# 1 Introduction

---

As the complexity of computer systems increases, so do the power dissipation requirements. Care must be taken to ensure that the additional power is properly dissipated. Typical methods to improve heat dissipation include selective use of ducting, and/or passive heatsinks.

The goals of this document are to:

- Outline the thermal and mechanical operating limits and specifications for the Intel® E8500 chipset North Bridge (NB) component and the Intel® E8500 chipset eXternal Memory Bridge (XMB) component.
- Describe two reference thermal solutions that meet the specification of the E8500 chipset NB component.
- Describe a reference thermal solution that meets the specification of the E8500 chipset XMB component.

Properly designed thermal solutions provide adequate cooling to maintain the E8500 chipset die temperatures at or below thermal specifications. This is accomplished by providing a low local-ambient temperature, ensuring adequate local airflow, and minimizing the die to local-ambient thermal resistance. By maintaining the E8500 chipset die temperature at or below the specified limits, a system designer can ensure the proper functionality, performance, and reliability of the chipset. Operation outside the functional limits can degrade system performance and may cause permanent changes in the operating characteristics of the component.

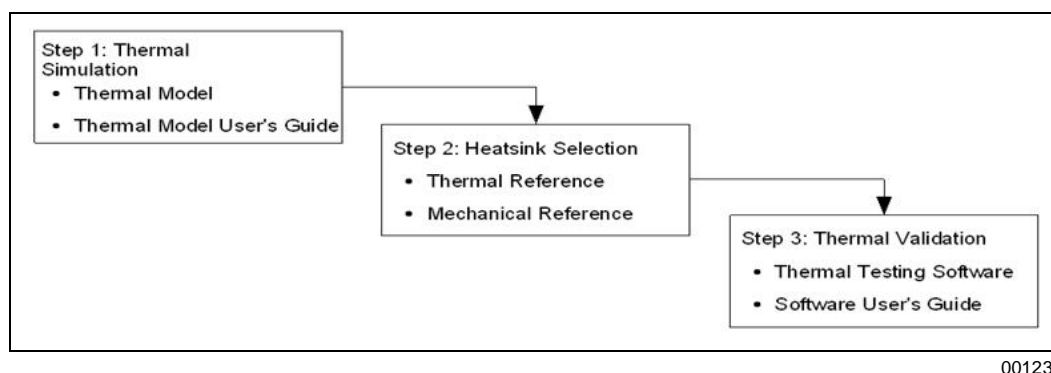

The simplest and most cost effective method to improve the inherent system cooling characteristics is through careful chassis design and placement of fans, vents, and ducts. When additional cooling is required, component thermal solutions may be implemented in conjunction with system thermal solutions. The size of the fan or heatsink can be varied to balance size and space constraints with acoustic noise.

This document addresses thermal design and specifications for the E8500 chipset NB and XMB components only. For thermal design information on other chipset components, refer to the respective component datasheet. For the Intel® 6700PXH 64-bit PCI Hub, refer to the *Intel® 6700PXH 64-bit PCI Hub Thermal Design Guidelines*. For the ICH5, refer to the *Intel® 82801EB I/O Controller Hub 5 (ICH5) and Intel® 82801ER I/O Controller Hub 5 R (ICH5R) Thermal Design Guide*.

## 2 Packaging Technology

The E8500 chipsets consist of four individual components: the NB, the XMB, the Intel® 6700PXH 64-bit PCI Hub and the I/O controller hub (ICH5r). The E8500 chipset NB component use a 42.5 mm squared, 12-layer flip chip ball grid array (FC-BGA) package (see Figure 2-1 through Figure 2-3). The E8500 chipset XMB component uses a 37.5mm squared, 10-layer FB-BGA package (see Figure 2-4 through Figure 2-6). For information on the Intel 6700PXH 64-bit PCI Hub package, refer to the *Intel® 6700PXH 64-bit PCI Hub Thermal/Mechanical Design Guide*. For information on the ICH5 package, refer to the *Intel® 82801EB I/O Controller Hub 5 (ICH5) and Intel® 82801ER I/O Controller Hub 5 R (ICH5R) Thermal Design Guide*.

## 2.1 Package Mechanical Requirements

The E8500 chipset NB package has an IHS and the XMB package has an exposed bare die which is capable of sustaining a maximum static normal load of 15-lbf. The package is NOT capable of sustaining a dynamic or static compressive load applied to any edge of the bare die. These mechanical load limits must not be exceeded during heatsink installation, mechanical stress testing, standard shipping conditions and/or any other use condition.

Notes:

1. The heatsink attach solutions must not include continuous stress onto the chipset package with the exception of a uniform load to maintain the heatsink-to-package thermal interface.
2. These specifications apply to uniform compressive loading in a direction perpendicular to the bare die/IHS top surface.
3. These specifications are based on limited testing for design characterization. Loading limits are for the package only

§

## 3 Thermal Specifications

### 3.1 Thermal Design Power (TDP)

Analysis indicates that real applications are unlikely to cause the E8500 chipset NB/XMB components to consume maximum power dissipation for sustained time periods. Therefore, in order to arrive at a more realistic power level for thermal design purposes, Intel characterizes power consumption based on known platform benchmark applications. The resulting power consumption is referred to as the Thermal Design Power (TDP). TDP is the target power level that the thermal solutions should be designed to. TDP is not the maximum power that the chipset can dissipate.

For TDP specifications, see [Table 3-1](#) for the E8500 chipset NB component and [Table 3-2](#) for the E8500 chipset XMB component. FC-BGA packages have poor heat transfer capability into the board and have minimal thermal capability without a thermal solution. Intel recommends that system designers plan for one or more heatsinks when using the E8500 chipsets NB/XMB components.

### 3.2 Die Case Temperature Specifications

To ensure proper operation and reliability of the E8500 chipset NB/XMB components, the die temperatures must be at or between the maximum/minimum operating temperature ranges as specified in [Table 3-1](#) and [Table 3-2](#). System and/or component level thermal solutions are required to maintain these temperature specifications. Refer to [Section 5](#) for guidelines on accurately measuring package die temperatures.

## 4 *Thermal Simulation*

---

Intel provides thermal simulation models of the E8500 chipset NB/XMB components and associated user's guides to aid system designers in simulating, analyzing, and optimizing their thermal solutions in an integrated, system-level environment. The models are for use with the commercially available Computational Fluid Dynamics (CFD)-based thermal analysis tool FLOTHERM\* (version 3.1 or higher) by Flomerics, Inc. These models are also available in ICEPAK\* format. Contact your Intel field sales representative to order the thermal models and user's guides.

§

## 5 Thermal Metrology

---

The system designer must make temperature measurements to accurately determine the thermal performance of the system. Intel has established guidelines for proper techniques to measure the NB/XMB die temperatures. [Section 5.1](#) provides guidelines on how to accurately measure the NB/XMB die temperatures. [Section 5.2](#) contains information on running an application program that will emulate anticipated maximum thermal design power. The flowchart in [Figure 5-1](#) offers useful guidelines for thermal performance and evaluation.

### 5.1 Die Case Temperature Measurements

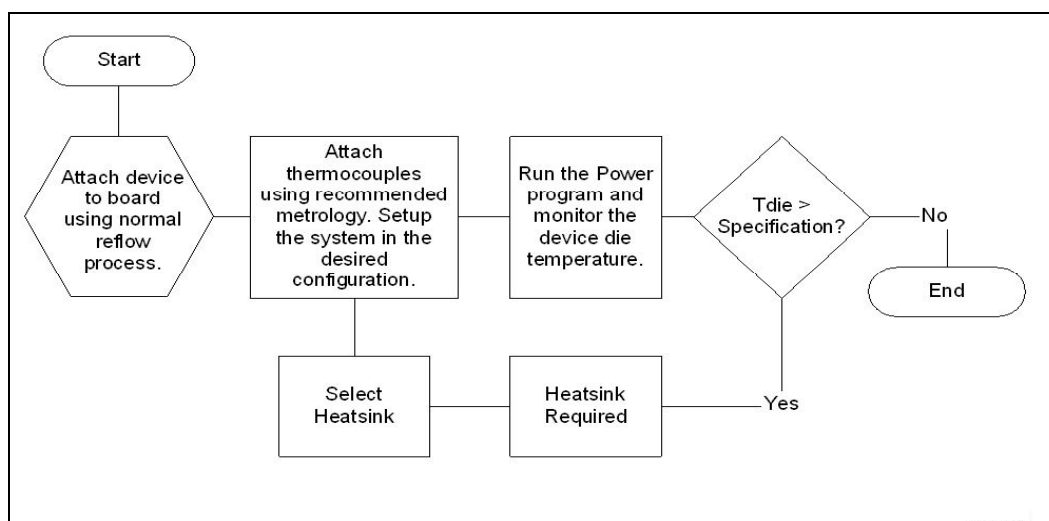

To ensure functionality and reliability, the  $T_{case}$  of the NB/XMB must be maintained at or between the maximum/minimum operating range of the temperature specification as noted in [Table 3-1](#) and [Table 3-2](#). The surface temperature at the geometric center of the die corresponds to  $T_{case}$ . Measuring  $T_{case}$  requires special care to ensure an accurate temperature measurement.

Temperature differences between the temperature of a surface and the surrounding local ambient air can introduce errors in the measurements. The measurement errors could be due to a poor thermal contact between the thermocouple junction and the surface of the package, heat loss by radiation and/or convection, conduction through thermocouple leads, and/or contact between the thermocouple cement and the heatsink base (if a heatsink is used). For maximize measurement accuracy, only the 0° thermocouple attach approach is recommended.

#### Zero Degree Angle Attach Methodology

1. Mill a 3.3 mm (0.13 in.) diameter and 1.5 mm (0.06 in.) deep hole centered on the bottom of the heatsink base.
2. Mill a 1.3 mm (0.05 in.) wide and 0.5 mm (0.02 in.) deep slot from the centered hole to one edge of the heatsink. The slot should be parallel to the heatsink fins (see [Figure 5-2](#)).
3. Attach thermal interface material (TIM) to the bottom of the heatsink base.
4. Cut out portions of the TIM to make room for the thermocouple wire and bead. The cutouts should match the slot and hole milled into the heatsink base.
5. Attach a 36 gauge or smaller calibrated K-type thermocouple bead or junction to the center of the top surface of the die using a high thermal conductivity cement. During this step, ensure no contact is present between the thermocouple cement and the heatsink base because any contact will affect the thermocouple reading. **It is critical that the thermocouple bead makes contact with the die** (see [Figure 5-3](#)).
6. Attach heatsink assembly to the NB/XMB and route thermocouple wires out through the milled slot.

## 5.2 Power Simulation Software

The power simulation software is a utility designed to dissipate the thermal design power on an E8500 chipset NB component or XMB component when used in conjunction with the 64-bit Intel® Xeon™ processor MP. The combination of the above mentioned processor and the higher bandwidth capability of the E8500 chipsets enable higher levels of system performance. To assess the thermal performance of the chipset thermal solution under “worst-case realistic application” conditions, Intel is developing a software utility that operates the chipset at near worst-case thermal power dissipation.

The power simulation software being developed should only be used to test thermal solutions at or near the thermal design power. [Figure 5-1](#) shows a decision flowchart for determining thermal solution needs. Real world applications may exceed the thermal design power limit for transient time periods. For power supply current requirements under these transient conditions, please refer to each component's datasheet for the ICC (Max Power Supply Current) specification. Contact your Intel field sales representative to order the power utility software and user's guide.

## 6 NB Reference Thermal Solution #1

---

Intel has developed two different reference thermal solutions designed to meet the cooling needs of the E8500 chipset NB component under operating environments and specifications defined in this document. This chapter describes the overall requirements for the 1<sup>st</sup> NB reference thermal solution including critical-to-function dimensions, operating environment, and validation criteria. Other chipset components may or may not need attached thermal solutions, depending on your specific system local-ambient operating conditions. For information on the Intel® 6700PXH 64-bit PCI Hub, refer to thermal specification in the *Intel® 6700PXH 64-bit PCI Hub Thermal/Mechanical Design Guide*. For information on the ICH5, refer to thermal specification in the *Intel® 82801EB I/O Controller Hub 5 (ICH5) and Intel® 82801ER I/O Controller Hub 5 R (ICH5R) Thermal Design Guide*.

### 6.1 Operating Environment

The reference thermal solution was designed assuming a maximum local-ambient temperature of 52°C. The minimum recommended airflow velocity through the cross section of the heatsink fins is 400 linear feet per minute (lfm). The approaching airflow temperature is assumed to be equal to the local-ambient temperature. The thermal designer must carefully select the location to measure airflow to obtain an accurate estimate. These local-ambient conditions are based on a 35°C external-ambient temperature at sea level. (External-ambient refers to the environment external to the system.)

The fasteners associated for this reference thermal solution is intended to be used on 0.062" thickness motherboard

### 6.2 Heatsink Performance

Figure 6-1 depicts the measured thermal performance of the 1<sup>st</sup> NB reference thermal solution versus approach air velocity. Since this data was measured at sea level, a correction factor would be required to estimate thermal performance at other altitudes.

**Figure 6-1. First NB Reference Heatsink Measured Thermal Performance vs. Approach Velocity**

## 6.3 Mechanical Design Envelope

While each design may have unique mechanical volume and height restrictions or implementation requirements, the height, width, and depth constraints typically placed on the E8500 chipset NB thermal solution are shown in [Figure 6-2](#).

When using heatsinks that extend beyond the NB reference heatsink envelope shown in [Figure 6-2](#), any motherboard components placed between the heatsink and motherboard cannot exceed 4.14 mm (0.16 in.) in height.

Figure 6-2. First NB Reference Heatsink Volumetric Envelope

## 6.4 Board-Level Components Keepout Dimensions

The location of hole pattern and keepout zones for the reference thermal solution are shown in Figure 6-3.

## 6.5 First NB Heatsink Thermal Solution Assembly

The reference thermal solution for the chipset NB component is a passive extruded heatsink with thermal interface. It is attached to the board by using four retaining Tuflok® fasteners. Figure 6-4 shows the reference thermal solution assembly and associated components.

Full mechanical drawings of the thermal solution assembly and the heatsink are provided in Appendix B. Appendix A contains vendor information for each thermal solution component.

**Figure 6-3. First NB Heatsink Board Component Keepout**

**NOTE:** All dimensions are in millimeters.

### 6.5.1 Heatsink Orientation

Since this solution is based on a unidirectional heatsink, mean airflow direction must be aligned with the direction of the heatsink fins.

Figure 6-4. First NB Heatsink Assembly

### 6.5.2 Extruded Heatsink Profiles

The reference NB thermal solution uses an extruded heatsink for cooling the chipset NB. [Figure 6-5](#) shows the heatsink profile. [Appendix A](#) lists a supplier for this extruded heatsink. Other heatsinks with similar dimensions and increased thermal performance may be available. Full mechanical drawing of this heatsink is provided in [Appendix B](#).

### 6.5.3 Mechanical Interface Material

There is no mechanical interface material associated with this reference solution.

### 6.5.4 Thermal Interface Material

A TIM provides improved conductivity between the die and heatsink. The reference thermal solution uses Chomerics THERMFLOW\* T710, 0.127 mm (0.005 in.) thick, 38.5 mm x 38.5 mm (1.5 in. x 1.5 in.) square.

Note: Unflowed or “dry” Chomerics THERMFLOW T710 has a material thickness of 0.005 inch. The flowed or “wet” Chomerics THERMFLOW T710 has a material thickness of ~0.0025 inch after it reaches its phase change temperature.

#### 6.5.4.1 Effect of Pressure on TIM Performance

As mechanical pressure increases on the TIM, the thermal resistance of the TIM decreases. This phenomenon is due to the decrease of the bond line thickness (BLT). BLT is the final settled thickness of the thermal interface material after installation of heatsink. The effect of pressure on

the thermal resistance of the Chomerics THERMFLOW T710 TIM is shown in [Table 6-1](#). The heatsink clip provides enough pressure for the TIM to achieve a thermal conductivity of  $0.17^{\circ}\text{C}/\text{inch}^2/\text{W}$ .

**Table 6-1. Chomerics THERMFLOW\* T710 TIM Performance as a Function of Attach Pressure**

| Pressure (psi) | Thermal Resistance ( $^{\circ}\text{C} \times \text{in}^2/\text{W}$ ) |
|----------------|---|
| 5              | 0.37  |
| 10             | 0.30  |
| 20             | 0.21  |
| 30             | 0.17  |

**NOTE:**

1. All measured at  $50^{\circ}\text{C}$ .

## 6.5.5 Heatsink Retaining Fastener

The reference solution uses four heatsink retaining Tufloks. The fasteners attach the heatsink to the motherboard by expanding its Tuflok prong to snap into each of the four heatsink mounting holes. These fasteners are intended to be used on a  $0.062''$  thickness motherboard with either of the two NB reference thermal solutions. See [Appendix B](#) for a mechanical drawing of the fastener.

**Figure 6-5. First NB Heatsink Extrusion Profile**

## 6.6 Reliability Guidelines

Each motherboard, heatsink and attach combination may vary the mechanical loading of the component. Based on the end user environment, the user should define the appropriate reliability test criteria and carefully evaluate the completed assembly prior to use in high volume. Some general recommendations are shown in [Table 6-2](#).

**Table 6-2. Reliability Guidelines**

| Test (1)         | Requirement   | Pass/Fail Criteria (2)                      |
|------------------|---|---|
| Mechanical Shock | 50 g, board level, 11 msec, 3 shocks/axis                             | Visual Check and Electrical Functional Test |
| Random Vibration | 7.3 g, board level, 45 min/axis, 50 Hz to 2000 Hz                     | Visual Check and Electrical Functional Test |
| Temperature Life | 85°C, 2000 hours total, checkpoints at 168, 500, 1000, and 2000 hours | Visual Check                                |
| Thermal Cycling  | –5°C to +70°C, 500 cycles   | Visual Check                                |
| Humidity         | 85% relative humidity, 55°C, 1000 hours                               | Visual Check                                |

**NOTES:**

1. It is recommended that the above tests be performed on a sample size of at least twelve assemblies from three lots of material.
2. Additional pass/fail criteria may be added at the discretion of the user.
