to examine variables and step through threaded code. You can use Intel® Inspector to detect many hard-to-find threading errors analytically. Sometimes, a process of elimination can help identify problems without resorting to sophisticated debugging tools.

Remember that most mistakes are race conditions. Most race conditions are caused by shared variables that really should have been declared private. Start by looking at the variables inside the parallel regions and make sure that the variables are declared private when necessary. Next, check functions called within parallel constructs.

The `DEFAULT(NONE)` clause can be used to help find those hard-to-spot variables. If you specify `DEFAULT(NONE)`, then every variable must be declared with a data-sharing attribute clause. For example:

```
!$OMP PARALLEL DO DEFAULT(NONE) PRIVATE(x,y) SHARED(a,b)
```

Another common mistake is using uninitialized variables. Remember that private variables do not have initial values upon entering a parallel construct. Use the `FIRSTPRIVATE` and `LASTPRIVATE` clauses to initialize them only when necessary, because doing so adds extra overhead.

If you still can't find the bug, then consider the possibility of reducing the scope. Try a binary-hunt. Another method is to force large chunks of a parallel region to be critical sections. Pick a region of the code that you think contains the bug and place it within a critical section. Try to find the section of code that suddenly works when it is within a critical section and fails when it is not. Now look at the variables, and see if the bug is apparent. If that still doesn't work, try setting the entire program to run in serial by setting the compiler-specific environment variable `KMP_LIBRARY=serial`.

If the code is still not working, and you are not using any OpenMP API function calls, compile it without the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option to make sure the serial version works. If you are using OpenMP API function calls, use the `/Qopenmp-stubs` (Windows) or `-qopenmp-stubs` (Linux and macOS) option.

## Performance

OpenMP threaded application performance is largely dependent upon the following things:

- The underlying performance of the single-threaded code.
- CPU utilization, idle threads, and load balancing.
- The percentage of the application that is executed in parallel by multiple threads.
- The amount of synchronization and communication among the threads.
- The overhead needed to create, manage, destroy, and synchronize the threads, made worse by the number of single-to-parallel or parallel-to-single transitions called fork-join transitions.
- Performance limitations of shared resources such as memory, bus bandwidth, and CPU execution units.
- Memory conflicts caused by shared memory or falsely shared memory.

Performance always begins with a properly constructed parallel algorithm or application. For example, parallelizing a bubble-sort, even one written in hand-optimized assembly language, is not a good place to start. Keep scalability in mind; creating a program that runs well on two CPUs is not as efficient as creating one that runs well on  $n$  CPUs. With OpenMP, the number of threads is chosen by the compiler, so programs that work well regardless of the number of threads are highly desirable. Producer/consumer architectures are rarely efficient, because they are made specifically for two threads.

Once the algorithm is in place, make sure that the code runs efficiently on the targeted Intel® architecture; a single-threaded version can be a big help. Turn off the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option to generate a single-threaded version, or build with the `/Qopenmp-stubs` (Windows) or `-qopenmp-stubs` (Linux and macOS) option, and run the single-threaded version through the usual set of optimizations.

Once you have gotten the single-threaded performance, it is time to generate the multi-threaded version and start doing some analysis.

Optimizations are really a combination of patience, experimentation, and practice. Make little test programs that mimic the way your application uses the computer resources to get a feel for what things are faster than others. Be sure to try the different scheduling clauses for the parallel sections of code. If the overhead of a parallel region is large compared to the compute time, you may want to use an `IF` clause to execute the section serially.

## OpenMP\* Implementation-Defined Behaviors

This topic summarizes the behaviors that are described as implementation-defined in the OpenMP\* API specification.

### NOTE

Internal Control Variables (ICVs) mentioned below are discussed in the OpenMP API specification.

Name	Description
<code>single</code> construct	The first thread that encounters the <code>single</code> construct executes the structured block.
<code>teams</code> construct	The number of teams that are created is equal to 1 if you don't specify the <code>num_teams</code> clause.
<code>dist_schedule</code> clause, <code>distribute</code> construct	If you don't specify the <code>dist_schedule</code> clause, then the schedule for the <code>distribute</code> construct is static.
<code>omp_set_num_threads</code> routine	If the argument is not a positive integer, then Intel's OpenMP implementation sets the value of the first element of the <code>nthreads-var</code> ICV of the current task to 1.
<code>omp_set_max_active_levels</code> routine	If the argument is a negative integer this call is ignored and the last valid setting is used.
<code>omp_get_max_active_levels</code> routine	When called from within any explicit parallel region the binding thread set, and binding region, if required, for the <code>omp_get_max_active_levels</code> region is the current task region.
<code>OMP_SCHEDULE</code> environment variable	If the value of the variable does not conform to the specified format then the value of the <code>run-sched-var</code> ICV is set to <code>static</code> .
<code>OMP_NUM_THREADS</code> environment variable	If any value of the list specified in the environment variable is negative then the whole list is ignored. If any value of the list is zero then this value is set to 1.
<code>OMP_PROC_BIND</code> environment variable	If the value is not <code>true</code> , <code>false</code> , or a comma separated list of <code>master</code> (deprecated), <code>primary</code> , <code>close</code> , or <code>spread</code> , then Intel's OpenMP implementation sets the value of <code>bind-var</code> ICV to <code>false</code> .
<code>OMP_DYNAMIC</code> environment variable	If the value is neither <code>true</code> nor <code>false</code> , then the implementation sets the value of <code>dyn-var</code> ICV to <code>false</code> .
<code>OMP_NESTED</code> environment variable	If the value is neither <code>true</code> nor <code>false</code> , then the implementation sets the value of <code>nest-var</code> ICV to <code>false</code> .
<code>OMP_STACKSIZE</code> environment variable	If the value does not conform to the specified format or the implementation cannot provide a stack of the specified size, then Intel's OpenMP

Name	Description
	implementation sets the value of <code>stacksize-var</code> ICV to the default size, which is specified as being from 1MB to 4MB depending on the architecture. On Linux*, the implementation can set the value of <code>stacksize-var</code> ICV up to 256MB, respecting the operating system's stack size limit.
<code>OMP_MAX_ACTIVE_LEVELS</code> environment variable	If the value is a negative integer or is greater than the number of parallel levels an implementation can support, then Intel's OpenMP implementation sets the value of the <code>max-active-levels-var</code> ICV to 1.
<code>OMP_THREAD_LIMIT</code> environment variable	If the requested value is greater than the number of threads an implementation can support, or if the value is a negative integer, then Intel's OpenMP implementation sets the value of the <code>thread-limit-var</code> ICV to the maximum number of threads supported on a particular platform. If the requested value is zero then the implementation sets the value of the <code>thread-limit-var</code> ICV to 1.
Runtime library definitions	Intel's OpenMP implementation provides both the include file <code>omp_lib.h</code> and the module <code>omp_lib</code> .

## OpenMP\* Examples

The following examples show how to use several OpenMP\* features.

### A Simple Difference Operator

This example shows a simple parallel loop where the amount of work in each iteration is different. Dynamic scheduling is used to improve load balancing.

The `END DO` directive has a `NOWAIT` clause because there is an implicit barrier at the end of the parallel region. Therefore it is not necessary to also have a barrier at the end of the `DO` region.

```

subroutine do_1(a,b,n)
  real a(n,n), b(n,n)
  !$OMP PARALLEL SHARED(A,B,N)
    !$OMP DO SCHEDULE(DYNAMIC,1) PRIVATE(I,J)
      do i = 2, n
        do j = 1, i
          b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
        end do
      end do
    !$OMP END DO NOWAIT
  !$OMP END PARALLEL
end

```

## Two Difference Operators: DO Loop Version

This example uses two parallel loops fused to reduce fork/join overhead. The first `END DO` directive has a `NOWAIT` clause because all the data used in the second loop is different than all the data used in the first loop.

```
subroutine do_2(a,b,c,d,m,n)
  real a(n,n), b(n,n), c(m,m), d(m,m)
  !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
    !$OMP DO SCHEDULE(DYNAMIC,1)
      do i = 2, n
        do j = 1, i
          b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
        end do
      end do
    !$OMP END DO NOWAIT
    !$OMP DO SCHEDULE(DYNAMIC,1)
      do i = 2, m
        do j = 1, i
          d(j,i) = ( c(j,i) + c(j,i-1) ) / 2.0
        end do
      end do
    !$OMP END DO NOWAIT
  !$OMP END PARALLEL
end
```

## Two Difference Operators: SECTIONS Version

This example demonstrates the use of the `SECTIONS` directive. The logic is identical to the preceding `DO` directive example, but uses a `SECTIONS` directive instead of a `DO` directive. Here the speedup is limited to two because there are only two units of work whereas in the example above there are  $(n-1) + (m-1)$  units of work.

```
subroutine sections_1(a,b,c,d,m,n)
  real a(n,n), b(n,n), c(m,m), d(m,m)
  !$OMP PARALLEL SHARED(A,B,C,D,M,N) PRIVATE(I,J)
    !$OMP SECTIONS
      !$OMP SECTION
        do i = 2, n
          do j = 1, i
            b(j,i) = ( a(j,i) + a(j,i-1) ) / 2.0
          end do
        end do
      !$OMP SECTION
        do i = 2, m
          do j = 1, i
            d(j,i) = ( c(j,i) + c(j,i-1) ) / 2.0
          end do
        end do
    !$OMP END SECTIONS NOWAIT
  !$OMP END PARALLEL
end
```

## Update a Shared Scalar

This example demonstrates how to use a `SINGLE` construct to update an element of the shared array `a`. The optional `NOWAIT` clause after the first loop is omitted because it is necessary to wait at the end of the loop before proceeding into the `SINGLE` construct to avoid a race condition.

```
subroutine sp_1a(a,b,n)
  real a(n), b(n)
  !$OMP PARALLEL SHARED(A,B,N) PRIVATE(I)
    !$OMP DO
      do i = 1, n
        a(i) = 1.0 / a(i)
      end do
    !$OMP SINGLE
      a(1) = min( a(1), 1.0 )
    !$OMP END SINGLE
    !$OMP DO
      do i = 1, n
        b(i) = b(i) / a(i)
      end do
    !$OMP END DO NOWAIT
  !$OMP END PARALLEL
end
```

# Coarrays

---

This section contains information about using arrays and how to debug a coarray application on Linux\*.

## Use Coarrays

---

Coarrays are not supported on macOS systems.

Coarrays, a data sharing concept standardized in Fortran 2008 and extended in Fortran 2018, enable parallel processing using multiple copies of a single program. Each copy, called an image, has ordinary local variables and also shared variables called coarrays or covariables.

A covariable, which can be either an array or a scalar, is a variable whose storage spans all the images of the team that was current when the covariable was established. In this Partitioned Global Address Space (PGAS) model, each image can access its own piece of a covariable as a local variable and can access those pieces that live on other images using coindices, which are enclosed in square brackets.

Intel® Fortran supports coarray programs that run using shared memory on a multicore or multiprocessor system. In some products (see the [Feature Requirements](#) section), coarray programs can also be built to run using distributed memory across a Linux\* or Windows\* cluster.

For more details, see the product system requirements in the Release Notes.

---

**NOTE**

Coarrays are only supported on 64-bit architectures.

---

For more information on how to write programs using coarrays, see books on the Fortran 2008 and Fortran 2018 languages or the ISO Fortran 2008 and Fortran 2018 standards.

## Use Coarray Program Syntax

The additional syntax required by Fortran 2008 coarrays includes:

- The `CODIMENSION` attribute and "[cobounds]" to declare an object a coarray (covariable)

- The [coindices] notation to reference covariables on other images
- The SYNC ALL, SYNC IMAGES, and SYNC MEMORY statements to provide points where images must communicate to synchronize shared data
- The CRITICAL and END CRITICAL statements to form a block of code executed by one image at a time
- The LOCK and UNLOCK statements to control objects called locks, used to synchronize actions on specific images
- The ERROR STOP statement to end all images
- The ALLOCATE and DEALLOCATE statements to specify coarrays
- Intrinsic procedures IMAGE\_INDEX, LCOBOUND, NUM\_IMAGES, THIS\_IMAGE, and UCBOUND
- Atomic subroutines ATOMIC\_DEFINE and ATOMIC\_REF to define and reference an atomic variable

The following Fortran 2018 coarray extensions are also supported:

- The CHANGE TEAM and END TEAM statements to change the current team on which the image is executing
- The EVENT POST and EVENT WAIT statements to synchronize execution between two images
- The FAIL IMAGE statement to simulate a failed image
- The FORM TEAM statement to create one or more teams of images from the current team
- The SYNC TEAM statement to synchronize a team of images
- Intrinsic procedures COSHAPE, EVENT\_QUERY, FAILED\_IMAGES, GET\_TEAM, IMAGE\_STATUS, STOPPED\_IMAGES, and TEAM\_NUMBER
- New forms of the IMAGE\_INDEX, NUM\_IMAGES, and THIS\_IMAGE with optional TEAM and/or TEAM\_NUMBER arguments
- Atomic subroutines ATOMIC\_ADD, ATOMIC\_AND, ATOMIC\_CAS, ATOMIC\_FETCH\_ADD, ATOMIC\_FETCH\_AND, ATOMIC\_FETCH\_OR, ATOMIC\_FETCH\_XOR, ATOMIC\_OR, and ATOMIC\_XOR
- Collective subroutines CO\_BROADCAST, CO\_MAX, CO\_MIN, CO\_REDUCE, and CO\_SUM
- Optional STAT= and ERRMSG= specifiers on a CRITICAL construct, optional arguments STAT and ERRMSG for the MOVE\_ALLOC intrinsic, and optional STAT=, TEAM=, and TEAM\_NUMBER specifiers on image selectors, and an optional STAT argument to ATOMIC\_DEFINE and ATOMIC\_REF subroutines
- TYPE TEAM\_TYPE defined in the intrinsic module ISO\_FORTRAN\_ENV allows creation of team variables
- The constants INITIAL\_TEAM, CURRENT\_TEAM, and PARENT\_TEAM defined in the intrinsic module ISO\_FORTRAN\_ENV
- An image selector that has a TEAM=, TEAM\_NUMBER= or a STAT= specifier.

## Use the Coarray Compiler Options

You must specify the `-coarray` (Linux) or `/Qcoarray` (Windows) compiler option (hereafter referred to as `[Q]coarray`) to enable the compiler to recognize coarray syntax. If you do not specify this compiler option, a program that uses coarray syntax or features produces a compile-time error.

Only one `[Q]coarray` option is valid on the command line. If multiple coarray compiler options are specified, the last one specified is used. An exception to this rule is the `[Q]coarray` compiler option using keyword `single`; if specified, this option takes precedence regardless of where it appears on the command line.

The following describes the option keywords:

- Using `[Q]coarray` with no keyword is equivalent to running on one node (shared memory).
- Using `[Q]coarray` with keyword `shared` causes the underlying Intel® MPI Library parallelization to run on one node with multiple cores or processors with shared memory.
- Using `[Q]coarray` with keyword `distributed` requires a special license to be installed (see the [Feature Requirements](#) section) and causes the underlying Intel® MPI Library parallelization to run in a multi-node environment (multiple CPUs with distributed memory).
- Using `[Q]coarray` with keyword `single` creates an executable that will not be replicated, resulting in a single running image. This is in contrast to the self-replicating behavior that occurs when any other coarray keyword is specified. This option is useful for debugging purposes.

No special procedure is necessary to run a program that uses coarrays. You simply run the executable file.

The underlying parallelization implementation uses the Intel® MPI Library. Installation of the compiler automatically installs the necessary runtime libraries to run on shared memory. Products supporting clusters will also install the necessary runtime libraries to run on distributed memory. Use of coarray applications with any other Intel® MPI Library implementation, or with OpenMP\*, is not supported.

By default, the number of images created is equal to the number of execution units on the current system. You can override this by specifying a number using the `[Q]coarray-num-images` compiler option on the `ifort` command line that compiles the main program. You can also specify the number of images at execution time in the environment variable `FOR_COARRAY_NUM_IMAGES`.

## Use a Configuration File

Using a configuration file by specifying compiler option `[Q]coarray-num-images` is appropriate in only a limited number of cases.

The main reason is if you want to take advantage of Intel® MPI Library features in the coarray environment. To do so, specify the command line segments used by "`mpiexec -config filename`" in a file named *filename* and pass that file name to the Intel® MPI Library using the `[Q]coarray-config-file` compiler option.

If the `[Q]coarray-num-images` compiler option also appears on the command line, it will be overridden by what is in the configuration file.

Rules for using an Intel® MPI Library configuration files are as follows:

- The format of a configuration file is described in the Intel® MPI Library documentation. You will need to add the Intel® MPI Library option "`-genv FOR_ICAF_STATUS launched`" in the configuration file in order for coarrays to work on multi-node (distributed memory) systems.
- You can also set the environment variable `FOR_COARRAY_CONFIG_FILE` to be the filename and path of the Intel® MPI Library configuration file you want to use at execution time.

## Use Configuration Environment Variables

Intel Fortran uses Intel® MPI Library as the transport layer for the coarray feature. Intel® MPI Library can be tuned to a particular usage pattern with environment variables.

Intel Fortran has chosen to set some Intel® MPI Library control variables to values that are good for most users and many patterns of coarray usage. However, you may want to experiment with other variables that Intel® Fortran does not set. They are not set by Intel Fortran because they may reduce performance with other usage patterns or because they may cause errors when used with older versions of Intel® MPI Library.

Applications running on shared memory with Intel® MPI Library version 2019 Update 5 or greater may benefit from setting the following two variables to "`shm`":

```
I_MPI_FABRICS
```

```
I_MPI_DEVICE
```

---

### NOTE

When the above environment variables are set on Linux systems, there may be hangs on Red Hat 7.2 and Ubuntu because they cause increased use of shared memory. Therefore, please note that you may need to increase the size of `/dev/shm` to avoid Linux bus error (SIGBUS).

---

Applications which over-subscribe (have more coarray images running than there are actual processors in the machine) may benefit from setting the following variable to 1:

```
I_MPI_WAIT_MODE
```

Applications which over-subscribe a great deal (more than four images per processor) may benefit from setting the following variable to 3:

I\_MPI\_THREAD\_YIELD

This is just an introduction to using configuration environment variables. There are many other environment variables that you can use to tune Intel® MPI Library. For more information, see topic *Other Environment Variables* in the Intel® MPI Library Developer Reference documentation.

## Examples

---

### Linux

- `-coarray=shared -coarray-num-images=8`

The above runs a coarray program on shared memory using 8 images.

- `-coarray=distributed -coarray-num-images=8`

The above runs a coarray program on distributed memory across 8 images.

### Windows

- `/Qcoarray:shared /Qcoarray-num-images:8`

The above runs a coarray program on shared memory using 8 images.

- `/Qcoarray:shared /Qcoarray-config-file:filename`

The above runs a coarray program on shared memory using the Intel® MPI Library configuration detailed in *filename*.

- `/Qcoarray:distributed /Qcoarray-config-file:filename`

The above runs a coarray program on distributed memory using the Intel® MPI Library configuration detailed in *filename*.

`coarray-num-images`, `Qcoarray-num-images` compiler option

Coarray constructs

## Debug a Coarray Application

---

To debug a coarray application, you need an application with shared variables or coarrays whose storage spans all the images in a program.

### Linux

Follow these steps to debug your coarray application:

1. Add a stall loop to your application before the area of code you wish to debug:

```
LOGICAL VOLATILE :: WAIT_FOR_DEBUGGER
LOGICAL, VOLATILE :: TICK
!
! Other code may be here
!
DO WHILE(WAIT_FOR_DEBUGGER)
TICK = .NOT. TICK
END DO
!
! Code you want to debug is here
```

Specify VOLATILE to ensure that the loop will not be removed by the compiler.

If the problem is only found on one image, you can wrap the loop in code such as the following:

```
IF (THIS_IMAGE() .EQ. 4) THEN
```

2. Specify compiler option `-g` to compile and link with debug enabled.
3. Create at least  $N+1$  terminal windows on the machine where the application will be running, where  $N$  is the number of images your application will have.
4. In a terminal window, start the application:

```
linuxprompt> ./my_app
```

5. In each of the other terminal windows, set your default directory to be the same as the location of the application executable. Use the `ps` command in one of the windows to find out which processes are running your application:

```
linuxprompt> ps -ef | grep 'whoami' | grep my_app
```

There will be several processes.

The oldest is the one you started in step 4 – it has run the Message Passing Interface (MPI) launcher and is now waiting for the others to terminate. Do not debug it.

The others will look like this:

```
<your-user-name> 25653 25650 98 15:06 ? 00:00:49 my_app
<your-user-name> 25654 25651 97 15:06 ? 00:00:48 my_app
<your-user-name> 25655 25649 98 15:06 ? 00:00:49 my_app
```

The first number is the PID of the process (for example, 25653 in the first line). In the steps below, the PIDs of these  $N$  processes are referred to as  $P_1$ ,  $P_2$ , and so on.

When you type the commands, replace the text `<P1>` with the actual value of the PID for process 1, and so on.

6. In each window other than the first, start your debugger and set it to stop processes when attached:

```
linuxprompt> gdb
```

7. Attach to one of the processes. For example, attach to  $P_1$  in window 1, attach to  $P_2$  in window 2, and so on:

```
(gdb) attach <P1>
```

8. Get execution out of the stall loop:

```
(gdb) set WAIT_FOR_DEBUGGER = .false.
```

To debug your coarray application, examine the data and code paths in the various images.

## Windows

For information about debugging coarray applications started in the Visual Studio\* debugger, see article [How to Gain Control of Debugging a Fortran Coarray Application](#).

---

# Automatic Parallelization

The auto-parallelization feature of the Intel® Fortran Compiler automatically translates serial portions of the input program into equivalent multithreaded code. Automatic parallelization determines the loops that are good worksharing candidates, performs the dataflow analysis to verify correct parallel execution, and partitions the data for threaded code generation as needed in programming with OpenMP\* directives. The OpenMP and auto-parallelization functionality provides the performance gains from shared memory on multiprocessor and dual core systems.

The auto-parallelizer analyzes the dataflow of the loops in the application source code and generates multithreaded code for those loops which can safely and efficiently be executed in parallel.

This behavior enables the potential exploitation of the parallel architecture found in symmetric multiprocessor (SMP) systems.

The guided auto-parallelization feature of the Intel®Fortran Compiler helps you locate portions in your serial code that can be parallelized further. You can invoke guidance for parallelization, vectorization, or data transformation using specified compiler options of the [Q]guide series.

Automatic parallelization frees developers from having to:

- Find loops that are good worksharing candidates.
- Perform the dataflow analysis to verify correct parallel execution.
- Partition the data for threaded code generation as is needed in programming with OpenMP directives.

Although OpenMP directives enable serial applications to transform into parallel applications quickly, you must explicitly identify specific portions of your application code that contain parallelism and add the appropriate compiler directives. Auto-parallelization, which is triggered by the [Q]parallel option, automatically identifies those loop structures that contain parallelism. During compilation, the compiler automatically attempts to deconstruct the code sequences into separate threads for parallel processing. No other effort is needed.

---

**NOTE** In order to execute a program that uses auto-parallelization on Linux\* or macOS systems, you must include the `-parallel` compiler option when you compile and link your program.

---

---

**NOTE**

Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

---

Serial code can be divided so that the code can execute concurrently on multiple threads. For example, consider the following serial code example.

**Example 1: Original Serial Code**

```
subroutine ser(a, b, c)
  integer, dimension(100) :: a, b, c
  do i=1,100
    a(i) = a(i) + b(i) * c(i)
  enddo
end subroutine ser
```

The following example illustrates one method showing how the loop iteration space, shown in the previous example, might be divided to execute on two threads.

**Example 2: Transformed Parallel Code**

```
subroutine par(a, b, c)
  integer, dimension(100) :: a, b, c
  ! Thread 1
  do i=1,50
    a(i) = a(i) + b(i) * c(i)
  enddo
  ! Thread 2
  do i=51,100
    a(i) = a(i) + b(i) * c(i)
  enddo
end subroutine par
```

## Auto-Vectorization and Parallelization

Auto-vectorization detects low-level operations in the program that can be done in parallel, and then converts the sequential program to process 2, 4, 8, or (up to) 16 elements in one operation, depending on the data type. In some cases, auto-parallelization and vectorization can be combined for better performance results. For example, in the code below, thread-level parallelism can be exploited in the outermost loop, while instruction-level parallelism can be exploited in the innermost loop.

### Example

```
DO I = 1, 100      ! Execute groups of iterations in different threads (TLP)
  DO J = 1, 32     ! Execute in SIMD style with multimedia extension (ILP)
    A(J,I) = A(J,I) + 1
  ENDDO
ENDDO
```

With the relatively small effort of adding OpenMP directives to existing code you can transform a sequential program into a parallel program. The `[Q]openmp` option must be specified to enable the OpenMP directives. The following example shows OpenMP directives within the code.

### Example

```
!OMP$ PARALLEL PRIVATE(NUM), SHARED (X,A,B,C)
! Defines a parallel region
!OMP$ PARALLEL DO
! Specifies a parallel region that
! implicitly contains a single DO directive
DO I = 1, 1000
  NUM = FOO(B(I), C(I))
  X(I) = BAR(A(I), NUM)
! Assume FOO and BAR have no other effect
ENDDO
```

### NOTE

Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the `SINGLE` construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

## Using Parallelism Reports

To generate a parallelism report, use the `-qopt-report-phase=par` (Linux and macOS) or the `/Qopt-report-phase:par` option along with the `qopt-report=n` or `/Qopt-report:n` option (Windows). By default the auto-parallelism report generates a medium level of detail, where  $n=2$ . You can use `[q or Q]opt-report` option along with the `[q or Q]opt-report-phase` option if you want a greater or lesser level of detail. Specifying a value of '5' generates the maximum diagnostic details.

Run the report by entering commands similar to the following:

Operating System	Command
Linux	<code>ifort -c -parallel qopt-report-phase=par qopt-report:5 sample.cpp</code>
macOS	<code>ifort -c -parallel qopt-report-phase=par qopt-report:5 sample.cpp</code>

Operating System	Command
Windows*	<code>ifort sample.cpp /c /Qparallel /Qopt-report-phase=par /Qopt-report:5</code>

**NOTE** The `-c` (Linux and macOS) or `/c` (Windows) prevents linking and instructs the compiler to stop compilation after the object file is generated. The example is compiled without generating an executable.

The output, by default, produces a file with the same name as the object file, with `.optrpt` extension, and is written into the same directory as the object file. Using the above command-line entries, you will obtain an output file called `sample.optrpt`. Use the `[q or Q]opt-report-file` option to specify any other name for the output file that captures the report results. Use the arguments `stdout` or `stderr` to send the optimization report to stdout or stderr.

For more information on options to generate reports see the [Optimization Report Options](#) topic.

## Enable Auto-Parallelization

To enable the auto-parallelizer, use the `[Q]parallel` option. This option detects parallel loops capable of being executed safely in parallel, and automatically generates multi-threaded code for these loops.

**NOTE** You may need to set the `KMP_STACKSIZE` environment variable to an appropriately large size to enable parallelization with this option.

### NOTE

Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

An example of the command using auto-parallelization is as follows:

**Command auto-parallelization in Linux\***

**Command auto-parallelization in Linux\***

```
ifort -c -parallel myprog.f
```

**Command auto-parallelization in Windows\***

```
ifort -c /Qparallel myprog.f
```

**Command auto-parallelization in macOS**

```
ifort -c -parallel myprog.f
```

Auto-parallelization uses two specific directives: `!DIR$ PARALLEL` and `!DIR$ NOPARALLEL`.

The format of an auto-parallelization compiler directive is below:

**Syntax**

```
!DIR$ <directive>
```

Because auto-parallelization directives begin with an exclamation point, the directives take the form of comments if you omit the `[Q]parallel` option.

The `!DIR$ PARALLEL` directive instructs the compiler to ignore dependencies that it assumes may exist and that would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored. In addition, `PARALLEL [ALWAYS]` overrides the compiler heuristics that estimate the likelihood that parallelization of a loop increases performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the `ASSERT` keyword is added, as in `!DIR$ PARALLEL [ALWAYS [ASSERT]]`, the compiler generates an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

The `!DIR$ NOPARALLEL` directive disables auto-parallelization.

For example, in the following code, the `NOPARALLEL` directive disables auto-parallelization.

**Example**

```
program main
parameter (n=100)
integer x(n),a(n)
!DIR$ NOPARALLEL
do i=1,n
  x(i) = i
enddo
!DIR$ PARALLEL
do i=1,n
  a( x(i) ) = i
enddo
end
```

## Programming with Auto-Parallelization

The auto-parallelization feature implements some concepts of OpenMP\*, such as the worksharing construct (with the `PARALLEL DO` directive). This section provides details on auto-parallelization.

## Guidelines for Effective Auto-Parallelization Usage

A loop can be parallelized if it meets the following criteria:

- The loop is countable at compile time: This means that an expression representing how many times the loop will execute (loop trip count) can be generated just before entering the loop.
- There are no `FLOW` (`READ` after `WRITE`), `OUTPUT` (`WRITE` after `WRITE`) or `ANTI` (`WRITE` after `READ`) loop-carried data dependencies. A loop-carried data dependency occurs when the same memory location is referenced in different iterations of the loop. At the compiler's discretion, a loop may be parallelized if any assumed inhibiting loop-carried dependencies can be resolved by runtime dependency testing.

The compiler may generate a runtime test for the profitability of executing in parallel for loop, with loop parameters that are not compile-time constants.

### Coding Guidelines

Enhance the power and effectiveness of the auto-parallelizer by following these coding guidelines:

- Expose the trip count of loops whenever possible; use constants where the trip count is known and save loop parameters in local variables.
- Avoid placing structures inside loop bodies that the compiler may assume to carry dependent data, for example, procedure calls, ambiguous indirect references or global references.
- Insert the `!DIR$ PARALLEL` directive to disambiguate assumed data dependencies.
- Insert the `!DIR$ NOPARALLEL` directive before loops known to have insufficient work to justify the overhead of sharing among threads.

## Auto-Parallelization Data Flow

For auto-parallelization processing, the compiler performs the following steps:

1. **Data flow analysis:** Computing the flow of data through the program.
2. **Loop classification:** Determining loop candidates for parallelization based on correctness and efficiency, as shown by [Enabling Auto-parallelization](#).
3. **Dependency analysis:** Computing the dependency analysis for references in each loop nest.
4. **High-level parallelization:** Analyzing the dependency graph to determine loops that can execute in parallel, and computing runtime dependency.
5. **Data partitioning:** Examining data reference and partition based on the following types of access: `SHARED`, `PRIVATE`, and `FIRSTPRIVATE`.
6. **Multithreaded code generation:** Modifying loop parameters, generating entry/exit per threaded task, and generating calls to parallel runtime routines for thread creation and synchronization.

---

### NOTE

Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the `SINGLE` construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

---

[Enabling Auto-Parallelization](#)

## Enable Further Loop Parallelization for Multicore Platforms

---

Parallelizing loops for multicore platforms is subject to certain conditions. Three requirements must be met for the compiler to parallelize a loop:

- The number of iterations must be known before entry into a loop to insure that the work can be divided in advance. A DO WHILE loop, for example, usually cannot be made parallel.
- There can be no jumps into or out of the loop.
- The loop iterations must be independent (no cross-iteration dependencies).

Correct results must not logically depend on the order in which the iterations are executed. There may be slight variations in the accumulated rounding error, for example, when the same quantities are added in a different order. In some cases, such as summing an array or other uses of temporary scalars, the compiler may be able to remove an apparent dependency by a simple transformation.

Potential aliasing of pointers or array references is another common impediment to safe parallelization. Two pointers are aliased if both point to the same memory location. The compiler may not be able to determine whether two pointers or array references point to the same memory location. For example, if they depend on function arguments, runtime data, or the results of complex calculations.

If the compiler cannot prove that pointers or array references are safe, it will not parallelize the loop. In limited cases, when it is deemed worthwhile to generate alternative code paths to test explicitly for aliasing at runtime, the compiler will still parallelize the loop.

If you know parallelizing a particular loop is safe and that potential aliases can be ignored, you can instruct the compiler to parallelize the loop using the `!DIR$ PARALLEL` directive.

### Parallelize Loops with Cross-iteration Dependencies

Before the compiler can auto-parallelize a loop, it must prove that the loop does not have potential cross-iteration dependencies that prevent parallelization. A cross-iteration dependency exists if a memory location is written to in an iteration of a loop and accessed (read from or written to) in another iteration of the loop. Cross-iteration dependencies often occur in loops that access overlapping array ranges, such as a loop that reads from `a(1:100)` and writes to `a(0:99)`.

Sometimes, even though a loop does not have cross-iteration dependencies, the compiler does not have enough information to prove it and does not parallelize the loop. In such cases, you can assist the compiler by providing additional information about the loop using the `!DIR$ PARALLEL` directive. Adding the `!DIR$ PARALLEL` directive before a DO loop informs the compiler that the loop does not have cross-iteration dependencies. Auto-parallelization analysis ignores potential dependencies that it assumes could exist. However, the compiler may not parallelize the loop if heuristics estimate parallelization is unlikely to increase performance of the loop.

The Fortran DO CONCURRENT construct also specifies that there are no cross-iteration dependencies.

The `!DIR$ PARALLEL ALWAYS` directive has the same effect to ignore potential dependencies as the `!DIR$ PARALLEL` directive, but it also overrides the compiler heuristics that estimate the likelihood that parallelization of a loop would increase performance. It allows a loop to be parallelized even when the compiler estimates that parallelization might not improve performance.

The `!DIR$ NOPARALLEL` directive prevents auto-parallelization of the immediately following DO loop. Unlike `!DIR$ PARALLEL`, which is a hint, the `NOPARALLEL` directive is guaranteed to prevent parallelization of the following loop.

These directives take effect only if auto-parallelization is enabled by the option `[Q]parallel`.

### Parallelize Loops with Private Clauses

When you use the Guided Auto Parallelism feature, the compiler's auto-parallelizer gives you advice on where to alter your program to enhance parallelization. For instance, you may get advice to check if a condition (that the compiler could not prove) is true. If the condition is true, the compiler inserts `!DIR$ PARALLEL` in your source code so that the associated loop is parallelized when you recompile.

To specify that it is legal for each thread to create a new, private copy (not visible by other threads) of a variable, and replace the original variable in the loop with the new private variable, use the `!DIR$ PARALLEL` directive with the `PRIVATE` clause. The `PRIVATE` clause allows you to list scalar and array type variables and specify the number of array elements to privatize.

Use the `FIRSTPRIVATE` clause to specify private variables that need to be initialized with the original value before entering the parallel loop.

Use the `LASTPRIVATE` clause to specify those variables with a value you want to reuse after it exits a parallelized loop. When you use the `LASTPRIVATE` clause to handle a particular privatized variable, the value is copied to the original variable when it exits from the parallelized loop.

---

**NOTE**

Do not use the same variable in both `PRIVATE` and `LASTPRIVATE` clauses for the same loop. You will get an error message.

---

## Parallelize Loops with External Function Calls

The compiler can only effectively analyze loops with a relatively simple structure. For example, the compiler cannot determine the thread safety of a loop containing external function calls because it does not know whether the function call might have side effects that introduce dependencies. Fortran90 programmers can use the `PURE` attribute to assert that subroutines and functions contain no side effects. You can invoke interprocedural optimization with the `[Q]ipo` option. Using this option allows the compiler to analyze the called function for side effects.

## Parallelize Loops with OpenMP\*

When the compiler is unable to automatically parallelize loops you know to be parallel, use OpenMP\*. OpenMP\* is the preferred solution because you understand the code better than the compiler and can express parallelism at a coarser granularity. Alternatively, automatic parallelization can be effective for nested loops, such as those in a matrix multiply. Moderately coarse-grained parallelism results from threading of the outer loop, allowing the inner loops to be optimized for fine-grained parallelism using vectorization or software pipelining.

## Threshold Parameter to Parallelize Loops

If a loop can be parallelized, it does not necessarily mean that it should be parallelized. The compiler uses a threshold parameter to decide whether to parallelize a loop. The `[Q]par-threshold` compiler option adjusts this behavior. The threshold ranges from *0* to *100*, where *0* instructs the compiler to always parallelize a safe loop and *100* instructs the compiler to only parallelize those loops for which a performance gain is highly probable. Use the `-qopt-report-phase=par` (Linux and macOS) or `/Qopt-report-phase:par` (Windows\*) option to determine which loops were parallelized. The compiler will also report which loops could not be parallelized and indicate probable reason(s) why. See [OpenMP\\* and Parallel Processing Options](#) for more information on the using these compiler options.

The following example illustrates using the options in combination.

### Example code

```
subroutine add(k, a, b)
  integer :: k
  real :: a(10000), b(10000)
  DO i = 1, 10000
    a(i) = a(i+k) + b(i)
  end do
end subroutine add
```

Because the compiler does not know the value of *k*, the compiler assumes the iterations depend on each other, for example if *k* equals -1, even if the actual case is otherwise. You can override the compiler by inserting the `!DIR$ PARALLEL` directive.

**Example**

```

subroutine add(k, a, b)
  integer :: k
  real :: a(10000), b(10000)
  !DIR$ PARALLEL
  do i = 1, 10000
    a(i) = a(i+k) + b(i)
  end do
end subroutine add

```

**Caution**

Do not call this function with a value of  $k$  that is less than 10000; passing a value less than 10000 could lead to incorrect results.

# Vectorization

Vectorization is the process of converting an algorithm from a scalar implementation, which does an operation one pair of operands at a time, to a vector process where a single instruction can refer to a vector (a series of adjacent values).

## Automatic Vectorization

The automatic vectorizer (also called the auto-vectorizer) is a component of the compiler that automatically uses SIMD instructions in the Intel® Streaming SIMD Extensions (Intel® SSE, Intel® SSE2, Intel® SSE3 and Intel® SSE4), Supplemental Streaming SIMD Extensions (SSSE3) instruction sets, Intel® Advanced Vector Extensions (Intel® AVX, Intel® AVX2) instruction sets, and Intel® Advanced Vector Extensions 512 (Intel® AVX-512) instruction set. The vectorizer detects operations in the program that can be done in parallel and converts the sequential operations to parallel; for example, the vectorizer converts the sequential SIMD instruction that processes up to 16 elements into a parallel operation, depending on the data type.

Automatic vectorization occurs when the compiler generates packed SIMD instructions to unroll a loop. Because the packed instructions operate on more than one data element at a time, the loop executes more efficiently. This process is referred to as auto-vectorization only to emphasize that the compiler identifies and optimizes suitable loops on its own, without external input. However, it is useful to note that in some cases, certain keywords or directives may be applied in the code for auto-vectorization to occur.

The compiler supports a variety of auto-vectorizing hints that can help the compiler to generate effective vector instructions. Automatic vectorization is supported on Intel® 64 architectures. Intel® Advisor, a separate tool included in the Intel® oneAPI Base Toolkit, provides a Vectorization Advisor feature that can analyze the compiler's optimization reports and make recommendations for enhancing vectorization.

**NOTE**

This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

## Vectorization Programming Guidelines

The goal of including the vectorizer component in the Intel® Fortran Compiler is to exploit single-instruction multiple data (SIMD) processing automatically. Users can help by supplying the compiler with additional information; for example, by using auto-vectorizer hints or directives.

**NOTE**

This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

## Guidelines to Vectorize Innermost Loops

Follow these guidelines to vectorize innermost loop bodies.

Use:

- Straight-line code (a single basic block).
- Vector data only (arrays and invariant expressions on the right hand side of assignments). Array references can appear on the left hand side of assignments.
- Only assignment statements.

Avoid:

- Function calls (other than math library calls).
- Non-vectorizable operations (either because the loop cannot be vectorized, or because an operation is emulated through a number of instructions).
- Mixing vectorizable types in the same loop (leads to lower resource utilization).
- Data-dependent loop exit conditions (leads to loss of vectorization).

To make your code vectorizable, you need to edit your loops. You should only make changes that enable vectorization, and avoid these common changes:

- Loop unrolling, which the compiler performs automatically.
- Decomposing one loop with several statements in the body into several single-statement loops.

## Restrictions

There are a number of restrictions that you should consider. Vectorization depends on two major factors: hardware and style of source code.

Factor	Description
Hardware	The compiler is limited by restrictions imposed by the underlying hardware. Intel® Streaming SIMD Extensions (Intel® SSE) has vector memory operations that are limited to stride-1 accesses with a preference to 16-byte-aligned memory references. This means that if the compiler abstractly recognizes a loop as vectorizable, it still might not vectorize it for a distinct target architecture.

Factor	Description
Style of source code	The style in which you write source code can inhibit vectorization. For example, a common problem with global pointers is that they often prevent the compiler from being able to prove that two memory references refer to distinct locations. Consequently, this prevents certain reordering transformations.

Many stylistic issues that prevent automatic vectorization by compilers are found in loop structures. The ambiguity arises from the complexity of the keywords, operators, data references, pointer arithmetic, and memory operations within the loop bodies.

By understanding these limitations and by knowing how to interpret diagnostic messages, you can modify your program to overcome the known limitations and enable effective vectorization.

## Guidelines for Writing Vectorizable Code

Follow these guidelines to write vectorizable code:

- Use simple `DO` loops. Avoid complex loop termination conditions – the upper iteration limit must be invariant within the loop. For the innermost loop in a nest of loops, you could set the upper limit iteration to be a function of the outer loop indices.
- Write straight-line code. Avoid branches such as `DO`, `GOTO`, or `ASSIGN` statements; most function calls; or `IF` constructs that cannot be treated as masked assignments.
- Avoid dependencies between loop iterations or at the least, avoid read-after-write dependencies.
- Try to use array notations instead of the use of pointers. Without help, the compiler often cannot tell whether it is safe to vectorize code containing pointers.
- Wherever possible, use the loop index directly in array subscripts instead of incrementing a separate counter for use as an array address.
- Access memory efficiently:
  - Favor inner loops with unit stride.
  - Minimize indirect addressing.
  - Align your data to 16-byte boundaries (for Intel® SSE instructions).
- Choose a suitable data layout with care. Most multimedia extension instruction sets are rather sensitive to alignment. The data movement instructions of Intel® SSE, for example, operate much more efficiently on data that is aligned at a 16-byte boundary in memory. Therefore, the success of a vectorizing compiler also depends on its ability to select an appropriate data layout which, in combination with code restructuring (like loop peeling), results in aligned memory accesses throughout the program.
- Use aligned data structures: Data structure alignment is the adjustment of any data object in relation with other objects.

---

**Caution** Use this hint with care. Incorrect usage of aligned data movements result in an exception when using Intel® SSE.

---

- Use structure of arrays (SoA) instead of array of structures (AoS): An array is the most common type of data structure that contains a contiguous collection of data items that can be accessed by an ordinal index. You can organize this data as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization is excellent for encapsulation, it can be a hindrance for use of vector processing. To make vectorization of the resulting code more effective, you can also select appropriate data structures.

## Dynamic Alignment Optimizations

Dynamic alignment optimizations can improve the performance of vectorized code, especially for long trip count loops. Disabling such optimizations can decrease performance, but it may improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

To enable or disable dynamic data alignment optimizations, specify the option `Qopt-dynamic-align[-]` (Windows) or `[no-]qopt-dynamic-align[-]` (Linux).

## Use Aligned Data Structures

Data structure alignment is the adjustment of any data object with relation to other objects. The Intel® Fortran Compiler may align individual variables to start at certain addresses to speed up memory access. Misaligned memory accesses can incur large performance losses on certain target processors that do not support them in hardware.

Alignment is a property of a memory address, expressed as the numeric address modulo of powers of two. In addition to its address, a single datum also has a size. A datum is called 'naturally aligned' if its address is aligned to its size, otherwise it is called 'misaligned'. For example, an 8-byte floating-point datum is naturally aligned if the address used to identify it is aligned to eight (8).

A data structure is a way of storing data in a computer so that it can be used efficiently. Often, a carefully chosen data structure allows a more efficient algorithm to be used. A well-designed data structure allows a variety of critical operations to be performed, using as little resources (execution time and memory space) as possible.

In the example data structure above, if the type `short` is stored in two bytes of memory then each member of the data structure is aligned to a boundary of two bytes. `Data1` would be at offset 0, `Data2` at offset 2 and `Data3` at offset 4. The size of this structure is six bytes. The type of each member of the structure usually has a required alignment, meaning that it is aligned on a pre-determined boundary, unless you request otherwise. In cases where the compiler has taken sub-optimal alignment decisions, you can use the declaration `declspec(align(base,offset))`, where  $0 \leq \text{offset} < \text{base}$  and `base` is a power of two, to allocate a data structure at offset from a certain base.

If the first element of both arrays is aligned at a 16-byte boundary, then either an unaligned load of elements from `b` or an unaligned store of elements into `a` must be used after vectorization.

In this instance, peeling off an iteration does not help but you can enforce the alignment shown below. This alignment results in two aligned access patterns after vectorization (assuming an 8-byte size for doubles):

Runtime optimization provides a generally effective way to obtain aligned access patterns at the expense of a slight increase in code size and testing. If incoming access patterns are aligned at a 16-byte boundary, you can avoid this overhead with the hint `__assume_aligned(x, 16)`; in the function to convey this information to the compiler.

For example, suppose you can introduce an optimization in the case where a block of memory with address `n2` is aligned on a 16-byte boundary. You could use `__assume(n2%16==0)`.

---

**Caution** Incorrect use of aligned data movements result in an exception for Intel® SSE.

---

## Use Structure of Arrays Versus Array of Structures

The most common and well-known data structure is the array that contains a contiguous collection of data items, which can be accessed by an ordinal index. This data can be organized as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization works excellently for encapsulation, for vector processing it works poorly.

You can select appropriate data structures to make vectorization of the resulting code more effective. To illustrate this point, compare the traditional array of structures (AoS) arrangement for storing the `x`, `y`, `z` components of a set of three-dimensional points with the alternative structure of arrays (SoA) arrangement for storing this set.

With the AoS arrangement, a loop that visits all components of an RGB point before moving to the next point exhibits a good locality of reference. This is because all elements in the fetched cache lines are used. The disadvantage of the AoS arrangement is that each individual memory reference in such a loop exhibits a non-unit stride, which, in general, adversely affects vector performance. Furthermore, a loop that visits only one component of all points exhibits less satisfactory locality of reference because many of the elements in the fetched cache lines remain unused.

With the SoA arrangement, the unit-stride memory references are more amenable to effective vectorization and still exhibit good locality of reference within each of the three data streams. Consequently, an application that uses the SoA arrangement may outperform an application based on the AoS arrangement when compiled with a vectorizing compiler. This performance difference may not be obviously apparent during the early implementation phase.

Before you start vectorization, try out some simple rules:

- Make your data structures vector-friendly.
- Make sure that inner loop indices correspond to the outermost (last) array index in your data (row-major order).
- Use structure of arrays over array of structures.

For instance when dealing with three-dimensional coordinates, use three separate arrays for each component (SoA), instead of using one array of three-component structures (AoS). To avoid dependencies between loops that will eventually prevent vectorization, use three separate arrays for each component (SoA), instead of one array of three-component structures (AoS). When you use the AoS arrangement, each iteration produces one result by computing XYZ, but it can at best use only 75% of the SSE unit because the fourth component is not used. Sometimes, the compiler may use only one component (25%). When you use the SoA arrangement, each iteration produces four results by computing XXXX, YYYY and ZZZZ, using 100% of the SSE unit. A drawback for the SoA arrangement is that your code will likely be three times as long.

If your original data layout is in AoS format, you may want to consider a conversion to SoA before the critical loop:

- Use the smallest data types that give the needed precision to maximize potential SIMD width. (If only 16-bits are needed, using a `short` rather than an `int` can make the difference between 8-way or four-way SIMD parallelism.)
- Avoid mixing data types to minimize type conversions.
- Avoid operations not supported in SIMD hardware.
- Use all the instruction sets available for your processor. Use the appropriate command line option for your processor type, or select the appropriate IDE option (Windows only):
  - **Project > Properties > Visual Fortran > Code Generation > Intel Processor-Specific Optimization**, if your application runs only on Intel® processors.
  - **Project > Properties > Visual Fortran > Code Generation > Enable Enhanced Instruction Set**, if your application runs on compatible, non-Intel processors.
- Vectorizing compilers usually have some built-in efficiency heuristics to decide whether vectorization is likely to improve performance. The Intel® Fortran Compiler disables vectorization of loops with many unaligned or non-unit stride data access patterns. If experimentation reveals that vectorization improves

performance, you can override this behavior using the `!DIR$ VECTOR ALWAYS` hint before the loop. The compiler vectorizes any loop regardless of the outcome of the efficiency analysis (provided that vectorization is safe).

compiler option

## Use Automatic Vectorization

Automatic vectorization is supported on IA-32 (ifort only) and Intel® 64 architectures (ifort and ifx). The information below will guide you in setting up the auto-vectorizer.

### Vectorization Speedup

Where does the vectorization speedup come from? Consider the following sample code, where `a`, `b`, and `c` are integer arrays:

```
do I=1,MAX
  C(I)=A(I)+B(I)
end do
```

If vectorization is not enabled, and you compile using the `O1`, `-no-vec-` (Linux), or `/Qvec-` (Windows) option, the compiler processes the code with unused space in the SIMD registers, even though each register can hold three additional integers. If vectorization is enabled (compiled using `O2` or higher options), the compiler may use the additional registers to perform four additions in a single instruction. The compiler looks for vectorization opportunities whenever you compile at default optimization (`O2`) or higher.

---

#### NOTE

This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

---

---

#### Tip

This tip is only for the Intel®Fortran (ifort) Classic Compiler. To allow comparisons between vectorized and non-vectorized code, disable vectorization using the `-no-vec` (Linux or macOS) or `/Qvec-` (Windows) option; enable vectorization using the `O2` option.

---

To learn if a loop was vectorized or not, enable generation of the optimization report using the options `qopt-report=1` `qopt-report-phase=vec` (Linux and macOS) or `Qopt-report:1` `Qopt-report-phase:vec` (Windows) options. These options generate a separate report in an `*.optrpt` file that includes optimization messages. In Microsoft Visual Studio, the program source is annotated with the report's messages, or you can read the resulting `.optrpt` file using a text editor. A message appears for every loop that is vectorized, for example:

```
ifort /Qopt-report:1 matvec.f90
type matvec.optrpt
...
```

```

LOOP BEGIN at C:\Projects\vec_samples\matvec.f90(38,6)
  remark #15300: LOOP WAS VECTORIZED
LOOP END

```

The source line number (38 in the above example) refers to either the beginning or the end of the loop.

To get details about the type of loop transformations and optimizations that took place, use the `[Q]opt-report-phase` option by itself or along with the `[Q]opt-report` option.

## Linux

To evaluate performance enhancement, run `Vectorize VecMatMult`:

1. Download and run the `driver.f90` and `matvec.f90` samples from [Vectorize VecMatMul src folder on GitHub](#).
2. This application multiplies a vector by a matrix using the following loop:

```

do i=1,size1
  c(i) = c(i) + a(i,j) * b(j)
end do

```

3. Compile and run the application, first without enabling auto-vectorization. The default `O2` optimization enables vectorization, so you need to disable it with a separate option.

```

ifort -no-vec driver.f90 matvec.f90 -o NoVectMult
./NoVectMult

```

4. Build and run the application, this time with auto-vectorization.

```

ifort driver.f90 matvec.f90 -o VectMult
./VectMult

```

## Windows

To evaluate performance enhancement, run `Vectorize VecMatMult`:

1. Select **Start > Intel oneAPI <version> > Intel oneAPI Command Prompt for Intel 64 for Visual Studio <version>**.
2. Download and run the `driver.f90` and `matvec.f90` samples from the [Vectorize VecMatMul src folder on GitHub](#).
3. This application multiplies a vector by a matrix using the following loop:

```

do i=1,size1
  c(i) = c(i) + a(i,j) * b(j)
end do

```

4. Compile and run the application, first without enabling auto-vectorization. The default `O2` optimization enables vectorization, so you need to disable it with a separate option.

```

ifort /Qvec- driver.f90 matvec.f90 /exe:NoVectMult
NoVectMult

```

5. Build and run the application, this time with auto-vectorization.

```

ifort driver.f90 matvec.f90 /exe:VectMult
VectMult

```

When you compare the timing of the two runs, you may see that the vectorized version runs faster. The time for the non-vectorized version is only slightly faster than would be obtained by compiling with the `O1` option.

## Obstacles to Vectorization

The following issues do not always prevent vectorization, but frequently cause the compiler to decide that vectorization would not be worthwhile.

- **Non-contiguous memory access:** Four consecutive integers or floating-point values, or two consecutive doubles, may be loaded directly from memory in a single SSE instruction. But if the four integers are not adjacent, they must be loaded separately using multiple instructions, which is considerably less efficient. The most common examples of non-contiguous memory access are loops with non-unit stride or with indirect addressing, shown in the examples below. The compiler rarely vectorizes these loops, unless the amount of computational work is larger compared to the overhead from non-contiguous memory access.

```
! arrays accessed with non-unit stride 2
do I=1,SIZE,2
    B(I)=B(I)+(A(I)*X(I))
end do

! inner loop accesses matrix A with non-unit stride SIZE2
do J=1,SIZE1
    do I=1,SIZE2
        B(I)=B(I)+(A(J,I)*X(J))
    end do
end do

! indirect addressing of X using index array INDX
do I=1,SIZE,2
    B(I)=B(I)+(A(I)*X(INDX(I)))
end do
```

The typical message from the vectorization report is: `vectorization possible but seems inefficient`, although indirect addressing may also result in the following report: `existence of vector dependence`.

- **Data dependencies:** Vectorization entails changes in the order of operations within a loop, since each SIMD instruction operates on several data elements at once. Vectorization is only possible if this change of order does not change the results of the calculation.
  - The simplest case is when data elements that are written (stored to) do not appear in any other iteration of the individual loop. In this case, all the iterations of the original loop are independent of each other, and can be executed in any order, without changing the result. The loop may be safely executed using any parallel method, including vectorization.
  - When a variable is written in one iteration and read in a subsequent iteration, there is a read-after-write dependency, also known as a flow dependency, for example:

```
do J=2,5
    A(J)=A(J-1)+1
end do
```

The value of `A(1)` is propagated to all `A(J)`. This cannot safely be vectorized: if the first two iterations are executed simultaneously by a SIMD instruction, the value of `A(2)` is used by the second iteration before it has been calculated by the first iteration.

- When a variable is read in one iteration and written in a subsequent iteration, this is a write-after-read dependency, also known as an anti-dependency, for example:

```
do J=2,5
    A(J-1)=A(J)+1
end do
! this is equivalent to:
A(1)=A(2)+1
A(2)=A(3)+1
A(3)=A(4)+1
A(4)=A(5)+1
```

This write-after-read dependency is not safe for general parallel execution, since the iteration with the write may execute before the iteration with the read. No iteration with a higher value of  $J$  can complete before an iteration with a lower value of  $J$ , and so vectorization is safe (it gives the same result as non-vectorized code).

The following example may not be safe, since vectorization might cause some elements of  $A$  to be overwritten by the first SIMD instruction  $A(J-1) = A(J) + 1$  before being used for  $B$  in the second SIMD instruction  $B(J) = B(J) + A(J)$ .

```
do J=2,5
  A(J-1)=A(J)+1
  B(J)=B(J)+A(J)
end do
! this is equivalent to:
A(1)=A(2)+1
B(2)=B(2)+A(2)
A(2)=A(3)+1
B(3)=B(3)+A(3)
A(3)=A(4)+1
B(4)=B(4)+A(4)
A(4)=A(5)+1
B(4)=B(4)+A(4)
```

- Read-after-read situations are not really dependencies, and do not prevent vectorization or parallel execution. If a variable is unwritten, it does not matter how often it is read.
- Write-after-write, or output dependencies, where the same variable is written to in more than one iteration, are generally unsafe for parallel execution, including vectorization.
- One important exception that contains all of the above types of dependency is:

```
MYSUM=0
do J=1,MAX
  MYSUM = MYSUM + A(J)*B(J)
end do
```

Although `MYSUM` is both read and written in every iteration, the compiler recognizes such reduction idioms, and is able to vectorize them safely. The loop in the first example was another example of a reduction, with a loop-invariant array element in place of a scalar.

These types of dependencies between loop iterations are sometimes known as loop-carried dependencies.

The above examples are of proven dependencies. The compiler cannot safely vectorize a loop if there is even a potential dependency. For example:

```
real, pointer :: A(:),B(:),C(:)
...
do I=1,SIZE
  C(I)=A(I)*B(I)
end do
...
```

In the above example, the compiler needs to determine whether, for some iteration  $I$ ,  $C(I)$  might refer to the same memory location as  $A(I)$  or  $B(I)$  for a different iteration. Such memory locations are sometimes said to be aliased. For example, if  $A(I)$  pointed to the same memory location as  $C(I-1)$ , there would be a read-after-write dependency. If the compiler cannot exclude this possibility, it will not vectorize the loop unless you provide the compiler with hints. You can also avoid this problem by making the arrays `ALLOCATABLE` instead of `POINTER`, as the compiler knows these cannot be aliased.

## Vectorization and Loops

This topic provides more information on the interaction between the auto-vectorizer and loops.

### Interactions with Loop Parallelization

Combine the [\[Q\]parallel](#) and [\[Q\]x](#) options to instruct the Intel® Fortran Compiler to attempt both [Automatic Parallelization](#) and automatic loop vectorization in the same compilation.

---

#### NOTE

Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

---

---

#### NOTE

This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

---

In most cases, the compiler will consider outermost loops for parallelization and innermost loops for vectorization. If deemed profitable, however, the compiler may even apply loop parallelization and vectorization to the same loop.

See [Programming with Auto-parallelization](#) and [Programming Guidelines for Vectorization](#).

In some rare cases, a successful loop parallelization (either automatically or by means of OpenMP directives) may affect the messages reported by the compiler for a non-vectorizable loop in a non-intuitive way; for example, in the cases where the `/Qopt-report:2 /Qopt-report-phase:vec` (Windows) or `-qopt-report=2 -qopt-report-phase=vec` (Linux and macOS) options indicate that loops were not successfully vectorized.

### Types of Vectorized Loops

For integer loops, the 128-bit Intel® Streaming SIMD Extensions (Intel® SSE) and the Intel® Advanced Vector Extensions (Intel® AVX) provide SIMD instructions for most arithmetic and logical operators on 32-bit, 16-bit, and 8-bit integer data types, with limited support for the 64-bit integer data type.

Vectorization may proceed if the final precision of integer wrap-around arithmetic is preserved. A 32-bit shift-right operator, for instance, is not vectorized in 16-bit mode if the final stored value is a 16-bit integer. Also, note that because the Intel® SSE and the Intel® AVX instruction sets are not fully orthogonal (shifts on byte operands, for instance, are not supported), not all integer operations can actually be vectorized.

For loops that operate on 32-bit single-precision and 64-bit double-precision floating-point numbers, Intel® SSE provides SIMD instructions for the following arithmetic operators:

- Addition (+)
- Subtraction (-)
- Multiplication (\*)

- Division (/)

Additionally, Intel® SSE provide SIMD instructions for the binary `MIN` and `MAX` and unary `SQRT` operators. SIMD versions of several other mathematical operators (like the trigonometric functions `SIN`, `COS`, and `TAN`) are supported in software in a vector mathematical runtime library that is provided with the compiler.

To be vectorizable, loops must be:

- **Countable:** The loop trip count must be known at entry to the loop at runtime, though it need not be known at compile time (that is, the trip count can be a variable but the variable must remain constant for the duration of the loop). This implies that exit from the loop must not be data-dependent.
- **Innermost loop of a nest:** The only exception is if an original outer loop is transformed into an inner loop as a result of some other prior optimization phase, such as unrolling, loop collapsing or interchange, or an original outermost loop is transformed to an innermost loop due to loop materialization.
- **Without function calls:** Even a `print` statement is sufficient to prevent a loop from getting vectorized. The vectorization report message is typically: non-standard loop is not a vectorization candidate. The two major exceptions are for intrinsic math functions and for functions that may be inlined.

Intrinsic math functions are allowed, because the compiler runtime library contains vectorized versions of these functions. See below for a list of these functions; most exist in both float and double versions:

- `acos`
- `acosh`
- `anint`
- `asin`
- `asinh`
- `atan`
- `atan2`
- `atanh`
- `ceiling`
- `cos`
- `cosh`
- `erf`
- `erfc`
- `exp`
- `exp2`
- `floor`
- `log`
- `log10`
- `sin`
- `sinh`
- `sqrt`
- `tan`
- `tanh`

## Statements in the Loop Body

The vectorizable operations are different for floating-point and integer data.

### Integer Array Operations

The statements within the loop body may be arithmetic or logical operations (again, typically for arrays). Arithmetic operations are limited to such operations as addition, subtraction, `ABS`, `MIN`, and `MAX`. Logical operations include bitwise `AND`, `OR`, and `XOR` operators. You can mix data types but this may potentially cost you in terms of lowering efficiency.

## Other Operations

No statements other than the preceding floating-point and integer operations are valid. The loop body cannot contain any function calls other than the ones described above.

## Data Dependency

Data dependency relations represent the required ordering constraints on the operations in serial loops. Because vectorization rearranges the order in which operations are executed, any auto-vectorizer must have at its disposal some form of [data dependency analysis](#).

An example where data dependencies prohibit vectorization is shown below. In this example, the value of each element of an array is dependent on the value of its neighbor that was computed in the previous iteration.

```
subroutine dep(data, n)
  real :: data(n)
  integer :: i
  do i = 1, n-1
    data(i) = data(i-1)*0.25 + data(i)*0.5 + data(i+1)*0.25
  end do
end subroutine dep
```

The loop in the above example is not vectorizable because the WRITE to the current element `data(i)` is dependent on the use of the preceding element `data(i-1)`, which has already been written to and changed in the previous iteration. To see this, look at the access patterns of the array for the first two iterations as shown below.

```
i=1: READ data[0]
      READ data[1]
      READ data[2]
      WRITE data[1]
i=2: READ data[1]
      READ data[2]
      READ data[3]
      WRITE data[2]
```

In the normal sequential version of this loop, the value of `DATA(1)` read from during the second iteration was written to in the first iteration. For vectorization, it must be possible to do the iterations in parallel, without changing the semantics of the original loop.

```
do i=1,100
  a(i)=b(i)
end do

! which has the following access pattern
  read b(1)
  write a(1)
  read b(2)
  write b(2)
```

## Data Dependency Analysis

Data dependency analysis involves finding the conditions under which two memory accesses may overlap. Given two references in a program, the conditions are defined by:

- The referenced variables may be aliases for the same (or overlapping) regions in memory.
- For array references, the relationship between the subscripts.

The data dependency analyzer for array references is organized as a series of tests, which progressively increase in power as well as in time and space costs.

First, a number of simple tests are performed in a dimension-by-dimension manner, since independency in any dimension will exclude any dependency relationship. Multidimensional arrays references that may cross their declared dimension boundaries can be converted to their linearized form before the tests are applied.

Some of the simple tests that can be used are the fast greatest common divisor (GCD) test and the extended bounds test. The GCD test proves independency if the GCD of the coefficients of loop indices cannot evenly divide the constant term. The extended bounds test checks for potential overlap of the extreme values in subscript expressions.

If all simple tests fail to prove independency, the compiler will eventually resort to a powerful hierarchical dependency solver that uses Fourier-Motzkin elimination to solve the data dependency problem in all dimensions.

#### Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at [www.Intel.com/PerformanceIndex](http://www.Intel.com/PerformanceIndex).

### Loop Constructs

Loops can be formed with the usual `DO...END DO` and `DO WHILE`, or by using an `IF/GOTO` and a label. Loops must have a single entry and a single exit to be vectorized. The following examples illustrate loop constructs that can and cannot be vectorized. The non-vectorizable structure example shows a loop that cannot be vectorized because of the inherent potential for an early exit from the loop.

Vectorizable structure:

```
subroutine vec(a, b, c)
  dimension a(100), b(100), c(100)
  integer i
  i = 1
  do while (i .le. 100)
    a(i) = b(i) * c(i)
    if (a(i) .lt. 0.0) a(i) = 0.0
    i = i + 1
  enddo
end subroutine vec
```

Non-vectorizable structure:

```
subroutine no_vec(a, b, c)
  dimension a(100), b(100), c(100)
  integer i
  i = 1
  do while (i .le. 100)
    a(i) = b(i) * c(i)
  ! The next statement allows early
  !
```

```
exit from the loop and prevents
! vectorization of the loop.
    if (a(i) .lt. 0.0) go to 10
    i = i + 1
enddo
10 continue
end subroutine no_vecN
END
```

## Loop Exit Conditions

Loop exit conditions determine the number of iterations a loop executes. For example, fixed indexes for loops determine the iterations. The loop iterations must be countable and the number of iterations must be expressed as one of the following:

- A constant.
- A loop invariant term.
- A linear function of outermost loop indices.

In the case where a loops exit depends on computation, the loops are not countable. The examples below show loop constructs that are countable and non-countable. The non-countable loop example demonstrates a loop construct that is non-countable due to dependency loop variant count value.

Countable loop, example one:

```
subroutine cnt1 (a, b, c, n, lb)
  dimension a(n), b(n), c(n)
  integer n, lb, i, count
! Number of iterations is "n - lb + 1"
  count = n
  do while (count .ge. lb)
    a(i) = b(i) * c(i)
    count = count - 1
    i = i + 1
  enddo ! lb is not defined within loop
end
```

Countable loop, example two:

```
! Number of iterations is (n-m+2)/2
subroutine cnt2 (a, b, c, m, n)
  dimension a(n), b(n), c(n)
  integer i, l, m, n
  i = 1;
  do l = m,n,2
    a(i) = b(i) * c(i)
    i = i + 1
  enddo
end
```

Non-countable loop:

```
! Number of iterations is dependent on a(i)
subroutine foo (a, b, c)
  dimension a(100),b(100),c(100)
  integer i
  i = 1
  do while (a(i) .gt. 0.0)
    a(i) = b(i) * c(i)
```

```

    i = i + 1
  enddo
end

```

## Strip-mining and Cleanup

Strip-mining, also known as loop sectioning, is a loop transformation technique for enabling SIMD-encoding of loops, as well as a means of improving memory performance. By fragmenting a large loop into smaller segments or strips, this technique transforms the loop structure in two ways:

- By increasing the temporal and spatial locality in the data cache if the data is reusable in different passes of an algorithm.
- By reducing the number of iterations of the loop by a factor of the length of each vector, or number of operations being performed per SIMD operation. With the Intel® Streaming SIMD Extensions (Intel® SSE), the vector or strip-length is reduced by four times: four floating-point data items per single Intel® SSE single-precision floating-point SIMD operation are processed.

First introduced for vectorizers, this technique consists of the generation of code when each vector operation is done for a size less than or equal to the maximum vector length on a given vector machine.

The compiler automatically strip-mines your loop and generates a cleanup loop. For example, assume the compiler attempts to strip-mine the loop before vectorization. After vectorization, the compiler might handle the strip mining and loop cleaning by restructuring the loop.

Before vectorization:

```

i = 1
do while (i<=n)
  a(i) = b(i) + c(i) ! Original loop code
  i = i + 1
end do

```

After vectorization:

```

!The vectorizer generates the following two loops
i = 1
do while (i < (n - mod(n,4)))
! Vector strip-mined loop.
  a(i:i+3) = b(i:i+3) + c(i:i+3)
  i = i + 4
end do
do while (i <= n)
  a(i) = b(i) + c(i)      !Scalar clean-up loop
  i = i + 1
end do

```

## Loop Blocking

It is possible to treat loop blocking as strip-mining in two or more dimensions. Loop blocking is a useful technique for memory performance optimization. The main purpose of loop blocking is to eliminate as many cache misses as possible. This technique transforms the memory domain into smaller chunks rather than sequentially traversing through the entire memory domain. Each chunk should be small enough to fit all the data for a given computation into the cache, maximizing data reuse.

Consider the following example. The two-dimensional array *A* is referenced in the *j* (column) direction and then in the *i* (row) direction (column-major order); array *B* is referenced in the opposite manner (row-major order). Assume that the memory layout is in column-major order; therefore, the access strides of array *A* and *B* for the code would be 1 and MAX, respectively.  $BS = \text{block\_size}$ ; MAX must be evenly divisible by BS.

The arrays could be blocked into smaller chunks so that the total combined size of the two blocked chunks is smaller than the cache size, which can improve data reuse. One way of doing this is shown in the transformed loop after blocking example.

Original loop:

```
REAL A(MAX,MAX), B(MAX,MAX)
DO I = 1, MAX
  DO J = 1, MAX
    A(I,J) = A(I,J) + B(J,I)
  ENDDO
ENDDO
```

Transformed loop after blocking:

```
REAL A(MAX,MAX), B(MAX,MAX)
DO I = 1, MAX, BS
  DO J = 1, MAX, BS
    DO II = I, I+MAX, BS-1
      DO JJ = J, J+MAX, BS-1
        A(II,JJ) = A(II,JJ) + B(JJ,II)
      ENDDO
    ENDDO
  ENDDO
ENDDO
```

## Loop Interchange and Subscripts with Matrix Multiply

Loop interchange is often used for improving memory access patterns. Matrix multiplication is commonly written as shown in the typical matrix multiplication example.

The use of  $B(K,J)$  is not a stride-1 reference and therefore will not be vectorized efficiently.

If the loops are interchanged, all the references become stride-1 as shown in the matrix multiplication with stride-1 example.

Typical matrix multiplication:

```
subroutine matmul_slow(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do i = 1, n
    do j = 1, n
      do k = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j)
      end do
    end do
  end do
end subroutine matmul_slow
```

Matrix multiplication with stride-1:

```
subroutine matmul_fast(a, b, c)
  integer :: i, j, k
  real :: a(100,100), b(100,100), c(100,100)
  do j = 1, n
    do k = 1, n
      do i = 1, n
        c(i,j) = c(i,j) + a(i,k)*b(k,j)
      enddo
    enddo
  enddo
```

```

    enddo
  enddo
end subroutine matmul_fast

```

Interchanging is not always possible because of dependencies, which can lead to different results.

## Explicit Vector Programming

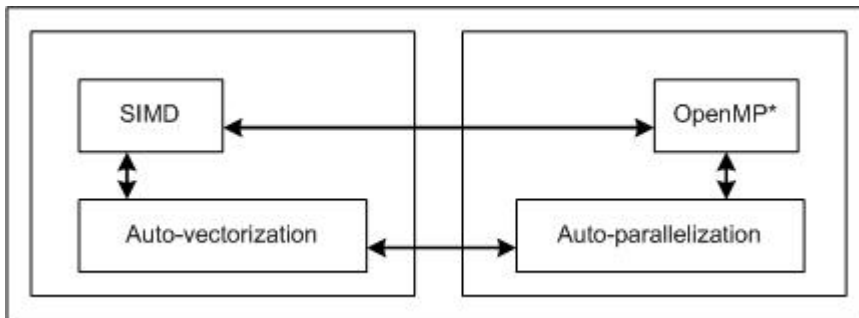

This section contains information about explicit vector programming.

### User-Mandated or SIMD Vectorization

User-mandated or SIMD vectorization supplements automatic vectorization just like OpenMP parallelization supplements automatic parallelization. The following figure illustrates this relationship. User-mandated vectorization is implemented as a single-instruction-multiple-data (SIMD) feature and is referred to as SIMD vectorization.

#### NOTE

The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

SIMD vectorization uses the `!$OMP SIMD` directive to effect loop vectorization. You must add this directive to a loop and recompile to vectorize the loop using the option `-qopenmp-simd` (Linux and macOS) or `Qopenmp-simd` (Windows).

For example, with the following code found in `example1.f` the compiler does not automatically vectorize the loop due to the unknown data dependence distance between `I` and `2*I`.

```

subroutine add(A, N, X)
integer N, X
real    A(N)
DO I=X, N
  A(I) = A(I) + A(2*I)
ENDDO
End

```

The example is compiled with the following command:

```
ifort example1.f -c -nologo -Qopt-report2 -Qopt-report-phase=vec -Qopt-report-file=stderr
```

The example gives output like the following, reporting that vectorization did not occur:

```

Begin optimization report for: ADD

Report from: Vector optimizations [vec]

```

```

LOOP BEGIN at example1.f(5,9)
<Multiversed v1>
  remark #15344: loop was not vectorized: vector dependence prevents vectorization. First
dependence is shown below. Use level 5 report for details
  remark #15346: vector dependence: assumed FLOW dependence between A(I) (6:11) and A(I*2)
(5:11)
LOOP END

LOOP BEGIN at example1.f(5,9)
<Remainder, Multiversed v1>
LOOP END

LOOP BEGIN at example1.f(5,9)
<Multiversed v2>
  remark #15304: loop was not vectorized: non-vectorizable loop instance from multiversioning
LOOP END

LOOP BEGIN at example1.f(5,9)
<Remainder, Multiversed v2>
LOOP END
=====

```

Using the previous example, if you know that  $X$  is large enough that data  $A(I)$  and  $A(2*I)$  do not overlap within a reasonable number of iterations you can enforce vectorization of the loop using `!$OMP SIMD`. If you know that they do not overlap in at least 8 iterations you may additionally specify `!$OMP SIMD SIMDLEN(8)` to avoid vectorization that is too wide, which might lead to overlap.

You can update your code from the previous example to use `!$OMP SIMD`:

```

subroutine add(A, N, X)
integer N, X
real    A(N)
!X may be 8 or more, so on overlap with 8 iterations at least
!$OMP SIMD SIMDLEN(8)
DO I=X, N
  A(I) = A(I) + A(2*I)
ENDDO
End

```

The example is compiled with the following command:

```

ifort example1.f -c -nologo -Qopt-report2 -Qopt-report-phase=vec -Qopt-report-file=stderr -
Qopenp-simd

```

The example gives output like the following, reporting that vectorization did occur:

```

Begin optimization report for: ADD

  Report from: Vector optimizations [vec]

LOOP BEGIN at example1.f(6,9)
<Peeled loop for vectorization>
LOOP END

LOOP BEGIN at example1.f(6,9)
  remark #15301: OpenMP SIMD LOOP WAS VECTORIZED
LOOP END

```

```

LOOP BEGIN at example1.f(6,9)
<Remainder loop for vectorization>
LOOP END
=====

```

---

**NOTE** The option `-qopt-report-phase` (Linux) and `/Qopt-report-phase` (Windows) is only available for ifort.

---

The difference between using `!$OMP SIMD` and auto-vectorization hints is that with `!$OMP SIMD`, the compiler generates a warning when it is unable to vectorize the loop. With auto-vectorization hints, actual vectorization is still under the discretion of the compiler, even when you use the `!DIR$ VECTOR ALWAYS` hint.

`!$OMP SIMD` has optional clauses to guide the compiler on how vectorization must proceed. Use these clauses appropriately so that the compiler obtains enough information to generate correct vector code. For more information on the clauses, see the `!$OMP SIMD` description.

### Additional Semantics

Note the following points when using the `!$OMP SIMD` directive.

- A variable may belong to zero or one of the following: private, linear, or reduction.
- Within the vector loop, an expression is evaluated as a vector value if it is private, linear, reduction, or it has a sub-expression that is evaluated to a vector value. Otherwise, it is evaluated as a scalar value (that is, broadcast the same value to all iterations). Scalar value does not necessarily mean loop invariant, although that is the most frequently seen usage pattern of scalar value.
- A vector value may not be assigned to a scalar L-value. It is an error.
- A scalar L-value may not be assigned under a vector condition. It is an error.
- The computed GOTO statement is not supported.

### Using vector Declaration

The following Intel® Visual Fortran example code shows how a program can compare serial and vector computations using a user-defined function, `foo()`.

---

**NOTE** All code examples in this section are applicable for Fortran on Windows only.

---

This example shows you code where the user-defined function is not vectorized:

```

!! file simdmain.f90
program simdttest
use IFPORT
! Test vector function in external file.
implicit none
interface
  integer function foo(a, b)
    integer a, b
  end function foo
end interface

integer, parameter :: M = 48, N = 64

integer i, j
integer, dimension(M,N) :: a1
integer, dimension(M,N) :: a2
integer, dimension(M,N) :: s_a3
integer, dimension(M,N) :: v_a3

```

```

logical :: err_flag = .false.

! compute random numbers for arrays
do j = 1, N
  do i = 1, M
    a1(i,j) = rand() * M
    a2(i,j) = rand() * M
  end do
end do

! compute serial results
do j = 1, N
!dir$ novector
  do i = 1, M
    s_a3(i,j) = foo(a1(i,j), a2(i,j))
  end do
end do

! compute vector results
do j = 1, N
  do i = 1, M
    v_a3(i,j) = foo(a1(i,j), a2(i,j))
  end do
end do

! compare serial and vector results
do j = 1, N
  do i = 1, M
    if (s_a3(i,j) .ne. v_a3(i,j)) then
      err_flag = .true.
      print *, s_a3(i, j), v_a3(i,j)
    end if
  end do
end do
if (err_flag .eq. .true.) then
  write(*,*) "FAILED"
else
  write(*,*) "PASSED"
end if
end program

!! file: vecfoo.f90
integer function foo(a, b)
implicit none
integer, intent(in) :: a, b
  foo = a - b
end function

```

This example gives output like the following, reporting that vectorization did not occur:

```
[49 C:/temp] ifort -nologo -qopt-report2 -qopt-report-phase=vec -qopt-report-file=stderr
simdmain.f90 vecfoo.f90
```

```
Begin optimization report for: SIMDTEST
```

```
Report from: Vector optimizations [vec]
```

```

    LOOP BEGIN at simdmain.f90(42,4)
        remark #15543: loop was not vectorized: loop with function call not considered an
        optimization candidate.
    LOOP END
LOOP END
=====

```

When you compile the above code, the loop containing the `f00()` function is not auto-vectorized because the auto-vectorizer does not know what `f00()` does unless it is inlined to this call site.

In such cases where the function call is not inlined, you can use the `!DIR$ ATTRIBUTES VECTOR::function-name-list` declaration to vectorize the loop and the function `f00()`. All you need to do is add the vector declaration to the function declaration, and recompile the code. The loop and function are vectorized.

For example, a loop with a user-defined function where the vector declaration is auto-vectorized:

```

!! file simdmain.f90
program simdttest
! Test vector function in external file.
use IFPORT
implicit none

```

```

interface
  integer function foo(a, b)
!$omp declare simd
    integer a, b
    end function foo
end interface

integer, parameter :: M = 48, N = 64

integer i, j
integer, dimension(M,N) :: a1
integer, dimension(M,N) :: a2
integer, dimension(M,N) :: s_a3
integer, dimension(M,N) :: v_a3
logical :: err_flag = .false.

! compute random numbers for arrays
do j = 1, N
  do i = 1, M
    a1(i,j) = rand() * M
    a2(i,j) = rand() * M
  end do
end do

! compute serial results
do j = 1, N
!dir$ novector
  do i = 1, M
    s_a3(i,j) = foo(a1(i,j), a2(i,j))
  end do
end do

! compute vector results
do j = 1, N
  do i = 1, M
    v_a3(i,j) = foo(a1(i,j), a2(i,j))
  end do
end do

! compare serial and vector results
do j = 1, N
  do i = 1, M
    if (s_a3(i,j) .ne. v_a3(i,j)) then
      err_flag = .true.
      print *, s_a3(i, j), v_a3(i,j)
    end if
  end do
end do
if (err_flag .eq. .true.) then
  write(*,*) "FAILED"
else
  write(*,*) "PASSED"
end if
end program

!! file: vecfoo.f90
integer function foo(a, b)
!$omp declare simd

```

```
implicit none
integer, intent(in) :: a, b
  foo = a - b
end function
```

This example gives output like the following, reporting that vectorization did occur:

```
[49 C:/temp] ifort -nologo -qopt-report2 -qopt-report-phase=vec -qopt-report-file=stderr
simdmain.f90 vecfoo.f90 -qopenmp

### Restrictions on Using an !\$OMP DECLARE SIMD Declaration

Vectorization depends on two major factors: hardware and the style of source code. When using the vector declaration, the following features are not allowed:

- Locks, barriers, atomic construct, critical sections (These are allowed inside !\$OMP ORDERED SIMD blocks).
- Computed and assigned GOTO and SELECT CASE constructs (in some cases these may be supported and converted to IF statements).
- The GOTO statement, into or out of a function.
- An ENTRY statement.

Non-vector function calls are generally allowed within vector functions but calls to such functions are serialized lane-by-lane and so might perform poorly. Also for SIMD-enabled functions it is not allowed to have side effects except writes by their arguments. This rule can be violated by non-vector function calls, so be careful executing such calls in SIMD-enabled functions and subroutines.

Formal parameters must be of the following data types:

- (un)signed 8, 16, 32, or 64-bit integer
- 32- or 64-bit floating point
- 64- or 128-bit complex

[Function Annotations and the SIMD Directive for Vectorization](#)

### Function Annotations and the SIMD Directive for Vectorization

This topic presents specific Fortran language features that better help to vectorize code.

---

**NOTE**

The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

---

The `!DIR$ ATTRIBUTES ALIGN:n` directive enables you to overcome hardware alignment constraints. The `restrict` qualifier and the auto-vectorization hints address the stylistic issues due to lexical scope, data dependency, and ambiguity resolution. The SIMD feature's directive allows you to enforce vectorization of loops.

You can use the `!DIR$ ATTRIBUTES VECTOR[:clauses]::function-name-list` directive to vectorize user-defined functions and loops. For SIMD usage, a function with the VECTOR attribute is called from a loop that is being vectorized.

You can use the `and` declarations to provide a user-defined vector implementation for a function.

The usage model of the VECTOR attribute takes a small section of code generated for the function ( `VECTORLENGTH` ) of the array and exploits SIMD parallelism. The implementation of task parallelism is done at the call site.

The following table summarizes the language features that help vectorize your code:

Language Feature	Description
<code>!DIR\$ ATTRIBUTES ALIGN : n :: var</code>	Directs the compiler to align the variable to an <i>n</i> -byte boundary. Address of the variable is <i>address mod n=0</i> .
	Directs the compiler to align the variable to an <i>n</i> -byte boundary with offset <i>off</i> within each <i>n</i> -byte boundary. Address of the variable is <i>address mod n=off</i> .
<code>__declspec(vector)</code> (Windows)	Combines with the <code>map</code> operation at the call site to provide the data parallel semantics. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced.
<code>__attribute__((vector))</code> (Linux and macOS)	
<code>!DIR\$ ATTRIBUTES VECTOR [: clauses] :: function-name-list</code>	Provides data parallel semantics by combining with the vectorized operations or loops at the call site. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced. The clauses are: <ul style="list-style-type: none"> <li>• PROCESSOR</li> <li>• VECTORLENGTH</li> <li>• LINEAR</li> <li>• UNIFORM</li> <li>• [NO]MASK</li> </ul>
<code>restrict</code>	Permits the disambiguator flexibility in alias assumptions, which enables more vectorization. <ul style="list-style-type: none"> <li>•</li> <li>• <code>simd-clauses</code> (optional): one or more of the clauses allowed for the vector attribute</li> </ul>
<code>__assume_aligned(a, n)</code>	Instructs the compiler to assume that array <i>a</i> is aligned on an <i>n</i> -byte boundary; used in cases where the compiler has failed to obtain alignment information.
<code>__assume(cond)</code>	Instructs the compiler to assume that the represented condition is true where the keyword appears. Typically used for conveying properties that the compiler can take advantage of for generating more efficient code, such as alignment information.

The following table summarizes the auto-vectorization hints that help vectorize your code:

Hint	Description
!DIR\$ IVDEP	Instructs the compiler to ignore assumed vector dependencies.
!DIR\$ VECTOR [ALWAYS]	Specifies how to vectorize the loop and indicates that efficiency heuristics should be ignored. Using the <code>ASSERT</code> keyword with the <code>VECTOR [ALWAYS]</code> directive generates an error-level assertion message if the compiler efficiency heuristics indicate that the loop cannot be vectorized. Use <code>DIR\$ IVDEP</code> to ignore the assumed dependencies.
!DIR\$ NOVECTOR	Specifies that the loop should never be vectorized.

**NOTE**

Some directives are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

The following table summarizes the user-mandated directives that help vectorize your code:

User-Mandated Directive	Description
!DIR\$ SIMD	Enforces vectorization of loops.
<a href="#">SIMD Directive (OpenMP)</a>	Requires and controls SIMD vectorization of loops.

## Guided Auto Parallelism

**NOTE** This feature is only available for ifort.

The Guided Auto Parallelism (GAP) feature of the Intel®Fortran Compiler is a tool that offers selective advice to improve the performance of serially-coded applications by suggesting changes that take advantage of the compiler's ability to automatically vectorize and parallelize code and improve the efficiency of data operations. Despite having the words "auto parallelism" in the name, this tool does not require a threaded code implementation to improve the execution performance of the code, or require that the code is already threaded or parallel.

Advanced optimization techniques, such as inter-procedural analysis or profile-guided feedback, are not needed to use this feature. Using the `[Q]guide` set of options in addition to the compiler options normally used is sufficient to enable the GAP feature, with the requirement that you must compile with `O2` or higher optimization levels. The compiler does not generate any object files or executables during the GAP run.

In debug mode (`/Zi` on Windows\*, `-g` on Linux\*), the compiler's optimization level defaults to `/Od` (on Windows\*) or `-O0` (on Linux\* and macOS); thus `O2` (or a higher level optimization) must be specified explicitly on the command-line.

---

**NOTE** Use the `[Q]diag-disable` option along with the `[Q]guide` option to direct the compiler to suppress specific diagnostic messages. For example, the options `-guide, -diag-disable:30534` (Linux) or `/Qguide, /Qdiag-disable:30534` (Windows) tell the compiler not to emit the 30534 diagnostic. The `[Q]diag-disable` mechanism works the same way as it does for compiler-warnings.

---

If you decide to follow the advice offered by the GAP tool by making the suggested code changes and/or using the suggested compiler options, you must then recompile the program without the `[Q]guide` option.

Any advice generated by the compiler when using the GAP tool is optional; it can be implemented or rejected. The advice typically falls under three broad categories:

- **Advice for source modifications:** The compiler advises you to make source changes that are localized to a loop-nest or a routine. For example, the tool may recommend that you use a local-variable for the upper-bound of a loop, or that you should initialize a local variable unconditionally at the top of the loop-body, .
- **Advice to apply directives:** The compiler advises you to apply a new directive on a certain loop-level if the directive semantics can be satisfied (you must verify this). In many cases, you may be able to apply the directive (thus implicitly asserting new program/loop properties) that the compiler can take advantage of to perform enhanced optimizations.
- **Advice to add compiler options:** The compiler advises you to add command-line options that assert new properties. These suggested compiler options apply to the entire file. It is your responsibility to check that the properties asserted by these options are valid for the entire file, and not just the loop in question.

If you use GAP options along with option `[Q]parallel`, the compiler may suggest options to further parallelize your application. The compiler may also offer advice on enabling other optimizations of your application, including vectorization.

If you use the GAP options without enabling auto parallelism (without using the `[Q]parallel` option), the compiler may only suggest enabling optimizations such as vectorization for your application. This approach is recommended when you wish to improve the performance of a single-threaded code without the use of parallelization or when you want to improve the performance of threaded applications that do not rely on the compiler for auto parallelism.

### Using Guided Auto Parallelism

`diag`

compiler option

`g`

compiler option

## Use Guided Auto Parallelism

---

---

**NOTE** This feature is only available for ifort.

---

The Guided Auto Parallelism feature of the Intel® Fortran Compiler is a tool offering selective advice to improve the performance of serially-coded applications. The tool suggests changes that take advantage of the compiler's ability to automatically vectorize and parallelize code as well as improve the efficiency of data operations. The tool does not require that you implement threaded code to improve the execution performance of your code, nor does it require that your code is already threaded or parallel code.

To invoke this tool, use the compiler option `[Q]guide[=n]`. Using this option causes the compiler to generate messages suggesting ways to optimize the performance of your application. You can also use more specific compiler options such as `[Q]guide-vec`, `[Q]guide-par`, and `[Q]guide-data-trans` , to perform individual guided optimizations for vectorizing, parallelizing, and data transformation of your application.

When any guided auto parallelism option is used, the compiler provides only diagnostic advice. Object files or executables are not created in this mode. See the table below for descriptions of the options.

Syntax	Description
[Q]guide	<p>Allows you to set a level of guidance for auto-vectorization and data transformation analysis.</p> <p>To obtain guidance for auto parallelism, you must use the [Q]parallel option along with the [Q]guide option.</p> <p>Allows you to set a level of guidance only for auto parallelism analysis.</p>
[Q]guide-par	<p><b>NOTE</b> You must use the [Q]parallel option along with the [Q]guide-par option to get this advice.</p>
[Q]guide-vec	Allows you to set a level of guidance for auto-vectorization analysis only.
[Q]guide-data-trans	Allows you to set a level of guidance for data transformation analysis only.

For all of the above options, the optional argument *n* specifies the level of guidance. The argument *n* takes the values 1–4. When *n* is not specified, the default is 4. If you specify *n*=1 or 2, a standard level of guidance is provided.

When you use *n*=3 or *n*=4, you may get advanced messages. For example, you may get messages about how to optimize a particular loop-nest or get a message on how exception-handling inside a loop-nest affects optimizations for that loop-nest. Or you may get a message on how to provide extra information to the compiler on cost-modeling (expected values of trip-counts, and so on).

If you simultaneously specify a level of guidance for the general [Q]guide option and also for one or more of the other specific guide options, the level of guidance (*n*) for the specific guide option overrides the general [Q]guide option setting.

If you do not specify a level of guidance for the general [Q]guide option, but do set a level of guidance for one or more of the specific guide options, the [Q]guide option is set equal to the greatest value passed to the specific guide options.

## Capture Guidance Messages

The guided auto parallelism tool analyzes all of your serial code or individual parts of your code and generates advisory messages. By default, messages that are generated by the guided auto parallelism tool are output to `stderr`.

To capture messages in a file, use the options listed in the following table.

### NOTE

The options listed in the following table must be used with the [Q]guide, [Q]guide-par, [Q]guide-vec, or [Q]guide-data-trans options. If not, they are ignored.

Syntax	Description
[Q]guide-file	Gathers all messages generated during a guided auto-parallelization run into the specified file.
[Q]guide-file-append	Allows you to specify the file into which all messages generated during a guided auto parallelism run should be appended.

For the above options, the *file\_name* argument can also include a path. If a path is not specified, the file is created in the current working directory. If there is already a file named *file\_name*, it is overwritten when you use the `[Q]guide-file` option. If you do not include an extension as part of the *file\_name*, the extension `.guide` is appended.

## Configure Code Regions for GAP Messages

To limit guided auto parallelism analysis to specific regions (hotspots) in your application, use the option mentioned in the table below.

Syntax	Description
<code>[Q]guide-opts</code>	Allows you to analyze specified code elements, identified by <i>string</i> .

You must use the `[Q]guide-opts` option along with one of the guided auto parallelism options, such as `[Q]guide`, `[Q]guide-vec`, `[Q]guide-par`, and `[Q]guide-data-trans`. Use the *string* parameter to provide information about known areas of interest (hotspots). The *string* parameter takes one or more of the following variables: *filename*, *routine*, *range*. The compiler parses the *string* parameter and generates syntax errors if there are any. For example:

### Linux

```
-guide-opts:string
```

### Windows

```
/Qguide-opts:string
```

Follow these guidelines when using the *string* parameter:

- Use only valid file names, routine names, and line numbers. The guided auto parallelism tool ignores invalid values and issues a diagnostic message stating what was ignored.
- Enclose routine names within single quotation marks. Specify original source names (demangled names) as routine names. A routine name alone may not always be sufficient to uniquely identify a routine. You may need to specify additional parameter information to uniquely identify the routine.

For any specified routine name, the GAP tool first tries to uniquely identify the routine using specified routine information. If that is not possible, then it selects all routines with the specified routine name. The GAP tool uses the parameter information, if specified, to narrow the selection.

- When inlining is involved, use the callee line numbers. The generated messages also use the callee line numbers.

# Guided Auto Parallelism Messages

---

---

**NOTE** This feature is only available for ifort.

---

The Guided Auto Parallelism (GAP) messages provide advice that should improve optimizations.

The messages provide suggestions for:

- Automatic parallelization of loop nests
- Automatic vectorization of inner loops
- Data transformation

You must decide whether to follow a particular suggestion. For example, if the advice is to apply a particular directive, you must understand the semantics of the directive and carefully consider whether it can be safely applied to the loop (or loop nest) in question.

If you apply the directive improperly, the compiler may generate incorrect code, causing the application to execute incorrectly.

If you do not fully understand the suggested advice, please refer to the relevant topics in the compiler documentation before applying that advice.

Once you apply the suggested advice, the compiler assumes that it is correct and it does not perform any checks or issue any warnings.

In general, messages that relate to loops tend to target vectorization and/or parallelization of loops. If you are not familiar with loop optimizations, please refer to the compiler documentation on this kind of optimization.

Optimizations can be helped or hindered when data is fetched from or stored to memory. Sometimes these fetch and store operations are referred to as reads and writes, but do not confuse these with `READ` and `WRITE` input/output statements. A `READ` statement (input) is only one of many ways to cause a store to memory, and a `WRITE` statement (output) is only one of many ways to cause a fetch from memory. Values in an expression must be fetched from (read from) memory before the expression can be evaluated. Variables on the left-hand side of an assignment will be the target of a store to (write to) memory. Actual arguments passed to called procedures can be fetched from and stored to memory.

## GAP Message (Diagnostic ID 30506)

---

**NOTE** This feature is only available for ifort.

---

## Message

If the following operations(s) can be safely performed unconditionally, the loop at line %d will be vectorized by adding a "%s ivdep" statement right before the loop: %s.

## Advice

Add `"!DIR$ IVDEP"` before the specified loop.

This directive enables the vectorization of the loop at the specified line. Insure that any conditional divide, sqrt, and inverse sqrt operations will not alter the exception semantics expected by the program when they are performed unconditionally.

## Example

Consider the following:

```

subroutine foo(a, n)
  integer n
  real a(n)
  do i=1,n
    if (a(i) .gt. 0) then
      a(i) = 1 / a(i)
    endif
  enddo
end

```

In this case, the compiler is unable to vectorize the loop since the condition `"a(i) .gt. 0"` may be guarding floating-point exceptions for the divide.

If you determine it is safe to do so, you can add the directive as follows:

```

subroutine foo(a, n)
  integer n
  real a(n)
!dir$ ivdep
  do i=1,n
    if (a(i) .gt. 0) then
      a(i) = 1 / a(i)
    endif
  enddo
end

```

## Verify

Confirm that the program operands have safe values for all iterations.

## GAP Message (Diagnostic ID 30513)

---

**NOTE** This feature is only available for ifort.

---

## Message

Insert a `"%s ivdep"` statement right before the loop at line `%d` to vectorize the loop.

## Advice

Add `"!DIR$ IVDEP"` before the specified loop. This directive enables the vectorization of the loop at the specified line by ignoring some of the assumed cross-iteration data dependencies.

## Example

Consider the following:

```
subroutine foo(a, m, n)
  integer m, n
  real a(n)
  do i=1,n
    a(i) = a(i+m) + 1
  enddo
end
```

In this case, the compiler is unable to vectorize the loop because *m* could be -1, where each iteration is dependent on the previous iteration. If *m* is known to be positive, you can vectorize this loop.

If you determine it is safe to do so, you can add the directive as follows:

```
subroutine foo(a, m, n)
  integer m, n
  real a(n)
!dir$ ivdep
  do i=1,n
    a(i) = a(i+m) + 1
  enddo
end
```

## Verify

Confirm that any arrays in the loop do not have unsafe cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a fetch or store operation in another iteration of the loop. Make sure that there are no such dependencies, or that any cross-iteration dependencies can be safely ignored.

## GAP Message (Diagnostic ID 30515)

---

**NOTE** This feature is only available for ifort.

---

## Message

Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be vectorized.

## Advice

You should unconditionally initialize the scalar variables at the beginning of the specified loop. This allows the vectorizer to privatize those variables for each iteration and vectorize the loop. You must ensure that all the uses of those variables see the same values before and after the source code change.

## Example

Consider the following:

```
subroutine foo(a, n)
  integer n
  do i=1,n
    if (a(i) .gt. 0) then
      b = a(i)
      a(i) = 1 / a(i)
    end if
  enddo
end
```

```

endif
if (a(i) .gt. 1) then
  a(i) = a(i) + b
endif
enddo
end

```

In this case, the compiler is unable to vectorize the loop because it failed to privatize the variable *b*. Vectorization is assisted when assignment to *b* occurs in each iteration where the value of *b* is used. One of the ways to do this is to assign the value in every iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```

subroutine foo(a, n)
  integer n
  real a(n), b
  do i=1,n
    b = a(i)
    if (a(i) .gt. 0) then
      a(i) = 1 / a(i)
    endif
    if (a(i) .gt. 1) then
      a(i) = a(i) + b
    endif
  enddo
end

```

## Verify

Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration.

## GAP Message (Diagnostic ID 30519)

---

**NOTE** This feature is only available for ifort.

---

## Message

Insert a "%s parallel" statement right before the loop at line %d to parallelize the loop.

## Advice

Add "!DIR\$ PARALLEL" before the specified loop. This directive enables the parallelization of the loop at the specified line by ignoring assumed cross-iteration data dependencies.

## Example

Consider the following:

```

subroutine foo(a, m, n)
  real a(n)
  do i=1,n
    a(i) = a(i+m) + 1
  enddo
end

```

In this case, the compiler is unable to parallelize the loop without further information about  $m$ . For example, if  $m$  is negative, then each iteration will be dependent on the previous iteration. However, if  $m$  is known to be greater than  $n$ , you can parallelize the loop.

If you determine it is safe to do so, you can add the directive as follows:

```
subroutine foo(a, m, n)
  real a(n)
  !dir$ parallel
  do i=1,n
    a(i) = a(i+m) + 1
  enddo
end
```

## Verify

Confirm that any arrays in the loop do not have cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a fetch or store operation in another iteration of the loop.

## GAP Message (Diagnostic ID 30521)

---

**NOTE** This feature is only available for ifort.

---

## Message

Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.

## Advice

Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a parallel directive (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

## Example

Consider the following:

```
subroutine foo (A, B, cond1, cond2)
  integer, parameter :: N = 100000
  integer I
  real(8) A(N), B(N), T
  logical cond1, cond2

  do I = 1, N
    if (cond1) T = i + 1
    if (cond2) T = i - 1
    A(I) = T
  end do
end
```

In this case, the compiler does not parallelize the loop because it cannot privatize the variable  $t$  without further information. If you know that  $\text{cond1}$  or  $\text{cond2}$  is true, or both  $\text{cond1}$  and  $\text{cond2}$  are true, then you can assist the parallelizer by ensuring that any iteration that uses  $t$  also writes to  $t$  before its use in the same iteration. One of the ways to do this is to assign a value to  $t$  at the top of each iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```
subroutine foo (A, B, cond1, cond2)
  integer, parameter :: N = 100000
  integer I
  real(8) A(N), B(N), T
  logical cond1, cond2

  do I = 1, N
    T = 0
    if (cond1) T = i + 1
    if (cond2) T = i - 1
    A(I) = T
  end do
end
```

## Verify

Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration.

## See Also

[GAP Message \(Diagnostic ID 30523\)](#)

## GAP Message (Diagnostic ID 30522)

---

**NOTE** This feature is only available for ifort.

---

## Message

Insert a "%s parallel private(%s)" statement right before the loop at line %d to parallelize the loop.

## Advice

Add "!DIR\$ PARALLEL PRIVATE" before the specified loop. This directive enables the parallelization of the loop at the specified line.

## Example

Consider the following:

```
subroutine foo (A, B, C, n, m1, m2)
  real (4) A(10000, 10), B(10000, 10), C(10000, 10)
  integer n, m1, m2
  real W(1000)
  integer i, j

  do i=1,n
    do j=1,m1
      W(j) = A(j,i) * B(j,i)
    end do
    do j=1,m2
      C(j,i) = W(j) + 1.0
    end do
  end
```

In this case, the compiler does not parallelize the loop since it cannot determine whether  $m1 \geq m2$ .

If you know that this property is true, and that no element of W is fetched before it is written to after the loop, then you can use the recommended directive.

If you determine it is safe to do so, you can add the directive as follows:

```
subroutine foo (A, B, C, n, m1, m2)
  real (4) A(10000, 10), B(10000, 10), C(10000, 10)
  integer n, m1, m2
  real W(1000)
  integer i, j

!DIR$ PARALLEL PRIVATE (W)
do i=1,n
  do j=1,m1
    W(j) = A(j,i) * B(j,i)
  end do
  do j=1,m2
    C(j,i) = W(j) + 1.0
  end do
end do
end
```

## Verify

Before an element of an array can be fetched in the loop, there must have been a previous store to it during the same loop iteration. In addition, if an element is fetched after the loop, there must have been a previous write to it before the fetch after the loop.

## GAP Message (Diagnostic ID 30523)

---

**NOTE** This feature is only available for ifort.

---

## Message

Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.

## Advice

Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a PARALLEL directive (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

## Verify

Confirm that in the original program, any variables fetched in any iteration of the loop have been defined earlier in the same iteration or have been privatized by means of the private clause of a PARALLEL directive.

## See Also

[GAP Message \(Diagnostic ID 30521\)](#)

## GAP Message (Diagnostic ID 30525)

---

**NOTE** This feature is only available for ifort.

---

## Message

Insert a "%s loop count min(%d)" statement right before the loop at line %d to parallelize the loop.

## Advice

Add "!DIR\$ LOOP COUNT" before the specified loop. This directive indicates the minimum trip count (number of iterations) of the loop that enables the parallelization of the loop.

## Example

Consider the following:

```

subroutine foo (n)
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  integer :: i, n
  do i =1, n
    A(i) = B(i) * B(i)
  end do
end subroutine foo

```

In this case, if the trip count of the loop at line 5 is greater than 128, then use the LOOP COUNT directive to parallelize this loop.

If you determine it is safe to do so, you can add the directive as follows:

```

subroutine foo (n)
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  integer :: i, n
  !dir$ loop count min(128)
  do i =1, n
    A(i) = B(i) * B(i)
  end do
end subroutine foo

```

Make sure that the loop has a minimum of 128 iterations.

## Verify

Confirm that the loop has the minimum number of iterations, as specified in the diagnostic message.

## See Also

[Guided Auto Parallelism Messages](#) provides advice for improving optimizations

## GAP Message (Diagnostic ID 30526)

---

**NOTE** This feature is only available for ifort.

---

## Message

To parallelize the loop at line %d, annotate the routine %s with %s.

## Advice

If the loop contains a call to a function, the compiler cannot parallelize the loop without more information about the function being called.

However, if the function being called in the loop is an elemental function or a function specified with `ATTRIBUTES CONcurrency_SAFE`, then the call does not inhibit parallelization of the loop.

### Example

Consider the following:

```
subroutine foo ()
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  interface
    function bar (k)
      integer :: bar, k
    end function bar
  end interface

  integer :: i
  do i =1, N2
    A(i) = B(i) * bar(N2)
  end do
end subroutine foo
```

In this case, to parallelize the loop at line 11, declare the routine `bar` as elemental.

If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```
subroutine foo ()
  integer, parameter :: N2 = 10000
  real (8) :: A(N2), B(N2)
  interface
    function bar (k)
      !dir$ attributes concurrency_safe : profitable :: bar
      integer :: bar, k
    end function bar
  end interface

  integer :: i
  do i =1, N2
    A(i) = B(i) * bar(N2)
  end do
end subroutine foo
```

### Verify

Confirm the routine satisfies the semantics of this annotation. A weaker annotation able to achieve a similar effect is `ATTRIBUTES CONcurrency_SAFE(PROFITABLE)`.

### See Also

[GAP Message \(Diagnostic ID 30528\)](#)

### GAP Message (Diagnostic ID 30528)

---

**NOTE** This feature is only available for ifort.

---

### Message

Add "%s" to the declaration of routine "%s" in order to parallelize the loop at line %d. Adding "%s" achieves a similar effect.

## Advice

Confirm that the routine specified is indeed an elemental function or an `ATTRIBUTES CONcurrency_SAFE` function before following the advice to add the annotation.

If the routine is not one of these kinds of functions, try to inline it with a `FORCEINLINE RECURSIVE` directive. This action may or may not be beneficial.

## Example

Consider the following:

```
subroutine foo ()
integer, parameter :: N2 = 10000
real (8) :: A(N2), B(N2)
interface
  function bar (k)
    integer :: bar, k
  end function bar
end interface

integer :: i
do i =1, N2
  A(i) = B(i) * bar(N2)
end do
end subroutine foo
```

In this case, to parallelize the loop at line 11, declare the routine `bar` as elemental.

If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```
subroutine foo ()
integer, parameter :: N2 = 10000
real (8) :: A(N2), B(N2)
interface
  function bar (k)
!dir$ attributes concurrency_safe : profitable
    integer :: bar, k
  end function bar
end interface

integer :: i
do i =1, N2
  A(i) = B(i) * bar(N2)
end do
end subroutine foo
```

## Verify

Confirm that the routine satisfies the semantics of this declaration. Another way to help the loop being parallelized is to inline the routine with the `FORCEINLINE RECURSIVE` directive, but this method does not guarantee parallelization.

### Message

Compile with the %s option to vectorize and/or parallelize the loop at line %d.

### Advice

Use the [q or Q]opt-subscript-in-range option for the specified file during compilation.

This option helps the compiler vectorize and parallelize the loop at the specified line. You must verify that the loops in the file do not contain very large integers and are not likely to generate very large integers in intermediate computations. A very large integer is loosely defined as follows: On an  $n$ -bit machine, a very large integer is typically  $\geq 2^{n-2}$ . For example, on a 32-bit machine, a very large integer would be  $\geq 2^{30}$ .

### Verify

Confirm that no loop in the program contains or generates very large integers (typically very large integers are  $\geq 2^{30}$ ).

### GAP Message (Diagnostic ID 30538)

---

**NOTE** This feature is only available for ifort.

---

### Message

Moving the block of code that consists of a function-call (line %d), if-condition (line %d), and an early return (line %d) to outside the loop may enable parallelization of the loop at line %d.

### Advice

Move the function call and an associated return from inside the loop (perhaps by inserting them before the loop) to help parallelize the loop.

This kind of function-leading-to-return inside a loop usually handles some error-condition inside the loop. If this error check can be done before starting the execution of the loop without changing the program semantics, the compiler may be able to parallelize the loop thus improving performance.

### Verify

Confirm that the function call does not rely on any computation inside the loop and that restructuring the code as suggested above, retains the original program semantics.

## Profile-Guided Optimization

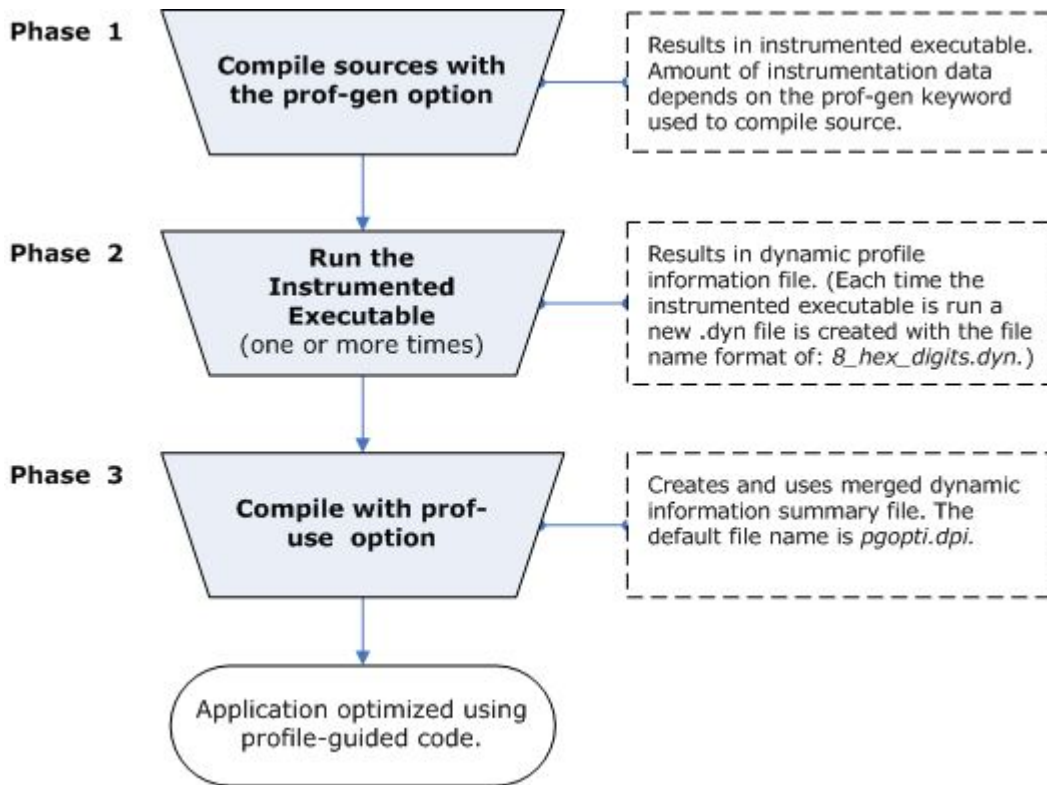

---

Profile-guided Optimization (PGO) improves application performance by shrinking code size, reducing branch mispredictions, and reorganizing code layout to reduce instruction-cache problems. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

PGO consists of three phases or steps.

1. Instrument the program. The compiler creates and links an instrumented program from your source code and special code from the compiler.
2. Run the instrumented executable. Each time you execute the instrumented code, the instrumented program generates a dynamic information file, which is used in the final compilation.

3. Final compilation. When you compile a second time, the dynamic information files are merged into a summary file. Using the summary of the profile information in this file, the compiler attempts to optimize the execution of the most heavily traveled paths in the program.

See [Profile-Guided Optimization Options](#) for information about the supported options and [Profile an Application](#) for specific details about using PGO from the command line.

PGO provides the following benefits:

- Use profile information for register allocation to optimize the location of spill code.
- Improve branch prediction for indirect function calls by identifying the most likely targets. Some processors have longer pipelines, which improves branch prediction and translates into high performance gains.
- Detect and do not vectorize loops that execute only a small number of iterations, reducing the runtime overhead that vectorization might otherwise add.

[Interprocedural optimization \(IPO\)](#) and PGO can affect each other; using PGO can often enable the compiler to make better decisions about [inline function expansion](#), which increases the effectiveness of interprocedural optimizations. Unlike other optimizations, such as those strictly for size or speed, the results of IPO and PGO vary. This variability is due to the unique characteristics of each program, which often include different profiles and different opportunities for optimizations.

## Performance Improvements with PGO

PGO works best for code with many frequently executed branches that are difficult to predict at compile time. An example is the code with intensive error-checking in which the error conditions are false most of the time. The infrequently executed (cold) error-handling code can be relocated so the branch is rarely predicted incorrectly. Minimizing cold code interleaved into the frequently executed (hot) code improves instruction cache behavior.

When you use PGO, consider the following guidelines:

- Minimize changes to your program after you execute the instrumented code and before feedback compilation. During feedback compilation, the compiler ignores dynamic information for functions modified after that information was generated. If you modify your program, the compiler can issue a warning that the dynamic information does not correspond to a modified function when PGO remarks are enabled or found in the optimization report.
- Repeat the instrumentation compilation if you make many changes to your source files after execution and before feedback compilation.
- Know the sections of your code that are the most heavily used. If the data set provided to your program is very consistent and displays similar behavior on every execution, then PGO can probably help optimize your program execution.
- Different data sets can result in different algorithms being called. The difference can cause the behavior of your program to vary for each execution. In cases where your code behavior differs greatly between executions, PGO may not provide noticeable benefits. If it takes multiple data sets to accurately characterize application performance, execute the application with all data sets then merge the dynamic profiles; this technique should result in an optimized application.

You must insure that the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

## Profile-Guided Optimization via Hardware Counters

A lightweight profiling mechanism can be used to achieve many of the benefits of instrumentation-based profiling, but without the overhead of inserting instrumentation into the application binary. This mode of operation can be beneficial in cases where increased code/data size or changes in runtime due to instrumentation may make regular Performance-Guided Optimization (PGO) infeasible. This approach requires the use of Intel® VTune™ Profiler to collect information from the hardware counters. The information is collected with minimal overhead, and combined with debug information produced by the compiler to identify the primary code path for optimizations.

Follow these steps to use this method:

1. Compile the application with the option `prof-gen-sampling`.

This option instructs the compiler to generate additional debug information for the application, which is used to map the information collected by the hardware counters to a specific source code. Using this option does not affect the generated instruction sequence in the way that instrumented PGO does. Optimizations may be enabled during this build, but it is recommended that you disable function inlining.

2. Run the generated executable on one or more representative workloads with the Intel VTune Profiler tool:

```
<installation-root>/bin64/amplxe-pgo-report.sh <your application and command line>
```

Additional information regarding options for data collection can be found in the Intel VTune Profiler documentation. This step generates files in the form: `rNNNpgo_icc.pgo` (where `NNN` is a three digit number). These files are used as input in the next steps.

3. Merge the report files produced during step 2.

The tool `profmergesampling` can be used to produce an indexed file of results that speeds up processing data during the next step.

```
profmergesampling -file <input-file[:input_file]*> -out <output_name>
```

4. Compile the application with the option `prof-use-sampling:input-file[:input_file]*`

In this step, one or more result files produced during step 2 (or an indexed file from step 3) can be fed into the compiler to direct the optimizations.

compiler option

## Profile an Application with Instrumentation

Profiling an application includes the following three phases:

- [Instrumentation compilation and linking](#)
- [Instrumented execution](#)
- [Feedback compilation](#)

This topic provides detailed information on how to profile an application by providing sample commands for each of the three phases (or steps).

### 1. Instrumentation compilation and linking

Use `[Q]prof-gen` to produce an executable with instrumented information included. Use `/Qcov-gen` (Windows) option to obtain minimum instrumentation only for code coverage.

Operating System	Commands
Linux and macOS	<pre>ifort -prof-gen -prof-dir /usr/profiled a1.f90 a2.f90 a3.f90  ifort -o a1 a1.o a2.o a3.o</pre>
Windows	<pre>ifort /Qprof-gen /Qprof-dir:c:\profiled a1.f90 a2.f90 a3.f90  ifort a1.obj a2.obj a3.obj</pre>
Windows	<pre>ifort /Qcov-gen /Qcov-dir:c:\cov_data a1.f90 a2.f90 a3.f90  ifort a1.obj a2.obj a3.obj</pre>

Use the `[Q]prof-dir` or `/Qcov-dir` (Windows) option if the application includes the source files located in multiple directories; using the option insures the profile information is generated in one consistent place. The example commands demonstrate how to combine these options on multiple sources.

The compiler gathers extra information when you use the `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows) option; however, the extra information is collected to provide support for specific Intel tools, including the code coverage Tool. If you do not expect to use such tools, do not specify `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows); the extended option does not provide better optimization and could slow parallel compile times. If you are interested in using the instrumentation only for code coverage, use the `/Qcov-gen` (Windows) option, instead of the `/Qprof-gen:srcpos` (Windows) option, to minimize instrumentation overhead.

PGO data collection is optimized for collecting data on serial applications at the expense of some loss of precision on areas of high parallelism. However, you can specify the `threadsafe` keyword with the `-prof-gen` (Linux\* and macOS) or the `/Qprof-gen` (Windows) compiler option for files or applications that contain parallel constructs using OpenMP\* features, for example. Using the `threadsafe` keyword produces instrumented object files that support the collection of PGO data on applications that use a high level of parallelism but may increase the overhead for data collection.

#### NOTE

Unlike serial programs, parallel programs using OpenMP\* may involve dynamic scheduling of code paths, and counts collected may not be perfectly reproducible for the same training data set.

### 2. Instrumented execution

Run your instrumented program with a representative set of data to create one or more dynamic information files.

Operating System	Command
Linux and macOS	<code>./a1.out</code>
Windows	<code>a1.exe</code>

Executing the instrumented applications generates a dynamic information file that has a unique name and .dyn suffix. A new dynamic information file is created every time you execute the instrumented program.

You can run the program more than once with different input data.

By default, the .dyn filename follows this naming convention: <timestamp>\_<pid>.dyn. The .dyn file is either placed into a directory specified by an environment variable, a compile-time specified directory, or the current directory.

To make it easy to distinguish files from different runs, you can specify a prefix for the .dyn filename in the environment variable, INTEL\_PROF\_DYN\_PREFIX. In such a case, executing the instrumented application generates a .dyn filename as follows: <prefix>\_<timestamp>\_<pid>.dyn, where <prefix> is the identifier that you have specified. Be sure to set the INTEL\_PROF\_DYN\_PREFIX environment variable prior to starting your instrumented application.

#### NOTE

The value specified in INTEL\_PROF\_DYN\_PREFIX environment variable must not contain < > : " / \ | ? \* characters. The default naming scheme will be used if an invalid prefix is specified.

### 3. Feedback compilation

Before this step, copy all .dyn and .dpi files into the same directory. Compile and link the source files with [Q]prof-use; the option instructs the compiler to use the generated dynamic information to guide the optimization:

Operating System	Examples
Linux and macOS	<code>ifort -prof-use -ipo -prof-dir /usr/ profiled a1.f90 a2.f90 a3.f90</code>
Windows	<code>ifort /Qprof-use /Qipo /Qprof- dir:c:\profiled a1.f90 a2.f90 a3.f90</code>

This final phase compiles and links the sources files using the data from the dynamic information files generated during instrumented execution (phase 2).

In addition to the optimized executable, the compiler produces a pgopti.dpi file.

Most of the time, you should specify the default optimizations, O2, for phase 1, and specify more advanced optimizations, [Q]ipo, during the phase 3 (final) compilation. The example shown above used O2 in step 1 and [Q]ipo in step 3.

#### NOTE

The compiler ignores the [Q]ipo or [Q]ip option during phase 1 with [Q]prof-gen.

## Profile-Guided Optimization Report

The PGO report can help identify where and how the compiler used profile information to optimize the source code. The PGO report can also identify where profile information was discarded due to source code changes made between the time of instrumentation and feedback steps. The PGO report is most useful when combined with the PGO compilation steps outlined in the topic, [Profile an Application with Instrumentation](#). Without the profiling data generated during the application profiling process the report will generally not provide useful information.

Combine the final PGO step with the reporting options by including `-prof-use` (Linux\* and macOS) or `/Qprof-use` (Windows\*). The following syntax examples demonstrate how to run the report using the combined options.

Operating System	Syntax Examples
Linux*	<code>ifort -prof-use -qopt-report-phase=pgo pgotools_sample.c</code>
macOS	<code>icpc -prof-use -qopt-report-phase=pgo pgotools_sample.c</code>  <code>ifort -prof-use -qopt-report-phase=pgo pgotools_sample.c</code>
Windows*	<code>ifort pgotools_sample.c /Qprof-use /Qopt-report- phase=pgo</code>

By default the PGO report generates a medium level of detail (where the `[q or Q]opt-report` argument `n=2`). You can use the `-qopt-report=n` (Linux and macOS) or `/Qopt-report:n` option along with the `[q or Q]opt-report-phase` option if you want a greater or lesser level of diagnostic detail.

The output, by default, comes out to a file with the same name as the object file but with an `.optrpt` extension and is written into the same directory as the object file. Using the entries in the example above, the output file will be `pgotools_sample.optrpt`. Use the `-qopt-report-file` (Linux and macOS) or the `/Qopt-report-file` (Windows) option to specify any other name for the output file that captures the report results, or to specify that the output should go to `stdout` or `stderr`.

[Profile an Application](#)

## PGO Tools

This section describes the tools that take advantage of or support the Profile-guided Optimizations (PGO) available in the compiler.

### Code Coverage Tool

The code coverage tool provides software developers with a view of how much application code is exercised when a specific workload is applied to the application. To determine which code is used, the code coverage tool uses Profile-guided Optimization (PGO) options and optimizations. The major features of the code coverage tool are listed below:

- Visually presenting code coverage information for an application with a customizable code coverage coloring scheme
- Displaying dynamic execution counts of each basic block of the application
- Providing differential coverage, or comparison, profile data for two runs of an application

The information about using the code coverage tool is separated into the following sections:

- [Code coverage tool Requirements](#)
- [Visually Presenting Code Coverage for an Application](#)

- [Excluding Code from Coverage Analysis](#)
- [Exporting Coverage Data](#)

The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate an HTML-formatted report and export data in both text-, and XML-formatted files. The reports can be further customized to show color-coded, annotated, source-code listings that distinguish between used and unused code.

The code coverage tool is available on all supported Intel architectures on Linux\*, Windows\*, and macOS operating systems.

You can use the tool in a number of ways to improve development efficiency, reduce defects, and increase application performance:

- During the project testing phase, the tool can measure the overall quality of testing by showing how much code is actually tested.
- When applied to the profile of a performance workload, the code coverage tool can reveal how well the workload exercises the critical code in an application. High coverage of performance-critical modules is essential to taking full advantage of the Profile-Guided Optimizations that Intel Compilers offer.
- The tool provides an option useful for both coverage and performance tuning, enabling developers to display the dynamic execution count for each basic block of the application.
- The code coverage tool can compare the profile of two different application runs. This feature can help locate portions of the code in an application that are unrevealed during testing but are exercised when the application is used outside the test space, for example, when used by a customer.

## Code Coverage Tool Requirements

To run the code coverage tool on an application, you must have following items:

- The application sources.
- The .spi file generated by the Intel® compiler when compiling the application for the instrumented binaries using the `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows) option.

### NOTE

Use the `-[Q]prof-gen:srcpos` option if you intend to use the collected data for code coverage and profile feedback. If you are only interested in using the instrumentation for code coverage, use the `/Qcov-gen` option. Using the `/Qcov-gen` option saves time and improves performance. This option can be used only on Windows platform for all architectures.

- A `pgopti.dpi` file that contains the results of merging the dynamic profile information (.dyn) files, which is most easily generated by the `profmerge` tool. This file is also generated implicitly by the Intel® compilers when compiling an application with `[Q]prof-use` options with available .dyn and .dpi files.

## Use the Tool

The tool uses the following syntax:

```
codecov [-codecov_option]
```

where `-codecov_option` is one or more optional parameters specifying the tool option passed to the tool. The available tool options are listed in the code coverage tools Options section. If you do not use any additional tool options, the tool will provide the top-level code coverage for the entire application.

In general, you must perform the following steps to use the code coverage tool:

1. Compile the application using `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows), and/or `/Qcov-gen` (Windows) option.

This step generates an instrumented executable and a corresponding static profile information (`pgopti.spi`) file when the `[Q]prof-gen=srcpos` option is used. When the `/Qcov-gen` option is used, minimum instrumentation only for code coverage and generation of .spi file is enabled.

**NOTE**

You can specify both the `/Qprof-gen=srcpos` and `/Qcov-gen` options on the command line. The higher level of instrumentation needed for profile feedback is enabled along with the profile option for generating the `.spi` file, regardless of the order the options are specified on the command line.

---

**2.** Run the instrumented application.

This step creates the dynamic profile information (`.dyn`) file. Each time you run the instrumented application, the compiler generates a unique `.dyn` file either in the current directory or the directory specified in by the `-prof-dir` (Linux or macOS) or `/Qprof-dir` (Windows) option, or `PROF_DIR` environment variable. On Windows, you can use the `/Qcov-dir` or `COV_DIR` environment variable. These have the same meaning as `/Qprof-dir` and `PROF_DIR`.

**3.** Use the `profmerge` tool to merge all the `.dyn` files into one `.dpi` (`pgopti.dpi`) file.

This step consolidates results from all runs and represents the total profile information for the application, generates an optimized binary, and creates the `dpi` file needed by the code coverage tool.

You can use the `profmerge` tool to merge the `.dyn` files into a `.dpi` file without recompiling the application. The `profmerge` tool can also merge multiple `.dpi` files into one `.dpi` file using the `profmerge -a` option. Select an alternate name for the output `.dpi` file using the `profmerge -prof_dpi` option.

**Caution**

The `profmerge` tool merges all `.dyn` files that exist in the given directory. Confirm that unrelated `.dyn` files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code.

---

**4.** Run the code coverage tool. The valid syntax and tool options are shown below.

This step creates a report or exported data as specified. If no other options are specified, the code coverage tool creates a single HTML file (`CODE_COVERAGE.HTML`) and a sub-directory (`CodeCoverage`) in the current directory. Open the file in a web browser to view the reports.

**NOTE**

Windows\* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

---

The code coverage tool allows you to name the project and specify paths to specific, necessary files. The following example demonstrates how to name a project and specify `.dpi` and `.spi` files to use:

```
codecov -prj myProject -spi pgopti.spi -dpi pgopti.dpi
```

The tool can add a contact name and generate an email link for that contact at the bottom of each HTML page. This provides a way to send an electronic message to the named contact. The following example demonstrates how to add specify a contact and the email links:

```
codecov -prj myProject -mname JoeSmith -maddr js@company.com
```

The following example demonstrates how to use the tool to specify the project name, specify the dynamic profile information file, and specify the output format and file name:

```
codecov -prj test1 -dpi test1.dpi -txtbcvrg test1_bcvrg.txt
```

**Code Coverage Tool Options**

Option	Default	Description
<code>-bcolor</code> <i>color</i>	#FFFF99	Specifies the HTML color name for code in the uncovered blocks.
<code>-beginblkdsbl</code> <i>string</i>		Specifies the comment that marks the beginning of the code fragment to be ignored by the coverage tool.
<code>-blockcounts</code>		When used with <code>-txtlcv</code> , reports individual bloc counts for lines that involved multiple blocks.
<code>-ccolor</code> <i>color</i>	#FFFFFF	Specifies the HTML color name or code of the covered code.
<code>-comp</code> <i>file</i>		Specifies the file name that contains the list of files being (or not) displayed.
<code>-counts</code>		Generates dynamic execution counts.
<code>-demang</code>		Demangles both function names and their arguments.
<code>-dpi</code> <i>file</i>	<code>pgopti.dpi</code>	Specifies the file name of the dynamic profile information file (.dpi).
<code>-endblkdsbl</code> <i>string</i>		Specifies the comment that marks the end of the code fragment to be ignored by the coverage tool.
<code>-fcolor</code> <i>color</i>	#FFCCCC	Specifies the HTML color name for code of the uncovered functions.
<code>-help, -h</code>		Prints tool option descriptions.
<code>-icolor</code> <i>color</i>	#FFFFFF	Specifies the HTML color name or code of the information lines, such as basic-block markers and dynamic counts.
<code>-include-nonexec</code>		Block details will also be listed for functions that did not execute, when used with <code>-xmlbcvrg[full]</code> or <code>-txtbcvrg[full]</code> options.
<code>-maddr</code> <i>string</i>	Nobody	Sets the email address of the web-page owner
<code>-mname</code> <i>string</i>	Nobody	Sets the name of the web-page owner.
<code>-nopartial</code>		Treats partially covered code as fully covered code.
<code>-nopmeter</code>		Turns off the progress meter. The meter is enabled by default.
<code>-nounwind</code>		Ignores compiler-generated unwind handlers for exception handling cleanup when computing and displaying basic block coverage.
<code>-onelinesdbl</code> <i>string</i>		Specifies the comment that marks individual lines of code or the whole functions to be ignored by the coverage tool.
<code>-pcolor</code> <i>color</i>	#FAFAD2	Specifies the HTML color name or code of the partially covered code.
<code>-prj</code> <i>string</i>		Sets the project name.
<code>-ref</code>		Finds the differential coverage with respect to <code>ref_dpi_file</code> .

Option	Default	Description
-showdirnames		Displays the full path name for source files in the HTML report, instead of just the base filename.
-spi <code>file</code>	pgopti.spi	Specifies the file name of the static profile information file (.spi).
-srcroot <code>dir</code>		Specifies a different top level project directory than was used during compiler instrumentation run to use for relative paths to source files in place of absolute paths.
<p><b>NOTE</b></p> <p>In order for the substitution to take place, the sources need to be compiled with one of the following options:  [Q]prof-src-root, [Q]prof-src-root-cwd. This option specifies the base directory that is to be treated as the project root directory.</p> <p>An example of use is:</p> <pre>C:&gt; ifort -Qprof-gen:srcpos -Qprof-src-root c:\workspaces\orig_project_dir test1.f90 test2.f90 C:&gt; test1.exe C:&gt; profmerge C:&gt; cd \workspaces\ C:&gt; mv orig_project_dir new_project_dir C:&gt; cd new_project_dir\src C:&gt; codecov -srcroot C:\workspaces\new_project_dir</pre> <p>Now, "C:\workspaces\new_project_dir" will be substituted for "c:\workspaces\orig_project_dir" when looking for the source files.</p> <p>For use of [Q]prof-src-root, [Q]prof-src-root-cwd options, refer to <a href="#">prof-src-root/Qprof-src-root</a>, <a href="#">prof-src-root-cwd/Qprof-src-root-cwd</a></p>		
-txtbcvrg <code>file</code>		Export block-coverage for covered functions as text format. The file parameter must be in the form of a valid file name.
-txtbcvrgfull <code>file</code>		Export block-coverage for entire application in text and HTML formats. The file parameter must be in the form of a valid file name.
-txtdcg <code>file</code>		Generates the dynamic call-graph information in text format. The file parameter must be in the form of a valid file name.
-txtfcvrg <code>file</code>		Export function coverage for covered function in text format. The file parameter must be in the form of a valid file name.
-txtlcov <code>file</code>		Generates line coverage in text format output files, instead of block coverage in HTML output files.
-ucolor <code>color</code>	#FFFFFF	Specifies the HTML color name or code of the unknown code.
-xcolor <code>color</code>	#90EE90	Specifies the HTML color of the code ignored.

Option	Default	Description
<code>-xmlbcvrgfile</code>		Export the block-coverage for the covered function in XML format. The file parameter must be in the form of a valid file name.
<code>-xmlbcvrgfullfile</code>		Export function coverage for entire application in XML format in addition to HTML output. The file parameter must be in the form of a valid file name.
<code>-xmlfcvrgfile</code>		Export function coverage for covered function in XML format. The file parameter must be in the form of a valid file name.

### Visually Present Code Coverage for an Application

Based on the profile information collected from running the instrumented binaries when testing an application, the Intel® compiler will create HTML-formatted reports using the code coverage tool. These reports indicate portions of the source code that were or were not exercised by the tests. When applied to the profile of the performance workloads, the code coverage information shows how well the training workload covers the application's critical code. High coverage of performance-critical modules is essential to taking full advantage of the profile-guided optimizations.

The code coverage tool can create two levels of coverage:

- Top level (for a group of selected modules)
- Individual module source views

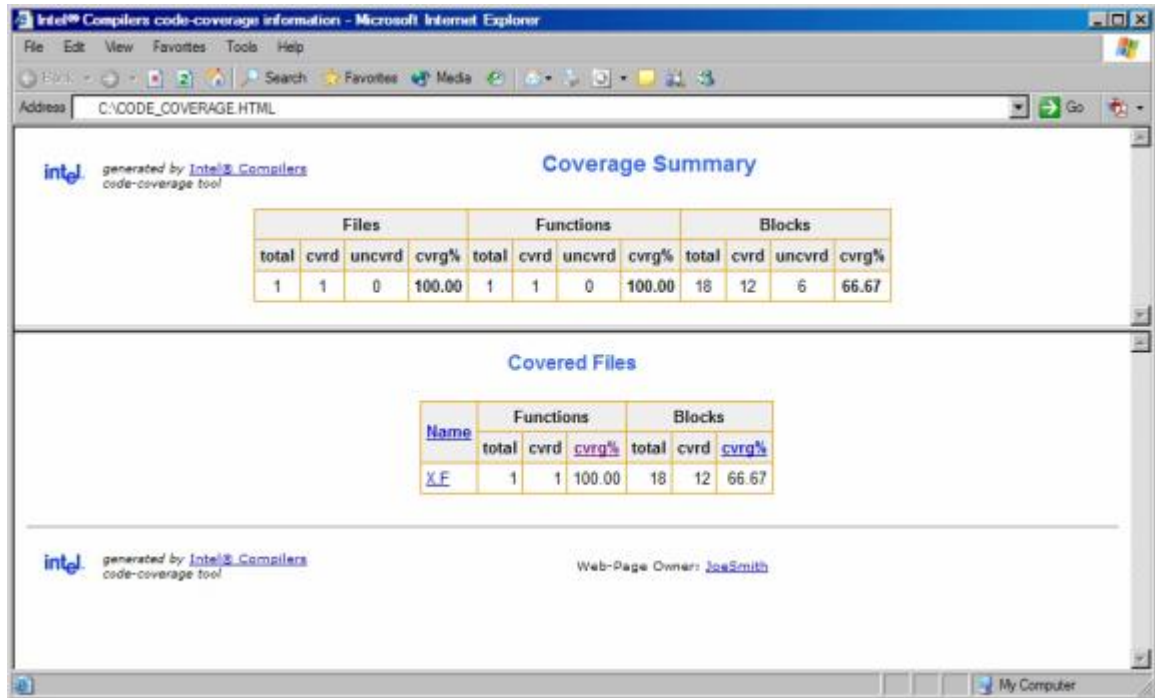

#### Top-Level Coverage

The top-level coverage reports the overall code coverage of the modules that were selected. The following options are provided:

- Select the modules of interest.
- For the selected modules, the tool generates a list with their coverage information. The information includes the total number of functions and blocks in a module and the portions that were covered.
- By clicking on the title of columns in the reported tables, the lists may be sorted in ascending or descending order based on:
  - Basic-block coverage
  - Function coverage
  - Function name

By default, the code coverage tool generates a single HTML file (CODE\_COVERAGE.HTML) and a subdirectory (CodeCoverage) in the current directory. The HTML file defines a frameset to display all of the other generated reports. Open the HTML file in a web-browser. The tool places all other generated report files in a CodeCoverage subdirectory.

If you choose to generate the html-formatted version of the report, you can view coverage source of that particular module directly from a browser. The following figure shows the top-level coverage report.

The coverage tool creates a frame set that allows quick browsing through the code to identify uncovered code. The top frame displays the list of uncovered functions while the bottom frame displays the list of covered functions. For uncovered functions, the total number of basic blocks of each function is also displayed. For covered functions, both the total number of blocks and the number of covered blocks as well as their ratio (that is, the coverage rate) are displayed.

For example, 66.67(4/6) indicates that four out of the six blocks of the corresponding function were covered. The block coverage rate of that function is thus 66.67%. These lists can be sorted based on the coverage rate, number of blocks, or function names. Function names are linked to the position in source view where the function body starts. With one click you can see the least-covered function in the list, and with another click you can see the body of the function. You can scroll down in the source view and browse through the function body.

### Individual Module Source View

Within the individual module source views, the tool provides the list of uncovered functions as well as the list of covered functions. The lists are reported in two distinct frames that provide easy navigation of the source code. The lists can be sorted based on:

- Number of blocks within uncovered functions
- Block coverage in the case of covered functions
- Function names

### Set the Coloring Scheme for the Code Coverage

The tool provides a visible coloring distinction of the following coverage categories: covered code, uncovered basic blocks, uncovered functions, partially covered code, and unknown code. The default colors that the tool uses for presenting the coverage information are shown in the tables that follows:

Category	Default	Description
Covered code	#FFFFFF	Indicates code was exercised by the tests. You can override the default color with the <code>-ccolor</code> tool option.

Category	Default	Description
Uncovered basic block	#FFFF99	Indicates the basic blocks that were not exercised by any of the tests. However, these blocks were within functions that were executed during the tests. You can override the default color with the <code>-bcolor</code> tool option.
Uncovered function	#FFCCCC	Indicates functions that were never called during the tests. You can override the default color with the <code>-fcolor</code> tool option.
Partially covered code	#FAFAD2	Indicates that more than one basic block was generated for the code at this position. Some of the blocks were covered and some were not. You can override the default color with the <code>-pcolor</code> tool option.
Ignored code	#90EE90	Indicates code that was specifically marked to be ignored. You can override this default color using the <code>-xcolor</code> tool option.
Information lines	#FFFFFF	Indicates basic-block markers and dynamic counts. You can override the default color with the <code>-icolor</code> tool option.
Unknown	#FFFFFF	Indicates that no code was generated for this source line. Most probably, the source at this position is a comment, a header-file inclusion, or a variable declaration. You can override the default color with the <code>-ucolor</code> tool option.

The default colors can be customized to be any valid HTML color name or hexadecimal value using the options mentioned for each coverage category in the table above.

For code coverage colored presentation, the coverage tool uses the following heuristic: source characters are scanned until reaching a position in the source that is indicated by the profile information as the beginning of a basic block. If the profile information for that basic block indicates that a coverage category changes, then the tool changes the color corresponding to the coverage condition of that portion of the code, and the coverage tool inserts the appropriate color change in the HTML-formatted report files.

#### NOTE

You need to interpret the colors in the context of the code. For example, comment lines that follow a basic block that was never executed would be colored in the same color as the uncovered blocks.

## Dynamic Counters

The coverage tool can be configured to generate the information about the dynamic execution counts. This ability can display the dynamic execution count of each basic block of the application and is useful for both coverage and performance tuning.

The custom configuration requires using the `-counts` option. The counts information is displayed under the code after a "^" sign precisely under the source position where the corresponding basic block begins.

If more than one basic block is generated for the code at a source position (for example, for macros), then the total number of such blocks and the number of the blocks that were executed are also displayed in front of the execution count. For example, line 11 in the following example code is an `IF` statement:

```

11  IF ((N .EQ. 1).OR. (N .EQ. 0))
    ^ 10 (1/2)
12    PRINT N
    ^ 7

```

The coverage lines under code lines 11 and 12 contain the following information:

- The `IF` statement in line 11 was executed 10 times.
- Two basic blocks were generated for the `IF` statement in line 11.
- Only one of the two blocks was executed, resulting in the partial coverage color.
- Only seven out of the ten times variable `n` had a value of 0 or 1.

In certain situations, it may be desirable to consider all the blocks generated for a single source position as one entity. In such cases, it is necessary to assume that all blocks generated for one source position are covered when at least one of the blocks is covered. This assumption can be configured with the `-nopartial` option. When this option is specified, decision coverage is disabled, and the related statistics are adjusted accordingly. The code lines 11 and 12 indicate that the `print` statement in line 12 was covered. However, only one of the conditions in line 11 was ever true. With the `-nopartial` option, the tool treats the partially covered code (like the code on line 11) as covered.

### Differential Coverage

Using the code coverage tool, you can compare the profiles from two runs of an application: a reference run, and a new run identifying the code that is covered by the new run but not covered by the reference run. Use this feature to find the portion of the applications code that is not covered by the applications tests but is executed when the application is run by a customer. It can also be used to find the incremental coverage impact of newly added tests to an applications test space.

### Generate Reference Data

Create the dynamic profile information for the reference data, which can be used in differential coverage reporting later, by using the `-ref` option. The following command demonstrates a typical command for generating the reference data:

```
codecov -prj Project_Name -dpi customer.dpi -ref appTests.dpi
```

The coverage statistics of a differential-coverage run shows the percentage of the code exercised on a new run but missed in the reference run. In such cases, the tool shows only the modules that included the code that was not covered. Keep this in mind when viewing the coloring scheme in the source views.

The code with the same coverage property (covered or not covered) on both runs is considered covered code. Otherwise, if the new run indicates that the code was executed, while in the reference run the code was not executed, then the code is treated as uncovered. Alternately, if the code is covered in the reference run but not covered in the new run, the differential-coverage source view shows the code as covered.

### Run Differential Coverage

To run the code coverage tool for differential coverage, you must have the application sources, the `.spi` file, and the `.dpi` file, as described in the code coverage tool Requirements section (above).

Once the required files are available, enter a command similar to the following to begin the process of differential coverage analysis:

```
codecov -prj Project_Name -spi pgopti.spi -dpi pgopti.dpi
```

Specify the `.dpi` and `.spi` files using the `-spi` and `-dpi` options.

### Exclude Code from Coverage Analysis

The code coverage tool allows you to exclude portions of your code from coverage analysis. This ability can be useful during development; for example, certain portions of code might include functions used for debugging only. The test case should not include tests for functionality that will be unavailable in the final application.

Another example of code that can be excluded is code that might be designed to deal with internal errors unlikely to occur in the application. In such cases, lack of a test case is preferred. You may want to ignore infeasible (dead) code in the coverage analysis. The code coverage tool provides several options for marking

portions of the code infeasible and ignoring the code at the file level, function level, line level, and arbitrary code boundaries indicated by user-specific comments. The following sections explain how to exclude code at different levels.

### Include and Exclude Coverage at the File Level

The code coverage tool provides the ability to selectively include or exclude files for analysis. Create a component file and add the appropriate string values that indicate the file and directory name for code you want included or excluded. Pass the file name as a parameter of the `-comp` option. The following example shows the general command:

```
codecov -comp file
```

where *file* is the name of a text file containing strings that act as file/directory name masks for including and excluding file-level analysis. For example, assume the following:

- You want to include all files with the string "source" in the file name or directory name.
- You create a component text file named `myComp.txt` with the selective inclusion string "source".

Once you have a component file, enter a command similar to the following:

```
codecov -comp myComp.txt
```

In this example, filenames with string "source" (like `source1.f` and `source2.f`) and all files within directories where the directory name contains the string "source" (like `source/file1.f` and `source2\file2.f`) are included in the analysis.

To exclude files or directories, add the tilde (~) prefix to the string. You can specify inclusion and exclusion in the same component file. For example, assume you want to analyze all individual files or files in a directory where the file/directory name includes the string "source", and you want to exclude all individual files and files in directories where the file/directory name includes the string "skip". You add content similar to the following to the component file (`myComp.txt`) and pass it to the `-comp` option:

```
source
~skip
```

Entering the `codecov -comp myComp.txt` command with both instructions in the component file, `myComp.txt`, instructs the tool to:

- Include files with filename containing "source" (like `source1.f` and `source2.f`)
- Include all files in directories with the directory name containing "source" (like `source/file1.f` and `source2\file2.f`)
- Exclude all files with filename containing "skip" (like `skipthis1.f` and `skipthis2.f`)
- Exclude all files in directories with the directory name containing "skip" (like `skipthese1\debug1.f` and `skipthese2\debug2.f`)

### Exclude Coverage at the Line and Function Level

You can mark individual lines for exclusion by passing string values to the `-onelinedsbl` option. For example, assume that you have some code similar to the following:

```
print*, "ERROR: n = ", n ! NO_COVER
print*, "      n2 = ", n2 ! INF IA-32 architecture
```

If you wanted to exclude all functions marked with the comments `NO_COVER` or `INF IA-32 architecture`, you would enter a command similar to the following:

```
codecov -onelinedsbl NO_COVER -onelinedsbl "INF IA-32 architecture"
```

You can specify multiple exclusion strings simultaneously, and you can specify any string values for the markers; however, you must remember the following guidelines when using this option:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

An entire function can be excluded from coverage analysis using the same methods. For example, the following function will be ignored from the coverage analysis when you issue example command shown above:

```
subroutine dumpInfo (n)
integer n ! NO_COVER
...
end subroutine
```

Additionally, you can use the code coverage tool to color the infeasible code with any valid HTML color code by combining the `-onelinedsbl` and `-xcolor` options. The following example commands demonstrate the combination:

```
codecov -onelinedsbl INF -xcolor lightgreen
codecov -onelinedsbl INF -xcolor #CCFFCC
```

### Exclude Code by Defining Arbitrary Boundaries

The code coverage tool provides the ability to arbitrarily exclude code from coverage analysis. This feature is most useful where the excluded code either occur inside of a function or spans several functions.

Use the `-beginblkdsbl` and `-endblkdsbl` options to mark the beginning and end (respectively) of any arbitrarily defined boundary to exclude code from analysis. Remember the following guidelines when using these options:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

For example assume that you have the following code:

```
integer n, n2
n = 123
n2 = n*n
if (n2 .lt. 0) then
! /* BINF */
  print*, "ERROR: n = ", n
  print*, "      n2 = ", n2
! // EINF
else if (n2 .eq. 0) then
  print*, "zero: n = ", n, " n2 = ", n2
else
  print*, "positive: n = ", n, " n2 = ", n2
endif
end
```

The following example commands demonstrate how to use the `-beginblkdsbl` option to mark the beginning and the `-endblkdsbl` option to mark the end of code to exclude from the sample shown above:

```
codecov -xcolor #ccFFCC -beginblkdsbl BINF -endblkdsbl EINF
codecov -xcolor #ccFFCC -beginblkdsbl "BEGIN_INF" -endblkdsbl "END_INF"
```

Notice that you can combine these options in combination with the `-xcolor` option.

### Export Coverage Data

The code coverage tool provides specific options to extract coverage data from the dynamic profile information (.dpi files) that result from running instrumented application binaries under various workloads. The tool can export the coverage data in various formats for post-processing and direct loading into databases: the default HTML, text, and XML. You can choose to export data at the function and basic block levels.

There are two basic methods for exporting the data: quick export and combined export. Each method has associated options supported by the tool

- **Quick export:** The first method is to export the data coverage to text- or XML-formatted files without generating the default HTML report. The application sources need not be present for this method. The code coverage tool creates reports and provides statistics only about the portions of the application executed. The resulting analysis and reporting occurs quickly, which makes it practical to apply the coverage tool to the dynamic profile information (the .dpi file) for every test case in a given test space instead of applying the tool to the profile of individual test suites or the merge of all test suites. The `-xmlfcvrg`, `-txtfcvrg`, `-xmlbcvrg` and `-txtbcvrg` options support the first method.
- **Combined export:** The second method is to generate the default HTML and simultaneously export the data to text- and XML-formatted files. This process is slower than first method since the application sources are parsed and reports generated. The `-xmlbcvrgfull` and `-txtbcvrgfull` options support the second method.

These export methods provide the means to quickly extend the code coverage reporting capabilities by supplying consistently formatted output from the code coverage tool. You can extend these by creating additional reporting tools on top of these report files.

### Quick Export

The profile of covered functions of an application can be exported quickly using the `-xmlfcvrg`, `-txtfcvrg`, `-xmlbcvrg`, and `-txtbcvrg` options. When using any of these options, specify the output file that will contain the coverage report. For example, enter a command similar to the following to generate a report of covered functions in XML formatted output:

```
codecov -prj test1 -dpi test1.dpi -xmlfcvrg test1_fcvg.xml
```

The resulting report will show how many times each function was executed and the total number of blocks of each function, together with the number of covered blocks and the block coverage of each function. The following example shows some of the content of a typical XML report:

```
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.F">
    <FUNCTION name="f0" freq="2">
      <BLOCKS total="6" covered="5" coverage="83.33%"></BLOCKS>
    </FUNCTION>
    ...
  </MODULE>
  <MODULE name = "D:\SAMPLE2.F">
    ...
  </MODULE>
</PROJECT>
```

In the above example, we note that function `f0`, which is defined in file `sample.f`, has been executed twice. It has a total number of six basic blocks, five of which are executed, resulting in an 83.33% basic block coverage.

You can also export the data in text format using the `-txtfcvrg` option. The generated text report, using this option, for the above example would be similar to the following example:

```
Covered Functions in File: "D:\SAMPLE.F"
"f0"   2      6      5      83.33
"f1"   1      6      4      66.67
"f2"   1      6      3      50.00
...
```

In the text formatted version of the report, the each line of the report should be read in the following manner:

Column 1	Column 2	Column 3	Column 4	Column 5
Function name	Execution frequency	Line number of the start of the function definition	Column number of the start of the function definition	Percentage of basic-block coverage of the function

Additionally, the tool supports exporting the block level coverage data using the `-xmlbcvrg` option. For example, enter a command similar to the following to generate a report of covered blocks in XML formatted output:

```
codecov -prj test1 -dpi test1.dpi -xmlbcvrg test1_bcvrg.xml
```

The example command shown above would generate XML-formatted results similar to the following:

```
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.cF90">
    <FUNCTION name="f0" freq="2">
      ...
      <BLOCK line="11" col="2">
        <INSTANCE id="1" freq="1"> </INSTANCE>
      </BLOCK>
      <BLOCK line="12" col="3">
        <INSTANCE id="1" freq="2"> </INSTANCE>
        <INSTANCE id="2" freq="1"> </INSTANCE>
      </BLOCK>
```

In the sample report, notice that one basic block is generated for the code in function `f0` at the line 11, column 2 of the file `sample.f90`. This particular block has been executed only once. Also notice that there are two basic blocks generated for the code that starts at line 12, column 3 of file. One of these blocks, which has `id = 1`, has been executed two times, while the other block has been executed only once. A similar report in text format can be generated through the `-txtbcvrg` option.

### Combined Exports

The code coverage tool has also the capability of exporting coverage data in the default HTML format while simultaneously generating the text- and XML-formatted reports.

Use the `-xmlbcvrgfull` and `-txtbcvrgfull` options to generate reports in all supported formats in a single run. These options export the basic-block level coverage data while simultaneously generating the HTML reports. These options generate more complete reports since they include analysis on functions that were not executed at all. However, exporting the coverage data using these options requires access to application source files and take much longer to run.

### Dynamic Call Graphs

Using the `-txtdcg` option the tool can provide detailed information about the dynamic call graphs in an application. Specify an output file for the dynamic call-graph report. The resulting call graph report contains information about the percentage of static and dynamic calls (direct, indirect, and virtual) at the application, module, and function levels.

### Test Prioritization Tool

The test prioritization tool, also known as the `tselect` tool, enables the profile-guided optimizations on all supported Intel® architectures, on Linux\*, Windows\*, and macOS operating systems, to select and prioritize tests for an application based on prior execution profiles.

The tool offers a potential of significant time saving in testing and developing large-scale applications where testing is the major bottleneck.

Development often requires changing applications modules. As applications change, developers can have a difficult time retaining the quality of their functional and performance tests so they are current and on-target. The test prioritization tool lets software developers select and prioritize application tests as application profiles change.

The information about the tool is separated into the following sections:

- Features and benefits
- Requirements and syntax
- Usage model
- Tool options
- Running the tool

## Features and Benefits

The test prioritization tool provides an effective testing hierarchy based on the code coverage for an application. The following list summarizes the advantages of using the tool:

- Minimizing the number of tests that are required to achieve a given overall coverage for any subset of the application. The tool defines the smallest subset of the application tests that achieve exactly the same code coverage as the entire set of tests.
- Reducing the turn-around time of testing. Instead of spending a long time on finding a possibly large number of failures, the tool enables the users to quickly find a small number of tests that expose the defects associated with the regressions caused by a change set.
- Selecting and prioritizing the tests to achieve certain level of code coverage in a minimal time based on the data of the tests' execution time.

See Understanding Profile-guided Optimization and Profile an Application topics for general information on creating the files needed to run this tool.

## Test Prioritization Tool Requirements

The test prioritization tool needs the following items to work:

- The .spi file generated by Intel® compilers when compiling the application for the instrumented binaries with the `-prof-gen=srcpos` (Linux\* and macOS) or `/Qprof-gen:srcpos` (Windows\*) option.
- The .dpi files generated by the profmerge tool as a result of merging the dynamic profile information .dyn files of each of the application tests. Run the profmerge tool on all .dyn files that are generated for each individual test and name the resulting .dpi in a fashion that uniquely identifies the test.
- User-generated file containing the list of tests to be prioritized. For successful instrumented code run, you should:
  - Name each test .dpi file so the file names uniquely identify each test.
  - Create a .dpi list file, which is a text file that contains the names of all .dpi test files.

Each line of the .dpi list file should include one, and only one .dpi file name. The name can optionally be followed by the duration of the execution time for a corresponding test in the dd:hh:mm:ss format.

For example: `Test1.dpi 00:00:60:35` states that Test1 lasted 0 days, 0 hours, 60 minutes and 35 seconds.

The execution time is optional. However, if it is not provided, then the tool will not prioritize the test for minimizing execution time. It will prioritize to minimize the number of tests only.

**Caution**

The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code. The tool uses the following general syntax:

**Tool Syntax**

```
tselect -dpi_listfile
```

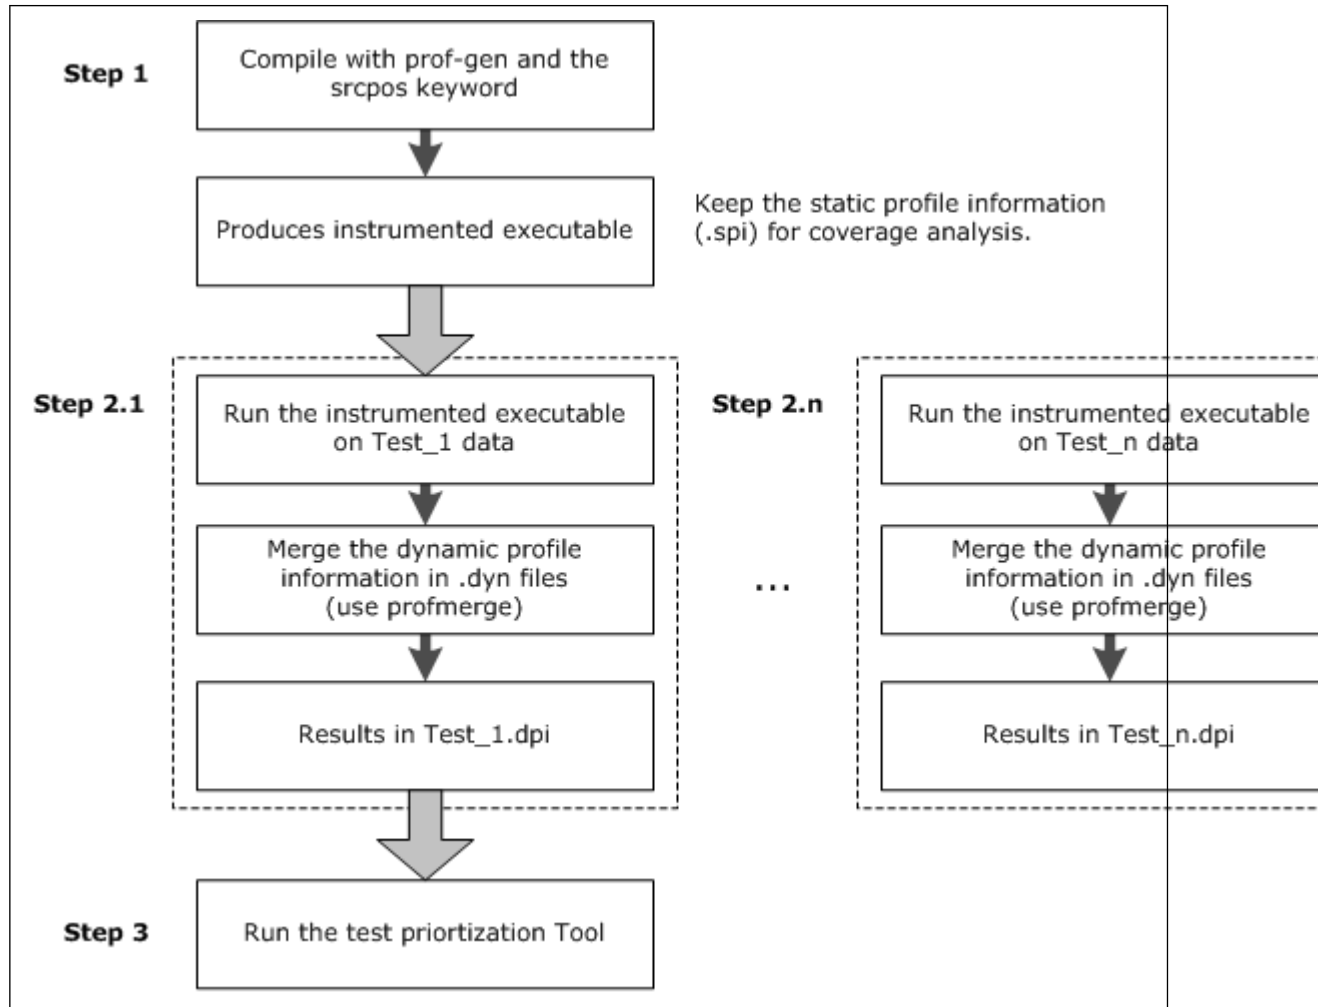

-dpi\_list is a required tool option that sets the path to the list file containing the list of the all .dpi files. All other tool commands are optional.

**NOTE**

Windows\* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

**Usage Model**

The following figure illustrates a typical test prioritization tool usage model.

## Test Prioritization Tool Options

The tool uses the options that are listed in the following table:

Option	Description
<code>-help</code>	Prints tool option descriptions.
<code>-dpi_listfile</code>	Required. Specifies the name of the file that contains the names of the dynamic profile information (.dpi) files. Each line of the file must contain only one .dpi file name, which can be followed by its execution time (optional). The name must uniquely identify the test.
<code>-spi file</code>	Specifies the file name of the static profile information file (.SPI). Default is <code>pgopti.spi</code>
<code>-ofile</code>	Specifies the file name of the output report file.
<code>-compfile</code>	Specifies the file name that contains the list of files of interest.
<code>-cutoffvalue</code>	Instructs the tool to terminate when the cumulative block coverage reaches a preset percentage, as specified by <code>value</code> , of pre-computed total coverage. <code>value</code> must be greater than 0.0 (for example, 99.00) but not greater than 100. <code>value</code> can be set to 100.
<code>-nototal</code>	Instructs the tool to ignore the pre-compute total coverage process.
<code>-mintime</code>	Instructs the tool to minimize testing execution time. The execution time of each test must be provided on the same line of <code>dpi_list</code> file, after the test name in dd:hh:mm:ss format.
<code>-srcbasedir dir</code>	Specifies a different top-level project directory than was used during compiler instrumentation run with the <code>prof-src-root</code> compiler option to support relative paths to source files in place of absolute paths.
<code>-verbose</code>	Instructs the tool to generate more logging information about program progress.

## Running the Tool

The following steps demonstrate one simple example for running the tool on IA-32 architectures.

1. Specify the directory by entering a command similar to the following:

### Example

```
set PROF_DIR=c:\myApp\prof-dir
```

2. Compile the program and generate instrumented binary by issuing commands similar to the following:

Operating System	Command
Linux and macOS	<code>ifort -prof-gen=srcpos myApp.f90</code>
Windows	<code>ifort /Qprof-gen:srcpos myApp.f90</code>

The commands shown above compile the program and generate instrumented binary `myApp`, as well as the corresponding static profile information `pgopti.spi`.

- Confirm that unrelated `.dyn` files are not present by issuing a command similar to the following:

**Example**

```
rm prof-dir \*.dyn
```

- Run the instrumented files by issuing a command similar to the following:

**Example**

```
myApp < data1
```

The command runs the instrumented application and generates one or more new dynamic profile information files that have an extension `.dyn` in the directory specified by the `-prof-dir` step above.

- Merge all `.dyn` file into a single file by issuing a command similar to the following:

**Example**

```
profmerge -prof_dpi Test1.dpi
```

The `profmerge` tool merges all the `.dyn` files into one file (`Test1.dpi`) that represents the total profile information of the application on `Test1`.

- Confirm again there are no unrelated `.dyn` files present a second time by issuing a command similar to the following:

**Example**

```
rm prof-dir \*.dyn
```

- Run the instrumented application, and generate one or more new dynamic profile information files that have an extension `.dyn` in the directory specified in the `prof-dir` step above by issuing a command similar to the following:

**Example**

```
myApp < data2
```

- Merge all `.dyn` files into a single file by issuing a command similar to the following:

**Example**

```
profmerge -prof_dpi Test2.dpi
```

At this step, the `profmerge` tool merges all the `.dyn` files into one file (`Test2.dpi`) that represents the total profile information of the application on `Test2`.

- Confirm that there are no unrelated `.dyn` files present for the final time by issuing a command similar to the following:

**Example**

```
rm prof-dir \*.dyn
```

10. Run the instrumented application and generate one or more new dynamic profile information files that have an extension `.dyn` in the directory specified by `-prof-dir` by issuing a command similar to the following:

**Example**

```
myApp < data3
```

11. Merge all `.dyn` file into a single file, by issuing a command similar to the following:

**Example**

```
profmerge -prof_dpi Test3.dpi
```

At this step, the `profmerge` tool merges all the `.dyn` files into one file (`Test3.dpi`) that represents the total profile information of the application on `Test3`.

12. Create a file named `tests_list` with three lines. The first line contains `Test1.dpi`, the second line contains `Test2.dpi`, and the third line contains `Test3.dpi`.

**Tool Usage Examples**

When these items are available, the test prioritization tool may be launched from the command line in the `prof-dir` directory as described in the following examples.

**Example 1: Minimizing the Number of Tests**

The following example describes how minimize the number of test runs.

**Example Syntax**

```
tselect -dpi_list tests_list -spi pgopti.spi
```

where the `-spi` option specifies the path to the `.spi` file.

The following sample output shows typical results.

**Sample Output**

```
Total number of tests   = 3
Total block coverage    ~ 52.17
Total function coverage ~ 50.00

num  %RatCvrg  %BlkCvrg  %FncCvrg  Test Name @ Options
---  -
1    87.50    45.65    37.50    Test3.dpi
2    100.50    52.17    50.00    Test2.dpi
```

In this example, the results provide the following information:

- By running all three tests, you achieve 52.17% block coverage and 50.00% function coverage.
- Test3 alone covers 45.65% of the basic blocks of the application, which is 87.50% of the total block coverage that can be achieved from all three tests.
- By adding Test2, you achieve a cumulative block coverage of 52.17% or 100% of the total block coverage of Test1, Test2, and Test3.
- Elimination of Test1 has no negative impact on the total block coverage.

## Example 2: Minimizing Execution Time

Assume you have the following execution time of each test in the `tests_list` file:

### Sample Output

```
Test1.dpi 00:00:60:35
Test2.dpi 00:00:10:15
Test3.dpi 00:00:30:45
```

The following command minimizes the execution time by passing the `-mintime` option:

### Sample Syntax

```
tselect -dpi_list tests_list -spi pgopti.spi -mintime
```

The following sample output shows possible results:

### Sample Output

```
Total number of tests   = 3
Total block coverage    ~ 52.17
Total function coverage ~ 50.00
Total execution time    = 1:41:35
```

num	elapsedTime	%RatCvrg	%BlkCvrg	%FncCvrg	Test Name @ Options
---	-----	-----	-----	-----	-----
1	10:15	75.00	39.13	25.00	Test2.dpi
2	41:00	100.00	52.17	50.00	Test3.dpi

In this case, the results indicate that running all tests sequentially would require one hour, 45 minutes, and 35 seconds, while the selected tests would achieve the same total block coverage in only 41 minutes.

The order of tests when based on minimizing time (first Test2, then Test3) may be different than when prioritization is done based on minimizing the number of tests. See Example 1 shown above: first Test3, then Test2. In Example 2, Test2 is the test that gives the highest coverage per execution time, so Test2 is picked as the first test to run.

## Using Other Options

The `-cutoff` enables the tool to exit when it reaches a given level of basic block coverage. The following example demonstrates how to use the option:

### Example

```
tselect -dpi_list tests_list -spi pgopti.spi -cutoff 85.00
```

If the tool is run with the cutoff value of 85.00, as in the above example, only Test3 will be selected, as it achieves 45.65% block coverage, which corresponds to 87.50% of the total block coverage that is reached from all three tests.

The tool does an initial merging of all the profile information to figure out the total coverage that is obtained by running all the tests. The `-cutoff` enables you to skip this step. In such a case, only the absolute coverage information will be reported, as the overall coverage remains unknown.

## Profmerge and Proforder Tools

### Profmerge Tool

Use the profmerge tool to merge dynamic profile information (`.dyn`) files and any specified summary files (`.dpi`). The compiler executes profmerge automatically during the feedback compilation phase when you specify the `[Q]prof-use` option.

The command-line syntax for profmerge is as follows:

```
profmerge [-prof_dir dir_name]
```

The tool merges all `.dyn` files in the current directory, or the directory specified by `-prof_dir`, and produces a summary file: `pgopti.dpi`.

#### NOTE

The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example `-prof_dir`) instead of the hyphen used by compiler options (for example `[Q]prof-dir`) to join words. Also, on Windows\* systems, the tool options are preceded by a hyphen ("-") unlike Windows\* compiler options, which are preceded by a forward slash ("/").

You can use profmerge tool to merge `.dyn` files into a `.dpi` file without recompiling the application. You can run the instrumented executable file on multiple systems to generate `.dyn` files, and optionally use profmerge with the `-prof_dpi` option to name each summary `.dpi` file created from the multiple `.dyn` files.

Because the profmerge tool merges all the `.dyn` files that exist in the given directory, confirm that unrelated `.dyn` files are not present; otherwise, profile information will be based on invalid profile data, which can negatively impact the performance of optimized code.

### Profmerge Options

The profmerge tool supports the following options:

Tool Option	Description
<code>-dump</code>	Displays profile information.
<code>-help</code>	Lists supported options.
<code>-nologo</code>	Disables version information. This option is supported on Windows* only.
<code>-exclude_filesfiles</code>	Excludes functions from the profile if the function comes from one of the listed files. The list items must be separated by a comma (","); you can use a period (".") as a wild card character in function names.
<code>-exclude_funcsfuctions</code>	Excludes functions from the profile. The list items must be separated by a comma (","); you can use a period (".") as a wild card character in function names.

Tool Option	Description
<code>-prof_dirdir</code>	Specifies the directory from which to read <code>.dyn</code> and <code>.dpi</code> files, and write the <code>.dpi</code> file. Alternatively, you can set the <a href="#">environment variable</a> <code>PROF_DIR</code> .
<code>-prof_dpifile</code>	Specifies the name of the <code>.dpi</code> file being generated.
<code>-prof_filefile</code>	Merges information from file matching: <code>dpi_file_and_dyn_tag</code> .
<code>-src_olddir-src_newdir</code>	Changes the directory path stored within the <code>.dpi</code> file.
<code>-no_src_dir</code>	Uses only the file name and not the directory name when reading <code>dyn/dpi</code> records. If you specify <code>-no_src_dir</code> , the directory name of the source file will be ignored when deciding which profile data records correspond to a specific application routine, and the <code>-src-root</code> option is ignored.
<code>-src-rootdir</code>	Specifies a directory path prefix for the root directory where the user's application files are stored. This option is ignored if you specify <code>-no_src_dir</code> .
<code>-afile1.dpi...fileN.dpi</code>	Specifies and merges available <code>.dpi</code> files.
<code>-verbose</code>	Instructs the tool to display full information during merge.
<code>-weighted</code>	Instructs the tool to apply an equal weighting (regardless of execution times) to the <code>.dyn</code> file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.
<code>-gen_weight_spec file</code>	Instructs the tool to generate a text file containing a list of the <code>.dyn</code> and <code>.dpi</code> file that were merged with default <code>weight=1/run_count</code> .  The text file is created in the directory specified by the <code>prof_dir</code> option.
<code>-weight_spec weight_spec.txt</code>	Instructs the <code>profmerge</code> tool to generate and use the text file, <code>weight_spec.txt</code> , listing individual <code>.dyn/.dpi</code> files or directory names along with weight values for them.  When the <code>-weight_spec</code> option is used: <ul style="list-style-type: none"> <li>• A new <code>.dpi</code> file is always created</li> <li>• Only files called out by the specification file are merged</li> </ul>

Tool Option	Description
	<ul style="list-style-type: none"> <li>• <code>.dyn</code> timestamps are ignored and merge always takes place</li> </ul> <p>The <code>prof_dir</code> option controls where the input/output <i>weight_spec.txt</i> is located, and the destination of the <code>.dpi</code> file.</p> <p>The <code>-weight_spec</code> option overrides:</p> <ul style="list-style-type: none"> <li>• Any values of <code>-a</code> option</li> <li>• Any computation from using <code>-weighted</code> option</li> </ul>

## Weight the Runs

Using the `-weight_spec` option results in a new `.dpi` file. Only the files listed in the text file are merged. No files in the current directory are used unless they are included in the text file.

## Relocate Source Files Using `profmerge`

The Intel® Fortran Compiler uses the full path to the source file for each routine to look up the profile summary information associated with that routine. By default, this prevents you from:

- Using the profile summary file (`.dpi`) if you move your application sources.
- Sharing the profile summary file with another user who is building identical application sources that are located in a different directory.

You can disable the use of directory names when reading `.dyn/.dpi` file records by specifying the `profmerge` option `-no_scr_dir`. This `profmerge` option is the same as the compiler option `-no-prof-src-dir` (Linux\* and macOS) and `/Qprof-src-dir-` (Windows\*).

To enable the movement of application sources, as well as the sharing of profile summary files, you can use the `profmerge` option `-src-root` to specify a directory path prefix for the root directory where the application files are stored. Alternatively, you can specify the option pair `-src_old-src_new` to modify the data in an existing summary `dpi` file. For example:

```
profmerge -prof_dir <dir1> -src_old <dir2> -src_new <dir3>
```

where `<dir1>` is the full path to dynamic information file (`.dpi`), `<dir2>` is the old full path to source files, and `<dir3>` is the new full path to source files. The example command (above) reads the `pgopti.dpi` file, in the location specified in `<dir1>`. For each routine represented in the `pgopti.dpi` file, whose source path begins with the `<dir2>` prefix, `profmerge` replaces that prefix with `<dir3>`. The `pgopti.dpi` file is updated with the new source path information.

You can run `profmerge` more than once on a given `pgopti.dpi` file. You may need to do this if the source files are located in multiple directories. For example:

## Linux\* and macOS

```
profmerge -prof_dir -src_old /src/prog_1 -src_new /src/prog_2
profmerge -prof_dir -src_old /proj_1 -src_new /proj_2
```

## Windows\*

```
profmerge -src_old "c:/program files" -src_new "e:/program files"
profmerge -src_old c:/proj/application -src_new d:/app
```

In the values specified for `-src_old` and `-src_new`, uppercase and lowercase characters are treated as identical in Windows. Likewise, forward slash ( `/` ) and backward slash ( `\` ) characters are treated as identical.

**NOTE**

Because the source relocation feature of profmerge modifies the `pgopti.dpi` file, consider making a backup copy of the file before performing the source relocation.

**Proforder Tool**

The proforder tool is used as part of the feedback compilation phase, to improve program performance. Use proforder to generate a function order list for use with the `/ORDER` linker option in Windows. The tool uses the following syntax:

```
proforder [-prof_dir dir] [-o file]
```

where *dir* is the directory containing the profile files ( `.dpi` and `.spi`), and *file* is the optional name of the function order list file. The default name is `proford.txt`.

**NOTE**

The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example `-prof_dir`) instead of the hyphen used by compiler options (for example `[Q]prof-dir`) to join words. Also, on Windows\* systems, the tool options are preceded by a hyphen ("-") unlike Windows\* compiler options, which are preceded by a forward slash ("/").

**Proforder Options**

The proforder tool supports the following options:

Tool Option	Default	Description
<code>-help</code>		Lists supported options.
<code>-nologo</code>		Disables version information. This option is supported on Windows* only.
<code>-omit_static</code>		Instructs the tool to omit static functions from function ordering.
<code>-prof_dir</code> <i>dir</i>		Specifies the directory where the <code>.spi</code> and <code>.dpi</code> file reside.
<code>-prof_dpi</code> <i>file</i>		Specifies the name of the <code>.dpi</code> file.
<code>-prof_file</code> <i>string</i>		Selects the <code>.dpi</code> and <code>.spi</code> files that include the substring value in the file name matching the values passed as string.
<code>-prof_spi</code> <i>file</i>		Specifies the name of the <code>.spi</code> file.
<code>-o</code> <i>file</i>	<code>proford.txt</code>	Specifies an alternate name for the output file.

## Use Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations

Instead of doing a full multi-file interprocedural build of your application by using the compiler option `[Q] ipo`, you can obtain some of the benefits by having the compiler and linker work together to make global decisions about where to place the procedures and data in your application. These optimizations are not supported on macOS systems.

The following table lists each optimization, the type of procedures or global data it applies to, and the operating systems and architectures that it is supported on.

Optimization	Type of Procedure or Data	Supported OS and Architectures
<p><b>Function Order Lists:</b> Specifies the order in which the linker should link the non-static routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging. Also see <a href="#">Comparison of Function Order Lists and IPO Code Layout</a>.</p>	EXTERNAL procedures and library procedures only (not other types of static procedures).	Windows: all Intel architectures Linux: not supported
<p><b>Function Grouping:</b> Specifies that the linker should place the extern and static routines (procedures) of your program into hot or cold program sections. This optimization can improve application performance by improving code locality and reduce paging.</p> <hr/> <p><b>NOTE</b> This option will cause functions to be placed into the linker sections named <code>".text.hot"</code> and <code>".text.unlikely."</code>. If you are using a custom linker script, you will need to specify memory placement for these sections.</p> <hr/>	EXTERNAL procedures and static procedures only (not library procedures).	Linux: IA-32 and Intel 64 architectures Windows: not supported
<p><b>Function Ordering:</b> Enables ordering of static and extern routines using profile information. Specifies the order in which the linker should link the routines (procedures) of your program. This optimization can improve application performance by improving code locality and reduce paging.</p>	EXTERNAL procedures and static procedures only (not library procedures)	Linux and Windows: all Intel architectures

Optimization	Type of Procedure or Data	Supported OS and Architectures
<b>Data Ordering:</b> Enables ordering of static global data items (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) based on profiling information. Specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.	Static global data (data in common blocks, module variables, and variables for which the compiler applied the SAVE attribute or statement) only	Linux and Windows: all Intel architectures

You can only use one of the function-related ordering optimizations listed above on each application. However, you can use the Data Ordering optimization with any one of the function-related ordering optimizations listed above, such as Data Ordering with Function Ordering, or Data Ordering with Function Grouping. In this case, specify the `prof-gen` option keyword `globdata` (needed for Data Ordering) instead of `srcpos` (needed for function-related ordering).

The following sections show the commands needed to implement each of these optimizations: [function order list](#), [function grouping](#), [function ordering](#), and [data ordering](#). For all of these optimizations, omit the `[Q]ipo` or equivalent compiler option.

### Generate a Function Order List on Windows

This section provides an example of the process for generating a function order list. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`. Additionally, assume you have created a directory for the profile data files called `c:\profdata`. You would enter commands similar to the following to generate and use a function order list for your Windows application.

1. Compile your program using the `/Qprof-gen:srcpos` option. Use the `/Qprof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

#### Example commands

```
ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90
```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

#### Example commands

```
myprog.exe
```

3. Before this step, copy all `.dyn` and `.dpi` files into the same directory. Merge the data from one or more runs of the instrumented program by using the [profmerge tool](#) to produce the `pgopti.dpi` file. Use the `/prof_dir` option to specify the directory location of the `.dyn` files.

#### Example commands

```
profmerge /prof_dir c:\profdata
```

4. Generate the function order list using the `proforder` tool. By default, the function order list is produced in the file `proford.txt`.

**Example commands**

```
proforder /prof_dir c:\profdata /o myprog.txt
```

5. Compile the application with the generated profile feedback by specifying the `ORDER` option to the linker. Use the `/Qprof-dir` option to specify the directory location of the profile files.

**Example commands**

```
ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /link /ORDER:@MYPROG.txt
```

**Use Function Grouping on Linux**

This section provides a general example of the process for using the function grouping optimization. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`. Additionally, assume you have created a directory for the profile data files called `profdata`. You would enter commands similar to the following to use a function grouping for your Linux application.

1. Compile your program using the `-prof-gen` option. Use the `-prof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

**Example commands**

```
ifort -o myprog -prof-gen -prof-dir ./profdata file1.f90 file2.f90
```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

**Example commands**

```
./myprog
```

3. Copy all `.dyn` and `.dpi` files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the [profmerge tools](#) to produce the `pgopti.dpi` file.
4. Compile the application with the generated profile feedback by specifying the `-prof-func-group` option to request the function grouping as well as the `-prof-use` option to request feedback compilation. Again, use the `-prof-dir` option to specify the location of the profile files.

**Example commands**

```
ifort /exe:myprog file1.f90 file2.f90 -prof-func-group -prof-use -prof-dir ./profdata
```

**NOTE** On Linux, the `-prof-func-group` option is on by default when `-prof-use` is selected.

Finer grain control over the number of functions placed into the hot region can be controlled with the `-prof-hotness-threshold` compiler option, see the command line reference for more details.

**Use Function Ordering**

This section provides an example of the process for using the function ordering optimization. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`, and that you have created a directory for the profile data files called `c:\profdata` (on Windows) or `./profdata` (on Linux). You would enter commands similar to the following to generate and use function ordering for your application.

1. Compile your program using the `-prof-gen=srcpos` (Linux) or `/Qprof-gen:srcpos` (Windows) option. Use the `[Q]prof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

Operating System	Example commands
Linux	<code>ifort -o myprog -prof-gen=srcpos -prof-dir ./profdata file1.f90 file2.f90</code>
Windows	<code>ifort /exe:myprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.f90 file2.f90</code>

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Operating System	Example commands
Linux	<code>./myprog</code>
Windows	<code>myprog.exe</code>

3. Copy all `.dyn` and `.dpi` files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the [profmerge tools](#) to produce the `pgopti.dpi` file.
4. Compile the application with the generated profile feedback by specifying the `[Q]prof-func-order` option to request the function ordering, as well as the `[Q]prof-use` option to request feedback compilation. Again, use the `[Q]prof-dir` option to specify the location of the profile files.

Operating System	Example commands
Linux	<code>ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-func-order-prof-use</code>
Windows	<code>ifort /exe:myprog /Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-func-order /Qprof-use</code>

## Use Data Ordering

This section provides an example of the process for using the data order optimization. Assume you have a Fortran program that consists of the following files: `file1.f90` and `file2.f90`, and that you have created a directory for the profile data files called `c:\profdata` (on Windows) or `./profdata` (on Linux). You would enter commands similar to the following to use data ordering for your application.

1. Compile your program using the `-prof-gen=globdata` (Linux) or `/Qprof-gen:globdata` (Windows) option. Use the `-prof-dir` (Linux) or `/Qprof-dir` (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

Operating System	Example commands
Linux	<code>ifort -o myprog -prof-gen=globdata -prof-dir ./profdata file1.f90 file2.f90</code>
Windows	<code>ifort /exe:myprog /Qprof-gen:globdata /Qprof-dir c:\profdata file1.f90 file2.f90</code>

- Run the instrumented program with one or more sets of input data. If you specified a location other than the current directory, change your directory to the directory where the executables are located. The program produces a .dyn file each time it is executed.

Operating System	Example commands
Linux	<code>./myprog</code>
Windows	<code>myprog.exe</code>

- Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the [profmerge tools](#) to produce the `pgopti.dpi` file.
- Compile the application with the generated profile feedback by specifying the `[Q]prof-data-order` option to request the data ordering as well as the `[Q]prof-use` option to request feedback compilation. Again, use the `[Q]prof-dir` option to specify the location of the profile files.

Operating System	Example commands
Linux	<code>ifort -o myprog -prof-dir ./profdata file1.f90 file2.f90 -prof-data-order-prof-use</code>
Windows	<code>ifort /exe:myprog Qprof-dir c:\profdata file1.f90 file2.f90 /Qprof-data-order/Qprof-use</code>

## Comparison of Function Order Lists and IPO Code Layout

The Intel® compiler provides two methods of optimizing the layout of functions in the executable:

- Using a function order list
- Using the `/Qipo` (Windows) compiler option

Each method has advantages. A function order list, created with `proforder`, lets you optimize the layout of non-static functions (external and library functions whose names are exposed to the linker).

The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

### Function Order List Effects

Function Type	IPO Code Layout	Function Ordering with <code>proforder</code>
Static	X	No effect
Extern	X	X
Library	No effect	X

Use the following guidelines to create a function order list:

- The order list only affects the order of non-static functions.
- You must compile with `/Gy` to enable function-level linking. (This option is active if you specify either option `/O1` or `/O2`.)

# High-Level Optimization

---

High-level Optimizations (HLO) exploit the properties of source code constructs (for example, loops and arrays) in applications developed in high-level programming languages. While the default optimization level, option `o2`, performs some high-level optimizations, specifying the `o3` option provides the best chance for performing loop transformations to optimize memory accesses.

---

**NOTE**

Loop optimizations may result in calls to library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The optimizations performed can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x` options. Additional HLO transformations may be performed for Intel® microprocessors than for non-Intel microprocessors.

---

Within HLO, loop transformation techniques include:

- Loop Permutation or Interchange
- Loop Distribution
- Loop Fusion
- Loop Unrolling
- Data Prefetching
- Scalar Replacement
- Unroll and Jam
- Loop Blocking or Tiling
- Partial-Sum Optimization
- Predicate Optimization
- Loop Reversal
- Profile-Guided Loop Unrolling
- Loop Peeling
- Data Transformation: Memset Combining, Memory Layout Change
- Loop Rerolling
- Memset and Malloc Recognition
- Statement Sinking for Creating Perfect Loopnests
- Multiversioning: Checks include Dependency of Memory References, and Trip Counts
- Loop Collapsing

# Interprocedural Optimization

---

Interprocedural Optimization (IPO) is an automatic, multi-step process that allows the compiler to analyze your code to determine where you can benefit from specific optimizations.

---

**NOTE** In the `ifort` compiler, support for Interprocedural Optimization (IPO) is disabled for macOS SDK 11 or higher.

---

The compiler may apply the following optimizations:

- Address-taken analysis
- Array dimension padding
- Alias analysis
- Automatic array transposition
- Automatic memory pool formation

- Common block variable coalescing
- Common block splitting
- Constant propagation
- Dead call deletion
- Dead formal argument elimination
- Dead function elimination
- Formal parameter alignment analysis
- Forward substitution
- Indirect call conversion
- Inlining
- Mod/ref analysis
- Partial dead call elimination
- Passing arguments in registers to optimize calls and register usage
- Points-to analysis
- Routine key-attribute propagation
- Specialization
- Stack frame alignment
- Structure splitting and field reordering
- Symbol table data promotion
- Un-referenced variable removal
- Whole program analysis

## IPO Compilation Models

IPO supports two compilation models: single-file compilation and multi-file compilation.

Single-file compilation uses the `[Q]ip` compiler option, and results in one, real object file for each source file being compiled. During single-file compilation the compiler performs inline function expansion for calls to procedures defined within the current source file.

The compiler performs some single-file interprocedural optimization at the `O2` default optimization level; additionally the compiler may perform some inlining for the `O1` optimization level, such as inlining functions marked with inlining directives.

Multi-file compilation uses the `[Q]ipo` option, and results in one or more mock object files rather than normal object files. (See the *Compilation* section below for information about mock object files.) Additionally, the compiler collects information from the individual source files that make up the program. Using this information, the compiler performs optimizations across functions and procedures in different source files.

---

### NOTE

Inlining and other optimizations are improved by profile information. For a description of how to use IPO with profile information for further optimization, see [Profile an Application](#).

---

## Compile with IPO

As each source file is compiled with IPO, the compiler stores an intermediate representation (IR) of the source code in a mock object file. The mock object files contain the IR instead of the normal object code. Mock object files can be ten times or more larger than the size of normal object files.

During the IPO compilation phase only the mock object files are visible.

## Link with IPO

When you link with the `[Q]ipo` compiler option the compiler is invoked a final time. The compiler performs IPO across all mock object files. The mock objects must be linked with the compiler or by using the Intel® linking tools. While linking with IPO, the compiler and other linking tools compile mock object files as well as invoke the real/true object files linkers provided on the user's platform.

Link-time optimization using the `-ffat-lto-objects` compiler option is provided for GCC compatibility. During IPO compilation, you can specify `-ffat-lto-objects` option, for the compiler to generate a fat link-time optimization (LTO) object that has both a real/true object and a discardable intermediate language section. This enables both link-time optimization linking and normal linking.

You can specify the `-fno-fat-lto-objects` option for the compiler to generate a link-time optimization object that only has a discardable intermediate language section; no real/true object is generated. These files are inserted into archives in the form in which they were created. Using this option may improve compilation time and save space for objects.

If you use `ld` rather than `xild` to link objects or `ar` instead of `xiar` to create an archive, the real/true object, generated during fat link-time optimization guarantees that there will be no impediment to linking/building the archive. However, cross-file optimizations are lost in this case. The extra true object also takes additional space and takes compile time to generate it, so using `-fno-fat-lto-objects` compiler option is an advantage provided that you link the IPO mock object files with `xild` and archive them with `xiar`.

## Whole Program Analysis

The compiler supports a large number of IPO optimizations that can be applied or have its effectiveness greatly increased when the whole program condition is satisfied.

During the analysis process, the compiler reads all Intermediate Representation (IR) in the mock file, object files, and library files to determine if all references are resolved and whether or not a given symbol is defined in a mock object file. Symbols that are included in the IR in a mock object file for both data and functions are candidates for manipulation based on the results of whole program analysis.

There are two types of whole program analysis - object reader method and table method. Most optimizations can be applied if either type of whole program analysis determines that the whole program conditions exists; however, some optimizations require the results of the object reader method, and some optimizations require the results of table method.

### Object reader method

In the object reader method, the object reader emulates the behavior of the native linker and attempts to resolve the symbols in the application. If all symbols are resolved, the whole program condition is satisfied. This type of whole program analysis is more likely to detect the whole program condition.

### Table method

In the table method the compiler analyzes the mock object files and generates a call-graph.

The compiler contains detailed tables about all of the functions for all important language-specific libraries, like the Fortran runtime libraries. In this second method, the compiler constructs a call-graph for the application. The compiler then compares the function table and application call-graph. For each unresolved function in the call-graph, the compiler attempts to resolve the calls by finding an entry for each unresolved function in the compiler tables. If the compiler can resolve the functions call, the whole program condition exists.

O

x, Qx

## Use Interprocedural Optimization

# Use Interprocedural Optimization

This topic discusses how to use IPO from the command line.

## Compile and Link Using IPO

To enable IPO, you first compile each source file, then link the resulting source files.

### Linux and macOS

1. Compile your source files with the `ipo` compiler option:

```
ifx -ipo -c a.f90 b.f90 c.f90
```

The command produces `a.o`, `b.o`, and `c.o` object files.

Use the `c` compiler option to stop compilation after generating `.o` object files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files.

2. Link the resulting files. The following example command will produce an executable named `app`:

```
ifx -ipo -o app a.o b.o c.o
```

The command invokes the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the `xild` tool, with the appropriate linking options.

The separate compile and link commands from the previous steps can be combined into a single command, for example:

```
ifx -ipo -o app a.f90 b.f90 c.f90
```

The `ifx` command, shown in the examples, calls `GCC ld` to link the specified object files and produce the executable application, which is specified by the `-o` option.

### Windows

1. Compile your source files with the `/Qipo` compiler option:

```
ifx /Qipo /c a.f90 b.f90 c.f90
```

The command produces `a.obj`, `b.obj`, and `c.obj` object files.

Use the `c` compiler option to stop compilation after generating `.obj` files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files.

2. Link the resulting files. The following example command will produce an executable named `app`:

```
ifx /Qipo /exe:app a.obj b.obj c.obj
```

The command invokes the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the `xilink` tool, with the appropriate linking options.

The separate compile and link commands from the previous steps can be combined into a single command, for example:

```
ifx /Qipo /exe:app a.f90 b.f90 c.f90
```

The `ifx` command, shown in the examples, calls `link.exe` to link the specified object files and produce the executable application, which is specified by the `/exe` option.

## Capture Intermediate IPO Output

The `[Q]ipo-c` and `[Q]ipo-S` compiler options are useful for analyzing the effects of multi-file IPO, or when experimenting with multi-file IPO between modules that do not make up a complete program.

- Use the `[Q]ipo-c` compiler option to optimize across files and produce an object file. The option performs optimizations as described for the `[Q]ipo` option but stops prior to the final link stage, leaving an optimized object file. The default name for this file is `ipo_out.o` (Linux and macOS) or `ipo_out.obj` (Windows).
- Use the `[Q]ipo-S` compiler option to optimize across files and produce an assembly file. The option performs optimizations as described for `[Q]ipo`, but stops prior to the final link stage, leaving an optimized assembly file. The default name for this file is `ipo_out.s` (Linux) or `ipo_out.asm` (Windows).

For both options, you can use the `-o` (Linux and macOS) or `/exe` (Windows) option to specify a different name.

These options generate multiple outputs if multi-object IPO is being used. The name of the first file is taken from the value of the `-o` (Linux and macOS) or `/exe` (Windows) option.

The names of subsequent files are derived from the first file with an appended numeric value to the file name. For example, if the first object file is named `foo.o` (Linux and macOS) or `foo.obj` (Windows), the second object file will be named `foo1.o` or `foo1.obj`.

You can use the object file generated with the `[Q]ipo-c` option, but you will not get the full benefit of whole program optimizations if you use this option.

The object file created using the `[Q]ipo-c` option is a real object file, in contrast to the mock file normally generated using IPO; however, the generated object file is significantly different than the mock object file. Whole program optimizations, which require a knowledge of how the real object file will be linked in with other files to produce an object, are not applied.

The compiler generates a message indicating the name of each object or assembly file it generates. These files can be added to the real link step to build the final application.

# Performance and Large Program Considerations

## IPO-related Performance Issues

There are some general optimization guidelines for using IPO that you should keep in mind:

- Using IPO on very large programs might trigger internal limits of other compiler optimization phases.

- Applications where the compiler does not have sufficient intermediate representation (IR) coverage to do whole program analysis might not perform as well as those where IR information is complete.

In addition to these general guidelines, there are some practices to avoid while using IPO. The following list summarizes the activities to avoid:

- Do not use the link phase of an IPO compilation using mock object files produced for your application by a different compiler. Intel® compilers cannot inspect mock object files generated by other compilers for optimization opportunities.
- Update make files to call the appropriate Intel linkers when using IPO from scripts. For Linux and macOS, replace all instances of `ld` with `xild`; for Windows, replace all instances of `link` with `xilink`.

## IPO for Large Programs

In most cases, IPO generates a single true object file for the link-time compilation. This behavior is not optimal for very large programs, perhaps even making it impossible to use `[Q]ipo` compiler option on the application.

The compiler provides two methods to avoid this problem. The first method is an automatic size-based heuristic, which causes the compiler to generate multiple true object files for large link-time compilations. The second method is to manually instruct the compiler to perform multi-object IPO.

- Use the `[Q]ipoN` compiler option and pass an integer value in the place of *N*.
- Use the `[Q]ipo-separate` compiler option.

The number of true object files generated by the link-time compilation is invisible to you unless the `[Q]ipo-c` or `[Q]ipo-S` compiler option is used.

Regardless of the method used, it is best to use the compiler defaults first and examine the results. If the defaults do not provide the desired results then experiment with generating a different number of object files.

You can use the `[Q]ipo-jobs` compiler option to control the number of processes, or jobs, executed during parallel IPO builds.

## Use `[Q]ipoN` to Create Multiple Object Files

If you specify `[Q]ipo0`, which is the same as not specifying a value, the compiler uses heuristics to determine whether to create one or more object files based on the expected size of the application. The compiler generates one object file for small applications, and two or more object files for large applications. If you specify any value greater than 0, the compiler generates that number of object files, unless the value you pass exceeds the number of source files. In that case, the compiler creates one object file for each source file then stops generating object files. The generated object files follow OS-specific naming conventions.

The following example commands demonstrate how to use `[Q]ipo2` option to compile large programs.

### Linux and macOS

```
ifort -ipo2 -c a.f90 b.f90
```

The resulting object files are `ipo_out.o`, `ipo_out1.o`, and `ipo_out2.o`.

### Windows

```
ifort /Qipo2 /c a.f90 b.f90
```

The resulting object files are `ipo_out.obj`, `ipo_out1.obj`, and `ipo_out2.obj`.

Link the resulting object files as shown in [Use Interprocedural Optimization](#) or [Linking Tools and Options](#).

## Create the Maximum Number of Object Files

Using `[Q]ipo-separate` allows you to force the compiler to generate the maximum number of true object files that the compiler will support during multiple object compilation. The maximum number of true object files is the equal to the number of mock object files passed on the link line.

For example, you can pass example commands similar to the following:

### Linux and macOS

```
ifort a.o b.o c.o -ipo-separate -ipo-c
```

### Windows

```
ifort a.obj b.obj c.obj /Qipo-separate /Qipo-c
```

The compiler generates multiple object files that use the same naming convention discussed above.

Link the resulting object files as shown in [Using IPO](#) or [Linking Tools and Options](#).

## Code Layout and Multi-object IPO

One of the optimizations performed during an IPO compilation is code layout. The analysis performed by the compiler during multi-file IPO determines a layout order for all of the routines for which it has intermediate representation (IR) information. For a multi-object IPO compilation, the compiler must tell the linker about the desired order.

The compiler first puts each routine in a named text section that varies depending on the operating system:

### Linux

The first routine is placed in `.text00001`, the second is placed in `.text00002`, and so on.

### Windows

The first routine is placed in `.text$00001`, the second is placed in `.text$00002`, and so on.

## Create a Library from IPO Objects

---

Libraries are often created using a library manager such as `xiar` for Linux/macOS or `xilib` for Windows. Given a list of objects, the library manager will insert the objects into a named library to be used in subsequent link steps.

### Linux and macOS

Use `xiar` to create a library from a list of objects. For example the following command creates a library named `user.a` containing the `a.o` and `b.o` objects:

```
xiar cru user.a a.o b.o
```

If the objects have been created using `[Q]ipo -c` then the archive will not only contain a valid object, but the archive will also contain intermediate representation (IR) for that object file. For example, the following example will produce `a.o` and `b.o` that may be archived to produce a library containing both object code and IR for each source file. For example:

```
ifort -ipo -c a.f90 b.f90
```

The commands generate mock object files, which when placed in archive will also be accompanied by a true object file.

Using `xiar` is the same as specifying `xild -lib`.

## macOS

When using `xilibtool`, specify `-static` to generate static libraries, or specify `dynamic` to create dynamic libraries. For example, the following command will create a static library named `mylib.a` that includes the `a.o`, `b.o`, and `c.o` objects:

```
xilibtool -static -o mylib.a a.o b.o c.o
```

Alternately, the following example command will create a dynamic library named `mylib.dylib` that includes the `a.o`, `b.o`, and `c.o` objects.

```
xilibtool -dynamic -o mylib.dylib a.o b.o c.o
```

Specifying `xilibtool` is the same as specifying `xild -libtool`.

## Windows

Use `xilib` or `xilink -lib` to create libraries of IPO mock object files and link them on the command line. For example:

1. Assume that you create three mock object files using a command similar to:

```
ifort /c /Qipo a.obj b.obj c.obj
```

2. Further assume `a.obj` contains the main subprogram. Create a library with a command similar to:

```
xilib -out:main.lib b.obj c.obj
```

or

```
xilink -lib -out:main.lib b.obj c.obj
```

3. Link the library and the main program object file with a command similar to:

```
xilink -out:result.exe a.obj main.lib
```

## Request Compiler Reports with the xi\* Tools

The compiler options `qopt-report` (Linux\* and macOS) and `[Q]opt-report` (Windows\*) generate optimization reports with different levels of detail. Related compiler options, listed under [Optimization Report Options](#), allow you to specify the phase, direct output to a file (instead of `stderr`), and request reports from all routines with names containing a specific string as part of their name.

The xi\* tools are used with interprocedural optimization (IPO) during the final stage of IPO compilation. You can request compiler reports to be generated during the final IPO compilation by using certain options. The supported xi\* tools are:

### Linux and macOS

- Linker: `xild`
- Library: `xiar`, `xilibtool` (macOS only)

### Windows

- Linker: `xilink`
- Library: `xilib`

The following table lists the compiler report options that can be used with the xi\* tools during the final IPO compilation:

Linux and macOS	Windows	Description
<code>-qopt-report[=<i>n</i>]</code>	<code>/Qopt-report[:<i>n</i>]</code>	Enables optimization report generation with different levels of detail. Valid values for <i>n</i> are 0 through 5. By default, when you specify this option without passing a value the compiler will generate a report with a medium level of detail. Higher numbers give greater levels of detail.
<code>-qopt-report-file=<i>filename</i></code>	<code>/Qopt-report-file:<i>filename</i></code>	Generates an optimization report and directs the report output to the specified <i>file</i> name. If you omit the path, the file is created in the current directory. To create the file in a different directory, specify the full path to the output file and its file name.
<code>-qopt-report-phase[=<i>list</i>]</code>	<code>/Qopt-report-phase[:<i>list</i>]</code>	Specifies a comma separated <i>list</i> of optimization phases to use when generating reports. If you do not specify a phase the compiler defaults to all. You can request a list of all available phases by using the <code>[Q]opt-report-help</code> option.  To generate a report for the IPO phase, use <code>-qopt-report-phase=<i>ipo</i></code> or <code>/Qopt-report-phase:<i>ipo</i></code> .  Available for <code>ifort</code> only.
<code>-qopt-report-routines=<i>substring</i></code>	<code>/Qopt-report-routines:<i>substring</i></code>	Generates reports for all routines with names containing <i>substring</i> as part of their name. You can also specify a sequence of substrings separated by commas. If you do this, the compiler generates an optimization report for each of the routines whose name contains one or more of these substrings.  If <i>substring</i> is not specified, the compiler generates reports on all routines.  Available for <code>ifort</code> only.
<code>-qopt-report-filter=<i>string</i></code>	<code>/Qopt-report-filter:<i>string</i></code>	Tells the compiler to find the indicated parts of your application specified by <i>string</i> , and generate optimization reports for them.  If both <code>-qopt-report-routines=<i>string1</i></code> and <code>qopt-report-filter=<i>string2</i></code> are specified, it is treated as <code>-qopt-report-filter=<i>string1;string2</i></code> .  Available for <code>ifort</code> only.
<code>-qopt-report-help</code>	<code>/Qopt-report-help</code>	Displays the optimization phases available to use when using the <code>-qopt-report-phase</code> (Linux and macOS) or <code>[q or Q]opt-report-phase</code> (Windows) option.

Linux and macOS	Windows	Description
		Available for <code>ifort</code> only.
<code>-qopt-report-names/</code>	<code>/Qopt-report-names</code>	Specifies whether mangled or unmangled names appear in the optimization report. If this option is not specified, unmangled names are used by default.
		If you specify mangled, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing. If you specify unmangled, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing. If you use this option, you do not have to specify the <code>-qopt-report</code> (Linux and macOS) or <code>/Qopt-report</code> (Windows) option.
		Available for <code>ifort</code> only.

## Inline Expansion of Functions

Inline function expansion does not require that the applications meet the criteria for whole program analysis normally required by IPO; so this optimization is one of the most important optimizations done in Interprocedural Optimization (IPO). For function calls that the compiler believes are frequently executed, the compiler often decides to replace the instructions of the call with code for the function itself.

In the compiler, inline function expansion is performed on relatively small user functions more often than on functions that are relatively large. This optimization improves application performance by performing the following:

- Removing the need to set up parameters for a function call
- Eliminating the function call branch
- Propagating constants

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler can examine the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

Specifying the `[Q]ip` compiler option, single-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined within the current source file; in contrast, specifying the `[Q]ipo` compiler option, multi-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined in other files.

**Caution**

Using the `[Q]ip` and `[Q]ipo` (Windows\*) options can, in some cases, significantly increase compile time and code size.

The compiler does a certain amount of inlining at the default level. Although such inlining is similar to what is done when you use the `[Q]ip` option, the amount of inlining done is generally less than when you use the option.

**Select Routines for Inlining**

The compiler attempts to select the routines whose inline expansions provide the greatest benefit to program performance. The selection is done using default heuristics. The inlining heuristics used by the compiler differ based on whether or not you use options for Profile-Guided Optimizations (PGO): `[Q]prof-use` compiler option.

When you use PGO with `[Q]ip` or `[Q]ipo`, the compiler uses the following guidelines for applying heuristics:

- The default heuristic focuses on the most frequently executed call sites, based on the profile information gathered for the program.
- The default heuristic always inlines very small functions that meet the minimum inline criteria.

**Use IPO with PGO**

Combining IPO and PGO typically produces better results than using IPO alone. PGO produces dynamic profiling information that can usually provide better optimization opportunities than the static profiling information used in IPO.

The compiler uses characteristics of the source code to estimate which function calls are executed most frequently. It applies these estimates to the PGO-based guidelines described above. The estimation of frequency, based on static characteristics of the source, is not always accurate.

**Compiler-directed Inline Expansion of Functions**

Without directions from the user, the compiler attempts to estimate what functions should be inlined to optimize application performance.

The following options are useful in situations where an application can benefit from user function inlining but does not need specific direction about inlining limits.

Option	Effect
<code>inline-level</code> (Linux* and macOS) or <code>Ob</code> (Windows*)	Specifies the level of inline function expansion. Note that the option <code>/Ob2</code> on Windows* is equivalent to <code>-inline-level=2</code> on Linux* and macOS. Allowed values are 0, 1, and 2.
<code>[Q]ip-no-inlining</code>	Disables only inlining enabled by the <code>[Q]ip</code> , <code>[Q]ipo</code> , or <code>Ob2</code> options.
<code>[Q]ip-no-pinlining</code>	Disables partial inlining enabled by the <code>[Q]ip</code> or <code>[Q]ipo</code> options.  No other IPO optimizations are disabled.
setting <code>inline-debug-info</code> for the <code>debug</code> option	Indicates that the source position information for an inlined function should be retained, rather than replaced, by that of the call which is being inlined.

## Developer-directed Inline Expansion of User Functions

In addition to the options that support compiler directed inline expansion of user functions, the compiler also provides compiler options and directives that allow you to more precisely direct when and if inline function expansion should occur.

The compiler measures the relative size of a routine in an abstract value of intermediate language units, which is approximately equivalent to the number of instructions that will be generated. The compiler uses the intermediate language unit estimates to classify routines and functions as relatively small, medium, or large functions. The compiler then uses the estimates to determine when to inline a function; if the minimum criteria for inlining is met and all other things are equal, the compiler has an affinity for inlining relatively small functions and not inlining relative large functions.

Typically, the compiler targets functions that have been marked for inlining based on the following:

- **Procedure-specific inlining directives:** Tells the compiler to inline calls within the targeted procedure if it is legal to do so. For example, `!DIR$ ATTRIBUTES INLINE, !DIR$ ATTRIBUTES FORCEINLINE`.

The following developer directed inlining options and directives provide the ability to change the boundaries used by the inliner to distinguish between small and large functions.

In general, you should use the `[Q]inline-factor` option before using the individual inlining options listed below; this single option effectively controls several other upper-limit options.

If your code hits an inlining limit, the compiler issues a warning at the highest warning level. The warning specifies which of the inlining limits have been hit, and the compiler option and/or directives needed to get a full report. For example, you could get a message as follows:

```
Inlining inhibited by limit max-total-size. Use -qopt-report -qopt-report-phase=ipo for full report.
```

Messages in the report refer directly to the command line options or directives that can be used to overcome the limits.

The following table lists the options you can use to fine-tune inline expansion of functions. The directives associated with the options are documented in the **Effect** column.

Option	Effect
<code>[Q]inline-factor</code>	<p>Controls the multiplier applied to all inlining options that define upper limits: <code>inline-max-size</code>, <code>inline-max-total-size</code>, <code>inline-max-per-routine</code>, and <code>inline-max-per-compile</code>. While you can specify an individual increase in any of the upper-limit options, this single option provides an efficient means of controlling all of the upper-limit options with a single command.</p> <p>By default, this option uses a multiplier of 100, which corresponds to a factor of 1. Specifying 200 implies a factor of 2, and so on. Experiment with the multiplier carefully. You could increase the upper limits to allow too much inlining, which might result in your system running out of memory.</p>
<code>[Q]inline-force-inline</code>	<p>Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.</p>

Option	Effect
	Without this option, the compiler treats functions declared with the ATTRIBUTES INLINE directive as merely being recommended for inlining. When this option is used, it is as if they were declared with the ATTRIBUTES FORCEINLINE directive.
[Q]inline-min-size	Redefines the maximum size of small routines; routines that are equal to or smaller than the value specified are more likely to be inlined.
[Q]inline-max-size	Redefines the minimum size of large routines; routines that are equal to or larger than the value specified are less likely to be inlined.
[Q]inline-max-total-size	Limits the expanded size of inlined functions.  You can also use !DIR\$ ATTRIBUTES OPTIMIZATION_PARAMETER:"INLINE_MAX_TOTAL_SIZE=N" to control the size an individual routine can grow through inlining.
[Q]inline-max-per-routine	Limits the number of times inlining can be applied within a routine.  You can also use !DIR\$ ATTRIBUTES OPTIMIZATION_PARAMETER:"INLINE_MAX_PER_ROUTINE=N" to control the number of times inlining may be applied to a routine.
[Q]inline-max-per-compile	Limits the number of times inlining can be applied within a compilation unit.  The compilation unit limit depends on the whether or not you specify the [Q]ipo compiler option. If you enable IPO, all source files that are part of the compilation are considered one compilation unit. For compilations not involving IPO each source file is considered an individual compilation unit.

`inline-min-size`, `Qinline-min-size` compiler option

## Inlining Report

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler examines the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

The Inlining Report is part of the Opt Report. The compiler options `-qopt-report` (Linux\* and macOS) and `/Qopt-report` (Windows\*) generate optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a specific file, `stdout` or `stderr`, and request reports from all routines with names containing a specific string as part of their name.

The inlining report is a description of the inlining choices that were made for each routine that is compiled in the program. It is produced as part of the opt report. To restrict the opt report to contain ONLY the inlining report, use the option `-qopt-report-phase=ipo` (Linux\* and macOS) or `/Qopt-report-phase:ipo` (Windows\*).

The user can control the amount of information by specifying a level for the inlining report. The level is shown by a number from 1 to 5. Level 1 contains the smallest amount of information, and each level adds information to the report. Level 2 is the default report.

Level	Summary
Level 1	Shows each call that was inlined
Level 2 (default report)	Shows the values of the key inlining options
Level 3	Shows the calls to routines with external linkage
Level 4	Shows: <ul style="list-style-type: none"> <li>• Whole program information</li> <li>• Size (sz) of the each routine inlined and the increase in application size (isz) due to each instance of inlining</li> <li>• Routine percentages</li> <li>• Calls that are not inlined</li> </ul>
Level 5	Shows inlining footnotes, which contain advice on how to change the inlining to potentially improve application performance

The inlining report gives you an in-depth overview of the compiler's inlining decisions, which occur within five levels of granularity. You can specify levels with `-qopt-report=1`, `-qopt-report=2`, etc., (Linux\* and macOS) or `/Qopt-report=1`, `/Qopt-report=2`, etc. (Windows\*). See below for specific level details.

### Level 1

The Inlining Report is activated when you run the Optimization Report, using `[q or Q]qopt-report`.

For each routine you compile, you get one report with the title **INLINE REPORT** that shows the calls inlined into that routine.

#### Example: Inlining Report Level 1 - Typical Routine

```

INLINE REPORT: (APPLU)
-> INLINE: (295,12) SETBV
   -> INLINE: (398,18) EXACT
   -> INLINE: (399,18) EXACT
   -> INLINE: (409,18) EXACT
   -> INLINE: (410,18) EXACT

```

**Example: Inlining Report Level 1 - Typical Routine**

```

-> INLINE: (420,18) EXACT
-> INLINE: (421,18) EXACT
-> INLINE: (299,12) SETIV
-> (303,12) ERHS
-> (307,12) SSOR
-> INLINE: (311,12) ERROR
  -> INLINE: (1518,24) EXACT
  -> INLINE: (1552,24) EXACT
-> INLINE: (315,12) PINTGR
-> (319,12) VERIFY

```

The report gives the name of the compiled routine (APPLU), and contains one line for each call that the compiler decided to inline or not inline. In the above report, the compiler made 15 inlining decisions for calls in the routine APPLU. It decided to inline 12 of the calls. These decisions are indicated by the lines which start with `-> INLINE`. It decided not to inline three of the calls. These decisions are indicated by the lines without the word `INLINE`.

On each line, the position of the call in the source code is given in parentheses, followed by the name of the routine being called. For example:

```
-> INLINE: (398,18) EXACT
```

This refers to a call at line 398 column 18 to a routine called EXACT.

**Level 2**

Level 2 includes the values of important compiler options related to inlining. Unless the user specifies one of these values by using the option on the command line, the default value of the option is shown. You can read more about the meaning of the individual inlining options in the [Inlining Options](#) section.

**Example: Inlining Report Level 2 - Values of Inlining Options**

```

INLINING OPTION VALUES:
-inline-factor: 100
-inline-min-size: 30
-inline-max-size: 230
-inline-max-total-size: 2000
-inline-max-per-routine: 10000
-inline-max-per-compile: 500000

```

**Level 3**

Level 3 contains one additional line for each call to an external routine made in the application. Such calls are not candidates for inlining, because the code for these routines is not present in the file or files being compiled.

**Example: Inlining Report Level 3 - External Linkage**

```

Begin optimization report for: APPLU
  Report from: Interprocedural optimizations [ipo]
INLINE REPORT: (APPLU) [1] applu.f (1,16)
  -> EXTERN: (1,16) for_set_reentrancy
  -> EXTERN: (80,7) for_read_seq_lis

```

## Level 4

Level 4 adds four additional pieces of information. The specifics are shown below:

- Whole Program values:

### Example: Whole Program

```
WHOLE PROGRAM [SAFE] [EITHER METHOD]: false
WHOLE PROGRAM [SEEN] [TABLE METHOD]: true
WHOLE PROGRAM [READ] [OBJECT READER METHOD]: false
```

An application for which whole program is determined is subject to a higher degree of optimization than one which is not. The Intel compiler uses two methods of determining whole program, a TABLE METHOD and an OBJECT READER METHOD.

- The size of the routine [sz] and the inlined size of the routine [isz]. Usually isz is less than sz:

### Example: Size of the Routine (sz) vs. Inlined Size of the Routine (isz)

```
-> INLINE: (295,12) SETBV (isz = 752) (sz = 755)
-> INLINE: (398,18) EXACT (isz = 98) (sz = 109)
```

In the above example, the routine SETBV was inlined into the routine that called it. The size of SETBV, before inlining, was 755 units. After inlining, the calling routine was increased by 752 units. The increase in the size of the calling routine is slightly less than the size of SETBV, because some of the overhead of calling SETBV was removed when SETBV was inlined.

- The percentage of time that has passed in the process of compiling the file:

### Example: Percentage of Time Passed During Compilation

```
INLINE REPORT: (APPLU) [1/16=6.2%] applu.f (1,16)
```

For example, on the line above, [1/16 = 6.2%] indicates that APPLU is the first routine out of 16 to be compiled, and when this routine is done being compiled, 6.2% of the compilation is finished. You can use these numbers to estimate how long the compilation is going to take.

- The calls that did not get inlined and the reason why they did not get inlined. The reason is shown in double brackets [[ ]].

### Example: Calls That Are Not Inlined

```
-> (303,12) ERHS (isz = 2125) (sz = 2128)
    [[ Inlining would exceed -inline-max-size value (2128>253)]]
```

In the above example, the routine ERHS is not inlined, because the size of the routine (2128 units) is larger than the allowable size (253 units). If you wish to inline routines that are this large, you can use the option `-inline-max-size=2128` (or larger).

## Level 5

Level 5 adds the inlining footnotes.

### Example: Use of Footnote

```
-> (303,12) ERHS (isz = 2058) (sz = 2061)
    [[ Inlining would exceed -inline-max-size-value (2061>230) <1>]]
```

The inlining footnotes explain the text found in the double brackets [[ ]]. They include a description for why an inlining call did not happen, and what you can do to make the inlining of this call happen.

The footnote annotation <1> refers to the first footnote in the INLINING FOOTNOTES section at the bottom of the inlining report, which is produced when the user selects Level 5. For example, the footnote produced for annotation <1> above is:

**Example: Footnote Text**

```
<1> The subprogram is larger than the inliner would normally inline. Use the
option -inline-max-size to increase the size of any subprogram that would
normally be inlined, add "!DIR$ATTRIBUTES FORCELINE" to the
declaration of the called function, or add "!DIR$ FORCELINE" before
the call site.
```

---

## Fortran Language Extensions

---

Intel® Fortran provides a number of additional implementation features designed to simplify or enhance application development. The features in the section are varied; your choice to employ each feature depends on your application and development needs.

The *Intel® Fortran Language Reference* contains a section showing a summary of all the language extensions (non-standard features).

## Support for 64-bit Architecture on Linux

---

Applications designed to take advantage of Intel® 64 architecture can be built with one of three memory models:

- `small (-mmodel=small)`

This causes code and data to be restricted to the first 2GB of address space so that all accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.

- `medium (-mmodel=medium)`

This causes code to be restricted to the first 2GB; however, there is no restriction on data. Code can be addressed with IP-relative addressing, but access of data must use absolute addressing.

- `large (-mmodel=large)`

There are no restrictions on code or data; access to both code and data uses absolute addressing.

IP-relative addressing requires only 32-bits, whereas absolute addressing requires 64-bits. This difference can affect code size and performance. (IP-relative addressing is somewhat faster.)

### Additional Notes on Memory Models and Large Data Objects

- When you specify option `-mmodel=medium` or `-mmodel=large`, it sets option `-shared-intel`. This ensures that the correct dynamic versions of the Intel runtime libraries are used.
- When you build shared objects (`.so`), Position-Independent Code (PIC) is specified (that is, `-fpic` is added by the compiler driver) so that a single `.so` can support all three memory models. However, code that is to be placed in a static library, or linked statically, must be built with the proper memory model specified. Note that there is a performance impact to specifying the medium or large memory models.
- The use of the memory model (medium, large) option and the `-shared-intel` option is required as a by-product of the code models stipulated in the 64-bit Application Binary Interface (ABI), which is written specifically for processors with the 64-bit memory extensions. Both the compiler and the GNU linker (`ld`) are responsible for generating the proper code and necessary relocations on this platform according to the chosen memory model.

- The 2GB restriction on Intel® 64 architecture involves not only arrays greater than 2GB, but also COMMON blocks and local data with a total size greater than 2GB. The Compiler Options reference contains additional discussion of the supported memory models and offers details about the 2GB restrictions for each model (see the description for option [mcmodel](#)).
- If, during linking, you fail to use the appropriate memory model and dynamic library options, an error message in this format occurs:

```
<some lib.a library>(some .o): In Function <function>:
: relocation truncated to fit: R_X86_64_PC32 <some symbol>
```

## Traceback

When a Fortran program terminates due to a severe error condition, the Fortran runtime system displays additional diagnostic information after the runtime message.

The Fortran runtime system attempts to walk back up the call chain and produce a report of the calling sequence leading to the error as part of the default diagnostic message report. This is known as traceback. The minimum information displayed includes:

- The standard Fortran runtime [Runtime Message Display and Format](#) text that explains the error condition.
- A tabular report that contains one line per call stack frame. This information includes at least the image name and a hexadecimal PC in that image.

The information displayed under the Routine, Line, and Source columns depends on whether your program was compiled with the `traceback` option.

For example, if the `traceback` option is specified, the displayed information might resemble the following:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
```

Image	PC	Routine	Line	Source
libifcoreert.dll	1000A3B2	Unknown	Unknown	Unknown
libifcoreert.dll	1000A184	Unknown	Unknown	Unknown
libifcoreert.dll	10009324	Unknown	Unknown	Unknown
libifcoreert.dll	10009596	Unknown	Unknown	Unknown
libifcoreert.dll	10024193	Unknown	Unknown	Unknown
teof.exe	004011A9	AGAIN	21	teof.for
teof.exe	004010DD	GO	15	teof.for
teof.exe	004010A7	WE	11	teof.for
teof.exe	00401071	HERE	7	teof.for
teof.exe	00401035	TEOF	3	teof.for
teof.exe	004013D9	Unknown	Unknown	Unknown
teof.exe	004012DF	Unknown	Unknown	Unknown
KERNEL32.dll	77F1B304	Unknown	Unknown	Unknown

If the same program is *not* compiled with the `traceback` option:

- The Routine name, Line number, and Source file columns would be reported as "Unknown."
- A link map file is usually needed to locate the cause of the error.

The `traceback` option provides program counter (PC) to source file line correlation information to appear in the displayed error message information, which simplifies the task of locating the cause of severe runtime errors.

For Fortran objects generated with the `traceback` option, the compiler generates additional information used by the Fortran runtime system to automatically correlate PC values to the routine name in which they occur, Fortran source file, and line number in the source file. This information is displayed in the runtime error diagnostic report.

Automatic PC correlation is only supported for Fortran code. For non-Fortran code, only the hexadecimal PC locations are reported.

[traceback](#) compiler option

## Traceback Tradeoffs and Restrictions

This topic describes tradeoffs and restrictions that apply to using traceback.

### Effect on Image Size

Using the `traceback` option to get automatic PC correlation increases the size of an image. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PCs with a map file is acceptable.

The approach of providing automatic correlation information in the image was used so that no runtime penalty is incurred by building the information "on the fly" as your application executes. No runtime diagnostic code is invoked unless your application is terminating due to a severe error.

### C Compiler Omit Frame Pointer Option on Systems Using IA-32 Architecture

The following routines are used to walk the stack:

- For Windows\*, the Windows API routine `StackWalk( )` in `imagehlp.dll`
- For Linux\* and for macOS, `_Unwind_ForcedUnwind( )`, `_Unwind_GetIP( )`, `_Unwind_GetRegionStart( )` and `_Unwind_GetGr( )` routines in `libunwind.so`

In an environment using IA-32 architecture, there are no firm software calling standards documented. Compiler developers are under no constraints to use machine registers in any particular way or to hook up procedures in any particular way. The stack walking routines listed above use a set of heuristics to determine how to walk the call stack. That is, they make a "best guess" to determine how a program reached a particular point in the call chain. With C code that has been compiled with Visual C++\* using the Omit Frame Pointer option -- either `-fomit-frame-pointer` (Linux and macOS) or `/Oy` (Windows) -- this "best guess" is not usually the correct one.

If you are mixing Fortran and C code and you are concerned about stack tracing, consider disabling the `-fomit-frame-pointer` or `/Oy` option in your C compilations. Otherwise, traceback will most likely not work for you.

### Inlined Routines Will Not Be Displayed

Inlining can cause some routines not to be realized as separate stack frames, so the traceback will not show inlined routines.

### Stack Trace Failure

Programs can fail for a number of reasons, often with unpredictable consequences. Memory corruption by erroneously executing code is one possibility. Stack memory can be corrupted in such a way that the attempt to trace the call stack will result in access violations or other undesirable consequences. The stack-tracing runtime code is guarded with a local exception filter. If the traceback attempt fails due to a hard detectable condition, the runtime will report this condition in its diagnostic output message as:

```
Stack trace terminated abnormally
```

Be forewarned, however: It is also possible for memory to be corrupted in such a way that a stack trace can seem to complete successfully with no hint of a problem. The bit patterns it finds in corrupted memory where the stack used to be, and then uses to access memory, may constitute perfectly valid memory addresses for the program to be accessing. However, they do not happen to have any connection to what the stack used to look like. So, if it appears that the stack walk completed normally, but the reported PCs make no sense to you, then consider ignoring the stack trace output in diagnosing your problem.

Another condition that will disable the stack trace process is your program exiting because it has exhausted virtual memory resources.

The stack trace can fail if the runtime system cannot dynamically load `libunwind.so` (Linux and macOS) or `imagehlp.dll` (Windows) or cannot find the necessary routines from that library. In this case, you still get the basic runtime diagnostic message; you will not get any call stack information.

### Linker /incremental:no Option on Windows

When incremental linking is enabled, automatic PC correlation does not work. Use of incremental linking always disables automatic PC correlation even if you specify `/traceback` during compilation.

When you use incremental linking, the default hexadecimal (hex) PC values will still appear in the output. To correlate from the hexadecimal PC values to routine containing the PC addresses requires use of a linker map file. However, if you request a map file during linking, incremental linking becomes disabled. Thus to allow any PC values generated for a runtime problem to be helpful, incremental linking must be disabled.

In the Integrated Development Environment, you can use the Call stack display, so incremental linking is not a problem.

### Sample Programs and Traceback Information

The following sections provide sample programs that show the use of traceback to locate the cause of the error:

- [Example: End-of-File Condition, Program teof](#)
- [Example: Machine Exception Condition, Program ovf](#)

Note that the hex PC's and contents of registers displayed in these program outputs are meant as representative examples of typical output. The PC's will change over time, as the libraries and other tools used to create an image change.

#### Example: End-of-File Condition, Program teof

In the following example, a `READ` statement creates an End-Of-File error, which the application has not handled:

```
program teof
  integer*4 i,res
  i=here( )
end
integer*4 function here( )
  here = we( )
end
integer*4 function we( )
  we = go( )
end
integer*4 function go( )
  go = again( )
end
integer*4 function again( )
  integer*4 a
  open(10,file='xxx.dat',form='unformatted',status='unknown')
  read(10) a
  again=a
end
```

The diagnostic output that results when this program is built with traceback enabled, optimization disabled, and linked against the shared Fortran runtime library on the Intel® 64 architecture platform is similar to the following:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image          PC          Routine          Line        Source
libifcorert.dll 000007FED2B232D9  Unknown          Unknown     Unknown
```

libifcoreert.dll	000007FED2B6CEE0	Unknown	Unknown	Unknown
teof.exe	000000013F931193	AGAIN	17	teof.f90
teof.exe	000000013F93109B	GO	12	teof.f90
teof.exe	000000013F931072	WE	9	teof.f90
teof.exe	000000013F931049	HERE	6	teof.f90
teof.exe	000000013F93101E	MAIN__	3	teof.f90
teof.exe	000000013F96ADCE	Unknown	Unknown	Unknown
teof.exe	000000013F96B64C	Unknown	Unknown	Unknown
kernel32.dll	0000000076CC59BD	Unknown	Unknown	Unknown
ntdll.dll	0000000076EFA2E1	Unknown	Unknown	Unknown

If optimization is not disabled (`/Od` on Windows\* or `-O0` on Linux\* and macOS), procedure inlining may collapse the call stack and make it more difficult to locate a problem.

The first line of the output is the standard Fortran runtime error message. What follows is the result of walking the call stack in reverse order to determine where the error originated. Each line of output represents a call frame on the stack. Since the application was compiled with the `traceback` option, the PCs that fall in Fortran code are correlated to their matching routine name, line number and source module. PCs that are not in Fortran code are not correlated and are reported as "Unknown."

The first two frames show the calls to routines in the Fortran runtime library (in reverse order). Since the application was linked against the shared version of the library, the image name reported is either `libifcore.so` (Linux\* and macOS) or `libifcoreert.dll` (Windows\*). These are the runtime routines that were called to do the READ and upon detection of the EOF condition, were invoked to report the error. In the case of an unhandled I/O programming error, there will always be a few frames on the call stack down in runtime code like this.

The stack frame of real interest to the Fortran developer is the first frame in image `teof.exe`, which shows that the error originated in the routine named `AGAIN` in source module `teof.f90` at line 17. Looking in the source code at line 21, you can see the Fortran READ statement that incurred the end-of-file condition.

The next four frames show the trail of calls in the Fortran user code that led to the routine that got the error (TEOF->HERE->WE->GO->AGAIN).

Finally, the bottom four frames are routines which handled the startup and initialization of the program.

If this program had been linked against the static Fortran runtime library, the output would then look like:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image      PC          Routine      Line      Source
teof.exe   000000013F941FFB   Unknown    Unknown   Unknown
teof.exe   000000013F9380A0   Unknown    Unknown   Unknown
teof.exe   000000013F931193   AGAIN      17        teof.f90
teof.exe   000000013F93109B   GO         12        teof.f90
teof.exe   000000013F931072   WE         9         teof.f90
teof.exe   000000013F931049   HERE      6         teof.f90
teof.exe   000000013F93101E   MAIN__    3         teof.f90
teof.exe   000000013F96ADCE   Unknown    Unknown   Unknown
teof.exe   000000013F96B64C   Unknown    Unknown   Unknown
kernel32.dll 0000000076CC59BD   Unknown    Unknown   Unknown
ntdll.dll  0000000076EFA2E1   Unknown    Unknown   Unknown
```

Notice that the initial two stack frames now show routines in image `teof.exe`, not `libifcore.so` (Linux and macOS) or `libifcoreert.dll` (Windows). The routines are the same two runtime routines as previously reported for the shared library case but since the application was linked against the archive library `libifcore.a` (Linux and macOS) or the static Fortran runtime library `libifcore.lib` (Windows), the object modules containing these routines were linked into the application image (`teof.exe`). You can use a [Generating Listing and Map Files](#) to determine the locations of uncorrelated PCs.

Now suppose the application was compiled *without* traceback enabled and, once again, linked against the static Fortran library. The diagnostic output would appear as follows:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
Image          PC          Routine          Line        Source
teof.exe       000000013F851FFB   Unknown          Unknown     Unknown
teof.exe       000000013F8480A0   Unknown          Unknown     Unknown
teof.exe       000000013F841193   Unknown          Unknown     Unknown
teof.exe       000000013F84109B   Unknown          Unknown     Unknown
teof.exe       000000013F841072   Unknown          Unknown     Unknown
teof.exe       000000013F841049   Unknown          Unknown     Unknown
teof.exe       000000013F84101E   Unknown          Unknown     Unknown
teof.exe       000000013F87ADCE   Unknown          Unknown     Unknown
teof.exe       000000013F87B64C   Unknown          Unknown     Unknown
kernel32.dll   0000000076CC59BD   Unknown          Unknown     Unknown
ntdll.dll     0000000076EFA2E1   Unknown          Unknown     Unknown
```

Without the correlation information in the image that option `traceback` previously supplied, the Fortran runtime system cannot correlate PC's to routine name, line number, and source file. You can still use the [Generating Listing and Map Files](#) to at least determine the routine names and what modules they are in.

Remember that compiling with the `traceback` option increases the size of your application's image because of the extra PC correlation information included in the image. You can see if the extra traceback information is included in an image (checking for the presence of a `.trace` section) by entering:

```
objdump -h your_app.exe    ! Linux OS
otool -l your_app.exe      ! macOS
link -dump -summary your_app.exe ! Windows OS
```

Build your application with and without traceback and compare the file size of each image. Check the file size with a simple directory command.

For this simple `teof.exe` example, the traceback correlation information adds about 512 bytes to the image size. In a real application, this would probably be much larger. For any application, the developer must decide if the increase in image size is worth the benefit of automatic PC correlation or if manually correlating PC's with a map file is acceptable.

If an error occurs when traceback was requested during compilation, the runtime library will produce the correlated call stack display.

If an error occurs when traceback was disabled during compilation, the runtime library will produce the uncorrelated call stack display.

If you do not want to see the call stack information displayed, you can set the [Supported Environment Variable](#) `FOR_DISABLE_STACK_TRACE` to true. You will still get the Fortran runtime error message:

```
forrtl: severe (24): end-of-file during read, unit 10, file E:\USERS\xxx.dat
```

### Example: Machine Exception Condition, Program ovf

The following program generates a floating-point overflow exception when compiled with the `fpe` option value 0:

```
program ovf
  real*4 a
  a=1e37
  do i=1,10
    a=hey(a)
  end do
  print *, 'a= ', a
```

```

end
real*4 function hey(b)
  real*4 b
  hey = watch(b)
end
real*4 function watch(b)
  real*4 b
  watch = out(b)
end
real*4 function out(b)
  real*4 b
  out = below(b)
end
real*4 function below(b)
  real*4 b
  below = b*10.0e0
end

```

Assume this program is compiled with the following:

- Option `fpe` value 0
- Option `traceback`
- Option `-O0` (Linux and macOS) or `/Od` (Windows)

On a system based on IA-32 architecture, the traceback output is similar to the following:

```

forrtl: error (72): floating overflow
Image          PC          Routine          Line        Source
ovf.exe        001211A3  _BELOW          23  ovf.f90
ovf.exe        0012116F  _OUT            19  ovf.f90
ovf.exe        0012113D  _WATCH          15  ovf.f90
ovf.exe        0012110B  _HEY            11  ovf.f90
ovf.exe        0012104E  _MAIN__         5   ovf.f90
ovf.exe        0015B31F  Unknown         Unknown      Unknown
ovf.exe        0015BADD  Unknown         Unknown      Unknown
kernel32.dll   7515338A  Unknown         Unknown      Unknown
ntdll.dll     770E9902  Unknown         Unknown      Unknown
ntdll.dll     770E98D5  Unknown         Unknown      Unknown

```

Notice that unlike the previous example of an unhandled I/O programming error, the stack walk can begin right at the point of the exception. There are no runtime routines on the call stack to dig through. The overflow occurs in routine `BELOW` at PC `001211A3`, which is correlated to line 23 of the source file `ovf.f90`.

When the program is compiled at a higher optimization level of `O2`, along with option `fpe` value 0 and the `traceback` option, the traceback output appears as follows:

```

forrtl: error (72): floating overflow
Image          PC          Routine          Line        Source
ovf.exe        00AE1059  _MAIN__         7   ovf.f90
ovf.exe        00B1B75F  Unknown         Unknown      Unknown
ovf.exe        00B1BADD  Unknown         Unknown      Unknown
kernel32.dll   7515338A  Unknown         Unknown      Unknown
ntdll.dll     770E9902  Unknown         Unknown      Unknown
ntdll.dll     770E98D5  Unknown         Unknown      Unknown

```

With `O2`, the entire program has been inlined.

The main program, `OVF`, no longer calls routine `HEY`. While the output is not quite what one might have expected intuitively, it is still entirely correct. You need to keep in mind the effects of compiler optimization when you interpret the diagnostic information reported for a failure in a release image.

If the same image were executed again, this time with the environment variable called `TBK_ENABLE_VERBOSE_STACK_TRACE` set to `True`, you would also see a dump of the exception context record at the time of the error. Here is an excerpt of how that might appear on a system using IA-32 architecture:

```
forrtl: error (72): floating overflow
Hex Dump Of Exception Record Context Information:

## Allocate Common Blocks

Use the `[Q]dyncom` option to dynamically allocate common blocks at runtime.

This option designates a common block to be dynamic. The space for its data is allocated at runtime rather than at compile time. On entry to each routine containing a declaration of the dynamic common block, a check is performed to see whether space for the common block has been allocated. If the dynamic common block is not yet allocated, space is allocated at that time.

### NOTE macOS

To successfully enable dynamic allocation of common blocks, you must specify the link-time option `-undefined dynamic_lookup` as well as option `-dyncom`.

The following command-line example specifies the dynamic common option with the names of the common blocks to be allocated dynamically at runtime:

```
ifort -dyncom "blk1,blk2,blk3" test.f ! Linux and macOS
ifort /Qdyncom"BLK1,BLK2,BLK3" test.f ! Windows
```

where `BLK1`, `BLK2`, and `BLK3` are the names of the common blocks to be made dynamic.

## Guidelines for the `[Q]dyncom` Option

The following are some limitations that you should be aware of when using the `[Q]dyncom` option:

- An entity in a dynamic common cannot be initialized in a DATA statement.
- Only named common blocks can be designated as dynamic COMMON.
- An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a static common block or a DATA-initialized variable.

## Why Use a Dynamic Common Block?

A main reason for using dynamic common blocks is to enable you to control the common block allocation by supplying your own allocation routine. To use your own allocation routine, you should link it ahead of the Fortran runtime library.

The C function prototype is:

```
void _FTN_ALLOC(void **mem, int *size, char *name);
```

where

- *mem* is the location of the base pointer of the common block that must be set by the routine to point to the block of memory allocated.
- *size* is the integer number of bytes of memory that the compiler has determined are necessary to allocate for the common block as it was declared in the program.

You can ignore this value and use whatever value is necessary for your purpose. You must return the size in bytes of the space you allocate. The library routine that calls the default or Fortran runtime function ensures that all other occurrences of this common block fit in the space you allocated. You can return the size in bytes of the space you allocate by modifying *size*.

- *name* is the name of the common block being dynamically allocated.

The equivalent Fortran INTERFACE specification is:

```
interface
  subroutine my_ftn_alloc (mem, size, name) bind (C, name="_FTN_ALLOC")
    use, intrinsic :: ISO_C_BINDING
    implicit none

    type(C_PTR), intent(OUT) :: mem
    integer(C_INT), intent(INOUT) :: size
    character, dimension(*), intent(IN) :: name
  end subroutine my_ftn_alloc
end interface
```

You can also use the Fortran runtime function `FOR_SET_FTN_ALLOC` to specify your own allocation routine. This method is especially helpful when you are using shared libraries. If you choose this method, it overrides the default routine `_FTN_ALLOC`.

## Allocate Memory to Dynamic Common Blocks

The runtime library routine, `f90_dyncom`, performs memory allocation. The compiler calls this routine at the beginning of each routine in a program that contains a dynamic common block. In turn, this library routine calls `_FTN_ALLOC` to allocate memory. By default, the compiler passes the size in bytes of the common block as declared in each routine to `f90_dyncom`, and then on to `_FTN_ALLOC`. The Fortran runtime library contains a default version of `_FTN_ALLOC`, which simply allocates the requested number of bytes and returns.

If you use the nonstandard extension having the common block of the same name declared with different sizes in different routines, you may get a runtime error depending on the order in which the routines containing the common block declarations are invoked.

You can now create your own routine to dynamically allocate common blocks, which is especially useful when you are sharing libraries. To use your own routine, you must specify the runtime function `FOR_SET_FTN_ALLOC`.

# Generate Listing and Map Files

Compiler-generated assembler output listings and linker-generated map files can help you understand the effects of compiler optimizations and see how your application is laid out in memory. They may also help you interpret the information provided in a stack trace at the time of an error.

## How to Generate Assembler Output

When compiling from the command line, specify the `s` option:

```
ifort -S file.f90 ! Linux and macOS
ifort file.f90 /S ! Windows OS
```

On Linux\* and macOS systems, the resulting assembly file name has an `.s` suffix. On Windows\* systems, the resulting assembly file name has an `.asm` suffix.

On Windows\*, you can also use the Microsoft Visual Studio\* Integrated Development Environment:

1. Select **Project > Properties**.
2. Click the **Fortran** tab.
3. In the **Output Files** category, change the **Assembler Output** settings according to your needs. You can choose from a number of options such as **No Listing**, **Assembly-only Listing**, and **Assembly, Machine Code and Source**.

## How to Generate a Link Map (.map) File

When compiling from the command line, specify the `-Xlinker` and `-M` options (Linux and macOS) or the `/map` (Windows) option:

```
ifort file.f90 -Xlinker -M ! Linux and macOS
ifort file.f90 /map ! Windows
```

On Windows systems, you can also use the Visual Studio Integrated Development Environment:

1. Select **Project>Properties**.
2. Click the **Linker** tab.
3. In the **Debug** category, select **Generate Map File**.

## How to Generate a Source File Listing

You can use the `list` compiler option to create a listing of the source file. The listing can contain the following information: a display of `INCLUDE` files, a symbol list with a line number cross reference for each routine, and a list of compiler options used for the compilation.

Use the `show` compiler option to control the contents of the listing file.

Additionally, on Windows systems, you can use the Visual Studio Integrated Development Environment to create a source file listing:

1. Select **Project > Properties**.
2. Click the **Fortran** tab.
3. In the **Output Files** category, change the **Source Listing** setting to **Yes**.

## Create Shared Libraries

You can create a shareable library by using one of the following compiler options.

Compiler Option	Library
<code>-shared</code> (Linux*)	<code>mylib.so</code>
<code>/libs:dll</code> (Windows*)	<code>mylib.dll</code>
<code>-dynamiclib</code> (macOS)	<code>mylib.dylib</code>

When you use any of these options, do not specify the `c` option.

## Specify Alternative Tools and Locations

The default tools are summarized in the table below.

Tool	Default	Provided with Intel® Fortran Compiler?
Assembler for IA-32 architecture-based applications and Intel® 64 architecture-based applications	MASM* (Windows*)	No
	operating system assembler, <code>as</code> (Linux* and macOS)	No
Linker	Microsoft* linker (Windows)	No
	System linker, <code>ld(1)</code> (Linux and macOS)	No

The Intel® Fortran Compiler lets you specify alternatives to default tools and locations for preprocessing, compilation, assembly, and linking. In addition, you can invoke options specific to the alternate tools on the command line. This functionality is provided by the `Qlocation` and `Qoption` options.

### See Also

[Qlocation](#) compiler option

[Qoption](#) compiler option

## Temporary Files Created by the Compiler or Linker

Temporary files created by the compiler or linker reside in the directory used by the operating system to store temporary files.

To store temporary files, the driver first checks for the `TMP` environment variable. If defined, the directory that `TMP` points to is used to store temporary files.

If the `TMP` environment variable is not defined, the driver then checks for the `TMPDIR` environment variable. If defined, the directory that `TMPDIR` points to is used to store temporary files.

If the `TMPPDIR` environment variable is not defined, the driver then checks for the `TEMP` environment variable. If defined, the directory that `TEMP` points to is used to store temporary files.

For Windows\*, if the `TEMP` environment variable is not defined, the current working directory is used to store temporary files. For Linux\* and macOS, if the `TEMP` environment variable is not defined, the `/tmp` directory is used to store temporary files.

Temporary files are usually deleted. Use the `[Q]save-temps` compiler option to save temporary files created by the compiler in the current working directory. This option only saves intermediate files that are normally created during compilation.

For performance reasons, use a local drive (rather than a network drive) to contain temporary files.

To view the file name and directory where each temporary file is created, use the `all` keyword for the `watch` option.

To create object files in your current working directory, use the `c` option.

Any object files that you specify on the command line are retained.

## Use the Intel® Fortran COM Server on Windows

---

The Component Object Model (COM) supports a model of client server interaction between a user of an object, the client, and the implementor of the object, the server.

This section discusses creating a COM server using Intel Fortran.

The following section, [Use the Intel\(R\) Fortran Module Wizard \(COM Client\)](#), discusses using COM and Automation objects from an Intel® Fortran application, using the Fortran COM Server.

### Advantages of a COM Server

A COM server consists of the implementation of one or more *object classes*. An object class is a type that describes the complete public calling interface ("signature") of an object. It describes the functionality that you want to make available to the users of the object. The COM server creates *instances* of the class, called *objects*, at the request of clients.

Some of the advantages of implementing your Fortran code as a COM server include:

- A COM server is a reusable component, which allows multiple applications to use the server. The classes specified by the server define a "contract" between the server and its clients. The server can change the specific implementation of the functionality without breaking the contract. That is, without requiring clients to be changed or rebuilt.
- A COM server is programming-language independent. Multiple development tools can be used to access the server's functionality, including Microsoft Visual Basic\*, C++, and Fortran.
- A COM server is self-describing. The server provides a type library that describes the classes and interfaces. Many tools can take advantage of this information and relieve the client programmer from needing to understand low-level invocation details, such as calling conventions. This is a great improvement over multi-language programming with DLLs, where the client programmer has to understand the details of data types and calling conventions.
- A COM server is self-registering. The clients do not need to worry about where the server is located on their system, as COM finds this information in the system registry.
- A COM server can be implemented as an in-process server. Like a DLL, it is loaded into the client's process. A COM server can also be implemented as a separate application and can even reside on a separate machine.

Intel Fortran provides the Fortran COM Server application wizard and special editor for modifying the COM Server structure and generating Fortran code necessary to implement a COM server. This allows you to concentrate on the code that is specific to the functionality that your server provides to its clients.

As explained in [Understanding COM and Automation Objects](#), COM supports two types of servers: COM servers and Automation servers. The Fortran COM Server Wizard can only create a COM server or a server that supports dual interfaces. The wizard cannot create an Automation-only interface.

For more information about creating COM servers, see [Creating the Fortran COM Server](#).

## COM Server Concepts

The Fortran COM Server application wizard generates an initial Visual Studio project and creates a COM Hierarchy file, which describes the infrastructure of a COM server. You can modify this file with the COM Server Hierarchy Editor to define the implementation of one or more *object classes*, including its interface(s), and method(s).

When you save the hierarchy file, the Fortran source files are generated. You then need to write code to implement each method.

### What Information You Need to Provide

When you create the COM Server project, you will need to describe the COM server classes that you want to implement.

A class implements one or more COM *interfaces*. In COM terminology, an interface is a semantically related set of functions. The interface as a whole represents a "feature", or set of related functionality, that is implemented by the class. An interface contains *methods*, otherwise known as member functions. A method is a routine that performs one of the actions that make up the feature. As far as the Fortran COM Server is concerned, methods are Fortran functions that take arguments and return a value like any other Fortran function.

Consider a simple example of a class that you will create using the Fortran COM Server Application Wizard, called *AddingMachine*. The class contains a single interface that we call *IAdd*. By convention, all interface names begin with a capital letter "I". You can define three methods in the *IAdd* interface:

- *Clear*, which takes no arguments and sets the current value of the adding machine to 0.
- *Add*, which takes a single REAL argument, the amount to add to the current value.
- *GetValue*, which returns the current value.

These methods allow you to perform specific, distinct tasks with the *IAdd* interface from any language that supports a COM client. The Fortran COM Server Editor provides a user interface to enter this information about the class (in this case the *AddingMachine* class), which is discussed later in [Creating the Fortran COM Server](#).

An interface can also contain *properties*. Properties are method pairs that set or return information about the state of an object. Properties must currently be implemented using the *get\_Method* and *put\_Method* and the same DISPID property.

In terms of the data associated with an object, a key concept of object-oriented programming is *encapsulation*. Encapsulation means that all of the details about how the object is implemented, including the data that it uses, and the logic that it uses to perform its work, is hidden from the client. The client's only access to the object is through the interfaces that the object supports.

You need to define the data that the object uses and code the logic of the methods. For the data, the Fortran COM Server Application Wizard uses the model that each instance of the object has an associated instance of a Fortran derived-type. The code generated by the wizard takes care of creating and destroying the instances of the derived-type as objects are created and destroyed.

You define the fields of the derived-type. For example, with our *AddingMachine*, each *AddingMachine* object needs to store the current value. The derived-type associated with each *AddingMachine* object would contain a single field of type REAL. We name it *CurrentValue*. Note that each instance of the *AddingMachine* object has its own instance of the derived-type and its own *CurrentValue*. This means that

the server could support multiple clients simultaneously and each client would see its own `AddingMachine`. That is, each client is unaffected by the existence of other clients. The derived-type associated with each object is discussed in detail in [Creating the Fortran COM Server](#).

To summarize, at a high level, what you need to do to create a COM server:

- Create the COM Server project using the COM Server Application Wizard.
- Define the class(es), interface(s), method(s), and properties using the COM Server Hierarchy Editor to create the Hierarchy file.
- Define the fields in the derived-type that is associated with each instance of a class.
- Write code that initializes the fields in the derived-type (if necessary), and code that releases any resources used by the fields in the derived-type (if necessary).
- Write the code that implements the methods.

### What the COM Server Will Provide

The Fortran COM Server Editor generates source files that implement all of the infrastructure, or "plumbing", of the COM server. The generated files take care of such tasks as:

- Defining the GUIDs that uniquely identify your classes and interfaces. For a discussion of GUIDs, see [Getting a Pointer to an Objects Interface](#).
- Registering the server and your classes and interfaces on the system.
- Implementing the class factory that creates instances of your object.
- Creating the Interface Definition Library (IDL) and type library that describes your classes and interfaces. For a discussion of type libraries, see [Using the Module Wizard to Generate Code](#).
- Implementing the `IUnknown` and `IDispatch` interfaces for your object. All of the interfaces created by the Fortran COM Server Editor are derived from `IUnknown` or `IDispatch` (dual interfaces).
- Creating and destroying instances of the derived-type associated with your object.
- Invoking the Fortran routines that implement your object's methods.

The majority of these source files are generated fully by the Fortran COM Server Editor and are not modified by you. Other files contain the skeleton or template of your derived-type and methods. You edit these Fortran source files to fill in your implementation. A walk-through of the `AddingMachine` example will show you how it's done.

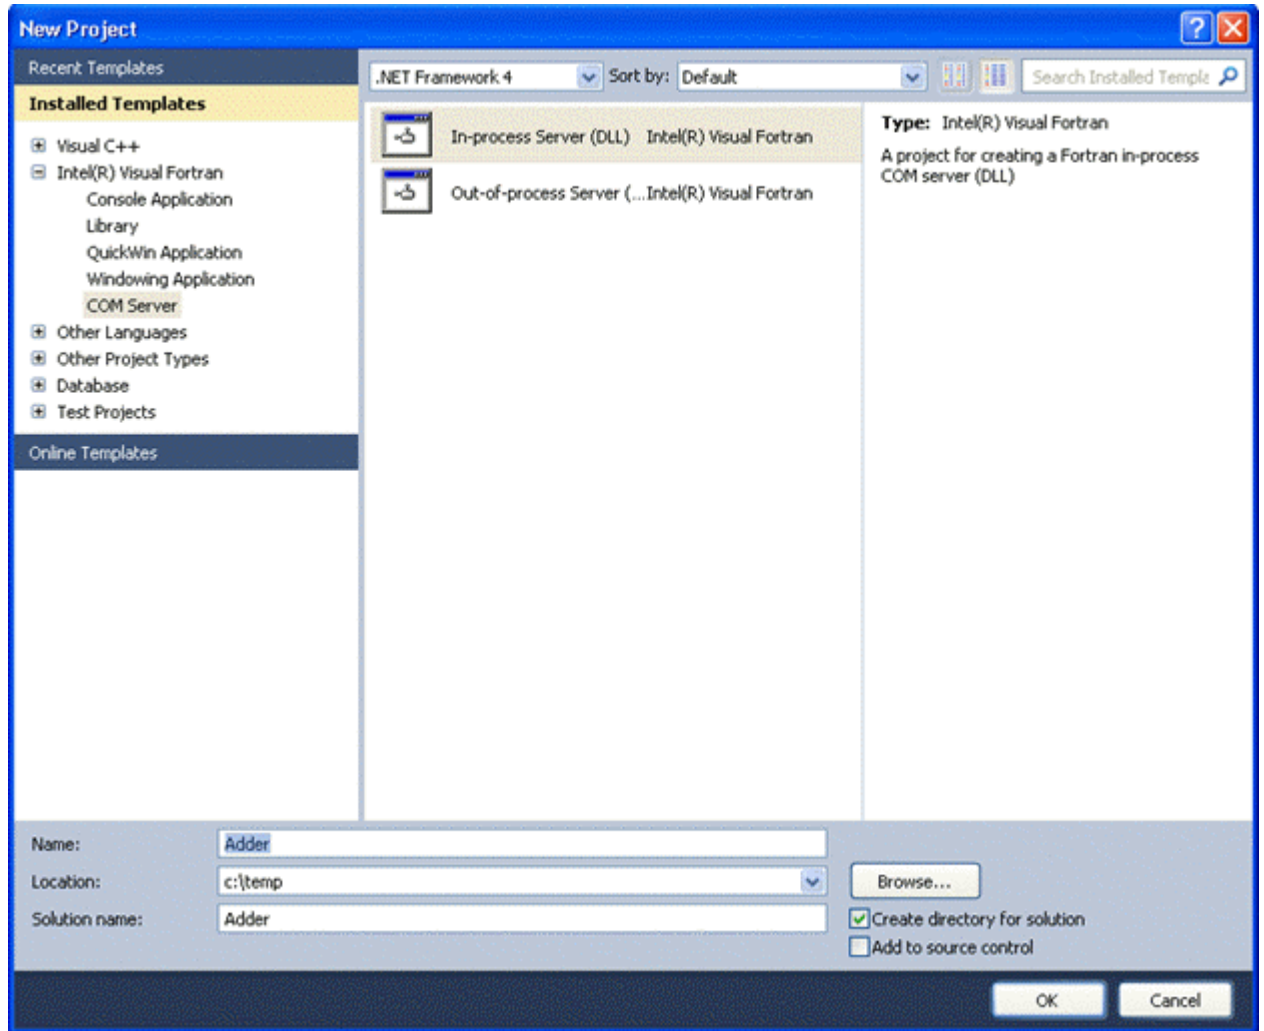

### Create the Fortran COM Server

This section shows how to create a project, specify the COM server characteristics, generate code for, and implement a sample Fortran COM server project called `Adder`.

The first step in creating a Fortran COM Server is to create a new project.

#### Create a Fortran COM Server Project using the Visual Studio\* IDE:

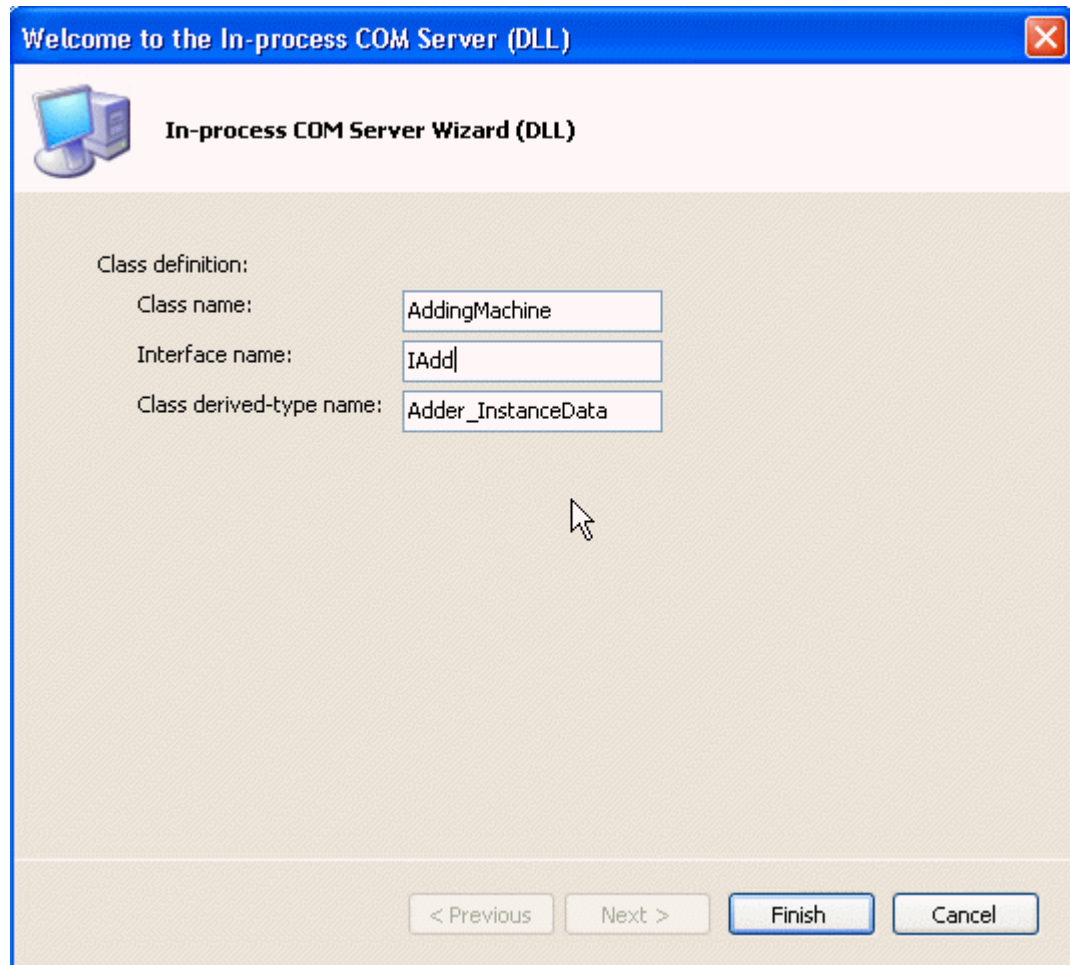

1. Start the Visual Studio IDE. Choose **File > New > Project**.
2. In the **New Project** dialog box, expand the Intel(R) Visual Fortran item and click **COM Server**.

To create the sample project, choose **In-process Server (DLL)**. Now do the following:

1. Enter **Adder** as the name of the project.
2. Accept or modify the project folder location.
3. Click **OK**.

You can use the project `AppWizard` once per project to create the project files and skeleton template. The Fortran COM Server `AppWizard` displays default text for the interface name and class derived type name.

Now do the following:

1. Enter class name `AddingMachine`.
2. Shorten the default interface name to `IAdd`.
3. Accept the default class derived type name.
4. Click **Finish**. (If you click **Cancel**, project creation is terminated.)

The project is created and the COM Server Hierarchy file (`adder.hie`) is opened in the COM Hierarchy Editor.

### Use the COM Hierarchy Editor to Define your COM Server

The COM Hierarchy Editor lets you interactively define the attributes (for example, classes, interfaces, and methods) for your COM server. The user interface contains two panes:

- The top pane is a tree control that displays attribute information in a hierarchy.
- The bottom pane is a panel that displays the IDL definition for a selected element in the hierarchy.

You can use "right-click" context menus to insert, delete, and modify items in the hierarchy. Context menus also let you change item properties. For example, you can right-click the `IAdd` element and select **Properties** to see the `IAdd` interface properties. You could then change the `Is Dual` property value to **False**; this value indicates that the `Adder` example only supports a COM server interface.

An explanation of the hierarchy follows:

- The root is the COM server itself.

- The immediate children of the COM server are classes. The hierarchy initially contains a single class, `AddingMachine`. You can add additional classes to the COM server.
- The immediate children of a class are interfaces and the class derived-type. In the example, the [hierarchy](#) contains the interface `IAdd` and the class derived-type `AddingMachine_InstanceData`. Each class contains one, and only one, class derived-type. You can add additional interfaces to the class.
- The immediate children of an interface are methods (one or more).
- The immediate children of a method are the method arguments (one or more).

**To add a class, interface, method, property, or argument:**

1. Select the parent item, right-click and select the appropriate **Add...** item.

**To delete an item:**

1. Select the item to be deleted, right-click and select **Delete**.
2. Click the **Delete** button.

Continuing with the Adder COM server example, add methods to the `IAdd` interface:

1. Right-click the `IAdd` interface and select **Add Method**.
2. Enter `Clear` as the name of the method.
3. Repeat steps 1 and 2, this time entering the name of `Add`.

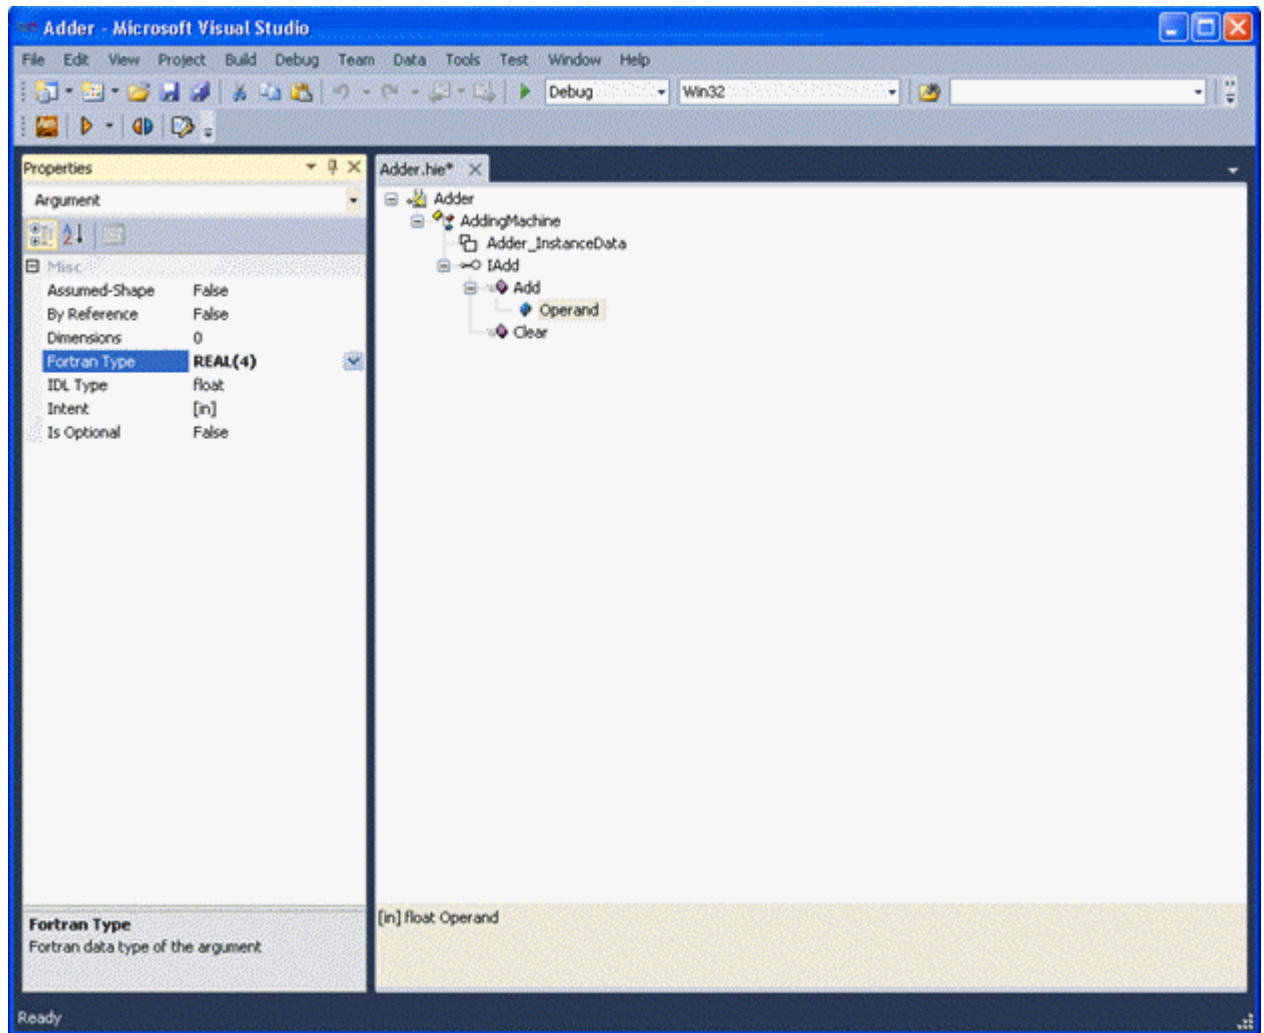

The `Add` method requires an argument. To add the `Operand` argument named `Operand`:

1. Right-click on the **Add** method and select **Add Argument**.
2. Enter the argument name, `Operand`.

The default data type of an argument is `INTEGER(4)`.

Proceeding with this example, use the Properties Window to change the Fortran Type property value to `REAL(4)`:

To add a third (and in this example, the last) method:

1. Right-click on the `IAdd` interface and select **Add Method**.
2. Enter `GetValue` as the name for the method.

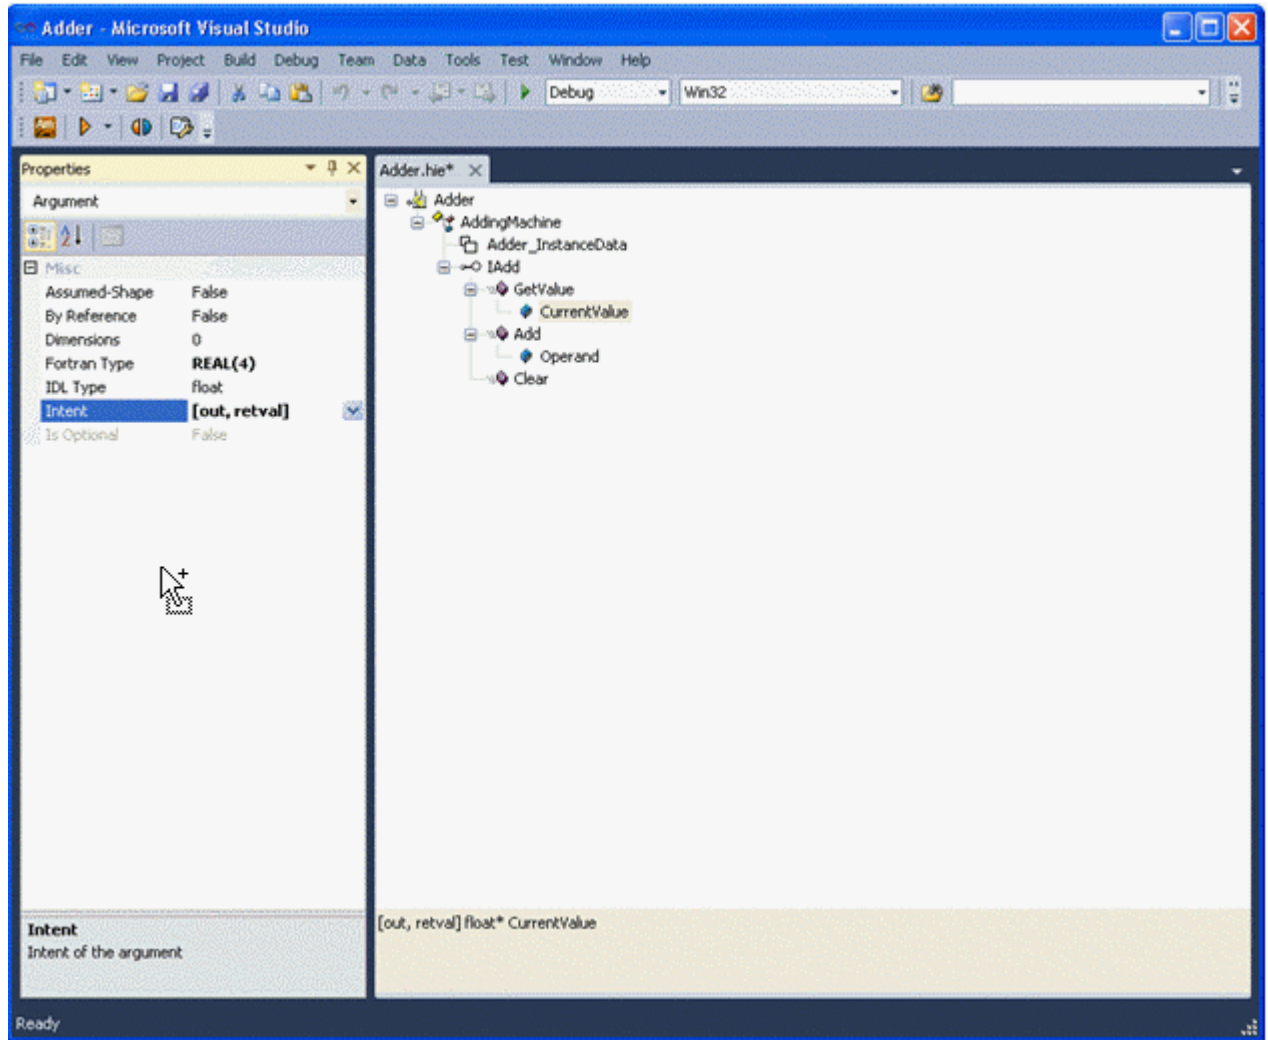

The `GetValue` method requires an argument, `CurrentValue`. To add the `CurrentValue` argument:

1. Right-click on the `GetValue` method and select **Add Argument**.
2. Enter `CurrentValue` as the name of the argument.

For the `CurrentValue` argument:

1. Set **Fortran Type** property value to `REAL(4)`.
2. Set **Intent** property values to `[out, retval]`.

The screen appears as follows:

The server definition is now complete for this example. When you save the file using **File > Save adder.hie**, the Fortran sources will be regenerated.

For detailed information about the property pages (right pane) for the server, class, interface, method, argument, or instance properties, see [Description of Property Pages](#).

To change the definition of your server, open `adder.hie` in the Editor.

### Work with the Hierarchy Pane

As you have seen in the `AddingMachine` example, the hierarchy pane represents the definition of your server; that is, the classes, interfaces, methods, and so on. The hierarchy pane's user interface supports the following functionality:

Expand/ contract an area	Click the plus sign (+) next to an item to display its children and the - to hide the children.
Add a new entry	Select the entry that will precede the new entry in the hierarchy, right-click and select one of the <b>New...</b> menu options.
Delete an entry	Select the item to be deleted, right-click and select <b>Delete</b> . All of an item's children are deleted when the item is deleted.

Rename a member	Select the item to be renamed, right-click and select <b>Rename</b> .
Change the order of items	<p>The hierarchy pane supports drag-and-drop to allow you to change the order of items. The order of some of the entries in the hierarchy is very important. In particular:</p> <ul style="list-style-type: none"> <li>• The order of the methods in an interface defines the order of the methods in the class' VTBL. Changing the order of the methods will break an existing client.</li> <li>• The order of the arguments in a method defines the order of the arguments in the method's interface. Changing the order of the arguments will break an existing client.</li> </ul>

## Description of Property Pages

Property pages appear in the **Properties** Window. Property pages are available for the following:

- [Server Properties](#)
- [Class Properties](#)
- [Interface Properties](#)
- [Method Properties](#)
- [Argument Properties](#)
- [Instance Type Properties](#)

### Server Properties:

Type Library GUID	The unique identifier of the server's type library. In general, use the default value generated by the Fortran COM Server Wizard.
Type Library Version	The current version of the Type Library.
HelpString	A string used to set the library's help string attribute in the IDL file.

### Class Properties:

ProgID	The version independent program ID (or text alias) for the class. The ProgID can be used in calls such as COMCreateObjectByProgID.
Version	The current version of the class. This value is appended to the ProgID to define the version-specific ProgID.
Short name	A short name for the class. This value is used in some of the generated file names.
Description	A string used as the default value of the class' ProgID keys in the registry. This string is often used by tools that display a list of the objects that are registered on the system, such as the OLE-COM Object Viewer.
Help String	A string used to set the class' help string attribute in the IDL file.
Threading model	The threading model of the class. The two choices are Apartment and Single. See Threading Models in <a href="#">Advanced COM Server Topics</a> for information about the implications of this choice.
CLSID	The unique identifier of the class. In general, use the default value generated by the Wizard.

### Interface Properties:

---

Is Dual	If true, then the dual interface attribute is set in the IDL file. A dual interface supports both COM and Automation clients.
Is OleAutomati on	If true, then the interface uses only Automation-compatible data types as described in <a href="#">Fortran COM Server Interface Design Considerations</a> .
Is Default	If true, then the default interface attribute is set for this interface in the IDL file. The default attribute represents the default programmability interface of the object, and is intended for use by macro languages.
Help String	A string used to set the interface's help string attribute in the IDL file.
IID	The unique identifier of the interface. In general, use the default value generated by the Wizard.

---

**Method Properties:**

---

DISPID	The identifier of the method used by Automation clients.
Help string	A string used to set the method's help string attribute in the IDL file.
Property Method	If checked, then the method is the get_ or put_ method of a property.

---

**Argument Properties:**

---

Fortran data type	The Fortran data type of the argument. Select one of the data types from the list, or type in the data type. See <a href="#">Fortran COM Server Interface Design Considerations</a> for a discussion of the implications of your choice.
IDL type	The IDL data type. If you select one of the Fortran data types from the predefined list, then this field defaults to the corresponding IDL data type. Select one of the data types from the list, or type in the data type. See <a href="#">Fortran COM Server Interface Design Considerations</a> for a discussion of the implications of your choice.
Intent	The INTENT of the argument, which is one of the following: <ul style="list-style-type: none"><li>• [in] - the argument value is read but not modified by the method.</li><li>• [out] - the argument value is not read, but is modified by the method.</li><li>• [in, out] - the argument value is both read and modified by the method.</li><li>• [out, retval] - the argument represents the return value of the method.</li></ul>
By Reference	Indicates that an argument is passed by reference rather than by value. Only valid with Intent In. Intent Out and Intent InOut are automatically passed by reference.
Is Optional	If true, then the argument is optional. Optional arguments are passed using the Variant data type.
Dimension s	Number of array dimensions (0 if the argument is scalar).

---

**Instance Type Properties:**

---

Module name	The name used for the module defined in the <code>UclassnameTY.f90</code> file.
Constructor name	The name used for the class constructor defined in the <code>UclassnameTY.f90</code> file.

**Destructor name** The name used for the class destructor defined in the `UclassnameTY.f90` file.

## Modify the Generated Code

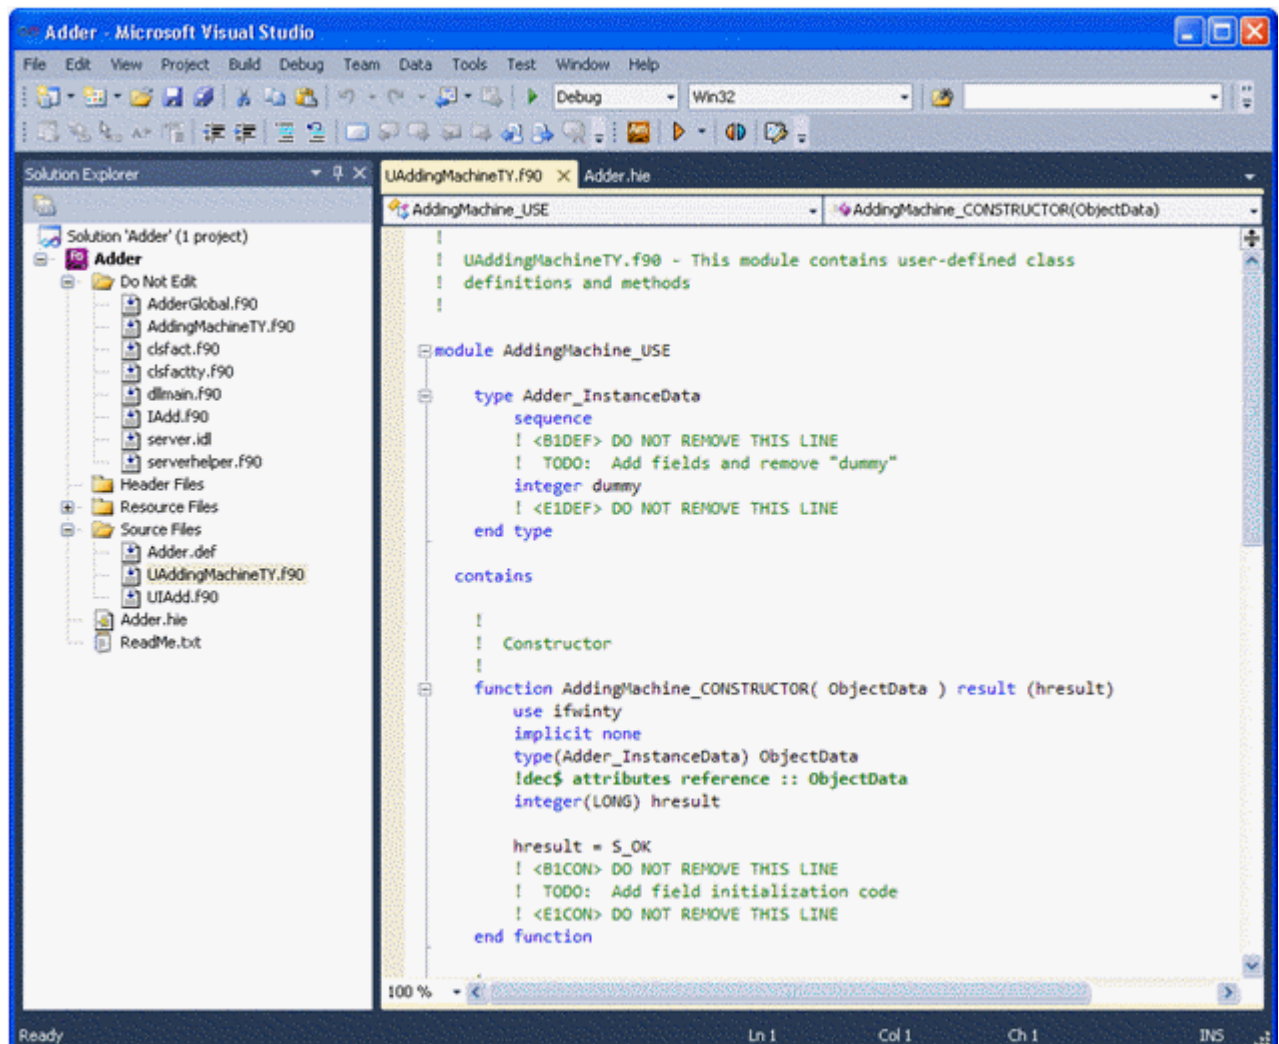

When you save the hierarchy file, Fortran sources are generated (or regenerated). Source files are stored as follows:

- Source files that you will need to modify are placed in the **Source Files** folder.
- Files that are complete and need no modification are placed in the **Do Not Edit** folder.

Modify the following files in the Source Files folder:

- `UAddingMachineTY.f90`, which contains a module that defines your class derived-type.
- `UIAdd.f90`, which contains the implementation of the `IAdd` methods.

Initially, the file `UAddingMachineTY.f90` contains the following code:

```

!
! UAddingMachineTY.f90 - This module contains user-defined class
! definitions and methods
!
module AddingMachine_USE

  type Adder_InstanceData
    sequence
    ! <B1DEF> DO NOT REMOVE THIS LINE
    ! TODO: Add fields and remove "dummy"
    integer dummy
    ! <E1DEF> DO NOT REMOVE THIS LINE
  end type

  contains

  !
  ! Constructor
  !
  function AddingMachine_CONSTRUCTOR( ObjectData ) result (hresult)
    use ifwinty
    implicit none
    type(Adder_InstanceData) ObjectData
    !dec$ attributes reference :: ObjectData
    integer(LONG) hresult

    hresult = S_OK
    ! <B1CON> DO NOT REMOVE THIS LINE
    ! TODO: Add field initialization code
    ! <E1CON> DO NOT REMOVE THIS LINE
  end function
end module AddingMachine_USE

```

The file contains a module named `AddingMachine_USE` (in the form `classname_USE`). There are three places in this module where you may need to add code specific to your class:

- The first entry in the module, marked by `<BnDEF>` and `<EnDEF>`, is your class derived-type. Initially it contains an "integer dummy" field to allow the module to be compiled without error. If your class has per-object data, remove the "integer dummy" field line and add your data to the derived-type. For the `AddingMachine` class, we add the following where the object stores the current value:

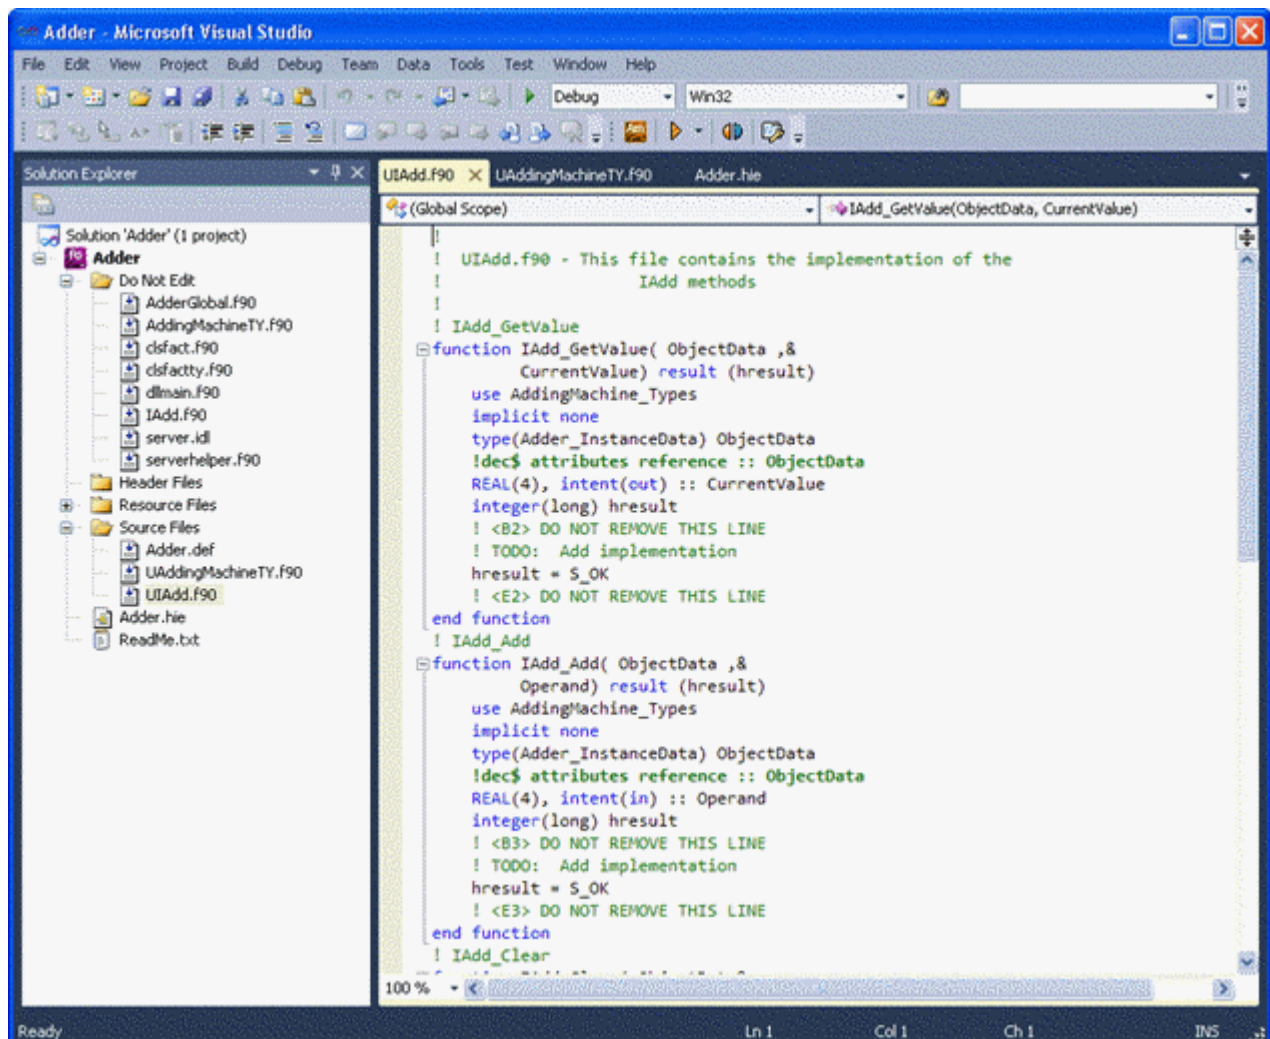

```
real (4) CurrentValue
```

- The module also contains two module procedures, `AddingMachine_CONSTRUCTOR` and `AddingMachine_DESTRUCTOR` (referred to as `classname_CONSTRUCTOR` and `classname_DESTRUCTOR` below). The former delineated with `<BnCON>` and `<EnCON>`; the latter is delineated with `<BnDES>` and `<EnDES>`.
- The `classname_CONSTRUCTOR` procedure is called immediately after an instance of the class derived-type is created because of the creation of a new object. This function is where you initialize the fields of the class derived-type, if necessary. The new derived-type is passed as an argument to the function. For the `AddingMachine` class, initialize the current value to 0 by adding the following statement:

```
ObjectData%CurrentValue = 0
```

- The `classname_DESTRUCTOR` procedure is called immediately before an instance of the class derived-type is destroyed because an object is being destroyed. This function is where you release any resources used by the fields of the class derived-type, if necessary. The derived-type is passed as an argument to the function. For the `AddingMachine` class, there is nothing that needs to be added.

Now modify the other source file called `UIAdd.f90`. The original file `UIAdd.f90` contains the following code:

A file by the name *Uinterfacename.f90* (for example *UIadd.f90*) is created for each interface defined by the class. The file contains the methods of the class. Each method is named *interfacename\_methodname*, for example: *IAdd\_Clear*. Each method is a function that is passed to the class derived-type as the first argument. It gives the function access to the per-object data. Each function returns a 32-bit COM status code called an HRESULT. *S\_OK* is a parameter that defines a success status. For additional information on COM status codes, see [Fortran COM Server Interface Design Considerations](#).

Replace the `! TODO: Add implementation` line in each method with the code for the method. For the *IAdd* interface, the implementation of its three methods is as follows:

For *IAdd\_Clear*: `ObjectData%CurrentValue = 0`

For *IAdd\_Add*: `ObjectData%CurrentValue = ObjectData%CurrentValue + Operand`

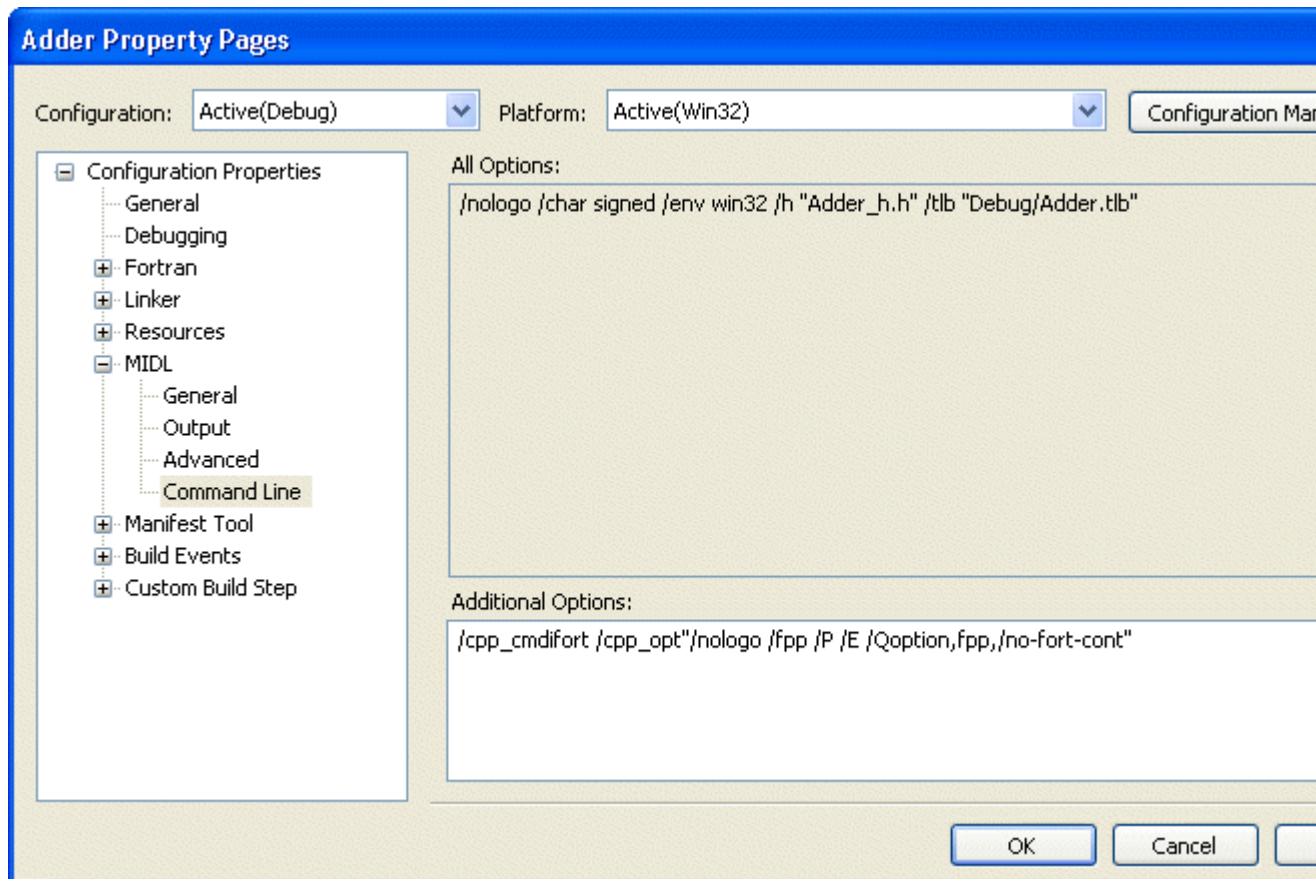

For *IAdd\_GetValue*: `CurrentValue = ObjectData%CurrentValue`

Save the file and, from the **Build** menu, click **Build Solution** to build the server. The COM server is now complete.

## COM Server Projects and the MIDL Compiler

During the creation of a COM Server project -- either In-process Server (DLL) or Out-of-process Server (EXE), as described in this section -- the application wizard determines whether Visual C++\* is installed. If it is installed, the MIDL compiler uses the Visual C++ C preprocessor. This setting is both the default and recommended setting. If Visual C++ is not installed, the application wizard specifies that the MIDL compiler use the Fortran preprocessor for preprocessing MIDL source files. It does this by setting the **Additional Options** property of the MIDL compiler to include the following: `/cpp_cmdifort /cpp_opt"/`

`nologo /fpp /P /E /Qoption,fpp,/no-fort-cont"`.

If, later, you install Visual C++ and want to specify that MIDL use the Visual C++ C preprocessor, remove these options from the MIDL compiler **Additional Options** property.

## Fortran COM Server Interface Design Considerations

This section provides information that should be considered when designing a Fortran COM server. It contains the following topics:

- [Method and Property Data Types](#)
- [COM Status Codes: HRESULT](#)
- [Visual Basic\\*, Visual C++\\*, and Intel® C++ Client Notes](#)

### Method and Property Data Types

COM places some restrictions on the data types used in COM methods and properties. The reason for the restrictions is that COM can pass arguments between threads, processes and machines. This behavior raises issues that are not present in older technologies, such as DLLs, that always run in the same address space as the caller.

COM defines set of data types called Automation-compatible data types. Automation-compatible data types are the only data types that can be used in Automation and Dual interfaces. The following are two advantages to restricting your COM interface to these data types:

- Your server will be usable from clients written in the largest set of languages, including Intel® Fortran, Visual Basic, and Visual C++.
- COM will automatically handle the passing of arguments between threads, processes and machines. This is called *Type Library Marshalling*. For more information, see *Marshalling, Proxies and Stubs* in [Advanced COM Server Topics](#).

To restrict your server to Automation-compatible data types:

1. Select Use only Automation data types on the Interface property page. When defining a dual interface, this selection is automatically set.
2. Use only the following combinations of Fortran data type and Interface data type on the Argument property page.

Note that Intel Fortran does not support the Currency, Decimal, or User Defined Type, Automation-compatible data types.

Fortran Date Type	Interface Data Type
INTEGER(1)	unsigned char
INTEGER(2)	short
INTEGER(4)	long
	SCODE
	Int
INTEGER(INT_PTR_KIND())	IUnknown*
	IDispatch*
REAL(4)	float
REAL(8)	double
	DATE
LOGICAL(2)	VARIANT_BOOL

Fortran Date Type	Interface Data Type
LOGICAL(4)	long
CHARACTER(1)	unsigned char
CHARACTER(*)	BSTR
BYTE	unsigned char
TYPE(VARIANT)	VARIANT (containing one of the above types or <i>SafeArray</i> )

If you decide not to restrict your interface to Automation-compatible data types, the next approach is to restrict your interface to data types that can be described in the Interface Description Language (IDL).

The Fortran COM Server Application Wizard automatically generates the IDL file from the description of your server. The MIDL compiler compiles the IDL file into a type library. MIDL can also automatically generate the code needed handle the passing of arguments between threads, processes and machines. Note, however, that a C compiler is required to use this option. For more information, see Discussion of Wizard Code Generation in [Advanced COM Server Topics](#).

If you decide not to restrict your interface to IDL data types, your only remaining options are:

- Implement Custom Marshalling - For more information, see Marshalling, Proxies and Stubs in [Advanced COM Server Topics](#).
- Decide that you will never use your server across apartment, thread, or process boundaries. The server will not be usable in this manner because there is no way to pass the arguments across these boundaries.

## COM Status Codes: HRESULT

Each function returns a 32-bit COM status code called an HRESULT. An HRESULT is divided into fields:

- The top bit (31) indicates whether the function succeeded or failed. The bit is set if the function failed. In Fortran, you can compare the HRESULT to  $< 0$  as a test to see if a function failed.
- Bits 16 to 27 contain a facility code to indicate the facility that issued the HRESULT. Microsoft predefines a number of facility codes for its own use. If you create your own status codes, use FACILITY\_ITF. All other facility codes are reserved by Microsoft.
- The first 16 bits, or low word, contain the error code specific to the error that occurred.

A typical HRESULT error value could be a value such as 0x80070057. The first hex digit, 8, indicates that bit 31 is set and that this value is an error value. Bits 16 to 27 contain the value 7. This value indicates the facility FACILITY\_WIN32. The low word contains the value 0057. This value is the specific code that identifies the error as E\_INVALIDARG.

To view the text description that corresponds to a system HRESULT value, use the Error Lookup tool in the Intel® Fortran program folder. For example, entering the value 0x80070057 retrieves the text message "The parameter is incorrect.", as shown below:

You can also search for HRESULT values in the `WINERROR.H` file in the `\VC\INCLUDE` directory.

## Visual Basic\*, Visual C++\*, and Intel® C++ Client Notes

To use an object from Visual Basic, you must add a "reference" to the object to the Visual Basic project. Use the References item in the Project menu to display a list of the registered objects. Select the object in the list to inform Visual Basic that you will be using the object.

Here are some points to be aware of when writing a server that can be used with Visual Basic clients:

- Use only the Automation-compatible data types (see [Method and Property Data Types](#)).
- Arguments to a method can be passed ByVal, ByRef, or they can be the function return value.
- An argument to be passed ByVal, must be defined with Intent set to In.
- An argument to be passed ByRef, must be defined with Intent set to InOut.
- A function return value must be defined with Intent set to Out. It must have the Return Value field checked. The argument must be the final argument of the method.
- An array is always passed as a `SafeArray` ByRef. Therefore it must be defined with Intent set to InOut.
- To use an argument of the Visual Basic Boolean data type, set the Fortran data type to `LOGICAL(2)` and set the Interface data type to `VARIANT_BOOL`.

To use an object from C++, use the `#import` directive. The syntax of the `#import` directive is:

```
#import "filename" [attributes]
#import <filename> [attributes]
```

The file name is the name of the file containing the type library information. The directive makes the information in the type library available to your source file as a set of C++ classes.

## Advanced COM Server Topics

Advanced topics about Fortran COM Servers described in this section include:

- [Choosing Between DLL or EXE COM Servers](#)
- [DLL Server Surrogates](#)
- [Discussion of Wizard Code Generation](#)
- [Threading Models](#)
- [Marshalling, Proxies and Stubs](#)
- [A Map of the Generated "Do Not Edit" Code](#)

### Choose Between DLL or EXE COM Servers

The basic tradeoff in choosing between a DLL (in-process) COM server and an EXE (out-of-process) COM server is one of performance vs. robustness:

- A DLL server provides the advantage of performance over an EXE server. Since the DLL server is loaded into the client's address space, there is less overhead involved in method calls. If the client code and the server object live in the same COM apartment, method calls are as efficient as DLL routine calls.
- An EXE server provides the advantage of robustness over a DLL server. Since the server object lives in a separate address space, the object cannot be affected by client memory handling bugs, and vice versa. If the server crashes, the client doesn't necessarily crash – as long as the client checks the results of all method calls and takes steps to recover from a "dead" object.

In addition to the tradeoff between performance and robustness, the following factors should also be considered:

- With an EXE server, the object can run in a separate security context from the client. With a DLL server, the code of the object's methods executes using the client's access token.
- An EXE server can be run on a remote machine using COM distributed object support.

You can load a DLL server into a surrogate to gain the benefits of an EXE server. This behavior is explained in the next section.

## DLL Server Surrogates

An in-process DLL server can be run in a separate process with the help of a *surrogate*. A surrogate runs as a separate process, loads the DLL server, and provides all of the mechanism that allows the DLL server to act as a local server. Windows provides a standard surrogate named `DLLHOST.EXE`. The primary advantage of using a surrogate is fault isolation. That is, if the server crashes it does not crash the client, and vice versa. The disadvantage is performance. Significant performance overhead occurs in executing methods in a separate application, as opposed to in a DLL.

A DLL server is associated with a surrogate via entries in the system registry. This action is done by associating the DLL server with an `AppID`. An `AppID` is a GUID. When using the standard surrogate, you can use the `CLSID` of a class in the DLL as the `AppID`, or a newly generated GUID. To generate a new GUID, use `GUIDGEN.EXE` in the Developer Studio Tools subdirectory:

1. Under the `HKEY_CLASSES_ROOT\CLSID\{xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx}` key of the class, add an `AppID` entry with the value of the `CLSID`. Using the `AddingMachine` class as an example, the registry key would be `HKEY_CLASSES_ROOT\CLSID\{904245FC-DD6D-11D3-9835-0000F875E193}` and the `AppID` value would be `{904245FC-DD6D-11D3-9835-0000F875E193}`.
2. Under the `HKEY_CLASSES_ROOT\AppID` key, add a key using the `AppID`. Using the `AddingMachine` class as an example, the registry key would be `HKEY_CLASSES_ROOT\AppID\{904245FC-DD6D-11D3-9835-0000F875E193}`. Use the class name for the default value of the key, for example, "AddingMachine Class". Add a "DllSurrogate" entry with an empty string for the value.

The client must request `CLSCTX_LOCAL_SERVER` rather than `CLSCTX_INPROC_SERVER` to use the surrogate rather than loading the DLL server in-process. Using a surrogate requires that the DLL server have a proxy/stub registered since the method invocations are between different processes. For information on proxies/stubs, see [Marshalling, Proxies and Stubs](#).

You can also write a custom surrogate. See the Windows Platform SDK documentation for information.

## Discussion of Wizard Code Generation

The COM Server Application Wizard generates the code for your project from the files in the subdirectory of your project named `templates`. The `project-name.hie` file contains the definition of your COM server in an undocumented text language. You should not manually edit the `project-name.hie` file; the Wizard will do that.

Most of the other files in the `templates` directory are templates of the source files generated for your project. These templates contain source code that is copied "as-is" to the generated sources, and embedded directives that guide the Wizard in generating the code specific to the COM server that you define. The directives use the information in the `project-name.hie` file. The directives are undocumented and subject to change.

When you create a new Fortran COM Server project, the `AppWizard` creates the `templates` directory and copies the templates from the Fortran COM Server templates directory, `...\Intel Fortran\Templates\COMServer`.

The files in the `templates` directory may change with each release, but the templates in your `templates` directory are never automatically updated. For example, if you create a COM server using Intel® Fortran Version 18.0 and the next release of Intel® Fortran (such as Version 18.1) contains updated templates, the templates for your COM server are not automatically updated to the new 18.1 templates. If you modify the definition of your server, your project continues to use the templates that it was created with. This behavior has the advantage of not introducing different code into a project that you have developed and tested.

However, there are two cases where you may want to modify the templates that are used by your project:

- A new release of Intel® Fortran may contain additional features that can be used in your COM server project. Some of the new features may depend upon the new templates. These features will not be available to a pre-existing project unless you update the templates in the `templates` directory. You do

this action by copying all of the files in the Fortran COM Server templates directory `...\Intel Fortran\Templates\COMServer` into the `templates` directory, replacing all files with the same name. Your project will then use the new templates the next time that the definition of your server is modified and the project sources are regenerated.

- When you want to modify the code generated by the Wizard. You may edit a template in your `templates` directory. Editing code that is copied "as-is" is straightforward. Attempting to modify the embedded directives is unsupported and could cause the Wizard to fail when using the modified template. The embedded directives begin with an @ (at-sign) character. The next character determines the type of directive. The end of many directives is also delimited by an @ character followed by the matching end character for the type of directive. For example, `@[` and `@]` are the delimiters for one type of directive.

The advantage of modifying a template is that you can customize the code generated by the Wizard. The disadvantages of modifying a template are:

- You must be very careful not to modify a template in a manner that causes the Wizard to generate bad code or fail.
- You will not be able to update the project templates with the templates from a new release of Intel® Fortran without having to re-apply your modifications to the new templates.

## Threading Models

The Wizard supports two COM threading models for the classes that you create in a DLL COM server, Apartment and Single. The Wizard uses the Apartment threading model (also known as the Single Threaded Apartment model "STA") by default. The basic rules of the Apartment threading model are:

- If two objects, *A* and *B*, are created in the same STA thread, and *A* is processing a method call, no other client can call either *A* or *B* until *A* completes.
- If *B* is created in a different thread from *A*, *B* can accept a method call while *A* is still processing and vice versa.

This means that if the class shares any global data among its objects, the global data must be protected from simultaneous access using thread synchronization primitives. This is because two instances of the class could be running in different threads. However the per-object instance data, that is, the fields in the class derived-type, are protected from simultaneous access by COM mechanisms. This is true except in the case where an object calls out to another object that triggers a reentrant invocation of the first object.

A class using the Single threading model need not worry about simultaneous access to class global data, as well as per-object data. All objects of the class are created in a single thread and therefore only a single object of the class can be executing at any time.

An EXE COM server generated by the wizard is single threaded. All method invocations are serialized by the server's message queue. Therefore, with an EXE server, you need not worry about simultaneous access to class global data, as well as per-object data.

Explaining the COM threading models in detail is beyond the scope of this documentation. See the Windows Platform SDK documentation for additional information.

## Marshalling, Proxies and Stubs

COM supports the use of objects in separate processes (as when using an EXE server or a DLL surrogate), and the threading models described above, by the use of marshalling, proxies and stubs. This section presents an overview of marshalling, proxies and stubs.

*Marshalling* is the process of reading the parameters for a method call and preparing them for transmission to another execution context (for example, thread, process, or machine). Marshalling is done by a *proxy*. From the client's perspective, a proxy has the same interface as the object itself. The proxy's job is to make the object look like an object in the same execution context as the client.

Proxies allow client code to be unconcerned about where the object actually lives. A proxy marshalls the method parameters and transmits them to a *stub* associated with the object in the server. The stub unmarshalls the parameters and invokes the method in the server. From the server's perspective, this behavior is no different from when it is called from a client in the same execution context. A server that is not an in-process DLL server always requires a proxy/stub pair. An in-process DLL server requires a proxy/stub pair when the client and object are in different apartments.

The following are the three ways to assign a proxy/stub pair to a server:

Type Library Marshalling:	If you use only Automation-compatible data types in your methods and properties, COM can automatically use the "Universal Marshaller" as the proxy/stub for the server. The Universal Marshaller uses the description of the server in the type library to decide how to marshall the parameters. This behavior is known as type library marshalling. Using type library marshalling requires no effort on your part, other than restricting your server to Automation-compatible data types.
MIDL-based Marshalling:	Your project uses the MIDL compiler to compile the IDL description of the server into a type library. At the same time, the MIDL compiler also generates the C source code necessary to build a proxy/stub DLL for the server. You must have a C compiler to build a proxy/stub DLL from the MIDL generated code. The proxy/stub DLL is itself an in-process DLL server and needs to be registered with the system. You would need to use MIDL-based marshalling if your server uses non-Automation-compatible data types, and is used by a client in a different execution context.
Custom Marshalling:	Your server can implement its own marshalling by implementing the <code>IMarshall</code> interface. This approach typically involves a lot of work and is done for performance reasons.

## A Map of the Generated "Do Not Edit" Code

This section presents an overview of which parts of the COM server functionality are implemented as "Do Not Edit" source files generated by the application wizard:

File Name	Description
server.idl	Contains the IDL description of the server. It is compiled by the MIDL compiler to produce the server's type library.
servernameglobal.f90	Contains the global data and functions for the server.
dllmain.f90 (DLL server)	Contains the exported functions that are required of all COM Server DLLs. These functions include <code>DllMain</code> , <code>DLLRegisterServer</code> , <code>DLLUnregisterServer</code> , <code>DllGetClassObject</code> , and <code>DllCanUnloadNow</code> .
exemain.f90 (EXE server)	Contains the main entry point of an EXE server. It also processes the command-line argument.
serverhelper.f90	Contains helper functions for the server.
clsfactty.f90	Contains definitions of the <code>IClassFactory</code> interface that is used to create instances of the classes defined by the server.
clsfact.f90	Contains methods of the <code>IClassFactory</code> interface that is used to create instances of the classes defined by the server.

File Name	Description
<i>classname</i> TY.f90	Defines a module that contains definitions of parameters and types used in the implementation of the class. It also contains the implementation of the <code>IUnknown</code> methods of the class. A separate instance of this file is generated for each class defined in the server.
<i>interfacename</i> .f90	Defines a module that contains the Fortran interfaces of the methods in the interface. It also contains the implementation of the Fortran "wrappers" that are called directly from the class' VTBL and call the methods implemented by the user. A separate instance of this file is generated for each interface defined in the class.

## Deploy the COM Server on Another System

When you have finished developing the COM server, you may want to deploy it on another system. Besides the server itself, you need to install the Fortran runtime DLLs and register the server:

1. Install (or copy) the COM server to an appropriate directory.
2. Register the server:
  - To register a DLL server, use the `REGSVR32.EXE` system tool, a command-line tool. To register the DLL server, specify the path to the DLL and its file name (*dll\_path*) by typing the following command:

```
REGSVR32 dll_path
```

- The file `REGSVR32.EXE` is in your system directory, such as the `\Winnt\System32` on Windows NT\* or Windows 2000 systems. If this directory is not in your PATH, include its path before the `REGSVR32` command.
- To register an EXE server, run the server with the `/REGSERVER` command-line option. For example:

```
exe_path /REGSERVER
```

If you are using MIDL-based Marshalling or Custom Marshalling, then the marshalling DLL also needs to be installed and registered. For information on marshalling, see [Advanced COM Server Topics](#).

## Use the Intel® Fortran Module Wizard (COM Client) on Windows

Intel® Fortran provides a wizard to simplify the use of Component Object Model (COM) and Automation (formerly called OLE Automation) objects. The Intel® Fortran Module Wizard generates Standard Fortran modules that simplify calling COM and Automation services from Fortran programs. This Fortran code lets you invoke methods of an Automation object and member functions of a Component Object Model (COM) object.

The following sections describe the use of COM and Automation objects as clients with Intel Fortran.

### COM and Automation Objects

This topic only applies to Windows.

This section provides a brief overview of:

- [COM Objects](#)
- [Automation Objects](#)
- [Object Servers](#)

## COM Objects

The Component Object Model (COM) provides mechanisms for creating reusable software components. COM is an object-based programming model designed to promote software interoperability; that is, to allow two or more applications or *components* to easily cooperate with one another, even if they were written by different vendors at different times, in different programming languages, or if they are running on different machines running different operating systems.

With COM, components interact with each other and with the system through collections of function calls, also known as methods or member functions or requests, called *interfaces*. An interface is a semantically related set of member functions. The interface as a whole represents a feature of an object. The member functions of an interface represent the operations that make up the feature. In general, an object can support multiple interfaces and you can use [COMQueryInterface \(W\\*32 W\\*64\)](#) to get a pointer to any of them.

The Intel Fortran COM routines provide a Fortran interface to basic COM functions.

## Automation Objects

The capabilities of an *Automation object* resemble those of a COM object. An Automation object is in fact a COM object that implements the interface IDispatch. An Automation object exposes:

- *Methods*, which are functions that perform an action on an object. These are very similar to the member functions of COM objects.
- *Properties*, which hold information about the state of an object. A property can be represented by a pair of methods; one for getting the property's current value, and one for setting the property's value.

The Intel® Visual Fortran AUTO routines provide a Fortran interface to invoking an automation object's methods and setting and getting its properties.

## Object Servers

COM and Automation objects are made available to users by COM and Automation *servers*. A COM or Automation server can be implemented either as:

- A DLL that is loaded into your process
- A separate executable program. The separate executable program can reside on the same system as your application or on a different system.

## The Role of the Module Wizard

This topic only applies to Windows.

### To use COM and Automation objects from a Fortran program:

1. Find or install the object server on the system. COM and Automation objects can be registered:
  - By other programs you install.
  - By creating the object server yourself, for example, by using Visual C++\*, or Visual Basic\*.

For example, the Microsoft visual development environment registers certain objects during installation (see the documentation on the Common Environment Object Model ).

Creating an object server involves deciding what type of object and what type of interfaces or methods should be available. The object's server must be designed, coded, and tested like any other application. For information about object server creation, see [Creating the Fortran COM Server](#).

2. Determine:

- Whether the object has a COM interface, Automation interface, or both.
- Where the object's type information is located.

You should be able to obtain this information from the object's documentation. You can use the OLE/COM Object Viewer tool from the development environment Tools menu to determine the characteristics of an object on your system.

### 3. Use the Intel® Fortran Module Wizard to generate code.

The module wizard is an application that allows you to select a COM or Automation object and set generated code options. The information collected by the module wizard is used in the generated code. To learn about using the Intel® Fortran module wizard, see [Using the Module Wizard to Generate Code](#).

### 4. Write a Fortran program to invoke the code generated by the Intel® Fortran module wizard.

To understand more about calling the interfaces and jacket routines created by the module wizard, see [Calling the Routines Generated by the Module Wizard](#).

## Use the Module Wizard to Generate Code

This topic only applies to Windows.

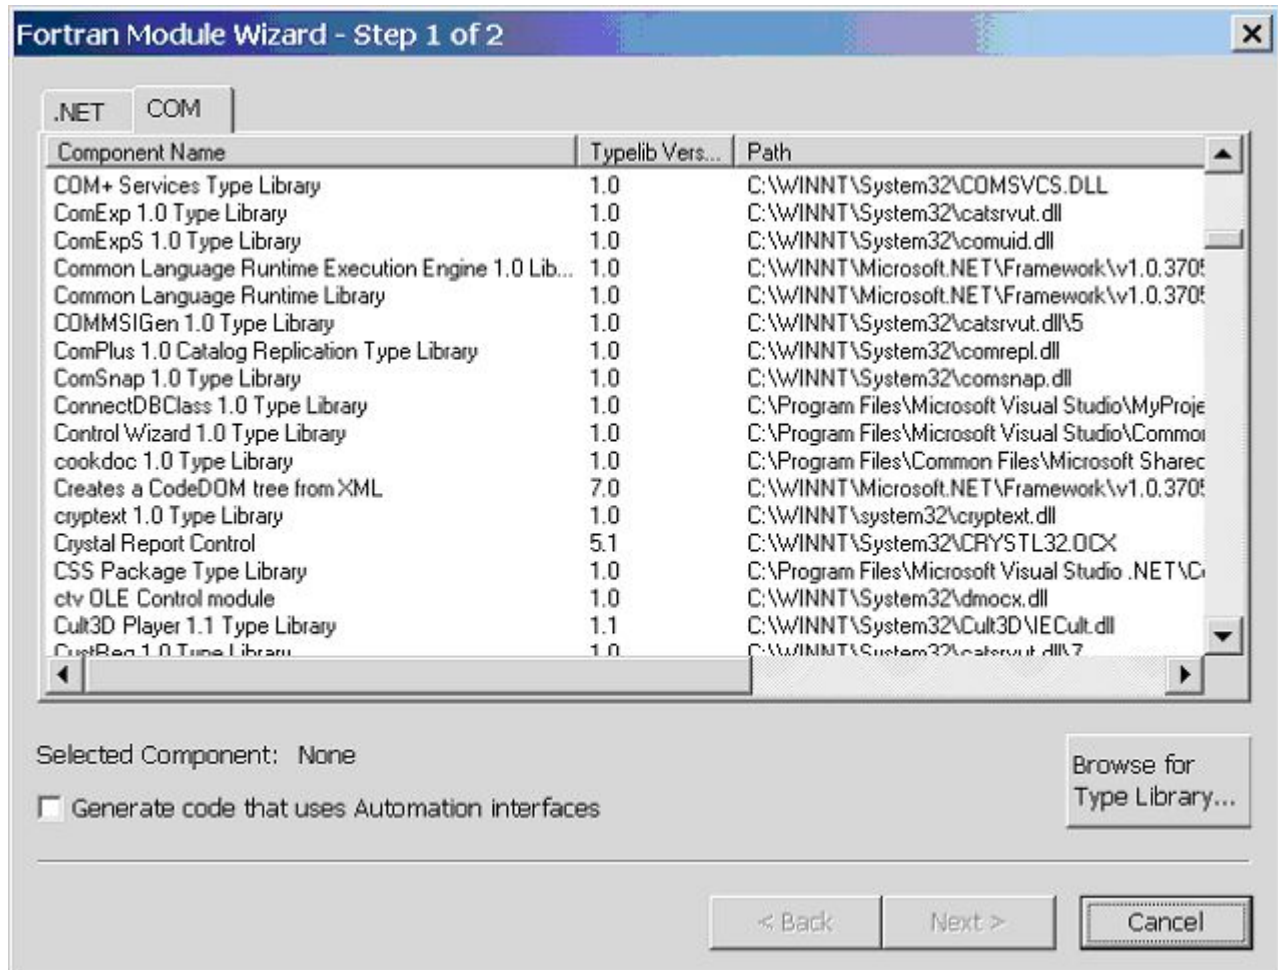

To run the Intel® Fortran Module Wizard, select **Tools > Intel Compiler > Intel® Fortran Module Wizard**.

The module wizard displays a series of dialog boxes allowing you to select the COM or Automation object and provide additional information.

COM and automation objects are self-describing, using type information. An object's type information contains programming language independent descriptions of the object's interfaces. Type information can be obtained from the object's type library.

A type library is a collection of type information for any number of object classes, interfaces, and so on. You can store a type library in a file of its own (usually with an extension of .TLB) or it can be part of another file. For example, the type library that describes a DLL can be stored in the DLL itself.

After you start the module wizard, the COM tab of the dialog box displays the list of type libraries that are registered on your system. (There is also a .NET tab, which is explained in [Using .NET Components](#).)

The list has three columns:

- The component name
- The component version number
- The path to the type library

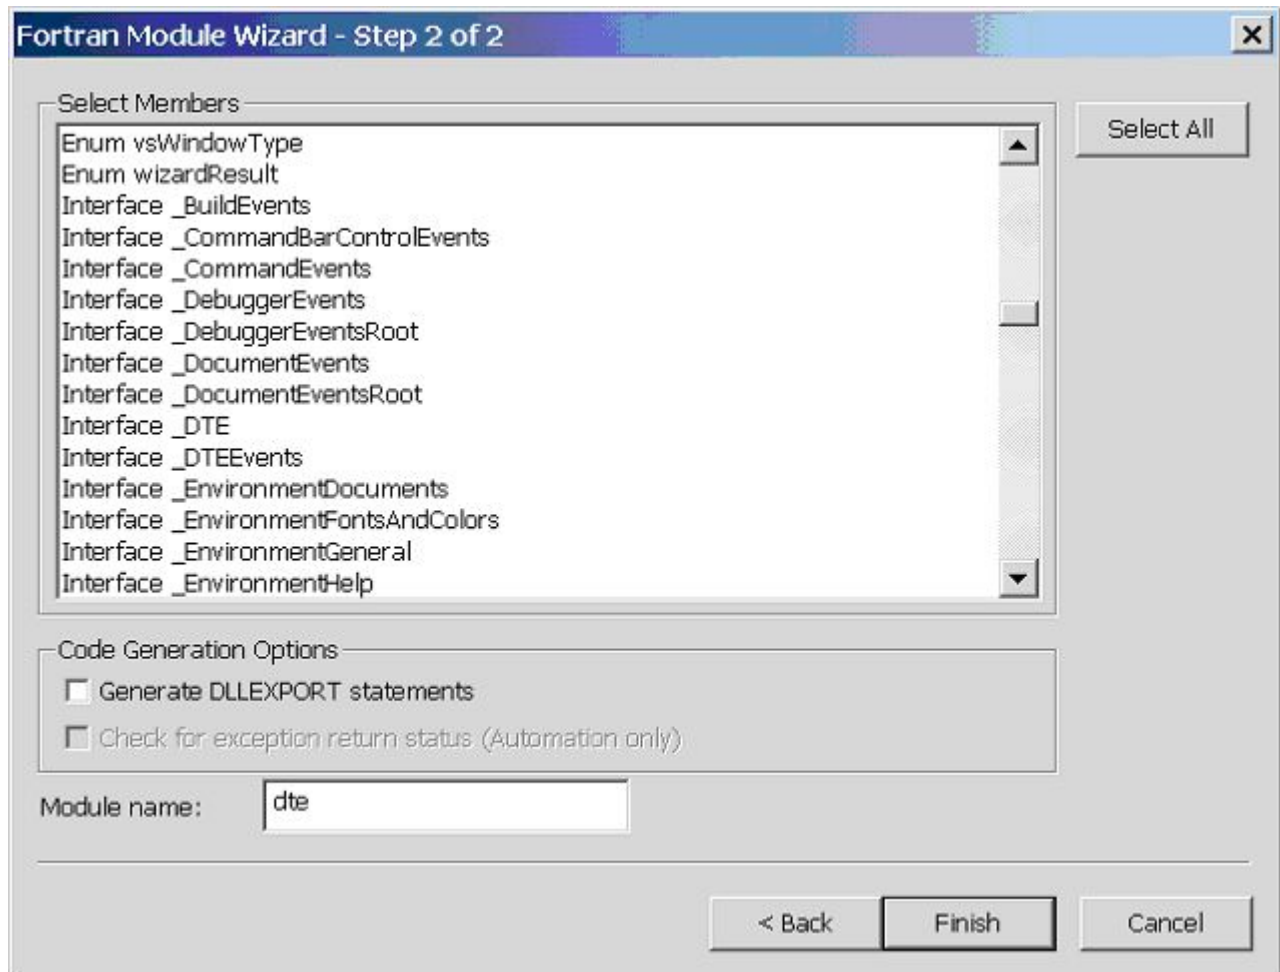

You may select a single component from the list, or click the **Browse for Type Library...** button to find a type library on your system.

The dialog box also provides the Generate code that uses **Automation interfaces** option. If the option is not selected, the Wizard will generate code to use the COM interfaces of the component.

The documentation of the component should tell you whether the component implements COM interfaces, Automation interfaces, or dual interfaces. A dual interface supports both COM and Automation interfaces. For a component that supports dual interfaces, you can check the Generate code that uses Automation interfaces option, or leave it unchecked. The COM interfaces tend to be more efficient (better runtime performance).

ActiveX controls implement an Automation interface. When using an ActiveX control, check the **Generate code** that uses Automation interfaces option.

After you select a component from the list or by browsing using the **Browse for Type Library...** button, click **Next>**.

This dialog box lists the members that are defined in the type library. Click the **Select All** button to select all of the members of the type library, or select individual members from the list. The Wizard uses the selected members.

This dialog box also contains two options regarding the code to be generated by the Wizard:

- Select **Generate DLLEXPORT statements** if you plan to place the generated module in a DLL for use by other projects. The Wizard will generate the DLLEXPORT statements to make the routines in the module visible outside of the DLL.
- **Check for exception return status (Automation only)** is active if you checked the Generate code that uses Automation interfaces option in the first dialog box. Select this option if you want the Wizard to generate code to check the return status of each Automation method or property invocation, and to display a dialog box when an error is generated.

Change the module name if desired and select **Finish**.

## Use .NET Components

The .NET tab is available on the first dialog box. The module wizard cannot directly read the type information of a .NET component. However, the .NET Framework Tools (provided with Visual Studio\*) contain the Type Library Exporter (Tlbexp.exe). The Type Library Exporter generates a COM type library that describes the types defined in a .NET component (also known as a common language runtime assembly).

Select the .NET tab to view the assemblies that are registered in your system's Global Assembly Cache (GAC). The list contains the same three columns as the COM tab, as well as a Browse for Assembly button. Select a .NET component from the list, or use the **Browse for Assembly** button to select a .NET component on your system.

Press **Next >** to run the Type Library Exporter tool to create a type library from the .NET component. If the tool returns an error message, the message is displayed in a dialog box and the Wizard returns to its first dialog box. In this case, no Fortran module is generated. If the tool succeeds, the second Wizard dialog box is displayed with the members found in the type library. There are restrictions on the .NET components that can be used with the Type Library Exporter tool. For example, a common error message returned by Type Library Exporter tool is:

You cannot use Tlbexp.exe to produce a type library from an assembly that was imported using the Type Library Importer (Tlbimp.exe). Instead, you should refer to the original type library that was imported with Tlbimp.exe.

In this case, the .NET assembly was created from the information in a type library, and you must obtain the original type library from the assembly provider in order to use it with the Module Wizard.

See the .NET Framework Tools documentation for details.

The Wizard runs the Type Library Exporter tool with the `/nologo/silent` options. You can also run the tool to create a type library before running the Module Wizard if you prefer.

## Intel® Fortran Module Wizard Command Line Interface

The Intel® Fortran Module Wizard also has a command-line interface. The `MODWIZ` command has the following form:

```
MODWIZ [options] typeinfo-name
```

For a list of `MODWIZ` command options and an explanation of *typeinfo-name*, type the following command in a Fortran command prompt (available from the Intel® Fortran Compiler program folder):

```
MODWIZ /?
```

## Call the Routines Generated by the Module Wizard

This topic only applies to Windows.

Although Standard Fortran does not support objects, it does provide Standard Fortran *modules*. A module is a set of declarations that are grouped together under a global name, and are made available to other program units by using the [USE](#) statement.

The Intel® Fortran Module Wizard generates a source file containing one or more modules. The types of information placed in the modules include:

- *Derived-type definitions* are Fortran equivalents of data structures that are found in the type information.
- *Constant definitions* are Fortran PARAMETER declarations that include identifiers and enumerations found in the type information.
- *Procedure interface definitions* are Fortran interface blocks that describe the procedures found in the type information.
- *Procedure definitions* are Fortran functions and subroutines that are jacket routines for the procedures found in the type information.

The jacket routines make the external procedures easier to call from Fortran by handling data conversion and low-level invocation details.

The use of modules allows the Intel® Fortran Module Wizard to encapsulate the data structures and procedures exposed by an object or DLL in a single place. You can then share these definitions in multiple Fortran programs.

The appropriate USE statement needs to be added in your program, as well as function invocations or subroutine calls.

The routines generated by the Intel® Fortran Module Wizard are designed to be called from Fortran. These routines in turn call the appropriate system routines (not designed to be called from Fortran), thereby simplifying the coding needed to use COM and Automation objects.

Intel® Visual Fortran provides a set of runtime routines that present to the Fortran programmer a higher level abstraction of the COM and Automation functionality. The Fortran interfaces that the wizard generates hide most of the differences between Automation objects and COM objects.

Depending on the options specified, the following routines can be present in the generated code:

---

#### **IFCOM Routines (COMxxxxx)**

---

COMAddObjectReference	Adds a reference to an object's interface.
COMCLSIDFromProgID	Passes a programmatic identifier and returns the corresponding class identifier.
COMCLSIDFromString	Passes a class identifier string and returns the corresponding class identifier.
COMCreateObject	A generic routine that executes either COMCreateObjectByProgID or COMCreateObjectByGUID.
COMCreateObjectByGUID	Passes a class identifier and creates an instance of an object. It returns a pointer to the object's interface.
COMCreateObjectByProgID	Passes a programmatic identifier and creates an instance of an object. It returns a pointer to the object's IDispatch interface.
COMGetActiveObjectByGUID	Pass a class identifier and returns a pointer to the interface of a currently active object.
COMGetActiveObjectByProgID	Passes a programmatic identifier and returns a pointer to the IDispatch interface of a currently active object.
COMInitialize	Initializes the COM library. You must initialize the library before calling any other COM or AUTO routine.
COMIsEqualGUID	Determines if two GUIDs are the same.
COMGetFileObject	Passes a file name and returns a pointer to the IDispatch interface of an Automation object that can manipulate the file.
COMQueryInterface	Passes an interface identifier and it returns a pointer to an object's interface.

**IFCOM Routines (COMxxxxx)**

<b>COMReleaseObject</b>	Indicates that the program is done with a reference to an object's interface.
<b>COMStringFromGUID</b>	Passes a GUID and returns the corresponding string representation.
<b>COMUninitialize</b>	Uninitializes the COM library. This must be the last COM routine that you call.

**IFAUTO Automation Routines (AUTOxxxxx)**

<b>AUTOAddArg</b> (W*32 W*64)	Passes an argument name and value and adds the argument to the argument list data structure.
<b>AUTOAllocateInvokeArgs</b> (W*32 W*64)	Allocates an argument list data structure that holds the arguments that you will pass to AUTOInvoke.
<b>AUTODEallocateInvokeArgs</b> (W*32 W*64)	Deallocates an argument list data structure.
<b>AUTOGetExceptionInfo</b> (W*32 W*64)	Retrieves the exception information when a method has returned an exception status.
<b>AUTOGetProperty</b> (W*32 W*64)	Passes the name or identifier of the property and gets the value of the Automation object's property.
<b>AUTOGetPropertyByID</b> (W*32 W*64)	Passes the member ID of the property and gets the value of the Automation object's property into the argument list's first argument.
<b>AUTOGetPropertyInvokeArgs</b> (W*32 W*64)	Passes an argument list data structure and gets the value of the Automation object's property specified in the argument list's first argument.
<b>AUTOInvoke</b> (W*32 W*64)	Passes the name or identifier of an object's method and an argument list data structure. It invokes the method with the passed arguments.
<b>AUTOSetProperty</b> (W*32 W*64)	Passes the name or identifier of the property and a value. It sets the value of the Automation object's property.
<b>AUTOSetPropertyByID</b> (W*32 W*64)	Passes the member ID of the property and sets the value of the Automation object's property using the argument list's first argument.
<b>AUTOSetPropertyInvokeArgs</b> (W*32 W*64)	Passes an argument list data structure and sets the value of the Automation object's property specified in the argument list's first argument.

The following code shows an annotated version of a portion of the code generated by the Intel® Fortran Module Wizard. This code is generated from the COM type information for the Save method of the IGeneric Document interface.

```

INTERFACE
! Saves the document to disk.          1
INTEGER*4 FUNCTION IGenericDocument_Save($OBJECT, vFilename, &
                                vBoolPrompt, pSaved)          2
USE IFWINTY
INTEGER (INT_PTR_KIND()), INTENT(IN) :: $OBJECT      ! Object Pointer

!DIR$ ATTRIBUTES VALUE      :: $OBJECT          3
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vFilename  ! (Optional Arg)          4
!DIR$ ATTRIBUTES REFERENCE      :: vFilename
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vBoolPrompt ! (Optional Arg)

```

```

!DIR$ ATTRIBUTES REFERENCE      :: vBoolPrompt
INTEGER, INTENT(OUT) :: pSaved      ! DsSaveStatus
!DIR$ ATTRIBUTES REFERENCE      :: pSaved
!DIR$ ATTRIBUTES STDCALL        :: IGenericDocument_Save
END FUNCTION IGenericDocument_Save
END INTERFACE
POINTER(IGenericDocument_Save_PTR, IGenericDocument_Save) ! routine pointer

```

Notes for this example:

<sup>1</sup> If the type information provides a comment that describes the member function, then the comment is placed before the beginning of the procedure.

<sup>2</sup> The first argument to the procedure is always \$OBJECT. It is a pointer to the object's interface. The remaining argument names are determined from the type information. For information on how to get a pointer to an object's interface, see [Getting a Pointer to an Objects Interface](#).

<sup>3</sup> This is an example of an ATTRIBUTES directive statement used to specify the calling convention of an argument.

<sup>4</sup> A VARIANT is a data structure that can contain any type of Automation data. It contains a field that identifies the type of data and a union that holds the data value. The use of a VARIANT argument allows the caller to use any data type that can be converted into the data type expected by the member function.

<sup>5</sup> Nearly every COM member function returns a status of type HRESULT. Because of this, if a COM member function produces output, it uses output arguments to return the values. In this example, the "pSaved" argument returns a routine specific status value.

<sup>6</sup> The interface of a COM member function looks very similar to the interface for a dynamic link library function with one major exception. Unlike a DLL function, the address of a COM member function is never known at program link time. You must get a pointer to an object's interface at runtime, and the address of a particular member function is computed from that.

The following code shows an annotated version of the wrapper generated by the Intel® Fortran Module Wizard for the "Save" function. The name of a wrapper is the same as the name of the corresponding member function, prefixed with a "\$" character.

```

! Saves the document to disk.
INTEGER*4 FUNCTION $IGenericDocument_Save($OBJECT, vFilename, & 1
      vBoolPrompt, pSaved)
IMPLICIT NONE
INTEGER(INT_PTR_KIND()), INTENT(IN) :: $OBJECT      ! Object Pointer
!DIR$ ATTRIBUTES VALUE :: $OBJECT
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vFilename
!DIR$ ATTRIBUTES REFERENCE :: vFilename
TYPE (VARIANT), INTENT(IN), OPTIONAL :: vBoolPrompt
!DIR$ ATTRIBUTES REFERENCE :: vBoolPrompt
INTEGER, INTENT(OUT) :: pSaved      ! DsSaveStatus
!DIR$ ATTRIBUTES REFERENCE :: pSaved
INTEGER(4) $RETURN
INTEGER(INT_PTR_KIND()) $VTBL      ! Interface Function Table
POINTER($VPTR, $VTBL)
TYPE (VARIANT) :: $VAR_vFilename
TYPE (VARIANT) :: $VAR_vBoolPrompt
IF (PRESENT(vFilename)) THEN
      $VAR_vFilename = vFilename
ELSE
      $VAR_vFilename = OPTIONAL_VARIANT
END IF
IF (PRESENT(vBoolPrompt)) THEN
      $VAR_vBoolPrompt = vBoolPrompt
ELSE
      $VAR_vBoolPrompt = OPTIONAL_VARIANT

```

```

END IF
$VPTR = $OBJECT          ! Interface Function Table      4
$VPTR = $VTBL + 84      ! Add routine table offset
IGenericDocument_Save_PTR = $VTBL
$RETURN = IGenericDocument_Save($OBJECT, $VAR_vFilename, &
$VAR_vBoolPrompt, pSaved)
$IGenericDocument_Save = $RETURN
END FUNCTION $IGenericDocument_Save

```

Notes for this example:

- <sup>1</sup> The wrapper takes the same argument names as the member function interface.
- <sup>2</sup> The wrapper computes the address of the member function from the interface pointer and an offset found in the interface's type information. In implementation terms, an interface pointer is a pointer to a pointer to an array of function pointers called an "Interface Function Table."
- <sup>3</sup> Arguments to a COM or Automation routine can be optional. The wrapper handles the invocation details for specifying an optional argument that is not present in the call.
- <sup>4</sup> The offset of the "Save" member function is 84. The code assigns the computed address to the function pointer IGenericDocument\_Save\_PTR, which was declared with the interface shown above, and then calls the function.

The following code shows an annotated version of a portion of the code generated by the Intel® Fortran Module Wizard from Automation type information for the Rebuild All method of the IApplication interface.

```

! Rebuilds all files in a specified configuration.
SUBROUTINE IApplication_RebuildAll($OBJECT, Configuration, $STATUS) 1
IMPLICIT NONE
INTEGER(INT_PTR_KIND()), INTENT(IN)          :: $OBJECT          ! Object Pointer
!DIR$ ATTRIBUTES VALUE          :: $OBJECT
TYPE (VARIANT), INTENT(IN), OPTIONAL :: Configuration
!DIR$ ATTRIBUTES REFERENCE      :: Configuration
INTEGER(4), INTENT(OUT), OPTIONAL  :: $STATUS          ! Method status
!DIR$ ATTRIBUTES REFERENCE      :: $STATUS
INTEGER(4) $$STATUS
INTEGER (INT_PTR_KIND) invokeargs
invokeargs = AUTOALLOCATEINVOKEARGS() 2
IF (PRESENT(Configuration)) CALL AUTOADDARG(invokeargs, '$ARG1', &
Configuration, AUTO_ARG_IN)
$$STATUS = AUTOINVOKE($OBJECT, 28, invokeargs) 3
IF (PRESENT($STATUS)) $STATUS = $$STATUS 4
CALL AUTODEALLOCATEINVOKEARGS (invokeargs) 5
END SUBROUTINE IApplication_RebuildAll

```

Notes for this example:

- <sup>1</sup>The first argument to the procedure is always \$OBJECT. It is a pointer to an Automation object's IDispatch interface. The last argument to the procedure is always \$STATUS. It is an optional argument that you can specify if you wish to examine the return status of the method. The IDispatch Invoke member function returns a status of type HRESULT. An HRESULT is a 32-bit value. It has the same structure as a Windows error code. In between the \$OBJECT and \$STATUS arguments are the method arguments' names determined from the type information. Sometimes, the type information does not provide a name for an argument. The Fortran Module Wizard creates a "\$ARGn" name in this case.
- <sup>2</sup> AUTOAllocateInvokeArgs allocates a data structure that is used to collect the arguments that you will pass to the method. AUTOAddArg adds an argument to this data structure.
- <sup>3</sup> AUTOInvoke invokes the named method passing the argument list. This returns a status result.
- <sup>4</sup> If the caller supplied a status argument, the code copies the status result to it.
- <sup>5</sup> AUTODeallocateInvokeArgs deallocates the memory used by the argument list data structure.

## Get a Pointer to an Object's Interface

This topic only applies to Windows.

To get a pointer to an object's interface, you need to know the object's unique identifier.

### Object Identification

Object identification enables the use of COM objects created by disparate groups of developers. To provide a method of uniquely identifying an object class regardless of where it came from, COM uses *globally unique identifiers* (GUIDs). A GUID is a 16-byte integer value that is guaranteed (for all practical purposes) to be unique across space and time. COM uses GUIDs to identify object classes, interfaces, and other things that require unique identification.

To create an instance of an object, you need to tell COM what the GUID of the object is. While using 16-byte integers for identification is fine for computers, it poses a challenge for the typical developer. So, COM also supports the use of a less precise, textual name called a *programmatically identifier* (ProgID). A ProgID takes the form:

```
application_name .object_name .object_version
```

### Obtain the Pointer to an Object's Interface

To use the routines generated by the Module Wizard, your application must get a pointer to an object's interface. This pointer is used as the value of the \$OBJECT argument, which is the first argument of every interface generated by the Module Wizard.

Typically, your application obtains its first pointer to an object's interface by calling the COM routine COMCreateObject. COMCreateObject creates a new instance of an object class and returns a pointer to it. COMCreateObject is the generic name of the two subroutines COMCreateObjectByProgID and COMCreateObjectByGUID.

- Use [COMCreateObjectByProgID](#) to create Automation objects. It accepts the progID of an object and returns a pointer to the object's `IDispatch` interface.
- Use [COMCreateObjectByGUID](#) to create both COM and Automation objects. It takes a GUID and returns a pointer to the object's interface (either Automation or COM - see [below](#))

The arguments to COMCreateObjectByGUID are as follows:

- The first argument is a class identifier (CLSID) that uniquely identifies the object's class. The Module Wizard defines a GUID parameter for each class selected from the Type library. These parameters are given the name in the form: `CLSID_class-name`.
- The second argument allows you to limit the type(s) of server that the call will accept. Most of the time you can use `CLSCTX_ALL` to accept any type of server.
- The third argument is an interface identifier (IID) that specifies the particular object interface you are requesting:
  - To request an Automation interface, use `IID_IDispatch`.
  - To request a COM interface, the Module Wizard defines a GUID parameter for each interface selected from the type library. These parameters are given a name in the form: `IID_interface-name`.
- The fourth argument is an output parameter that returns the object's interface pointer.

The COMCreateObjectByProgID and COMCreateObjectByGUID subroutines return an interface pointer of an object that the server has defined as being externally creatable. However, not all objects are externally creatable. Often, a server implements a hierarchy of objects, or *object model*. COMCreateObject is called to obtain a pointer to an interface of the root object in the hierarchy. Methods and/or properties of the root object are used to obtain pointers to child objects, and so on, down the hierarchy.

All objects must implement the `IUnknown` interface. Every object also implements one or more additional interfaces. You can always get a pointer to any of the object's interfaces from any of the object's interface pointers by using the `COMQueryInterface` subroutine. It is important that you have a pointer to the correct object interface when calling a routine generated by the Module Wizard. If not, your application will likely terminate unexpectedly.

## Release the Pointer to an Object's Interface

When you have finished using an object's interface pointer, you must call `COMReleaseObject` with the pointer. This includes releasing object pointers that you have received using any method, including `COMCreateObject`, `COMQueryInterface`, or by calling an object's method.

## Additional Resources about COM and Automation

This topic only applies to Windows.

A number of published books and articles exist about COM and Automation. Some of these are listed here as additional resources to assist customers who want to learn more about the subject matter. This list does not comment -- either negatively or positively -- on any documents listed or not yet listed. Books and related resources about COM and Automation include:

- *Inside COM+ Base Services* by Guy Eddon, Henry Eddon. Published by Microsoft Press (Redmond, Washington) 1999
- *Understanding COM+* by David S. Platt. Published by Microsoft Press (Redmond, Washington) 1999
- *Inside Distributed COM* by Guy Eddon; Henry Eddon. Published by Microsoft Press (Redmond, Washington) 1998
- *Inside COM* by Dale Rogerson. Published by Microsoft Press (Redmond, Washington) 1996
- *Understanding ActiveX and OLE* by David Chappell. Published by Microsoft Press (Redmond, Washington) 1996
- *Automation Programmer's Reference* by Microsoft. Published by Microsoft Press (Redmond, Washington) 1997
- *ActiveX Controls Inside Out*, Second Edition by Adam Denning. Published by Microsoft Press (Redmond, Washington) 1997
- *Platform SDK* online version. Relevant titles include *Platform SDK*, *COM and ActiveX Object Services*.
- *Visual C++ User's Guide* online version

## IFPORT Portability Library

---

Intel® Fortran includes functions and subroutines that ease porting of code to or from a PC, or allow you to write code on a PC that is compatible with other platforms.

The portability library is called `LIBIFPORT.LIB` (Windows\*) or `libifport.a` (Linux\* and macOS). Frequently used functions are included in a portability module called `IFPORT`.

The portability library also contains IEEE\* POSIX library functions. These functions are included in a module called `IFPOSIX`.

You can use the portability library in one of two ways:

- Add the statement `USE IFPORT` to your program. This statement includes the `IFPORT` module.
- Call portability routines using the correct parameters and return value.

The portability library is passed to the linker by default during linking. To prevent this behavior, specify the `fpscomp` compiler option with the `nolib` keyword.

Using the `IFPORT` mod file provides interface blocks and parameter definitions for the routines, as well as compiler verification of calls.

`fpscomp`  
compiler option

# fpp Preprocessing

The Intel® Fortran Compiler includes the preprocessor `fpp`. When you use a preprocessor for Intel® Fortran source files, the generated output files are used as input source files by the compiler.

Preprocessing performs tasks such as preprocessor symbol (macro) substitution, conditional compilation, and file inclusion. Intel® Fortran predefined symbols are described in topic [Using Predefined Preprocessor Symbols](#).

`fpp` has some of the capabilities of the ANSI C preprocessor and supports a similar set of preprocessor directives. Preprocessor directives must begin in column 1 of any Fortran source file. Preprocessor directives are not part of the Fortran language and not subject to the rules for Fortran statements. Syntax for preprocessor directives is based on that of the C preprocessor.

The compiler includes a limited conditional compilation capability, based on directives, that does not require use of `fpp`. The `IF` directive construct provides the capability of limited conditional compilation.

Note that you can also specify an alternate Fortran preprocessor instead of the `fpp` preprocessor. For more information, see compiler option [fpp-name](#).

## Automatic Preprocessing by the Compiler

By default, the preprocessor is not run on files before compilation. However, the Intel® Fortran Compiler automatically calls `fpp` when compiling source files that have file extension `.fpp` or `.FPP`, `.f` or `.F`, `.f90` or `.F90`, `.for` or `.FOR`, `.ftn` or `.FTN`, and `.fpp` or `.FPP`.

For example, the following command preprocesses a source file that contains `fpp` preprocessor directives, then passes the preprocessed file to the compiler and linker:

```
ifort source.fpp
```

If you want to preprocess files that have other Fortran extensions than those listed, you have to explicitly specify the preprocessor by using compiler option `fpp`.

The `fpp` preprocessor can process both free-format and fixed-format Fortran source files. By default, file names with the extension `.f` or `.F`, `.for` or `.FOR`, `.ftn` or `.FTN`, and `.fpp` or `.FPP` are assumed to be fixed format. File names with a suffix of `.F90` or `.f90` (or any other suffix not specifically mentioned here) are assumed to be free format. You can explicitly indicate free format by specifying compiler option `free`. You can explicitly indicate fixed format by specifying compiler option `fixed`.

The `fpp` preprocessor recognizes tab format in a source line in fixed form.

## Runn fpp to Preprocess Files

You can explicitly run `fpp` in the following ways:

- On the command line, use the `ifort` command with the `fpp` compiler option. By default, the specified files are then compiled and linked. To retain the intermediate (`.i` or `.i90`) file, specify the `[Q]save-temps` compiler option.
- On the command line, use the `fpp` command. In this case, the compiler is not invoked. When using `fpp` on the command line, you need to specify the input file and the intermediate (`.i` or `.i90`) output file. For more information, type `fpp -help` (Linux and macOS) or `fpp /help` (Windows) on the command line.
- In the Microsoft Visual Studio\* IDE, set the **Preprocess Source File** option to **Yes** in the **Fortran Preprocessor Option** Category. To retain the intermediate files, add `/Qsave-temps` to **Additional Options** in the **Fortran Command Line Category**.

The following table lists some common `cpp` features that are supported by `fpp` and some common `cpp` features that are not supported.

Supported cpp features:	Unsupported cpp features:
#define, #undef, #ifdef, #ifndef, #if, #elif, #else, #endif, #include, #error, #warning, #line	#pragma and #ident
# (stringize) and ## (concatenation) operators	spaces or tab characters preceding the initial "#" character
	# followed by empty line
! as negation operator	\ backslash-newline

Unlike `cpp`, `fpp` does not merge continued lines into a single line when possible.

You do not usually need to specify preprocessing for Fortran source programs unless your program uses `fpp` preprocessing commands, such as those listed above.

### Caution

Using a preprocessor that does not support Fortran can damage your Fortran code.

For example, consider the following code:

```
FORMAT (\\I4)
```

In this case, most C++ and C preprocessors will change the meaning of the program by interpreting the double backslash "\\" as end-of-record.

## fpp Source Files

A source file can contain `fpp` tokens in the following forms:

- `fpp` preprocessor directive names

For more information on `fpp` preprocessor directives, see topic [Using fpp Preprocessor Directives](#).

- Symbolic names including Fortran keywords

`fpp` permits the same characters in names as Fortran. For more information on symbolic names, see topic [Using Predefined Preprocessor Symbols](#).

- Constants

Integer, real, double, and quadruple precision real, binary, octal, hexadecimal (including alternate notation), character, and Hollerith constants are allowed.

- Special characters, space, tab, and newline characters
- Comments, including the following:

- Fortran language comments

A fixed-form source line containing one of the symbols C, c, \*, d, or D in the first position is considered a comment line.

The ! symbol is interpreted as the beginning of a comment extending to the end of the line, except when the ! occurs within a constant-expression in an `#if` or `#elif` directive. Within such comments, macro expansions are not performed, but they can be switched ON by specifying `-f-com=no`.

- `fpp` comments

These comments appear between symbols `/*` and `*/`. They are excluded from the output and macro expansions are not performed within these symbols. `fpp` comments can be nested: for each `/*` there must be a corresponding `*/`.

`fpp` comments are useful for excluding from the compilation large portions of source instead of commenting every line with a Fortran comment symbol.

- C++-like line comments

These comments begin with symbol `//` (double-slash)

A string that is a token can occupy several lines, but only if its input includes continued line characters using the Fortran continuation character `&`. `fpp` will not merge such lines into one line.

`fpp` always places identifiers on one line. For example, if an input identifier occupies several lines, it will be merged by `fpp` into one line.

## fpp Output

Output consists of a modified copy of the input, plus lines of the following form:

```
#line_number file_name
```

These lines indicate the original source line number and file name of the output line that follows. Use the `fpp` preprocessor option `P` to disable the generation of these lines.

## Diagnostics

There are three kinds of `fpp` diagnostic messages:

- Warnings

`fpp` preprocessing continues but the return value is set to zero.

- Errors

`fpp` preprocessing continues but the return value is set to a nonzero value indicating the number of errors.

- Fatal errors

`fpp` stops preprocessing and returns a nonzero value.

The messages produced by `fpp` are intended to be self-explanatory. The line number and file name where the error occurred are displayed along with the diagnostic on `stderr`.

# fpp Preprocessor Directives

All `fpp` preprocessor directives start with the number sign (`#`) as the first character on a line. White space (blank or tab characters) can appear after the initial `"#"` for indentation.

`fpp` preprocessor directives can be placed anywhere in source code, but they usually appear before a Fortran continuation line. However, `fpp` preprocessor directives within a macro call can not be divided among several lines by means of continuation symbols.

`fpp` preprocessor directives can be grouped according to their purpose.

## Preprocessor directives for string substitution

The following `fpp` preprocessor directives cause substitutions in your program:

Preprocessor Directive	Result
<code>__FILE__</code>	Replaces a string with the input file name (a character string literal).
<code>__LINE__</code>	Replaces a string with the current line number in the input file (an integer constant).
<code>__DATE__</code>	Replaces a string with the date that <code>fpp</code> processed the input file (a character string literal in the form <code>Mmm dd yyyy</code> ).
<code>__TIME__</code>	Replaces a string with the time that <code>fpp</code> processed the input file (a character string literal in the form <code>hh:mm:ss</code> ).
<code>__TIMESTAMP__</code>	Replaces a string with the timestamp that <code>fpp</code> processed the input file (a character string literal in the form "day date time year", where <i>day</i> is a 3-letter abbreviation, <i>date</i> is <code>Mmm dd</code> , <i>time</i> is <code>hh:mm:ss</code> and <i>year</i> is <code>yyyy</code> ).

## Preprocessor directive for inclusion of external files

To include external files, preprocessor directive `#include` can be specified in one of the following forms:

```
#include "filename"
```

```
#include <filename>
```

`#include` reads in the contents of the named file into the specified or default location in the source. The lines read in from the file are processed by `fpp` as if they were part of the current file.

When the `<filename>` notation is used, the compiler only searches for the file name in the standard "include" directories. For more information, see the `fpp` preprocessor options `Idir` and `Ydir` options. No additional tokens are allowed on the directive line after the final `"` or `>`.

For `#include "filename"`, file names are searched for in the following order:

- In the directory in which the source file resides
- In the directories specified by the `I` or `Y` preprocessor option
- In the default directory

For `#include <filename>`, filenames are searched for in the following order:

- In the directories specified by the `I` or `Y` preprocessor option
- In the default directory

## Preprocessor directive for line control

The preprocessor directive `#line-number` generates line control information for the compiler. It takes the following form:

```
#line-number "filename"
```

`#line-number` is an integer constant that is the line number of the next line. `"filename"` is the name of the file containing the line. If `"filename"` is not provided, the current file name is assumed.

## Preprocessor directive for fpp variable and macro definitions

The preprocessor directive `#define` can be used to define both simple string variables and more complicated macros. It can take two forms.

- Definition of an fpp variable:

```
#define nametoken-string
```

In the above, occurrences of *name* in the source file will be replaced by *token-string*.

- Definition of an fppmacro:

```
#define name(argument[,argument] ... ) token-string
```

In the above, occurrences of the macro *name* followed by the comma-separated list of actual arguments within parentheses, will be replaced by *token-string*. Each occurrence of *argument* in *token-string* is replaced by the token sequence representing the corresponding "actual" argument in the macro call.

An error occurs if the number of macro call arguments is not the same as the number of arguments in the corresponding macro definition. For example, consider this macro definition:

```
#define INTSUB(m, n, o) call mysub(m, n, o)
```

Any use of the macro `INTSUB` must have three arguments. In macro definitions, spaces between the macro name and the open parenthesis "(" are prohibited to prevent the directive from being interpreted as an fpp variable definition with the rest of the line beginning with the open parenthesis "(" being interpreted as its token-string.

An fpp variable or macro definition can be of any length and is limited only by the newline symbol. It can be defined in multiple lines by continuing it to the next line with the insertion of "\". For example:

```
#define long_macro_name(x,\
y) x*y
```

The occurrence of a newline without a macro-continuation signifies the end of the macro definition.

The scope of a definition begins from the `#define` and encloses all the source lines (and source lines from `#include` files) to the end of the current file, except for:

- Files included by Fortran `INCLUDE` statements
- fpp and Fortran comments
- Fortran `IMPLICIT` statements that specify a single letter
- Fortran `FORMAT` statements
- Numeric, typeless, and character constants

## Preprocessor directive for undefining a macro

The preprocessor directive `#undef` takes the following form:

```
#undef name
```

This preprocessor directive removes any definition for *name* produced by the `D` preprocessor option, the `#define` preprocessor directive, or by default. No additional tokens are permitted on the directive line after *name*.

If *name* has not been previously defined, then `#undef` has no effect.

## Preprocessor directive for macro expansion

If, during expansion of a macro, the column width of a line exceeds column 72 (for fixed format) or column 132 (for free format), `fpp` inserts appropriate Fortran continuation lines.

For fixed format, there is a limit on macro expansions in label fields (positions 1-5):

- A macro call (together with possible arguments) should not extend beyond column 5.
- A macro call whose name begins with one of the Fortran comment symbols is considered to be part of a comment.
- A macro expansion may produce text extending beyond column 5. In this case, a warning will be issued.

In fixed format, when the `fpp` preprocessor option `xw` has been specified, an ambiguity may occur if a macro call occurs in a statement position and a macro name begins or coincides with a Fortran keyword. For example, consider the following:

```
#define callp(x)    call f(x)
                  call p(0)
```

In this case, `fpp` cannot determine how to interpret the `callp` token sequence. It could be considered to be a macro name. The current implementation does the following:

- The longer identifier is chosen (`callp` in this case)
- From this identifier the longest macro name or keyword is extracted
- If a macro name has been extracted, a macro expansion is performed. If the name begins with some keyword, `fpp` issues an appropriate warning
- The rest of the identifier is considered a whole identifier

In the previous example, the macro expansion is performed and the following warning is produced:

```
warning: possibly incorrect substitution of macro callp
```

This situation appears only when preprocessing fixed-format source code and when the space symbol is not interpreted as a token delimiter.

In the following case, a macro name coincides with a beginning of a keyword:

```
#define INT  INTEGER*8
              INTEGER k
```

The `INTEGER` keyword will be found earlier than the `INT` macro name. There will be no warning when preprocessing such a macro definition.

## Preprocessor directives for conditional selection of source text

The following three preprocessor directives are conditional constructs that you can use to select source text.

- `#if` preprocessor directive

When `#if` is specified, subsequent lines up to the matching `#else`, `#elif`, or `#endif` preprocessor directive appear in the output only if *condition* evaluates to `.TRUE.`.

The following shows an example:

```
#if condition_1block_1
#elif condition_2block_2
#elif ...
#else
  block_n
#endif
```

- `#ifdef` preprocessor directive

When `#ifdef` is specified, subsequent lines up to the matching `#else`, `#elif`, or `#endif` preprocessor directive appear in the output only if *name* has been defined, either by a `#define` preprocessor directive or by the `D` preprocessor option, with no intervening `#undef` preprocessor directive. No additional tokens are permitted on the preprocessor directive line after *name*.

The following shows an example:

```
#ifdef nameblock_1
#elif conditionblock_2
#elif ...
#else
    block_n
#endif
```

- **`#ifndef` preprocessor directive**

When `#ifndef` is specified, subsequent lines up to the matching `#else`, `#elif`, or `#endif` preprocessor directive appear in the output only if *name* has not been defined, or if its definition has been removed with an `#undef` preprocessor directive. No additional tokens are permitted on the directive line after *name*.

The following shows an example:

```
#ifndef nameblock_1
#elif conditionblock_2
#elif ...
#else
    block_n
#endif
```

The `#else`, `#elif`, or `#endif` preprocessor directives are optional. They can be used in the above preprocessor directives.

Subsequent lines up to the matching `#else`, `#elif`, or `#endif` appear in the output only if all of the following occur:

- The condition in the preceding `#if` directive evaluates to `.FALSE.`, the name in the preceding `#ifdef` directive is not defined, or the name in the preceding `#ifndef` directive is defined
- The conditions in all of the preceding `#elif` directives evaluate to `.FALSE.`
- The condition in the current `#elif` evaluates to `.TRUE.`

Any condition allowed in an `#if` directive is allowed in an `#elif` directive. Any number of `#elif` directives may appear between an `#if`, `#ifdef`, or `#ifndef` directive and a matching `#else` or `#endif` directive.

### Conditional expressions

*condition\_1*, *condition\_2*, etc. are logical expressions involving `fpp` constants, macros, and intrinsic functions. The following items are permitted in conditional expressions:

- C language operations: `<`, `>`, `==`, `!=`, `>=`, `<=`, `+`, `-`, `/`, `*`, `%`, `<<`, `>>`, `&`, `~`, `|`, `&&`, and `||`

They are interpreted by `fpp` in accordance to the C language semantics. This facility is provided for compatibility with "old" Fortran programs using `cpp`.

- Fortran language operations: `.AND.`, `.OR.`, `.NEQV.`, `.XOR.`, `.EQV.`, `.NOT.`, `.GT.`, `.LT.`, `.LE.`, `.GE.`, `.NE.`, `.EQ.`, `**` (power).
- Fortran logical constants: `.TRUE.`, `.FALSE.`
- The `fpp` intrinsic function "defined": `defined(name)` or `defined name`, which returns `.TRUE.` if *name* is defined as an `fpp` variable or a macro. It returns `.FALSE.` if the name is not defined.

`#ifdef` is shorthand for `#if defined(name)` and `#ifndef` is shorthand for `#if .not. defined(name)`.

Only these items, integer constants, and names can be used within a constant expression.

A name that has not been defined with the `D` preprocessor option, a `#define` preprocessor directive, or defined by default, has a value of zero.

The C operation `!=` (not equal) can be used in the `#if` or `#elif` preprocessor directive, but not in the `#define` preprocessor directive, where the symbol `!` is considered to be the Fortran comment symbol by default.

## Predefined Preprocessor Symbols

IA-32 is not available on macOS. IA-32 is deprecated on other operating systems and will be removed in a future release.

Preprocessor symbols (macros) let you substitute values in a program before it is compiled. The substitution is performed in the preprocessing phase.

The preprocessor symbols shown in the table below are predefined by the compiler system and are available to compiler directives and to `fpp`. If you want to use other symbol names, you need to specify them on the command line.

You can use the `D` compiler option to define the symbol names to be used during preprocessing. This option performs the same function as the `#define` preprocessor directive.

Preprocessing with `fpp` replaces every occurrence of the defined symbol name with the specified value. Preprocessing compiler directives only allow `IF` and `IF DEFINED`.

If you want to disable symbol replacement (also known as macro expansion) during the preprocessor step, you can specify the `macro=no` preprocessor option for `fpp`.

Disabling preprocessor symbol replacement is useful for running `fpp` to perform conditional compilation (using `#ifdef`, etc.) without replacement.

You can use the `U` preprocessor option to suppress an automatic definition of a preprocessor symbol. This option suppresses any symbol definition currently in effect for the specified *name*. This option also performs the same function as an `#undef` preprocessor directive.

The symbols in the following table can be used in both `fpp` and Fortran compiler conditional compilations.

Symbol	Description
<code>__APPLE__</code> (macOS)	Defined as '1'.
<code>__AVX512BW__</code> (Windows, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Byte and Word Instructions (BWI).  <code>__AVX512BW__</code> is also defined as '1' when option <code>[Q]xCORE-AVX512</code> or higher processor-targeting options are specified.
<code>__AVX512CD__</code> (Windows, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Conflict Detection Instructions (CDI).  <code>__AVX512CD__</code> is also defined as '1' when option <code>[Q]xCORE-AVX512</code> , <code>[Q]xCOMMON-AVX512</code> , or higher processor-targeting options are specified.

Symbol	Description
<code>__AVX512DQ__</code> (Windows, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Doubleword and Quadword Instructions (DQI).  <code>__AVX512DQ__</code> is also defined as '1' when option <code>[Q]xCORE-AVX512</code> or higher processor-targeting options are specified.
<code>__AVX512ER__</code> (Windows, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Exponential and Reciprocal Instructions.
<code>__AVX512F__</code> (Windows, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions.  <code>__AVX512ER__</code> is also defined as '1' when option <code>[Q]xCORE-AVX512</code> , <code>[Q]xCOMMON-AVX512</code> , or higher processor-targeting options are specified.
<code>__AVX512PF__</code> (Windows, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) PreFetch Instructions (PFI).
<code>__AVX512VL__</code> (Windows, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Vector Length Extensions (VLE).  <code>__AVX512VL__</code> is also defined as '1' when option <code>[Q]xCORE-AVX512</code> or higher processor-targeting options are specified.
<code>_DEBUG</code> (Windows)	Defined as '1' only if options <code>/dbglibs</code> , <code>/MT[d]</code> , or <code>/MD[d]</code> are specified.
<code>_DLL</code> (Windows)	Defined as '1' only if one of the following options is specified or implied: <ul style="list-style-type: none"> <li>• <code>/libs:dll</code></li> <li>• <code>/MD</code></li> <li>• <code>/MDd</code></li> <li>• <code>/MDs</code></li> </ul>
<code>__ELF__</code> (Linux)	Defined as '1' at the start of compilation.
<code>__gnu_linux__</code> (Linux)	Defined as '1' at the start of compilation.
<code>__i386__</code> <code>__i386</code> <code>i386</code> (Linux, macOS)	Defined as '1' for compilations targeting IA-32 architecture (C++ only). IA-32 is not available on macOS. IA-32 is deprecated on other operating systems and will be removed in a future release.
<code>__INTEL_COMPILER</code> (Windows, Linux, macOS)	For ifx: The version of the compiler in the form VVVVMU, where VVVV is the major version, M is the minor version, and U is the update version. For

Symbol	Description
<p>example, Version 2021.1.2 is indicated by a value of 202112. See also symbol <code>__INTEL_LLVM_COMPILER</code>.</p> <p>For ifort: The version of the compiler in the form VVVV, where VVVV is the major version. For example, Version 2021.1.2 is indicated by a value of 2021.</p>

## Fortran Preprocessor Options

The Fortran preprocessor `fpp` can be invoked automatically or by specifying compiler option `fpp`.

The following preprocessor options are available if you use the `fpp` compiler option.

### Linux and macOS

Preprocessor options must start with a dash (-); for example, `-macro=no`.

### Windows

Preprocessor options must start with a slash (/); for example, `/macro=no`.

Preprocessor Option	Description
<code>B</code>	Specifies that C++-style comments should not be recognized.
<code>C</code>	Specifies that C-style comments should not be recognized. This is the same as specifying <code>c_com=no</code> .
<code>c_com={yes no}</code>	Determines whether C-style comments are recognized. If you specify <code>c_com=no</code> or <code>C</code> , C-style comments are not recognized. By default, C-style comments are recognized; that is, <code>c_com=yes</code> .
<code>Dname</code>	Defines the preprocessor variable <i>name</i> as 1 (one). This is the same as if a <code>Dname=1</code> option appeared on the <code>fpp</code> command line. This is also the same as specifying the following line in the source file processed by <code>fpp</code> : <pre>#define name 1</pre>
<code>Dname=val</code>	Defines <i>name</i> as if by a <code>#define</code> directive. This is the same as specifying the following line in the source file processed by <code>fpp</code> : <pre>#define name var</pre> <p><code>Dname=val</code> will be ignored if there are any non-alphabetic, non-numeric characters in <i>name</i>.</p> <p>The <code>D</code> option has lower precedence than the <code>U</code> option. That is, if the same name is used in both a <code>U</code> option and a <code>D</code> option, the name will be undefined regardless of the order of the options.</p>
<code>e</code>	For fixed-format source files, tells the compiler to accept extended source lines, up to 132 characters long.
<code>e80</code>	For fixed-format source files, tells the compiler to accept extended source lines, up to 80 characters long.

Preprocessor Option	Description
<code>f_com={yes no}</code>	<p>Determines whether Fortran-style end-of-line comments are recognized or ignored by <code>fpp</code>. If you specify <code>f_com=no</code>, Fortran style end-of-line comments are processed as part of the preprocessor directive.</p> <p>By default, Fortran style end-of-line comments are identified by <code>fpp</code> on preprocessor lines and are then ignored by <code>fpp</code>; that is, <code>f_com=yes</code>. For example:</p> <pre>#define max 100 ! max number do i = 1, max + 1</pre> <p>If you specify <code>f_com=yes</code>, <code>fpp</code> will output the following:</p> <pre>do i = 1, 100 + 1</pre> <p>If you specify <code>f_com=no</code>, <code>fpp</code> will output the following:</p> <pre>do i = 1, 100 ! max number + 1</pre>
<code>f77</code>	Tells the compiler to assume FORTRAN 77 language input source.
<code>f90</code>	Tells the compiler to assume Fortran 90 language input source.
<code>fixed</code>	Tells the compiler to assume fixed format in the source file.
<code>free</code>	Tells the compiler to assume free format in the source file.
<code>help</code>	Displays information about <code>fpp</code> options.
<code>I<sub>dir</sub></code>	<p>Inserts directory <i>dir</i> into the search path for files with names not beginning with <code>/</code>.</p> <p>The <code>#include <i>dir</i></code> is inserted ahead of the standard list of "include" directories so that <code>#include</code> files with names enclosed in double-quotes (<code>"</code>) are searched for first in the directory of the file with the <code>#include</code> line, then in directories named with <code>I</code> options, and lastly, in directories from the standard list.</p> <p>For <code>#include</code> files with names enclosed in angle-brackets (<code>&lt; &gt;</code>), the directory of the file with the <code>#include</code> line is not searched.</p>
<code>M</code>	Generates make dependencies.
<code>m</code>	Expands macros everywhere. This is the same as specifying <code>macro=yes</code> .

Preprocessor Option	Description
<code>macro={yes no_com no}</code>	Determines the behavior of macro expansion. If you specify <code>macro=no_com</code> , macro expansion is turned off in comments. If you specify <code>macro=no</code> , no macro expansion occurs anywhere. By default, macros are expanded everywhere; that is, <code>macro=yes</code> .
<code>macro_expand={vc cpp}</code>	Determines the mode of macro expansion. If you specify <code>macro_expand=vc</code> , macros are expanded in Microsoft Visual C/C++ order. If you specify <code>macro_expand=cpp</code> , macros are expanded in GNU CPP order.
<code>MF=</code> <i>file</i>	Makes <code>fpp</code> append dependencies to <i>file</i> .
<code>noB</code>	Specifies that C++-style comments should be recognized.
<code>noC</code>	Specifies that C-style comments should be recognized. This is the same as <code>c_com=yes</code> .
<code>noJ</code>	Specifies that F90-style comments should be recognized in a <code>#define</code> line. This is the same as <code>f_com=no</code> .
<code>no-fort-cont</code>	<p>Specifies that IDL-style format should be recognized. This option is only for the IDE.</p> <p>Note that macro arguments in IDL may have a C-like continuation character <code>\</code>, which is different from the Fortran continuation character <code>&amp;</code>. The <code>fpp</code> preprocessor should recognize the C-like continuation character and process some other non-Fortran tokens so that the IDL processor can recognize them.</p>
<code>P</code>	<p>Tells the compiler that line-numbering directives should not be added to the output file. This line-numbering directive appears as follows:</p> <pre>#line-number file-name</pre>
<code>U</code> <i>name</i>	<p>Removes any initial definition of <i>name</i>, where <i>name</i> is an <code>fpp</code> variable that is predefined on a particular preprocessor.</p> <p>The following shows an example of symbols that may be predefined, depending upon the architecture of the system:</p> <p>Operating System: <code>__APPLE__</code>, <code>__unix</code>, and <code>__linux</code></p> <p>Hardware: <code>__i386</code>, <code>__x86_64</code></p>

Preprocessor Option	Description
<code>undef</code>	Removes initial definitions for all predefined symbols.
<code>V</code>	Displays the fpp version number.
<code>w[0]</code>	Prevents warnings from being output. By default, warnings are output to standard error stream ( <code>stderr</code> ).
<code>what</code>	Displays detailed version information.
<code>Xu</code>	Converts uppercase letters to lowercase, except within character-string constants. The default is to leave the case as is.
<code>Xw</code>	Tells the compiler that in fixed-format source files, the blank or space symbol " " is insignificant. By default, the space symbol is the delimiter of tokens for this format.
<code>Ydir</code>	Adds directory <i>dir</i> to the end of the system include paths.

## Methods to Optimize Code Size

This section provides some guidance on how to achieve smaller object and smaller executable size when using the optimizing features of Intel compilers.

There are two compiler options that are designed to prioritize code size over performance:

Option	Result	Notes
<code>O<sub>s</sub></code>	Favors size over speed	<p>This option enables optimizations that do not increase code size; it produces smaller code size than option <code>O<sub>2</sub></code>.</p> <p>Option <code>O<sub>s</sub></code> disables some optimizations that may increase code size for a small speed benefit.</p>
<code>O<sub>1</sub></code>	Minimizes code size	<p>Compared to option <code>O<sub>s</sub></code>, option <code>O<sub>1</sub></code> disables even more optimizations that are generally known to increase code size. Specifying option <code>O<sub>1</sub></code> implies option <code>O<sub>s</sub></code>.</p> <p>As an intermediate step in reducing code size, you can replace option <code>O<sub>3</sub></code> with option <code>O<sub>2</sub></code> before specifying option <code>O<sub>1</sub></code>.</p>

Option	Result	Notes
		Option <code>o1</code> may improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops.

For more information about compiler options mentioned in this topic, see their full descriptions in the [Compiler Reference](#).

The rest of this topic briefly discusses other methods that may help you further improve code size even when compared to the default behaviors of options `os` and `o1`.

Things to remember:

- Some of these methods may already be applied by default when options `os` and `o1` are specified. All the methods mentioned in this topic can be applied at higher optimization levels.
- Some of the options referred to in this topic will not necessarily cause code size reduction, and they may provide varying results (good, bad, or neutral) based on the characteristics of the target code. Still, these are the recommended things to try to see if they cause your binaries to become smaller while maintaining acceptable performance.

## Disable or Decrease the Amount of Inlining

Inlining replaces a call to a function with the body of the function. This lets the compiler optimize the code for the inlined function in the context of its caller, usually yielding more specialized and better performing code. This also removes the overhead of calling the function at runtime.

However, replacing a call to a function by the code for that function usually increases code size. The code size increase can be substantial. To eliminate this code size increase, at the cost of the potential performance improvement, inlining can be disabled.

As an alternative to completely disabling inlining, the default amount of inlining can be decreased by using an inline factor less than the default value of 100. It corresponds to scaling the default values of the main inlining parameters by  $n\%$ .

- Advantage: Disabling or reducing this optimization can reduce code size.
- Disadvantage: Performance is likely to be sacrificed by disabling or reducing inlining especially for applications with many small functions.

Use options to disable inlining:

### Linux and macOS

```
fno-inline
```

### Windows

```
Ob0
```

Use options to reduce inlining and factor the main inlining parameters:

---

**NOTE** This option is only for ifort.

---

### Linux and macOS

```
inline-factor= $n$ 
```

### Windows

```
Qinline-factor: $n$ 
```

Use options to fine tune the main inlining parameters:

---

**NOTE** This option is only for ifort.

---

**Linux and macOS**

- `inline-factor`
- `inline-max-per-compile`
- `inline-max-per-routine`
- `inline-max-size`
- `inline-max-total-size`
- `inline-min-size`

**Windows**

- `Qinline-factor`
- `Qinline-max-per-compile`
- `Qinline-max-per-routine`
- `Qinline-max-size`
- `Qinline-max-total-size`
- `Qinline-min-size`

**Strip Symbols from Your Binaries**

You can specify a compiler option to omit debugging and symbol information from the executable without sacrificing its operability.

- Advantage: This method noticeably reduces the size of the binary.
- Disadvantage: It may be very difficult to debug a stripped application.

Use options:

**Linux**

`Wl, --strip-all`

**Windows**

None

**Dynamically Link Intel-provided Libraries**

By default, some of the Intel support and performance libraries are linked statically into an executable. As a result, the library codes are linked into every executable being built. This means that codes are duplicated.

It may be more profitable to link them dynamically.

- Advantage: Performance of the resulting executable is normally not significantly affected. Library codes that are otherwise linked in statically into every executable will not contribute to the code size of each executable with this option. These codes will be shared between all executables using them, and they will be available independent of those executables.
- Disadvantage: The libraries on which the resulting executable depends must be re-distributed with the executable for it to work properly. When libraries are linked statically, only library content that is actually used is linked into the executable. Dynamic libraries contain all the library content. Therefore, it may not be beneficial to use this option if you only need to build and/or distribute a single executable. The executable itself may be much smaller when linked dynamically, compared to a statically linked executable. However, the total size of the executable plus shared libraries or DLLs may be much larger than the size of the statically linked executable.

Use Options:

**Linux and macOS**

shared-intel

## Windows

MD or libs:dll

---

**NOTE** Option MD affects all libraries, not only the Intel-provided ones.

---

## Disable Inline Expansion of Standard Library or Intrinsic Functions

In some cases, disabling the inline expansion of standard library or intrinsic functions may noticeably improve the size of the produced object or binary.

Use Options:

### Linux and macOS

nolib-inline

## Windows

None

## Disable Passing Arguments in Registers Instead of on the Stack

This content is specific to ifort; it does not apply to ifx.

You can specify an option that causes the compiler to pass arguments in registers rather than on the stack. This can yield faster code.

However, doing this may require the compiler to create an additional entry point for any function that can be called outside the code being compiled.

In many cases, this will lead to an increase in code size. To prevent this increase in code size, you can disable this optimization.

- Advantage: Disabling this optimization can reduce code size.
- Disadvantage: The amount of code size saved may be small when compared to the corresponding performance loss of disabling the optimization.

Use Options:

### Linux and macOS

qopt-args-in-regs=none

## Windows

Qopt-args-in-regs:none

Additional information:

- Specify **none** for option [q or Q]opt-args-in-regs. The default behavior for the option is that parameters are passed in registers when they are passed to routines whose definition is seen in the same compilation unit.
- Depending on code characteristics, this option can sometimes increase binary size.

## Disable Loop Unrolling

Unrolling a loop increases the size of the loop proportionally to the unroll factor.

Disabling (or limiting) this optimization may help reduce code size at the expense of performance.

- Advantage: Code size is reduced.

- Disadvantage: Performance of otherwise unrolled loops may noticeably degrade because this limits other possible loop optimizations.

Use Options:

### Linux and macOS

```
unroll=0
```

### Windows

```
Qunroll:0
```

Additional information:

This option is already the default if you specify option `Os` or option `O1`.

## Disable Automatic Vectorization

The compiler finds possibilities to use SIMD (Intel® Streaming SIMD Extensions (Intel® SSE)/Intel® Advanced Vector Extensions (Intel® AVX)) instructions to improve performance of applications. This optimization is called automatic vectorization.

In most cases, this optimization involves transformation of loops and increases code size, in some cases significantly.

Disabling this optimization may help reduce code size at the expense of performance.

- Advantage: Compile-time is also improved significantly.
- Disadvantage: Performance of otherwise vectorized loops may suffer significantly. If you care about the performance of your application, you should use this option selectively to suppress vectorization on everything except performance-critical parts.

Use Options:

### Linux and macOS

```
no-vec
```

### Windows

```
Qvec-
```

Additional information:

Depending on code characteristics, this option can sometimes increase binary size.

## Avoid Unnecessary 16-Byte Alignment

This topic only applies to Linux systems on IA-32 architecture.

This method should only be used in certain situations that are well understood. It can potentially cause correctness issues when linking with other objects or libraries that aren't built with this option.

The 32-bit Linux ABI states that stacks need only maintain 4-byte alignment. However, for performance reasons in modern architectures, GCC and ICC maintain an alignment of 16-bytes on the stack. Maintaining 16-byte alignment may require additional instructions to adjust the stack on function entries where no stack adjustment would otherwise be needed. This can impact code size, especially in code that consists of many small routines.

You can specify a compiler option that will revert ICC back to maintaining 4-byte alignment, which can eliminate the need for extra stack adjust instructions in some cases.

Use this option *only* if one of the following is true:

- Your code does not call any other object or library that can be built without this option and, therefore, may rely on the stack being aligned to 16-bytes when called.

- Your code is targeted for architectures that do not have or support SSE instructions; therefore, it would never need 16-byte alignment for correctness reasons.
- Advantage: Code size can be smaller because you do not need extra instructions to maintain 16-byte alignment when not needed. This method can improve performance in some cases because of this reduction of instructions.
- Disadvantage: This method can cause incompatibility when linked with other objects or libraries that rely on the stack being 16-byte aligned across the calls.

Use Options:

#### **Linux**

`falign-stack=assume-4-byte`

macOS

None

#### **Windows**

None

Additional information:

Depending on code characteristics, this option can sometimes increase binary size.

### **Use Interprocedural Optimization**

Using interprocedural optimization (IPO) may reduce code size. It enables dead code elimination and suppresses generation of code for functions that are always inlined or proven that they are never to be called during execution.

- Advantage: Depending on the code characteristics, this optimization can reduce executable size and improve performance.
- Disadvantage: Binary size can increase depending on code/application..

Use Options:

#### **Linux and macOS**

`ipo`

#### **Windows**

`Qipo`

---

**NOTE** This method is not recommended if you plan to ship object files as part of a final product.

---

## *National Language Support Routines*

---

Intel® Fortran provides a complete National Language Support (NLS) library of language-localization routines and multibyte-character routines. You can use these routines to write applications in many different languages.

In many languages, the standard ASCII character set is not enough because it lacks common symbols and punctuation (such as the British pound sign), or because the language uses a non-ASCII script (such as Cyrillic for Russian) or because the language consists of too many characters for each to be represented by a single byte (such as Chinese).

In the case of many non-ASCII languages, such as Arabic and Russian, an extended single-byte character set is sufficient. You need only change the language locale and codepage, which can be done at a system level or within your program. However, Eastern languages such as Japanese and Chinese use thousands of separate characters that cannot be encoded as single-byte characters. Multibyte characters are needed to represent them.

Character sets are stored in tables called code sets. There are three components of a code set: the locale, which is a language and country (since, for instance, the language Spanish may vary among countries), the codepage, which is a table of characters to make up the computer's alphabet, and the font used to represent the characters on the screen. These three components can be set independently. Each computer running Windows operating systems comes with many code sets built into the system, such as English, Arabic, and Spanish. Multibyte code sets, such as Chinese and Japanese, are not standard but come with special versions of the operating system (for instance, Windows NT-J comes with the Japanese code set).

The default code set is obtained from the operating system when a program starts up. When you install your operating system, you should install the system supplied code sets. Thereafter, they are always available. You can switch among them by:

- Open the Control Panel (available from Settings)
- Click the Regional Settings icon
- Choose from the dropdown list of available locales (languages and countries).

When you select a new locale, it becomes the default system locale, and will remain the default locale until you change it. Each locale has a default codepage associated with it, and a default currency, number, and date format.

---

**NOTE**

The default codepage does not change when you select a new locale until you reboot your computer.

---

You can change the currency, number, and date format in the International dialog box or the Regional Setting dialog box independently of the locale.

The locale determines the character set available to the user. The locale you select becomes the default for the NLS routines described in this section, but the NLS routines allow you to change locales and their parameters from within your programs. These routines are useful for creating original foreign-language programs or different versions of the same program for various international markets. Changes you make to the locale from within a program affect only the program. They do not change the system default settings.

The codepage you select, which can be set independently, controls the multibyte (MB routines) character routines described in this section. Only users with special multibyte-character code sets installed on their computers need to use MB routines. The standard code sets all use single-byte character code sets.

Note that in Intel Fortran source code, multibyte characters can be used only in character strings and source comments. They cannot be used within variable names or statements. Like program changes to the locale, program changes to codepages affect only the program, not the system defaults.

To access the routines, the following statement should be present in any program unit that uses NLS or MB routines:

```
USE IFNLS
```

## Understand Single and Multibyte Character Sets on Windows

The ASCII character set defines the characters from 0 to 127 and an extended set from 128 to 255. Several alternative single-byte character sets, primarily European, define the characters from 0 to 127 identically to ASCII, but define the characters from 128 to 255 differently. With this extension, 8-bit representation is sufficient for defining the needed characters in most European-derived languages. However, some languages, such as Japanese Kanji, include many more characters than can be represented with a single byte. These languages require multibyte coding.

A multibyte character set consists of both one-byte and two-byte characters. A multibyte-character string can contain a mix of single and double-byte characters. A two-byte character has a lead byte and a trail byte. In a particular multibyte character set, the lead and trail byte values can overlap, and it is then necessary to use the byte's context to determine whether it is a lead or trail byte.

# ***Compatibility and Portability***

---

This section contains information about conformance to language standards, language compatibility, and portability.

## **Portability Considerations**

Topics in this section help you understand how language standards, operating system differences, and computing hardware influence your use of Intel® Fortran and the portability of your programs.

Your program is portable if you can implement it on one hardware-software platform and then move it to additional systems with minimum changes to the source code. Correct results on the first system should be correct on the additional systems. The number of changes you might have to make when moving your program varies significantly. You might have no changes at all (strictly portable), or enough that it is more efficient to design or implement a new program (non-portable customization). Most programs in their lifetime will need to be ported from one system to another, and this section can help you write code that makes this easy.

# ***Fortran Language Standards***

---

A language standard specifies the form and establishes the interpretation of programs expressed in the language. Its primary purpose is to promote portability of programs across a variety of systems among vendors and users.

The vendor-user community has adopted a series of major Fortran language standards. The primary organizations that develop and publish the standards are the InterNational Committee for Information Technology Standards (INCITS) and International Standards Organization (ISO).

The major Fortran language standards are:

- Fortran 2018

American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1:2018, Information technology – Programming languages – Fortran. This standard introduced enhancements to coarrays including teams, events, and collective and atomic subroutines, enhanced interoperability with C, and bindings to ISO/IEC/IEEE 60559:2011 (IEEE floating point arithmetic). For more information on supported Fortran 2018 features, see the Intel® Fortran Language Reference.

- Fortran 2008

American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1:2010, Information technology -- Programming languages -- Fortran. This standard introduces support for submodules and coarrays, and includes various performance enhancements such as the DO CONCURRENT construct. For more information on supported Fortran 2008 language features, see the Intel® Fortran Language Reference.

- Fortran 2003

American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1:2004, Information technology -- Programming languages -- Fortran. This standard introduces extended support for floating-point exception handling, object-oriented programming, and improved interoperability with the C language. For more information on supported Fortran 2003 features, see the Intel® Fortran Language Reference.

- Fortran 95

American National Standard Programming Language Fortran and International Standards Organization, ISO/IEC 1539-1: 1997(E), Information technology -- Programming languages -- Fortran. This standard introduces certain language elements and corrections into Fortran 90. Fortran 95 includes Fortran 90 and most features of FORTRAN 77. For information about differences between Fortran 95 and Fortran 90, see the Intel® Fortran Language Reference.

- Fortran 90

American National Standard Programming Language Fortran, ANSI X3.198-1992 and International Standards Organization, ISO/IEC 1539: 1991, Information technology -- Programming languages -- Fortran. This standard emphasizes modernization of the language by introducing new developments. For information about differences between Fortran 90 and FORTRAN 77, see the Intel® Fortran Language Reference.

- FORTRAN 77

American National Standard Programming Language FORTRAN, ANSI X3.9-1978. This standard added new features based on vendor extensions to FORTRAN 66 and addressed problems associated with large-scale projects, such as improved control structures.

- FORTRAN 66

American National Standard Programming Language FORTRAN, ANSI X3.9-1966. This was the first attempt to standardize the languages called FORTRAN by many vendors. The language was based heavily on IBM's FORTRAN IV language.

Although a language standard seeks to define the form and the interpretation uniquely, a standard may not cover all areas of interpretation. It may also include some ambiguities. You need to carefully craft your program in these cases to insure that you get the desired answers when producing a portable program.

## Use Standard Features

Use standard language features to achieve the greatest degree of portability for your Intel® Fortran programs. You can design a robust implementation to improve the portability of your program, or you can choose to use extensions to the standard to increase the readability, functionality, and efficiency of your programs.

You can request that the compiler warn you about program syntax that violates the standard's numbered syntax rules and constraints. While this does not insure that the program as a whole is standard-conforming, it can help to avoid many possible compatibility issues. The `/stand` (Windows\*) or `-std` (Linux\* and macOS) options enable this checking, and you can specify the desire standard to check against. If you do not specify a standard, Fortran 2018 is used.

You can use the `standard-semantics` compiler option to enable all of the options that implement the current Fortran Standard behavior of the compiler where those differ from the compiler's default.

## Use Standard Extensions

Not all extensions to the Fortran standard cause problems when porting to other platforms. Many extensions are supported on a wide range of platforms, and if a system you are porting a program to supports an extension, there is no reason to avoid using it. There is no guarantee, however, that the same feature on another system will be implemented in the same way as with Intel® Fortran. Only the Fortran standard is guaranteed to coexist uniformly on all platforms.

The Intel® Fortran Compiler supports many language extensions on multiple platforms, including Linux\*, macOS, and Microsoft Windows\* operating systems. The Intel® *Fortran Language Reference Manual* identifies whether each language element is supported on other platforms.

It is a good programming practice to declare any external procedures either in an `EXTERNAL` statement or in a procedure interface block, for the following reasons:

- The newer Fortran standards have added many new intrinsic procedures to the language.  
Programs that conformed to earlier Fortran Standards (such as FORTRAN 77) may include non-intrinsic functions or subroutines having the same name as new Fortran Standard procedures.
- Some processors include nonstandard intrinsic procedures that might conflict with procedure names in your program.

If you do not explicitly declare the external procedures and the name duplicates an intrinsic procedure, the processor calls the intrinsic procedure, not your external routine. For more information on how the Intel® Fortran Compiler resolves name definitions, see [Resolving Procedure References](#).

## Use Compiler Optimizations

Many Fortran compilers perform code-generation optimizations to increase the speed of execution or to decrease the required amount of memory for the generated code. Although the behaviors of both the optimized and non-optimized programs fall within the language standard specification, different behaviors can occur in areas not covered by the language standard. Compiler optimization can influence floating-point numeric results.

The Intel® Fortran Compiler can perform optimizations to increase execution speed and to improve floating-point numerical consistency.

Floating-point consistency refers to obtaining results consistent with the IEEE binary floating-point standards. For more information, refer to the `/fp:consistent` option of `fp-model`.

### Product and Performance Information

# Conformance, Compatibility, and Fortran Features

---

This section contains information about Fortran language standards conformance, language compatibility, and supported features.

- [Fortran 2018 Features](#)
- [Fortran 2008 Features](#)
- [Fortran 2003 Features](#)

## Language Standards Conformance

The Fortran standard has undergone several revisions since its initial publication as FORTRAN 66 (also known as FORTRAN IV). Subsequent revisions have been FORTRAN 77, Fortran 90, Fortran 95, Fortran 2003, Fortran 2008, and Fortran 2018. Each revision has added new features; some revisions have labeled features as "deprecated" (or obsolescent) or they have removed them. Intel® Fortran continues to support deprecated and deleted features.

Intel® Fortran conforms to the Fortran 2018 standard (ISO/IEC 1539-1:2018), Fortran 2008 standard (ISO/IEC 1539-1:2010), Fortran 2003 standard (ISO/IEC 1539-1:2004), American National Standard Fortran 95 (ANSI X3J3/96-007)<sup>1</sup>, and American National Standard Fortran 90 (ANSI X3.198-1992).<sup>2</sup>

The Fortran Standards committee is currently answering questions of interpretation on Fortran 2018 language features. Any answers given by the committee that are related to features implemented in Intel® Fortran may result in changes in future releases of the Intel® Fortran Compiler, even if the changes produce incompatibilities with earlier releases of Intel® Fortran.

Intel Fortran provides a number of extensions to the Fortran 2018 Standard. In the language reference, extensions (non-standard features) are displayed in this color.

Intel® Fortran also includes support for programs that conform to the previous Fortran standards (ANSI X3.9-1978 and ANSI X3.0-1966), the International Standards Organization standard ISO 1539-1980 (E), the Federal Information Processing Institute standard FIPS 69-1, and the Military Standard 1753 Language Specification.

## Language Compatibility

Intel® Fortran is highly source-compatible with Compaq\* Visual Fortran on supported systems, and it is substantially source-compatible with DEC\* Fortran 90 and VAX\* FORTRAN 77.

## Fortran 2018 Features

The following Fortran 2018 feature is new in this release:

- ifort now enforces strict F2018 conformance for arguments to the C\_LOC function.

The following Fortran 2018 features are also supported:

- Coarray teams have been implemented.
- The derived type TEAM\_TYPE has been added to the ISO\_FORTRAN\_ENV intrinsic module.
- The CHANGE TEAM and END TEAM statements have been implemented.
- The FORM TEAM statement has been implemented.
- The SYNC TEAM statement has been implemented.

---

<sup>2</sup> This is the same as International Standards Organization standard ISO/IEC 1539-1:1997 (E).

<sup>3</sup> This is the same as International Standards Organization standard ISO/IEC 1539:1991 (E).

- The TEAM\_NUMBER intrinsic function has been implemented.
- The GET\_TEAM intrinsic function has been implemented.
- The TEAM argument has been added to the intrinsic functions [FAILED\\_IMAGES](#), [IMAGE\\_STATUS](#), and [STOPPED\\_IMAGES](#).
- The optional TEAM argument has been added to the intrinsic functions STOPPED\_IMAGES, NUM\_IMAGES, and IMAGE\_STATUS.
- New forms of the intrinsic function IMAGE\_INDEX and NUM\_IMAGES allow optional TEAM and TEAM\_NUMBER arguments have been implemented.
- A new form of THIS\_IMAGE with a TEAM argument has been implemented.
- An optional TEAM or TEAM\_NUMBER specifier is now permitted in image selectors.
- Implicit allocation of an unallocated coarray in a variable definition context is now prohibited.
- Nonpolymorphic pointer arguments to the EXTENDS\_TYPE\_OF and SAME\_TYPE\_AS intrinsics no longer need to have defined allocation status.
- Deallocation during finalization has been clarified and now occurs using the semantics defined in Fortran 2018.
- Output from the STOP and ERROR\_STOP statement may now be conditionally suppressed.
- STOP and ERROR STOP codes can now be non-constant expressions.
- Named constants of type LOCK\_TYPE are no longer allowed.
- The DIM argument to the intrinsic functions ALL, ANY, IALL, IANY, IPARITY, MAXLOC, MAXVAL, MINLOC, MINVAL, NORM2, PARITY, PRODUCT, SUM, and THIS\_IMAGE may now be a present OPTIONAL dummy argument.
- VALUE dummy arguments to PURE procedures may appear in variable definition contexts.
- The optional ERRMSG argument has been added to the intrinsic procedures GET\_COMMAND\_ARGUMENT, GET\_ENVIRONMENT\_VARIABLE, and GET\_COMMAND.
- The OUT\_OF\_RANGE intrinsic function has been implemented.
- The RANDOM\_INIT intrinsic subroutine has been implemented.
- Dummy arguments to defined assignment and operator procedures need not have the INTENT(IN) attribute if they have the VALUE attribute.
- A dummy argument of PURE procedure may appear in a variable definition context if it has the VALUE attribute.
- Constant properties of an object can be used in the objects initialization.
- Polymorphic structure constructor components no longer need to have the same dynamic type as their corresponding structure component expression.
- The RANDOM\_INIT intrinsic subroutine has been implemented.
- Several new Fortran 2018 terms have been added to the Glossary; for example: current team, ancestor team, parent team, and established coarrays.
- Non-pointer variables with the PROTECTED attribute may no longer appear as a data-target or as a initial-data-target.
- VOLATILE variables are now prohibited in PURE procedures and statement functions.
- The type and kind of an implied DO loop variable can now be specified in an implied-do loop of array constructors and data statements.
- Floating point comparisons perform IEEE compareSignaling<relation> operations when the `assume ieee_compares` or `-standard-semantics` compiler option is specified.
- The REDUCE intrinsic that performs user-defined reductions has been implemented.
- Enhancements to the IMPLICIT NONE statement allow specifying that all external procedures must be declared as EXTERNAL.
- Enhancements to the GENERIC statement permit it to be used to declare generic interfaces.
- You can now specify locality for variables in a [DO CONCURRENT](#) statement.
- Enhancements to edit descriptor forms E and D, EN, ES, and G allow a field width of zero, analogous to the F edit descriptor.
- The exponent width e in a data edit descriptor can now be zero, analogous to a field width of zero.
- The RN edit descriptor now rounds to nearest as specified by Fortran 2018 and ISO/IEC/IEEE 60559:2011.

- The EX edit descriptor allows for hexadecimal format output of floating-point values, and hexadecimal format floating-point values are allowed on input.
- SIZE= can be specified for non-advancing I/O.
- The values for SIZE= and POS= in an INQUIRE statement for pending asynchronous operations have been standardized.
- The value assigned to the RECL= specifier in an INQUIRE statement now has standardized values.
- A new form of the intrinsic function CMPLX does not require the KIND= keyword if the first argument is type COMPLEX.
- The arguments to the SIGN function can be of different kinds.
- The named constants STAT\_FAILED\_IMAGE and STAT\_UNLOCKED\_FAILED\_IMAGE have been defined in the intrinsic ISO\_FORTRAN\_ENV modules.
- The named constant kind type C\_PTRDIFF\_T has been added to the intrinsic module ISO\_C\_BINDING.
- The non-block DO statement and the arithmetic IF statement are now deleted in Fortran 2018. Intel® Fortran fully supports features deleted in the Fortran Standard.
- COMMON, EQUIVALENCE and BLOCKDATA statements are now obsolescent.
- The labeled form of a DO loop is now obsolescent.
- Specific names of intrinsic procedures are now obsolescent.
- The following atomic subroutines have been implemented: [ATOMIC\\_ADD](#), [ATOMIC\\_AND](#), [ATOMIC\\_CAS](#), [ATOMIC\\_FETCH\\_ADD](#), [ATOMIC\\_FETCH\\_AND](#), [ATOMIC\\_FETCH\\_OR](#), [ATOMIC\\_FETCH\\_XOR](#), [ATOMIC\\_OR](#), and [ATOMIC\\_XOR](#).
- The following collective subroutines have been implemented: [CO\\_BROADCAST](#), [CO\\_MAX](#), [CO\\_MIN](#), [CO\\_REDUCE](#), and [CO\\_SUM](#).
- The [SELECT RANK](#) construct has been implemented allowing manipulation of assumed rank dummy arguments..
- The compiler will now diagnose the use of nonstandard intrinsic procedures and modules as required by Fortran 2018.
- To comply with the latest Fortran 2018 standards, [C\\_F\\_PROCPOINTER](#) is now IMPURE.
- Transformational intrinsic functions from the intrinsic modules ISO\_C\_BINDING, IEEE\_ARITHMETIC, and IEEE\_EXCEPTIONS are now allowed in specification expressions.
- You can now specify optional argument RADIX for the IEEE\_GET\_ROUNDING\_MODE and IEEE\_SET\_ROUNDING\_MODE intrinsic module procedures.
- IEEE\_ROUND\_TYPE and IEEE\_AWAY have been added to the IEEE\_ARITHMETIC intrinsic module.
- The optional ROUND argument has been added to the IEEE\_RINT function defined in the intrinsic module IEEE\_ARITHMETIC.
- The intrinsic module IEEE\_ARITHMETIC now includes the functions [IEEE\\_FMA](#), [IEEE\\_SIGNBIT](#), [IEEE\\_NEXT\\_UP](#), and [IEEE\\_NEXT\\_DOWN](#).
- The intrinsic module IEEE\_EXCEPTIONS now contains a new derived type, IEEE\_MODES\_TYPE, which can be used to save and restore the IEEE\_MODES using the [IEEE\\_GET\\_MODES](#) and the [IEEE\\_SET\\_MODES](#) intrinsic module procedures.
- SUBNORMAL is now synonymous with DENORMAL.
- The following intrinsic module procedures have been implemented:
  - [IEEE\\_MAX\\_NUM](#), [IEEE\\_MAX\\_NUM\\_MAG](#), [IEEE\\_MIN\\_NUM](#), and [IEEE\\_MIN\\_NUM\\_MAG](#)
  - [IEEE\\_QUIET\\_EQ](#), [IEEE\\_QUIET\\_GE](#), [IEEE\\_QUIET\\_GT](#), [IEEE\\_QUIET\\_LE](#), [IEEE\\_QUIET\\_LT](#), [IEEE\\_QUIET\\_NE](#), [IEEE\\_SIGNALING\\_EQ](#), [IEEE\\_SIGNALING\\_GE](#), [IEEE\\_SIGNALING\\_GT](#), [IEEE\\_SIGNALING\\_LE](#), [IEEE\\_SIGNALING\\_LT](#), and [IEEE\\_SIGNALING\\_NE](#)
  - [IEEE\\_SUPPORT\\_SUBNORMAL](#)
- An optional STAT= specifier has been added to [ATOMIC\\_REF](#) and [ATOMIC\\_DEFINE](#) intrinsic procedures.
- Optional STAT= and ERRMSG= specifiers have been added to the [MOVE\\_ALLOC](#) intrinsic procedure, to [image selectors](#), and to the [CRITICAL statement and construct](#).
- INTEGER and LOGICAL arguments to intrinsic procedures are no longer required to be of default kind.
- The intrinsic module procedures [IEEE\\_INT](#) and [IEEE\\_REAL](#) have been implemented.
- The [FAIL IMAGE](#) statement has been implemented. It allows debugging recovery code for failed images without having to wait for an actual image failure.
- Intrinsic functions [FAILED\\_IMAGES](#), [IMAGE\\_STATUS](#), and [STOPPED\\_IMAGES](#) have been implemented.

- The [COSHAPE](#) intrinsic function returns the cobounds of a coarray argument.
- You can now add module names, OpenMP reduction identifiers, and defined I/O generic specs to [PUBLIC](#) and [PRIVATE](#) statements.
- Coarray EVENTS provide synchronization capabilities between images:
  - [EVENT\\_QUERY](#) intrinsic subroutine
  - [EVENT\\_POST](#) and [EVENT\\_WAIT](#) statements
- The [derived type EVENT\\_TYPE](#) is defined in the [ISO\\_FORTRAN\\_ENV](#) intrinsic module.
- The [IMPORT statement](#) can now be used in internal subprograms and BLOCK constructs to control host association. There are three new forms:
  - [IMPORT, ALL](#)
  - [IMPORT, NONE](#)
  - [IMPORT, ONLY: import-name-list](#)
- A module name that is accessed via used association can appear in a PUBLIC or PRIVATE access-id-list . It can be used to set the default accessibility for all accessible entities from that module.
- C language interoperability :
  - An assumed-rank array is now permitted to be an argument to the [C\\_SIZEOF](#) intrinsic function.
  - With the exception of [C\\_F\\_POINTER](#), all standard procedures in the [ISO\\_C\\_BINDING](#) intrinsic module are now PURE.
  - Assumed type variables
  - [Assumed-rank](#) arrays
  - C descriptors
  - [RANK intrinsic](#) function
- The [NON\\_RECURSIVE](#) keyword declares a procedure as not recursive. The default in previous Fortran standards was that procedures were non-recursive unless declared [RECURSIVE](#). Fortran 2018 changes that default. Intel® Fortran has implemented the [NON\\_RECURSIVE](#) keyword, but the default compilation mode for this release remains non-recursive.
- The [ERROR STOP](#) statement is allowed in [PURE](#) procedures

## Fortran 2008 Features

The following Fortran 2008 features are new in this release:

- Specification expressions can now contain user-defined operators.
- Direct access user-defined I/O has been implemented.

The following Fortran 2008 features are also supported:

- The [FINDLOC](#) intrinsic function
- You can specify optional argument [BACK](#) in [MAXLOC](#) and [MINLOC](#) intrinsic functions.
- You can declare multiple type-bound procedures in a [PROCEDURE](#) list.
- Intrinsic assignment to an allocatable polymorphic variable is allowed if the variable is not a coarray. For more information, see [Examples of Intrinsic Assignment to Polymorphic Variables](#).
- The intrinsic module functions [COMPILER\\_OPTIONS](#) and [COMPILER\\_VERSION](#)
- Subscripts and nested implied-DO limits in a data statement can be any constant expression instead of being limited to combinations of constants, implied-DO variables, and intrinsic operations.
- The intrinsic functions [ACOS](#), [ACOSH](#), [ASIN](#), [ASINH](#), [ATAN](#), [ATANH](#), [COSH](#), [SINH](#), [TAN](#), and [TANH](#) now take arguments of type [COMPLEX](#). The intrinsic function [ATAN](#) (Y, X) is defined as [ATAN2](#) (Y, X).
- A pointer dummy argument with [INTENT\(IN\)](#) can be argument associated with a non-pointer actual argument with the [TARGET](#) attribute.
- A reference to a function that returns a data pointer is treated as a variable and is permitted in any [variable-definition context](#) .
- Allocatable components are allowed to be of recursive type, that is, the type being defined, or of a forward type, that is, a derived type that is not yet defined.

- In an ALLOCATE statement, you can specify more than one allocate object for a given SOURCE= or MOLD=. Also, if you do not specify upper and lower bounds in an ALLOCATE statement's *s-spec* list, the shape of the array is that of SOURCE=*source-expr* or MOLD=*source-expr*.
- Initialization expressions are now referred to as constant expressions.
- An EXIT statement can appear in a BLOCK, IF, ASSOCIATE, SELECT CASE, or SELECT TYPE construct.
- You can specify intrinsic types in a TYPE statement
- You can specify implied-shape array specifications for named constant arrays
- You can specify %re and %im designators for the real and imaginary parts of values of COMPLEX type
- Pointer Initialization
- Binary, octal, and hexadecimal constants are allowed for one or more arguments in intrinsic routines BGE, BGT, BLE, BLT, CMPLX, DBLE, DSHIFTL, DSHIFTR, IAND, IEOR, INT, IOR, MERGE\_BITS, and REAL.
- You can specify an optional integer datatype for the *subscript-name* in the *triplet-spec* in the FORALL statement.
- An ALLOCATE statement can give a polymorphic variable the shape and type of another variable without copying the value. This is done with MOLD= replacing SOURCE=.
- Except for procedure arguments and pointer dummy arguments, a PURE function may have a dummy argument with the VALUE attribute without the explicit INTENT(IN) attribute.
- Dummy arguments of ELEMENTAL procedures may appear in specification expressions in the procedure.
- You can specify an optional RADIX argument for the intrinsic function SELECTED\_REAL\_KIND and the intrinsic module procedure IEEE\_SELECTED\_REAL\_KIND.
- Submodules
- IMPURE keyword
- The EXECUTE\_COMMAND\_LINE subroutine
- The BLOCK construct
- The FUNCTION and SUBROUTINE keywords on the END statement are optional for internal procedures and module procedures.
- A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign
- Generic resolution of procedures where one dummy argument has the ALLOCATABLE attribute and the other has the POINTER attribute without INTENT (IN), or where one is a procedure and the other is a data object.
- The ENTRY statement is an obsolescent feature.
- A source statement can begin with one or more semicolon characters.
- Coarray intrinsic routines: ATOMIC\_DEFINE and ATOMIC\_REF
- A polymorphic MOLD= specifier for ALLOCATE
- Coarrays (Windows\* and Linux\* only)
- Image control statements: SYNC ALL, SYNC IMAGES, SYNC MEMORY, CRITICAL, LOCK, and UNLOCK
- Coarray intrinsic routines: IMAGE\_INDEX, LCOBOUND, NUM\_IMAGES, THIS\_IMAGE, and UCBOUND
- CRITICAL construct
- Maximum array rank of 15 (Intel® Fortran allows 31 dimensions)
- G0 and G0.d format edit descriptors
- FINAL routines
- GENERIC, OPERATOR, and ASSIGNMENT overloading in type-bound procedures
- A generic interface may have the same name as a derived type
- Bounds specification and bounds remapping list on a pointer assignment
- In formatting, a \* indicates an unlimited repeat count
- NEWUNIT= specifier in OPEN
- A CONTAINS section can be empty
- Attributes CODIMENSION and CONTIGUOUS
- Coarrays can be specified in ALLOCATABLE, ALLOCATE, and TARGET statements
- MOLD keyword in ALLOCATE
- DO CONCURRENT statement
- ERROR STOP statement

- Intrinsic functions BESSEL\_J0, BESSEL\_J1, BESSEL\_JN, BESSEL\_Y0, BESSEL\_Y1, BESSEL\_YN, BGE, BGT, BLE, BLT, DSHIFTL, DSHIFTR, ERF, ERFC, ERFC\_SCALED, GAMMA, HYPOT, IALL, IANY, IPARITY, IS\_CONTIGUOUS, LEADZ, LOG\_GAMMA, MASKL, MASKR, MERGE\_BITS, NORM2, PARITY, POPCNT, POPPAR, SHIFTA, SHIFTL, SHIFTR, STORAGE\_SIZE, TRAILZ
- ISO\_FORTRAN\_ENV module constants ATOMIC\_INT\_KIND, ATOMIC\_LOGICAL\_KIND, CHARACTER\_KINDS, INTEGER\_KINDS, INT8, INT16, INT32, INT64, LOGICAL\_KINDS, REAL\_KINDS, REAL32, REAL64, REAL128, STAT\_LOCKED, STAT\_LOCKED\_OTHER\_IMAGE, STAT\_UNLOCKED
- ISO\_FORTRAN\_ENV type LOCK\_TYPE
- SCALAR keyword for ALLOCATED

## Fortran 2003 Features

Fortran 2003 is fully supported, including the following features:

- Parameterized derived types with KIND and LENGTH type parameters and the %KIND and %LEN type parameter designators
- A polymorphic dummy argument that has the attribute INTENT(OUT) becomes UNDEFINED or it will have DEFAULT\_INITIALIZATION applied.
- User-Defined Derived-Type I/O
- A polymorphic SOURCE= specifier for ALLOCATE
- Bounds specification and bounds remapping list on a pointer assignment
- FINAL routines
- GENERIC, OPERATOR, and ASSIGNMENT overloading in type-bound procedures
- Enumerators
- Type extension (not polymorphic)
- Type-bound procedures
- Allocatable scalar variables (not deferred-length character)
- ERRMSG keyword for ALLOCATE and DEALLOCATE
- SOURCE= keyword for ALLOCATE
- Character arguments for MAX, MIN, MAXVAL, MINVAL, MAXLOC, and MINLOC
- Intrinsic modules IEEE\_EXCEPTIONS, IEEE\_ARITHMETIC and IEEE\_FEATURES
- ASSOCIATE construct
- DO CONCURRENT construct
- PROCEDURE declaration
- Procedure pointers
- ABSTRACT INTERFACE
- PASS and NOPASS attributes
- CONTIGUOUS attribute
- Structure constructors with component names and default initialization
- Array constructors with type and character length specifications
- I/O keywords BLANK, DECIMAL, DELIM, ENCODING, IOMSG, PAD, ROUND, SIGN, and SIZE
- Format edit descriptors DC, DP, RD, RC, RN, RP, RU, and RZ
- The COUNT\_RATE argument to the SYSTEM\_CLOCK intrinsic may be a REAL of any kind.
- NAMELIST I/O for internal files
- Intrinsic functions EXTENDS\_TYPE\_OF and SAME\_TYPE\_AS
- SELECT TYPE construct
- CLASS declaration
- PUBLIC types with PRIVATE components and PRIVATE types with PUBLIC components
- RECORDTYPE setting STREAM\_CRLF
- A file can be opened for stream access (ACCESS='STREAM')
- Specifier POS can be specified in an INQUIRE, READ, or WRITE statement
- BIND attribute and statement
- Language binding can be specified in a FUNCTION or SUBROUTINE statement, or when defining a derived type
- IS\_IOSTAT\_END intrinsic function

- IS\_IOSTAT\_EOR intrinsic function
- INTRINSIC and NONINTRINSIC can be specified for modules in USE statements
- ASYNCHRONOUS attribute and statement
- VALUE attribute and statement
- Specifier ASYNCHRONOUS can be specified in an OPEN, INQUIRE, READ, or WRITE statement
- An ID can be specified for a pending data transfer operation
- FLUSH statement
- WAIT statement
- IMPORT statement
- NEW\_LINE intrinsic function
- SELECTED\_CHAR\_KIND intrinsic function
- Intrinsic modules ISO\_C\_BINDING and ISO\_FORTRAN\_ENV
- Specifiers ID and PENDING can be specified in an INQUIRE statement
- User-defined operators can be renamed in USE statements
- MOVE\_ALLOC intrinsic subroutine
- PROTECTED attribute and statement
- Pointer objects can have the INTENT attribute
- GET\_COMMAND intrinsic
- GET\_COMMAND\_ARGUMENT intrinsic
- COMMAND\_ARGUMENT\_COUNT intrinsic
- GET\_ENVIRONMENT\_VARIABLE intrinsic
- Allocatable components of derived types
- Allocatable dummy arguments
- Allocatable function results
- VOLATILE attribute and statement
- Names of length up to 63 characters
- Statements up to 256 lines
- A named PARAMETER constant may be part of a complex constant
- In all I/O statements, the following numeric values can be of any kind: UNIT=, IOSTAT=
- The following OPEN numeric values can be of any kind: RECL=
- The following READ and WRITE numeric values can be of any kind: REC=, SIZE=
- The following INQUIRE numeric values can be of any kind: NEXTREC=, NUMBER=, RECL=, SIZE=
- Recursive I/O is allowed when the new I/O being started is internal I/O that does not modify any internal file other than its own
- IEEE infinities and Nans are displayed by formatted output as specified by Fortran 2003
- In an I/O format, the comma after a P edit descriptor is optional when followed by a repeat specifier
- The following intrinsics take an optional KIND= argument: ACHAR, COUNT, IACHAR, ICHAR, INDEX, LBOUND, LEN, LEN\_TRIM, MAXLOC, MINLOC, SCAN, SHAPE, SIZE, UBOUND, VERIFY
- Square brackets [ ] are permitted to delimit array constructors instead of (/ /)
- The Fortran character set has been extended to contain the 8-bit ASCII characters ~ \ [ ] ` ^ { } | # @

# Minimize Operating System-Specific Information

---

The operating system influences your program both externally and internally. For increased portability, you need to minimize the amount of operating-system-specific information required by your program. The Fortran language standards do not specify this information.

Operating-system-specific information consists of non-intrinsic extensions to the language, compiler and linker options, and possibly the graphical user interface of Windows\*. Input and output operations use devices that may be system-specific and may involve a file system with system-specific record and file structures.

The operating system also governs resource management and error handling. You can depend on default resource management and error handling mechanisms or provide mechanisms of your own. For information on special library routines to help port your program from one system to another, see [IFPORT Portability Library](#) and related topics.

The minimal interaction with the operating system is for input/output (I/O) operations and usually consists of knowing the standard units preconnected for input and output. You can use default file units with the asterisk (\*) unit specifier.

To increase the portability of your programs across operating systems, consider the following:

- Do not assume the use of a particular type of file system.
- Do not embed filenames or paths in the body of your program. Define them as constants at the beginning of the program or read them from input data.
- Do not assume a particular type of standard I/O device or the "size" of that device (number of rows and columns).
- Do not assume display attributes for the standard I/O device. Some environments do not support attributes such as color, underlined text, blinking text, highlighted text, inverse text, protected text, or dim text.

## *Store and Represent Data*

---

The Fortran language standard specifies little about the storage of data types.

This loose specification of storage for data types results from a great diversity of computing hardware. This diversity poses problems in representing data and especially in transporting stored data among a multitude of systems. The size (as measured by the number of bits) of a storage unit (a word, usually several bytes) varies from machine to machine. In addition, the ordering of bits within bytes and bytes within words varies from one machine to another. Furthermore, binary representations of negative integers and floating-point representations of real and complex numbers take several different forms.

The simplest and most reliable means of transferring data between dissimilar systems is in *character* and not binary form. Simple programming practices ensure that your data as well as your program is portable.

## *Data Portability*

---

This section contains information about issues related to portability of data.

### **Format Data for Transportability**

---

You can achieve the highest transportability of your data by formatting it as 8-bit character data. Use a standard character set, such as the ASCII standard, for encoding your character data. Although this practice is less efficient than using binary data, it will save you from shuffling and converting your data.

If you are transporting your data by means of a record-structured medium, it is best to use the Fortran sequential files. See [Record Types](#) in the reference guide for more information.

Remember also that some systems use a carriage return/linefeed pair as an end-of-record indicator, while other systems use linefeed only. There might be system-dependent values embedded within your data that complicate its transport.

Implementing a strictly portable solution requires a careful effort. Maximizing portability may also mean making compromises to the efficiency and functionality of your solution. If portability is not your highest priority, you can use some of the techniques that appear in later sections to ease your task of customizing a solution.

[Supported Native and Non-native Numeric Formats](#)

## Supported Native and Non-Native Numeric Formats

Data storage in different computers uses a convention of either little endian or big endian storage. The storage convention generally applies to numeric values that span multiple bytes, as follows:

Little endian storage occurs when:

- The least significant bit (LSB) value is in the byte with the lowest address.
- The most significant bit (MSB) value is in the byte with the highest address.
- The address of the numeric value is the byte containing the LSB. Subsequent bytes with higher addresses contain more significant bits.

Big endian storage occurs when:

- The least significant bit (LSB) value is in the byte with the highest address.
- The most significant bit (MSB) value is in the byte with the lowest address.
- The address of the numeric value is the byte containing the MSB. Subsequent bytes with higher addresses contain less significant bits.

Intel® Fortran expects numeric data to be in native little endian order, in which the least-significant, right-most zero bit (bit 0) or byte has a lower address than the most-significant, left-most bit (or byte).

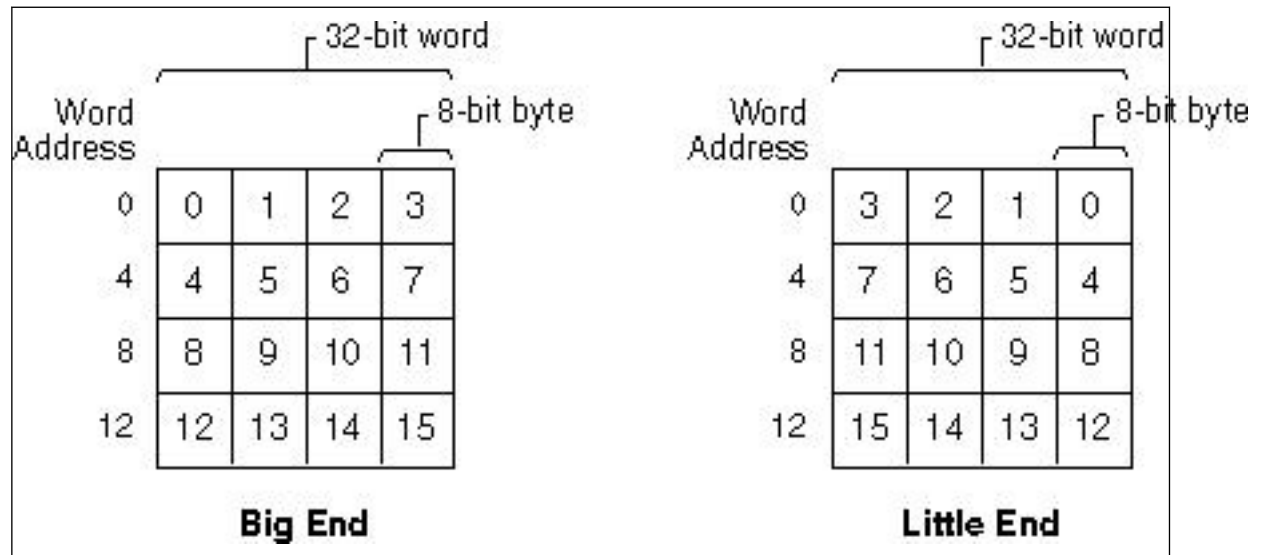

The following figures show the difference between the two byte-ordering schemes:

### Little and Big Endian Storage of an INTEGER Value

The following figure illustrates the difference between the two conventions for the case of addressing bytes within words.

**Byte Order Within Words: (a) Big Endian, (b) Little Endian**

Data types stored as subcomponents (bytes stored in words) end up in different locations within corresponding words of the two conventions. The following figure illustrates the difference between the representations of several data types in the two conventions. Letters represent 8-bit character data, while numbers represent the 8-bit partial contribution to 32-bit integer data.

**Character and Integer Data in Words: (a) Big Endian, (b) Little Endian**

If you serially transfer bytes now from the big endian words to the little endian words (BE byte 0 to LE byte 0, BE byte 1 to LE byte 1, and so on), the left half of the figure shows how the data ends up in the little endian words. Note that data of size one byte (characters in this case) is ordered correctly, but that integer

data no longer correctly represents the original binary values. The right half of the figure shows that you need to swap bytes around the middle of the word to reconstitute the correct 32-bit integer values. After swapping bytes, the two preceding figures are identical.

**Data Sent from Big to Little: (a) After Transfer, (b) After Byte Swaps**

You can generalize the previous example to include floating-point data types and to include multiple-word data types.

Moving unformatted data files between big endian and little endian computers requires that the data be converted.

Intel Fortran provides the capability for programs to read and write unformatted data (originally written using unformatted I/O statements) in several non-native floating-point formats and in big endian INTEGER or floating-point format. Supported non-native floating-point formats include Compaq\* VAX\* little endian floating-point formats supported by Digital\* FORTRAN for OpenVMS\* VAX Systems, standard IEEE big endian floating-point format found on most Sun Microsystems\* systems and IBM RISC\* System/6000 systems, IBM floating-point formats (associated with the IBM's System/370 and similar systems), and CRAY\* floating-point formats.

Converting unformatted data instead of formatted data is generally faster and is less likely to lose precision of floating-point numbers. For unformatted files that contain record lengths before and after the data, specifying big-endian conversion will interpret the lengths as big-endian.

**Caution:**

Intel Fortran support of data conversion applies only to I/O list items of intrinsic type (REAL, INTEGER, and so on). I/O list items of derived type are not converted.

The native memory format includes little endian integers and little endian IEEE floating-point formats, IEEE binary32 for REAL(KIND=4) and COMPLEX(KIND=4) declarations, IEEE binary64 for REAL(KIND=8) and COMPLEX(KIND=8) declarations, and IEEE binary128 for REAL(KIND=16) and COMPLEX(KIND=16) declarations.

The keywords for supported non-native unformatted file formats and their data types are listed in the following table:

Keyword	Description
BIG_ENDIAN	Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian IEEE floating-point formats for REAL and COMPLEX single-, double-, and extended-precision numbers. INTEGER(KIND=1) data is the same for little endian and big endian.
CRAY	Big endian integer data of the appropriate size (one, two, four, or eight bytes) and big endian CRAY proprietary floating-point format for REAL and COMPLEX single- and double-precision numbers.
FDX	Little endian integer data of the appropriate size (one, two, four, or eight bytes) and the following little endian proprietary floating-point formats: <ul style="list-style-type: none"> <li>• VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)</li> <li>• VAX D_float for REAL (KIND=8) and COMPLEX (KIND=8)</li> <li>• IEEE binary128 for REAL (KIND=16) and COMPLEX (KIND=16)</li> </ul>
FGX	Little endian integer data of the appropriate size (one, two, four, or eight bytes) and the following little endian proprietary floating-point formats: <ul style="list-style-type: none"> <li>• VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)</li> <li>• VAX G_float for REAL (KIND=8) and COMPLEX (KIND=8)</li> <li>• IEEE binary128 for REAL (KIND=16) and COMPLEX (KIND=16)</li> </ul>
IBM	Big endian integer data of the appropriate INTEGER size (one, two, or four bytes) and big endian IBM proprietary (System\370 and similar) floating-point format for REAL and COMPLEX single- and double-precision numbers.
LITTLE_ENDIAN	Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following native little endian IEEE floating-point formats: <ul style="list-style-type: none"> <li>• IEEE binary32 for REAL (KIND=4) and COMPLEX (KIND=4)</li> <li>• IEEE binary64 for REAL (KIND=8) and COMPLEX (KIND=8)</li> <li>• IEEE binary128 for REAL (KIND=16) and COMPLEX (KIND=16)</li> </ul> For additional information on supported ranges for these data types, see Native IEEE Floating-Point Representations.
NATIVE	No conversion occurs between memory and disk. This is the default for unformatted files.
VAXD	Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following little endian VAX proprietary floating-point formats: <ul style="list-style-type: none"> <li>• VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)</li> <li>• VAX D_float for REAL (KIND=8) and COMPLEX (KIND=8)</li> <li>• VAX H_float for REAL (KIND=16) and COMPLEX (KIND=16)</li> </ul>
VAXG	Native little endian integers of the appropriate INTEGER size (one, two, four, or eight bytes) and the following little endian VAX proprietary floating-point formats: <ul style="list-style-type: none"> <li>• VAX F_float for REAL (KIND=4) and COMPLEX (KIND=4)</li> <li>• VAX G_float for REAL (KIND=8) and COMPLEX (KIND=8)</li> <li>• VAX H_float for REAL (KIND=16) and COMPLEX (KIND=16)</li> </ul>

When reading a non-native format, the non-native format on disk is converted to native format in memory. If a converted non-native value is outside the range of the native data type, a runtime message is displayed.

Environment Variable [F\\_UFMTENDIAN](#) Method

## Port Non-Native Data

When porting non-native data, consider the following:

- Vendors might use different units for specifying the record length (`RECL` specifier) of unformatted files. While formatted files are specified in units of characters (bytes), unformatted files are specified in longword units for Intel® Fortran (default) and some other vendors.

To allow you to specify `RECL` units (bytes or longwords) for unformatted files without source file modification, use the `assume byterecl` compiler option.

- Certain vendors apply different `OPEN` statement defaults to determine the record type. The default record type (`RECORDTYPE`) with Intel® Fortran depends on the values for the `ACCESS` and `FORM` specifiers for the `OPEN` statement.
- Certain vendors use a different identifier for the logical data types, such as hex `FF` and hex `00` instead of `01` to denote `.TRUE.` and `.FALSE.` See the `fpscomp:logicals` compiler option.
- Source code being ported may be coded specifically for big endian use.

## Specify the Data Format

There are a number of methods for specifying a non-native numeric format for unformatted data:

- [Environment Variable `FORT\_CONVERT.ext` or `FORT\_CONVERT\_ext` Method](#)

Set an environment variable for a specific file name extension before the file is opened. The environment variable is named `FORT_CONVERT.ext` or `FORT_CONVERT_ext`, where `ext` is the file name extension (suffix).

- [Environment Variable `FORT\_CONVERTn` Method](#)

Set an environment variable for a specific unit number before the file is opened. The environment variable is named `FORT_CONVERTn`, where `n` is the unit number.

- [Environment Variable `F\_UFMTENDIAN` Method](#)

Set an environment variable for a set of units before the application is executed. The environment variable is named `F_UFMTENDIAN`.

- [OPEN Statement `CONVERT` Method](#)

Specify the `CONVERT` keyword in the `OPEN` statement for a specific unit number.

- [OPTIONS Statement Method](#)

Compile the program with an `OPTIONS` statement that specifies the `CONVERT=keyword` qualifier. This method affects all unit numbers using unformatted data specified by the program.

- [Compiler Option `-convert` or `/convert` Method](#)

Compile the program with the appropriate compiler option, which affects all unit numbers that use unformatted data specified by the program. Use the `convert` compiler option.

If none of these methods are specified, the native `LITTLE_ENDIAN` format is assumed (no conversion occurs between disk and memory).

Any keyword listed in [Supported Native and Non-native Numeric Formats](#) can be used with any of these methods, except for the Environment Variable `F_UFMTENDIAN` Method, which supports only `LITTLE_ENDIAN` and `BIG_ENDIAN`.

If you specify more than one method, the order of precedence when you open a file with unformatted data is below:

1. Check for an environment variable (`FORT_CONVERTn`) for the specified unit number (applies to any file opened on a particular unit).
2. Check for an environment variable (`FORT_CONVERT.ext` is checked before `FORT_CONVERT_ext`) for the specified file name extension (applies to all files opened with the specified file name extension).
3. Check for an environment variable (`F_UFMTENDIAN`) for the specified unit number (or for all units).

---

### NOTE

This environment variable is checked only when the application starts executing.

---

4. Check the OPEN statement CONVERT specifier.
5. Check whether an OPTIONS statement with a CONVERT:*keyword* qualifier was present when the program was compiled.
6. Check whether the `convert` compiler option was present when the program was compiled.

### Environment Variable FORT\_CONVERT.ext or FORT\_CONVERT\_ext Method

Use this method to specify a non-native numeric format for each specified file name extension (suffix). Specify the numeric format at runtime by setting the appropriate environment variable before an implicit or explicit OPEN to one or more unformatted files. Use the format FORT\_CONVERT.ext or FORT\_CONVERT\_ext (where *ext* is the file extension or suffix). The FORT\_CONVERT.ext environment variable is checked before FORT\_CONVERT\_ext environment variable (if *ext* is the same).

For example, assume you have a previously compiled program that reads numeric data from one file and writes to another file using unformatted I/O statements. You want the program to read non-native big endian (IEEE floating-point) format from a file with a .dat file extension and write that data in native little endian format to a file with an extension of .data. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format (IEEE binary32 and IEEE binary64) when read from *file.dat*, and then written without conversion in native little endian IEEE format to the file with a suffix of .data, assuming that environment variables FORT\_CONVERT.DATA and FORT\_CONVERT*n* (for that unit number) are not defined.

Without requiring source code modification or recompilation of a program, the following command sets the appropriate environment variables before running the program:

#### Linux\*

```
setenv FORT_CONVERT.DAT BIG_ENDIAN
```

#### Windows\*

```
set FORT_CONVERT.DAT=BIG_ENDIAN
```

The FORT\_CONVERT*n* method takes precedence over this method. When the appropriate environment variable is set when you open the file, the FORT\_CONVERT.ext or FORT\_CONVERT\_ext environment variable is used if a FORT\_CONVERT*n* environment variable is not set for the unit number.

The FORT\_CONVERT*n* and the FORT\_CONVERT.ext or FORT\_CONVERT\_ext environment variable methods take precedence over the other methods. For instance, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

You can set the appropriate environment variable using the format FORT\_CONVERT.ext or FORT\_CONVERT\_ext. If you also use Intel® Fortran on Linux\* systems, consider using the FORT\_CONVERT\_ext form, because a dot (.) cannot be used for environment variable names on certain Linux\* command shells. If you do define both FORT\_CONVERT.ext and FORT\_CONVERT\_ext for the same extension (*ext*), the file defined by FORT\_CONVERT.ext is used.

On Windows\* systems, the file name extension (suffix) is not case-sensitive. The extension must be part of the file name (not the directory path).

### Environment Variable FORT\_CONVERTn Method

You can use this method to specify a non-native numeric format for each specified unit number. You specify the numeric format at runtime by setting the appropriate environment variable before an implicit or explicit OPEN to that unit number.

When the appropriate environment variable is set when you open the file, the environment variable is always used because this method takes precedence over the other methods. For example, you might use this method to specify that a unit number will use a particular format instead of the format specified in the program (perhaps for a one-time file conversion).

For example, assume you have a previously compiled program that reads numeric data from unit 28 and writes it to unit 29 using unformatted I/O statements. You want the program to read non-native big endian (IEEE floating-point) format from unit 28 and write that data in native little endian format to unit 29. In this case, the data is converted from big endian IEEE format to native little endian IEEE memory format when read from unit 28, and then written without conversion in native little endian IEEE format to unit 29.

Without requiring source code modification or recompilation of this program, the following command sequence sets the appropriate environment variables before running a program.

#### Linux

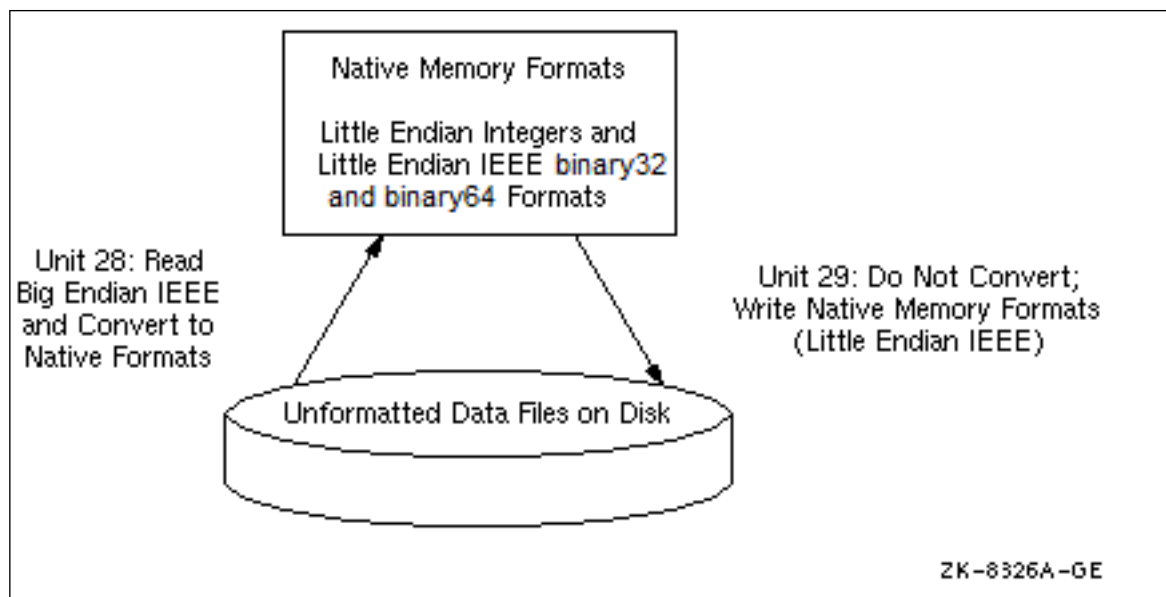

```
setenv FORT_CONVERT28 BIG_ENDIAN
setenv FORT_CONVERT29 NATIVE
```

#### Windows

```
set FORT_CONVERT28=BIG_ENDIAN
set FORT_CONVERT29=NATIVE
```

The following figure shows the data formats used on disk and in memory when the program is run after the environment variables are set.

#### Sample Unformatted File Conversion

This method takes precedence over other methods.

#### Environment Variable `F_UFMTENDIAN` Method

This little-endian-big-endian conversion feature is intended for Fortran unformatted input/output operations. It enables the development and processing of files with little-endian and big-endian data organization.

The `F_UFMTENDIAN` environment variable is processed once at the beginning of program execution. Whatever it specifies for specific units or for all units continues for the rest of the execution.

Specify the numbers of the units to be used for conversion purposes by setting `F_UFMTENDIAN`. Then, the READ/WRITE statements that use these unit numbers will perform relevant conversions. Other READ/WRITE statements will work in the usual way.

#### General Syntax for `F_UFMTENDIAN`

In the general case, the variable consists of two parts divided by a semicolon. No spaces are allowed inside the `F_UFMTENDIAN` value:

```
F_UFMTENDIAN=MODE | [MODE;] EXCEPTION
```

where:

```
MODE = big | little
EXCEPTION = big:ULIST | little:ULIST | ULIST
ULIST = U | ULIST,U
U = decimal | decimal -decimal
```

- `MODE` defines current format of data, represented in the files; it can be omitted.

The keyword `little` means that the data has little endian format and will not be converted. This is the default.

The keyword `big` means that the data has big endian format and will be converted.

- `EXCEPTION` is intended to define the list of exclusions for `MODE.EXCEPTION` keyword (`little` or `big`) defines data format in the files that are connected to the units from the `EXCEPTION` list. This value overrides `MODE` value for the units listed.

The `EXCEPTION` keyword and the colon can be omitted. The default when the keyword is omitted is `big`.

- Each list member `U` is a simple unit number or a number of units. The number of list members is limited to 64.
- `decimal` is a non-negative decimal number less than 232.

Converted data should have basic data types or arrays of basic data types. Derived data types are disabled.

Error messages may be issued during the little-endian-to-big-endian conversion. They are all fatal.

On Linux\* systems, the command line for the variable setting in the shell is:

```
Sh: export F_UFMTENDIAN=MODE;EXCEPTION
```

#### NOTE

The environment variable value should be enclosed in quotes if the semicolon is present.

The environment variable can also have the following syntax:

```
F_UFMTENDIAN=u[,u] . . .
```

#### Examples

1. `F_UFMTENDIAN=big`

All input/output operations perform conversion from big-endian to little-endian on READ and from little-endian to big-endian on WRITE.

2. `F_UFMTENDIAN="little;big:10,20"`

or `F_UFMTENDIAN=big:10,20`

or `F_UFMTENDIAN=10,20`

The input/output operations perform big-endian to little endian conversion only on unit numbers 10 and 20.

3. `F_UFMTENDIAN="big;little:8"`

No conversion operation occurs on unit number 8. On all other units, the input/output operations perform big-endian to little-endian conversion.

4. `F_UFMTENDIAN=10-20`

The input/output operations perform big-endian to little-endian conversion on units 10, 11, 12 , ... 19, 20.

5. Assume you set `F_UFMTENDIAN=10,100` and run the following program.

```
integer*4    cc4
integer*8    cc8
integer*4    c4
integer*8    c8
c4 = 456
c8 = 789

! prepare a little endian representation of data

open(11,file='lit.tmp',form='unformatted')
write(11) c8
write(11) c4
close(11)

! prepare a big endian representation of data

open(10,file='big.tmp',form='unformatted')
write(10) c8
write(10) c4
close(10)

! read big endian data and operate with them on
! little endian machine.

open(100,file='big.tmp',form='unformatted')
read(100) cc8
read(100) cc4

! Any operation with data, which have been read

! . . .
close(100)
stop
end
```

Now compare `lit.tmp` and `big.tmp` files with the help of the `od` utility:

```
> od -t x4 lit.tmp
0000000 00000008 00000315 00000000 00000008
0000020 00000004 000001c8 00000004
0000034
> od -t x4 big.tmp
0000000 08000000 00000000 15030000 08000000
0000020 04000000 c8010000 04000000
0000034
```

You can see that the byte order is different in these files.

## OPEN Statement CONVERT Method

Use this method to specify a non-native numeric format for each specified unit number. This method requires an explicit file [OPEN](#) statement to specify the numeric format of the file for that unit number.

This method takes precedence over the `OPTIONS` statement and the compiler option `CONVERT[:]  
keyword` method, but has a lower precedence than the environment variable methods.

For example, the following source code shows how the `OPEN` statement would be coded to read unformatted VAXD numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20 (the absence of the `CONVERT` keyword or environment variables `FORT_CONVERT20`, `FORT_CONVERT.dat`, or `FORT_CONVERT_dat` indicates native little endian data for unit 20):

```
OPEN (CONVERT='VAXD', FILE='graph3.dat', FORM='UNFORMATTED', UNIT=15)
...
OPEN (FILE='graph3_t.dat', FORM='UNFORMATTED', UNIT=20)
```

A hard-coded `OPEN` statement `CONVERT` keyword value cannot be changed after compile time. However, to allow selection of a particular format at runtime, equate the `CONVERT` keyword to a variable and provide the user with a menu that allows selection of the appropriate format (menu choice sets the variable) before the `OPEN` occurs.

You can also select a particular format at runtime for a unit number by using one of the environment variable methods ( [Environment Variable FORT\\_CONVERTn Method](#), [Environment Variable FORT\\_CONVERT.ext or FORT\\_CONVERT\\_ext Method](#), or [Environment Variable F\\_UFMTENDIAN Method](#)), which take precedence over the `OPEN` statement `CONVERT` keyword method.

### OPTIONS Statement Method

You can only specify one numeric file format for all unformatted file unit numbers using this method unless you also use one of the environment variable methods or `OPEN` statement `CONVERT` keyword method.

You specify the numeric format at compile time and must compile all routines under the same `OPTIONS` statement `CONVERT=keyword` qualifier. You could use one source program and compile it using different `ifort` commands to create multiple executable programs that each read a certain format.

The environment variable methods and the `OPEN` statement `CONVERT=keyword` method take precedence over this method. For example, you might use the `FORT_CONVERTn` environment variable or `OPEN CONVERT=keyword` method to specify each unit number that will use a format other than that specified using the `ifortoption` method.

This method takes precedence over the `ifortconvert[:]keyword` compiler option method.

You can use `OPTIONS` statements to specify the appropriate floating-point formats (in memory and in unformatted files) instead of using the corresponding `ifort` command qualifiers. For example, to use VAX F\_floating, G\_floating, and H\_floating as the unformatted file format, specify the following `OPTIONS` statement:

```
OPTIONS /CONVERT=VAXG
```

Because this method affects all unit numbers, you cannot read data in one format and write it in another format, unless you use it in combination with one of the environment variable methods or the `OPEN` statement `CONVERT` keyword method to specify a different format for a particular unit number.

For more information, see the [OPTIONS](#) statement.

### Compiler Option -convert or /convert Method

You can only specify one numeric format for all unformatted file unit numbers using the `convert` compiler option unless you also use one (or more) of the previous data format methods.

You specify the numeric format at compile time and must compile all routines under the same `convert keyword` compiler option. You can use the same source program and compile it using different `ifort` commands (or the equivalent in the IDE) to create multiple executable programs that each read a certain format.

If you specify other methods, the other methods take precedence over using this method. For instance, you might use the environment variable or OPEN statement CONVERT specifier method to specify each unit number that will use a format different than that specified using the `convert` *keyword* compiler option method for all other unit numbers.

For example, the following command compiles program `file.for` to use VAX D\_floating (and F\_floating) floating-point data for all unit numbers (unless superseded by one of the other methods). Data is converted between the file format and the little endian memory format (little endian integers, IEEE binary32, IEEE binary64, and IEEE binary128 little endian IEEE\* floating-point format). The created file, `vconvert.exe`, can then be run:

### Linux and macOS

```
ifort file.for -o vconvert.exe -convert vaxd
```

### Windows

```
ifort file.for /convert:vaxd /link /out:vconvert.exe
```

Because this method affects all unformatted file unit numbers, you cannot read data in one format and write it in another file format using only the `convert` *keyword* compiler option. You can if you use it in combination with the environment variable methods or the OPEN statement CONVERT specifier method to specify a different format for a particular unit number.

character sets  
    ANSI 1163

- multibyte (*continued*)
  - ASCII 1161
  - Fortran 2003 790
  - function scanning for characters in 1887
  - Intel Fortran 790
  - key codes 1164
    - multibyte
    - NLS routines 2664
  - single and multibyte 2664
- character storage unit 1145
- character string
  - function adjusting to the left 1248
  - function adjusting to the right 1248
  - function concatenating copies of 1871
  - function locating index of last occurrence of substring in 1878
  - function locating last nonblank character in 1714
  - function reading from keyboard 1582
  - function returning length minus trailing blanks 1707
  - function returning length of 1706
  - function scanning for characters in 1887
  - function trimming blanks from 2014
  - option affecting backslash character in 436
  - subroutine sending to screen (including blanks) 2262, 2263
  - subroutine sending to screen (special fonts) 2262
- character string edit descriptors 1065
- character string editing 1065
- character strings
  - as edit descriptors 1065
  - comparing 2050
  - function checking for all characters in 2050
  - mixed-language programming 705
- character substrings
  - making equivalent 894
- character type declarations 882
- character type functions 1552
- character values
  - transferring 1050
- character variables 811
- CHARACTER\*(\*) 1151
- characters
  - carriage-control for printing 1099
  - function returning 1364
  - function returning next available 1509, 1560
  - function returning position of 1591, 1598
  - function writing to file 1544
    - multibyte
    - NLS routines 2664
  - portability routines that read and write 1176
- charts for character and key codes 1161
- CHDIR
  - POSIX version of 2071
- check
  - floating-point stacks 613
  - stacks 613
- check compiler option 721
- Check floating-point stack state 613
- child window
  - function appending list of names to menu 2218
  - function making active 2210
  - function returning unit number of active 2191
  - function setting properties of 2215
- CHMOD
  - POSIX version of 2072
- chunk size
  - in DO directive 1452
- circles
  - circles (*continued*)
    - functions drawing 2225
  - circular shift
    - function performing 1693
- CLASS 1369
- CLASS DEFAULT
  - in SELECT TYPE construct 1896

- CO\_MAX 1375
- CO\_MIN 1376
- CO\_REDUCE 1377
- CO\_SUM 1378
- coarray cobounds
  - function returning 2029

- coarray cobounds (*continued*)
  - function returning lower 1704
- coarray cosubscripts
  - function converting to an image index 1656
- coarray images
  - function returning number of 1772
  - referencing 851
  - specifying data objects for 852
  - statements controlling 911
- coarray statements
  - LOCK 1715
  - SYNC ALL 1958
  - SYNC IMAGES 1959
  - SYNC MEMORY 1961
  - UNLOCK 1715
- coarray-spec 851
- coarrays
  - allocatable 1253
  - attribute and statement specifying 1380
  - deferred-coshape 850
  - established 850
  - explicit-coshape 851
  - function returning codimensions of 1396
  - function returning number of images 1772
  - image control statements for 911
  - image selectors 848
  - option enabling 190
  - program syntax 2503
  - using 2503
- Coarrays
  - steps to debug application 2506
- cobounds
  - function returning lower 1704
  - function returning upper 2029
- code
  - methods to optimize size of 2659
  - option generating feature-specific 145, 154
  - option generating feature-specific for Windows\* OS 142
  - option generating for specified CPU 158
  - option generating specialized 176
  - option generating specialized and optimized 172
- Code Coverage
  - in Microsoft Visual Studio\* 72
- Code Coverage dialog box 99
- code coverage tool
  - color scheme 2560
  - dynamic counters in 2560
  - exporting data 2560
  - including and excluding files 2560
  - pgopti.dpi file 2560
  - pgopti.spi file 2560
  - syntax of 2560
- code layout 2592
- code size
  - methods to optimize 2659
  - option affecting inlining 2659
  - option disabling expansion of certain functions 2659
  - option disabling expansion of functions 2659
  - option disabling loop unrolling 2659
  - option dynamically linking libraries 2659
  - option excluding data 2659
  - option for certain exception handling 2659
  - option passing arguments in registers 2659
  - option stripping symbols 2659
  - option to avoid 16-byte alignment (Linux only) 2659
  - option to avoid library references 2659
  - using IPO 2659
- CODE\_ALIGN
  - option for ATTRIBUTES directive 1300
- codecov tool
  - option producing an instrumented file for 262
  - option specifying a directory for profiling output for 260
  - option specifying a file name for summary files for 261
- codepage
  - function setting current 2185
  - function setting for current console 2184
  - subroutine retrieving current 2176
- codepage number
  - function returning for console codepage 2176
  - function returning for system codepage 2176
- codepages
  - function returning array of 2171
- CODIMENSION 1380
- codimensions of coarray
  - function returning 1396
- COLLAPSE
  - in OpenMP\* DISTRIBUTE directive 1447
  - in OpenMP\* DO directive 1452
  - in OpenMP\* TASKLOOP directive 1992
  - in SIMD OpenMP\* Fortran 1916
- collective subroutines
  - CO\_BROADCAST 1375
  - CO\_MAX 1375
  - CO\_MIN 1376
  - CO\_REDUCE 1377
  - CO\_SUM 1378
  - overview of 962
  - table of 1203
- colon
  - in array specifications 842, 885, 888, 889, 891, 892
- colon editing 1063
- color index
  - function returning current 2232
  - function returning for multiple pixels 2244
  - function returning for pixel 2242
  - function returning text 2246
  - function setting current 2283
  - function setting for multiple pixels 2295
  - function setting for pixel 2292
- color RGB value
  - function returning current 2233
  - function setting current 2283
- COM hierarchy editor 2616
- COM object interface
  - determining 2635
- COM objects
  - obtaining pointer to 2643
  - resources for understanding 2644
  - using 2634
- COM routines
  - A to Z 2145
  - COMAddObjectReference 2152
  - COMCLSIDFromProgID 2152

  - using to obtain an object pointer 2643
- COMGetActiveObjectByGUID 2155
- COMGetActiveObjectByProgID 2155
- COMGetFileObject 2156
- COMInitialize 2156
- COMIsEqualGUID 2157
- comma
  - as external field separator 1028
  - using to separate input data 1053
- command arguments
  - function returning number of 1382
- command interpreter
  - function sending system command to 1965
- command invoking a program
  - subroutine returning 1562
- command line
  - running applications from 58
  - subroutine executing 1498
  - using with Intel® Fortran 55
- COMMAND\_ARGUMENT\_COUNT 1382
- command-line arguments
  - function returning index of 1594
  - function returning number of 1594, 1763
  - subroutine returning full 1563
  - subroutine returning specified 1559
- command-line syntax
  - for make and nmake command 61
- command-line window
  - and using Window applications 58
  - setting environment 58
  - setting search paths for .mod files 2436
  - setting search paths for include files 2438
  - setting up 58
- comment indicator
  - general rules for 791
- comment lines
  - for fixed and tab source 795
  - for free source 793
- COMMITQQ 1383
- COMMON
  - interaction with EQUIVALENCE 897
- common block association 1384
- common blocks
  - allocating 2611
  - defining initial values for variables in named 1329
  - directive modifying alignment of data in 1778
  - directive modifying characteristics of 1830
  - effect in SAVE 1882
  - EQUIVALENCE interaction with 897
  - extending 897
  - option enabling dynamic allocation of 476
  - using a routine to dynamically allocate 1520
- common blocks (*continued*)
  - using derived types in 1900
  - viewing in debugger 2426
  - volatile 2051
- Compaq Visual Fortran
  - compatibility with 2670
- Compatibility with
  - Compaq Visual Fortran 2670

  - hexadecimal-significand 1046
  - scientific notation 1045
  - with exponents 1042
  - without exponents 1040
- real maximum values 630
- real model
  - function returning exponent part in 1503
  - function returning fractional part in 1544
  - function returning largest number in 1590
  - function returning number closest to unity in 1484
  - function returning smallest number in 2008
- real numbers
  - directive specifying default kind 1858
  - function resulting in single-precision type 1859
  - function returning absolute spacing of 1930
  - function returning ceiling of 1349
  - function returning class of IEEE 1543
  - function returning difference between 1442
  - function returning floor of 1516
  - function returning fractional part for model of 1905
  - function returning scale of model for 1884
  - function rounding 1262
  - function truncating 1250
- real types
  - maximum values for 630
- real values
  - transferring 1040, 1047
  - transferring in exponential form 1042
  - transferring using engineering notation 1044
  - transferring using scientific notation 1045
- real-coordinate graphics
  - function converting to double precision 1415
  - function converting to quad precision 1837
- real-time clock
  - subroutine returning data from 1964
- REAL(16)
  - constants 807
- REAL(4)
  - constants 805
- REAL(8)
  - constants 806
- REAL\*16 804
