1. How to Use this Handbook

The External Memory Interface Handbook contains information that you require to implement an external memory interface. The handbook focuses on the Altera® solution for DDR, DDR2, DDR3 SDRAM; QDR II and QDR II+ SRAM; and RLDRAM II interfaces. The handbook is organized with a typical design flow in mind, into the following six volumes:

- “Introduction to Altera External Memory Interfaces”
- “Device, Pin, and Board Layout Guidelines”
- “Implementing Altera Memory Interface IPs”
- “Simulation, Timing Analysis, and Debugging”
- “Implementing a Custom PHY”
- “Design Flow Tutorials”

Introduction to Altera External Memory Interfaces

This volume includes this How to Use this Handbook chapter, recommended design flow, and a glossary. In addition, this volume includes basic information for various memory standards. The Specifications section lists a complete scorecard of Altera device family support for various memory standards.

Device, Pin, and Board Layout Guidelines

This volume describes the initial steps of selecting the correct Altera device with the right resources and number of user I/O available for that interface. The second section of the volume describes how you can select the correct termination and drive strength based on your board simulation for DDR, DDR2, and DDR3 SDRAM interfaces. It offers board results correlated with board simulation and the Altera recommended settings based on this correlation.

Implementing Altera Memory Interface IPs

This volume covers the following Altera memory IP products:

- DDR and DDR2 SDRAM High Performance Controllers
- DDR and DDR2 SDRAM High Performance Controllers II
- DDR3 SDRAM High Performance Controllers
- QDR II and QDR II+ SRAM Controllers with UniPHY
- RLDRAM II Controllers with UniPHY
Each IP has two modules: the PHY and the memory controller. The DDR, DDR2, and DDR3 SDRAM high-performance controllers use the Altera ALTMEMPHY megafunction for the PHY, which you can use standalone from the controller. The QDR II, QDR II+, and RLDRAM II IP use the Altera UniPHY PHY.

The functional description of each of these modules is described separately so you do not need to read the memory controller functional description if you are creating your own custom memory controller.

The volume also contains information on how to implement the IP, including a description of the parameterization GUI, the required constraints, and latency information. The last chapter of this volume includes timing diagrams showing the memory operations that may help you debug your system or help you create a custom memory controller.

### Simulation, Timing Analysis, and Debugging

When you have implemented your external memory interface, you can use this volume for information on how to perform functional simulation, how to analyze timing, and how to debug your design.

### Implementing a Custom PHY

This volume describes the steps to create a custom PHY and offers examples on some custom PHYs that are already available for some interfaces.

### Design Flow Tutorials

This volume offers step-by-step tutorials in creating a memory interface for specific Altera development boards for debugging and testing. In addition, this volume also discusses special information such as how to implement external memory interfaces using SOPC builder or how to implement multiple memory interfaces. The design flow tutorials follow the flow in “Recommended Design Flow” on page 2–1.
This chapter describes the Altera-recommended design flow for successfully implementing external memory interfaces in Altera devices. Altera recommends that you create an example top-level file with the desired pin outs and all interface IP instantiated, which enables the Quartus® II software to validate your design and resource allocation before PCB and schematic sign off. Use the “Design Checklist” on page 2–6, to verify whether you have performed all the recommended steps in creating a working and robust external memory interface.

Figure 2–1 shows the design flow to provide the fastest out-of-the-box experience with external memory interfaces in Altera devices. This topic directs you where to find information on how to perform each step of the recommended design flow. The flow assumes that you are using Altera IP to implement the external memory interface.

For design examples that follow the recommended design flow in this chapter, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.

Does the Design Have Positive Margin?

No → Adjust Constraints

Yes → Optional
Select a Device

For more information on selecting a device, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.

Determine Board Layout

Altera recommends prelayout SI simulations (line simulations) should take place before board layout and that you use these parameters and rules during the initial design development cycle. Advanced I/O timing and board trace models now directly impact device timing closure.

In addition, the termination scheme that you use, the drive strength setting on the FPGA, and the loading seen by the driver can directly affect the signal integrity. You must understand the tradeoffs between the different types of termination schemes and the effects of output drive strengths and loading, to choose the best possible settings for your designs.

For more information, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook.

Perform Board-Level Simulations

To determine the correct board constraints, perform board-level simulations to see if the settings provide the optimal signal quality. With many variables that can affect the signal integrity of the memory interface, simulating the memory interface provides an initial indication of how well the memory interface performs. There are various EDA simulation tools available to perform board-level simulations. The simulations should be performed on the data, data strobe, control, command, and address signals. If the memory interface does not have good signal integrity, adjust the settings, such as drive strength setting, termination scheme or termination values to improve the signal integrity (realize that changing these settings affects the timing and it may be necessary to go back to the timing closure if these change).

For detailed information about understanding the different effects on signal integrity design, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook.

Enter topology information from your board-level simulations into the Quartus II board trace model information. The typical information required includes, but is not limited to, the following values:

- Near and far trace lengths
- Near and far trace distributed inductance
- Near and far trace distributed capacitance
- Near end deration capacitor values (if fitted)
- Far end capacitive (IC) load
- Far end termination values
Device-Side Termination

Many Altera devices support both series and parallel OCT resistors to improve signal integrity. OCT eliminates the need for external termination resistors on the FPGA side, which simplifies board design and reduces overall board cost. You can dynamically switch between the series and parallel OCT resistor depending on whether the FPGA devices are performing a write or a read operation. The OCT features offer user-mode calibration to compensate for any variation in VT during normal operation to ensure that the OCT values remain constant. The parallel and series OCT features are available in either 25 or 50 Ω settings.

Memory-Side Termination

The DDR2, DDR3 SDRAM, and QDR II SRAM have a dynamic parallel ODT feature that you can turn on when the FPGA is writing to the memory and turn off when the FPGA is reading from the memory. To further improve signal integrity, DDR2 SDRAM supports output drive strength control so that the driver can better match the transmission line. DDR3 SDRAM devices additionally support calibrated output impedances.

Adjust Termination and Drive Strength

Although the recommended terminations are based on the simulations and experimental results, you must perform simulations, either using I/O buffer information specification (IBIS) or HSPICE models, to determine the quality of signal integrity on your designs.

Any changes made to the board should also be made in the board trace model in the Quartus II software.

For information on Altera-recommended terminations for memory interfaces, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook.

Instantiate PHY and Controller

After selecting the appropriate device and memory type, create a project in the Quartus II software that targets the device and memory type.

When implementing external memory interfaces, Altera recommends that you use Altera memory interface IP, which includes a PHY that you can use with the Altera high-performance controller or with your own custom controller.

Instantiating the PHY and controller includes the following steps:

- Specify parameters
- Perform functional simulation
- Add constraints and compile design
Verify Timing

For more information about verifying timing, refer to the *Timing Analysis* section in volume 4 of the *External Memory Interface Handbook.*

Adjust Constraints

In the timing report of the design, you can see the worst case setup and hold margin for the different paths in the design. If the setup and hold margin are unbalanced, achieve a balanced setup and hold margin by adjusting the phase setting of the clocks associated with these paths.

For example, for the address and command margin, the address and command outputs are clocked by an address and command clock that can be different with respect to the system clock, which is $-30^\circ$. The system clock controls the clock outputs going to the memory. If the report timing script indicates that using the default phase setting for the address and command clock results in more hold time than setup time, adjust the address and command clock to be less negative than the default phase setting with respect to the system clock, so that there is less hold margin. Similarly, adjust the address and command clock to be more negative than the default phase setting with respect to the system clock if there is more setup margin.

For more information on adjusting constraints, refer to the *Timing Analysis* section in volume 4 of the *External Memory Interface Handbook.*

Perform Timing Simulation

This step is optional, but recommended to ensure that the IP is working properly. This step only applies to UniPHY-based interfaces (on Arria® II GX and Stratix® IV devices only), as ALTMEMPHY-based interfaces do not support timing simulation.

For more information about simulating, refer to the *Simulation* section in volume 4 of the *External Memory Interface Handbook.*

Verify Design Functionality

Perform system level verification to correlate the system against your design targets, using the Altera SignalTap® II logic analyzer.

For more information about using the SignalTap II analyzer, refer to the *Debugging* section in volume 4 of the *External Memory Interface Handbook.*
Design Checklist

This topic contains a design checklist that you can use when implementing external memory interfaces in Altera devices.

Done

Select Device

1. ☐ Select the memory interface frequency of operation and bus width.
   For information about selecting memory, refer to the Memory Standard Overview section in volume 1 of the External Memory Interface Handbook.

2. ☐ Select the FPGA device density and package combination that you want to target.
   For information about selecting an Altera device, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.

3. ☐ Ensure that the target FPGA device supports the desired clock rate and memory bus width. Also the FPGA must have sufficient I/O pins for the DQ/DQS read and write groups.
   For detailed device resource information, refer to the relevant device handbook chapter on external memory interface support.
   For information about supported clock rates for external memory interfaces, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

Determine Board Layout

4. ☐ Select the termination scheme and drive strength settings for all the memory interface signals on the memory side and the FPGA side.

5. ☐ Ensure you apply appropriate termination and drive strength settings on all the memory interface signals, and verify using board level simulations.

6. ☐ Use board level simulations to pick the optimal setting for best signal integrity. On the memory side, Altera recommends the use of external parallel termination on input signals to the memory (write data, address, command, and clock signals).
   For information, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook.

Perform Board Level Simulations

7. ☐ Perform board level simulations, to ensure electrical and timing margins for your memory interface

8. ☐ Ensure you have a sufficient eye opening using simulations. Use the latest FPGA and memory IBIS models, board trace characteristics, drive strength, and termination settings in your simulation.
   Any timing uncertainties at the board level that you calculate using simulations must be used to adjust the input timing constraints to ensure the accuracy of Quartus II timing margin reports. For example crosstalk, ISI, and slew rate deration.
   For information, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook.

Instantiate PHY and Controller
Parameterize and instantiate the Altera external memory IP for your target memory interface.

You have the following three choices in implementing a memory interface in the Quartus II software:

- Using the Altera memory controller and PHY.
  - For information about how to implement a specific memory interface, refer to Volume 3: Implementing Altera Memory Interface IP of the External Memory Interface Handbook.
  - The Parameter Settings chapter of each section describes the IP supported features page by page.

- Using the Altera PHY with your own custom controller.
  - For information about how to implement a specific memory interface, refer to Volume 3: Implementing Altera Memory Interface IP of the External Memory Interface Handbook.
  - The Parameter Settings chapter of each section describes the IP supported features page by page. The Functional Description chapter describes the workings of the PHY and how you can connect a custom controller to the PHY.

- Implement a custom PHY and custom controller.
  For information about creating custom IP, refer to Volume 5: Implementing Custom Memory Interface PHY of the External Memory Interface Handbook.

Ensure that you perform the following actions:

- Pick the correct memory interface data rates, width, and configurations.
- For DDR, DDR2, and DDR3 SDRAM interfaces, ensure that you derate the tIS, tIH, tDS, and tDH parameters, as necessary.
- Include the board skew parameter for your board.

Connect the PHY’s local signals to your driver logic and the PHY’s memory interface signals to top-level pins.

Ensure that the local interface signals of the PHY are appropriately connected to your own logic. If the ALTMEMPHY megafunction is compiled without these local interface connections, you may encounter compilation problems, when the number of signals exceeds the pins available on your target device.

For more information about the example top-level file, refer to the Functional Description chapter for the relevant memory controller.

You may also use the example top-level file as an example on how to connect your own custom controller to the Altera memory PHY.

**Perform Functional Simulation**

Simulate your design using the RTL functional model.

Use the IP functional simulation model with your own driver logic, testbench, and a memory model, to ensure correct read and write transactions to the memory.

You may need to prepare the memory functional model by setting the speed grade and device bus mode.

For more information about simulation, refer to the Simulation section in Volume 4 of the External Memory Interface Handbook.
Done

13. Add timing constraints. The wizard-generated .sdc file adds timing constraints to the interface. However, you may need to adjust these settings to best fit your memory interface configuration.

14. Add pin settings and DQ group assignments. The wizard-generated .tcl file includes I/O standard and pin loading constraints to your design.

15. Ensure that generic pin names used in the constraint scripts are modified to match your top-level pin names. The loading on memory interface pins is dependent on your board topology (memory components).

16. Add pin location assignments. However, you need to assign the pin location assignments manually using the Pin Planner.

17. Ensure that the example top-level file or your top-level logic is set as top-level entity.

18. Adjust optimization techniques, to ensure the remaining unconstrained paths are routed with the highest speed and efficiency:
   a. On the Assignments menu click Settings.
   b. Select Analysis & Synthesis Settings.
   c. Select Speed under Optimization Technique.
   d. Expand Fitter Settings.
   e. Turn on Optimize Hold Timing and select All Paths.
   f. Turn on Optimize Fast Corner Timing.
   g. Select Standard Fit under Fitter Effort.

19. Provide board trace delay model. For accurate I/O timing analysis, you specify the board trace and loading information in the Quartus II software. This information should be derived and refined during your board development process of prelayout (line) simulation and finally post-layout (board) simulation. Provide the board trace information for the output and bidirectional pins through the board trace model in the Quartus II software.

   For more information, refer to the Add Constraints chapter for the relevant memory standard in volume 3 of the External Memory Interface Handbook or refer to Volume 6: Design Flow Tutorials.

Compile Design and Verify Timing

20. Compile your design and verify timing closure using all available models.

21. Run the wizard-generated <variation_name>_report_timing.tcl file, to generate a custom timing report for each of your IP instances. Run this process across all device timing models (slow 0°C, slow 85°C, fast 0°C).

22. If there are timing violations, adjust your constraints to optimize timing

23. As required, adjust PLL clock phase shift settings or appropriate timing and location assignments margins for the various timing paths within the IP.

   For information, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.

Perform Timing Simulation
Done

24. ☐ Perform gate-level or timing simulation to ensure that all the memory transactions meet the timing specifications with the vendor’s memory model. Timing simulation is only supported with UniPHY-based memory interfaces.
   For more information about simulation, refer to the Simulation section in volume 4 of the External Memory Interface Handbook.

Verify Design Functionality

25. ☐ Verify the functionality of your memory interface in the system
   For more information, refer to Volume 6: Design Flow Tutorials in the External Memory Interface Handbook.
3. Glossary

This chapter lists the definitions of the terms that the Altera external memory interfaces solutions use.

Table 3–1 shows a glossary of terms.

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>×36 emulation</td>
<td>A QDR II or QDR II+ SRAM implementation to support ×36 QDR II and QDR II+ SRAM devices with Stratix III or Stratix IV devices that do not support ×36 DQS groups. Two ×18 DQS groups are combined to emulate the ×36 group. The CQ and CQn signals have to be split on the board to go to the DQS and CQn pins of the two ×18 DQS groups.</td>
</tr>
<tr>
<td>Advanced I/O timing</td>
<td>Advanced I/O timing allows the TimeQuest timing analyzer to produce enhanced timing reports based on the board layout information included in the design. Use advanced I/O timing with the board trace model.</td>
</tr>
<tr>
<td>Altera PHY interface (AFI)</td>
<td>The bus that connects calibrated PHYs with the Altera memory controller IP.</td>
</tr>
<tr>
<td>ALTMEMPHY megafuction</td>
<td>The Altera PHY IP that the high-performance controllers use. The latest generation PHY is the UniPHY IP.</td>
</tr>
<tr>
<td>Board trace model</td>
<td>The board trace model in the Quartus II software includes the board termination, trace length, and impedance in the project so that TimeQuest can produce enhanced timing reports with the included board information. You must have the advance I/O timing enabled when using the board trace model.</td>
</tr>
<tr>
<td>Calibration</td>
<td>The process of setting up the initial relationship between clocks. For example, the resynchronization window to provide the greatest timing margin in DDR, DDR2, and DDR3 SDRAM interfaces in Altera devices. The initial calibration is done only once at system reset after device initialization is complete.</td>
</tr>
<tr>
<td>Cascaded PLLs</td>
<td>A scheme whereby the clock for the PLL in the memory interface IP comes from another PLL. For more information about cascaded PLLs, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.</td>
</tr>
<tr>
<td>Cascaded</td>
<td>A signal topology, in which a signal is routed from one component to the next in series, but is buffered by each component.</td>
</tr>
<tr>
<td>Column address strobe (CAS)</td>
<td>A signal sent from a memory controller to a DRAM circuit to indicate the column address lines are valid.</td>
</tr>
<tr>
<td>Complementary clocks</td>
<td>A clocking scheme where only the rising edges of a clock and its inverted clock clock double data rate data into a device, for example on QDR II and QDR II+ SRAM interfaces.</td>
</tr>
<tr>
<td>Daisy-chain</td>
<td>A routing topology in which a single trace is routed from one component to the next, and so on, in series to the last component.</td>
</tr>
<tr>
<td>DDR</td>
<td>Double data-rate transfer, where data is latched and sent at both rising and falling edges of the (accompanying) clock. Operates at the full-rate clock frequency (twice the width of SDR data).</td>
</tr>
<tr>
<td>DDR3 SDRAM with leveling</td>
<td>A standard DDR3 SDRAM topology that requires the use of the ALTMEMPHY megafuction with read and write leveling. DDR3 SDRAM with levelling applies to any DDR3 DIMM interfaces.</td>
</tr>
<tr>
<td>DDR3 SDRAM without leveling</td>
<td>A non standard topology with synchronous DDR2-like balanced address, command, and clock layout.</td>
</tr>
</tbody>
</table>
### Table 3–1. Glossary of Terms (Part 2 of 3)

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deskew</td>
<td>Aligning the data signals with respect to the clock signal to compensate for the skew between the data and clock signals, by using the delay chains in the IOEs.</td>
</tr>
<tr>
<td>Fly-by topology</td>
<td>When the termination is placed after the component at the end of the line.</td>
</tr>
<tr>
<td>Full-rate clock</td>
<td>Clock with a frequency that is equal to the frequency of the memory interface clock.</td>
</tr>
<tr>
<td>Full-rate controller</td>
<td>A memory controller implemented as a full-rate design.</td>
</tr>
<tr>
<td>Full-rate design</td>
<td>A variation of the memory interfaces where the clock frequency of the controller and user-interface logic is the same as the memory interface clock (refer to Figure 3–1).</td>
</tr>
<tr>
<td>Half data rate (HDR)</td>
<td>Data that changes on one edge of the half-rate clock (twice the width of DDR data and four times the width of SDR data).</td>
</tr>
<tr>
<td>Half-rate clock</td>
<td>Clock with a frequency that is half the frequency of the memory interface clock.</td>
</tr>
<tr>
<td>Half-rate controller</td>
<td>A memory controller implemented as a half-rate design.</td>
</tr>
<tr>
<td>Half-rate design</td>
<td>A variation of the memory interface where the clock frequency of the controller and user-interface logic is half of the memory interface clock frequency (refer to Figure 3–1).</td>
</tr>
<tr>
<td>High-performance controller</td>
<td>Altera memory controller that uses the ALTMEMPHY megafun for the datapath. Altera offers the high-performance controller for DDR, DDR2, and DDR3 SDRAM interfaces.</td>
</tr>
<tr>
<td>High-performance controller II</td>
<td>Latest version of the Altera memory controller for DDR, DDR2, and DDR3 interfaces. Several new features, including command look-ahead, which improves interface efficiency.</td>
</tr>
<tr>
<td>Hybrid</td>
<td>Obsolete term for wraparound I/Os.</td>
</tr>
<tr>
<td>Legacy controller</td>
<td>The legacy integrated static datapath and controller MegaCore® functions with no support for calibration and tracking. For more information about legacy integrated static datapath and controller MegaCore functions, refer to the DDR and DDR2 SDRAM Controller Compiler User Guide, QDR II SRAM Controller MegaCore Function User Guide, and RLDRAM II Controller MegaCore Function User Guide.</td>
</tr>
<tr>
<td>Memory pessimism removal (MPR)</td>
<td>Memory chip calibration—when the PHY calibrates some portion of the JEDEC variation.</td>
</tr>
<tr>
<td>Multiple chip select and multiple rank</td>
<td>Multiple chip select is the general term, whereas multiple rank is reserved for DIMMs. A rank refers to a group of DRAM components. Each rank has an individual CS signal. When there are $N$ such ranks in a system, it is referred to as multiple rank.</td>
</tr>
<tr>
<td>Non-AFI</td>
<td>The legacy interface standard between the controller and PHY. Not recommended for new designs.</td>
</tr>
<tr>
<td>On-chip termination (OCT)</td>
<td>An FPGA device feature that eliminates the need for external resistors for termination. The ALTMEMPHY megafun supports dynamic OCT for DDR2 and DDR3 SDRAM variations for Altera devices and static OCT for QDR II and QDR II+ SRAM and RLDRAM II variations.</td>
</tr>
<tr>
<td>On-die termination (ODT)</td>
<td>A memory vendor device feature equivalent to Altera’s OCT.</td>
</tr>
<tr>
<td>Planar</td>
<td>Topology of some DIMM raw cards.</td>
</tr>
<tr>
<td>Quad data rate (QDR)</td>
<td>Two data writes and two data reads per memory clock cycle.</td>
</tr>
<tr>
<td>RLDRAM II</td>
<td>A DDR memory standard that has reduced latency and simpler bank management compared to the DDR, DDR2, or DDR3 SDRAM memory standard.</td>
</tr>
<tr>
<td>RLDRAM II CIO</td>
<td>A variant of the RLDRAM II devices that uses common I/O pins for read and write data pins.</td>
</tr>
<tr>
<td>RLDRAM II SIO</td>
<td>A variant of the RLDRAM II devices that uses separate I/O pins for read and write data pins.</td>
</tr>
<tr>
<td>Row address strobe (RAS)</td>
<td>A signal sent from a memory controller to a DRAM circuit to indicate the row address lines are valid.</td>
</tr>
<tr>
<td>$R_{UP}$ and $R_{ON}$ pins</td>
<td>Reference pins for the OCT block.</td>
</tr>
<tr>
<td>Sequencer</td>
<td>The logic block that performs calibration and tracking operations.</td>
</tr>
</tbody>
</table>

This chapter details some of the high-speed memory selection criteria and describes some typical applications where these memories are used. It looks at the main types of high-speed memories available, memory selection based on strengths and weaknesses, and which Altera® FPGAs these devices can interface with. It concludes with some typical application examples.

This chapter highlights the memory component's capability. The Altera IP may or may not support all of the features supported by the memory.

For the maximum supported performance supported by Altera FPGAs, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

System architects must resolve a number of complex issues in high-performance system applications that range from architecture, algorithms, and features of the available components. Typically, one of the fundamental problems in these applications is memories, as the bottlenecks and challenges of system performance often reside in its memory architecture. As higher speeds become necessary for external memories, signal integrity gets more difficult. Newer devices have added several features to overcome this issue. Altera FPGAs also support these advancements with dedicated I/O circuitry, various I/O standard support, and specialized intellectual property (IP).

Memory Overview

The main considerations for choosing an external memory device are bandwidth, size, cost, latency, and power. Since no single memory type can excel in every area, system architects must determine the right balance for their design.

There are two common types of high-speed memories: DRAM and SRAM. DRAM devices are volatile memories offering a lower cost per bit than SRAM devices. A compact memory cell consisting of a capacitor and a single transistor makes this possible, as opposed to the six-transistor cell used in SRAM. However, as the capacitor discharges, the memory cell loses its state. This means that DRAM memory must be refreshed periodically, resulting in lower overall efficiency and more complex controllers. Generally, designers only choose DRAM where cost per bit is important.

**DDR, DDR2, and DDR3 SDRAM**

The desktop computing market has positioned double data rate (DDR) SDRAM as a mainstream commodity product, which means this memory is very low-cost. DDR SDRAM is also high-density and low-power. Relative to other high-speed memories, DDR SDRAM has higher latency—they have a multiplexed address bus, which reduces the pin count (minimizing cost) at the expense of a longer and more complex bus
cycle. DDR2 SDRAM includes additional features such as increased bandwidth due to higher clock speeds, improved signal integrity on DIMMs with on-die terminations, and lower supply voltages to reduce power. DDR3 SDRAM is the latest generation of SDRAM and further increases bandwidth, lowers power, and improves signal integrity with fly-by and dynamic on-die terminations.

**RLDRAM and RLDRAM II**

Reduced latency DRAM (RLDRAM) is optimized to reduce latency primarily for networking and cache applications. RLDRAM is partitioned into eight smaller banks. This partitioning reduces the parasitic capacitance of the address and data lines, allowing faster accesses and reducing the probability of random access conflicts. Also, most DRAM memory types need both a row and column phase on a multiplexed address bus to support full random access, while RLDRAM supports a non-multiplexed address, saving bus cycles at the expense of more pins. RLDRAM utilizes higher operating frequencies and uses the 1.8V High-Speed Transceiver Logic (HSTL) standard with DDR data transfer to provide a very high throughput. RLDRAM II offers faster random access times, on-die termination, a delay-locked loop (DLL) for higher frequency operation, larger densities, wider data paths, and higher bus utilization compared with RLDRAM.

**QDR, QDR II, and QDR II+ SRAM**

SRAMs are fundamentally different from DRAMs in that a typical SRAM memory cell consists of six transistors, while a DRAM cell consists of a transistor and a capacitor used to store a charge. Inherently, SRAM is a low-density, high-power memory device, with very low latency compared to DRAM (as the capacitor in the DRAM is slow). In most cases, SRAM latency is one clock cycle.

Quad Data Rate (QDR) SRAM has independent read and write ports that run concurrently at double data rate. QDR SRAM is true dual-port (although the address bus is still shared), which gives this memory a significantly higher bandwidth. QDR SRAM is best suited for applications where the required read/write ratio is near one-to-one. QDR II SRAM includes additional features such as increased bandwidth due to higher clock speeds, lower voltages to reduce power, and on-die termination to improve signal integrity. QDR II+ SDRAM is the latest and fastest generation.

**Memory Selection**

One of the first considerations in choosing a high-speed memory is data bandwidth. Based on the system requirements, an approximate data rate to the external memory should be determined. Table 1–1 details the memory bandwidth for various technologies with the assumptions of a 32-bit data bus, operating at the maximum supported frequency in a Stratix® IV FPGA. The bandwidth column in this table includes a conservative DRAM bandwidth at 70 percent efficiency, which takes into consideration bus turnaround, refresh, burst length, and random access latency. The calculation assumes 85 % efficiency for QDR and QDR II SRAM.
You must also consider other memory attributes, including how much memory is required (density), how much latency can be tolerated, what is the power budget, and whether the system is cost sensitive. Table 1–2 is an overview of high-speed memories, and details some of the features and target markets of each technology.

Altera supports these memory interfaces, provides various IP for the physical interface and the controller, and offers many reference designs (refer to Altera’s Memory Solutions Center).

For Altera support and the maximum performance for the various high-speed memory interfaces, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

High-Speed Memory in Embedded Processor Application Example

In embedded processor applications—any system that uses processors, excluding desktop processors—DDR SDRAM is typically used for main memory due to its very low cost, high density, and low power. Next-generation processors invest a large amount of die area to on-chip cache memory to prevent the execution pipelines from sitting idle. Unfortunately, these on-chip caches are limited in size, as a balance of performance, cost, and power must be taken into consideration. In many systems, external memories are used to add another level of cache. In high-performance systems, three levels of cache memory is common: level one (8 Kbytes is common) and level two (512 Kbytes) on chip, and level three off chip (2 Mbytes).

High-end servers, routers, and even video game systems are examples of high-performance embedded products that require memory architectures that are both high speed and low latency. Advanced memory controllers are required to manage transactions between embedded processors and their memories. Altera Arria® series and Stratix series FPGAs optimally implement advanced memory controllers by utilizing their built-in DQS (strobe) phase shift circuitry. Figure 1–1 highlights some of the features available in an Altera FPGA in an embedded application, where DDR2 SDRAM is used as the main memory and QDR II SRAM or RLDRAM II is an external cache level.
One of the target markets of RLDRAM II and QDR/QDR II SRAM is external cache memory. RLDRAM II has a read latency close to SSRAM, but with the density of SDRAM. A 16 times increase in external cache density is achievable with one RLDRAM II versus that of SSRAM. In contrast, consider QDR and QDR II SRAM for systems that require high bandwidth and minimal latency. Architecturally, the dual-port nature of QDR and QDR II SRAM allows cache controllers to handle read data and instruction fetches completely independent of writes.

**High-Speed Memory in Telecom Application Example**

Because telecommunication network architectures are becoming more complex, high-end network systems are running multiple 10-Gbps line cards that connect to multi-shelf switch fabrics scaling to Terabits per second. Figure 1–2 shows an example of a typical system line interface card. These line cards offer interfaces ranging from a single-port OC-192 to multi-port Gigabit Ethernet, and consist of a number of devices, including a PHY/framer, network processors, traffic managers, fabric interface devices, and high-speed memories.
As packets traverse from the PHY/framer device to the switch fabric interface, they are buffered into memories, while the data path devices process headers (determining the destination, classifying packets, and storing statistics for billing) and control the flow of packets into the network to avoid congestion. Typically DDR/DDR2/DDR3 SDRAM and RLDRAM II are used for large buffer memories off network processors, traffic managers, and fabric interfaces, while QDR and QDR II SRAMs are used for look-up tables (LUTs) off preprocessors and coprocessors.

In many designs, FPGAs connect devices together for interoperability and coprocessing, implement features that are not supported by ASIC devices, or implement a device function entirely. Altera Stratix series FPGAs implement traffic management, packet processing, switch fabric interfaces, and coprocessor functions, using features such as 1 Gbps LVDS I/O, high-speed memory interface support, multi-gigabit transceivers, and IP cores. Figure 1–3 highlights some of these features in a packet buffering application where RLDRAM II is used for packet buffer memory and QDR II SRAM is used for control memory.
SDRAM is usually the best choice for buffering at high data rates due to the large amounts of memory required. Some system designers take a hybrid approach to the memory architecture, using SRAM to store the packet headers and DRAM to store the payload. The depth of the memories depends on the architecture and throughput of the system.

The buffer memory for the packet buffering application of an OC-192 line card (approximately 10 Gbps) must be able to sustain a minimum of one write and one read operation, which requires a memory bandwidth of 20 Gbps to operate at full line rate (more bandwidth is required if the headers are modified). The bandwidth requirement for memory is a key factor in memory selection (see Table 1–1). As an example, a simple first-order calculation using RLDRAM II as buffer memory requires a bus width of 48 bits to sustain 20 Gbps (300 MHz × 2 DDR × 0.70 efficiency × 48 bits = 20.1 Gbps), which needs two RLDRAM II parts (one ×18 and one ×36). RLDRAM II also inherently includes the additional memory bits used for parity or error correction code (ECC).

QDR and QDR II SRAM have bandwidth and low random access latency advantages that make them useful for control memory in queue management and traffic management applications. Another typical implementation for this memory is billing and packet statistics, where each packet requires counters to be read from memory, incremented, and then rewritten to memory. The high bandwidth, low latency, and optimal one-to-one read/write ratio make QDR SRAM ideal for this feature.
2. DDR, DDR2, and DDR3 SDRAM Overview

This chapter provides an overview of DDR, DDR2, and DDR3 SDRAM in Altera devices. DDR3 SDRAM is the latest generation of DDR SDRAM technology, with improvements that include lower power consumption, higher data bandwidth, enhanced signal quality with multiple on-die termination (ODT) selection and output driver impedance control. DDR3 SDRAM brings higher memory performance to a broad range of applications, such as PCs, embedded processor systems, image processing, storage, communications, and networking. DDR2 SDRAM is the second generation of DDR SDRAM technology. DDR and DDR2 SDRAMs are available as components and modules, such as DIMMs, SODIMMs, and RDIMMs.

For more information about Altera DDR3 SDRAM IP, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

**DDR SDRAM Overview**

DDR SDRAM is a 2n prefetch architecture with two data transfers per clock cycle. It uses a single-ended strobe, DQS, which is associated with a group of data pins, DQ, for read and write operations. Both DQS and DQ ports are bidirectional. Address ports are shared for read and write operations.

Write and read operations are sent in bursts, DDR SDRAM supports burst lengths of 2, 4, and 8. The column address strobe (CAS) latency is the latency between when the read command is clocked into the memory and the requested data is presented at the memory pins. DDR SDRAM can have CAS latencies of 2, 2.5, and 3, depending on operating frequency.

DDR SDRAM devices use the SSTL-2 2.5V I/O standard and can hold between 64 MB and 1 GB of data. Each device is divided into four banks, and each bank has a fixed number of rows and columns. Only one row per bank can be accessed at a time. The ACTIVATE command opens a row and the PRECHARGE command closes a row.

DDR SDRAM has a maximum frequency of 200 MHz or 400 Mbps per DQ pin.

**DDR2 SDRAM Overview**

DDR2 SDRAM is the second generation of the DDR SDRAM standard. It is a 4n prefetch architecture (internally the memory operates at half the interface frequency) with two data transfers per clock cycle. DDR2 SDRAM can use a single-ended or differential strobe, DQS or DQSn, which is associated with a group of data pins, DQ, for read and write operations. DQS, DQSn, and DQ ports are bidirectional. Address ports are shared for read and write operations.

Write and read operations are sent in bursts, DDR2 SDRAM supports burst lengths of 4 and 8. DDR2 SDRAM supports CAS latencies of 2, 3, 4, and 5.
DDR2 SDRAM devices use the SSTL-18 1.8-V I/O standard and can hold between 256 MB and 4 GB of data. All DDR2 SDRAM devices have at least four banks, but higher-density devices (typically 1 GB and above) have eight internal banks. With more banks available, the page-to-hit ratio is twice as great when compared to DDR SDRAM. DDR2 SDRAM also allows bank interleaving, which represents a significant advantage for applications accessing random data. Bank interleaving can be extremely effective for concurrent operations and can hide the timing overhead that are otherwise required for opening and closing individual banks.

DDR2 SDRAM also supports ODT signal options of 50, 75, or 150 \(\Omega\) on all DQ, DM, and DQS and DQSn signals.

DDR2 SDRAM has a maximum frequency of 533 MHz or 1,066 Mbps per DQ pin.

### DDR3 SDRAM Overview

DDR3 SDRAM is more effective at saving system power and increasing system performance than DDR2 SDRAM. DDR3 SDRAM offers lower power by using 1.5 V for the supply and I/O voltage compared to the 1.8-V supply and I/O voltage used by DDR2 SDRAM. DDR3 SDRAM also has better maximum throughput compared to DDR2 SDRAM by increasing the data rate per pin and the number of banks (to eight banks). DDR3 SDRAM also has the following additional benefits:

- Supports read/write levelling functionality required in the FPGA to interface with DDR3 DIMMs.
- Supports calibrated parallel ODT via an external resistor \(R_{ZQ}\) signal termination options of \(R_{ZQ}/2\), \(R_{ZQ}/4\), or \(R_{ZQ}/6\) \(\Omega\) on all DQ, DM, and DQS and DQSn signals.
- Supports controlled output driver impedance options of \(R_{ZQ}/6\) or \(R_{ZQ}/7\).
- Maximum frequency of 800 MHz or 1600 Mbps per DQ pin.
- Minimum operating frequency is 300 MHz.

The DDR3 SDRAM high-performance controller only supports local interfaces running at half the rate of the memory interface.

DDR3 SDRAMs are available as components and modules, such as DIMMs, SODIMMs, and RDIMMs.

DDR3 SDRAM is internally configured as an eight-bank DRAM. DDR3 SDRAM uses an 8n prefetch architecture to achieve high-speed operation. The 8n prefetch architecture is combined with an interface that transfers two data words per clock cycle at the I/O pins. A single read or write operation for DDR3 SDRAM consists of a single 8n-bit wide, four-clock data transfer at the internal DRAM core and two corresponding n-bit wide, one-half clock cycle data transfers at the I/O pins.

Read and write operations to the DDR3 SDRAM are burst oriented. Operation begins with the registration of an active command, which is then followed by a read or write command. The address bits registered coincident with the active command select the bank and row to be activated (BA0 to BA2 select the bank; A0 to A15 select the row). The address bits registered coincident with the read or write command select the
starting column location for the burst operation, determine if the auto precharge command is to be issued (via A10), and select burst chop (BC) of 4 or burst length (BL) of 8 mode at runtime (via A12), if enabled in the mode register. Before normal operation, the DDR3 SDRAM must be powered up and initialized in a predefined manner.

Differential strobes DQS and DQSn are mandated for DDR3 SDRAM and are associated with a group of data pins, DQ, for read and write operations. DQS, DQSn, and DQ ports are bidirectional. Address ports are shared for read and write operations.

Write and read operations are sent in bursts, DDR3 SDRAM supports BC of 4 and BL of 8. DDR3 SDRAM supports CAS latencies of 5 to 10.

DDR3 SDRAM devices use the SSTL-15 1.5-V I/O standard and can hold between 512 MB and 8 GB of data. The 1.5-V operational voltage reduces power consumption by 17% compared to DDR2 SDRAM.

All DDR3 SDRAM devices have eight internal banks. With more banks available, the page-to-hit ratio is twice that of DDR SDRAM. DDR3 SDRAM also allows bank interleaving, which represents a significant advantage for applications accessing random data. Bank interleaving can be extremely effective for concurrent operations and can hide the timing overhead that is otherwise required for opening and closing individual banks.

2–4 Chapter 2: DDR, DDR2, and DDR3 SDRAM Overview

Chapter 2: DDR, DDR2, and DDR3 SDRAM Overview

DDR, DDR2, and DDR3 SDRAM Overview

This section describes the DDR, DDR2, and DDR3 SDRAM interface pins.

Clock Signals

DDR, DDR2, and DDR3 SDRAM devices use CK and CK# signals to clock the address and command signals into the memory. Furthermore, the memory uses these clock signals to generate the DQS signal during a read through the DLL inside the memory. The SDRAM data sheet specifies the following timings:

- **tDQCK** is the skew between the CK or CK# signals and the SDRAM-generated DQS signal
- **tDSH** is the DQS falling edge from CK rising edge hold time
- **tDSS** is the DQS falling edge from CK rising edge setup time
- **tDQSS** is the positive DQS latching edge to CK rising edge

These SDRAM have a write requirement (tDQSS) that states the positive edge of the DQS signal on writes must be within ±25% (±90°) of the positive edge of the SDRAM clock input. Therefore, you should generate the CK and CK# signals using the DDR registers in the IOE to match with the DQS signal and reduce any variations across process, voltage, and temperature. The positive edge of the SDRAM clock, CK, is aligned with the DQS write to satisfy tDQSS.

The Altera SDRAM high-performance controllers generate the CK and CK# signals using the DDR registers in the IOE with the DQS signal and reduce any variations across process, voltage, and temperature.

DDR3 SDRAM can use a daisy-chained CAC topology, the memory clock must arrive at each chip at a different time. To compensate for this flight-time skew between devices across a typical DIMM, write leveling must be employed.

Data, Data Strobes, DM, and Optional ECC Signals

DDR SDRAM uses bidirectional single-ended data strobe (DQS); DDR3 SDRAM uses bidirectional differential data strobes. The DQSn pins in DDR2 SDRAM devices are optional but recommended for DDR2 SDRAM designs operating at more than 333 MHz. Differential DQS operation enables improved system timing due to reduced crosstalk and less simultaneous switching noise on the strobe output drivers. The DQ
pins are also bidirectional. Regardless of interface width, DDR SDRAM always operates in ×8 mode DQS groups. DQ pins in DDR2 and DDR3 SDRAM interfaces can operate in either ×4 or ×8 mode DQS groups, depending on your chosen memory device or DIMM, regardless of interface width. The ×4 and ×8 configurations use one pair of bidirectional data strobe signals, DQS and DQSn, to capture input data. However, two pairs of data strobes, UDQS and UDQS# (upper byte) and LDQS and LDQS# (lower byte), are required by the ×16 configuration devices. A group of DQ pins must remain associated with its respective DQS and DQSn pins.

The DQ signals are edge-aligned with the DQS signal during a read from the memory and are center-aligned with the DQS signal during a write to the memory. The memory controller shifts the DQ signals by ~90° during a write operation to center align the DQ and DQS signals. ALTMEMPHY delays the DQS signal during a read, so that the DQ and DQS signals are center aligned at the capture register. Altera devices use a phase-locked loop (PLL) to center-align the DQS signal with respect to the DQ signals during writes and Altera devices (except Cyclone III devices) use dedicated DQS phase-shift circuitry to shift the incoming DQS signal during reads. Figure 2–1 shows an example where the DQS signal is shifted by 90° for a read from the DDR2 SDRAM.

Figure 2–1. DQ and DQS Relationship During a DDR2 SDRAM Read in Burst-of-Four Mode

<table>
<thead>
<tr>

<th>DQS at DQ I/OE registers</th>
<th>DQ at DQ I/OE registers</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The memory device’s setup (tDS) and hold times (tDH) for the write DQ and DM pins are relative to the edges of DQS write signals and not the CK or CK# clock. Setup and hold requirements are not necessarily balanced in in DDR2 and DDR3 SDRAM, unlike in DDR SDRAM devices.

Figure 2–2. DQ and DQS Relationship During a DDR2 SDRAM Write in Burst-of-Four Mode

<table>
<thead>
<tr>
<th>DQS at FPGA Pin</th>
<th>DQ at FPGA Pin</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The DQS signal is generated on the positive edge of the system clock to meet the t_{DQSS} requirement. DQ and DM signals use a clock shifted –90° from the system clock, so that the DQS edges are centered on the DQ or DM signals when they arrive at the DDR2 SDRAM. The DQS, DQ, and DM board trace lengths need to be tightly matched (20 ps).

The SDRAM uses the DM pins during a write operation. Driving the DM pins low shows that the write is valid. The memory masks the DQ signals if the DM pins are driven high. While you can use any of the I/O pins in the same bank as the associated DQS and DQ pins, to generate the DM signal, Altera recommends that you use the spare DQ pin within the same DQS group as the respective data, to minimize skew.

The DM signal's timing requirements at the SDRAM input are identical to those for DQ data. The DDR registers, clocked by the –90° shifted clock, create the DM signals.

Some SDRAM modules support error correction coding (ECC) to allow the controller to detect and automatically correct error in data transmission. The 72-bit SDRAM modules contain eight extra data pins in addition to 64 data pins. The eight extra ECC pins should be connected to a single DQS or DQ group on the FPGA.

**Address and Command Signals**

Address and command signals in SDRAM devices are clocked into the memory device using the CK or CK# signal. These pins operate at single data rate (SDR) using only one clock edge. The number of address pins depends on the SDRAM device capacity. The address pins are multiplexed, so two clock cycles are required to send the row, column, and bank address. The CS#, RAS, CAS, WE, CKE, and ODT pins are SDRAM command and control pins. DDR3 SDRAM has additional pins: RESET#, PAR_In and ERR_OUT#. The RESET# pin uses 1.5-V LVCMOS I/O standard, while the rest of the DDR3 SDRAM pins use the SSTL-15 I/O standard.

The DDR2 SDRAM address and command inputs do not have a symmetrical setup and hold time requirement with respect to the SDRAM clocks, CK, and CK#.

For ALTMEMPHY or Altera SDRAM high-performance controllers in Stratix III and Stratix IV devices, the address and command clock is a dedicated PLL clock output whose phase can be adjusted to meet the setup and hold requirements of the memory clock. The address and command clock is also typically half-rate, although a full-rate implementation can also be created. The command and address pins use the DDIO output circuitry to launch commands from either the rising or falling edges of the clock. The chip select (mem_cs_n), clock enable (mem_cke), and ODT (mem_odt) pins are only enabled for one memory clock cycle and can be launched from either the rising or falling edge of the address and command clock signal. The address and other command pins are enabled for two memory clock cycles and can also be launched from either the rising or falling edge of the address and command clock signal.

In ALTMEMPHY-based designs, the address and command clock ac_clk_1x is always half rate. However, because of the output enable assertion, CS#, CKE, and ODT behave like full-rate signals even in a half-rate PHY.

In Arria II GX and Cyclone III devices, the address and command clock is either shared with the write_clk_2x or the mem_clk_2x clock.
DIMM Options

Compared to the unbuffered DIMMs (UDIMM), both single-rank and double-rank registered DIMMs (RDIMM) use only one pair of clocks and two chip selects CS#[1:0] in DDR3. An RDIMM has extra parity signals for address, RAS#, CAS#, and WE#.

Dual-rank DIMMs have the following extra signals for each side of the DIMM:

- CS# (RDIMM always has two chip selects, DDR3 uses a minimum of 2 chip selects, even on a single rank module)
- CK (only UDIMM)
- ODT signal
- CKE signal

Table 2–2 compares the UDIMM and RDIMM pin options.

Note to Table 2–2:
(1) DQS[#8:0] is optional in DDR2 SDRAM and is not supported in DDR SDRAM interfaces.
This chapter provides an overview of QDR II and QDR II+ SRAM in Altera devices. Synchronous static RAM (SRAM) architectures support the high throughput requirements of communications, networking, and digital signal processing (DSP) systems. The successor to quad data rate (QDR) SRAM, QDR II+ and QDR II SRAM support higher memory bandwidth and improved timing margins and offer more flexibility in system designs.

For more information about Altera QDR II and QDR II+ SRAM IP, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

QDR II+ and QDR II SRAM can perform two data writes and two data reads per clock cycle. They use one port for writing data (D) and another port for reading data (Q). These unidirectional data ports support simultaneous reads and writes and allows back-to-back transactions without the contention issues that can occur when using a single bidirectional data bus. Write and read operations share address ports.

The QDR II SRAM devices are available in ×8, ×9, ×18, and ×36 data bus width configurations. The QDR II+ SRAM devices are available in ×9, ×18, and ×36 data bus width configurations. Write and read operations are burst-oriented. All the data bus width configurations of QDR II SRAM support burst lengths of two and four. QDR II+ SRAM supports only a burst length of four. Burst-of-two and burst-of-four for QDR II and burst-of-four for QDR II+ SRAM devices provide the same overall bandwidth at a given clock speed.

Read latency is the time between the read command being clocked into memory and the time data is presented at the memory pins. For QDR II SRAM devices, the read latency is 1.5 clock cycles, while for QDR II+ SRAM devices it is 2 or 2.5 clock cycles, depending on the memory device. Write latency is the time between the write command being clocked into memory and the time data is presented at the memory pins. For QDR II+ and burst-of-four QDR II SRAM devices, the write commands and addresses are clocked on the rising edge of clock and write latency is one clock cycle. For burst-of-two QDR II SRAM devices, the write command is clocked on the rising edge of clock and the write address is clocked on the falling edge of clock. Therefore, the write latency is zero, because the write data is presented at the same time as the write command.

Altera supports both 1.5-V and 1.8-V HSTL I/O standards for QDR II+ and QDR II SRAM interfaces. QDR II+ and QDR II SRAM interfaces use a delay-locked loop (DLL) inside the device to edge-align the data with respect to the \( K \) and \( K_n \) or \( C \) and \( C_n \) pins. You can optionally turn off the DLL, but the performance of the QDR II+ and QDR II SRAM devices is degraded. All timing specifications listed in this document assume that the DLL is on.

QDR II+ and QDR II SRAM devices also offer programmable impedance output buffers. You can set the buffers by terminating the \( Z_Q \) pin to \( V_{SS} \) through a resistor, \( R_Q \). The value of \( R_Q \) should be five times the desired output impedance. The range for \( R_Q \) should be between 175 \( \Omega \) and 350 \( \Omega \) with a tolerance of 10%.
QDR II+ and QDR II SRAM Interface Pin Description

This section provides a description of the clock, control, address, and the data signals on QDR II and QDR II+ SRAM devices.

Clock Signals

QDR II+ and QDR II SRAM devices have three pairs of clocks:
- Input clocks $K$ and $K^#$
- Input clocks $C$ and $C^#$
- Echo clocks $CQ$ and $CQ^#$

The positive input clock, $K$, is the logical complement of the negative input clock, $K^#$. Similarly, $C$ and $CQ$ are complements of $C^#$ and $CQ^#$, respectively. With these complementary clocks, the rising edges of each clock leg latch the DDR data.

The QDR II+ and QDR II SRAM devices use the $K$ and $K^#$ clocks for write access and the $C$ and $C^#$ clocks for read accesses only when interfacing more than one QDR II+ or QDR II SRAM device. Because the number of loads that the $K$ and $K^#$ clocks drive affects the switching times of these outputs when a controller drives a single QDR II+ or QDR II SRAM device, $C$ and $C^#$ are unnecessary. This is because the propagation delays from the controller to the QDR II+ or QDR II SRAM device and back are the same. Therefore, to reduce the number of loads on the clock traces, QDR II+ and QDR II SRAM devices have a single clock mode, and the $K$ and $K^#$ clocks are used for both reads and writes. In this mode, the $C$ and $C^#$ clocks are tied to the supply voltage ($V_{DD}$).

$CQ$ and $CQ^#$ are the source-synchronous output clocks from the QDR II or QDR II+ SRAM device that accompanies the read data.

The Altera device outputs the $K$ and $K^#$ clocks, data, address, and command lines to the QDR II+ or QDR II SRAM device. For the controller to operate properly, the write data ($D$), address ($A$), and control signal trace lengths (and therefore the propagation times) should be equal to the $K$ and $K^#$ clock trace lengths.

You can generate $C$, $C^#$, $K$, and $K^#$ clocks using any of the PLL registers via the DDR registers. Because of strict skew requirements between $K$ and $K^#$ signals, use adjacent pins to generate the clock pair. The propagation delays for $K$ and $K^#$ from the FPGA to the QDR II+ or QDR II SRAM device are equal to the delays on the data and address ($D$, $A$) signals. Therefore, the signal skew effect on the write and read request operations is minimized by using identical DDR output circuits to generate clock and data inputs to the memory.

Command Signals

QDR II+ and QDR II SRAM devices use the write port select ($WPSn$) signal to control write operations and the read port select ($RPSn$) signal to control read operations. The byte write select signal ($BWSn$) is a third control signal that indicates to the QDR II+ or QDR II SRAM device which byte to write into the QDR II+ or QDR II SRAM device. You can use any of the FPGA’s user I/O pins to generate control signals, preferably on the same side and the same bank.
Address Signals

QDR II+ and QDR II SRAM devices use one address bus (A) for both read and write addresses. You can use any of the FPGA’s user I/O pins to generate address signals, preferably on the same side and the same banks.

Data and QVLD Signals

QDR II+ and QDR II SRAM devices use two unidirectional data buses: one for writes (D) and one for reads (Q). The read data is edge-aligned with the CQ and CQ# clocks while the write data is center-aligned with the K and K# clocks (see Figure 3–1 and Figure 3–2).

QDR II+ SRAM devices also have a QVLD pin that indicates valid read data. The QVLD signal is edge-aligned with the echo clock and is asserted high for approximately half a clock cycle before data is output from memory.

The Altera QDR II+ SRAM Controller MegaCore function does not use the QVLD signal.
This chapter provides an overview of RLDRAM II in Altera devices.

Reduced latency DRAM II (RLDRAM II) is a DRAM-based point-to-point memory device designed for communications, imaging, and server systems requiring high density, high memory bandwidth, and low latency. The fast random access speeds in RLDRAM II devices make them a viable alternative to SRAM devices at a lower cost.

For more information about Altera RLDRAM II IP, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

There are two types of RLDRAM II devices: common I/O (CIO) and separate I/O (SIO). CIO devices share a single data I/O bus which is similar to the double data rate (DDR) SDRAM interface. SIO devices, with separate data read and write buses, have an interface similar to SRAM.

Compared to DDR SDRAM, RLDRAM II has simpler bank management and lower latency inside the memory. RLDRAM II devices are divided into eight banks instead of the typical four banks in most memory devices, providing a more efficient data flow within the device. RLDRAM II offers up to 2.4 Gigabytes per second (Gbps) aggregate bandwidth.

RLDRAM II uses a DDR scheme, performing two data transfers per clock cycle. RLDRAM II CIO devices use the bidirectional data pins (DQ) for both read and write data, while RLDRAM II SIO devices use D pins for write data (input to the memory) and Q pins for read data (output from the memory). Both types use two pairs of uni-directional free-running clocks. The memory uses DK and DK# pins during write operations, and generates QK and QK# pins during read operations. In addition, RLDRAM II uses the system clocks (CK and CK# pins) to sample commands and addresses and generate the QK and QK# read clocks. Address ports are shared for write and read operations.

The RLDRAM II SIO devices are available in ×9 and ×18 data bus width configurations, while the RLDRAM II CIO devices are available in ×9, ×18, and ×36 data bus width configurations. RLDRAM II CIO interfaces may require an extra cycle for bus turnaround time for switching read and write operations.

Write and read operations are burst oriented and all the data bus width configurations of RLDRAM II support burst lengths of two and four. In addition, RLDRAM II devices with data bus width configurations of ×9 and ×18 also support burst length of eight.

The read latency is the time between when the read command is clocked into the memory and the time data is presented at the memory pins. There is a similar latency for write operations called the write latency. The write latency is equal to the read latency plus one clock cycle. The RLDRAM devices have up to three programmable configuration settings that determine the row cycle times, read latency, and write latency of the interface at a given frequency of operation.
RLDRAM II devices use either the 1.5-V HSTL or 1.8-V HSTL I/O standard. You can use either I/O standard to interface with Altera FPGAs. Each RLDRAM II device is divided into eight banks, where each bank has a fixed number of rows and columns. Only one row per bank is accessed at a time. The memory (instead of the controller) controls the opening and closing of a row, which is similar to an SRAM interface.

RLDRAM II also offers programmable impedance output buffers and on-die termination. The programmable impedance output buffers are for impedance matching and are guaranteed to produce 25- to 60-ohm output impedance. The on-die termination is dynamically switched on during read operations and switched off during write operations. Perform an IBIS simulation to observe the effects of this dynamic termination on your system. IBIS simulation can also show the effects of different drive strengths, termination resistors, and capacitive loads on your system.

**RLDRAM II Interface Pin Description**

This section describes the RLDRAM II interface pin description.

**Clock Signals**

RLDRAM II devices use $CK$ and $CK\#$ signals to clock the command and address bus in single data rate (SDR). There is one pair of $CK$ and $CK\#$ pins per RLDRAM II device.

Instead of a strobe, RLDRAM II devices use two sets of free-running differential clocks to accompany the data. The $DK$ and $DK\#$ clocks are the differential input data clocks used during writes while the $QK$ or $QK\#$ clocks are the output data clocks used during reads. Even though $QK$ and $QK\#$ signals are not differential signals according to the RLDRAM II data sheets, Micron treats these signals as such for their testing and characterization. Each pair of $DK$ and $DK\#$, or $QK$ and $QK\#$ clocks are associated with either 9 or 18 data bits.

The exact clock-data relationships are as follows:

- For $\times36$ data bus width configuration, there are 18 data bits associated with each pair of write and read clocks. So, there are two pairs of $DK$ and $DK\#$ pins and two pairs of $QK$ or $QK\#$ pins.
- For $\times18$ data bus width configuration, there are 18 data bits per one pair of write clocks and nine data bits per one pair of read clocks. So, there is one pair of $DK$ and $DK\#$ pins, but there are two pairs of $QK$ and $QK\#$ pins.
- For $\times9$ data bus width configuration, there are nine data bits associated with each pair of write and read clocks. So, there is one pair of $DK$ and $DK\#$ pins and one pair of $QK$ and $QK\#$ pins each.

There are $t_{\text{CKDR}}$ timing requirements for skew between $CK$ and $DK$ or $CK\#$ and $DK\#$. Because of the loads on these I/O pins, the maximum frequency you can achieve depends on the number of RLDRAM II devices you are connecting to the Altera device. Perform SPICE or IBIS simulations to analyze the loading effects of the pin-pair on multiple RLDRAM II devices.
Data, DM and QVLD Signals

The read data is edge-aligned with the $QK$ or $QK\#$ clocks while the write data is center-aligned with the $DK$ and $DK\#$ clocks (see Figure 4–1 and Figure 4–2). The memory controller shifts the $DK$ or $DK\#$ signal to center align the $DQ$ and $DK$ or $DK\#$ signal during a write and to shift the $QK$ signal during a read, so that read data ($DQ$ or $Q$ signals) and $QK$ clock is center-aligned at the capture register. Altera devices use dedicated DQS phase-shift circuitry to shift the incoming $QK$ signal during reads and use a PLL to center-align the $DK$ and $DK\#$ signals with respect to the $DQ$ signals during writes.

Figure 4–1. DQ and QK Relationship During RLDRAM II Read

![DQ and QK Relationship During RLDRAM II Read](image)

Notes to Figure 4–1:
(1) This is an example of a 90° shift. The required phase shift for your system should be based on your timing analysis and may not be 90°.

Figure 4–2. DQ and QK Relationship During RLDRAM II Write

![DQ and QK Relationship During RLDRAM II Write](image)

The RLDRAM II data mask ($DM$) pins are only used during a write. The memory controller drives the $DM$ signal low when the write is valid and drives it high to mask the $DQ$ signals. There is one $DM$ pin per RLDRAM II device.

The DM timing requirements at the input to the RLDRAM II are identical to those for DQ data. The DDR registers, clocked by the write clock, create the $DM$ signals. This reduces any skew between the $DQ$ and $DM$ signals.
The RLDRAM II device's setup time \( t_{DS} \) and hold \( t_{DH} \) time for the write \( DQ \) and \( DM \) pins are relative to the edges of the \( DK \) or \( DK# \) clocks. The \( DK \) and \( DK# \) signals are generated on the positive edge of system clock, so that the positive edge of \( CK \) or \( CK# \) is aligned with the positive edge of \( DK \) or \( DK# \) respectively to meet the RLDRAM II \( t_{CKDK} \) requirement. The \( DQ \) and \( DM \) signals are clocked using a shifted clock so that the edges of \( DK \) or \( DK# \) are center-aligned with respect to the \( DQ \) and \( DM \) signals when they arrive at the RLDRAM II device.

The clocks, data, and DM board trace lengths should be tightly matched to minimize the skew in the arrival time of these signals.

RLDRAM II devices also have a QVLD pin indicating valid read data. The QVLD signal is edge-aligned with \( QK \) or \( QK# \) and is high approximate half a clock cycle before data is output from the memory.

The Altera RLDRAM II Controller IP does not use the QVLD signal.

**Commands and Addresses**

The \( CK \) and \( CK# \) signals clock the commands and addresses into RLDRAM II devices. These pins operate at single data rate using only one clock edge. RLDRAM II devices have 18 to 21 address pins, depending on the data bus width configuration and burst length. RLDRAM II supports both non-multiplexed and multiplexed addressing. Multiplexed addressing allows you to save a few user I/O pins while non-multiplexed addressing allows you to send the address signal within one clock cycle instead of two clock cycles. \( CS# \), \( REF# \), and \( WE# \) pins are input commands to the RLDRAM II device.

The commands and addresses must meet the memory address and command setup \( t_{AS}, t_{CS} \) and hold \( t_{AH}, t_{CH} \) time requirements.

1. DDR SDRAM Specifications

This chapter describes the following specifications when using the Altera® DDR SDRAM IP:

- Maximum clock rate supported
- Maximum number of interfaces
- Unsupported features

**Maximum Clock Rate Support**

The DDR SDRAM IP offers the following features:

- Full-rate and half-rate designs
- Both UDIMM and RDIMM in any form factor (refer to “DDR, DDR2, and DDR3 SDRAM Overview” on page 2–1)
- Burst length of 4 when using DDR SDRAM high-performance controller; burst length of 8 (for half-rate designs) or 4 (for full-rate designs) when using the DDR SDRAM high-performance controller II

Table 1–1 shows supported features at maximum clock rates for ALTMEMPHY-based DDR SDRAM controllers (such as the DDR SDRAM high-performance controller) on various Altera devices. The number in brackets is the memory component required clock rate. For example, you require a 200-MHz memory component to get 133-MHz maximum frequency on an Cyclone IV E device.

For recommended termination and drive strength settings, refer to the *Board Layout Guidelines* section in volume 2 of the *External Memory Interface Handbook*.

**Note to Table 1–1:**

1. The first number is the maximum clock rate. The number in brackets is the memory device speed grade. If there is no number in brackets, use the same memory component speed grade as the maximum clock rate shown.
2. Multiple chip select and multiple rank DIMMs are supported at a lower maximum clock rate based on your board layout. To calculate the maximum clock rate for designs with multiple chip select, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.
3. In Cyclone IV GX devices, left side is not supported for external memory interface.
4. Cyclone III LS devices do not support C6 and A7 speed grades. These frequencies are only applicable to Cyclone III non LS devices.
5. In Stratix IV devices, class II termination is not available on row I/Os.
Maximum Number of Interfaces

Table 1–2 shows available device resources for DDR SDRAM. Table 1–2 also describes the maximum number of ×8 DDR SDRAM components fit in the smallest and biggest devices and pin packages assuming the device is blank.

Each \( n \) (where \( n \) is a multiple of 8) interface consists of:

- \( n \) DQ pins (including ECC)
- \( n/8 \) DM pins
- \( n/8 \) DQS pins
- 18 address pins
- 7 command pins (CAS, RAS, WE, CKE, ODT, reset, and CS)
- 1 CK, CK# pin pair for every three ×8 DDR SDRAM components

Unless otherwise noted, this calculation for the maximum number of interfaces is based on independent interfaces where the address or command pins are not shared.

Timing closure depends on device resource and routing utilization.

For more information about timing closure, refer to the *Area and Timing Optimization Techniques* chapter in the *Quartus II Handbook*.

You need to share DLLs if the total number of interfaces is more than 4. You may also need to share PLL clock outputs depending on your clock network usage, refer to the *Device and Pin Planning* section in volume 2 of the *External Memory Interface Handbook*.

For information on the number of DQ and DQS in other packages, refer to the DQ and DQS tables in the relevant device handbook.

Unsupported Features

For features not supported by Altera memory IP, you can create a controller using a custom PHY with the ALTDQ_DQS megafunction. However, you must create the timing constraints and timing analysis methodology to determine your maximum interface frequency. Altera only supports the ALTDQ_DQS part of your design.

Cyclone III devices do not support ×4 DQS groups and hence cannot support ×4 DDR SDRAM components or DIMMs.
This chapter describes the following specifications when using the Altera DDR2 SDRAM IP:

- Maximum clock rate supported
- Maximum number of interfaces
- Unsupported features

### Maximum Clock Rate Support

The DDR2 SDRAM IP offers the following features:

- Full-rate and half-rate designs
- Both UDIMM and RDIMM in any form factor (refer to “DDR, DDR2, and DDR3 SDRAM Overview” on page 2–1)
- Burst length of 4 when using DDR2 SDRAM high-performance controller; burst length of 8 (for half-rate designs) or 4 (for full-rate designs) when using the DDR2 SDRAM high-performance controller II
- Multiple component in a single rank UDIMM or RDIMM layout

Table 2–1 and Table 2–2 show supported features at maximum clock rates for ALTMEMPHY-based DDR2 SDRAM controllers (such as the DDR2 SDRAM high-performance controller) on various Altera devices. The number in brackets is the memory component required clock rate. For example, you require a 400-MHz memory component to get 300-MHz maximum frequency on an Arria II GX device.

For recommended termination and drive strength settings, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook.

### Note to Table 2–1:

1. The first number is the maximum clock rate. The number in brackets is the memory device speed grade. If there is no number in brackets, you may use the same memory component speed grade as the maximum clock rate shown.

2. In Cyclone IV GX devices, left side is not supported for external memory interface.

3. Cyclone III LS devices do not support C6 and A7 speed grades. These frequencies are only applicable to Cyclone III non LS devices.

4. For a Q240 C8 device with 167-MHz performance on column I/Os, a 333-MHz DDR2 SDRAM component is required.

5. You need 267-MHz memory component speed grade when using class I I/O standard and 333-MHz memory component speed grade when using Class II I/O standard.

6. Multiple chip select and multiple rank DIMMs are supported at a lower maximum clock rate based on your board layout. To calculate the maximum clock rate for designs with multiple chip select, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.

7. In Stratix IV devices, class II termination is not available on row I/Os.

8. VCCL = 0.9 V.

Note to Table 2–2:

1. The first number is the maximum clock rate. The number in brackets is the memory device speed grade. If there is no number in brackets, you may use the same memory component speed grade as the maximum clock rate shown.
2. In Cyclone IV GX devices, left side is not supported for external memory interface.
3. Cyclone III LS devices do not support C6 and A7 speed grades. These frequencies are only applicable to Cyclone III non LS devices.
4. For a Q240 C8 device with 167-MHz performance on column I/Os, a 333-MHz DDR2 SDRAM component is required.
5. You need 267-MHz memory component speed grade when using class I I/O standard and 333-MHz memory component speed grade when using Class II I/O standard.
6. Multiple chip select and multiple rank DIMMs are supported at a lower maximum clock rate based on your board layout. To calculate the maximum clock rate for designs with multiple chip select, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.
7. May require some optimization to meet core timing.
8. In Stratix IV devices, class II termination is not available on row I/Os.
9. VCCL = 0.9 V.

Maximum Number of Interfaces

Table 2–3 shows available device resources for DDR2 SDRAM. Table 2–3 describes the maximum number of ×8 DDR2 SDRAM components that can be fitted in the smallest and biggest devices and pin packages assuming the device is blank.

Each n (where n is a multiple of 8) interface consists of:
- n DQ pins (including ECC)
- n/8 DM pins
- n/8 DQS,DQSn pin pairs
- 18 address pins
- 7 command pins (CAS, RAS, WE, CKE, ODT, reset, and CS)
- 1 CK, CK# pin pair for every three ×8 DDR2 components

Unless otherwise noted, this calculation for the maximum number of interfaces is based on independent interfaces where the address or command pins are not shared.

Timing closure depends on device resource and routing utilization.

For more information about timing closure, refer to the Area and Timing Optimization Techniques chapter in the Quartus II Handbook.

You need to share DLLs if your total number of interfaces is more than 4. You may also need to share PLL clock outputs depending on your clock network usage, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.

For information on the number of DQ and DQS in other packages, refer to the DQ and DQS tables in the relevant device handbook.

Unsupported Features

For features not supported by Altera memory IP, you can create a controller using a custom PHY with the ALTDQ_DQS megafunction. However, you must create the timing constraints and timing analysis methodology to determine your maximum interface frequency. Altera only supports the ALTDQ_DQS part of your design.

</tbody>
</table>
This chapter describes the following specifications when using the Altera DDR3 SDRAM IP:

- Maximum clock rate supported
- Maximum number of interfaces
- Unsupported features

### Maximum Clock Rate Support

The DDR3 SDRAM IP supports the following features:

- Half-rate designs
- Leveling support:
  - Without leveling for Arria II GX and Stratix III devices up to 400 MHz and for Stratix IV devices up to 533 MHz
    
    ! You must set the Memory Format to Discrete Device in the MegaWizard Plug-In, even if you are interfacing with multiple DDR3 SDRAM components laid out on the board like a (T-topology) DDR2 SDRAM UDIMM.
  
  - With leveling for Stratix III and Stratix IV devices between 400 and 533 MHz
    
    ! You must set the Memory Format to Unbuffered DIMM in the MegaWizard Plug-In, even if you are interfacing with multiple DDR3 SDRAM components laid out on the board like a (fly-by) DDR3 SDRAM UDIMM.
  
  - Maximum data width with leveling is 80 bits
    
    ! The leveling delay on the board between first and last DDR3 SDRAM component laid out as a DIMM must be less than a single memory clock cycle period.
  
  - Both UDIMM and RDIMM support for Stratix III and Stratix IV devices in any form factor (refer to “DDR, DDR2, and DDR3 SDRAM Overview” on page 2–1)
  
  - No quad-rank RDIMM support
  
  - Burst length of 8 and burst chop of 4
  
  - A single DDR3 SDRAM component
  
  - Multiple DDR3 SDRAM components in a single-rank DDR2 SDRAM UDIMM or RDIMM layout
  
  - Multiple DDR3 SDRAM components in a single-rank DDR3 SDRAM UDIMM or RDIMM layout (except for Arria II GX devices)
Table 3–1 and Table 3–2 show supported features at maximum clock rates for ALTMEMPHY-based DDR3 SDRAM controllers (such as the DDR3 SDRAM high-performance controller) on various Altera devices. The number in brackets is the memory component required clock rate. For example, you require a 400-MHz memory component to get 300-MHz maximum frequency on an Arria II GX device.

Table 3–1 shows DIMM support; Table 3–2 shows component support.

**Note to Table 3–1:**

1. The first number is the maximum clock rate. The number in brackets is the memory device speed grade. If there is no number in brackets, you may use the same memory component speed grade as the maximum clock rate shown.
2. Multiple chip select and multiple rank DIMMs are supported at a lower maximum clock rate based on your board layout. To calculate the maximum clock rate for designs with multiple chip select, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.
3. Any DDR3 SDRAM interfaces operating higher than 400 MHz must use the leveling circuitry, and the memory components must be laid out like a (fly-by) DDR3 SDRAM UDIMM. The leveling circuitry is enabled by setting the Memory Format to Unbuffered DIMM.
4. In Stratix IV devices, class II termination is not available on row I/Os.
5. Applies to VCCL=1.1 V only. There is no DDR3 SDRAM support for VCCL = 0.9V.

</tbody>
</table>

**Note to Table 3–1:**

1. The first number is the maximum clock rate. The number in brackets is the memory device speed grade. If there is no number in brackets, you may use the same memory component speed grade as the maximum clock rate shown.

2. To achieve the maximum frequency, you require a low board skew within a DQS or DQ group.

3. Multiple chip select and multiple rank DIMMs are supported at a lower maximum clock rate based on your board layout. To calculate the maximum clock rate for designs with multiple chip select, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.

4. Any DDR3 SDRAM interfaces operating higher than 400 MHz must use the leveling circuitry, and the memory components must be laid out like a (fly-by) DDR3 SDRAM UDIMM. The leveling circuitry is enabled by setting the Memory Format to Unbuffered DIMM.

5. In Stratix IV devices, class II termination is not available on row I/Os.

6. Applies to VCCL=1.1 V only. There is no DDR3 SDRAM support for VCCL = 0.9V.
Maximum Number of Interfaces

Table 3–3 shows available device resources for DDR3 SDRAM. Table 3–3 also describes the maximum number of ×8 DDR3 SDRAM components that can be fitted in the smallest and biggest devices and pin packages assuming the device is blank.

Each \( n \) (where \( n \) is a multiple of 8) interface consists of:

- \( n \) DQ pins (including ECC)
- \( n/8 \) DM pins
- \( n/8 \) DQS,DQSn pin pairs
- 17 address pins
- 7 command pins (CAS, RAS, WE, CKE, ODT, reset, and CS)
- 1 CK, CK# pin pair

Unless otherwise noted, this calculation for the maximum number of interfaces is based on independent interfaces where the address or command pins are not shared.

Timing closure depends on device resource and routing utilization.

For more information about timing closure, refer to the Area and Timing Optimization Techniques chapter in the Quartus II Handbook.

You need to share DLLs if your total number of interfaces is more than 4. You may also need to share PLL clock outputs depending on your clock network usage, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.

For information on the number of DQ and DQS in other packages, refer to the DQ and DQS tables in the relevant device handbook.

</table>
Unsupported Features

For features not supported by Altera memory IP, you can create a controller using a custom PHY with the ALTDQ_DQS megafonction. However, you must create the timing constraints and timing analysis methodology to determine your maximum interface frequency. Altera only supports the ALTDQ_DQS part of your design.

Altera DDR3 SDRAM IP does not support the following features:
- Quad-rank RDIMMs and any form of DIMM in Arria II GX devices
- Full-rate designs
- Data widths greater than 80 bits when using leveling
This chapter describes the following specifications when using the Altera QDR II and QDR II+ SRAM IP:

- Maximum clock rate supported
- Maximum number of interfaces
- Unsupported features

### Maximum Clock Rate Support

The QDR II and QDR II+ SRAM controllers with UniPHY give the following support:

- **Burst length:**
  - 4 (half rate)
  - 2 or 4 (full rate)

- **Memory read latency:**
  - 2 and 2.5 for ×9, ×18, and ×36 QDR II+
  - 1.5 for QDR II

Table 4–1 shows supported features at maximum clock rates for QDR II SRAM controllers with UniPHY on various Altera devices. Table 4–2 shows supported features at maximum clock rates for QDR II+ SRAM controllers with UniPHY on various Altera devices.

For recommended termination and drive strength settings, refer to the *Board Layout Guidelines* section in volume 2 of the *External Memory Interface Handbook*.

</table>

Note to Table 4–1:
(1) The same frequency for column, row, and wraparound I/Os.
(2) Not supported with wraparound I/Os.
(3) In Stratix IV devices, class II termination is not available on row I/Os.
(4) VCCL = 0.9 V
Table 4–3 shows available device resources for QDR II and QDR II+ SRAM. Table 4–3 also describes the maximum number of independent QDR II+ or QDR II SRAM interfaces that can be fitted in the smallest and biggest devices and pin packages assuming the device is blank.

One interface of ×36 consists of:

- 36 Q pins
- 36 D pins
- 1 K, K# pin pairs
- 1 CQ, CQ# pin pairs
- 19 address pins
- 4 BSWn pins
Chapter 4: QDR II and QDR II+ SRAM Specifications

Maximum Number of Interfaces

- WPS, RPS
  One interface of ×9 consists of:
  - 9 Q pins
  - 9 D pins
  - 1 K, K# pin pairs
  - 1 CQ, CQ# pin pairs
  - 21 address pins
  - 1 BWSn pin
  - WPS, RPS

Unless otherwise noted, this calculation for the maximum number of interfaces is based on independent interfaces where the address or command pins are not shared.

Timing closure depends on device resource and routing utilization.

For more information about timing closure, refer to the Area and Timing Optimization Techniques chapter in the Quartus II Handbook.

You need to share DLLs if your total number of interfaces is more than 4. You may also need to share PLL clock outputs depending on your clock network usage, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.

For information on the number of DQ and DQS in other packages, refer to the DQ and DQS tables in the relevant device handbook.

Unsupported Features

For features not supported by Altera memory IP, you can create a controller using a custom PHY with the ALTDQ_DQS megafonction. However, you must create the timing constraints and timing analysis methodology to determine your maximum interface frequency. Altera only supports the ALTDQ_DQS part of your design.

Altera QDR II and QDR II+ SRAM IP does not support the following features:

- Multiple chip selects
- Width expansion
- Deterministic latency
- ECC
- Controlled input and output impedance (ODT)

This chapter describes the following specifications when using the Altera RLDRAM II IP:

- Maximum clock rate supported
- Maximum number of interfaces
- Unsupported features

### Maximum Clock Rate Support

The RLDRAM II controller with UniPHY supports the following features:

- Burst length:
  - 4 and 8 (half rate)
  - 2, 4, and 8 (full rate)

Table 5–1 shows supported features at maximum clock rates for RLDRAM II controllers with UniPHY on various Altera devices.

For recommended termination and drive strength settings, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook.

**Note to Table 5–1:**

1. The same frequency for column, row, and wraparound I/Os.
2. In Stratix IV devices, class II termination is not available on row I/Os.
3. Support for VCCL= 1.1V only
Maximum Number of Interfaces

Table 5–2 shows available device resources for RLDRAM II. Table 5–2 also describes the maximum number of independent RLDRAM II interfaces that can be fitted in the smallest and biggest devices and pin packages assuming the device is blank.

One common I/O ×36 interface consists of:
- 36 DQ
- 1 DM pin
- 2 DK, DK# pin pairs
- 2 QK, QK# pin pairs
- 1 CK, CK# pin pair
- 24 address pins
- 1 CS# pin
- 1 REF# pin
- 1 WE# pin
- 1 QVLD pin

One common I/O ×9 interface consists of:
- 9 DQ
- 1 DM pins
- 1 DK, DK# pin pair
- 1 QK, QK# pin pair
- 1 CK, CK# pin pair
- 25 address pins
- 1 CS# pin
- 1 REF# pin
- 1 WE# pin
- 1 QVLD pin

Unless otherwise noted, this calculation for the maximum number of interfaces is based on independent interfaces where the address or command pins are not shared.

Timing closure depends on device resource and routing utilization.

For more information about timing closure, refer to the Area and Timing Optimization Techniques chapter in the Quartus II Handbook.

You need to share DLLs if your total number of interfaces is more than 4. You may also need to share PLL clock outputs depending on your clock network usage, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.
For information on the number of DQ and DQS in other packages, refer to the DQ and DQS tables in the relevant device handbook.

Unsupported Features

For features not supported by Altera memory IP, you can create a controller using a custom PHY with the ALTDQ_DQS megafuction. However, you must create the timing constraints and timing analysis methodology to determine your maximum interface frequency. Altera only supports the ALTDQ_DQS part of your design.

Altera RLDRAM II IP does not support the following features:

- Multiplexed addressing
- Width expansion
- Multiple chip selects
- Separate I/O
- Dynamic read latency change
- ECC
- Multicast write
- VCCL = 0.9 V
■ Controlled input and output impedance (ODT)

1. Select a Device

This chapter is for use as part of the planning stage, to ensure that you know what to look for when selecting the right Altera® FPGA device for your memory interface.

Use this document with “Pin and Resource Planning” on page 2–1, before you start implementing your external memory interface.

Memory controllers in Altera devices require access to dedicated IOE features, PLLs, and several clock networks. Altera devices are feature rich in all these areas, so you must consider detailed resource and pin planning whenever implementing complex IP or multiple IP cores. This chapter provides an overview of what to consider in such instances.

For information about the terms used in this document, refer to the Glossary chapter in volume 1 of the External Memory Interface Handbook.

For more information about supported memory types and configurations, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

When selecting the optimal Altera device for your memory interface, consider the following topics:

- “Memory Standards and Configurations” on page 1–1
- “Bandwidth” on page 1–2
- “Device Pin Count” on page 1–2
- “IP Support” on page 1–4
- “External Memory Interface Features of Altera Devices” on page 1–5

Memory Standards and Configurations

There are two common types of high-speed memories that are supported by Altera devices: DRAM and SRAM. Commonly used DRAM devices are DDR, DDR2, DDR3 SDRAM, and RLDRAM II; SRAM devices include QDR II and QDR II+ SRAM.

Different Altera devices support different memory types; not all Altera devices support all memory types and configurations. Before you start your design, you must select an Altera device, which supports the memory standard and configurations you plan to use.

For more information about these memory standards, refer to the Memory Standard Overview section in volume 1 of the External Memory Interface Handbook.
Bandwidth

Before designing any memory interface, determine the required bandwidth of the memory interface. Bandwidth can be expressed as:

\[
\text{Bandwidth} = \text{data width (bits)} \times \text{data transfer rate (1/s)} \times \text{efficiency}
\]

Data rate transfer (1/s) = 2 × frequency of operation (4 × for QDR SRAM interfaces)

After calculating the bandwidth requirements of your system, determine which memory type and device to use.

DRAM typically has an efficiency of around 70%, but when using the Altera memory controller efficiency can vary from 10 to 92%.

In QDR II+ or QDR II SRAM the IP implements two separate unidirectional write and read data buses, so the data transfer rate is four times the clock rate. The data transfer rate for a 400-MHz interface is 1,600 Mbps. The efficiency is the percentage of time the data bus is transferring data. It is dependent on the type of memory. For example, in a QDR II+ or QDR II SRAM interface with separate write and read ports, the efficiency is 100%, when there is an equal number of read and write operations on these memory interfaces.

In addition, Altera’s FPGA devices support various data widths for different memory interfaces. The memory interface support between density and package combinations differs, so you must determine which FPGA device density and package combination best suits your application.

Device Pin Count

To meet the growing demand for memory bandwidth and memory data rates, memory interface systems use parallel memory channels and multiple controller interfaces. However, the number of memory channels is limited by the package pin count of the Altera devices. Hence, you must consider device pin count when you select a device—you must select a device with enough I/O pins for your memory interface requirement.

The number of device pins depends on the memory standard, the number of memory interfaces, and the memory data width. For example, a ×72 DDR3 SDRAM single-rank interface requires 125 I/O pins:

- 72 DQ pins (including ECC)
- 9 DM pins
- 9 DQS, DQSn differential pin pairs
- 17 address pins (address and bank address)
- 7 command pins (CAS, RAS, WE, CKE ODT, reset, and CS)
- 1 CK, CK# differential pin pair

For the available number of DQS groups and the maximum number of controllers that is supported by the FPGAs for different memory types, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.
Altera devices do not limit the interface widths beyond the following requirements:

- DQS, DQ, clock, and address signals of the entire interface should reside within the same bank or side of the device if possible, to achieve better performance. Although wraparound interfaces are also supported at limited frequencies.

- The maximum possible interface width in any particular device is limited by the number of DQS and DQ groups available within that bank or side.

- Sufficient regional clock networks are available to the interface PLL to allow implementation within the required number of quadrants.

- Sufficient spare pins exist within the chosen bank or side of the device to include all other clock, address, and command pin placement requirements.

- The greater the number of banks, the greater the skew. Altera recommends that you always compile a test project of your desired configuration and confirm that it meets timing requirement.

There is a constraint in Arria® II GX devices when assigning DQS and DQ pins. You are only allowed to use twelve of the sixteen I/O pins in an I/O module for DQ pin. The remaining four pins can only be used as input pin.

For DQS groups pin-out restriction format, refer to Arria II GX Pin Connection Guidelines.

Your pin count calculation also determines which device side to use (top or bottom, left or right, and wraparound).

**Top or Bottom and Left or Right Interfaces**

Ideally any interface should wholly reside in a single bank. However, interfaces that span across multiple adjacent banks or the entire side of a device are also fully supported. Although vertical and horizontal I/O timing parameters are not identical, timing closure can be achieved on all sides of the FPGA for the maximum interface frequency.

Arria II GX, Cyclone® III, and Cyclone IV GX devices support interfaces spanning the top and bottom sides. In addition, Cyclone III devices also supports interfaces spanning left and right sides.

Arria II GX and Cyclone IV GX devices do not support the left interface. There is no user I/O pins, other than the transceiver pins available in these devices.

**Wraparound Interfaces**

For maximum performance, Altera recommends that data groups for external memory interfaces should always be within the same side of a device, ideally reside within a single bank. High-speed memory interfaces using top or bottom I/O bank versus left or right I/O bank have different timing characteristics, so the timing margins are also different. However, Altera can support interfaces with wraparound data groups that wraparound a corner of the device between vertical and horizontal I/O banks at some speeds. Some devices wraparound interfaces are same speed as row or column interfaces.
Arria II GX, Cyclone III and Cyclone IV GX devices can support wraparound interface across all sides of devices that are not used for transceivers. Other Altera devices only support interfaces with data groups that wraparound a corner of the device.

**IP Support**

Altera offers IP solutions to help you create your own external memory interface system. There are two parts of the external memory interface IPs:

- PHY
- Memory controller

For more information on the IP Altera offers, refer to *Volume 3: Implementing Altera Memory Interface IP* of the *External Memory Interface Handbook*.

**PHY**

Altera offers external memory interface PHYs for calibration and tracking mechanisms. These PHYs support full-rate and half-rate interfaces, which you can then plug a custom controller with the PHY using the AFI. For example, the ALTMEMPHY megafunction.

The Altera UniPHY IP provides better performance and lower latency. The UniPHY IP instantiates the PLL and DLL in the top-level design to support multiple interfaces.

Alternatively, you can build a custom PHY using the ALTDLL or ALTDQ_DQS megafonctions. However, you are then responsible for determining the maximum interface frequency of your system and in creating the timing constraints required to create a robust PHY.

For more information about creating custom interfaces, refer to *Volume 5: Implementing Custom Memory Interface PHY* of the *External Memory Interface Handbook*.

**Controllers**

Altera offers controllers for a full solution that you can immediately integrate with your user logic. For example, the DDR, DDR2, or DDR3 SDRAM high-performance controllers, or the RLDRAM II or QDR II controllers with UniPHY. These controllers include the Altera PHY IP and thus provide a simplified interface to DDR, DDR2, DDR3 SDRAM, RLDRAM II, and QDR II and QDR II+ SRAM components.

**Full or Half Rate SDRAM Controller**

When implementing memory controllers consider whether a half-rate or a full-rate datapath is optimal for your design. Full or half-rate designs have the following definitions:

- Full-rate designs present data to the local interface at twice the width of the actual SDRAM interface at the full SDRAM clock rate
- Half-rate designs present data to the local interface at four times the width of the actual SDRAM interface at half the SDRAM clock rate
Implementing half-rate memory controllers results in the highest possible SDRAM clock frequency, at the expense of latency and efficiency. You need to decide whether system efficiency or system bandwidth is more important.

This implementation is most useful when core HDL designs are difficult to implement at the higher SDRAM clock frequency, but the required SDRAM bandwidth per I/O pin is still quite high.

However, full-rate controller operations are faster with the IP operating at the same clock frequency as your system.

Consider that DDR devices can have a number of banks open at once. Each bank has a currently selected row. Changing the column within the selected row of an open bank requires no additional bank management commands to be issued. Changing the row in an active bank, or changing the bank, both incur a protocol penalty that requires the precharge (PCH) command closes the active row or bank, and the activate (ACT) command opens (or activates) the new row or bank combination.

The duration of this penalty is a function of the controller clock frequency, the memory clock frequency, and the memory device characteristics. Calculating the impact of a change of memory and controller configuration on a given system is not a trivial task, as it depends on the nature of the accesses that are performed.

In this example each command takes a single clock cycle in a full-rate controller, but two clock cycles in a half-rate controller. The bank is not available for the subsequent ACT command until \( t_{SP} \) after the PCH. So while the issuing of commands can be slower using a half-rate controller, the respective memory timing parameters remain the same.

Hence, when a design uses a half-rate memory controller, the control circuitry is clocked at half rate and so control operations are slower than a full-rate design. However, the memory’s clock frequency and physical properties are not affected.

## External Memory Interface Features of Altera Devices

This topic describes features from the Altera device families that enable external memory interfaces.

For more information on the external memory interface circuitry in an Altera FPGA device family, refer to the External Memory Interfaces chapter in the relevant device family handbook.

### IOE Dedicated Features

When selecting an Altera device for your external memory system, you must select a device that is equipped with the features that suit your memory system requirements and configurations.

Altera devices have enhanced upon the IOE DDR capabilities by including the feature functionality availability directly in the IOE.

Table 1–1 shows which device families support these features.
To use these features implement one of the Altera high-performance controllers (a complete solution) or Altera PHY IP. Alternatively, you may access these IOE features directly using the following low-level megafunctions:

- **ALTDQ_DQS megafunction**—allows you to parameterize the following features:
  - DDR I/O registers
  - Alignment and synchronization registers
  - Half data rate registers
  - DQS bus mode
- **ALTDLL megafunction**—allows you to parameterize the DQS phase-shift circuitry
- **ALTOCT megafunction**—allows you to parameterize the IOE OCT features.
- **ALTPLL megafunction**—allows you to parameterize the device PLL
- **ALTIOBUF megafunction**—allows you to parameterize the device IO features

Altera offers no support using these low-level megafunctions as an external memory PHY to implement your memory interfaces. If you use low-level megafunctions, you are solely responsible in creating every aspect of the interface, including timing analysis and debugging.
DDR Input and Output Registers

DDR input and output registers are provided on all sides of the Stratix® III and Stratix IV devices. In Arria II GX and Cyclone IV GX devices the left side of the device is not available for interfacing. The DDR I/O structures can be directly implemented in the IOE in these devices, thus saving core logic and ensuring tight skew is easily maintained, which eases timing.

For Cyclone III and Cyclone IV GX devices, the DDR input registers are implemented in the core of the device. For Cyclone III and Cyclone IV GX devices, the read capture clock is derived from the PHY and is generated by the PLL to clock the DDR capture registers instead of using DQS read clock strobe from the memory device.

Synchronization and Alignment Registers

Resynchronization registers resynchronize the data from memory clock domain to the memory controller system clock domain. Alignment registers align the data after read resynchronization or write leveling process.

In some devices, the synchronization registers are located in the core of the device, which makes the placement of these registers with respect to the DDR IOE critical to ensure that timing is achieved. Stratix III and Stratix IV devices have been enhanced to include the alignment and synchronization registers directly within the IOE, hence timing is now significantly improved and you are no longer concerned with ensuring critical register placement with respect to the DDR IOE. Typically, the resynchronization register is clocked via a dedicated output from the PLL. However, it may also be clocked directly from the read-leveling delay chain. The output alignment registers are typically clocked from the PLL.

If the resynchronization clock is sourced from the leveling delay chain, it may be cascaded from bank to bank, say 1A to 1B. In this configuration, memory controllers must form a single contiguous block of DQS groups that are not staggered or interleaved with another memory controller. Additionally, two PHYs cannot share the same subbank as only one leveling delay chain exists per subbank.

Arria II GX, Cyclone III, and Cyclone IV GX devices do not have leveling circuitry, so there is no need for alignment registers. Synchronization registers for Arria II GX devices are implemented in the IOE. These synchronization registers in Cyclone III and Cyclone IV GX devices are implemented in the FPGA core fabric and are clocked directly by the PLL. In Cyclone III and Cyclone IV GX devices, these registers are clocked by the same PLL output clock that also clocks the DDR registers.

Generally, alignment and synchronization registers are optional and can be bypassed if not required. However, Altera external memory interface IP always implements these synchronization registers, regardless of interface speed. Hence latency through the PHY may not be optimal for lower frequency designs.

Half-Rate Data Registers

As external memory interface clock speeds increase, the core \( f_{MAX} \) can become the limiting factor in interface design. A common solution, which increases core \( f_{MAX} \) timing problems, is to implement a half-rate architecture. This solution doubles the data width on the core side interfaces compared to a full-rate SDR solution, but also halves the required operating frequency.
Stratix III and Stratix IV devices include dedicated full-rate to half-rate registers within the IOE.

Arria II GX, Cyclone III, and Cyclone IV GX devices implement half-rate registers in the core of the device.

**DQS Phase-Shift Circuitry**

Devices that use DQS or CQ pins to clock the read data during read operation offer DQS phase-shift circuitry. This circuitry phase shifts the DQS and CQn pins during the transaction, to obtain optimal read capture margin. DQS phase-shift circuitry consists of a DLL and phase offset control block, to further fine tune the DQS phase shift.

Cyclone III and Cyclone IV GX devices do not have this feature, because DQS signals are not needed during read operations at lower frequencies.

**DQS Postamble Circuitry**

DQS postamble circuitry eliminates invalid DQ data capturing, because of the postamble glitches on the DQS signals through an override on DQS. This feature ensures the correct clock cycle timing of the postamble enable signal.

DQS postamble circuitry is only needed in devices that use the DQS scheme in read operation for clocking read data. Arria II GX, Stratix III, Stratix IV devices have this feature.

As Cyclone III and Cyclone IV GX devices do not use DQS for capturing read data, they do not have this circuitry.

**Differential DQS Signaling**

Altera devices (except Cyclone III and Cyclone IV GX devices) directly support differential DQS signalling and the single-ended standard supported in previous device families. DDR SDRAM only supports single-ended DQS, DDR2 SDRAM additionally includes the option of differential DQS signaling. DDR3 SDRAM only supports differential DQS signaling.

Differential DQS signaling is recommended for DDR2 SDRAM designs operating at or above 333 MHz. Differential DQS strobe operation enables improved system timing due to reduced crosstalk and less simultaneous switching noise on the strobe output drivers. You can use single-ended DQS mode for DDR2 SDRAM interfaces, but it requires more pessimistic timing data and hence results in less system timing margin.

Cyclone III and Cyclone IV devices do not support differential signalling and thus do not support DDR3 SDRAM, which requires DQS signaling.

**Read and Write Leveling**

Stratix III and Stratix IV I/O registers include read and write leveling circuitry to enable skew to be removed or applied to the interface on a DQS group basis. There is one leveling circuit located in each I/O subbank.
ALTMEMPHY-based designs for DDR and DDR2 SDRAM (and DDR3 SDRAM without leveling) do not use leveling circuitry, as it is not needed by the memory standard.

ALTMEMPHY-based designs for DDR3 SDRAM DIMMs (and components with fly-by topology like DIMMs) use leveling circuitry.

**Dynamic OCT**

Stratix III and Stratix IV devices support dynamic calibrated OCT. This feature allows the specified series termination to be enabled during writes, and parallel termination to be enabled during reads. These I/O features allow you to greatly simplify PCB termination schemes.

**Clock Divider**

To ease data alignment, a single I/O clock divider may be used for an entire interface, as the half-rate resynchronization clock can be cascaded from DQ group to the adjacent DQ group. Hence, when using a common I/O clock divider, data alignment may be performed across the entire interface. Individual I/O clock dividers require the data alignment to be performed on a DQ group basis.

Stratix III and Stratix IV devices include a dedicated I/O clock divider on a per DQS group basis, to simplify and reduce the number of clocks required. The output of this clock divider can then directly source the half-rate resynchronization clock from the full-rate version.

Arria II GX, Cyclone III, and Cyclone IV GX devices do not have the clock divider feature, and so must use separate PLL output.

ALTMEMPHY-based designs support both balanced (without leveling) and unbalanced (with leveling) CAC topologies. ALTMEMPHY-based designs with leveling designs use multiple I/O clock dividers on a DQ group basis and do not support balanced CAC topologies, as a dedicated resynchronization and half-rate resynchronization clock is required on a per DQS group basis. ALTMEMPHY-based designs without leveling designs use a single I/O clock divider for the whole interface to reduce PHY complexity and reduce latency. However, ALTMEMPHY-based without leveling interfaces cannot be interleaved, because of FPGA limitations.

**Programmable Delay**

I/O registers include programmable delay chains that you may use to deskew interfaces. Each pin can have different delay settings, hence read and write margins can be increased as uncertainties between signals can be minimized.

The DQ-DQS offset scheme is applicable for interfacing systems using QDR II and QDR II+ SRAM, RLDRAM II, DDR, DDR2 and DDR3 SDRAM components for frequencies of 400 MHz and below. For interfacing system using DDR3 SDRAM components with frequencies above 400 MHz, a dynamic deskew scheme improves the timing margins.

For DQ-DQS offset schemes, delay-chains in the IOE shift the offset between DQ and DQS, to meet timing. The offsets employed are FPGA family, speed grade and frequency dependent.
For systems using DDR3 SDRAM interfaces at frequencies above 400 MHz, the timing margins are too small to be fixed by the static DQ-DQS offset scheme. Hence, a dynamic scheme improves the setup and hold margin at the memory component with the DLL set to 8-tap mode. Configurable delay elements and delay-chains in the IOE observe the write window in the DDR3 SDRAM components. This information configures the delays for each individual DQ and DM pins, to meet the memory component setup and hold requirements and reduce skew between DQ and DM pins in a DQS group.

**PLL and DLL**

Altera devices use PLLs to generate the memory controller clocks. The simplest slowest speed memory controllers may only require two clocks (0° system clock and –90° write clock). However, as interface speeds increase, it becomes harder to close timing and so dedicated resynchronization, postamble, and address and command clocks are typically required. Additionally, at higher frequencies the maximum frequency becomes the bottleneck and half-rate designs are the typical solution. Thus complex half high data rate designs require typically 10 clock networks. Altera devices are well equipped to address the clocking requirements of external memory interfaces. This topic describes the availability of PLL and DLL for each of the Altera devices.

**Arria II GX Devices**

Arria II GX devices offer up to six PLLs per device with seven outputs per PLL. Each corner of the device has one PLL. Another two PLLs are located at the middle of the right side of the device.

There is a total maximum of 64 clock networks provided in Arria II GX devices. 16 global clock networks and 48 regional clock networks. Each corner PLL has access to the 8 global clocks and 24 regional clocks. Each middle PLL has access to 4 global clocks and 12 regional clocks.

Arria II GX devices support two DLLs. They are located in the top-left and bottom-right corners of the device. These two DLLs can support a maximum of two different frequencies, with each DLL running at one frequency. Each DLL can have two outputs with different phase offsets, which allows one Arria II GX device to have four different DLL phase-shift settings. Each DLL can access the top, bottom, and right side of the device. Each I/O bank is accessible by two DLLs, giving more flexibility to create multiple frequencies and multiple-type interfaces. The DLL outputs the same DQS delay settings for the different sides of the device.

For more information, refer to the *Clock Networks and PLLs in Arria II GX Devices* chapter and the *External Memory Interfaces* chapter in the *Arria II GX Device Handbook*.

Figure 1–1 shows the PLL and DLL locations in Arria II GX devices.
Consider the following points:

- Each corner PLL in Arria II GX devices connects to eight global clock nets and 24 regional clock nets.
- Center PLLs in Arria II GX devices connect to four maximum global clock nets and 12 regional clock nets.
- Arria II GX devices have two PLLs at the middle of right side of the device and one PLL at each of the corners of the device.
- Dual regional clock nets are created by using a regional clock net from each region. For example, a single dual regional clock net uses two regional clock nets.
If the design uses a dedicated PLL to only generate a DLL input reference clock, the PLL mode must be set to No Compensation or the Quartus® II software forces this setting automatically. No compensation mode is used to minimize jitter. The PLL does not generate other outputs, so it does not need to compensate for any clock paths.

If the design cascades PLLs, the source (upstream) PLL must have a low-bandwidth setting, while the destination (downstream) PLL must have a high-bandwidth setting.

In Arria II GX devices, PLL_5 and PLL_6 on the right side may be cascaded to each other as you can then use the direct connection between these two PLLs instead of going through the clock network. The direct connection is required when you have to cascade PLLs for external memory interface to reduce the output clock jitter from the cascaded PLL. Cascaded PLLs are not recommended for external memory interface designs, as jitter can accumulate with the use of cascaded PLLs. The memory output clock may violate the memory device jitter specification.

Input and output delays are only fully compensated for when the dedicated clock input pins associated with that specific PLL are used as the clock source.

If the clock source for the PLL is not a dedicated clock pin for that specific PLL, jitter is increased, timing margin suffers, and the design may require an additional global or regional clock. Hence, dedicated PLL input clock pin is strongly recommended for clock source for the PLL.

The following additional IP-specific points apply:

- ALTMEMPHY megafunctions require five global clock nets in Arria II GX devices; UniPHY IP requires three global clock networks.
- Ideally, you must pick a PLL and PLL input clock pin that are located on the same side of the device as the memory interface pins.
- You may also share the DLL and PLL static clocks for multiple memory interfaces provided the controllers are on the same side or adjacent side of the device and running at the same memory clock.
- If a single memory interface spans two right-side quadrants, a middle-side PLL must be the source for that interface.

For more information about clock networks, refer to the Clock Networks and PLLs in Arria II GX Devices chapter in volume 1 of the Arria II GX Device Handbook.

Cyclone III and Cyclone IV GX Devices

There are a maximum of four PLLs in Cyclone III and Cyclone IV GX devices with five PLL clock outputs each. Each PLL is located in each corner of the device and drives up to 10 global clock networks. Cyclone III and Cyclone IV GX devices only have global clock network and offer up to 20 global clock networks.

Cyclone III and Cyclone IV GX devices do not have DLL circuitry. Cyclone III and Cyclone IV GX devices use a PLL clock generated by the PHY to clock the read capture register during the read operation. The DQS strobe from the memory component is ignored during the read operation.
For more information, refer to the *Clock Networks and PLLs in Cyclone III Devices* chapter and the *External Memory Interfaces* chapter in the *Cyclone III Device Handbook*.

Figure 1–2 shows the PLL locations and resources in Cyclone III devices.

**Figure 1–2.** PLL Locations in Cyclone III Devices

---

Figure 1–3 shows the PLL locations in Cyclone IV GX devices.
Consider the following points:

- Cyclone III and Cyclone IV GX devices only support global clock networks.
- Each PLL in Cyclone III and Cyclone IV GX devices connects to a maximum of ten global clock networks.
- Cyclone III and Cyclone IV GX devices have a maximum of four PLLs. Each PLL is located at each corner of the device.
- You do not need to set the PLL in With No Compensation mode as the jitter for Cyclone III and Cyclone IV GX PLLs in normal mode is low. Changing the PLL compensation mode may result in inaccurate timing results.
- Cascading PLLs is not supported in Cyclone III and Cyclone IV GX devices.
- Input and output delays are only fully compensated for when the dedicated clock input pins associated with that specific PLL are used as the clock source.
- Ensure the clock source for the PLL is a dedicated clock pin for that specific PLL, to reduce jitter, improve timing margins, and to avoid the design requiring an additional global clock.

The following additional ALTMEMPHY megafuntion-specific points apply:

- ALTMEMPHY megafuntions require four global clock nets in Cyclone III and Cyclone IV GX devices.
- Any PLL on any side of a Cyclone III or Cyclone IV GX device can support an ALTMEMPHY interface. Ideally, you must pick a PLL and PLL input clock pin that are located on the same side of the device as the memory interface pins.
■ You may also share the PLL static clocks for multiple ALTMEMPHY interface, provided the controllers are on the same side or adjacent side of the device and running at the same memory clock.

**Stratix III and Stratix IV Devices**

Stratix III and Stratix IV PLLs have an increased number of outputs and global clock routing resources when compared to earlier device generations. Stratix III and Stratix IV top and bottom PLLs feature 10 output (C) counters, also left and right PLLs feature 7 output (C) counters. This increased number of PLL outputs allows for the use of dedicated clock phases. In previous Stratix II designs, clock phases had to be shared.

In general, each Stratix III or Stratix IV PLL has access to four global clocks (GCLK) and six regional clocks (RCLK) (left and right) or ten RCLK (top and bottom).

Stratix III and Stratix IV devices also feature four DLLs (one located in each corner of the device). Thus the FPGA can support a maximum of four unique frequencies, with each DLL running at one frequency. Each DLL can also support two different phase offsets, which allow a single Stratix III or Stratix IV device to support eight different DLL phase shift settings. Additionally, each DLL can access the two sides adjacent to its location. Thus each I/O bank is accessible by two different DLLs, giving more flexibility when creating multiple frequency and phase shift memory interfaces. Figure 1–4 shows PLL and DLL locations in Stratix III and Stratix IV devices with global and regional clock resources.

For more information, refer to the Clock Networks and PLLs in Stratix III Devices chapter and the External Memory Interfaces chapter in the Stratix III Device Handbook or refer to the Clock Networks and PLLs in Stratix IV Devices chapter and the External Memory Interfaces chapter in the Stratix IV Device Handbook.
Consider the following points:

- Each PLL connects to four maximum global clock nets.
- Top or bottom PLLs connect to ten maximum regional clock nets.
- Left or right PLLs connect to six maximum regional clock nets.
- EP4S…110 and smaller devices have only one PLL located in the middle of each side of the device.
- EP3S…80 and larger devices and EP4S…180 and larger devices have two PLLs in the middle of each side of the device.
- EP3S…200 and larger devices, and also EP4S…290 and larger devices additionally have corner PLLs, which connect to six regional clock nets only.
Dual regional clock nets are created by using a regional clock net from each region. For example, a single dual regional clock net uses two regional clock nets.

If the design uses a dedicated PLL to only generate a DLL input reference clock, the PLL mode must be set to No Compensation, or the Quartus II software forces this setting automatically.

If the design cascades PLLs, the source (upstream) PLL should have a low-bandwidth setting, while the destination (downstream) PLL should have a high-bandwidth setting.

If you are required to cascade two PLLs, use two adjacent PLLs, as you can use a direct connection instead of going through the clock network. The direct connection is required when you have to cascade PLLs for external memory interface to reduce the output clock jitter from the cascaded PLL. Cascaded PLLs are not recommended for external memory interface designs, as jitter can accumulate with the use of cascaded PLLs. The memory output clock may violate the memory device jitter specification.

Input and output delays are only fully compensated for, when the dedicated clock input pins associated with that specific PLL are used as its clock source.

If the clock source for the PLL is not a dedicated clock pin for that specific PLL, jitter is increased, timing margin suffers, and the design may require an additional global or regional clock. Hence, a dedicated PLL input clock pin is recommended for the PLL clock source.

The following additional IP specific points apply for Stratix III and Stratix IV devices:

- ALTMEMPHY megafunctions require one global or regional clock, and six regional clock nets. Hence seven clock nets in total are required. RLDRAM II controller with UniPHY requires one global clock net and four regional clock nets; QDR II SRAM with controller UniPHY requires three regional clock nets.

- Ideally, you should pick a PLL and a PLL input clock pin that are located on the same side of the device as the memory interface pins.

- You may also share the DLL and PLL static clocks for multiple memory interfaces, provided the controllers are on the same side or adjacent side of the device and running at the same memory clock.

- As each PLL can only connect to four global clock nets, while the memory IP requires more than four clock nets, an external memory interface design cannot cross from one side of a device to the other. For example, an external memory interface design can only exist within a dual regional side of a device.

- If a single memory interface spans two top or bottom quadrants, a middle top or bottom PLL must be the source for that interface. The ten dual region clocks that the single interface require should not block the design using the adjacent PLL (if available) for a second interface.

For more information on clock networks, refer to Clock Networks and PLLs in Stratix III Devices in the Stratix III Device Handbook and Clock Networks and PLLs in Stratix IV Devices in the Stratix IV Device Handbook.

For more information on multiple memory controllers, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.
2. Pin and Resource Planning

This chapter is for board designers who need to determine the FPGA pin usage, to create the board layout for the system, as the board design process sometimes occurs concurrently with the RTL design process.

Use this document with the *External Memory Interfaces* chapter of the relevant device family handbook.

All external memory interfaces typically require the following FPGA resources:

- I/O pins
- PLL and clock network
- DLL (not applicable in Cyclone III and Cyclone IV GX devices)
- Other FPGA resources—for example, core fabric logic, and on-chip termination (OCT) calibration blocks

When you know the requirements for your memory interface, you can then start planning how you can architect your system. The I/O pins and internal memory cannot be shared for other applications or memory interfaces. However, if you do not have enough PLLs, DLLs, or clock networks for your application, you may share these resources among multiple memory interfaces or modules in your system.

Ideally, any interface should wholly reside in a single bank. However, interfaces that span multiple adjacent banks or the entire side of a device are also fully supported. In addition, you may also have wraparound memory interfaces, where the design uses two adjacent sides of the device and the memory interface logic resides in a device quadrant. In some cases, top or bottom bank interfaces have higher supported clock rate than left or right or wraparound interfaces.

For the maximum clock rate supported for your memory interface, refer to the *External Memory Interface System Specifications* section in volume 1 of the *External Memory Interface Handbook*.

For information about the terms used in this document, refer to the *Glossary* chapter in volume 1 of the *External Memory Interface Handbook*.

**I/O Pins**

Any I/O banks that do not support transceiver operations in Arria II GX, Cyclone III, Cyclone IV GX, Stratix III, and Stratix IV devices, support memory interfaces. However, DQS (data strobe or data clock) and DQ (data) pins are listed in the device pin tables and fixed at specific locations in the device. You must adhere to these pin locations as these locations are optimized in routing to minimize skew and maximize margin. Always check the external memory interfaces chapters for the number of DQS and DQ groups supported in a particular device and the pin table for the actual locations of the DQS and DQ pins.
For maximum performance and best skew across the interface, each required memory interface should completely reside within a single I/O bank, or at least one side of the device. Address and command pins can be constrained in a different side of the device if there are not enough pins available. For example, you may have the read and write data pins on the top side of the device, and have the address and command pins on the left side of the device. In memory interfaces with unidirectional data, you may also have all the read data pins on the top side of the device and the write data pin on the left side of the device. However, you should not break a unidirectional pin group across multiple sides of the device. Memory interfaces typically have the following pin groups:

- Write data pin group and read data pin group
- Address and command pin group

Table 2–1 shows a summary of the number of pins required for various example memory interfaces. Table 2–1 uses series OCT with calibration, parallel OCT with calibration, or dynamic calibrated OCT, when applicable, shown by the usage of R\textsubscript{UP} and R\textsubscript{DN} pins.

For the memory device pin description, refer to the Memory Standard Overview section in volume 1 of the External Memory Interface Handbook.

</table>
For more information on the following topics, refer to the External Memory Interface chapter of the relevant FPGA family handbook.

Maximum interface width varies from device to device depending on the number of I/O pins and DQS or DQ groups available. Achievable interface width also depends on the number of address and command pins that the design requires. To ensure adequate PLL, clock, and device routing resources are available, you should always test fit any IP in the Quartus II software before PCB sign-off.

Altera devices do not limit the width of external memory interfaces beyond the following requirements:

- Maximum possible interface width in any particular device is limited by the number of DQS groups available.
- Sufficient clock networks are available to the interface PLL as required by the IP.
- Sufficient spare pins exist within the chosen bank or side of the device to include all other address and command, and clock pin placement requirements.
- The greater the number of banks, the greater the skew, hence Altera recommends that you always generate a test project of your desired configuration and confirm that it meets timing.

While you should use the Quartus II software for final pin fitting, you can estimate whether you have enough pins for your memory interface using the following steps:
1. Find out how many read data pins are associated per read data strobe or clock pair, to determine which column of the DQS and DQ group availability (×4, ×8/×9, ×16/×18, or ×32/×36) look at the pin table.

2. Check the device density and package offering information to see if you can implement the interface in one I/O bank or on one side or on two adjacent sides.

   If you target Arria II GX devices and you do not have enough I/O pins to have the memory interface on one side of the device, you may place them on the other side of the device. Arria II GX devices are the only family that allow a memory interface to span across the top and bottom sides of the device.

3. Calculate the number of other memory interface pins needed, including any other clocks (write clock or memory system clock), address, command, R_UP and R_DOWN, and any other pins to be connected to the memory components. Ensure you have enough pins to implement the interface in one I/O bank or one side or on two adjacent sides.

   The DQS groups in Arria II GX devices reside on I/O modules, each consisting of 16 I/O pins. You can only use a maximum of 12 pins per I/O modules when the pins are used as DQS or DQ pins or HSTL/SSTL output or HSTL/SSTL bidirectional pins. When counting the number of available pins for the rest of your memory interface, ensure you do not count the leftover four pins per I/O modules used for DQS, DQ, address and command pins. The leftover four pins can be used as input pins only.

   Refer to the device pinout tables and look for the blank space in the relevant DQS group column to identify the four pins that cannot be used in an I/O module.

You should always try the proposed pinouts with the rest of your design in the Quartus II software (with the correct I/O standard and OCT connections) before finalizing the pinouts, as there may be some interactions between modules that are illegal in the Quartus II software that you may not find out unless you try compiling a design and use the Quartus II Pin Planner.

**OCT Support for Arria II GX, Stratix III, and Stratix IV Devices**

This section is not applicable to Cyclone III and Cyclone IV GX devices as OCT is not used by the Altera IP.

   If you use OCT for your memory interfaces, refer to the Device I/O Features chapter in the Cyclone III or Cyclone IV GX Device Handbook.

If your system uses any FPGA OCT calibrated series, parallel, or dynamic termination for any I/O in your design, you need a calibration block for the OCT circuitry. This calibration block is not required to be within the same bank or side of the device as the I/O pins it is serving. However, the block requires a pair of R_UP and R_DOWN pins that must be placed within an I/O bank that has the same V_CCIO voltage as the V_CCIO voltage of the I/O pins that use the OCT calibration block.
The R_UP and R_DN pins in Stratix III and Stratix IV devices are dual functional pins that can also be used as DQ and DQS pins in Stratix III and Stratix IV devices when they are not used to support OCT, giving the following impacts on your DQS groups:

- If the R_UP and R_DN pins are part of a ×4 DQS group, you cannot use that DQS group in ×4 mode.

- If the R_UP and R_DN pins are part of a ×8 DQS group, you can only use this group in ×8 mode if either of the following conditions apply:
  - You are not using DM or BWSn pins.
  - You are not using a ×8 or ×9 QDR II and QDR II+ SRAM devices, as the R_UP and R_DN pins may have dual purpose function as the CQn pins. In this case, pick different pin locations for R_UP and R_DN pins, to avoid conflict with memory interface pin placement. You have the choice of placing the R_UP and R_DN pins in the same bank as the write data pin group or address and command pin group.

1 The QDR II and QDR II+ SRAM controller with UniPHY do not support ×8 QDR II and QDR II+ SRAM devices in the Quartus II software version 9.1.

- You are not using complementary or differential DQS pins

A DQS/DQ ×8/×9 group in Stratix III and Stratix IV devices comprises 12 pins. A typical ×8 memory interface consists of one DQS, one DM, and eight DQ pins which add up to 10 pins. If you choose your pin assignment carefully, you can use the two extra pins for R_UP and R_DN. However, if you are using differential DQS, you do not have enough pins for R_UP and R_DN as you only have one pin leftover. In this case, as you do not have to put the OCT calibration block with the DQS or DQ pins, you can pick different locations for the R_UP and R_DN pins. As an example, you can place it in the I/O bank that contains the address and command pins, as this I/O bank has the same V_{CCIO} voltage as the I/O bank containing the DQS and DQ pins.

There is no restriction when using ×16/×18 or ×32/×36 DQS groups that include the ×4 groups when pin members are used as R_UP and R_DN pins, as there are enough extra pins that can be used as DQS or DQ pins.

You need to pick your DQS and DQ pins manually for the ×8, ×9, ×16 and ×18, or ×32 and ×36 groups, if they are using R_UP and R_DN pins within the group. The Quartus II software may not place these pins optimally and may give you a no-fit.

**General Pinout Guidelines**

Altera recommends that you place all the pins for one memory interface (attached to one controller) on the same side of the device. For projects where I/O availability is a challenge and therefore it is necessary spread the interface on two sides, for optimal performance, place all the input pins on one side, and the output pins on an adjacent side of the device along with their corresponding source-synchronous clock.
For a unidirectional data bus as in QDR II and QDR II+ SRAM interfaces, do not split a read data pin group or a write data pin group onto two sides. It is also strongly recommended not to split the address and command group onto two sides either, especially when you are interfacing with QDR II and QDR II+ SRAM burst-length-of-two devices, where the address signals are double data rate also. Failure to adhere to these rules may result in timing failure.

In addition, there are some exceptions for the following interfaces:

- ×36 emulated QDR II and QDR II+ SRAM in Arria II GX, Stratix III and Stratix IV devices
- RLDRAM II CIO devices—RLDRAM II SIO pinout guidelines are covered in the general pinout guidelines
- QDR II/+ SDRAM burst-length-of-two devices

You need to compile the design in Quartus II to ensure that you are not violating signal integrity and Quartus II placement rules, which is critical when you have transceivers in the same design.

The following list gives some general guidelines on how to place pins optimally for your memory interfaces:

1. For Arria II GX, Stratix III, and Stratix IV designs, if you are using OCT, the R_UP and R_DN pins need to be in any bank with the same I/O voltage as your memory interface signals and often use two DQS and DQ pins from a group. If you decide to place the R_UP and R_DN pins in a bank where the DQS and DQ groups are used, place these pins first and then see how many DQ pins you have left after, to find out if your data pins can fit in the remaining pins. Refer to “OCT Support for Arria II GX, Stratix III, and Stratix IV Devices” on page 2–4.

2. Use the PLL that is on the same side of the memory interface. If the interface is spread out on two adjacent sides, you may use the PLL that is located on either adjacent side. You must use the dedicated input clock pin to that particular PLL as the reference clock for the PLL as the input of the memory interface PLL cannot come from the FPGA clock network.

3. The Altera IP uses the output of the memory interface PLL for the DLL input reference clock. Therefore, ensure you pick a PLL that can directly feed a suitable DLL.

Alternatively, you can use an external pin to feed into the DLL input reference clock. The available pins are also listed in the External Memory Interfaces chapter of the relevant device family handbook. You can also activate an unused PLL clock outputs, set it at the desired DLL frequency, and route it to a PLL dedicated output pin. Connect a trace on the PCB from this output pin to the DLL reference clock pin, but be sure to include any signal integrity requirements such as terminations.

4. Read data pins require the usage of DQS and DQ group pins to have access to the DLL control signals.
In addition, QVLD pins in RLDRAM II and QDR II+ SRAM must use DQS group pins, when the design uses the QVLD signal. None of the Altera IP uses QVLD pins as part of read capture, so theoretically you do not need to connect the QVLD pins if you are using the Altera solution. It is good to connect it anyway in case the Altera solution gets updated to use QVLD pins.

5. The read data strobe or read data clock must connect to a DQS pin. In differential clocking (DDR3/DDR2 SDRAM and RLDRAM II interfaces), connect the negative leg of the read data strobe or clock to a DQSn pin. In complementary clocking (QDR II and QDR II+ SRAM interfaces), connect the complement clock (CQn) pin to the CQn pin (and not the DQSn pin) from the pin table.

6. Write data (if unidirectional) and data mask pins (DM or BWSn) pins must use DQS groups. While the DLL phase shift is not used, using DQS groups for write data minimizes skew, and must use the SW and TCCS timing analysis methodology.

7. Place the write data strobe or write data clock (if unidirectional) in the corresponding DQS/DQSn pin with the write data groups that place in DQ pins (except in RLDRAM II CIO devices, refer to “Pinout Rule Exceptions” on page 2–8)

When interfacing with a DDR, or DDR2, or DDR3 SDRAM without leveling, put the three CK and CK# pairs in a single \( \times 4 \) DQS group to minimize skew between clocks and maximize margin for the \( t_{DQSS} \), \( t_{DSS} \), and \( t_{DSH} \) specifications from the memory devices.

8. Place memory clock pins in the following way:

- For DDR and DDR2 SDRAM, if you are using single-ended DQS signaling, use any DIFFOUT pins in the same bank or on the same side as the data pins. If you are using differential DQS signaling, the first CK/CK# pairs (namely \( \text{mem}_{-}\text{clk}[0] \) or \( \text{mem}_{-}\text{clk}_{-}\text{n}[0] \) in the IP) must use any unused DIFFIO_RX pins in the same bank or on the same side as the data pins. You can use either
side of the device for wraparound interfaces. This placement allows the mimic path, for IP VT tracking, to go through differential I/O buffers, to mimic the differential DQS signals. Any other CK and CK# pairs \( \text{mem clk}[n:1] \) and \( \text{mem clk n}[n:1] \) can use any unused \( \text{DIFFOUT} \) pins in the same bank or on the same side as the data pins.

- For DDR3 SDRAM, place the first CK and CK# pairs (namely \( \text{mem clk}[0] \) or \( \text{mem clk n}[0] \) in the IP) and any unused \( \text{DIFFIO_RX} \) pins in the same bank or on the same side as the data pins. You can use either side of the device for wraparound interfaces. This placement allows the mimic path that the IP VT tracking uses to go through differential I/O buffers to mimic the differential DQS signals. Any other CK and CK# pairs \( \text{mem clk}[n:1] \) and \( \text{mem clk n}[n:1] \) can use any unused \( \text{DIFFOUT} \) pins in the same bank or on the same side as the data pins.

- For QDR II and QDR II+ SRAM, place the K and K# signal on the DQS and DQSn pins associated with the write data pins. The C and C# clock pins should also be placed within the write data DQS groups.

- For RLDRAM II, place any differential output-capable pins in the same bank as the address and command pins

9. Place any address pins on any user I/O pin. To minimize skew within the address pin group, you should place address and command pins in the same bank or side of the device.

10. Place command pins on any I/O pins and place in the same bank or device side as the other memory interface pins, especially address and memory clock pins. The memory device usually uses the same clock to register address and command signals.

In QDR II and QDR II+ SRAM interfaces where the memory clock also registers the write data, place the address and command pins in the same I/O bank or same side as the write data pins, to minimize skew.

### Pinout Rule Exceptions

The following sub sections described exceptions to the rule described in the “General Pinout Guidelines” on page 2–5.

#### Exceptions for ×36 Emulated QDR II and QDR II+ SRAM Interfaces in Arria II GX, Stratix III and Stratix IV Devices

A few packages in the Arria II GX, Stratix III, and Stratix IV device families do not offer any ×32/×36 DQS groups where one read clock or strobe is associated with 32 or 36 read data pins. This limitation exists in the following I/O banks:

- All I/O banks in U358-pin and F572 packages for all Arria II GX devices
- All I/O banks in F484-pin packages for all Stratix III devices
- All I/O banks in F780-pin and F1152-pin packages for all Stratix III and Stratix IV devices
- Side I/O banks in F1517-pin and F1760-pin packages for all Stratix III devices

Side I/O banks in F1517-, F1760-, and F1932-pin packages for all Stratix IV devices

This limitation limits support for ×36 QDR II and QDR II+ SRAM devices. To support these memory devices, this following section describes how you can emulate the ×32/×36 DQS groups for these devices.

The maximum frequency supported in ×36 QDR II and QDR II+ SRAM interfaces using ×36 emulation is lower than the maximum frequency when using a native ×36 DQS group.

The F484-pin package in Stratix III devices cannot support ×32/×36 DQS group emulation, as it does not support ×16/×18 DQS groups.

To emulate a ×32/×36 DQS group, combine two ×16/×18 DQS groups together. For ×36 QDR II and QDR II+ SRAM interfaces, the 36-bit wide read data bus uses two ×16/×18 groups; the 36-bit wide write data uses another two ×16/×18 groups or four ×8/×9 groups. The CQ and CQn signals from the QDR II and QDR II+ SRAM device traces are then split on the board to connect to two pairs of CQ/CQn pins in the FPGA. You may then need to split the QVLD pins also (if you are connecting them). These connections are the only connections on the board that you need to change for this implementation. There is still only one pair of K and Kn# connections on the board from the FPGA to the memory (see Figure 2–1). Use an external termination for the CQ/CQn signals at the FPGA end. You can use the FPGA OCT features on the other QDR II interface signals with ×36 emulation. In addition, there may be extra assignments to be added with ×36 emulation.

Other QDR II and QDR II+ SRAM interface rules also apply for this implementation.

You may also combine four ×9 DQS groups (or two ×9 DQS groups and one ×18 group) on the same side of the device, if not the same I/O bank, to emulate a x36 write data group, if you need to fit the QDR II interface in a particular side of the device that does not have enough ×18 DQS groups available for write data pins. Altera does not recommend using ×4 groups as the skew may be too large, as you need eight ×4 groups to emulate the ×36 write data bits.

You cannot combine four ×9 groups to create a ×36 read data group as the loading on the CQ pin is too large and hence the signal is degraded too much.

When splitting the CQ and CQn signals, the two trace lengths that go to the FPGA pins must be as short as possible to reduce reflection. These traces must also have the same trace delay from the FPGA pin to the Y or T junction on the board. The total trace delay from the memory device to each pin on the FPGA should match the Q trace delay (Tq).

You must match the trace delays. However, matching trace length is only an approximation to matching actual delay.
Figure 2–1. Board Trace Connection for Emulated x36 QDR II and QDR II+ SRAM Interface
Timing Impact on x36 Emulation

With x36 emulation, the CQ/CQn signals are split on the board, so these signals see two loads (to the two FPGA pins)—the DQ signals still only have one load. The difference in loading gives some slew rate degradation, and a later CQ/CQn arrival time at the FPGA pin.

The slew rate degradation factor is taken into account during timing analysis when you indicate in the ALTMEMPHY Preset Editor that you are using x36 emulation mode. However, you must determine the difference in CQ/CQn arrival time as it is highly dependent on your board topology.

The slew rate degradation factor for x36 emulation assumes that CQ/CQn has a slower slew rate than a regular x36 interface. The slew rate degradation is assumed not to be more than 500 ps (from 10% to 90% $V_{CCO}$ swing). You may also modify your board termination resistor to improve the slew rate of the x36-emulated CQ/CQn signals. If your modified board does not have any slew rate degradation, you do not need to enable the x36 emulation timing in the ALTMEMPHY wizard.

For more information on how to determine the CQ/CQn arrival time skew, see “Determining the CQ/CQn Arrival Time Skew” on page 2-12.

Because of this effect, the maximum frequency supported using x36 emulation is lower than the maximum frequency supported using a native x36 DQS group, as indicated in the Stratix III and Stratix IV device family handbook.

Rules to Combine Groups

For information about group combining in Arria II GX devices, refer to the External Memory Interface chapter in the Arria II GX Device Handbook.

For devices that do not have four x16/x18 groups in a single side of the device to form two x36 groups for read and write data, you can form one x36 group on one side of the device, and another x36 group on the other side of the device. All the read groups have to be on the same edge (column I/O or row I/O) and all write groups have to be on the same type of edge (column I/O or row I/O), so you can have an interface with the read group in column I/O and the write group in row I/O. The only restriction is that you cannot combine an x18 group from column I/O with an x18 group from row IO to form a x36-emulated group.

For vertical migration with the x36 emulation implementation, check if migration is possible and enable device migration in the Quartus II software.

I/O bank 1C in both Stratix III and Stratix IV devices has dual-function configuration pins. Some of the DQS pins may not be available for memory interfaces if these are used for device configuration purposes.

Each side of the device in these packages has four remaining x8/x9 groups. You can combine four of the remaining for the write side (only) if you want to keep the x36 QDR II and QDR II+ SRAM interface on one side of the device, by changing the Memory Interface Data Group default assignment, from the default 18 to 9.
The ALTMEMPHY megafunction does not support ×36 mode emulation wraparound interface, where the ×36 group consists of a ×18 group from the top/bottom I/O bank and a ×18 group from the side I/O banks.

**Determining the CQ/CQn Arrival Time Skew**

Before compiling a design in Quartus II, you need to determine the CQ/CQn arrival time skew based on your board simulation. You then need to apply this skew in the `report_timing.tcl` file of your QDR II and QDR II+ SRAM interface in the Quartus II software. Figure 2–2 shows an example of a board topology comparing an emulated case where CQ is double-loaded and a non-emulated case where CQ only has a single load.

**Figure 2–2. Board Simulation Topology Example**

Run the simulation and look at the signal at the FPGA pin. Figure 2–3 shows an example of the simulation results from Figure 2–2. As expected, the double-loaded emulated signal, in pink, arrives at the FPGA pin later than the single-loaded signal, in red. You then need to calculate the difference of this arrival time at V\(_{\text{REF}}\) level (0.75 V in this case). Record the skew and re-run the simulation in the other two cases (slow-weak and fast-strong). To pick the largest and smallest skew to be included in Quartus II timing analysis, follow these steps:

1. Open the `<variation_name>_report_timing.tcl` and search for `tmin_additional_dqs_variation`.
2. Set the minimum skew value from your board simulation to `tmin_additional_dqs_variation`.
3. Set the maximum skew value from your board simulation to `tmax_additional_dqs_variation`.

4. Save the `.tcl` file.

**Exceptions for RLDRAM II Interfaces**

RLDRAM II CIO devices have one bidirectional bus for the data, but there are two different sets of clocks: one for read and one for write. As the QK and QK# already occupies the DQS and DQSn pins needed for read, placement of DK and DK# pins are restricted due to the limited number of pins in the FPGA. This limitations causes the exceptions to the previous rules, which are discussed in the following sections.

DK and DK# signals need to use DQS- and DQSn-capable pins to ensure accurate timing analysis, as the TCCS specifications are characterized using DQS and DQSn pins. As you must use the DQS and DQSn pins for the DQS group to connect to QK and QK# pins, pick a pair of DQ pins that are DQS and DQSn pins when configured as a smaller DQS group size. For example, if the interfaces uses a ×16/×18 DQS group, the DQS and DQSn pins connect to QK and QK# pins, pick differential DQ pin pairs from that DQS group that are DQS and DQSn pins for ×8/×9 DQS groups or ×4 DQS groups.

**Interfacing with ×9 RLDRAM II CIO Devices**

These devices have the following pins:

- 2 pins for QK and QK# signals
- 9 DQ pins (in a ×8/×9 DQS group)
2–14 Chapter 2: Pin and Resource Planning

Pinout Rule Exceptions

Device and Pin Planning © November 2009 Altera Corporation

Preliminary

■ 2 pins for DK and DK# signals
■ 1 DM pin
■ 1 QVLD pins
■ 15 pins total

In the FPGA, the ×8/×9 DQS group consists of 12 pins: 2 for the read clocks and 10 for the data. In this case, move the QVLD (if you want to keep this connected even though this is not used in the Altera memory interface solution) and the DK and DK# pins to the adjacent DQS group. If that group is in use, move to any available user I/O pins in the same I/O bank. The DK and DK# must use DQS- and DQSn-capable pins.

Interfacing with ×18 RLDRAM II CIO Devices

These devices have the following pins:
■ 4 pins for QK/QK# signals
■ 18 DQ pins (in ×8/×9 DQS group)
■ 2 pins for DK/DK# signals
■ 1 DM pin
■ 1 QVLD pins
■ 26 pins total

In the FPGA, you use two ×8/×9 DQS group totaling 24 pins: 4 for the read clocks and 20 for the data. In this case, move the DK and DK# pins to DQS- and DQSn-capable pins in the adjacent DQS group. Or if that group is in use, move to any DQS- and DQSn-capable pins in the same I/O bank.

Each ×8/×9 group has one DQ pin left over that can either use QVLD or DM, so one ×8/×9 group has the DM pin associated with that group and one ×8/×9 group has the QVLD pin associated with that group.

Interfacing with RLDRAM II ×36 CIO Devices

These devices have the following pins:
■ 4 pins for QK/QK# signals
■ 36 DQ pins (in x16/x18 DQS group)
■ 4 pins for DK/DK# signals
■ 1 DM pins
■ 1 QVLD pins
■ 46 pins total

In the FPGA, you use two ×16/×18 DQS groups totaling 48 pins: 4 for the read clocks and 36 for the read data. Configure each ×16/×18 DQS group to have:
■ Two QK/QK# pins occupying the DQS/DQSn pins
■ Pick two DQ pins in the ×16/×18 DQS groups that are DQS and DQSn pins in the ×4 or ×8/×9 DQS groups for the DK and DK# pins
■ 18 DQ pins occupying the DQ pins
There are two DQ pins leftover that you can use for QVLD or DM pins. Put the DM pin in the group associated with DK[1] and the QVLD pin in the group associated with DK[0].

Check that DM is associated with DK[1] for your chosen memory component.

Exceptions for QDR II and QDR II+ SRAM Burst-Length-Of-Two Interfaces

Altera IP does not support QDR II and QDR II+ SRAM burst-length-of-two devices. If you are using the QDR II SRAM controller with UniPHY or creating your own interface for QDR II and QDR II+ SRAM burst-length-of-two devices, you may want to place the address pins in a DQS group also, because these pins are now double data rate too. The address pins typically do not exceed 22 bits, so you may use one ×18 DQS groups or two ×9 DQS groups on the same side of the device, if not the same I/O bank. In Stratix III and Stratix IV devices, one ×18 group typically has 22 DQ bits and 2 pins for DQS/DQSn pins, while one ×9 group typically has 10 DQ bits with 2 pins for DQS/DQSn pins. Using ×4 DQS groups should be a last resort.

Pin Connection Guidelines Tables

Table 2–2 shows the FPGA pin utilizations for DDR, DDR2 SDRAM, and DDR3 SDRAM without leveling interfaces.

PLLs and Clock Networks

The exact number of clocks and hence PLLs required in your design depends greatly on the memory interface frequency, and the IP that your design uses.

For example, you can build simple DDR slow-speed interfaces that typically require only two clocks: system and write. You can then use the rising and falling edges of these two clocks to derive four phases (0, 90, 180, and 270°). However, as clock speeds increase, the timing margin decreases and additional clocks are required, to optimize setup and hold and meet timing. Typically, at higher clock speeds, you need to have dedicated clocks for resynchronization, and address and command paths.

In addition, some memory controller designs that use the ALTMEMPHY megafuntion, use a VT tracking clock to measure and compensate for VT changes and their effects.
Altera memory interface IP uses one PLL, which generates the various clocks needed in the memory interface data path and controller, and provides the required phase shifts for the write clock and address and command clock. The PLL is instantiated when you generate the Altera memory interface MegaCore functions or megafUNCTIONs.

By default, the PLL also generates the input reference clock for the DLL, available in all device families except for the Cyclone III and Cyclone IV GX devices. This method eliminates the need of an extra pin for the DLL input reference clock.

The input reference clock to the DLL can come from certain input clock pins or clock output from certain PLLs.

For the actual pins and PLLs connected to the DLLs, refer to the External Memory Interfaces chapter of the relevant device family handbook.

You must use the PLL located in the same device quadrant or side as the memory interface and the corresponding dedicated clock input pin for that PLL, to ensure optimal performance and accurate timing results from the Quartus II software. The input clock to the PLL should not fan out to any logic other than the PHY, as you cannot use a global clock resource for the path between the clock input pin to the PLL.

Table 2–7 and Table 2–8 show a comparison of the number of PLLs and dedicated clock outputs available respectively in Arria II GX, Cyclone III, Stratix III, and Stratix IV devices.

In every ALTMEMPHY solution, the measure_clk and resynch_clk_2x clocks (Table 2–11) are calibrated and hence may not be shared or used for other modules in your system. You may be able to share the other statically phase-shifted clocks with other modules in your system provided that you do not change the clock network used.

Changing the clock network that the ALTMEMPHY solution uses may affect the output jitter, especially if the clock is used to generate the memory interface output pins. Always check the clock network output jitter specification in the DC and Switching Characteristics chapter of the device handbook, before changing the ALTMEMPHY clock network, to ensure that it meets the memory standard jitter specifications, which includes period jitter, cycle-to-cycle jitter and half duty cycle jitter.

If you need to change the resynch_clk_2x clock network, you have to change the measure_clk_1x clock network also to ensure accurate VT tracking of the memory interface.

For more information about sharing clocks in multiple controllers, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.

In addition, you should not change the PLL clock numbers as the wizard-generated .sdc file assumes certain counter outputs from the PLL (Table 2–12 through Table 2–13).

---

**Notes to Table 2–11:**

1. For more information on the clocks used in the ALTMEMPHY megafunction, refer to the Clock Networks and PLL chapter of the respective device family handbook for more details.
2. This clock should be of the same clock network clock as the resync_clk_2x clock.
PLL Cascading

Stratix III PLLs, Stratix IV PLLs, and the two middle PLLs in Arria II GX EP2AGX125 EP2AGX190, and EP2AGX260 devices can be cascaded using either the global or regional clock trees, or the cascade path between two adjacent PLLs.

</table>
Use this feature at your own risk. You should use faster memory devices to maximize timing margins.

Cyclone III and Cyclone IV GX devices do not support PLL cascading for external memory interfaces.

ALTMEMPHY supports PLL cascading using the cascade path without any additional timing derating when the bandwidth and compensation rules are followed. The timing constraints and analysis assume that there is no additional jitter due to PLL cascading when the upstream PLL uses no compensation and low bandwidth, and the downstream PLL uses no compensation and high bandwidth.

ALTMEMPHY does not support PLL cascading using the global and regional clock networks. You can implement PLL cascading at your own risk without any additional guidance and specifications from Altera. The Quartus II software does issue a critical warning suggesting use of the cascade path to minimize jitter, but does not explicitly state that Altera does not support cascading using global and regional clock networks.

The Quartus II software does not issue a critical warning stating that Cyclone III ALTMEMPHY designs do not support PLL cascading; it issues the Stratix III warning message requiring use of cascade path.

Some Arria II GX devices (EP2AGX125, EP2AGX190, and EP2AGX260) have direct cascade path for two middle right PLLs. Arria II GX PLLs have the same bandwidth options as Stratix IV GX left and right PLLs.

The Altera memory interface IP uses one DLL (except in Cyclone III and Cyclone IV GX devices, where this resource is not available). The DLL is located at the corner of the device and can send the control signals to shift the DQS pins on its adjacent sides for Stratix-series devices, or DQS pins in any I/O banks in Arria II GX devices.

For example, the top-left DLL can shift DQS pins on the top side and left side of the device. The DLL generates the same phase shift resolution for both sides, but can generate different phase offset to the two different sides, if needed. Each DQS pin can be configured to use or ignore the phase offset generated by the DLL.

The DLL cannot generate two different phase offsets to the same side of the device. However, you can use two different DLLs to for this functionality.

DLL reference clocks must come from either dedicated clock input pins located on either side of the DLL or from specific PLL output clocks. Any clock running at the memory frequency is valid for the DLLs.

To minimize the number of clocks routed directly on the PCB, typically this reference clock is sourced from the memory controllers PLL. In general, DLLs can use the PLLs directly adjacent to them (corner PLLs when available) or the closest PLL located in the two sides adjacent to its location.

By default, the DLL reference clock in Altera external memory IP is from a PLL output.
When designing for 780-pin packages with SE80, SE110 and SL150 devices, the PLL to DLL reference clock connection is limited.

Figure 2–6 shows the 780-pin package devices PLL and DLL reference clock connections. DLL3 is isolated from a direct PLL connection and can only receive a reference clock externally from pins \( \text{clk}[11:4] \).

**Figure 2–6. PLL and DLL Reference Clock Connections in 780-pin Package Devices**

The DLL reference clock should be the same frequency as the memory interface, but the phase is not important.

The required DQS capture phase is optimally chosen based on operating frequency and external memory interface type (DDR, DDR2, DDR3 SDRAM, and QDR II SRAM, or RLDRAM II). As each DLL supports two possible phase offsets, two different memory interface types operating at the same frequency can easily share a single DLL. More may be possible, depending on the phase shift required.

Altera memory IP always specifies a default optimal phase setting, to override this setting, refer to the **DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide** section and the **DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide** section in volume 3 of the **External Memory Interface Handbook**.
When sharing DLLs, your memory interfaces must be of the same frequency. If the required phase shift is different amongst the multiple memory interfaces, you can use a different delay chain in the DQS logic block or use the DLL phase offset feature.

To simplify the interface to IP connections, multiple memory interfaces operating at the same frequency usually share the same system and static clocks as each other where possible. This sharing minimizes the number of dedicated clock nets required and reduces the number of different clock domains found within the same design.

As each DLL can directly drive four banks, but each PLL only has complete C (output) counter coverage of two banks (using dual regional networks), situations can occur where a second PLL operating at the same frequency is required. As cascaded PLLs increase jitter and reduce timing margin, you are advised to first ascertain if an alternative second DLL and PLL combination is not available and more optimal.

Select a DLL that is available for the side of the device where the memory interface resides. If you select a PLL or a PLL input clock reference pin that can also serve as the DLL input reference clock, you do not need an extra input pin for the DLL input reference clock.

**Other FPGA Resources**

The Altera memory interface IP uses FPGA fabric, including registers and the TriMatrix Memory Block to implement the memory interface.

For resource utilization examples to ensure that you can fit your other modules in the device, refer to the DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section and the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section in volume 3 of the External Memory Interface Handbook.

In addition, one OCT calibration block is used if you are using the FPGA OCT feature in the memory interface. The OCT calibration block uses two pins (RUP and RDN), (“OCT Support for Arria II GX, Stratix III, and Stratix IV Devices” on page 2–4). You can select any of the available OCT calibration block as you do not need to place this block in the same bank or device side of your memory interface. The only requirement is that the I/O bank where you place the OCT calibration block uses the same $V_{CCIO}$ voltage as the memory interface. You can share multiple memory interfaces with the same OCT calibration block if the $V_{CCIO}$ voltage is the same.

Even though Cyclone III devices support OCT, this feature is not turned on by default in the Altera IP solution.
Section II. Board Layout Guidelines

This chapter recommends the ideal termination schemes for the DDR2 SDRAM interface with Arria® GX, Arria II GX, Cyclone® II, Cyclone III, Stratix® III, and Stratix IV devices.

This chapter focuses on the following key factors that affect signal quality at the receiver:

- Proper use of termination
- Output driver drive strength setting
- Loading at the receiver
- Layout guidelines

As memory interface performance increases, board designers must pay closer attention to the quality of the signal seen at the receiver because poorly transmitted signals can dramatically reduce the overall data-valid margin at the receiver. Figure 1–1 shows the differences between an ideal and real signal seen by the receiver.

**Figure 1–1.** Ideal and Real Signal at the Receiver

In addition, this chapter compares various types of termination schemes, and their effects on the signal quality on the receiver. It also discusses the proper drive strength setting on the FPGA to optimize the signal integrity at the receiver, and the effects of different loading types, such as components versus DIMM configuration, on signal quality. Finally, this chapter provides DDR2 SDRAM layout guidelines.

The objective of this chapter to understand the trade-offs between different types of termination schemes, the effects of output drive strengths, and different loading types, so you can swiftly navigate through the multiple combinations and choose the best possible settings for your designs.

**Board Termination**

In board-level design, you can use a variety of termination schemes. DDR2 adheres to the JEDEC standard of governing Stub-Series Terminated Logic (SSTL), JESD8-15a, which includes four different termination schemes.
Two commonly used termination schemes of SSTL are:

- Single parallel terminated output load with or without series resistors (Class I, as stated in JESD8-15a)
- Double parallel terminated output load with or without series resistors (Class II, as stated in JESD8-15a)

Depending on the type of signals you choose, you can use either termination scheme. Also, depending on your design’s FPGA and SDRAM memory devices, you may choose external or internal termination schemes.

With the ever-increasing requirements to reduce system cost and simplify printed circuit board (PCB) layout design, you may choose not to have any parallel termination on the transmission line, and use point-to-point connections between the memory interface and the memory. In this case, you may take advantage of internal termination schemes such as on-chip termination (OCT) on the FPGA side and on-die termination (ODT) on the SDRAM side when it is offered on your chosen device.

**External Parallel Termination**

If you use external termination, you must study the locations of the termination resistors to determine which topology works best for your design. Figure 1–2 and Figure 1–3 illustrate the two most commonly used termination topologies: fly-by topology and non-fly-by topology, respectively.

**Figure 1–2. Fly-By Placement of a Parallel Resistor**

With fly-by topology (Figure 1–2), you place the parallel termination resistor after the receiver. This termination placement resolves the undesirable unterminated stub found in the non-fly-by topology. However, using this topology can be costly and complicate routing. The Stratix II Memory Board 2 uses the fly-by topology for the parallel terminating resistors placement. The Stratix II Memory Board 2 is a memory test board available only within Altera for the purpose of testing and validating Altera’s memory interface.
With non-fly-by topology (Figure 1–3), the parallel termination resistor is placed between the driver and receiver (closest to the receiver). This termination placement is easier for board layout, but results in a short stub, which causes an unterminated transmission line between the terminating resistor and the receiver. The unterminated transmission line results in ringing and reflection at the receiver.

If you do not use external termination, DDR2 offers ODT and Altera® FPGAs have varying levels of OCT support. You should explore using ODT and OCT to decrease the board power consumption and reduce the required board real estate.

**On-Chip Termination**

OCT technology is offered on Arria II GX, Cyclone III, Stratix III, and Stratix IV devices. Table 1–1 summarizes the extent of OCT support for each device. This table provides information about SSTL-18 standards because SSTL-18 is the supported standard for DDR2 memory interface by Altera FPGAs.

On-chip series (Rs) termination is supported only on output and bidirectional buffers. The value of Rs with calibration is calibrated against a 25-Ω resistor for class II and 50-Ω resistor for class I connected to R\textsubscript{UP} and R\textsubscript{DN} pins and adjusted to ± 1% of 25 Ω or 50 Ω. On-chip parallel (Rt) termination is supported only on inputs and bidirectional buffers. The value of Rt is calibrated against 100 Ω connected to the R\textsubscript{UP} and R\textsubscript{DN} pins. Calibration occurs at the end of device configuration. Dynamic OCT is supported only on bidirectional I/O buffers.

The dynamic OCT scheme is only available in Stratix III and Stratix IV FPGAs. The dynamic OCT scheme enables series termination (Rs) and parallel termination (Rt) to be dynamically turned on and off during the data transfer.

The series and parallel terminations are turned on or off depending on the read and write cycle of the interface. During the write cycle, the Rs is turned on and the Rt is turned off to match the line impedance. During the read cycle, the Rs is turned off and the Rt is turned on as the Stratix III FPGA implements the far-end termination of the bus (Figure 1–4).

**Figure 1–4.** Dynamic OCT for Memory Interfaces

### Simulation and Measurement Setup

To study the different types of termination schemes properly, the simulation and measurement setups described in this chapter use two options:

- Altera Stratix III FPGA interfacing with a 400-MHz DDR2 SDRAM unbuffered DIMM
- Altera Stratix II FPGA interfacing with a 267-MHz DDR2 SDRAM unbuffered DIMM

The maximum achievable frequency in Stratix II DDR2 SDRAM is 333 MHz. The 267 MHz frequency is due to the device speed grade mounted on the Stratix II Memory Board 2 board.

**Note to Table 1–1:**

1. Programmable Drive Strength
2. Non-dynamic on-chip parallel termination is only supported for input pins.
The Stratix III FPGA is interfacing with a 400-MHz DDR2 SDRAM unbuffered DIMM. This DDR2 memory interface is built on the Stratix III Host Development Kit Board (Figure 1–5). This board is available for purchase at the Altera web site.

**Figure 1–5.** Stratix III Host Development Kit Board with DDR2 SDRAM DIMM Interface

The Altera Stratix II FPGA is interfacing with a 267-MHz DDR2 SDRAM unbuffered DIMM. This DDR2 memory interface is built on the Stratix II Memory Board 2 (Figure 1–6), and is not available to customers. This board is used internally within Altera for validation and testing of memory interfaces with Stratix II devices.
The DDR2 SDRAM DIMM on both Stratix III and Stratix II boards contains a 22-Ω external series termination resistor for each data line, so all of the measurements and simulations must account for the effect of these series termination resistors.

To correlate the bench measurements performed on the Stratix III Host Development Kit Board and the Stratix II Memory Board 2, the simulations are performed using HyperLynx LineSim software with IBIS models from Altera and memory vendors. Figure 1–7 and Figure 1–8 show the setup in HyperLynx used for the simulation for Stratix III and Stratix II boards. The simulation files, Simulation Example are on the Altera website.
The trace length of DQ0 from DDR2 SDRAM memory interface in the FPGA to DQ0 at DDR2 SDRAM DIMM is extracted for the simulation and is approximately 3 inches long for both the Stratix III device on the Stratix III Development Kit Board and the Stratix II device on the Stratix II Memory Board 2.

In Figure 1–7, resistance, inductance, and capacitance (RLC) values of the Stratix III FPGA I/O package are extracted from Stratix3_rlc.xls document in the Altera Device IBIS Models available on the Altera IBIS Models page at Altera’s web site. At the point of measurements, 0.85 pF of capacitance was added to represent the scope cable.

The trace information for DDR2 SDRAM DIMM on the Stratix II Memory Board 2 can be found in the PC4300 DDR2 SDRAM Unbuffered DIMM Design Specification.

The trace information for DDR2 SDRAM DIMM on the Stratix III Host Development Kit Board can be found in the PC5300/6400 DDR2 SDRAM Unbuffered DIMM Design Specification.
Recommended Termination Schemes

Table 1–2 provides the recommended termination schemes for major DDR2 memory interface signals. Signals include data (DQ), data strobe (DQS/DQSn), data mask (DM), clocks (mem_clk/mem_clk_n), and address and command signals.

When interfacing with multiple DDR2 SDRAM components where the address, command, and memory clock pins are connected to more than one load, follow these steps:

1. Simulate the system to get the new slew-rate for these signals.
2. Use the derated tIS and tIH specifications from the DDR2 SDRAM datasheet based on the simulation results.
3. If timing deration causes your interface to fail timing requirements, consider signal duplication of these signals to lower their loading, and hence improve timing.

Altera uses Class I and Class II termination in this table to refer to drive strength, and not physical termination.

You must simulate your design for your system to ensure correct functionality.

Notes to Table 1–2:

1. N/A is not available.
2. R is series resistor.
3. P is parallel resistor.
4. DYN is dynamic OCT.
5. NO CAL is OCT without calibration.
6. CAL is OCT with calibration.
7. HALF is reduced drive strength.
8. ODT75 vs. ODT50 on the memory has the effect of opening the eye more, with a limited increase in overshoot/undershoot.
9. FULL is full drive strength.
10. x1 is a single-device load.
11. x2 is two-device load.

Dynamic On-Chip Termination

The termination schemes are described in JEDEC standard JESD8-15a for SSTL 18 I/O. Dynamic OCT is available in Stratix III and Stratix IV. When the Stratix III FPGA (driver) is writing to the DDR2 SDRAM DIMM (receiver), series OCT is enabled dynamically to match the impedance of the transmission line. As a result, reflections are significantly reduced. Similarly, when the FPGA is reading from the DDR2 SDRAM DIMM, the parallel OCT is dynamically enabled.

For information about setting the proper value for termination resistors, refer to the *Stratix III Device I/O Features* chapter in the *Stratix III Device Handbook* and the *I/O Features in Stratix IV Devices* chapter in the *Stratix IV Device Handbook*.
FPGA Writing to Memory

Figure 1–9 shows dynamic series OCT scheme when the FPGA is writing to the memory. The benefit of using dynamic series OCT is that when driver is driving the transmission line, it “sees” a matched transmission line with no external resistor termination.

**Figure 1–9.** Dynamic Series OCT Scheme with ODT on the Memory

![Dynamic Series OCT Scheme with ODT on the Memory](image)

Figure 2 and Figure 1–10 show the simulation and measurement results of a write to the DDR2 SDRAM DIMM. The system uses Class I termination with a 50-Ω series OCT measured at the DIMM with a full drive strength and a 75 Ω ODT at the DIMM. Both simulation and bench measurements are in 200 pS/div and 200 mV/div.

**Figure 2.** HyperLynx Simulation FPGA Writing to Memory

![HyperLynx Simulation FPGA Writing to Memory](image)
Table 1–3 summarizes the comparison between the simulation and the board measurement of the signal seen at the DDR2 SDRAM DIMM.

Table 1–3. Signal Comparison When the FPGA is Writing to the Memory  

<table>
<thead>
<tr>
<th></th>
<th>Eye Width (ns)</th>
<th>Eye Height (V)</th>
<th>Overshoot (V)</th>
<th>Undershoot (V)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simulation</td>
<td>1.194</td>
<td>0.740</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Board Measurement</td>
<td>1.08</td>
<td>0.7</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Notes to Table 1–3:
(1) N/A is not applicable.
(2) The eye width is measured from $V_{IH}/V_{IL}(ac) = V_{REF} \pm 250$ mV to $V_{IH}/V_{IL}(dc) = V_{REF} \pm 125$ mV, where $V_{IH}$ and $V_{IL}$ are determined per the JEDEC specification for SSTL-18.

The data in Table 1–3 and Figure 2 and Figure 1–10 suggest that when the FPGA is writing to the memory, the bench measurements are closely matched with simulation measurements. They indicate that using the series dynamic on-chip termination scheme for your bidirectional I/Os maintains the integrity of the signal, while it removes the need for external termination.

Depending on the I/O standard, you should consider the four parameters listed in Table 1–3 when designing a memory interface. Although the simulation and board measurement appear to be similar, there are some discrepancies when the key parameters are measured. Although simulation does not fully model the duty cycle distortion of the I/O, crosstalk, or board power plane degradation, it provides a good indication on the performance of the board.
For memory interfaces, the eye width is important when determining if there is a sufficient window to correctly capture the data. Regarding the eye height, even though most memory interfaces use voltage-referenced I/O standards (in this case, SSTL-18), as long as there is sufficient eye opening below and above VIL and VIH, there should be enough margin to correctly capture the data. However, because effects such as crosstalk are not taken into account, it is critical to design a system to achieve the optimum eye height, because it impacts the overall margin of a system with a memory interface.

Refer to the memory vendors when determining the over- and undershoot. They typically specify a maximum limit on the input voltage to prevent reliability issues.

**FPGA Reading from Memory**

Figure 1–11 shows the dynamic parallel termination scheme when the FPGA is reading from memory. When the DDR2 SDRAM DIMM is driving the transmission line, the ringing and reflection is minimal because the FPGA-side termination 50-Ω pull-up resistor is matched with the transmission line. Figure 1–12 shows the simulation and measurement results of a read from DDR2 SDRAM DIMM. The system uses Class I termination with a 50-Ω calibrated parallel OCT measured at the FPGA end with a full drive strength and a 75-Ω ODT at the memory. Both simulation and bench measurements are in 200 pS/div and 200 mV/div.

**Figure 1–11. Dynamic Parallel OCT Scheme with Memory-Side Series Resistor**
Table 1–4 summarizes the comparison between the simulation and the board measurement of the signal seen at the FPGA end.

**Table 1–4. Signal Comparison When the FPGA is Reading from the Memory** *(Note 1), (2)*

<table>
<thead>
<tr>
<th></th>
<th>Eye Width (ns) <em>(3)</em></th>
<th>Eye Height (V)</th>
<th>Overshoot (V)</th>
<th>Undershoot (V)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Simulation</td>
<td>1.206</td>
<td>0.740</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Board Measurement</td>
<td>1.140</td>
<td>0.680</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Notes to Table 1–4:**

1. The drive strength on the memory DIMM is set to Full.
2. N/A is not applicable.
3. The eye width is measured from \( V_{O_H}/V_{O_L}(ac) = V_{REF} \pm 250 \text{ mV} \) to \( V_{O_H}/V_{O_L}(dc) = V_{REF} \pm 125 \text{ mV} \), in which \( V_{O_H} \) and \( V_{O_L} \) are determined per the JEDEC specification for SSTL-18.

The data in **Table 1–4** and **Figure 1–12** suggest that bench measurements are closely matched with simulation measurements when the FPGA is reading from the memory. They indicate that using the parallel dynamic on-chip termination scheme in bidirectional I/Os maintains the integrity of the signal, while it removes the need for external termination.
On-Chip Termination (Non-Dynamic)

When you use the 50-Ω OCT feature in a Class I termination scheme using ODT with a memory-side series resistor, the output driver is tuned to 50Ω, which matches the characteristic impedance of the transmission line. Figure 1–13 shows the Class I termination scheme using ODT when the 50-Ω OCT on the FPGA is turned on.

Figure 1–13. Class I Termination Using ODT with 50-Ω OCT

The resulting signal quality has a similar eye opening to the 8 mA drive strength setting (refer to “Drive Strength” on page 1–31) without any over- or undershoot. Figure 1–14 shows the simulation and measurement of the signal at the memory side (DDR2 SDRAM DIMM) with the drive strength setting of 50-Ω OCT in the FPGA.

Figure 1–14. HyperLynx Simulation and Measurement, FPGA Writing to Memory

Table 1–5 shows data for the signal at the DDR2 SDRAM DIMM of a Class I scheme termination using ODT with a memory-side series resistor. The FPGA is writing to the memory with 50-Ω OCT.
When you use the 50-Ω OCT setting on the FPGA, the signal quality for the Class I termination using ODT with a memory-side series resistor is further improved with lower over- and undershoot.

In addition to the 50-Ω OCT setting, Stratix II devices have a 25-Ω OCT setting that you can use to improve the signal quality in a Class II terminated transmission line. Figure 1–15 shows the Class II termination scheme using ODT when the 25-Ω OCT on the FPGA is turned on.

**Figure 1–15.** Class II Termination Using ODT with 25-Ω OCT

<td>0.51</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Note to Table 1–6:

(1) N/A is not applicable.

This type of termination scheme is only used for bidirectional signals, such as data (DQ), data strobe (DQS), data mask (DM), and memory clocks (CK) found in DRAMs.

**Class II External Parallel Termination**

The double parallel (Class II) termination scheme is described in JEDEC standards JESD8-6 for HSTL I/O, JESD8-9b for SSTL-2 I/O, and JESD8-15a for SSTL-18 I/O. When the FPGA (driver) is writing to the DDR2 SDRAM DIMM (receiver), the transmission line is terminated at the DDR2 SDRAM DIMM. Similarly, when the FPGA is reading from the DDR2 SDRAM DIMM, the DDR2 SDRAM DIMM is now the driver and the transmission line is terminated at the FPGA (receiver). This type of termination scheme is typically used for bidirectional signals, such as data (DQ) and data strobe (DQS) signal found in DRAMs.
FPGA Writing to Memory

Figure 1–17 shows the Class II termination scheme when the FPGA is writing to the memory. The benefit of using Class II termination is that when either driver is driving the transmission line, it sees a matched transmission line because of the termination resistor at the receiver-end, thereby reducing ringing and reflection.

Figure 1–17. Class II Termination Scheme with Memory-Side Series Resistor

Figure 1–18 and Figure 1–19 show the simulation and measurement result of a write to the DDR2 SDRAM DIMM. The system uses Class II termination with a source-series resistor measured at the DIMM with a drive strength setting of 16 mA.

Figure 1–18. HyperLynx Simulation, FPGA Writing to Memory

The simulation shows a clean signal with a good eye opening, but there is slight over- and undershoot of the 1.8-V signal specified by DDR2 SDRAM. The over- and undershoot can be attributed to either overdriving the transmission line using a higher than required drive strength setting on the driver or the over-termination on the receiver side by using an external resistor value that is higher than the characteristic impedance of the transmission line. As long as the over- and undershoot do not exceed the absolute maximum rating specification listed in the memory.
The vendor’s DDR2 SDRAM data sheet, it does not result in any reliability issues. The simulation results are then correlated with actual board level measurements. Figure 1–19 shows the measurement obtained from the Stratix II Memory Board 2. The FPGA is using a 16 mA drive strength to drive the DDR2 SDRAM DIMM on a Class II termination transmission line.

Notes to Table 1–7:
(1) The drive strength on the FPGA is set to 16 mA.
(2) The eye width is measured from V_{REF} ± 125 mV where V_{IH} and V_{IL} are determined per the JEDEC specification for SSTL-18.

A closer inspection of the simulation shows an ideal duty cycle of 50%–50%, while the board measurement shows that the duty cycle is non-ideal, around 53%–47%, resulting in the difference between the simulation and measured eye width. In addition, the board measurement is conducted on a 72-bit memory interface, but the simulation is performed on a single I/O.

**FPGA Reading from Memory**

Figure 1–20 shows the Class II termination scheme when the FPGA is reading from memory. When the DDR2 SDRAM DIMM is driving the transmission line, the ringing and reflection is minimal because of the matched FPGA-side termination pull-up resistor with the transmission line.
Figure 1–21 and Figure 1–22 show the simulation and measurement, respectively, of the signal at the FPGA side with the full drive strength setting on the DDR2 SDRAM DIMM. The simulation uses a Class II termination scheme with a source-series resistor transmission line. The FPGA is reading from the memory with a full drive strength setting on the DIMM.

Figure 1–21. HyperLynx Simulation, FPGA Reading from Memory
Table 1–8 summarizes the comparison between the simulation and board measurements of the signal seen by the FPGA when the FPGA is reading from memory (driver).

**Note to Table 1–8:**

1. The drive strength on the DDR2 SDRAM DIMM is set to full strength.
2. N/A is not applicable.

Both simulation and measurement show a clean signal and a good eye opening without any over- and undershoot. However, the eye height when the FPGA is reading from the memory is smaller compared to the eye height when the FPGA is writing to the memory. The reduction in eye height is attributed to the voltage drop on the series resistor present on the DIMM. With the drive strength setting on the memory already set to full, you cannot increase the memory drive strength to improve the eye height. One option is to remove the series resistor on the DIMM when the FPGA is reading from memory (refer to the section “Component Versus DIMM” on page 1–33). Another option is to remove the external parallel resistor near the memory so that the memory driver sees less loading. For a DIMM configuration, the latter option is a better choice because the series resistors are part of the DIMM and you can easily turn on the ODT feature to use as the termination resistor when the FPGA is writing to the memory and turn off when the FPGA is reading from memory.
The results for the Class II termination scheme demonstrate that the scheme is ideal for bidirectional signals such as data strobe and data for DDR2 SDRAM memory. Terminations at the receiver eliminate reflections back to the driver and suppress any ringing at the receiver.

**Class I External Parallel Termination**

The single parallel (Class I) termination scheme refers to when the termination is located near the receiver side. Typically, this scheme is used for terminating unidirectional signals (such as clocks, address, and command signals) for DDR2 SDRAM.

However, because of board constraints, this form of termination scheme is sometimes used in bidirectional signals, such as data (DQ) and data strobe (DQS) signals. For bidirectional signals, you can place the termination on either the memory or the FPGA side. This section focuses only on the Class I termination scheme with memory-side termination. The memory-side termination ensures impedance matching when the signal reaches the receiver of the memory. However, when the FPGA is reading from the memory, there is no termination on the FPGA side, resulting in impedance mismatch. This section describes the signal quality of this termination scheme.

**FPGA Writing to Memory**

When the FPGA is writing to the memory (Figure 1–23), the transmission line is parallel-terminated at the memory side, resulting in minimal reflection on the receiver side because of the matched impedance seen by the transmission line. The benefit of this termination scheme is that only one external resistor is required. Alternatively, you can implement this termination scheme using an ODT resistor instead of an external resistor.

Refer to the section “Class I Termination Using ODT” on page 1–24 for more information about how an ODT resistor compares to an external termination resistor.

**Figure 1–23. Class I Termination Scheme with Memory-Side Series Resistor**

Figure 1–24 shows the simulation and measurement of the signal at the memory (DDR2 SDRAM DIMM) of Class I termination with a memory-side resistor. The FPGA writes to the memory with a 16 mA drive strength setting.
Table 1–9 summarizes the comparison of the signal at the DDR2 SDRAM DIMM of a Class I and Class II termination scheme using external resistors with memory-side series resistors. The FPGA (driver) writes to the memory (receiver).

**Note to Table 1–9:**

(1) The drive strength on the FPGA is set to 16 mA.

Table 1–9 shows the overall signal quality of a Class I termination scheme is comparable to the signal quality of a Class II termination scheme, except that the eye height of the Class I termination scheme is approximately 30% larger. The increase in eye height is due to the reduced loading “seen” by the driver, because the Class I termination scheme does not have an FPGA-side parallel termination resistor. However, increased eye height comes with a price: a 50% increase in the over- and undershoot of the signal using Class I versus Class II termination scheme. You can decrease the FPGA drive strength to compensate for the decreased loading seen by the driver to decrease the over- and undershoot.

Refer to the section “Drive Strength” on page 1–31 for more information about how drive strength affects the signal quality.
FPGA Reading from Memory

As described in the section “FPGA Writing to Memory” on page 1–21, in Class I termination, the termination is located near the receiver. However, if you use this termination scheme to terminate a bidirectional signal, the receiver can also be the driver. For example, in DDR2 SDRAM, the data signals are both receiver and driver.

Figure 1–25 shows a Class I termination scheme with a memory-side resistor. The FPGA reads from the memory.

Figure 1–25. Class I Termination Scheme with Memory-Side Series Resistor

When the FPGA reads from the memory (Figure 1–25), the transmission line is not terminated at the FPGA, resulting in an impedance mismatch, which then results in over- and undershoot. Figure 1–26 shows the simulation and measurement of the signal at the FPGA side (receiver) of a Class I termination. The FPGA reads from the memory with a full drive strength setting on the DDR2 SDRAM DIMM.

Figure 1–26. HyperLynx Simulation and Board Measurement, FPGA Reading from Memory

Table 1–10 summarizes the comparison of the signal “seen” at the FPGA of a Class I and Class II termination scheme using an external resistor with a memory-side series resistor. The FPGA (receiver) reads from the memory (driver).
When the FPGA reads from the memory using the Class I scheme, the signal quality is comparable to that of the Class II scheme, in terms of the eye height and width. Table 1–10 shows the lack of termination at the receiver (FPGA) results in impedance mismatch, causing reflection and ringing that is not visible in the Class II termination scheme. As such, Altera recommends using the Class I termination scheme for unidirectional signals (such as command and address signals), between the FPGA and the memory.

### Class I Termination Using ODT

Presently, ODT is becoming a common feature in memory, including SDRAMs, graphics DRAMs, and SRAMs. ODT helps reduce board termination cost and simplify board routing. This section describes the ODT feature of DDR2 SDRAM and the signal quality when the ODT feature is used.

#### FPGA Writing to Memory

DDR2 SDRAM has built-in ODT that eliminates the need for external termination resistors. To use the ODT feature of the memory, you must configure the memory to turn on the ODT feature during memory initialization. For DDR2 SDRAM, set the ODT feature by programming the extended mode register. In addition to programming the extended mode register during initialization of the DDR2 SDRAM, an ODT input pin on the DDR2 SDRAM must be driven high to activate the ODT.

Refer to the respective memory data sheet for additional information about setting the ODT feature and the timing requirements for driving the ODT pin in DDR2 SDRAM.

The ODT feature in DDR2 SDRAM is controlled dynamically—it is turned on while the FPGA is writing to the memory and turned off while the FPGA is reading from the memory. The ODT feature in DDR2 SDRAM has three settings: 50Ω, 75Ω, and 150Ω. If there are no external parallel termination resistors and the ODT feature is turned on, the termination scheme resembles the Class I termination described in “Class I External Parallel Termination” on page 1–21.

Figure 1–27 shows the termination scheme when the ODT on the DDR2 SDRAM is turned on.

When the ODT feature is enabled in the DDR2 SDRAM, the eye width is improved. There is some degradation to the eye height, but it is not significant. When ODT is enabled, the most significant improvement in signal quality is the reduction of the over- and undershoot, which helps mitigate any potential reliability issues on the memory devices.

Using memory ODT also eliminates the need for external resistors, which reduces board cost and simplifies board routing, allowing you to shrink your boards. Therefore, Altera recommends using the ODT feature on the DDR2 SDRAM memory.

**FPGA Reading from Memory**

Altera’s Stratix II series, Arria GX and Cyclone series of devices are not equipped with ODT. When the DDR2 SDRAM ODT feature is turned off when the FPGA is reading from the memory, the termination scheme resembles the no-parallel termination scheme illustrated by Figure 1–31 on page 1–28.

**No-Parallel Termination**

The no-parallel termination scheme is described in the JEDEC standards JESD8-6 for HSTL I/O, JESD8-9b for SSTL-2 I/O, and JESD8-15a for SSTL-18 I/O. Designers who attempt series-only termination schemes such as this often do so to eliminate the need for a VTT power supply.

This is typically not recommended for any signals between an FPGA and DDR2 interface; however, information about this topic is included here as a reference point to clarify the challenges that may occur if you attempt to avoid parallel termination entirely.

**FPGA Writing to Memory**

Figure 1–29 shows a no-parallel termination transmission line of the FPGA driving the memory. When the FPGA is driving the transmission line, the signals at the memory-side (DDR2 SDRAM DIMM) may suffer from signal degradation (for example, degradation in rise and fall time). This is due to impedance mismatch, because there is no parallel termination at the memory-side. Also, because of factors such as trace length and drive strength, the degradation seen at the receiver-end might be sufficient to result in a system failure. To understand the effects of each termination scheme on a system, perform system-level simulations before and after the board is designed.
Figure 1–29. No-Parallel Termination Scheme

![Diagram](image)

Figure 1–30 shows a HyperLynx simulation and measurement of the FPGA writing to the memory at 533 MHz with a no-parallel termination scheme using a 16 mA drive strength option. The measurement point is on the DDR2 SDRAM DIMM.

The simulated and measured signal shows that there is sufficient eye opening but also significant over- and undershoot of the 1.8-V signal specified by the DDR2 SDRAM. From the simulation and measurement, the overshoot is approximately 1 V higher than 1.8 V, and undershoot is approximately 0.8 V below ground. This over- and undershoot might result in a reliability issue, because it has exceeded the absolute maximum rating specification listed in the memory vendors’ DDR2 SDRAM data sheet.

Table 1–12 summarizes the comparison of the signal visible at the DDR2 SDRAM DIMM of a no-parallel and a Class II termination scheme when the FPGA writes to the DDR2 SDRAM DIMM.

### Table 1–12. Signal Comparison When the FPGA is Writing to Memory (Part 1 of 2)  (Note 1)

<td>1.10</td>
<td>0.90</td>
<td>0.80</td>
</tr>
</tbody>
</table>
Although the appearance of the signal in a no-parallel termination scheme is not clean, when you take the key parameters into consideration, the eye width and height is comparable to that of a Class II termination scheme. The major disadvantage of using a no-parallel termination scheme is the over- and undershoot. There is no termination on the receiver, so there is an impedance mismatch when the signal arrives at the receiver, resulting in ringing and reflection. In addition, the 16-mA drive strength setting on the FPGA also results in overdriving the transmission line, causing the over- and undershoot. By reducing the drive strength setting, the over- and undershoot decreases and improves the signal quality “seen” by the receiver.

For more information about how drive strength affects the signal quality, refer to “Drive Strength” on page 1–31.

**FPGA Reading from Memory**

In a no-parallel termination scheme (Figure 1–31), when the memory is driving the transmission line, the resistor, Rs acts as a source termination resistor. The DDR2 SDRAM driver has two drive strength settings:

- Full strength, in which the output impedance is approximately 18Ω
- Reduced strength, in which the output impedance is approximately 40Ω

When the DDR2 SDRAM DIMM drives the transmission line, the combination of the 22-Ω source-series resistor and the driver impedance should match that of the characteristic impedance of the transmission line. As such, there is less over- and undershoot of the signal visible at the receiver (FPGA).

</table>

**Note to Table 1–13:**

(1) The drive strength on the DDR2 SDRAM DIMM is set to full strength.
(2) N/A is not applicable.

As in the section “FPGA Writing to Memory” on page 1–26, the eye width and height of the signal in a no-parallel termination scheme is comparable to a Class II termination scheme, but the disadvantage is the over- and undershoot. There is over- and undershoot because of the lack of termination on the transmission line, but the magnitude of the over- and undershoot is not as severe when compared to that described in “FPGA Writing to Memory” on page 1–26. This is attributed to the presence of the series resistor at the source (memory side), which dampens any reflection coming back to the driver and further reduces the effect of the reflection on the FPGA side.

When the memory-side series resistor is removed (Figure 1–33), the memory driver impedance no longer matches the transmission line and there is no series resistor at the driver to dampen the reflection coming back from the unterminated FPGA side.
Figure 1–33. No-Parallel Termination Scheme, FPGA REading from Memory

**Note to Table 1–14:**

(1) The drive strength on the memory is set to full drive strength.
Table 1–14 highlights the effect of the series resistor on the memory side with the dramatic increase in over- and undershoot and the decrease in the eye height. This result is similar to that described in “FPGA Writing to Memory” on page 1–26. In that simulation, there is a series resistor but it is located at the receiver side (memory-side), so it does not have the desired effect of reducing the drive strength of the driver and suppressing the reflection coming back from the unterminated receiver-end. As such, in a system without receiver-side termination, the series resistor on the driver helps reduce the drive strength of the driver and dampen the reflection coming back from the unterminated receiver-end.

Summary

This section compared the various types of termination schemes and studied the benefits and disadvantages of each scheme.

For bidirectional signals, such as the DQ and DQS signals of DDR2 SDRAM, dynamic OCT should be regarded as the ideal termination method when the feature is available; otherwise, a Class II termination scheme with fly-by topology should be regarded as the ideal termination method.

For unidirectional signals, such as the command and address signals of DDR and DDR2 SDRAM, a memory-side Class I termination scheme with fly-by topology provides the best results.

If board real estate and cost is prohibitive to placing on-board termination resistors, you can use the ODT feature on the DDR2 SDRAM memory for the memory-side Class II termination when the controller drives the transmission line. If a Stratix III series device is used, dynamic OCT can achieve a termination solution comparable to a fully discrete terminated system.

Drive Strength

Altera’s FPGA products offer numerous drive strength settings, allowing you to optimize your board designs to achieve the best signal quality. This section focuses on the most commonly used drive strength settings of 8 mA and 16 mA, as recommended by JEDEC for Class I and Class II termination schemes.

You are not restricted to using only these drive strength settings for your board designs. You should perform simulations using I/O models available from Altera and memory vendors to ensure that you use the proper drive strength setting to achieve optimum signal integrity.

How Strong is Strong Enough?

Figure 1–19 on page 1–18 shows a signal probed at the DDR2 SDRAM DIMM (receiver) of a far-end series-terminated transmission line when the FPGA writes to the DDR2 SDRAM DIMM using a drive strength setting of 16 mA. The resulting signal quality on the receiver shows excessive over- and undershoot. To reduce the over- and undershoot, you can reduce the drive strength setting on the FPGA from 16 mA to 8 mA. Figure 1–35 shows the simulation and measurement of the FPGA with a drive strength setting of 8 mA driving a no-parallel termination transmission line.
Table 1–15 compares the signals at the DDR2 SDRAM DIMM with no-parallel termination and memory-side series resistors when the FPGA is writing to the memory with 8-mA and 16-mA drive strength settings.

</tbody>
</table>

With a lower strength drive setting, the overall signal quality is improved. The eye width is reduced, but the eye height is significantly larger with a lower drive strength and the over- and undershoot is reduced dramatically.

To improve the signal quality further, you should use 50-Ω on-chip series termination in place of an 8mA drive strength and 25-Ω on-chip series termination in place of a 16 mA drive strength. Refer to “On-Chip Termination (Non-Dynamic)” on page 1–14 for simulation and board measurements.

**Summary**

This section compared the effects of drive strength on the signal quality seen at the receiver. As shown, the drive strength setting is highly dependent on the termination scheme, so it is critical that you perform pre- and post-layout board-level simulations to determine the proper drive strength settings. However, page 1–14 through page 1–16 show that 50-Ω OCT and 25-Ω OCT drive strength settings for Class I and
Class II, respectively, provide the optimum signal quality because the output driver matches the impedance “seen” by the driver. In addition, using the OCT feature in Altera’s FPGA devices eliminates the need for external series resistors and simplifies board design. Finally, using the FPGA’s OCT with the SDRAM ODT feature results in the best signal quality without any over- or undershoot.

**System Loading**

You can use memory in a variety of forms, such as individual components or multiple DIMMs, resulting in different loading seen by the FPGA. This section describes the effect on signal quality when interfacing memories in component, dual rank, and dual DIMMs format.

**Component Versus DIMM**

When using discrete DDR2 SDRAM components, the additional loading from the DDR2 SDRAM DIMM connector is eliminated and the memory-side series resistor on the DDR2 SDRAM DIMM is no longer there. You must decide if the memory-side series resistor near the DDR2 SDRAM is required.

**FPGA Writing to Memory**

Figure 1–36 shows the Class II termination scheme without the memory-side series resistor when the FPGA is writing to the memory in the component format.

**Figure 1–36. Class II Termination Scheme without Memory-Side Series Resistor**

Note to Table 1–16:
(1) The drive strength on the FPGA is set to Class II 16 mA.
(2) N/A is not applicable.

The overall signal quality is comparable between the single rank DDR2 SDRAM DIMM and the single DDR2 SDRAM component, but the elimination of the DIMM connector and memory-side series resistor results in a more than 50% improvement in the eye height.
**FPGA Reading from Memory**

Figure 1–38 shows the Class II termination scheme without the memory-side series resistor when the FPGA is reading from memory. Without the memory-side series resistor, the memory driver has less loading to drive the Class II termination. Compare this result to the result of the DDR2 SDRAM DIMM described in “FPGA Reading from Memory” on page 1–28 where the memory-side series resistor is on the DIMM.

**Figure 1–38. Class II Termination Scheme without Memory-Side Series Resistor**

![Class II Termination Scheme without Memory-Side Series Resistor](image)

Figure 1–39 shows the simulation and measurement results of the signal seen at the FPGA. The FPGA reads from memory without the source-series resistor near the DDR2 SDRAM component on a Class II-terminated transmission line. The FPGA reads from memory with a full drive strength setting.

**Figure 1–39. HyperLynx Simulation and Measurement, FPGA Reading from the DDR2 SDRAM Component**

![HyperLynx Simulation and Measurement](image)

Table 1–17 compares the signal at a single rank DDR2 SDRAM DIMM and a single DDR2 SDRAM component of a Class II termination scheme. The FPGA is reading from memory with a full drive strength setting.
The effect of eliminating the DIMM connector and memory-side series resistor is evident in the improvement in the eye height.

**Single- Versus Dual-Rank DIMM**

DDR2 SDRAM DIMMs are available in either single- or dual-rank DIMM. Single-rank DIMMs are DIMMs with DDR2 SDRAM memory components on one side of the DIMM. Higher-density DIMMs are available as dual-rank, which has DDR2 SDRAM memory components on both sides of the DIMM. With the dual-rank DIMM configuration, the loading is twice that of a single-rank DIMM. Depending on the board design, you must adjust the drive strength setting on the memory controller to account for this increase in loading. Figure 1–40 shows the simulation result of the signal seen at a dual rank DDR2 SDRAM DIMM. The simulation uses Class II termination with a memory-side series resistor transmission line. The FPGA uses a 16-mA drive strength setting.

**Figure 1–40.** HyperLynx Simulation with a 16-mA Drive Strength Setting on the FPGA

**Note to Table 1–17:**

(1) N/A is not applicable.
Table 1–18 compares the signals at a single- and dual-rank DDR2 SDRAM DIMM of a Class II and far-end source-series termination when the FPGA is writing to the memory with a 16-mA drive strength setting.

In a dual-rank DDR2 SDRAM DIMM, the additional loading leads to a slower edge rate, which affects the eye width. The slower edge rate leads to the degradation of the setup and hold time required by the memory as well, which must be taken into consideration during the analysis of the timing for the interface. The overall signal quality remains comparable, but eye width is reduced in the dual-rank DIMM. This reduction in eye width leads to a smaller data capture window that must be taken into account when performing timing analysis for the memory interface.

### Single DIMM Versus Multiple DIMMs

Some applications, such as packet buffering, require deeper memory, making a single DIMM interface insufficient. If you use a multiple DIMM configuration to increase memory depth, the memory controller is required to interface with multiple data strobes and the data lines instead of the point-to-point interface in a single DIMM configuration. This results in heavier loading on the interface, which can potentially impact the overall performance of the memory interface.

For detailed information about a multiple DIMM DDR2 SDRAM memory interface, refer to Chapter 3, Dual-DIMM DDR2 and DDR3 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

### Summary

This section compared the effects of various loading styles on the system. With larger loading, the eye width is reduced, shrinking the data capture window, which must be taken into account when performing the timing analysis for the memory interface.

### DDR2 SDRAM Design Layout Guidelines

Table 1–19 summarizes DDR2 SDRAM layout guidelines.

The following layout guidelines include several +/- length based rules. These length based guidelines for first order timing approximations if you cannot simulate the actual delay characteristic of the interface. They do not include any margin for crosstalk.
Altera advise that when possible customers simulate their specific implementation to get accurate time base skew numbers.

Table 1–19. DDR2 SDRAM Layout Guidelines (Part 1 of 3) *(Note 1)*

<tr>
<td>DIMMs</td>
<td>If you consider a normal DDR2 unbuffered, unregistered DIMM, essentially you are planning to perform the DIMM routing directly on your PCB. Therefore, each address and control pin routes from the FPGA (single pin) to all memory devices must be on the same side of the FPGA.</td>
</tr>
</tbody>
</table>
| Impedance       | ■ All signal planes must be 50-60-Ω, single-ended, ±10%  
■ All signal planes must be 100Ω, differential ±10%  
■ All unused via pads must be removed, because they cause unwanted capacitance |
| Decoupling Parameter | ■ Use 0.1 μF in 0402 size to minimize inductance  
■ Make VTR, voltage decoupling close to pull-up resistors  
■ Connect decoupling caps between VTR and ground  
■ Use a 0.1μF cap for every other VTR pin and 0.01μF cap for every VDD and VDDQ pin |
| Power           | ■ GND, 2.5 V/1.8 V must be routed as planes  
■ VCCD for memories must be routed in a single split plane with at least a 20-mil (0.020 inches, or 0.508 mm) gap of separation  
■ VTR must be routed as islands or 250-mil (6.35-mm) power traces  
■ Oscillators and PLL power must be routed as islands or 100-mil (2.54-mm) power traces |
| General Routing | All specified delay matching requirements include PCB trace delays, different layer propagation velocity variance, and crosstalk. To minimise PCB layer propagation variance, Altera recommend that signals from the same net group always be routed on the same layer.  
■ Use 45° angles *(not 90° corners)*  
■ Avoid T-Junctions for critical nets or clocks  
■ Avoid T-junctions greater than 250 mils (6.35 mm)  
■ Disallow signals across split planes  
■ Restrict routing other signals close to system reset signals  
■ Avoid routing memory signals closer than 0.025 inch (0.635 mm) to PCI or system clocks  
■ All data, address, and command signals must have matched length traces ± 50 ps (±0.250 inches or 6.35 mm)  
■ All signals within a given Byte Lane Group should be matched length with maximum deviation of ±10 ps or approximately ±0.050 inches (1.27 mm) and routed in the same layer. |

</table>
For more information about how the memory manufacturers route these address and control signals on their DIMMs, refer to the Cadence PCB browser from the Cadence website, at www.cadence.com. The various JEDEC example DIMM layouts are available from the JEDEC website, at www.jedec.org.

### Conclusion

This chapter provides Altera’s recommendations about the termination schemes to use when interfacing Altera FPGA devices with DDR2 SDRAM devices. However, you must simulate your own design to find the best-suited termination scheme for your design.

This chapter also provides data comparisons from simulation and experimental bench results, so you can draw your own conclusions for optimum design guidelines to achieve the best signal quality.

For termination schemes, Altera recommends that receiver-side parallel termination be used for best signal quality. Therefore, for a bidirectional signal, such as data (DQ) or data strobe (DQS), the recommended termination scheme is Class II termination. You can implement Class II termination by using external parallel resistors at the FPGA and memory side, ODT and OCT at the memory and FPGA side, or a combination of the DDR2 SDRAM ODT and an external parallel resistor at the FPGA side. For a unidirectional signal, such as command or address, the recommended termination scheme is Class I termination, in which the termination is located at the memory side. If you use on-chip termination, refer to Table 1–2 on page 1–8.

</tbody>
</table>

**Notes to Table 1–19:**

(1) For point-to-point and DIMM interface designs, refer to the Micron website, www.micron.com.
Choosing the drive strength setting on the FPGA depends on the termination scheme—Class I or Class II—but the simulation results show that you should set the drive strength to match the loading the output driver sees. For Class II termination, Altera recommends using 25-Ω OCT drive strength settings. They offer the best results because the impedance of the output driver impedance matches the impedance the output driver sees. For a Class I termination scheme, Altera recommends the 50-Ω OCT drive strength setting.

Moreover, this chapter describes the effects that different memory loading styles (such as component versus DIMM) have on signal quality. From the results in “Single-Versus Dual-Rank DIMM” on page 1–36, the higher loading decreases the edge rates of the signal, thus reducing the eye width visible at the receiver. You can increase the edge rates by using a higher drive strength setting on the FPGA, but the output driver impedance decreases because the higher drive strength setting causes impedance mismatch.

Finally, this chapter provides DDR2 SDRAM layout guidelines. Although the recommendations in this chapter are based on the simulations and experimental results of the Stratix III Host Development Board and Stratix II Memory Board 2, you can apply the same general principles when determining the best termination scheme, drive strength setting, and loading style to any board designs. Even armed with this knowledge, it is still critical that you perform simulations, either using IBIS or HSPICE models, to determine the quality of signal integrity on your designs.

Bibliography

“Stratix II Memory Board 2 Layout Guidelines Rev 0.4,” Altera’s High-Speed/End Applications Team, 2004.

This chapter provides guidelines on how to improve the signal integrity of your system and layout guidelines to help you successfully implement a DDR3 SDRAM interface on your system.

Synchronous Dynamic Random Access Memory (SDRAM) has continually evolved over the years to keep up with ever-increasing computing needs. The latest addition to SDRAM technology is DDR3 SDRAM. DDR3 SDRAM is the third generation of the DDR SDRAM family, and offers improved power, higher data bandwidth, and enhanced signal quality with multiple on-die termination (ODT) selection and output driver impedance control while maintaining partial backward compatibility with the existing DDR2 SDRAM standard.

DDR3 SDRAM offers features designed to improve signal integrity of increased bus speed. While some of the features are already available in DDR2 SDRAM, these features are further enhanced in DDR3 SDRAM. For example, the ODT feature is available in both DDR2 and DDR3 SDRAM, but in DDR3 SDRAM, the values of the ODT are based on the value of an external resistor—the RZQ resistor. In addition to using this ZQ resistor for setting the ODT value, it is also used for calibrating the ODT value so that it maintains its resistance value to within a 10% tolerance. This chapter describes the following updated and new features in DDR3 SDRAM:

- ODT values selection
- Output driver impedance selection
- ZQ calibration
- Dynamic ODT usage

To take advantage of these new features offered by DDR3 SDRAM, Altera’s Stratix III and Stratix IV FPGAs have special features to ease and expedite your implementation of DDR3 SDRAM interfaces.

**With Leveling or Without Leveling**

Altera offers the DDR3 SDRAM PHY with or without leveling.

**With Leveling**

DDR3 SDRAM DIMMs, as specified by JEDEC, always use a fly-by topology for the address, command, and clock signals. This standard DDR3 SDRAM topology requires the use of the Altera DDR3 SDRAM ALTMEMPHY megafunction with read and write leveling.

Altera recommends that for full DDR3 SDRAM compatibility when using discrete DDR3 SDRAM components, you should mimic the JEDEC DDR3 uDIMMs fly-by topology on your custom PCBs.
Arria II GX devices do not support DDR3 SDRAM with read or write leveling, so standard DDR3 SDRAM DIMMs or DDR3 SDRAM components using the standard DDR3 SDRAM fly-by address, command, and clock layout topology are not supported. Refer to “Termination for DDR3 SDRAM Components (Without Leveling)” on page 2–26, for more information on how to use DDR3 SDRAM components with Arria II GX devices.

Use of the standard JEDEC DDR3 fly-by topology with leveling offers the following advantages:

- Easier layout
- Lower SSN for the memory
- Higher data rates

Refer to “Read and Write Leveling” on page 2–2 for more detailed information on read and write leveling.

Without Leveling

Altera also supports DDR3 SDRAM components without leveling, using a nonstandard, synchronous DDR2-like balanced address, command, and clock layout topology. DDR3 SDRAM interfaces without leveling operate at lower maximum data rates compared to the standard fly-by topology. DDR3 SDRAM interfaces without leveling may be desirable for the following reasons:

- The Arria II GX device family does not support read and write leveling, so DDR3 SDRAM DIMMs or topology is not supported, but the I/O electrical standard is supported
- DDR3 SDRAM PHYs without leveling typically have a slightly lower PHY latency when compared to the DDR3 SDRAM PHY with leveling
- The DDR3 SDRAM PHY without leveling typically requires less FPGA resources than an equivalent DDR3 SDRAM PHY with leveling
- You may only require DDR2-like interface performance but want to use the lower power, potential cost, and availability benefits of DDR3 SDRAM components

Comparing DDR3 and DDR2

The following sections review the differences between DDR2 and DDR3 SDRAM and the changes in the features that were made to DDR3 SDRAM. Understanding these differences makes the design process for your DDR3 SDRAM interface easier.

Read and Write Leveling

One major difference between DDR2 and DDR3 SDRAM is the use of leveling. To improve signal integrity and support higher frequency operations, the JEDEC committee defined a fly-by termination scheme used with the clocks and command and address bus signals. Fly-by topology reduces simultaneous switching noise (SSN) by deliberately causing flight-time skew between the data and strobes at every DRAM as the clock, address, and command signals traverse the DIMM (Figure 2–1).
Comparing DDR3 and DDR2

The flight-time skew due to the fly-by topology led the JEDEC committee to introduce the write leveling feature on the DDR3 SDRAMs, thus requiring controllers to compensate for this skew by adjusting the timing per byte lane.

During a write, DQS groups are launched at separate times to coincide with a clock arriving at components on the DIMM, and must meet the timing parameter between the memory clock and DQS defined as $t_{DQSS}$ of $\pm 0.25 \ t_{CK}$.

During the read operation, the memory controller must compensate for the delays introduced by the fly-by topology. In Stratix® III and Stratix IV FPGAs, there are alignment and synchronization registers built in the input output element (IOE) to properly capture the data. Figure 2–2 shows two DQS groups returning from the DIMM for the same read command.

For information about the IOE block in Stratix III devices, refer to the *External Memory Interfaces in Stratix III Devices* chapter in volume 1 of the *Stratix III Device Handbook*.

For information about the IOE block in Stratix IV devices, refer to the *External Memory Interfaces in Stratix IV Devices* chapter in volume 1 of the *Stratix IV Device Handbook*.

Comparing DDR3 and DDR2

Chapter 2: DDR3 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines

Calibrated Output Impedance and ODT

In DDR2 SDRAM, there are only two drive strength settings, full or reduced, which correspond to the output impedance of 18 Ω and 40 Ω, respectively. These output drive strength settings are static settings and are not calibrated; as a result, the output impedance varies as the voltage and temperature drifts. The DDR3 SDRAM uses a programmable impedance output buffer. Currently, there are two drive strength settings, 34 Ω and 40 Ω. The 40-Ω drive strength setting is currently a reserved specification defined by JEDEC, but available on the DDR3 SDRAM, as offered by some memory vendors. Refer to the datasheet of the respective memory vendors for more information about the output impedance setting. The drive strength setting is selected by programming the memory mode register setting defined by mode register 1 (MR1). To calibrate output driver impedance, an external precision resistor, RZQ, is connected between the ZQ pin and VSSQ. The value of this resistor must be 240 Ω ± 1%. If you are using a DDR3 SDRAM DIMM, RZQ is soldered on the DIMM so you do not need to layout your board to account for it. Output impedance is set during initialization. To calibrate output driver impedance after power-up, the DDR3 SDRAM needs a calibration command that is part of the initialization and reset procedure and is updated periodically when the controller issues a calibration command.

In addition to calibrated output impedance, the DDR3 SDRAM also supports calibrated parallel ODT via the same external precision resistor, RZQ, which is possible by using a merged output driver structure in the DDR3 SDRAM, which also helps to improve pin capacitance in the DQ and DQS pins. The ODT values supported in DDR3 SDRAM are 20 Ω, 30 Ω, 40 Ω, 60 Ω, and 120 Ω, assuming that RZQ is 240 Ω.

In DDR3 SDRAM, there are two commands related to the calibration of the output driver impedance and ODT. The first calibration command, ZQ CALIBRATION LONG (ZQCL), is often used at initial power-up or when the DDR3 SDRAM is in a reset condition. This command calibrates the output driver impedance and ODT to the initial temperature and voltage condition, and compensates for any process variation due to manufacturing. If the ZQCL command is issued at initialization or reset, it takes 512 memory clock cycles to complete; otherwise, it requires 256 memory clock cycles to complete. The second calibration command, ZQ CALIBRATION SHORT (ZQCS) is used during regular operation to track any variation in temperature or voltage. The ZQCS command takes 64 memory clock cycles to complete. Use the ZQCL command any time there is more impedance error than can be corrected with a ZQCS command.

For more information about using ZQ Calibration in DDR3 SDRAM, refer to the application note by Micron, TN-41-02 DDR3 ZQ Calibration.

Dynamic ODT

Dynamic ODT is a new feature in DDR3 SDRAM, and not available in DDR2 SDRAM. Dynamic ODT can change the ODT setting without issuing a mode register set (MRS) command. When you enable dynamic ODT, and there is no write operation, the DDR3 SDRAM is terminated to a termination setting of RTT_NORM; when there is a write operation, the DDR3 SDRAM is terminated to a setting of RTT_WR. The values of RTT_NORM and RTT_WR are preset by programming the mode registers, MR1 and MR2. Figure 2–3 shows the behavior of ODT when dynamic ODT is enabled.
In the two-DIMM DDR3 SDRAM configuration, dynamic ODT helps reduce the jitter at the module being accessed, and minimizes reflections from any secondary modules.

For more information about using the dynamic ODT on DDR3 SDRAM, refer to the application note by Micron, *TN-41-04 DDR3 Dynamic On-Die Termination*.

**Dynamic OCT in Stratix III and Stratix IV Devices**

Stratix III and Stratix IV devices support on-off dynamic series and parallel termination for a bi-directional I/O in all I/O banks. Dynamic OCT is a new feature in Stratix III and Stratix IV FPGA devices. Dynamic parallel termination is enabled only when the bi-directional I/O acts as a receiver and is disabled when it acts as a driver. Similarly, dynamic series termination is enabled only when the bi-directional I/O acts as a driver and is disabled when it acts as a receiver. The default setting for dynamic OCT is series termination, to save power when the interface is idle (no active reads or writes).

Additionally, the dynamic control operation of the OCT is separate to the output enable signal for the buffer. Hence, the Altera ALTMEMPHY megafunction can only enable parallel OCT during read cycles, saving power when the interface is idle.
This feature is useful for terminating any high-performance bi-directional path because signal integrity is optimized depending on the direction of the data. In addition, dynamic OCT also eliminates the need for external termination resistors when used with memory devices that support ODT (such as DDR3 SDRAM), thus reducing cost and easing board layout.

However, dynamic OCT in Stratix III and Stratix IV FPGA devices is different from dynamic ODT in DDR3 SDRAM mentioned in previous sections and these features should not be assumed to be identical.

For detailed information about the dynamic OCT feature in the Stratix III FPGA, refer to the *Stratix III Device I/O Features* chapter in volume 1 of the *Stratix III Device Handbook*.

For detailed information about the dynamic OCT feature in the Stratix IV FPGA, refer to the *I/O Features in Stratix IV Devices* chapter in volume 1 of the *Stratix IV Device Handbook*.

**Termination for DDR3 SDRAM Unbuffered DIMMs**

The following sections describe the correct way to terminate a DDR3 SDRAM interface together with Altera® Stratix III and Stratix IV FPGA devices.
**DDR3 SDRAM Unbuffered DIMM**

The most common implementation of the DDR3 SDRAM interface is the unbuffered DIMM. Unbuffered DDR3 SDRAM DIMMs can be found in many applications, especially in personal computer (PC) applications. A DDR3 SDRAM unbuffered DIMM interface can be implemented in several permutations, such as single DIMM or multiple DIMMs, using either single-ranked or dual-ranked unbuffered DIMMs. In addition to the unbuffered DIMMs form factor, these termination recommendations are also valid for small-outline (SO) DIMMs and MicroDIMMs.

Table 2–1 outlines the different permutations of a two-slot DDR3 SDRAM interface and the recommended ODT settings on both the memory and controller when writing to memory.

**Notes to Table 2–1:**

1. SR: single-ranked DIMM; DR: dual-ranked DIMM.
2. These recommendations are taken from the DDR3 ODT and Dynamic ODT session of the JEDEC DDR3 2007 Conference, Oct 3-4, San Jose, CA.
3. The controller in this case is the FPGA.
4. Dynamic ODT is required. For example, the ODT of Slot 2 is set to the lower ODT value of 40 Ω when the memory controller is writing to Slot 1, resulting in termination and thus minimizing any reflection from Slot 2. Without dynamic ODT, Slot 2 will not be terminated.

Table 2–2 outlines the different permutations of a two-slot DDR3 SDRAM interface and the recommended ODT settings on both the memory and controller when reading from memory.

Notes to Table 2–2:
1. SR: single-ranked DIMM; DR: dual-ranked DIMM.
2. These recommendations are taken from the DDR3 ODT and Dynamic ODT session of the JEDEC DDR3 2007 Conference, Oct 3-4, San Jose, CA.
3. The controller in this case is the FPGA. JEDEC typically recommends 60 Ω, but this value assumes that the typical motherboard trace impedance is 60 Ω and that the controller supports this termination. Altera recommends using a 50-Ω parallel OCT when reading from the memory.

DQS, DQ, and DM for DDR3 SDRAM Unbuffered DIMM

On a single-ranked DIMM, DQS, DQ, and DM signals are point-to-point signals. Figure 2–5 shows the net structure for differential DQS and DQ signals. There is an external 15-Ω stub resistor, Rs, on each of the DQS and DQ signals soldered on the DIMM, which helps improve signal quality by dampening reflections from unused slots in a multi-DIMM configuration.

Figure 2–5. DQ and DQS Net Structure for 64-Bit DDR3 SDRAM Unbuffered DIMM (Note 1)

Notes to Figure 2–5:
1. Source: PC3-6400/PC3-8500/PC3-10600/PC3-12800 DDR3 SDRAM Unbuffered DIMM Design Specification, July 2007, JEDEC Solid State Technology Association. For clarity of the signal connections in the illustration, the same SDRAM is drawn as two separate SDRA Ms.

As mentioned in “Dynamic ODT” on page 2–5, DDR3 SDRAM supports calibrated ODT with different ODT value settings. If dynamic ODT is not enabled, there are three possible ODT settings available for \( R_{TT\_NORM} \): 40 Ω, 60 Ω, and 120 Ω. When dynamic ODT is enabled, the number of possible ODT settings available for \( R_{TT\_NORM} \) increases from three to five with the addition of 20 Ω and 30 Ω. Table 2–1 shows that the recommended ODT setting on the DDR3 SDRAM is 120 Ω. Trace impedance on the DIMM is 60 Ω, and over-terminating the DDR3 SDRAM components on the DIMM with 120 Ω compensates for trace impedance variation on the DIMM due to manufacturing.
Figure 2–6 shows the write-eye diagram at the DQ0 of a DDR3 SDRAM DIMM using the 120-Ω ODT setting, driven by a Stratix III or Stratix IV FPGA using a calibrated series 50-Ω OCT setting.

**Figure 2–6.** Simulated Write-Eye Diagram of a DDR3 SDRAM DIMM Using a 120-Ω ODT Setting

When over-terminating the receiver, the mismatch between load impedance and trace impedance causes ringing at the receiver (Figure 2–6). When the DDR3 SDRAM ODT setting is set to 60 Ω, there is less ringing at the receiver (Figure 2–7).

**Figure 2–7.** Simulated Write-Eye Diagram of a DDR3 SDRAM DIMM Using a 60-Ω ODT Setting

Table 2–3 compares the effects of the ODT setting on the eye diagram at the DDR3 SDRAM (receiver) when the Stratix III or Stratix IV FPGA is writing to memory.
Table 2–3. Write-Eye Diagram Using Different ODT Setting

<table>
<thead>
<tr>
<th>ODT</th>
<th>Eye Height (V)</th>
<th>Eye Width (ps)</th>
<th>Overshoot (V)</th>
<th>Undershoot (V)</th>
</tr>
</thead>
<tbody>
<tr>
<td>120-Ω ODT</td>
<td>0.84</td>
<td>713</td>
<td>—</td>
<td>—</td>
</tr>
<tr>
<td>60-Ω ODT</td>
<td>0.73</td>
<td>715</td>
<td>—</td>
<td>—</td>
</tr>
</tbody>
</table>

Although both 120-Ω and 60-Ω ODT settings result in excellent signal quality and acceptable eye opening, using 120 Ω results in a larger eye height because of under-termination, yet it has a minimal effect on eye width. Because the use of 60-Ω ODT results in less ringing, the 60-Ω ODT setting is used on the remaining DDR3 SDRAM DIMM testing featured in this document. Figure 2–8 shows the measured write-eye diagram using Altera’s Stratix III and Stratix IV memory board.

**Figure 2–8.** Measured Write-Eye Diagram of a DDR3 SDRAM DIMM Using the 60-Ω ODT Setting

The measured eye diagram correlates well with the simulation. The faint line in the middle of the eye diagram is the effect of the refresh operation during a regular operation. Because these simulations and measurements are based on a narrow set of constraints, you must perform your own board-level simulation to ensure that the chosen ODT setting is right for your setup.

**Memory Clocks for DDR3 SDRAM Unbuffered DIMM**

For the DDR3 SDRAM unbuffered DIMM, memory clocks are already terminated on the DIMM, so you do not need to place any termination on your board. Figure 2–9 shows the net structure for the memory clocks and the location of the termination resistors, R_TT. The value of R_TT is 36 Ω, which results in an equivalent differential termination value of 72 Ω. On the DDR3 SDRAM DIMM, there is also a compensation capacitor, C_COMP of 2.2 pF, placed between the differential memory clocks to improve signal quality.
From Figure 2–9, you can see that the DDR3 SDRAM clocks are routed in a fly-by topology, as mentioned in “Read and Write Leveling” on page 2–2, resulting in the need for write-and-read leveling. Figure 2–10 shows the HyperLynx simulation of the differential clock seen at the first and last DDR3 SDRAM component on the unbuffered DIMM using the 50-Ω OCT setting on the output driver of the Stratix III and Stratix IV FPGA.

Figure 2–10 shows that the memory clock seen at the first DDR3 SDRAM component (the yellow signal) leads the memory clock seen at the last DDR3 SDRAM component (the green signal) by 1.3 ns, which is about 0.69 t<sub>CK</sub> for a 533 MHz operation.
Commands and Addresses for DDR3 SDRAM Unbuffered DIMM

Similar to memory clock signals, the command and address signals are also terminated on the DIMM, so you do not need to place any termination on your board. Figure 2–11 shows the net structure for the command and address signals and the location of the termination resistor, $R_{TT}$, which has an $R_{TT}$ value of 39 Ω.

**Figure 2–11.** Command and Address Net Structure for a 64-Bit DDR3 SDRAM Unbuffered DIMM (Note 1)

![Command and Address Net Structure for a 64-Bit DDR3 SDRAM Unbuffered DIMM](image)

Note to Figure 2–11:

In Figure 2–11, you can see that the DDR3 SDRAM command and address signals are routed in a fly-by topology, as mentioned in “Read and Write Leveling” on page 2–2, resulting in the need for write-and-read leveling.

Figure 2–12 shows the HyperLynx simulation of the command and address signal seen at the first and last DDR3 SDRAM component on the unbuffered DIMM, using a 25-Ω OCT setting on the output driver of the Stratix III and Stratix IV FPGA.

**Figure 2–12.** Command and Address Eye Diagram of a DDR3 SDRAM DIMM at the First and Last DDR3 SDRAM Component at 533 MHz (Note 1)

![Command and Address Eye Diagram of a DDR3 SDRAM DIMM at the First and Last DDR3 SDRAM Component at 533 MHz](image)

Note to Figure 2–12:
(1) The command/address simulation is performed using a bit period of 1.875 ns.
Figure 2–12 shows that the command and address signal seen at the first DDR3 SDRAM component (the green signal) leads the command and address signals seen at the last DDR3 SDRAM component (the red signal) by 1.2 ns, which is 0.64 tCK for a 533-MHz operation.

Stratix III and Stratix IV FPGAs

The following sections review termination used on the single-ranked single DDR3 SDRAM DIMM interface side and investigate the use of different termination features available in Stratix III and Stratix IV FPGA devices to achieve optimum signal integrity for your DDR3 SDRAM interface.

DQS, DQ, and DM for Stratix III and Stratix IV FPGA

As mentioned in “Dynamic OCT in Stratix III and Stratix IV Devices” on page 2–6, Stratix III and Stratix IV FPGAs support the dynamic OCT feature, which switches from series termination to parallel termination depending on the mode of the I/O buffer. Because DQS and DQ are bi-directional signals, DQS and DQ can be both transmitters and receivers. “DQS, DQ, and DM for DDR3 SDRAM Unbuffered DIMM” on page 2–9 describes the signal quality of DQ, DQS, and DM when the Stratix III or Stratix IV FPGA device is the transmitter with the I/O buffer set to a 50-Ω series termination. This section details the condition when the Stratix III or Stratix IV device is the receiver, the Stratix III and Stratix IV I/O buffer is set to a 50-Ω parallel termination, and the memory is the transmitter. DM is a unidirectional signal, so the DDR3 SDRAM component is always the receiver. Refer to “DQS, DQ, and DM for DDR3 SDRAM Unbuffered DIMM” on page 2–9 for receiver termination recommendations and transmitter output drive strength settings.

Figure 2–13 illustrates the DDR3 SDRAM interface when the Stratix III and Stratix IV FPGA device is reading from the DDR3 SDRAM using a 50-Ω parallel OCT setting on the Stratix III and Stratix IV FPGA device, and the DDR3 SDRAM driver output impedance is set to 34 Ω.

Figure 2–13. DDR3 SDRAM Component Driving the Stratix III and Stratix IV FPGA Device with Parallel 50-Ω OCT Turned On

Figure 2–14 shows the simulation of a read from the DDR3 SDRAM DIMM with a 50-Ω parallel OCT setting on the Stratix III and Stratix IV FPGA device.
Use of the Stratix III and Stratix IV parallel 50-Ω OCT feature matches receiver impedance with the transmission line characteristic impedance. This eliminates any reflection that causes ringing, and results in a clean eye diagram at the Stratix III and Stratix IV FPGA.

**Memory Clocks for Stratix III and Stratix IV FPGA**
Memory clocks are unidirectional signals. Refer to “Memory Clocks for DDR3 SDRAM Unbuffered DIMM” on page 2–11 for receiver termination recommendations and transmitter output drive strength settings.

**Commands and Addresses for Stratix III and Stratix IV FPGA**
Commands and addresses are unidirectional signals. Refer to “Commands and Addresses for DDR3 SDRAM Unbuffered DIMM” on page 2–13 for receiver termination recommendations and transmitter output drive strength settings.

**Summary**
This section discusses terminations used for implementing the DDR3 SDRAM interface using the single-ranked, single unbuffered DIMM. Terminations for unidirectional signals, such as memory clocks and addresses and commands, are placed on the DIMM, thus eliminating the need to place terminations on the board. In addition, using the ODT feature on the DDR3 SDRAM and the Dynamic OCT feature of Stratix III and Stratix IV FPGA devices completely eliminates any external termination resistors, thus simplifying the layout for the DDR3 SDRAM interface when compared to that of the DDR2 SDRAM interface.
Termination for DDR3 SDRAM Components (With Leveling)

In addition to using DDR3 SDRAM DIMM to implement your DDR3 SDRAM interface, you can also use DDR3 SDRAM components. However, for applications that have limited board real estate, using DDR3 SDRAM components reduces the need for a DIMM connector and places components closer, resulting in denser layouts.

DDR3 SDRAM Components

The DDR3 SDRAM unbuffered DIMM is laid out to the JEDEC specification. The JEDEC specification is available from either the JEDEC Organization website (www.JEDEC.org) or from the memory vendors. However, when you are designing the DDR3 SDRAM interface using discrete SDRAM components, you may desire a layout scheme that is different than the DIMM specification. You have the following two options:

- Mimic the standard DDR3 SDRAM DIMM, using a fly-by topology for the memory clocks, address, and command signals. This option needs read and write leveling, so you must use the ALTMEMPHY megafunction with leveling.

  For more information on this fly-by configuration, continue reading this chapter.

- Mimic a standard DDR2 SDRAM DIMM, using a balanced (symmetrical) tree-type topology for the memory clocks, address, and command signal. Using this topology results in unwanted stubs on the command, address, and clock, which degrades signal integrity and limits the performance of the DDR3 SDRAM interface.

  For more information on using this non-standard symmetrical configuration, refer to “Termination for DDR3 SDRAM Components (Without Leveling)” on page 2–26.

DQS, DQ, and DM for DDR3 SDRAM Components

When you are laying out the DDR3 SDRAM interface using Stratix III or Stratix IV devices, you do not need to include the 15-Ω stub series resistor that is on every DQS, DQ, and DM signal, because DQS, DQ, and DM are point-to-point connections. Therefore, the recommended DQS, DQ, and DM topology appears (Figure 2–15) when the Stratix III or Stratix IV FPGA is writing to the DDR3 SDRAM.
When you are using DDR3 SDRAM components, there are no DIMM connectors. This minimizes any impedance discontinuity, resulting in better signal integrity. Figure 2–16 shows the simulated write-eye diagram at the DQ0 of a DDR3 SDRAM component using the 120-Ω ODT setting, and driven by a Stratix III or Stratix IV FPGA using a calibrated series 50-Ω OCT setting.

Similarly, Figure 2–17 shows the simulated write-eye diagram at the DQ0 of a DDR3 SDRAM component using the 60-Ω ODT setting, and driven by a Stratix III or Stratix IV FPGA using a calibrated series 50-Ω OCT setting.
Table 2–4 compares the effects of the series stub resistor on the eye diagram at the DDR3 SDRAM (receiver) when the Stratix III or Stratix IV FPGA is writing to memory.

<table>

</tbody>
</table>

Without the 15-Ω stub series resistor to dampen the signal arriving at the receiver of the DDR3 SDRAM component, the signal at the receiver of that component is larger than the signal at the receiver of a DIMM (Figure 2–6 and Figure 2–7).

**Memory Clocks for DDR3 SDRAM Components**

When you use DDR3 SDRAM components, you must account for the compensation capacitor and differential termination resistor between the differential memory clocks of the DIMM. Figure 2–18 shows the HyperLynx simulation of the differential clock seen at the first and last DDR3 SDRAM component using a flyby topology on a board, without the 2.2 pF compensation capacitor using the 50-Ω OCT setting on the output driver of the Stratix III and Stratix IV FPGA.
Without the compensation capacitor, the memory clocks (the yellow signal) at the first component have significant ringing, whereas, with the compensation capacitor the ringing is dampened. Similarly, the differential termination resistor needs to be included in the design. Depending on your board stackup and layout requirements, you choose your differential termination resistor value. Figure 2–19 shows the HyperLynx simulation of the differential clock seen at the first and last DDR3 SDRAM component using a fly-by topology on a board, and terminated with 100 Ω instead of the 72 Ω used in the DIMM.

**Figure 2–19.** Differential Memory Clock of a DDR3 SDRAM DIMM Terminated with 100 Ω at the First and Last Component Using a Fly-by Topology on a Board
Terminating with 100 Ω instead of 72 Ω results in a slight reduction in peak-to-peak amplitude. To simplify your design, use the terminations outlined in the JEDEC specification for unbuffered DDR3 SDRAM DIMM as your guide and perform simulation to ensure that the unbuffered DDR3 SDRAM DIMM terminations provide you with optimum signal quality.

In addition to choosing the value of the differential termination, you must consider the trace length of the memory clocks. There is no specification on the flight-time skew between the first and last component when designing with DDR3 SDRAM components on your board. Altera’s DDR3 ALTMEMPHY megafunction currently supports a flight-time skew of no more than 0.69 t\textsubscript{CK}. If you use Altera’s DDR3 ALTMEMPHY megafunction to create your DDR3 SDRAM interface, ensure that the flight-time skew of your memory clocks is not more than 0.69 t\textsubscript{CK}.

Refer to “Layout Considerations (with Leveling)” on page 2–23 for more information about layout guidelines for DDR3 SDRAM components.

**Commands and Addresses for DDR3 SDRAM Components**

As with memory clock signals, you must account for the termination resistor on the command and address signals when you use DDR3 SDRAM components. Choose your termination resistor value depending on your board stackup and layout requirements. Figure 2–20 shows the HyperLynx simulation of the command and address seen at the first and last DDR3 SDRAM component using a flyby topology on a board terminated with 60 Ω instead of the 39 Ω used in the DIMM.

**Figure 2–20.** Command and Address Eye Diagram of a DDR3 SDRAM Component Using Flyby Topology on a Board at the First and Last DDR3 SDRAM Component at 533 MHz, Terminated with 60 Ω
Terminating with 60 Ω instead of 39 Ω results in eye closure in the signal at the first component (the green signal), while there is no effect on the signal at the last component (the red signal). To simplify your design with discrete DDR3 SDRAM components, use the terminations outlined in the JEDEC specification for unbuffered DDR3 SDRAM DIMM as your guide, and perform simulation to ensure that the unbuffered DDR3 SDRAM DIMM terminations provide you with the optimum signal quality.

As with memory clocks, you must consider the trace length of the command and address signals so that they match the flight-time skew of the memory clocks.

**Stratix III and Stratix IV FPGAs**

The following sections describe termination used on the DDR3 SDRAM component interface side and investigate using the different termination features available in Stratix III and Stratix IV FPGA devices, so you can achieve optimum signal integrity for your DDR3 SDRAM interface.

**DQS, DQ, and DM Termination for Stratix III and Stratix IV FPGA**

Similar to the scenario highlighted in “DQS, DQ, and DM for Stratix III and Stratix IV FPGA” on page 2–14, the Stratix III and Stratix IV FPGA device is the receiver, the Stratix III and Stratix IV I/O buffer is set to a 50-Ω parallel termination, and the memory is the transmitter. The difference between the setup in “DQS, DQ, and DM for Stratix III and Stratix IV FPGA” on page 2–14 and the setup in this section is that there is no series stub resistor on the DQS, DQ, and DM signals. DM is a unidirectional signal, so the DDR3 SDRAM component is always the receiver. Refer to “DQS, DQ, and DM for DDR3 SDRAM Components” on page 2–16 for receiver termination recommendations and transmitter output drive strength settings.

Figure 2–21 illustrates the DDR3 SDRAM interface when the Stratix III and Stratix IV FPGA device is reading from the DDR3 SDRAM using a 50-Ω parallel OCT termination on the Stratix III and Stratix IV FPGA device and the DDR3 SDRAM driver output impedance is set to 34 Ω without the series stub resistor of 15 Ω.

Figure 2–22 shows a simulation of a read from the DDR3 SDRAM DIMM with a 50-Ω parallel OCT setting on the Stratix III or Stratix IV FPGA device.
Table 2–5 compares the effects of the series stub resistor on the eye diagram at the Stratix III and Stratix IV FPGA (receiver) when the Stratix III or Stratix IV FPGA is reading from the memory.

Table 2–5. Read-Eye Diagram with and without RS Using 50- Parallel OCT

<table>

Without the 15- stub series resistor to dampen the signal, the signal at the receiver of the Stratix III and Stratix IV FPGA driven by the DDR3 SDRAM component is larger than the signal at the receiver of the Stratix III and Stratix IV FPGA driven by DDR3 SDRAM DIMM (Figure 2–13), and similar to the write-eye diagram in “DQS, DQ, and DM for DDR3 SDRAM Components” on page 2–16.

Memory Clocks Termination for Stratix III and Stratix IV FPGA
Memory clocks are unidirectional signals. Refer to “Memory Clocks for DDR3 SDRAM Components” on page 2–18 for receiver termination recommendations and transmitter output drive strength settings.

Command and Address Termination for Stratix III and Stratix IV FPGA
Commands and addresses are unidirectional signals. Refer to “Commands and Addresses for DDR3 SDRAM Components” on page 2–20 for receiver termination recommendations and transmitter output drive strength setting.
Summary

This section discusses terminations used to achieve optimum performance for designing the DDR3 SDRAM interface using discrete DDR3 SDRAM components. Though you must include termination for unidirectional signals, the overall layout for the DDR3 SDRAM interface using discrete DDR3 SDRAM components is easier compared to DDR2 SDRAM interfaces using discrete DDR2 SDRAM components, because of the fly-by daisy chain topology. To simplify your design processes, use the DDR3 SDRAM unbuffered DIMM specification provided by JEDEC as your guideline, because the trace length and termination values used in the DIMM configuration provide excellent signal quality.

Layout Considerations (with Leveling)

This section discusses general layout guidelines for designing your DDR3 SDRAM interface. These layout guidelines help you plan your board layout, but are not meant as strict rules that must be adhered to. Altera recommends that you perform your own board-level simulations to ensure that the layout you choose for your board allows you to achieve your desired performance.

Trace Impedance

The layout of single-ended signal traces are to be 50 Ω and the differential signal traces are to be 100 Ω with a ± 10% tolerance. Remove unused via pads as these cause unwanted capacitance.

Decoupling

To minimize inductance, use 0.1 µF in 0402 size or smaller capacitors. Keep VTT voltage decoupling close to the DDR3 SDRAM components and pull-up resistors. Connect decoupling capacitors between VTT and ground using a 0.1 µF capacitor for every other VTT pin. For VDD and VDDQ, use 0.1 µF and 0.01 µF capacitors for every VDD and VDDQ pin.

Power

Route the ground, 1.5 V, and 0.75 V as planes. Route VCCIO for memories in a single-split plane with at least a 20-mil (0.508 mm) gap of separation. Route VTT as islands or 250-mil (6.35 mm) power traces. Route oscillators and PLL power as islands or 100-mil (2.54 mm) power traces.

Maximum Trace Length

Maximum trace length for all signals from FPGA to first DIMM slot is 4.5 inches. Maximum trace length for all signals from DIMM slot to DIMM slot is 0.425 inches.

When interfacing with multiple DDR3 SDRAM components, the maximum trace length for address, command, control and clock from FPGA to first component is maximum 7 inches, minimum of 3 inches.

Maximum trace length for DQ, DQS, DQS#, and DM from FPGA to first component is 5 inches.
General Routing Guidelines
Route using 45° angles and not 90° corners. Do not route critical signals across split planes. Route over appropriate VCC and ground planes. Avoid routing memory signals closer than 25-mil (0.635 mm) to the memory clocks. Keep the signal routing layers close to ground and power planes. All specified delay matching requirements include PCB trace delays, different layer propagation velocity variance, and crosstalk. To minimise PCB layer propagation variance, Altera recommend that signals from the same net group always be routed on the same layer.

Clock Routing Guidelines
Route clocks on inner layers with outer-layer run lengths held to under 500 mils (12.7 mm).

- 10-mil spacing for parallel runs < 0.5 inches (2× trace-to-plane distance)
- 15-mil spacing for parallel runs between 0.5 and 1.0 inches (3× trace-to-plane distance)
- 20-mil spacing for parallel runs between 1 and 6 inches (4× trace-to-plane distance)

Clocks must maintain a length matching between clock pairs of ±5 ps or approximately ± 25 mils (0.635 mm). Differential clocks need to maintain length matching between positive and negative signals of ±2 ps or approximately ± 10 mils (0.254 mm), routed in parallel. The space between differential pairs must be at least 2× the trace width of the differential pair to minimize loss and maximize interconnect density. The maximum length from the first SDRAM to the last SDRAM must be no more than 6 inches (approximately 153 mm) or 0.69 tCK, which is the same maximum length for clocks specified by JEDEC for unbuffered DIMM. This maximum clock-length specification is only valid for unbuffered DIMM. For other DIMM configurations, check the necessary JEDEC specifications, as the maximum clock length may be different. For example, JEDEC specifies the maximum clock length for SODIMM to be 6.5 inches (approximately 166 mm).

For example, differential clocks must be routed differentially (5 mil trace width, 10-15 mil space on centers, and equal in length to signals in the Address/Command Group). Take care with the via pattern used for clock traces. To avoid transmission-line-to-via mismatches, Altera recommends that your clock via pattern be a Ground-Signal-Signal-Ground (GSSG) topology (via topology: GND | CLKP | CLKN | GND).

Address and Command Routing Guidelines
Similar to the clock signals in DDR3 SDRAM, address and command signals are routed in a daisy chain topology from the first SDRAM to the last SDRAM. The maximum length from the first DRAM to the last SDRAM must be no more than 6 inches (approximately 153 mm) or 0.69 tCK, which is the same maximum length for clocks specified by JEDEC for unbuffered DIMMs. Ensure that each net maintains the same consecutive order. Unbuffered DIMMs are more susceptible to crosstalk and are generally noisier than buffered DIMMs. Route the address and command signals of
unbuffered DIMMs on a different layer than DQ and DM, and with greater spacing. Do not route differential clock and clock enable signals close to address signals. Route all addresses and commands to match the clock signals to within ±25 ps or approximately ± 125 mil (± 3.175 mm) to each discrete memory component. Figure 2–23 shows the DDR3 SDRAM routing guidelines, where:

- \( x = y \pm 125 \text{ mil} \)
- \( x + x_1 = y + y_1 \pm 125 \text{ mil} \)
- \( x + x_1 + x_2 = y + y_1 + y_2 \pm 125 \text{ mil} \)

**Figure 2–23. DDR3 SDRAM Component Routing Guidelines**

DQ, DQS, and DM Routing Guidelines

All signals within a given byte-lane group must be matched in length with a maximum deviation of ±10 ps or approximately ± 50 mils (± 1.27 mm). Ensure all signals within a given byte lane group are routed on the same layer to avoid layer to layer transmission velocity differences, which otherwise increase the skew within the group. Keep the maximum byte-lane group-to-byte group matched length deviation to ± 150 ps or ± 0.8 inches (± 20 mm).

Maintain all other signals to a spacing that is based on its parallelism with other nets:

- 5 mils for parallel runs < 0.5 inches (approximately 1× spacing relative to plane distance)
- 10 mils for parallel runs between 0.5 and 1.0 inches (approximately 2× spacing relative to plane distance)
- 15 mils for parallel runs between 1.0 and 6.0 inches (approximately 3× spacing relative to plane distance)

**Figure 2–24 shows the DDR3 SDRAM components DQ, DQS, and DM guidelines, where:**

- \( X > 2 + 0.5 + 0.125 \text{ inches} \)
- \( X < 2 + 0.5 - 0.125 \text{ inches} \)
- So, 2.375 inches < \( X < 2.625 \text{ inches} \)
Do not use DDR3 deskew to correct for more than 20 ps of DQ group skew. The deskew algorithm only removes the following possible uncertainties:

- Minimum and maximum die IOE skew or delay mismatch
- Minimum and maximum device package skew or mismatch
- Board delay mismatch of 20 ps
- Memory component DQ skew mismatch

Hence increasing any of these four parameters runs the risk of the deskew algorithm limiting, failing to correct for the total observed system skew. If the algorithm cannot compensate without limiting the correction, timing analysis shows reduced margins.

**Termination**

The previous sections use the combination of DDR3 SDRAM ODT and Stratix III and Stratix IV Dynamic OCT for DQS, DQS#, DQ, and DM. This practice reduces the need for external termination, and thus reduces both bill-of-materials (BOM) cost and PCB size.

When using DIMMs, you have no concerns about terminations on memory clocks, addresses, and commands. If you are using components, use an external parallel termination of 40 $$\Omega$$ to $V_{TT}$ at the end of the fly-by daisy chain topology on the addresses and commands. For memory clocks, use an external parallel termination of 75 $$\Omega$$ differential at the end of the fly-by daisy chain topology on the memory clocks. Using fly-by daisy chain topology helps reduce any stub reflection. Keep the length of the traces to the termination to within 0.5 inch (14 mm). Use resistors with tolerances of 1 to 2%.

**Termination for DDR3 SDRAM Components (Without Leveling)**

Altera support the use of DDR3 SDRAM components using a PHY without leveling. To use the PHY without leveling, you should layout the DDR3 SDRAM components on your PCB in a DDR2-like topology. Operating DDR3 SDRAM components without leveling requires tighter layout rules and the use of more complex topologies. This section discusses these termination and layout requirements.
DDR3 SDRAM Components

This chapter describes how to implement the nonstandard DDR2-like balanced (symmetrical) topology for command, address, and clock signals. Using this alternative topology results in unwanted stubs on the address, command, and clock signals, which degrades signal integrity and limits the performance of any DDR3 SDRAM interface.

DQS, DQ, and DM for DDR3 SDRAM Components

The DDR3 SDRAM PHY without leveling uses the same topology and termination settings for the DQS, DQ and DM signals as the DDR3 SDRAM with leveling (refer to “DQS, DQ, and DM for DDR3 SDRAM Components” on page 2–16). However, while the topology and termination of these signals is identical, the layout rules differ, because of the balanced command, address, and clock signals. DDR3 SDRAM without leveling interfaces require much tighter DQ group to DQ group timing, refer to “Layout Considerations (without Leveling)” on page 2–31.

Memory Clocks for DDR3 SDRAM Components

Memory clocks in a DDR3 SDRAM interface without leveling should follow the same topology guidelines as a DDR2 SDRAM-type interface. However, SSTL15 type signaling is used instead of SSTL18.

For more information, refer to Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

If your DDR3 SDRAM interface connects to a single component, you can use a simple point-to-point topology a 100 Ω differential terminator at the component end of the line.

Most interfaces use two, four, or eight DDR3 SDRAM components, so you should use a balanced T-type routing pattern, where all the trace segments are balanced for each path. The total trace length to the first DDR3 SDRAM component is identical to that of the last component, hence the trace delay for each component is the same, ensuring matched timing while helping to control any reflections.

Differentially terminate clocks at the component end of the line with a 100 Ω resistor. For more than one DDR3 SDRAM component, split the clock using a balanced T-topology. Place the 100 Ω termination resistor at the first split in the T (refer to Figure 2–25), or increase the resistor value and place a resistor at the end of each segment at the DDR3 SDRAM component (refer to Figure 2–26). Typically two segments require 200 Ω resistors; and four segments require 400 Ω resistors, but Altera recommend that you simulate your specific topology to be ascertain the correct value.
Loading must not excessively degrade the slew rate of the memory clocks, so ideally a single differential clock pair does not drive more than four components. If a single clock pair drives eight or larger numbers of DDR3 SDRAM components, you must perform setup and hold deration, to allow accurate timing analysis. Altera recommend that you simulate any proposed topology before board completion, so you can perform deration and final timing analysis. DDR3 setup and hold deration may result in a lower than stated interface frequency to be achieved in any given device or speed grade combination.
**Command and Address for DDR3 SDRAM Components**

Command and address signals are similar to memory clocks in topology, so you should use a balanced T-type routing pattern, where all the trace segments are balanced for each path. The loading on the address and command signals is typically larger with eight or sixteen loads not unusual. You should mimic the topologies that J edec uses on DDR2 unbuffered DIMM raw cards A to C, as these topologies provide the best results.

Avoid topologies that J edec uses on DDR2 unbuffered DIMM raw cards D, E, and F. Raw card D topologies typically suffer from loading resonances, which reduce timing margin. Additionally, raw cards E and F are not symmetrical balanced trees, as they use a planar solution, which again can reduce timing margin.

Command and address signals should always be terminated with a 50 \( \Omega \) resistor to \( V_{TT} \). Always place this single 50 \( \Omega \) resistor at the first split in the T (Figure 2–27).

**Figure 2–27.** Placing the 50-Ω Resistor

---

**Stratix III and Stratix IV FPGAs**

The following sections describe the termination used on the DDR3 SDRAM components interface side and the different termination features available in the Stratix III and Stratix IV FPGAs when using a PHY without leveling, so that optimum signal integrity can be achieved for your DDR3 SDRAM interface.
DQS, DQ, and DM Termination for Stratix III Stratix IV FPGAs

It should be understood that the termination and topology for DQS, DQ, and DM signals is identical. The choice of leveling or without leveling DDR3 SDRAM PHY only affects the address, command, and clock termination schemes (refer to “DQS, DQ, and DM for Stratix III and Stratix IV FPGA” on page 2–14).

Because of the different timing requirements, the layout (trace matching) constraints for DQS, DQ, and DM do differ (refer to “Layout Considerations (without Leveling)” on page 2–31).

Memory Clocks Termination for Stratix III and Stratix IV FPGA

Memory clocks are unidirectional signals. When using DDR3 SDRAM components without leveling, mimic the termination and topology used for DDR2 SDRAM components, substituting differential SSTL18 class I with differential SSTL15 class I.

For more information, refer to Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

Command and Address for Termination for Stratix III and Stratix IV FPGAs

Commands and addresses are unidirectional signals. When using DDR3 SDRAM components without leveling, mimic the termination and topology used for DDR2 SDRAM components, substituting SSTL18 class I with SSTL15 class I.

For more information, refer to Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

Arria II GX FPGA

The following sections describe the termination used on the DDR3 SDRAM components interface side and the different termination features available in the Arria II GX devices when using a PHY without leveling, so that optimum signal integrity can be achieved for your DDR3 SDRAM interface without leveling.

DDR3 SDRAM component interfaces without leveling are routed identically to DDR2 SDRAM interfaces without leveling, hence DDR2 SDRAM interface recommendations apply.

DQS, DQ and DM Termination for Arria II GX FPGAs

The termination and topology and layout of DQS, DQ, and DM signals is identical if DDR2 (differential DQS mode) is compared to DDR3 SDRAM.

DDR3 SDRAM without leveling on Arria II GX devices should be considered identical to any DDR2 SDRAM components interface.

The memory end termination (Table 2–1 and Table 2–2) still applies. But you should use the FPGA end termination settings from AN 408: DDR2 Memory Interface Termination, Drive Strength, Loading, and Design Layout Guidelines.

As Arria II GX devices don’t feature dynamic OCT, 50 Ω parallel discrete termination to $V_{TT}$ should be used at the FPGA end of the line.

For more information, refer to “Layout Considerations (without Leveling)” on page 2–31.
Memory Clocks Termination for Arria II GX FPGAs
Memory clocks are unidirectional signals. When using DDR3 SDRAM components without leveling, mimic the termination and topology used for DDR2 SDRAM components, substituting Differential SSTL18 Class I with Differential SSTL15 Class I.

For more information about component termination and FPGA drive strength settings, refer to “Memory Clocks for DDR3 SDRAM Components” on page 2–18 and Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

Command and Address for Termination for Arria II GX FPGAs
Commands and addresses are unidirectional signals. When using DDR3 SDRAM components without leveling, mimic the termination and topology used for DDR2 SDRAM components, substituting Differential SSTL18 Class I with Differential SSTL15 Class I.

For more information about component termination and FPGA drive strength settings, refer to “Commands and Addresses for DDR3 SDRAM Components” on page 2–20 and Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

Summary
This section discusses the I/O standards, drive strength, termination and topologies to use so that you achieve optimum performance when designing with DDR3 SDRAM components without leveling. The topology is more challenging for command, address, and clock signals, but it is no harder than the previous generation DDR2 SDRAM interface, as the same requirements are used.

Layout Considerations (without Leveling)
This section discusses general layout guidelines for designing your DDR3 SDRAM component without leveling interface. These guidelines help you plan your board layout, but are not meant as strict rules that must be adhered to. Altera recommends that you perform your own board-level simulations to ensure that your implemented topology allows you to achieve your desired performance.

For more information, refer to Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

When mimicking DDR2 unbuffered DIMM JEDEC topologies, Altera recommends that you use only raw cards A to C, as these are balanced symmetrical topologies and result in the optimum performance. Raw cards D to F are not symmetrical and are planar solutions, so should be avoided where possible.

When following DDR2 SDRAM component guidelines, the I/O standard for DDR3 is SSTL15 and not SSTL18. DDR3 SDRAM components have enhanced ODT and output drive strength features that you can use to improve the SI performance of a DDR3 SDRAM component without leveling solution, above that of a standard DDR2 implementation.
Altera’s timing analysis assumes single-ranked DDR3 SDRAM designs only. Dual or quad ranked designs require timing deration. For more information on multirank topologies and layout guidelines, refer to Chapter 3, Dual-DIMM DDR2 and DDR3 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

Conclusion

By using the new features of DDR3 SDRAM and the Stratix III and Stratix IV FPGAs, you simplify your design process for DDR3 SDRAM. Using the fly-by daisy chain topology increases the complexity of the datapath and controller design to achieve leveling, but also greatly improves performance and eases board layout for DDR3 SDRAM.

DDR3 SDRAM components without leveling can also be used in an design when this may result in a more optimal solution or for use with devices that support the required electrical interface standard, but do not support the required read and write leveling functionality.

By using Altera FPGAs and the DDR3 SDRAM ALTMEMPHY megafuction, you simplify the datapath design and can take advantage of either the higher DDR3 SDRAM performance and straightforward board design in a design with leveling, or the lower power and cost performance advantages of DDR3 SDRAM components in a design without leveling.

This chapter describes guidelines for implementing dual-unbuffered DIMM DDR2 and DDR3 SDRAM interfaces. This chapter discusses the impact on signal integrity of the data signal with the following conditions in a dual-DIMM configuration:

- Populating just one slot versus populating both slots
- Populating slot 1 versus slot 2 when only one DIMM is used
- On-die termination (ODT) setting of 75 Ω versus an ODT setting of 150 Ω

For detailed information about a single-DIMM DDR2 SDRAM interface, refer to Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

**DDR2 SDRAM**

This section describes guidelines for implementing a dual slot unbuffered DDR2 SDRAM interface, operating at up to 400-MHz and 800-Mbps data rates. Figure 3–1 shows a typical DQS, DQ, and DM signal topology for a dual-DIMM interface configuration using the ODT feature of the DDR2 SDRAM components.

**Figure 3–1. Dual-DIMM DDR2 SDRAM Interface Configuration (Note 1)**

![Diagram of Dual-DIMM DDR2 SDRAM Interface Configuration](Image)

**Note to Figure 3–1:**

1. The parallel termination resistor $R_T = 54$ Ω to $V_{TT}$ at the FPGA end of the line is optional for devices that support dynamic on-chip termination (OCT).

The simulations in this section use a Stratix® II device-based board. Because of limitations of this FPGA device family, simulations are limited to 266 MHz and 533 Mbps so that comparison to actual hardware results can be directly made.
Stratix II High Speed Board

To properly study the dual-DIMM DDR2 SDRAM interface, the simulation and measurement setup evaluated in the following analysis features a Stratix II FPGA interfacing with two 267-MHz DDR2 SDRAM unbuffered DIMMs. This DDR2 SDRAM interface is built on the Stratix II High-Speed High-Density Board (Figure 3–2).

For more information about the Stratix II High-Speed High-Density Board, contact your Altera representative.

Figure 3–2. Stratix II High-Speed Board with Dual-DIMM DDR2 SDRAM Interface

The Stratix II High-Speed Board uses a Stratix II 2S90F1508 device. For DQS, DQ, and DM signals, the board is designed without external parallel termination resistors near the DDR2 SDRAM DIMMs, to take advantage of the ODT feature of the DDR2 SDRAM components. Stratix II FPGA devices are not equipped with dynamic OCT, so external parallel termination resistors are used at the FPGA end of the line.

Stratix III and Stratix IV devices, which support dynamic OCT, do not require FPGA end parallel termination. Hence this discrete parallel termination is optional.

The DDR2 SDRAM DIMM contains a 22-Ω external series termination resistor for each data strobe and data line, so all the measurements and simulations need to account for the effect of these series termination resistors.
To correlate the bench measurements done on the Stratix II High Speed High Density Board, the simulations are performed using HyperLynx LineSim Software with IBIS models from Altera and memory vendors. Figure 3–3 is an example of the simulation setup in HyperLynx used for the simulation.

**Figure 3–3.** HyperLynx Setup for Simulating the Stratix II High Speed High Density with Dual-DIMM DDR2 SDRAM Interface

---

**Overview of ODT Control**

When there is only a single-DIMM on the board, the ODT control is relatively straightforward. During write to the memory, the ODT feature of the memory is turned on; during read from the memory, the ODT feature of the memory is turned off. However, when there are multiple DIMMs on the board, the ODT control becomes more complicated.

With a dual-DIMM interface on the system, the controller has different options for turning the memory ODT on or off during read or write. Table 3–1 shows the DDR2 SDRAM ODT control during write to the memory; Table 3–2 during read from the memory. These DDR2 SDRAM ODT controls are recommended by Samsung Electronics. The JEDEC DDR2 specification was updated to include optional support for $R_{TT}$(nominal) = 50 Ω.

For more information about the DDR2 SDRAM ODT controls recommended by Samsung, refer to the *Samsung DDR2 Application Note: ODT (On Die Termination) Control*. 
A 54-Ω external parallel termination resistor is placed on all the data strobes and data lines near the Stratix II device on the Stratix II High Speed High Density Board. Although the characteristic impedance of the transmission is designed for 50 Ω to account for any process variation, it is advisable to underterminate the termination seen at the receiver. This is why the termination resistors at the FPGA side use 54-Ω resistors.

DIMM Configuration

While populating both memory slots is common in a dual-DIMM memory system, there are some instances when only one slot is populated. For example, some systems are designed to have a certain amount of memory initially and as applications get more complex, the system can be easily upgraded to accommodate more memory by populating the second memory slot without re-designing the system. The following section discusses a dual-DIMM system where the dual-DIMM system only has one slot populated at one time and a dual-DIMM system where both slots are populated. ODT controls recommended by the memory vendors listed in Table 3–1 as well as other possible ODT settings will be evaluated for usefulness in an FPGA system.

Dual-DIMM Memory Interface with Slot 1 Populated

This section focuses on a dual-DIMM memory interface where slot 1 is populated and slot 2 is unpopulated. This section examines the impact on the signal quality due to an unpopulated DIMM slot and compares it to a single-DIMM memory interface.

FPGA Writing to Memory

In the DDR2 SDRAM, the ODT feature has two settings: 150 Ω and 75 Ω. In Table 3–1, the recommended ODT setting for a dual DIMM configuration with one slot occupied is 150 Ω.

On DDR2 SDRAM devices running at 333 MHz/667 Mbps and above, the ODT feature supports an additional setting of 50 Ω.

Refer to the respective memory decathlete for additional information about the ODT settings in DDR2 SDRAM devices.

Write to Memory Using an ODT Setting of 150Ω

Figure 3–4 shows a double parallel termination scheme (Class II) using ODT on the memory with a memory-side series resistor when the FPGA is writing to the memory using a 25-Ω OCT drive strength setting on the FPGA.

Figure 3–4. Double Parallel Termination Scheme (Class II) Using ODT on DDR2 SDRAM DIMM with Memory-Side Series Resistor
Figure 3–5 shows a HyperLynx simulation and board measurement of a signal at the memory of a double parallel termination using ODT 150 Ω with a memory-side series resistor transmission line when the FPGA is writing to the memory with a 25-Ω OCT drive strength setting.

Table 3–3 summarizes the comparison between the simulation and board measurements of the signal at the memory of a single-DIMM and a dual-DIMM memory interface with slot 1 populated using a double parallel termination using an ODT setting of 150 Ω with a memory-side series resistor with a 25-Ω OCT strength setting on the FPGA.

Table 3–3 indicates that there is not much difference between a single-DIMM memory interface or a dual-DIMM memory interface with slot 1 populated. The over and undershooting observed in both the simulations and board measurements can be attributed to the use of the ODT setting of 150 Ω on the memory resulting in over-termination at the receiver. In addition, there is no significant effect of the extra DIMM connector due to the unpopulated slot.
When the ODT setting is set to 75 Ω, there is no difference in the eye width and height compared to the ODT setting of 150 Ω. However, there is no overshoot and undershoot when the ODT setting is set to 75 Ω, which is attributed to proper termination resulting in matched impedance seen by the DDR2 SDRAM devices.

For information about results obtained from using an ODT setting of 75 Ω refer to page 3–24.

Reading from Memory

During read from the memory, the ODT feature is turned off. Thus, there is no difference between using an ODT setting of 150 Ω and 75 Ω. As such, the termination scheme becomes a single parallel termination scheme (Class I) where there is an external resistor on the FPGA side and a series resistor on the memory side as shown in Figure 3–6.

Figure 3–6. Single Parallel Termination Scheme (Class I) Using External Resistor and Memory-Side Series Resistor

Figure 3–7 shows the simulation and board measurement of the signal at the FPGA of a single parallel termination using an external parallel resistor on the FPGA side with a memory-side series resistor with full drive strength setting on the memory.

Figure 3–7. HyperLynx Simulation and Board Measurement of the Signal at the FPGA When Reading From Slot 1 With Slot 2 Unpopulated
Table 3–4 summarizes the comparison between the simulation and board measurements of the signal seen at the FPGA of a single-DIMM and a dual-DIMM memory interface with a slot 1 populated memory interface using a single parallel termination using an external parallel resistor at the FPGA with a memory-side series resistor with full strength setting on the memory.

Note to Table 3–4:
(1) The simulation and board measurements of the single-DIMM DDR2 SDRAM interface are based on the Stratix II Memory Board 2. For more information about the single-DIMM DDR2 SDRAM interface, refer to Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

Table 3–4 demonstrates that there is not much difference between a single-DIMM memory interface or a dual-DIMM memory interface with only slot 1 populated. There is no significant effect of the extra DIMM connector due to the unpopulated slot.

**Dual-DIMM with Slot 2 Populated**

This section focuses on a dual-DIMM memory interface where slot 2 is populated and slot 1 is unpopulated. Specifically, this section discusses the impact of location of the DIMM on the signal quality.

**FPGA Writing to Memory**

The previous section focused on the dual-DIMM memory interface where slot 1 is populated resulting in the memory being located closer to the FPGA. When slot 2 is populated, the memory is located further away from the FPGA, resulting in additional trace length that potentially affects the signal quality seen by the memory. The next section explores if there are any differences between populating slot 1 and slot 2 of the dual-DIMM memory interface.

**Write to Memory Using an ODT Setting of 150Ω**

Figure 3–8 shows the double parallel termination scheme (Class II) using ODT on the memory with the memory-side series resistor when the FPGA is writing to the memory using a 25-Ω OCT drive strength setting on the FPGA.
Figure 3–9 shows the simulation and board measurement of the signal at the memory of a double parallel termination using an ODT setting of 150 Ω with a memory-side series resistor transmission line when the FPGA is writing to the memory with a 25-Ω OCT drive strength setting.

Table 3–5 summarizes the comparison between the simulation and board measurements of the signal seen at the DDR2 SDRAM DIMM of a dual-DIMM memory interface with either only slot 1 populated or only slot 2 populated using a double parallel termination using an ODT setting of 150 Ω with a memory-side series resistor with a 25-Ω OCT strength setting on the FPGA.

Table 3–5 shows that there is not much difference between populating slot 1 or slot 2 in a dual-DIMM memory interface. The over and undershooting observed in both the simulations and board measurements can be attributed to the use of the ODT setting of 150 Ω on the memory, resulting in under-termination at the receiver.

When the ODT setting is set to 75 Ω, there is no difference in the eye width and height compared to the ODT setting of 150 Ω. However, there is no overshoot and undershoot when the ODT setting is set to 75 Ω, which is attributed to proper termination resulting in matched impedance seen by the DDR2 SDRAM devices.

For detailed results for the ODT setting of 75 Ω, refer to page 3–25.

**Reading from Memory**

During read from memory, the ODT feature is turned off, thus there is no difference between using an ODT setting of 150 Ω and 75 Ω. As such, the termination scheme becomes a single parallel termination scheme (Class I) where there is an external resistor on the FPGA side and a series resistor on the memory side, as shown in Figure 3–10.

Figure 3–10. Single Parallel Termination Scheme (Class I) Using External Resistor and Memory-Side Series Resistor

Figure 3–11 shows the simulation and board measurement of the signal at the FPGA of a single parallel termination using an external parallel resistor on the FPGA side with a memory-side series resistor with full drive strength setting on the memory.
Table 3–6 summarizes the comparison between the simulation and board measurements of the signal seen at the FPGA of a dual-DIMM memory interface with either slot 1 or slot 2 populated using a single parallel termination using an external parallel resistor at the FPGA with a memory-side series resistor with full strength setting on the memory.

From Table 3–6, you can see the signal seen at the FPGA is similar whether the memory DIMM is located at either slot 1 or slot 2.

**Dual-DIMM Memory Interface with Both Slot 1 and Slot 2 Populated**

This section focuses on a dual-DIMM memory interface where both slot 1 and slot 2 are populated. As such, you can write to either the memory in slot 1 or the memory in slot 2.

**FPGA Writing to Memory**

In Table 3–1, the recommended ODT setting for a dual DIMM configuration with both slots occupied is 75 Ω. Since there is an option for an ODT setting of 150 Ω, this section explores the usage of the 150 Ω setting and compares the results to that of the recommended 75 Ω.
Write to Memory in Slot 1 Using an ODT Setting of 75-Ω

Figure 3–12 shows the double parallel termination scheme (Class II) using ODT on the memory with the memory-side series resistor when the FPGA is writing to the memory using a 25-Ω OCT drive strength setting on the FPGA. In this scenario, the FPGA is writing to the memory in slot 1 and the ODT feature of the memory at slot 2 is turned on.

Figure 3–12. Double Parallel Termination Scheme (Class II) Using ODT on DDR2 SDRAM DIMM with a Memory-Side Series Resistor

Figure 3–13 shows a HyperLynx simulation and board measurement of the signal at the memory in slot 1 of a double parallel termination using an ODT setting of 75 Ω with a memory-side series resistor transmission line when the FPGA is writing to the memory with a 25-Ω OCT drive strength setting.
Table 3–7 summarizes the comparison of the signal at the memory of a dual-DIMM memory interface with one slot and with both slots populated using a double parallel termination using an ODT setting of 75 Ω with a memory-side series resistor with a 25-Ω OCT strength setting on the FPGA.

| Dual-DIMM interface with slot 1 populated   | 1.68           | 0.97           | 0.06          | NA             | 2.08                    | 2.08                     |
| Measurements                              | 1.30           | 0.63           | 0.22          | 0.20           | 1.74                    | 1.82                     |

Table 3–7 shows that there is not much difference in the eye height between populating one slot or both slots. However, the additional loading due to the additional memory DIMM results in a slower edge rate, which results in smaller eye width and degrades the setup and hold time of the memory. This reduces the available data valid window.

When the ODT setting is set to 150 Ω, there is no difference in the eye width and height compared to the ODT setting of 75 Ω. However, there is some overshoot and undershoot when the ODT setting is set to 150 Ω, which is attributed to under termination resulting in mismatched impedance seen by the DDR2 SDRAM devices.

For more information about the results obtained from using an ODT setting of 150 Ω, refer to page 3–26.
Write to Memory in Slot 2 Using an ODT Setting of 75-Ω

In this scenario, the FPGA is writing to the memory in slot 2 and the ODT feature of the memory at slot 1 is turned on. Figure 3–14 shows the HyperLynx simulation and board measurement of the signal at the memory in slot 1 of a double parallel termination using an ODT setting of 75 Ω with a memory-side series resistor transmission line when the FPGA is writing to the memory with a 25-Ω OCT drive strength setting.

Figure 3–14. HyperLynx Simulation and Board Measurements of the Signal at the Memory in Slot 2 With Both Slots Populated

Table 3–8 summarizes the comparison of the signal at the memory of a dual-DIMM memory interface with slot 1 populated using a double parallel termination using an ODT setting of 75 Ω with a memory-side series resistor with a 25-Ω OCT strength setting on the FPGA.

</tbody>
</table>

From Table 3–8, you can see that both simulations and board measurements demonstrate that the eye width is larger when writing to slot 1, which is due to better edge rate seen when writing to slot 1. The improvement on the eye when writing to slot 1 can be attributed to the location of the termination. When you are writing to slot 1, the ODT feature of slot 2 is turned on, resulting in a fly-by topology. When you are writing to slot 2, the ODT feature of slot 1 is turned on resulting in a non fly-by topology.
When the ODT setting is set to 150 Ω, there is no difference in the eye width and height compared to the ODT setting of 75 Ω. However, there is some overshoot and undershoot when the ODT setting is set to 150 Ω, which is attributed to under termination resulting in mismatched impedance seen by the DDR2 SDRAM devices.

For more information about the results obtained from using an ODT setting of 150 Ω, refer to “Write to Memory in Slot 2 Using an ODT Setting of 150 Ω With Both Slots Populated” on page 3–27.

**Reading From Memory**

In Table 3–1, the recommended ODT setting for a dual-DIMM configuration with both slots occupied is to turn on the ODT feature using a setting of 75 Ω on the slot that is not read from. Since there is an option for an ODT setting of 150 Ω, this section explores the usage of the 150 Ω setting and compares the results to that of the recommended 75 Ω.

**Read From Memory in Slot 1 Using an ODT Setting of 75-Ω on Slot 2**

Figure 3–15 shows the double parallel termination scheme (Class II) using ODT on the memory with the memory-side series resistor when the FPGA is reading from the memory using a full drive strength setting on the memory. In this scenario, the FPGA is reading from the memory in slot 1 and the ODT feature of the memory at slot 2 is turned on.
Figure 3–15. Double Parallel Termination Scheme (Class II) Using External Resistor and Memory-Side Series Resistor and ODT Feature Turned On

Figure 3–16 shows the simulation and board measurement of the signal at the FPGA when the FPGA is reading from the memory in slot 1 using a full drive strength setting on the memory.
Table 3–9 summarizes the comparison between the simulation and board measurements of the signal seen at the FPGA of a dual-DIMM memory interface with both slots populated and a dual-DIMM memory interface with a slot 1 populated memory interface.

Table 3–9 shows that when both slots are populated, the additional loading due to the additional memory DIMM results in a slower edge rate, which results in a degradation in the eye width.

For more information about the results obtained from using an ODT setting of 150 Ω, refer to “Read from Memory in Slot 1 Using an ODT Setting of 150 Ω on Slot 2 with Both Slots Populated” on page 3–28.

Read From Memory in Slot 2 Using an ODT Setting of 75-Ω on Slot 1

In this scenario, the FPGA is reading from the memory in slot 2 and the ODT feature of the memory at slot 1 is turned on.
Figure 3–18 shows the HyperLynx simulation and board measurement of the signal at the FPGA of a double parallel termination using an external parallel resistor on the FPGA side with a memory-side series resistor and an ODT setting of 75 Ω with a full drive strength setting on the memory.
Table 3–10 summarizes the comparison between the simulation and board measurements of the signal seen at the FPGA of a dual-DIMM memory interface with both slots populated and a dual-DIMM memory interface with a slot 1 populated memory interface.

Table 3–10 shows that when only one slot is populated in a dual-DIMM memory interface, the eye width is larger as compared to a dual-DIMM memory interface with both slots populated. This can be attributed to the loading from the DIMM located in slot 1.

When the ODT setting is set to 150 $\Omega$, there is no difference in the signal quality compared to the ODT setting of 75 $\Omega$.

For more information about the results obtained from using an ODT setting of 150 $\Omega$, refer to “Read From Memory in Slot 2 Using an ODT Setting of 150 $\Omega$ on Slot 1 With Both Slots Populated” on page 3–29.
FPGA OCT Features

Many FPGA devices offer OCT. Depending on the chosen device family, series (output), parallel (input) or dynamic (bidirectional) OCT may be supported.

For more information specific to your device family, refer to the respective I/O features chapter in the relevant device handbook.

Use series OCT in place of the near-end series terminator typically used in both Class I or Class II termination schemes that both DDR2 and DDR3 type interfaces use.

Use parallel OCT in place of the far-end parallel termination typically used in Class I termination schemes on unidirectional input only interfaces. For example, QDR II-type interfaces, when the FPGA is at the far end.

Use dynamic OCT in place of both the series and parallel termination at the FPGA end of the line. Typically use dynamic OCT for DQ and DQS signals in both DDR2 and DDR3 type interfaces. As the parallel termination is dynamically disabled during writes, the FPGA driver only ever drives into a Class I transmission line. When combined with dynamic ODT at the memory, a truly dynamic Class I termination scheme exists where both reads and writes are always fully Class I terminated in each direction. Hence, you can use a fully dynamic bidirectional Class I termination scheme instead of a static discretely terminated Class II topology, which saves power, PCB real estate, and component cost.

Stratix III and Stratix IV Devices

Stratix III and Stratix IV devices feature full dynamic OCT termination capability, Altera advise that you use this feature combined with the SDRAM ODT to simplify PCB layout and save power.

Arria II GX Devices

Arria II GX devices do not support dynamic OCT. Altera recommend that you use series OCT with SDRAM ODT. Use parallel discrete termination at the FPGA end of the line when necessary,

For more information, refer to Chapter 1, DDR2 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

Dual-DIMM DDR2 Clock, Address, and Command Termination and Topology

The address and command signals on a DDR2 SDRAM interface are unidirectional signals that the FPGA memory controller drives to the DIMM slots. These signals are always Class-I terminated at the memory end of the line (Figure 3–19). Always place DDR2 SDRAM address and command Class-I termination after the last DIMM. The interface can have one or two DIMMs, but never more than two DIMMs total.
In Figure 3–19, observe the following points:

- Board trace A = 1.9 to 4.5 inches (48 to 115 mm)
- Board trace B = 0.425 inches (10.795 mm)
- Board trace C = 0.2 to 0.55 inches (5 to 13 mm)
- Total of board trace A + B + C = 2.5 to 5 inches (63 to 127 mm)
- $R_P = 36$ to $56 \, \Omega$
- Length match all address and command signals to $+250$ mils (+5 mm) or $+/- 50$ ps of memory clock length at the DIMM.

You may place a compensation capacitor directly before the first DIMM slot 1 to improve signal quality on the address and command signal group. If you fit a capacitor, Altera recommend a value of 24 pF.

For more information, refer to *Micron TN47-01*.

**Address and Command Signals**

The address and command group of signals: bank address, address, RAS#, CAS#, and WE# operate a different toggle rate depending on whether you implement a full-rate or half-rate memory controller.

In full-rate designs, the address and command group of signals are 1T signals, which means that the signals can change every memory clock cycle. Address and command signals are also single data rate (SDR). Hence in a full-rate PHY design, the address and command signals operate at a maximum frequency of $0.5 \times$ the data rate. For example in a 266-MHz full rate design, the maximum address and command frequency is 133 MHz.
In half-rate designs the address and command group of signals are 2T signals, which means that the signals change only every two memory clock cycles. As the signals are also SDR, in a half-rate PHY design, the address and command signals operate at a maximum frequency of 0.25 × the data rate. For example, in a 400-MHz half-rate design, the maximum address and command frequency is 100 MHz.

Control Group Signals

The control group of signals: chip select CS#, clock enable CKE, and ODT are always 1T regardless of whether you implement a full-rate or half-rate design. As the signals are also SDR, the control group signals operate at a maximum frequency of 0.5 × the data rate. For example, in a 400-MHz design, the maximum control group frequency is 200 MHz.

Clock Group Signals

Depending on the specific form factor, DDR2 SDRAM DIMMs have two or three differential clock pairs, to ensure that the loading on the clock signals is not excessive. The clock signals are always terminated on the DIMMs and hence no termination is required on your PCB. Additionally, each DIMM slot is required to have its own dedicated set of clock signals. Hence clock signals are always point-to-point from the FPGA PHY to each individual DIMM slot. Individual memory clock signals should never be shared between two DIMM slots.

A typical two slot DDR2 DIMM design therefore has six differential memory clock pairs—three to the first DIMM and three to the second DIMM. All six memory clock pairs must be delay matched to each other to ±25 mils (±0.635 mm) and ±10 mils (±0.254 mm) for each CLK to CLK# signal.

You may place a compensation capacitor between each clock pair directly before the DIMM connector, to improve the clock slew rates. As FPGA devices have fully programmable drive strength and slew rate options, this capacitor is usually not required for FPGA design. However, Altera advise that you simulate your specific implementation to ascertain if this capacitor is required or not. If fitted the best value is typically 5 pF.

DDR3 SDRAM

This section details the system implementation of a dual slot unbuffered DDR3 SDRAM interface, operating at up to 400 MHz and 800 Mbps data rates. Figure 3–20 shows a typical DQS, DQ, and DM, and address and command signal topology for a dual-DIMM interface configuration, using the on-die termination (ODT) feature of the DDR3 SDRAM components combined with the dynamic OCT features available in Stratix III and Stratix IV devices.
In Figure 3–20, observe the following points:

- Board trace A = 1.9 to 4.5 inches (48 to 115 mm)
- Board trace B = 0.425 inches (10.795 mm)
- This topology to both DIMMs is accurate for DQS, DQ, and DM, and address and command signals
- This topology is not correct for CLK and CLK# and control group signals (CS#, CKE, and ODT), which are always point-to-point single rank only.

**Comparison of DDR3 and DDR2 DQ and DQS ODT Features and Topology**

DDR3 and DDR2 SDRAM systems are quite similar. The physical topology of the data group of signals may be considered nearly identical. The FPGA end (driver) I/O standard changes from SSTL18 for DDR2 to SSTL15 for DDR3, but all other OCT settings are identical. DDR3 offers enhanced ODT options for termination and drive-strength settings at the memory end of the line.

For more information, refer to the DDR3 SDRAM ODT matrix for writes and the DDR3 SDRAM ODT matrix for reads tables in Chapter 2, DDR3 SDRAM Interface Termination, Drive Strength, Loading, and Board Layout Guidelines.

**Dual-DIMM DDR3 Clock, Address, and Command Termination and Topology**

One significant difference between DDR3 and DDR2 DIMM based interfaces is the address, command, and clock signals. DDR3 uses a daisy chained based architecture when using JEDEC standard modules. The address, command, and clock signals are routed on each module in a daisy chain and feature a fly-by termination on the module. Impedance matching is required to make the dual-DIMM topology work effectively—40 to 50 Ω traces should be targeted on the main board.
Address and Command Signals

Two unbuffered DIMMs result in twice the effective load on the address and command signals, which reduces the slew rate and makes it more difficult to meet setup and hold timing (\(t_{\text{setup}}\) and \(t_{\text{hold}}\)). However, address and command signals operate at half the interface rate and are SDR. Hence a 400-Mbps data rate equates to an address and command fundamental frequency of 100 MHz.

Control Group Signals

The control group signals (chip Select CS#, clock enable CKE, and ODT) are only ever single rank. A dual-rank capable DDR3 DIMM slot has two copies of each signal, and a dual-DIMM slot interface has four copies of each signal. Hence the signal quality of these signals is identical to a single rank case. The control group of signals, are always 1T regardless of whether you implement a full-rate or half-rate design. As the signals are also SDR, the control group signals operate at a maximum frequency of 0.5 × the data rate. For example, in a 400 MHz design, the maximum control group frequency is 200 MHz.

Clock Group Signals

Like the control group signals, the clock signals in DDR3 SDRAM are only ever single rank loaded. A dual-rank capable DDR3 DIMM slot has two copies of the signal, and a dual-slot interface has four copies of the \(\text{mem}\_\text{clk}\) and \(\text{mem}\_\text{clk}\_n\) signals.

For more information about a DDR3 two-DIMM system design, refer to Micron TN-41-08: DDR3 Design Guide for Two-DIMM Systems.

The Altera DDR3 ALTMEMPHY megafunction does not support the 1T address and command topology referred to in this Micron Technical Note—only 2T implementations are supported.

Write to Memory in Slot 1 Using an ODT Setting of 75 \(\Omega\) With One Slot Populated

Figure 3–21 shows the simulation and board measurement of the signal at the memory when the FPGA is writing to the memory with an ODT setting of 75 \(\Omega\) and using a 25-\(\Omega\) OCT drive strength setting on the FPGA.
Table 3–11 summarizes the comparison between the simulation and board measurements of the signal seen at the DDR2 SDRAM of a dual-DIMM with slot 1 populated by a memory interface using a different ODT setting.

Write to Memory in Slot 2 Using an ODT Setting of 150 Ω With Both Slots Populated

Figure 3–24 shows the HyperLynx simulation and board measurement of the signal at the memory in slot 2 of a double parallel termination using an ODT setting of 150 Ω on slot 1 with a memory-side series resistor transmission line when the FPGA is writing to the memory with a 25-Ω OCT drive strength setting.
Table 3–14 summarizes the comparison between the simulation and board measurements of the signal seen at the memory of a dual-DIMM memory interface with both slots populated using a double parallel termination using a different ODT setting on Slot 1 with a memory-side series resistor with a 25-Ω OCT strength setting on the FPGA.

**Conclusion**

This chapter looks at single- and dual-DIMM DDR2 and DDR3 SDRAM interfaces and makes recommendations on topology and termination, to ensure optimum design guidelines and best signal quality.

In the design of any dual-DIMM interface, you should follow the memory vendor recommendations on the optimum ODT setting, slot population, and operations to the DIMM locations. In addition, this chapter recommends the OCT settings to use at the FPGA, to ensure optimum configuration.
The simulations and experiments referenced throughout this chapter show that you can achieve good signal quality, if you follow the memory vendors recommended ODT settings. Although the DDR2 simulations and experimental results in this chapter are based on the Stratix II High Speed High Density Board, you can apply the general principles to any dual-DIMM design. The addition of dynamic OCT in Stratix III and Stratix IV devices has simplified the board design further by removing the need for the previously required FPGA end discrete parallel termination.

Even though this chapter covers several combinations of ODT and OCT termination, it is critical that as a board designer you perform system specific simulations to ensure good signal integrity in your dual-DIMM SDRAM designs.

**Note to Table 4–1:**

1. To decrease the estimation time, you can skip power estimation during calibration. Power consumption during calibration is typically equivalent to power consumption during user mode.
2. Power analysis using timing simulation vectors is not supported.

When using Altera IP, you can use the zero-delay simulation method to analyze the power required for the external memory interface. Zero-delay simulation is as accurate as timing simulation for 95% designs (designs with no glitching). For a design with glitching, power may be under estimated.

For more information about zero-delay simulation, refer to the Power Estimation and Analysis section in the Quartus II Handbook.

The size of the vector file (.vcd) generated by zero-delay simulation of an Altera DDR3 SDRAM High-Performance Controller Example Design is 400 GB. The .vcd includes calibration and user mode activities. When vector generation of calibration phase is skipped, the vector size decreases to 1 GB.

To perform vector-based PPPA using zero-delay simulation, follow these steps:

1. Perform design compilation in the Quartus® II software to generate your design’s Netlist `<project_name>.vo`.

   The `<project_name>.vo` is generated in the last stage of a compile EDA Netlist Writer.
2. In `<project_name>.vo`, search for the include statement for `<project_name>.sdo`, comment the statement out, and save the file.

3. Create a simulation script containing device model files and libraries and design specific files:
   - Netlist file for the design, `<project_name>.vo`
   - RTL or netlist file for the memory device
   - Testbench RTL file

4. Compile all the files.

5. Invoke simulator with commands to generate `.vcd` files.

6. Generate `.vcd` files for the parts of the design that contribute the most to power dissipation.

7. Run simulation

8. Use the generated `.vcd` files in PPPA tool as the signal activity input file.

9. Run PPPA

For more information about estimating power, refer to the *Power Estimation and Analysis* section in the *Quartus II Handbook*.
How to Contact Altera

For the most up-to-date information about Altera® products, see the following table.

Typographic Conventions

The following table shows the typographic conventions that this document uses.

<table>
<thead>
<tr>
<th>Visual Cue</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bold Type with Initial Capital Letters</strong></td>
<td>Indicates command names, dialog box titles, dialog box options, and other GUI labels. For example, <strong>Save As</strong> dialog box. For GUI elements, capitalization matches the GUI.</td>
</tr>
<tr>
<td><strong>bold type</strong></td>
<td>Indicates directory names, project names, disk drive names, file names, file name extensions, dialog box options, software utility names, and other GUI labels. For example, <code>{designs}</code> directory, <code>d:</code> drive, and <code>chiptrip.gdf</code> file.</td>
</tr>
<tr>
<td><em>Italic Type with Initial Capital Letters</em></td>
<td>Indicates document titles. For example, <em>AN 519: Stratix IV Design Guidelines.</em></td>
</tr>
<tr>
<td><strong>Italic type</strong></td>
<td>Indicates variables. For example, <code>n + 1</code>. Variable names are enclosed in angle brackets (<code>&lt; &gt;</code>). For example, <code>&lt;file name&gt;</code> and <code>&lt;project name&gt;.pof</code> file.</td>
</tr>
<tr>
<td>Initial Capital Letters</td>
<td>Indicates keyboard keys and menu names. For example, Delete key and the Options menu.</td>
</tr>
<tr>
<td>“Subheading Title”</td>
<td>Quotation marks indicate references to sections within a document and titles of Quartus II Help topics. For example, “Typographic Conventions.”</td>
</tr>
<tr>
<td><strong>Courier type</strong></td>
<td>Indicates signal, port, register, bit, block, and primitive names. For example, <code>data1</code>, <code>tdi</code>, and <code>input</code>. Active-low signals are denoted by suffix <code>n</code>. For example, <code>resetn</code>. Indicates command line commands and anything that must be typed exactly as it appears. For example, <code>c:\qdesigns\tutorial\chiptrip.gdf</code>. Also indicates sections of an actual file, such as a Report File, references to parts of files (for example, the AHDL keyword <code>SUBDESIGN</code>), and logic function names (for example, <code>TRI</code>).</td>
</tr>
</tbody>
</table>

The Altera® DDR and DDR2 SDRAM High-Performance Controller MegaCore® functions provide simplified interfaces to industry-standard DDR SDRAM and DDR2 SDRAM. The ALTMEMPHY megafuction is an interface between a memory controller and the memory devices, and performs read and write operations to the memory. The MegaCore functions work in conjunction with the Altera ALTMEMPHY megafuction.

The DDR and DDR2 SDRAM High-Performance Controller MegaCore functions and ALTMEMPHY megafuction offer full-rate or half-rate DDR and DDR2 SDRAM interfaces. The DDR and DDR2 SDRAM High-Performance Controller MegaCore functions offer two controller architectures: high-performance controller (HPC) and high-performance controller II (HPC II). HPC II provides higher efficiency and more advanced features.

The DDR and DDR2 SDRAM high-performance controllers denote both HPC and HPC II unless indicated otherwise.

Figure 1–1 shows a system-level diagram including the example top-level file that the DDR or DDR2 SDRAM High-Performance Controller MegaCore functions create for you.

The MegaWizard™ Plug-In Manager generates an example top-level file, consisting of an example driver, and your DDR or DDR2 SDRAM high-performance controller custom variation. The controller instantiates an instance of the ALTMEMPHY megafuction which in turn instantiates a PLL and DLL. You can optionally instantiate the DLL outside the ALTMEMPHY megafuction to share the DLL between multiple instances of the ALTMEMPHY megafuction. You cannot share a PLL between multiple instances of the ALTMEMPHY megafuction, but you may share some of the PLL clock outputs between these multiple instances.

The example top-level file is a fully-functional design that you can simulate, synthesize, and use in hardware. The example driver is a self-test module that issues read and write commands to the controller and checks the read data to produce the pass or fail, and test complete signals.
The ALTMEMPHY megafunction creates the datapath between the memory device and the memory controller. The megafunction is available as a stand-alone product or can be used in conjunction with Altera high-performance memory controllers. As a stand-alone product, use the ALTMEMPHY megafunction with either custom or third-party controllers.

### Release Information

Table 1–1 provides information about this release of the DDR and DDR2 SDRAM high-performance controllers and ALTMEMPHY IP.

Alterna verifies that the current version of the Quartus® II software compiles the previous version of each MegaCore function. The MegaCore IP Library Release Notes and Errata report any exceptions to this verification. Altera does not verify compilation with MegaCore function versions older than one release. For information about issues on the DDR and DDR2 SDRAM high-performance controllers and the ALTMEMPHY megafunction in a particular Quartus II version, refer to the Quartus II Software Release Notes.

### Device Family Support

The MegaCore functions provide either full or preliminary support for target Altera device families:

- Full support means the megafunction meets all functional and timing requirements for the device family and can be used in production designs.
- Preliminary support means the megafunction meets all functional requirements, but can still be undergoing timing analysis for the device family.
Table 1–2 shows the level of support offered by the DDR and DDR2 SDRAM high-performance controller to each of the Altera device families.

<table>

Features

The ALTMEMPHY megafunction offers the following features:

- Simple setup
- Support for the Altera PHY Interface (AFI) for DDR and DDR2 SDRAM on all supported devices
- Automated initial calibration eliminating complicated read data timing calculations
- VT tracking that guarantees maximum stable performance for DDR and DDR2 SDRAM interfaces
- Self-contained datapath that makes connection to an Altera controller or a third-party controller independent of the critical timing paths
- Full-rate and half-rate DDR and DDR2 SDRAM interfaces
- Easy-to-use MegaWizard interface
In addition, Table 1–3 shows the features provided by the DDR and DDR2 SDRAM HPC and HPC II.

<td>✓</td>
</tr>
<tr>
<td>Verilog HDL simulator</td>
<td></td>
</tr>
</tbody>
</table>

**Notes to Table 1–3:**

1. HPC II supports additive latency values greater or equal to $t_{AC} - 1$, in clock cycle unit ($t_{CK}$).
2. HPC II only supports memory burst length of 4 in full-rate mode.
3. HPC II only supports memory burst length of 8 in half-rate mode.
Unsupported Features

- Timing simulation
- Burst length of 2
- Partial burst and unaligned burst in ECC and non-ECC mode when DM pins are disabled.

MegaCore Verification

MegaCore verification involves simulation testing. Altera has carried out extensive random, directed tests with functional test coverage using industry-standard Denali models to ensure the functionality of the DDR and DDR2 SDRAM high-performance controllers.

Resource Utilization

The following sections show the resource utilization data for the ALTMEMPHY megafunction, and the DDR and DDR2 high-performance controllers (HPC and HPC II).

ALTMEMPHY Megafunction

Table 1–4 through Table 1–7 show the typical size of the ALTMEMPHY megafunction with the AFI in the Quartus II software version 9.1 for the following devices:

- Arria II GX (EP2AGX260FF35C4) devices
- Cyclone III (EP3C16F484C6) devices
- Stratix II (EP2S60F1020C3) devices
- Stratix III (EP3SL110F1152C2) devices
- Stratix IV (EP4SGX230HF35C2) devices

The resource utilization for Arria and Stratix GX devices is similar to Stratix II devices.

Table 1–4. Resource Utilization in Arria II GX Devices (Part 1 of 2) (Note 1)

System Requirements

The DDR and DDR2 SDRAM High-Performance Controller MegaCore functions are part of the MegaCore IP Library, which is distributed with the Quartus II software and downloadable from the Altera website, www.altera.com.

For system requirements and installation instructions, refer to Altera Software Installation & Licensing.

Installation and Licensing

Figure 1–2 shows the directory structure after you install the DDR and DDR2 SDRAM High-Performance Controller MegaCore functions, where <path> is the installation directory. The default installation directory on Windows is c:\altera\<version>; on Linux it is /opt/altera\<version>.

You need a license for the MegaCore function only when you are completely satisfied with its functionality and performance, and want to take your design to production.
To use the DDR or DDR2 SDRAM HPC, you can request a license file from the Altera website at www.altera.com/licensing and install it on your computer. When you request a license file, Altera emails you a license.dat file. If you do not have Internet access, contact your local representative.

To use the DDR or DDR2 HPC II, contact your local sales representative to order a license.

**Free Evaluation**

Altera’s OpenCore Plus evaluation feature is only applicable to the DDR or DDR2 SDRAM HPC. With the OpenCore Plus evaluation feature, you can perform the following actions:

- Simulate the behavior of a megafuction (Altera MegaCore function or AMPPSTM megafuction) within your system
- Verify the functionality of your design, as well as evaluate its size and speed quickly and easily
- Generate time-limited device programming files for designs that include MegaCore functions
- Program a device and verify your design in hardware

You need to purchase a license for the megafunction only when you are completely satisfied with its functionality and performance, and want to take your design to production.

**OpenCore Plus Time-Out Behavior**

OpenCore Plus hardware evaluation can support the following two modes of operation:

- Untethered—the design runs for a limited time
- Tethered—requires a connection between your board and the host computer. If tethered mode is supported by all megafunctions in a design, the device can operate for a longer time or indefinitely

All megafunctions in a device time-out simultaneously when the most restrictive evaluation time is reached. If there is more than one megafuction in a design, a specific megafunction’s time-out behavior may be masked by the time-out behavior of the other megafunctions.

For MegaCore functions, the untethered time-out is 1 hour; the tethered time-out value is indefinite.

Your design stops working after the hardware evaluation time expires and the local_ready output goes low.
2. Getting Started

Design Flow

You can implement a DDR or DDR2 SDRAM High-Performance Controller MegaCore functions using either one of the following flows:

- SOPC Builder flow
- MegaWizard Plug-In Manager flow

You can only instantiate the ALTMEMPHY megafuction using the MegaWizard Plug-In Manager flow.

Figure 2–1 shows the stages for creating a system in the Quartus II software using either one of the flows.

Figure 2–1. Design Flow
The SOPC Builder flow offers the following advantages:

- Generates simulation environment
- Creates custom components and integrates them via the component wizard
- Interconnects all components with the Avalon-MM interface

The MegaWizard Plug-In Manager flow offers the following advantages:

- Allows you to design directly from the DDR or DDR2 SDRAM interface to peripheral device or devices
- Achieves higher-frequency operation

**SOPC Builder Flow**

The SOPC Builder flow allows you to add the DDR and DDR2 SDRAM high-performance controllers directly to a new or existing SOPC Builder system.

You can also easily add other available components to quickly create an SOPC Builder system with a DDR or DDR2 SDRAM high-performance controller, such as the Nios II processor and scatter-gather direct memory access (DMA) controllers. SOPC Builder automatically creates the system interconnect logic and system simulation environment.

For more information about SOPC Builder, refer to *volume 4 of the Quartus II Handbook*. For more information about how to use controllers with SOPC Builder, refer to the *DDR, DDR2, and DDR3 SDRAM Design Tutorials* section in *volume 6 of the External Memory Interface Handbook*. For more information on the Quartus II software, refer to the *Quartus II Help*.

**Specify Parameters**

To specify the parameters for the DDR and DDR2 SDRAM high-performance controllers using the SOPC Builder flow, perform the following steps:

1. In the Quartus II software, create a new Quartus II project with the *New Project Wizard*.
2. On the Tools menu, click *SOPC Builder*.
3. For a new system, specify the system name and language.
4. Add *DDR or DDR2 SDRAM High-Performance Controller* to your system from the *System Contents* tab.
   
   - The *DDR or DDR2 SDRAM High-Performance Controller* is in the *SDRAM* folder under the *Memories and Memory Controllers* folder.

5. Specify the required parameters on all pages in the *Parameter Settings* tab.
   
   - For detailed explanation of the parameters, refer to the “Parameter Settings” on page 3–1.

6. Click *Finish* to complete parameterizing the DDR or DDR2 SDRAM high-performance controller and add it to the system.
Complete the SOPC Builder System

To complete the SOPC Builder system, perform the following steps:

1. In the System Contents tab, select Nios II Processor and click Add.
2. On the Nios II Processor page, in the Core Nios II tab, select altmemddr for Reset Vector and Exception Vector.
3. Change the Reset Vector Offset and the Exception Vector Offset to an Avalon address that is not written to by the ALTMEMPHY megafuction during its calibration process.

The ALTMEMPHY megafuction performs memory interface calibration every time it is reset, and in doing so, writes to a range of addresses. If you want your memory contents to remain intact through a system reset, you should avoid using these memory addresses. This step is not necessary if you reload your SDRAM memory contents from flash every time you reset your system.

If you are upgrading your Nios system design from version 8.1 or previous, ensure that you change the Reset Vector Offset and the Exception Vector Offset to AFI mode.

To calculate the Avalon-MM address equivalent of the memory address range 0x0 to 0x1f, multiply the memory address by the width of the memory interface data bus in bytes. Refer to Table 2–1 for more Avalon-MM addresses.

Table 2–1. Avalon-MM Addresses for AFI Mode

<table>
<thead>
<tr>
<th>External Memory Interface Width</th>
<th>Reset Vector Offset</th>
<th>Exception Vector Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>0×40</td>
<td>0×60</td>
</tr>
<tr>
<td>16</td>
<td>0×80</td>
<td>0×A0</td>
</tr>
<tr>
<td>32</td>
<td>0×100</td>
<td>0×120</td>
</tr>
<tr>
<td>64</td>
<td>0×200</td>
<td>0×220</td>
</tr>
</tbody>
</table>

4. Click Finish.
6. Select JTAG UART and click Add.
7. Click Finish.

If there are warnings about overlapping addresses, on the System menu, click Auto Assign Base Addresses.

If you enable ECC and there are warnings about overlapping IRQs, on the System menu click Auto Assign IRQs.

8. For this example system, ensure all the other modules are clocked on the altmemddr_sysclk, to avoid any unnecessary clock-domain crossing logic.
9. Click Generate.
Among the files generated by SOPC Builder is the Quartus II IP File (.qip). This file contains information about a generated IP core or system. In most cases, the .qip file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. Generally, a single .qip file is generated for each SOPC Builder system. However, some more complex SOPC Builder components generate a separate .qip file. In that case, the system .qip file references the component .qip file.

10. Compile your design, refer to “Compile and Simulate” on page 4–1.

MegaWizard Plug-In Manager Flow

The MegaWizard Plug-In Manager flow allows you to customize the DDR and DDR2 SDRAM high-performance controllers or ALTMEMPHY megafunction, and manually integrate the function into your design.

You can alternatively use the IP Advisor to help you start your DDR or DDR2 SDRAM high-performance controller design. On the Quartus II Tools menu, point to Advisors, and then click IP Advisor. The IP Advisor guides you through a series of recommendations for selecting, parameterizing, evaluating, and instantiating a DDR2 SDRAM high-performance controller into your design. It then guides you through a complete Quartus II compilation of your project.

For more information about the MegaWizard Plug-In Manager and the IP Advisor, refer to the Quartus II Help.

Specify Parameters

To specify parameters using the MegaWizard Plug-In Manager flow, perform the following steps:

1. In the Quartus II software, create a new Quartus II project with the New Project Wizard.

2. On the Tools menu, click MegaWizard Plug-In Manager to start the MegaWizard Plug-In Manager.

   - The DDR or DDR2 SDRAM high-performance controller is in the Interfaces folder under the External Memory folder.
   - The ALTMEMPHY megafunction is in the I/O folder.

   The <variation name> must be a different name from the project name and the top-level design entity name.

3. Specify the parameters on all pages in the Parameter Settings tab.

   For detailed explanation of the parameters, refer to the “Parameter Settings” on page 3–1.
4. On the **EDA** tab, turn on **Generate simulation model** to generate an IP functional simulation model for the MegaCore function in the selected language.

   An IP functional simulation model is a cycle-accurate VHDL or Verilog HDL model produced by the Quartus II software.

   ![Caution](image.png)

   Use the simulation models only for simulation and not for synthesis or any other purposes. Using these models for synthesis creates a nonfunctional design.

   ![Tip](image.png)

   Some third-party synthesis tools can use a netlist that contains only the structure of the MegaCore function, but not detailed logic, to optimize performance of the design that contains the MegaCore function. If your synthesis tool supports this feature, turn on **Generate netlist**.

   When targeting a VHDL simulation model, the MegaWizard Plug-In Manager still generates the `<variation_name>_alt_mem_phy.v` file for the Quartus II synthesis. Do not use this file for simulation. Use the `<variation_name>.vho` file for simulation instead.

   The ALTMEMPHY megafunction only supports functional simulation. You cannot perform timing or gate-level simulation when using the ALTMEMPHY megafunction.

5. On the **Summary** tab, select the files you want to generate. A gray checkmark indicates a file that is automatically generated. All other files are optional.

6. Click **Finish** to generate the MegaCore function and supporting files. A generation report appears.

7. If you generate the MegaCore function instance in a Quartus II project, you are prompted to add the `.qip` files to the current Quartus II project. When prompted to add the `.qip` files to your project, click **Yes**. The addition of the `.qip` files enables their visibility to Nativelink. Nativelink requires the `.qip` files to include libraries for simulation.

   ![Tip](image.png)

   The `.qip` file is generated by the MegaWizard interface, and contains information about the generated IP core. In most cases, the `.qip` file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. The MegaWizard interface generates a single `.qip` file for each MegaCore function.

8. After you review the generation report, click **Exit** to close the MegaWizard Plug-In Manager.

9. For the high-performance controller (HPC or HPC II), set the `<variation name>_example_top.v` or `.vhd` file to be the project top-level design file.
   a. On the File menu, click **Open**.
   b. Browse to `<variation name>_example_top` and click **Open**.
   c. On the Project menu, click **Set as Top-Level Entity**.
## Generated Files

Table 2–2 shows the ALTMEMPHY generated files.

<td>Generates the DQ, DQS, DM, and QVLD I/O pins.</td>
</tr>
<tr>
<td><code>&lt;variation_name&gt;_alt_mem_phy_mimic</code></td>
<td>DDR2/DDR SDRAM ALTMEMPHY variation</td>
<td>Creates the VT tracking mechanism for DDR and DDR2 SDRAM PHYs.</td>
</tr>
</tbody>
</table>
Table 2–4 through Table 2–6 show the additional files generated by the high-performance controllers, that may be in your project directory. The names and types of files specified in the MegaWizard Plug-In Manager report vary based on whether you created your design with VHDL or Verilog HDL.

In addition to the files in Table 2–4 through Table 2–6, the MegaWizard also generates the ALTMEMPHY files in Table 2–2, but with a _phy prefix. For example, `<variation_name>_alt_mem_phy_delay.vhd` becomes `<variation_name>_phy_alt_mem_phy_delay.vhd`.

ALTMEMPHY Parameter Settings

The ALTMEMPHY Parameter Settings page in the ALTMEMPHY MegaWizard interface (Figure 3–1) allows you to parameterize the following settings:

- Memory Settings
- PHY Settings
- Board Settings
- Controller Interface Settings

Figure 3–1. ALTMEMPHY Parameter Settings Page
The text window at the bottom of the MegaWizard Plug-In Manager displays information about the memory interface, warnings, and errors if you are trying to create something that is not supported. The Finish button is disabled until you correct all the errors indicated in this window.

The following sections describe the four tabs of the Parameter Settings page in more detail.

**Memory Settings**

In the Memory Settings tab, you can select a particular memory device for your system and choose the frequency of operation for the device. Under General Settings, you can choose the device family, speed grade, and clock information. In the middle of the page (left-side), you can filter the available memory device listed on the right side of the Memory Presets dialog box, refer to Figure 3–1. If you cannot find the exact device that you are using, choose a device that has the closest specifications, then manually modify the parameters to match your actual device by clicking Modify parameters, next to the Selected memory preset field.

Table 3–1 describes the General Settings available on the Memory Settings page of the ALTMEMPHY MegaWizard interface.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device family</td>
<td>Targets device family (for example, Stratix III). Table 1–2 on page 1–3 shows supported device families. The device family selected here must match the device family selected on MegaWizard page 2a.</td>
</tr>
<tr>
<td>Speed grade</td>
<td>Selects a particular speed grade of the device (for example, 2, 3, or 4 for the Stratix III device family).</td>
</tr>
<tr>
<td>PLL reference clock frequency</td>
<td>Determines the clock frequency of the external input clock to the PLL. Ensure that you use three decimal points if the frequency is not a round number (for example, 166.667 MHz or 100 MHz) to avoid a functional simulation or a PLL locking problem.</td>
</tr>
<tr>
<td>Memory clock frequency</td>
<td>Determines the memory interface clock frequency. If you are operating a memory device below its maximum achievable frequency, ensure that you enter the actual frequency of operation rather than the maximum frequency achievable by the memory device. Also, ensure that you use three decimal points if the frequency is not a round number (for example, 333.333 MHz or 400 MHz) to avoid a functional simulation or a PLL locking issue.</td>
</tr>
<tr>
<td>Controller data rate</td>
<td>Selects the data rate for the memory controller. Sets the frequency of the controller to equal to either the memory interface frequency (full-rate) or half of the memory interface frequency (half-rate).</td>
</tr>
<tr>
<td>Enable half rate bridge</td>
<td>This option is only available for HPC II.</td>
</tr>
<tr>
<td></td>
<td>Turn on to keep the controller in the memory full clock domain while allowing the local side to run at half the memory clock speed, so that latency can be reduced.</td>
</tr>
<tr>
<td>Local interface clock frequency</td>
<td>Value that depends on the memory clock frequency and controller data rate, and whether or not you turn on the Enable Half Rate Bridge option.</td>
</tr>
<tr>
<td>Local interface width</td>
<td>Value that depends on the memory clock frequency and controller data rate, and whether or not you turn on the Enable Half Rate Bridge option.</td>
</tr>
</tbody>
</table>
Table 3–2 describes the options available to filter the Memory Presets that are displayed. This set of options is where you indicate whether you are creating for DDR or DDR2 SDRAM.

Table 3–2. Memory Presets List

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory type</td>
<td>You can filter the type of memory to display, for example, DDR2 SDRAM. The ALTMEMPHY megafunction supports DDR SDRAM and DDR2 SDRAM.</td>
</tr>
<tr>
<td>Memory vendor</td>
<td>You can filter the memory types by vendor. JEDEC is also one of the options, allowing you to choose the JEDEC specifications. If your chosen vendor is not listed, you can choose JEDEC for the DDR and DDR2 SDRAM interfaces. Then, pick a device that has similar specifications to your chosen device and check the values of each parameter. Make sure you change the each parameter value to match your device specifications.</td>
</tr>
<tr>
<td>Memory format</td>
<td>You can filter the type of memory by format, for example, discrete devices or DIMM packages.</td>
</tr>
<tr>
<td>Maximum frequency</td>
<td>You can filter the type of memory by the maximum operating frequency.</td>
</tr>
</tbody>
</table>

Use the Preset Editor to Create a Custom Memory Preset

Pick a device in the Memory Presets list that is closest or the same as the actual memory device that you are using. Then, click the Modify Parameters button to parameterize the following settings in the Preset Editor dialog box:

- Memory attributes—These are the settings that determine your system’s number of DQ, DQ strobe (DQS), address, and memory clock pins.
- Memory initialization options—These settings are stored in the memory mode registers as part of the initialization process.
- Memory timing parameters—These are the parameters that create and time-constrain the PHY.

Even though the device you are using is listed in Memory Presets, ensure that the settings in the Preset Editor dialog box are accurate, as some parameters may have been updated in the memory device datasheets.

You can change the parameters with a white background to reflect your system. You can also change the parameters with a gray background so the device parameters match the device you are using. These parameters in gray background are characteristics of the chosen memory device and changing them creates a new custom memory preset. If you click Save As (at the bottom left of the page) and save the new settings in the \<quartus_install_dir>\quartus\common\ip\altera\altmemphy\lib\ directory, you can use this new memory preset in other Quartus II projects created in the same version of the software.

When you click Save, the new memory preset appears at the bottom of the Memory Presets list in the Memory Settings tab.

If you save the new settings in a directory other than the default directory, click Load Preset in the Memory Settings tab to load the settings into the Memory Presets list.
Figure 3–2 shows the Preset Editor dialog box for a DDR2 SDRAM.

The **Advanced** option is only available for Arria II GX and Stratix IV devices. This option shows the percentage of memory specification that is calibrated by the FPGA. The percentage values are estimated by Altera based on the process variation.
Table 3–3 through Table 3–5 describe the DDR2 SDRAM parameters available for memory attributes, initialization options, and timing parameters. DDR SDRAM has the same parameters, but their value ranges are different than DDR2 SDRAM.

**Table 3–3. DDR2 SDRAM Attributes Settings (Part 1 of 2)**

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Range (1)</th>
<th>Units</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output clock pairs from FPGA</td>
<td>1–6 pairs</td>
<td></td>
<td>Defines the number of differential clock pairs driven from the FPGA to the memory. More clock pairs reduce the loading of each output when interfacing with multiple devices. Memory clock pins use the signal splitter feature in Arria II GX, Stratix IV and Stratix III devices for differential signaling.</td>
</tr>
<tr>
<td>Memory chip selects</td>
<td>1, 2, 4, or 8 bits</td>
<td></td>
<td>Sets the number of chip selects in your memory interface. The depth of your memory in terms of number of chips. You are limited to the range shown as the local side binary encodes the chip select address. You can set this value to the next higher number if the range does not meet your specifications. However, the highest address space of the ALTMEMPHY megafUNCTION is not mapped to any of the actual memory address. The ALTMEMPHY megafUNCTION works with multiple chip selects and calibrates against all chip select, mem_cs_n signals.</td>
</tr>
<tr>
<td>Memory interface DQ width</td>
<td>4–288 bits</td>
<td></td>
<td>Defines the total number of DQ pins on the memory interface. If you are interfacing with multiple devices, multiply the number of devices with the number of DQ pins per device. Even though the GUI allows you to choose 288-bit DQ width, the interface data width is limited by the number of pins on the device. For best performance, have the whole interface on one side of the device.</td>
</tr>

<td>0–0.3</td>
<td>tCK</td>
<td>Positive DQS latching edge to associated clock edge.</td>
</tr>
<tr>
<td>tDS</td>
<td>10–600</td>
<td>ps</td>
<td>DQ and DM input setup time relative to DQS, which has a derated value depending on the slow rate of the DQS (for both DDR and DDR2 SDRAM interfaces) and whether DQS is single-ended or differential (for DDR2 SDRAM interfaces). Ensure that you are using the correct number and that the value entered is referenced to VREF(dc), not VDD(ac) min or VSS(ac) max. Refer to “Derate Memory Setup and Hold Timing” on page 3–8 for more information about how to derate this specification.</td>
</tr>
<tr>
<td>tDQH</td>
<td>10–600</td>
<td>ps</td>
<td>DQ and DM input hold time relative to DQS, which has a derated value depending on the slow rate of the DQS (for both DDR and DDR2 SDRAM interfaces) and whether DQS is single-ended or differential (for DDR2 SDRAM interfaces). Ensure that you are using the correct number and that the value entered is referenced to VREF(dc), not VDD(dc) min or VSS(dc) max. Refer to “Derate Memory Setup and Hold Timing” on page 3–8 for more information about how to derate this specification.</td>
</tr>
<tr>
<td>tDQSH</td>
<td>0.1–0.5</td>
<td>tCK</td>
<td>DQS falling edge hold time from CK.</td>
</tr>
</tbody>
</table>
Derate Memory Setup and Hold Timing

Because the base setup and hold time specifications from the memory device datasheet assume input slew rates that may not be true for Altera devices, derate and update the following memory device specifications in the Preset Editor dialog box:

- $t_{DS}$
- $t_{DH}$
- $t_{IH}$
- $t_{IS}$

For Arria II GX and Stratix IV devices, you need not derate using the Preset Editor. You only need to enter the parameters referenced to $V_{REF}$, and the deration is done automatically when you enter the slew rate information on the Board Settings tab.

After derating the values, you then need to normalize the derated value because Altera input and output timing specifications are referenced to $V_{REF}$. However, JEDEC base setup time specifications are referenced to $V_{IH}/V_{IL}$ AC levels; JEDEC base hold time specifications are referenced to $V_{IH}/V_{IL}$ DC levels.

When the memory device setup and hold time numbers are derated and normalized to $V_{REF}$, update these values in the Preset Editor dialog box to ensure that your timing constraints are correct.
For example, according to JEDEC, 400-MHz DDR2 SDRAM has the following specifications, assuming 1V/ns DQ slew rate rising signal and 2V/ns differential slew rate:

- Base $t_{DS} = 50$
- Base $t_{DH} = 125$
- $V_{IH(ac)} = V_{REF} + 0.2\, V$
- $V_{IH(dc)} = V_{REF} + 0.125\, V$
- $V_{IL(ac)} = V_{REF} - 0.2\, V$
- $V_{IL(dc)} = V_{REF} - 0.125\, V$

JEDEC lists two different sets of base and derating numbers for $t_{DS}$ and $t_{DH}$ specifications, whether you are using single-ended or differential DQS signaling, for any DDR2 SDRAM components with a maximum frequency up to 267 MHz. In addition, the $V_{IL(ac)}$ and $V_{IH(ac)}$ values may also be different for those devices.

The $V_{REF}$ referenced setup and hold signals for a rising edge are:

- $t_{DS}(V_{REF}) = Base\, t_{DS} + delta\, t_{DS} + (V_{IH(ac)} - V_{REF})/slew\_rate = 50 + 0 + 200 = 250\, ps$
- $t_{DH}(V_{REF}) = Base\, t_{DH} + delta\, t_{DH} + (V_{IH(dc)} - V_{REF})/slew\_rate = 125 + 0 + 67.5 = 192.5\, ps$

If the output slew rate of the write data is different from 1V/ns, you have to first derate the $t_{DS}$ and $t_{DH}$ values, then translate these AC/DC level specs to $V_{REF}$ specification.

For a 2V/ns DQ slew rate rising signal and 2V/ns DQS-DQSn slew rate:

- $t_{DS}(V_{REF}) = Base\, t_{DS} + delta\, t_{DS} + (V_{IH(ac)} - V_{REF})/slew\_rate = 25 + 100 + 100 = 225\, ps$
- $t_{DH}(V_{REF}) = Base\, t_{DH} + delta\, t_{DH} + (V_{IH(dc)} - V_{REF})/slew\_rate = 100 + 45 + 33.75 = 178.75\, ps$

For a 0.5V/ns DQ slew rate rising signal and 1V/ns DQS-DQSn slew rate:

- $t_{DS}(V_{REF}) = Base\, t_{DS} + delta\, t_{DS} + (V_{IH(ac)} - V_{REF})/slew\_rate = 25 + 0 + 400 = 425\, ps$
- $t_{DH}(V_{REF}) = Base\, t_{DH} + delta\, t_{DH} + (V_{IH(dc)} - V_{REF})/slew\_rate = 100 - 65 + 250 = 285\, ps$
PHY Settings

Click Next or the PHY Settings tab to set the options described in Table 3–6. The options are available if they apply to the target Altera device.

Table 3–6. ALTMEMPHY PHY Settings (Part 1 of 2)

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Applicable Device Families</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use dedicated PLL outputs to drive memory clocks</td>
<td>HardCopy II and Stratix II (prototyping for HardCopy II)</td>
<td>Turn on to use dedicated PLL outputs to generate the external memory clocks, which is required for HardCopy II ASICs and their Stratix II FPGA prototypes. When turned off, the DDIO output registers generate the clock outputs. When you use the DDIO output registers for the memory clock, both the memory clock and the DQS signals are well aligned and easily meets the tDQSS specification. However, when the dedicated clock outputs are for the memory clock, the memory clock and the DQS signals are not aligned properly and requires a positive phase offset from the PLL to align the signals together.</td>
</tr>
<tr>
<td>Dedicated memory clock phase</td>
<td>HardCopy II and Stratix II (prototyping for HardCopy II)</td>
<td>The required phase shift to align the CK/CK# signals with DQS/DQS# signals when using dedicated PLL outputs to drive memory clocks.</td>
</tr>
<tr>
<td>Use differential DQS</td>
<td>Arria II GX, Stratix III, and Stratix IV</td>
<td>Enable this feature for better signal integrity. Recommended for operation at 333 MHz or higher. An option for DDR2 SDRAM only, as DDR SDRAM does not support differential DQSS.</td>
</tr>
<tr>
<td>Enable external access to reconfigure PLL prior to calibration</td>
<td>HardCopy II and Stratix II (prototyping for HardCopy II)</td>
<td>When enabling this option for Stratix II and HardCopy II devices, the inputs to the ALTPLL_RECONFIG megafunction are brought to the top level for debugging purposes. This option allows you to reconfigure the PLL before calibration to adjust, if necessary, the phase of the memory clock (mem_clk_2x) before the start of the calibration of the resynchronization clock on the read side. The calibration of the resynchronization clock on the read side depends on the phase of the memory clock on the write side.</td>
</tr>
<tr>
<td>Instantiate DLL externally</td>
<td>All supported device families, except for Cyclone III devices</td>
<td>Use this option with Stratix III, Stratix IV, HardCopy III, or HardCopy IV devices, if you want to apply a non-standard phase shift to the DQS capture clock. The ALTMEMPHY DLL offsetting I/O can then be connected to the external DLL and the Offset Control Block. As Cyclone III devices do not have DLLs, this feature is not supported.</td>
</tr>
</tbody>
</table>
**Board Settings**

Click Next or the Board Settings tab to set the options described in Table 3–7. The board settings parameters are set to model the board level effects in the timing analysis. The options are available if you choose Arria II GX or Stratix IV device for your interface. Otherwise, the options are disabled.
Controller Interface Settings

The **Controller Interface Settings** tab allows you to specify the native interface or the default Avalon-MM interface for your local interface as required by the ALTMEMPHY megafuntion for DDR and DDR2 SDRAM. The options are disabled if you select **AFI** for the controller-to-PHY interface protocol. The Avalon-MM interface is the only local interface supported in these variations.

Alterna recommends that you use the AFI for new designs; only use the non-AFI for existing designs.

Native interface is a superset of the Avalon-MM interface, containing the following additional signals in addition to the Avalon-MM interface signals:

- **local_init_done**
- **local_refresh_req**
local_refresh_ack
local_wdata_req

These signals provide extra information and control that is not possible in the Avalon-MM bus protocol.

The other difference between the native and the Avalon-MM local interface is in the write transaction. In an Avalon-MM interface, the write data is presented along with the write request. In native local interfaces, the write data (and byte enables) are presented in the clock cycle after the local_wdata_req signal is asserted. Avalon-MM interfaces do not use the local_wdata_req signal.

There is no difference in latency between the native and Avalon-MM interfaces.

### DDR or DDR2 SDRAM High-Performance Controller Parameter Settings

The DDR or DDR2 SDRAM High-Performance Controller Parameter Settings page in the DDR or DDR2 SDRAM High-Performance Controller MegaWizard interface (Figure 3–3) allows you to parameterize the following settings:

- Memory Settings
- PHY Settings
- Board Settings
- Controller Settings

The Memory Settings, PHY Settings, and Board Settings tabs provide the same options as in the ALTMEMPHY Parameter Settings page.
Controller Settings

Table 3–8 shows the options provided in the Controller Settings tab.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Controller Architecture</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Controller architecture</td>
<td>—</td>
<td>Specifies the controller architecture.</td>
</tr>
<tr>
<td>Enable self-refresh controls</td>
<td>Both</td>
<td>Turn on to enable the controller to allow you to have control on when to place the external memory device in self-refresh mode, refer to &quot;User-Controlled Self-Refresh Logic&quot; on page 7–7.</td>
</tr>
<tr>
<td>Enable power down controls</td>
<td>HPC</td>
<td>Turn on to enable the controller to allow you to have control on when to place the external memory device in power-down mode.</td>
</tr>
</tbody>
</table>
### Table 3–8. Controller Settings (Part 2 of 3)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Controller Architecture</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable auto power down</td>
<td>HPC II</td>
<td>Turn on to enable the controller to automatically place the external memory device in power-down mode after a specified number of idle controller clock cycles is observed in the controller. You can specify the number of idle cycles after which the controller powers down the memory in the <strong>Auto Power Down Cycles</strong> field, refer to “Automatic Power-Down with Programmable Time-Out” on page 7–7.</td>
</tr>
<tr>
<td>Auto power down cycles</td>
<td>HPC II</td>
<td>Determines the desired number of idle controller clock cycles before the controller places the external memory device in a power-down mode. The legal range is 1 to 65,535. The auto power-down mode is disabled if you set the value to 0 clock cycles.</td>
</tr>
<tr>
<td>Enable user auto-refresh controls</td>
<td>Both</td>
<td>Turn on to enable the controller to allow you to have control on when to place the external memory device in refresh mode.</td>
</tr>
<tr>
<td>Enable auto-precharge control</td>
<td>Both</td>
<td>Turn on to enable the auto-precharge control on the controller top level. Asserting the auto-precharge control signal while requesting a read or write burst allows you to specify whether or not the controller should close (auto-precharge) the current opened page at the end of the read or write burst.</td>
</tr>
<tr>
<td>Local-to-memory address mapping</td>
<td>HPC II</td>
<td>Allows you to control the mapping between the address bits on the Avalon interface and the chip, row, bank, and column bits on the memory interface. If your application issues bursts that are greater than the column size of the memory device, choose the Chip-Row-Bank-Column option. This option allows the controller to use its look-ahead bank management feature to hide the effect of changing the currently open row when the burst reaches the end of the column. On the other hand, if your application has several masters that each use separate areas of memory, choose the Chip-Bank-Row-Column option. This option allows you to use the top address bits to allocate a physical bank in the memory to each master. The physical bank allocation avoids different masters accessing the same bank which is likely to cause inefficiency, as the controller must then open and close rows in the same bank.</td>
</tr>
<tr>
<td>Command queue look-ahead depth</td>
<td>HPC II</td>
<td>This option allows you to select a command queue look-ahead depth value to control the number of read or write requests the look-ahead bank management logic examines, refer to “Command Queue” on page 7–4.</td>
</tr>
<tr>
<td>Local maximum burst count</td>
<td>HPC II</td>
<td>Specifies a burst count to configure the maximum Avalon burst count that the controller slave port accepts.</td>
</tr>
</tbody>
</table>
Enable configuration and status register interface | HPC II | Turn on to enable run-time configuration and status retrieval of the memory controller. Enabling this option adds an additional Avalon-MM slave port to the memory controller top level that allows run-time reconfiguration and status retrieving for memory timing parameters, memory address size and mode register settings, and controller features. If the **Error Detection and Correction Logic** option is enabled, the same slave port also allows you to control and retrieve the status of this logic. Refer to “Configuration and Status Register (CSR) Interface” on page 7–7.

Enable error detection and correction logic | Both | Turn on to enable error correction coding (ECC) for single-bit error correction and double-bit error detection. Refer to “Error Correction Coding (ECC)” on page 6–5 for HPC, and “Error Correction Coding (ECC)” on page 7–7 for HPC II.

Enable auto error correction | HPC II | Turn on to allow the controller to perform auto correction when ECC logic detects a single-bit error. Alternatively, you can turn off this option and schedule the error correction at a desired time for better system efficiency. Refer to “Error Correction Coding (ECC)” on page 7–7.

Enable multi-cast write control | HPC II | Turn on to enable the multi-cast write control on the controller top level. Asserting the multi-cast write control when requesting a write burst causes the write data to be written to all the chip selects in the memory system. Multi-cast write is not supported for registered DIMM interfaces or if the ECC logic is enabled.

Multiple controller clock sharing | Both | This option is only available in SOPC Builder Flow. Turn on to allow one controller to use the Avalon clock from another controller in the system that has a compatible PLL. This option allows you to create SOPC Builder systems that have two or more memory controllers that are synchronous to your master logic. Refer to

Local interface protocol | HPC | Specifies the local side interface between the user logic and the memory controller. The Avalon-MM interface allows you to easily connect to other Avalon-MM peripherals. The HPC II architecture supports only the Avalon-MM interface.
4. Compile and Simulate

After setting the parameters to the MegaCore function, you can now integrate the MegaCore function variation into your design, and compile and simulate. The following sections detail the steps you need to perform to compile and simulate your design:

- Compile the Design
- Simulate the Design

Compile the Design

Figure 4–1 shows the top-level view of the Altera high-performance controller design as an example on how your final design looks after you integrate the controller and the user logic.

![High-Performance Controller System-Level Diagram](image)

Figure 4–1. High-Performance Controller System-Level Diagram

Note to Figure 4–1:
(1) When you choose Instantiate DLL Externally, DLL is instantiated outside the controller.

Before compiling a design with the ALTMEMPHY variation, you must edit some project settings, include the .sdc file, and make I/O assignments. I/O assignments include I/O standard, pin location, and other assignments, such as termination and drive strength settings. Some of these tasks are listed at the ALTMEMPHY Generation window. For most systems, Altera recommends that you use the Advanced I/O Timing feature by using the Board Trace Model command in the Quartus II software to set the termination and output pin loads for the device.

You cannot compile the ALTMEMPHY variation as a stand-alone top-level design because the generated .sdc timing constraints file requires the ALTMEMPHY variation be part of a larger design (with a controller and/or example driver). If you want to check whether the ALTMEMPHY variation meets your required target frequency before your memory controller is ready, create a top-level file that instantiates this ALTMEMPHY variation.
To use the Quartus II software to compile the example top-level file and perform post-compilation timing analysis, follow these steps:

1. Set up the TimeQuest timing analyzer:
   a. On the Assignments menu, click **Timing Analysis Settings**, select **Use TimeQuest Timing Analyzer during compilation**, and click **OK**.
   b. Add the Synopsys Design Constraints (.sdc) file, `<variation name>_phy_ddr_timing.sdc`, to your project. On the Project menu, click **Add/Remove Files in Project** and browse to select the file.
   c. Add the .sdc file for the example top-level design, `<variation name>_example_top.sdc`, to your project. This file is only required if you are using the example as the top-level design.

2. You can either use the `<variation name>_pin_assignments.tcl` or the `<variation name>.ppf` file to apply the I/O assignments generated by the MegaWizard Plug-In Manager. Using the .ppf file and the Pin Planner gives you the extra flexibility to add a prefix to your memory interface pin names. You can edit the assignments either in the Assignment Editor or Pin Planner. Use one of the following procedures to specify the I/O standard assignments for pins

   - If you have a single SDRAM interface, and your top-level pins have default naming shown in the example top-level file, run `<variation name>_pin_assignments.tcl`.
   
   - Or

   - If your design contains pin names that do not match the design, edit the `<variation name>_pin_assignments.tcl` file before you run the script. Follow these steps:
     a. Open `<variation name>_pin_assignments.tcl` file.
     b. Based on the flow you are using, set the `sopc_mode` value to Yes or No.

       - SOPC Builder System flow:
         
         ```tcl
         if {![info exists sopc_mode]} {set sopc_mode YES}
         ```

       - MegaWizard Plug-In Manager flow:
         
         ```tcl
         if {![info exists sopc_mode]} {set sopc_mode NO}
         ```

     c. Type your preferred prefix in the `pin_prefix` variable. For example, to add the prefix `my_mem`, do the following:

       ```tcl
       if {![info exists set_prefix]}{set pin_prefix "my_mem_"}
       ```

       After setting the prefix, the pin names are expanded as shown in the following:

       - SOPC Builder System flow:
         ```c
         my_mem_cs_n_from_the_<your_instance_name>
         ```

       - MegaWizard Plug-In Manager flow:
         ```c
         my_mem_cs_n[0]
         ```
If your top-level design does not use single bit bus notation for the single-bit memory interface signals (for example, `mem_dqs` rather than `mem_dqs[0]`), in the Tcl script you should change `set single_bit {[0]}` to `set single_bit {}`.

or

Alternatively, to change the pin names that do not match the design, you can add a prefix to your pin names by doing the following:

a. On the Assignments menu, click Pin Planner.

b. On the Edit menu, click Create/Import Megafunction.

c. Select Import an existing custom megafuction and navigate to `<variation name>.ppf`.

d. Type the prefix you want to use in Instance name. For example, change `mem_addr` to `core1_mem_addr`.

3. Set the top-level entity to the top-level design.

a. On the File menu, click Open.

b. Browse to your SOPC Builder system top-level design or `<variation name>_example_top` if you are using MegaWizard Plug-In Manager, and click Open.

c. On the Project menu, click Set as Top-Level Entity.

4. Assign the DQ and DQS pin locations.

a. You should assign pin locations to the pins in your design, so the Quartus II software can perform fitting and timing analysis correctly.

b. Use either the Pin Planner or Assignment Editor to assign the clock source pin manually. Also choose which DQS pin groups should be used by assigning each DQS pin to the required pin. The Quartus II Fitter then automatically places the respective DQ signals onto suitable DQ pins within each group.

To avoid no-fit errors when you compile your design, ensure that you place the `mem_clk` pins to the same edge as the `mem_dq` and `mem_dqs` pins, and set an appropriate I/O standard for the non-memory interfaces, such as the clock source and the reset inputs, when assigning pins in your design. For example, for DDR SDRAM select 2.5 V and for DDR2 SDRAM select 1.8 V. Also select in which bank or side of the device you want the Quartus II software to place them.

5. For Stratix III and Stratix IV designs, if you are using advanced I/O timing, specify board trace models in the Device & Pin Options dialog box. If you are using any other device and not using advanced I/O timing, specify the output pin loading for all memory interface pins.

6. Select your required I/O driver strength (derived from your board simulation) to ensure that you correctly drive each signal or ODT setting and do not suffer from overshoot or undershoot.

7. To compile the design, on the Processing menu, click Start Compilation.
To attach the SignalTap® II logic analyzer to your design, refer to AN 380: Test DDR or DDR2 SDRAM Interfaces on Hardware Using the Example Driver.

After you have compiled the example top-level file, you can perform RTL simulation or program your targeted Altera device to verify the example top-level file in hardware.

**Simulate the Design**

During system generation, SOPC Builder optionally generates a simulation model and testbench for the entire system, which you can use to easily simulate your system in any of Altera’s supported simulation tools. The MegaWizard also generates a set of ModelSim Tcl scripts and macros that you can use to compile the testbench, IP functional simulation models, and plain-text RTL design files that describe your system in the ModelSim simulation software (refer to “Generated Files” on page 2–6).

For more information about simulating SOPC Builder systems, refer to volume 4 of the *Quartus II Handbook* and AN 351: Simulating Nios II Systems. For more information about simulation, refer to the Simulating an External Memory Interface Design section in volume 4 of the *External Memory Interfaces Handbook*. For more information about how to include your board simulation results in the Quartus II software and how to assign pins using pin planners, refer to DDR, DDR2, and DDR3 Tutorials in volume 6 of the *External Memory Interfaces Handbook*.

In ALTMEMPHY variations for DDR or DDR2 SDRAM interfaces, you have the following simulation options:

- **Skip calibration**—Performs a static setup of the ALTMEMPHY megafunction to skip calibration and go straight into user mode.

  Skip calibration mode supports the default ALTMEMPHY parameterization with CAS latency of 3 for DDR memory, and all CAS latencies for DDR2 memory. The additive latency must be disabled for all memory types.

- **Quick calibration**—Performs a calibration on a single pin and chip select.

  You may see memory model warnings about initialization times.

- **Full calibration**—Across all pins and chip selects. This option allows for longer simulation time.

  In quick and skip calibration modes, the ALTMEMPHY megafunction is not able to cope with any delays, and it simply assumes that all delays in the testbench and memory model are 0 ps. In order to successfully simulate a design with delays in the testbench and memory model, you must generate a full calibration mode model in the MegaWizard Plug-In Manager.
Simulating Using NativeLink

To set up simulation using NativeLink for the DDR or DDR2 high-performance controllers (HPC and HPC II), follow these steps:

1. Create a custom variation with an IP functional simulation model, refer to step 4 in the “Specify Parameters” section on page 2–4.

2. Set the top-level entity to the example project.
   a. On the File menu, click Open.
   b. Browse to <variation name>_example_top and click Open.
   c. On the Project menu, click Set as Top-Level Entity.

3. Set up the Quartus II NativeLink.
   a. On the Assignments menu, click Settings. In the Category list, expand EDA Tool Settings and click Simulation.
   b. From the Tool name list, click on your preferred simulator.
   c. Check that the absolute path to your third-party simulator executable is set. On the Tools menu, click Options and select EDA Tools Options.
   d. In NativeLink settings, select Compile test bench and click Test Benches.
   
4. On the New Test Bench Settings dialog box, do the following:
   a. Type a name for the Test bench name.
   b. In Top level module in test bench, type the name of the automatically generated testbench, <variation name>_example_top_tb.
   c. In Design instance in test bench, type the name of the top-level instance, dut.
   d. Under Simulation period, set Run simulation until all vector simul are used.
   e. Add the testbench files and automatically-generated memory model files. In the File name field, browse to the location of the memory model and the testbench, click Open and then click Add. The testbench is <variation name>_example_top_tb.v; memory model is <variation name>_mem_model.v.

   The auto generated generic SDRAM model may be used as a placeholder for a specific memory vendor supplied model.
   f. Select the files and click OK.

5. On the Processing menu, point to Start and click Start Analysis & Elaboration to start analysis.
6. On the Tools menu, point to Run EDA Simulation Tool and click EDA RTL Simulation.

![Note] Ensure that the Quartus II EDA Tool Options are configured correctly for your simulation environment. On the Tools menu, click Options. In the Category list, click EDA Tool Options and verify the locations of the executable files.

If your Quartus II project appears to be configured correctly but the example testbench still fails, check the known issues on the Knowledge Database page before filing a service request.

**IP Functional Simulations**

For VHDL simulations with IP functional simulation models, perform the following steps:

1. Create a directory in the `<project directory>\testbench` directory.
2. Launch your simulation tool from this directory and create the following libraries:
   - altera_mf
   - lpm
   - sgate
   - `<device name>`
   - altera
   - ALTGXB
   - `<device name>_hssi`
   - auk_ddr_hp_user_lib
3. Compile the files into the appropriate library (AFI mode) as shown in Table 4–1. The files are in VHDL93 format.

**Table 4–1. Files to Compile—VHDL IP Functional Simulation Models (Part 1 of 2)**

<table>
<thead>
<tr>
<th>Library</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>altera_mf</td>
<td><code>&lt;QUARTUS ROOTDIR&gt;/eda/sim_lib/altera_mf_components.vhd</code> <code>&lt;QUARTUS ROOTDIR&gt;/eda/sim_lib/altera_mf.vhd</code></td>
</tr>
<tr>
<td>lpm</td>
<td><code>/eda/sim_lib/220pack.vhd</code> <code>&lt;/eda/sim_lib/220model.vhd</code></td>
</tr>
<tr>
<td>sgate</td>
<td><code>eda/sim_lib/sgate_pack.vhd</code> <code>eda/sim_lib/sgate.vhd</code></td>
</tr>
<tr>
<td><code>&lt;device name&gt;</code></td>
<td><code>eda/sim_lib/&lt;device name&gt;_atoms.vhd</code> <code>eda/sim_lib/&lt;device name&gt;_components.vhd</code> <code>eda/sim_lib/&lt;device name&gt;_hssi_atoms.vhd (1)</code></td>
</tr>
<tr>
<td>altera</td>
<td><code>eda/sim_lib/altera_primitives_components.vhd</code> <code>eda/sim_lib/altera_primitives.vhd</code> <code>eda/sim_lib/altera_syn_attributes.vhd</code> <code>eda/sim_lib/altera_primitives.vhd</code></td>
</tr>
</tbody>
</table>
If you are targeting Stratix IV devices, you need both the Stratix IV and Stratix III files (stratixiv_atoms and stratixiii_atoms) to simulate in your simulator, unless you are using NativeLink.

4. Load the testbench in your simulator with the timestep set to picoseconds.

For Verilog HDL simulations with IP functional simulation models, follow these steps:

1. Create a directory in the `<project directory>\testbench` directory.
2. Launch your simulation tool from this directory and create the following libraries:
   - altera_mf_ver
   - lpm_ver
   - sgate_ver
   - <device name>_ver
   - altera_ver
   - ALTGXB_ver
   - <device name>_hssi_ver
   - auk_ddr_hp_user_lib

3. Compile the files into the appropriate library as shown in Table 4–2.

Table 4–2. Files to Compile—Verilog HDL IP Functional Simulation Models (Part 1 of 3)

<table>

Notes for Table 4–2:

1. Applicable only for Arria GX, Arria II GX, Stratix GX, Stratix II GX and Stratix IV devices.
2. Applicable only for Arria GX, Hardcopy II, Stratix II and Stratix II GX devices.
5. Functional Description—ALTMEMPHY

The ALTMEMPHY megafunction creates the datapath between the memory device and the memory controller, and user logic in various Altera devices. The ALTMEMPHY megafunction GUI helps you configure multiple variations of a memory interface. You can then connect the ALTMEMPHY megafunction variation with either a user-designed controller or with an Altera high-performance controller. In addition, the ALTMEMPHY megafunction and the Altera high-performance controllers are available for full-rate and half-rate DDR and DDR2 SDRAM interfaces.

For legacy device families not supported by the ALTMEMPHY megafunction (such as Cyclone, Cyclone II, Stratix, and Stratix GX devices), use the Altera legacy integrated static datapath and controller MegaCore functions.

If the ALTMEMPHY megafunction does not meet your requirements, you can also create your own memory interface datapath using the ALTDLL and ALTDQ_DQS megafucntions, available in the Quartus II software. However, you are then responsible for every aspect of the interface, including timing analysis and debugging.

This chapter describes the DDR and DDR2 SDRAM ALTMEMPHY megafunction, which uses AFI as the interface between the PHY and the controller.

Block Description

Figure 5–1 on page 5–2 shows the major blocks of the ALTMEMPHY megafunction and how it interfaces with the external memory device and the controller. The ALTPLL megafunction is instantiated inside the ALTMEMPHY megafunction, so that you do not need to generate the clock to any of the ALTMEMPHY blocks.
The ALTMEMPHY megafunction comprises the following blocks:

- Write datapath
- Address and command datapath
- Clock and reset management, including DLL and PLL
- Sequencer for calibration
- Read datapath

**Calibration**

This section describes the calibration that the sequencer performs, to find the optimal clock phase for the memory interface.

The ALTMEMPHY variation for DDR/DDR2 SDRAM interfaces has a similar calibration process for the AFI and non-AFI.
The calibration process for the DDR/DDR2 SDRAM PHY includes the following steps:

- “Step 1: Memory Device Initialization”
- “Step 2: Write Training Patterns”
- “Step 3: Read Resynchronization (Capture) Clock Phase”
- “Step 4: Read and Write Datapath Timing”
- “Step 5: Address and Command Clock Cycle”
- “Step 6: Postamble”
- “Step 7: Prepare for User Mode”

For more detailed information about each calibration step, refer to the Hardware Debugging section in volume 4 of the External Memory Interfaces Handbook.

Figure 5–2 shows the calibration flow.
Step 1: Memory Device Initialization

This step initializes the memory device according to the DDR and DDR2 SDRAM specification. The initialization procedure includes specifying the mode registers and memory device ODT setting (DDR2 only), and initializing the memory device DLL. Calibration requires overriding some of the user-specified mode register settings, which are reverted in “Step 7: Prepare for User Mode”.

Step 2: Write Training Patterns

In this step, a pattern is written to the memory to be read in later calibration stages. The matched trace lengths to DDR SDRAM devices mean that after memory initialization, write capture functions. The pattern is 0x30F5 and comprises the following separately written patterns:

- All 0: ‘b0000 - DDIO high and low bits held at 0
- All 1: ‘b1111 - DDIO high and low bits held at 1
- Toggle: ‘b0101 - DDIO high bits held at 0 and DDIO low bits held at 1
- Mixed: ‘b0011 - DDIO high and low bits have to toggle

This pattern is required to match the characterization behavior for non-DQS capture-based schemes, for example, the Cyclone III devices.

Loading a mixed pattern is complex, because the write latency is unknown at this time. Two sets of write and read operations (single pin resynchronization (capture) clock phase sweeps, (“Step 3: Read Resynchronization (Capture) Clock Phase”) are required to accurately write the mixed pattern to memory.

Memory bank 0, row 0, and column addresses 0 to 55 store calibration data.

Step 3: Read Resynchronization (Capture) Clock Phase

This step adjusts the phase of the resynchronization (or capture) clock to determine the optimal phase that gives the greatest margin. For DQS-based capture schemes, the resynchronization clock captures the outputs of DQS capture registers (DQS is the capture clock). In a non-DQS capture-based scheme, the capture clock captures the input DQ pin data (the DQS signal is unused, and there is no resynchronization clock).

To correctly calibrate resynchronization (or capture) clock phase, based on a data valid window, requires the following degrees of phase sweep:

- 720° for all half-rate interfaces and full-rate DQS-based capture PHY
- 360° for a full-rate non-DQS capture PHY
Step 4: Read and Write Datapath Timing

In this step, the sequencer calculates the calibrated write latency (the $ctl_wlat$ signal) between write commands and write data. The sequencer also calculates the calibrated read latency (the $ctl_rlat$ signal) between the issue of a read command and valid read data. Both read and write latencies are output to a controller. In addition to advertising the read latency, the sequencer calibrates a read data valid signal to the delay between a controller issuing a read command and read data returning. The controller can use the read data valid signal in place of the advertised read latency, to determine when the read data is valid.

Step 5: Address and Command Clock Cycle

For half-rate interfaces, this step also optionally adds an additional memory clock cycle of delay from the address and command path. This delay aligns write data to memory commands given in the controller clock domain. If you require this additional delay, this step reruns the calibration (“Step 2: Write Training Patterns” to “Step 4: Read and Write Datapath Timing”) to calibrate to the new setting.

Step 6: Postamble

This step sets the correct clock cycle for the postamble path. The aim of the postamble path is to eliminate false DQ data capture because of postamble glitches on the DQS signal, through an override on DQS. This step ensures the correct clock cycle timing of the postamble enable (override) signal.

Postamble is only required for DQS-based capture schemes.

Step 7: Prepare for User Mode

In this step, the PHY applies user mode register settings and performs periodic VT tracking.

VT Tracking

VT tracking is a background process that tracks the voltage and temperature variations to maintain the relationship between the resynchronization or capture clock and the data valid window that are achieved at calibration.

When the data calibration phase is completed, the sequencer issues the mimic calibration sequence every 128 ms.

During initial calibration, the mimic path is sampled using the measure clock (measure_clk has a `_1x` or `_2x` suffix, depending whether the ALTMEMPHY is a full-rate or half-rate design). The sampled value is then stored by the sequencer. After a sample value is stored, the sequencer uses the PLL reconfiguration logic to change the phase of the measure clock by one VCO phase tap. The control sequencer then stores the sampled value for the new mimic path clock phase. This sequence continues until all mimic path clock phases are swept. After the control sequencer stores all the mimic path sample values, it calculates the phase which corresponds to the center of the high period of the mimic path waveform. This reference mimic path sampling phase is used during the VT tracking phase.
In user mode, the sequencer periodically performs a tracking operation as defined in the tracking calibration description. At the end of the tracking calibration operation, the sequencer compares the most recent optimum tracking phase against the reference sampling phase. If the sampling phases do not match, the mimic path delays have changed due to voltage and temperature variations.

When the sequencer detects that the mimic path reference and most recent sampling phases do not match, the sequencer uses the PLL reconfiguration logic to change the phase of the resynchronization clock by the VCO taps in the same direction. This allows the tracking process to maintain the near-optimum capture clock phase setup during data tracking calibration as voltage and temperature vary over time.

The relationship between the resynchronization or capture clock and the data valid window is maintained by measuring the mimic path variations due to the VT variations and applying the same variation to the resynchronization clock.

**Mimic Path**

The mimic path mimics the FPGA elements of the round-trip delay, which enables the calibration sequencer to track delay variation due to VT changes during the memory read and write transactions without interrupting the operation of the ALTMEMPHY megafunction.

The assumption made about the mimic path is that the VT variation on the round trip delay path that resides outside of the FPGA is accounted for in the board skew and memory parameters entered in the MegaWizard Plug-In Manager. For the write direction, any VT variation in the memory devices is accounted for by timing analysis. **Figure 5–3** shows the mimic path in Arria GX, Cyclone III, Stratix II, and Stratix II GX devices, which mimics the delay of the clock outputs to the memory as far as the pads of the FPGA and the delay from the input DQS pads to a register in the FPGA core. During the tracking operation, the sequencer measures the delay of the mimic path by varying the phase of the measure clock. Any change in the delay of the mimic path indicates a corresponding change in the round-trip delay, and a corresponding adjustment is made to the phase of the resynchronization or capture clock.

![The mimic path in Arria II GX, Stratix III and Stratix IV devices is similar to Figure 5–3. The only difference is that the \texttt{mem\_clk[0]} pin is generated by DDIO register; \texttt{mem\_clk\_n[0]} is generated by signal splitter.](image-url)
Address and Command Datapath

This topic describes the address and command datapath.

**Arria GX, Arria II GX, Cyclone III, HardCopy II, Stratix II, and Stratix II GX Devices**

The address and command datapath for full-rate designs is similar to half-rate designs, except that the address and command signals are all asserted for one memory clock cycle only (1T signaling).

The address and command datapath is responsible for taking the address and command outputs from the controller and converting them from half-rate clock to full-rate clock. Two types of addressing are possible:

- **1T (full rate)**—The duration of the address and command is a single memory clock cycle (mem_clk_2x, Figure 5–4). This applies to all address and command signals in full-rate designs or mem_cs_n, mem_cke, and mem_odt signals in half-rate designs.

- **2T (half rate)**—The duration of the address and command is two memory clock cycles. For half-rate designs, the ALTMEMPHY megafunction supports only a burst size of four, which means the burst size on the local interface is always set to 1. The size of the data is 4n-bits wide on the local side and is n-bits wide on the memory side. To transfer all the 4n-bits at the double data rate, two memory-clock cycles are required. The new address and command can be issued to memory every two clock cycles. This scheme applies to all address and command signals, except for mem_cs_n, mem_cke, and mem_odt signals in half-rate mode.

Refer to Table 5–4 in “PLL” on page 5–9 to see the frequency relationship of mem_clk_2x with the rest of the clocks.

**Figure 5–4** shows a 1T chip select signal (mem_cs_n), which is active low, and disables the command in the memory device. All commands are masked when the chip-select signal is inactive. The mem_cs_n signal is considered part of the command code.
The command interface is made up of the signals \text{mem\_ras\_n}, \text{mem\_cas\_n}, \text{mem\_we\_n}, \text{mem\_cs\_n}, \text{mem\_cke}, and \text{mem\_odt}.

The waveform in Figure 5–4 shows a NOP command followed by back-to-back write commands. The following sequence corresponds with the numbered items in Figure 5–4:

1. The commands are asserted either on the rising edge of \text{ac\_clk\_2x}. The \text{ac\_clk\_2x} is derived from either \text{mem\_clk\_2x} (0°), \text{write\_clk\_2x} (270°), or the inverted variations of those two clocks (for 180° and 90° phase shifts). This depends on the setting of the address and command clock in the ALTMEMPHY MegaWizard interface. Refer to “Address and Command Datapath” on page 5–7 for illustrations of this clock in relation to the \text{mem\_clk\_2x} or \text{write\_clk\_2x} signals.

2. All address and command signals (except for \text{mem\_cs\_ns}, \text{mem\_cke}, and \text{mem\_odt} signals) remain asserted on the bus for two clock cycles, allowing sufficient time for the signals to settle.

3. The \text{mem\_cs\_n}, \text{mem\_cke}, and \text{mem\_odt} signals are asserted during the second cycle of the address/command phase. By asserting the chip-select signal in alternative cycles, back-to-back read or write commands can be issued.

4. The address is incremented every other \text{ac\_clk\_2x} cycle.

\text{ac\_clk\_2x} clock is derived from either \text{mem\_clk\_2x} (when you choose 0° or 180° phase shift) or \text{write\_clk\_2x} (when you choose 90° or 270° phase shift).

The address and command clock can be 0, 90, 180, or 270° from the system clock (refer to “Address and Command Datapath” on page 5–7).
Stratix III and Stratix IV Devices

The address and command clock in Stratix III and Stratix IV devices is one of the PLL dedicated clock outputs whose phase can be adjusted to meet the setup and hold requirements of the memory clock. The Stratix III address and command clock, ac_clk_1x, is half-rate. The command and address pins use the DDIO output circuitry to launch commands from either the rising or falling edges of the clock. The chip select (cs_n) pins and ODT are only enabled for one memory clock cycle and can be launched from either the rising or falling edge of ac_clk_1x signal, while the address and other command pins are enabled for two memory clock cycles and can also be launched from either the rising or falling edge of ac_clk_1x signal.

The full-rate address and command datapath is the same as that of the half-rate address and command datapath, except that there is no full-rate to half-rate conversion in the IOE. The address and command signals are full-rate here.

Clock and Reset Management

This topic describes the clock and reset management for specific device types.

Arria GX, Arria II GX, HardCopy II, Stratix II, and Stratix II GX Devices

The clocking and reset block is responsible for clock generation, reset management, and phase shifting of clocks. It also has control of clock network types that route the clocks.

Clock Management

The clock management feature allows the ALTMEMPHY megafunction to work out the optimum resynchronization clock phase during calibration, and track the system voltage and temperature (VT) variations. Clock management is achieved by phase-shifting the clocks relative to each other.

Clock management circuitry is implemented by the following device resources:

- PLL
- PLL reconfiguration
- DLL

PLL

The ALTMEMPHY MegaWizard interface automatically generates an ALTP PLL megafunction instance. The ALTP PLL megafunction is responsible for generating the different clock frequencies and relevant phases used within the ALTMEMPHY megafunction.

The minimum PHY requirement is to have 16 phases of the highest frequency clock. The PLL uses the With No Compensation option to minimize jitter.

You must choose a PLL and PLL input clock pin that are located on the same side of the memory interface to ensure minimal jitter. Cascaded PLLs are not recommended for DDR/DDR2 SDRAM interfaces as jitter can accumulate with the use of cascaded PLLs causing the memory output clock to violate the memory device jitter specification. Also, ensure that the input clock to the PLL is stable before the PLL locks. If not, you must perform a manual PLL reset and relock the PLL to ensure that the phase relationship between all PLL outputs are properly set.
If the design cascades PLLs, the source (upstream) PLL should have a low-bandwidth setting; the destination (downstream) PLL should have a high-bandwidth setting. Adjacent PLLs cascading is recommended to reduce clock jitters.

For more information about the VCO frequency range and the available phase shifts, refer to the *PLLs in Stratix II and Stratix II GX Devices* chapter in the respective device family handbook.

Table 5-4 shows the clock outputs for Arria GX, HardCopy II, Stratix II, and Stratix II GX devices.

**Note to Table 5–2:**

(1) In full-rate designs, a _1x clock may run at full-rate clock rate.
PLL Reconfiguration

The ALTMEMPHY MegaWizard interface automatically generates the PLL reconfiguration block by instantiating an ALTPLL_RECONFIG variation for Stratix II and Stratix II GX devices to match the generated ALTPLL megafunction instance. The ALTPLL_RECONFIG megafunction varies the resynchronization clock phase and the measure clock phase.

The ALTMEMPHY MegaWizard interface does not instantiate an ALTPLL_RECONFIG megafunction for Arria II GX devices, as this device uses the dedicated phase stepping I/O on the PLL.

DLL

A DLL instance is included in the generated ALTMEMPHY variation. When using the DQS to capture the DQ read data, the DLL center-aligns the DQS strobe to the DQ data. The DLL settings depend on the interface clock frequency.

For more information, refer to the External Memory Interfaces chapter in the device handbook for your target device family.

Reset Management

The reset management block is responsible for the following:

- Provides appropriately timed resets to the ALTMEMPHY megafunction datapaths and functional modules
- Performs the reset sequencing required for different clock domains
- Provides reset management of PLL and PLL reconfiguration functions
- Manages any circuit-specific reset sequencing

Each reset is an asynchronous assert and synchronous deassert on the appropriate clock domain. The reset management design uses a standard two-register synchronizer to avoid metastability. A unique reset metastability protection circuit for the clock divider circuit is required because the phy_clk domain reset metastability protection flipflops have fan-in from the soft_reset_n input, and so these registers cannot be used.

Figure 5–5 shows the ALTMEMPHY reset management block for Arria GX, Arria II GX, HardCopy II, Stratix II, and Stratix II GX devices. The pll_ref_clk signal goes directly to the PLL, eliminating the need for global clock network routing. If you are using the pll_ref_clk signal to feed other parts of your design, you must use a global clock network for the signal. If pll_reconfig_soft_reset_en signal is held low, the PLL reconfig is not reset during a soft reset, which allows designs targeting HardCopy II devices to hold the PHY in reset while still accessing the PLL reconfig block. However, designs targeting Arria GX, Arria II GX, or Stratix II devices are expected to tie the pll_reconfig_soft_en shell to VCC to enable PLL reconfig soft resets.
Clock management circuitry is implemented using the ALTPLL megafunction.

The ALTPLL megafunction is instantiated within the ALTMEMPHY megafunction and is responsible for generating all the clocks used by the ALTMEMPHY megafunction and the memory controller.

The minimum PHY requirement is to have 48 phases of the highest frequency clock. The PLL uses Normal mode, unlike other device families. Cyclone III PLL in normal mode emits low jitter already such that you do not require to set the PLL in the **With no compensation** option. Changing the PLL compensation mode may result in inaccurate timing results.

**Cyclone III Devices**

The reset circuit for Arria II GX and Cyclone III devices have no PLL reconfig block.

---

**Figure 5–5.** ALTMEMPHY Reset Management Block for Arria GX, Arria II GX, Cyclone III, HardCopy II, Stratix II, and Stratix II GX Devices  
*(Note 1)*

**Note to Figure 5–5:**

(1) The reset circuit for Arria II GX and Cyclone III devices have no PLL reconfig block.
You must choose a PLL and PLL input clock pin that are located on the same side of the memory interface to ensure minimal jitter. Cascaded PLLs are not recommended as jitter can accumulate with the use of cascaded PLLs causing the memory output clock to violate the memory device jitter specification. Also, ensure that the input clock to the PLL is stable before the PLL locks. If not, you must perform a manual PLL reset and relock the PLL to ensure that the phase relationship between all PLL outputs are properly set.

Table 5–3 lists the clocks generated by the ALTPLL megafuction.

Reset Management
The reset management for Cyclone III devices is instantiated in the same way as it is with Stratix II devices.

Stratix III and Stratix IV Devices
The clocking and reset block is responsible for clock generation, reset management, and phase shifting of clocks. It also has control of clock network types that route the clocks.

The ability of the ALTMEMPHY megafuntion to work out the optimum phase during calibration and to track voltage and temperature variation relies on phase shifting the clocks relative to each other.

Certain clocks need to be phase shifted during the ALTMEMPHY megafuntion operation.

Clock management circuitry is implemented by using:
- PLL
- DLL
PLL
The ALTMEMPHY MegaWizard interface automatically generates an ALTPLL megafunction instance. The ALTPLL megafunction is responsible for generating the different clock frequencies and relevant phases used within the ALTMEMPHY megafunction.

The device families available have different PLL capabilities. The minimum PHY requirement is to have 16 phases of the highest frequency clock. The PLL uses With No Compensation operation mode to minimize jitter. Changing the PLL compensation mode may result in inaccurate timing results.

You must choose a PLL and PLL input clock pin that are located on the same side of the device as the memory interface to ensure minimal jitter. Cascaded PLLs are not recommended as jitter can accumulate, causing the memory output clock to violate the memory device jitter specification. Also, ensure that the input clock to the PLL is stable before the PLL locks. If not, you must perform a manual PLL reset (by driving the global_reset_n signal low) and relock the PLL to ensure that the phase relationship between all PLL outputs are properly set.

For more information about the VCO frequency range and the available phase shifts, refer to the Clock Networks and PLLs in Stratix III Devices chapter in volume 1 of the Stratix III Device Handbook or the Clock Networks and PLLs in Stratix IV Devices chapter in volume 1 of the Stratix IV Device Handbook.

For Stratix IV and Stratix III devices, the PLL reconfiguration is done using the phase-shift inputs on the PLL instead of using the PLL reconfiguration megafunction. Table 5–4 shows the Stratix IV and Stratix III PLL clock outputs.

</tr>
</tbody>
</table>
Clock and reset management for full-rate designs is similar to half-rate support (see Table 5-4 on page 5-19). The PLL is configured exactly in the same way as for half-rate support. The mem_clk_2x output acts as the PHY full-rate clock. Also, instead of going through the I/O clock divider, the resync_clk_2x output is now directly connected to the resynchronization registers. The rest of the PLL outputs are connected in the same way as for half-rate support.

You must choose a PLL and PLL input clock pin that are located on the same side of the device as the memory interface to ensure minimal jitter. Cascaded PLLs are not recommended as jitter can accumulate, causing the memory output clock to violate the memory device jitter specification. Also, ensure that the input clock to the PLL is stable before the PLL locks. If not, you must perform a manual PLL reset (by driving the global_reset_n signal low) and relock the PLL to ensure that the phase relationship between all PLL outputs are properly set. The PLL restrictions in half-rate designs also applies to full-rate designs.

**DLL**

DLL settings are set depending on the memory clock frequency of operation.

*(1)* In full-rate designs a _1x clock may run at full-rate clock rate.

*(2)* This clock should be of the same clock network clock as the resync_clk_2x clock.
For more information on the DLL, refer to the *External Memory Interfaces in Stratix III Devices* chapter in volume 1 of the *Stratix III Device Handbook* and the *External Memory Interfaces in Stratix IV Devices* chapter in volume 1 of the *Stratix IV Device Handbook*.

**Reset Management**

Figure 5–6 shows the main features of the reset management block for the DDR3 SDRAM PHY. You can use the `pll_ref_clk` input to feed the optional `reset_request_n` edge detect and reset counter module. However, this requires the `pll_ref_clk` signal to use a global clock network resource.

There is a unique reset metastability protection circuit for the clock divider circuit because the `phy_clk` domain reset metastability protection registers have fan-in from the `soft_reset_n` input so these registers cannot be used.

**Figure 5–6. ALTMEMPHY Reset Management Block for Stratix IV and Stratix III Devices**

---

**Read Datapath**

This topic describes the read datapath.

**Arriva GX, Arriva II GX, HardCopy II, Stratix II, and Stratix II GX Devices**

The following section discusses support for DDR/DDR2 SDRAM for Arriva GX, Arriva II GX, HardCopy II, Stratix II, and Stratix II GX devices.

The full-rate datapath is similar to the half-rate datapath. The full-rate datapath also consists of a RAM with the same width as the data input (just like that of the half-rate), but the width on the data output of the RAM is half that of the half-rate PHY. The function of the RAM is to transfer the read data from the resynchronization clock domain to the system clock domain.
The read datapath logic is responsible for capturing data sent by the memory device and subsequently aligning the data back to the system clock domain. The following functions are performed by the read datapath:

1. Data capture and resynchronization
2. Data demultiplexing
3. Data alignment

Figure 5–7 shows the order of the functions performed by the read datapath, along with the frequency at which the read data is handled.

Figure 5–7. DDR/DDR2 SDRAM Read Datapath in Arria GX, Arria II GX, HardCopy II, Stratix II, and Stratix II GX Devices  
(Note 1)

Note to Figure 5–7:  
(1) In Arria II GX devices the resynchronization register is implemented in IOE.

Data Capture and Resynchronization

Data capture and resynchronization is the process of capturing the read data (DQ) with the DQS strobe and re-synchronizing the captured data to an internal free-running full-rate clock supplied by the enhanced phase-locked loop (PLL).

The resynchronization clock is an intermediate clock whose phase shift is determined during the calibration stage.

Timing constraints ensure that the data resynchronization registers are placed close to the DQ pins to achieve maximum performance. Timing constraints also further limit skew across the DQ pins. The captured data (rdata_2x_p and rdata_2x_n) is synchronized to the resynchronization clock (resync_clk_2x), refer to Figure 5–7.
Data Demultiplexing

Data demultiplexing is the process of SDR data into HDR data. Data demultiplexing is required to bring the frequency of the resynchronized data down to the frequency of the system clock, so that data from the external memory device can ultimately be brought into the FPGA DDR or DDR2 SDRAM controller clock domain. Before data capture, the data is DDR and \( n \)-bit wide. After data capture, the data is SDR and \( 2n \)-bit wide. After data demuxing, the data is HDR of width \( 4n \)-bits wide. The system clock frequency is half the frequency of the memory clock.

Demultiplexing is achieved using a dual-port memory with a \( 2n \)-bit wide write-port operating on the resynchronization clock (SDR) and a \( 4n \)-bit wide read-port operating on the PHY clock (HDR). The basic principle of operation is that data is written to the memory at the SDR rate and read from the memory at the HDR rate while incrementing the read- and write-address pointers. As the SDR and HDR clocks are generated, the read and write pointers are continuously incremented by the same PLL, and the \( 4n \)-bit wide read data follows the \( 2n \)-bit wide write data with a constant latency.

Read Data Alignment

Data alignment is the process controlled by the sequencer to ensure the correct captured read data is present in the same half-rate clock cycle at the output of the read data DPRAM. Data alignment is implemented using either M4K or M512K memory blocks. The bottom of Figure 5–8 shows the concatenation of the read data into valid HDR data.

Postamble Protection

The ALTMEMPHY megafuction provides the DQS postamble logic. The postamble clock is derived from the resynchronization clock and is the negative edge of the resynchronization clock. The ALTMEMPHY megafuction calibrates the resynchronization clock such that it is in the center of the data-valid window. The clock that controls the postamble logic, the postamble clock, is the negative edge of the resynchronization clock. No additional clocks are required. Figure 5–8 shows the relationship between the postamble clock and the resynchronization clock.

Figure 5–8. Relationship Between Postamble Clock and Resynchronization Clock (Note 1)
Cyclone III Devices

Figure 5–9 shows the Cyclone III read datapath for a single DQ pin. The diagram shows a half-rate read path where four data bits are produced for each DQ pin. Unlike Stratix® II and Stratix III devices, data capture is entirely done in the core logic because the I/O element (IOE) does not contain DDIO capture registers (nonDQS capture).

Capture and Pipelining

The DDR and DDR2 SDRAM read data is captured using registers in the Cyclone III FPGA core. These capture registers are clocked using the capture clock \( \text{resync clk}_2x \). The captured read data generates two data bits per DQ pin; one data bit for the read data captured by the rising edge of the capture clock and one data bit for the read data captured by the falling edge of the capture clock.

After the read data has been captured, it may be necessary to insert registers in the read datapath between the capture registers and the read data FIFO buffer to help meet timing. These registers are known as pipeline registers and are clocked off the same clock used by the capture registers, the capture clock \( \text{resync clk}_2x \).
Data Demultiplexing
The data demultiplexing for Cyclone III devices is instantiated in the same way as it is with Stratix II devices.

Postamble Protection
Postamble protection circuitry is not required in the Cyclone III device implementation as DQS mode capture of the DQ data is not supported. The data capture is done using the clock (resync_clk_2x) generated from the ALTPLL megafunction.

Stratix III and Stratix IV Devices
Stratix IV and Stratix III devices support half-rate or full-rate DDR/DDR2 SDRAM. The Stratix IV and Stratix III read datapath (Figure 5–10) consists of two main blocks:
- Data capture, resynchronization, and demultiplexing
- Read datapath logic (read datapath)

Figure 5–10. DDR/DDR2 SDRAM Data Capture and Read Data Mapping in Stratix IV and Stratix III Devices

Note to Figure 5–10: (1) This figure shows a half-rate variation. For a full-rate controller, dio_rdata2_1x and dio_rdata3_1x are unconnected.

Data Capture, Resynchronization, and Demultiplexing
In Stratix IV and Stratix III devices, the smart interface module in the IOE performs the following tasks:
- Captures the data
- Resynchronizes the captured data from the DQS domain to the resynchronization clock (resync_clk_1x) domain
- Converts the resynchronized data into half-rate data, which is performed by feeding the resynchronized data into the HDR conversion block within the IOE, which is clocked by the half-rate version of the resynchronization clock. The resync_clk_1x signal is generated from the I/O clock divider module based on the resync_clk_2x signal from the PLL.
For more information about IOE registers, refer to the *External Memory Interfaces in Stratix III Devices* chapter in volume 1 of the *Stratix III Device Handbook* and the *External Memory Interfaces in Stratix IV Devices* chapter in volume 1 of the *Stratix IV Device Handbook*.

**Data Resynchronization**

The read datapath block performs the following two tasks:

1. Transfers the captured read data (rdata[n]_1x) from the half-rate resynchronization clock (resync_clk_1x) domain to the half-rate system clock (phy_clk_1x) domain using DPRAM. Resynchronized data from the FIFO buffer is shown as ram_data_1x.

2. Reorders the resynchronized data (ram_rdata_1x) into ctl_mem_rdata.

The full-rate datapath is similar to the half-rate datapath, except that the resynchronization FIFO buffer converts from the full-rate resynchronization clock domain (resync_clk_2x) to the full-rate PHY clock domain, instead of converting it to the half-rate PHY clock domain as in half-rate designs.

**Postamble Protection**

A dedicated postamble register controls the gating of the shifted DQS signal that clocks the DQ input registers at the end of a read operation. This ensures that any glitches on the DQS input signals at the end of the read postamble time do not cause erroneous data to be captured as a result of postamble glitches. The postamble path is also calibrated to determine the correct clock cycle, clock phase shift, and delay chain settings. You can see the process in simulation if you choose Full calibration (long simulation time) mode in the MegaWizard Plug-In Manager.

For more information about the postamble protection circuitry, refer to the *External Memory Interfaces in Stratix III Devices* chapter in volume 1 of the *Stratix III Device Handbook* and the *External Memory Interfaces in Stratix IV Devices* chapter in volume 1 of the *Stratix IV Device Handbook*.

**Write Datapath**

This topic describes the write datapath.

**Arria GX, Arria II GX, Cyclone III, HardCopy II, Stratix II, and Stratix II GX Devices**

The write datapath logic efficiently transfers data from the HDR memory controller to DDR SDRAM-based memories. The write datapath logic consists of:

- DQ and DQ output-enable logic
- DQS and DQS output-enable logic
- Data mask (DM) logic

The memory controller interface outputs 4n-bit wide data (ctl_wdata[4n]) at half-rate frequency. Figure 5–11 shows that the HDR write data (ctl_wdata[4n]) is clocked by the half-rate clock phy_clk_1x and is converted into SDR which is represented by wdp_wdata_h and wdp_wdata_l and clocked by the full-rate clock write_clk_2x.

The DQ IOEs convert 2-n SDR bits to n-DDR bits.
The write datapath for full-rate PHYs is similar to the half-rate PHY. The IOE block is identical to the half-rate PHY. The latency of the write datapath in the full-rate PHY is less than in the half-rate PHY because the full-rate PHY does not have the half-rate-to-full-rate conversion logic.

**Stratix III and Stratix IV Devices**

The memory controller interface outputs $4n$-bit wide data (ctl_wdata) at phy_clk_1x frequency. The write data is clocked by the system clock phy_clk_1x at half data rate and reordered into HDR of width $4n$-bits represented in Figure 5–12 by wdp_wdata3_1x, wdp_wdata2_1x, wdp_wdata1_1x, and wdp_wdata0_1x.

All of the write datapath registers in the Stratix IV and Stratix III devices are clocked by the half-rate clock, phy_clk_1x.
For full-rate controllers, phy_clk_1x runs at full rate and there are only two bits of wdata.

The write datapath for full-rate PHYs is similar to the half-rate PHY. The IOE block is identical to the half-rate PHY. The latency of the write datapath in the full-rate PHY is less than in the half-rate PHY because the full-rate PHY does not have half-rate to full-rate conversion logic.

ALTMEMPHY Signals

This section describes the ALMEMPHY megafucton ports for AFI variants. Table 5–5 through Table 5–7 show the signals.

Signals with the prefix mem_ connect the PHY with the memory device; signals with the prefix ctl_ connect the PHY with the controller.

The signal lists include the following signal groups:
- I/O interface to the SDRAM devices
- Clocks and resets
- External DLL signals
- User-mode calibration OCT control
- Write data interface
- Read data interface
- Address and command interface
- Calibration control and status interface
- Debug interface

<tr>
<td>reset_request_n</td>
<td>Output</td>
<td>1</td>
<td>Directly connected to the locked output of the PLL and is intended for optional use either by automated tools such as SOPC Builder or could be manually ANDed with any other system-level signals and combined with any edge detect logic as required and then fed back to the global_reset_n input. Reset request output that indicates when the PLL outputs are not locked. Use this as a reset request input to any system-level reset controller you may have. This signal is always low while the PLL is locking (but not locked), and so any reset logic using it is advised to detect a reset request on a falling-edge rather than by level detection.</td>
</tr>
<tr>
<td>ctl_clk</td>
<td>Output</td>
<td>1</td>
<td>Half-rate clock supplied to controller and system logic. The same signal as the non-AFI phy_clk.</td>
</tr>
<tr>
<td>ctl_reset_n</td>
<td>Output</td>
<td>1</td>
<td>Reset output on ctl_clk clock domain.</td>
</tr>
<tr>
<td><strong>Other Signals</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>aux_half_rate_clk</td>
<td>Output</td>
<td>1</td>
<td>In half-rate designs, a copy of the phy_clk_1x signal that you can use in other parts of your design, same as phy_clk port.</td>
</tr>
</tbody>
</table>
### ALTMEMPHY Signals

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Type</th>
<th>Width (1)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aux_full_rate_clk</td>
<td>Output</td>
<td>1</td>
<td>In full-rate designs, a copy of the mem_clk_2x signal that you can use in other parts of your design.</td>
</tr>
<tr>
<td>aux_scan_clk</td>
<td>Output</td>
<td>1</td>
<td>Low frequency scan clock supplied primarily to clock any user logic that interfaces to the PLL and DLL reconfiguration interfaces.</td>
</tr>
<tr>
<td>aux_scan_clk_reset_n</td>
<td>Output</td>
<td>1</td>
<td>This reset output asynchronously asserts (drives low) when global_reset_n is asserted and de-asserts (drives high) synchronous to aux_scan_clk when global_reset_n is deasserted. It allows you to reset any external circuitry clocked by aux_scan_clk.</td>
</tr>
</tbody>
</table>

**Write Data Interface**

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Type</th>
<th>Width (1)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctl_dqs_burst</td>
<td>Input</td>
<td>MEM_IF_DQS_WIDTH × DWIDTH_RATIO / 2</td>
<td>When asserted, mem_dqs is driven. The ctl_dqs_burst signal must be asserted before ctl_wdata_valid and must be driven for the correct duration to generate a correctly timed mem_dqs signal.</td>
</tr>
<tr>
<td>ctl_wdata_valid</td>
<td>Input</td>
<td>MEM_IF_DQS_WIDTH × DWIDTH_RATIO / 2</td>
<td>Write data valid. Generates ctl_wdata and ctl_dm output enables.</td>
</tr>
<tr>
<td>ctl_wdata</td>
<td>Input</td>
<td>MEM_IF_DWIDTH × DWIDTH_RATIO</td>
<td>Write data input from the controller to the PHY to generate mem_dq.</td>
</tr>
<tr>
<td>ctl_dm</td>
<td>Input</td>
<td>MEM_IF_DM_WIDTH × DWIDTH_RATIO</td>
<td>DM input from the controller to the PHY.</td>
</tr>
<tr>
<td>ctl_wlat</td>
<td>Output</td>
<td>5</td>
<td>Required write latency between address/command and write data that is issued to ALTMEMPHY controller local interface.</td>
</tr>
</tbody>
</table>

This signal is only valid when the ALTMEMPHY sequencer successfully completes calibration, and does not change at any point during normal operation.

The legal range of values for this signal is 0 to 31; and the typical values are between 0 and ten, 0 mostly for low CAS latency DDR memory types.

**Read Data Interface**

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Type</th>
<th>Width (1)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ctl_doing_rd</td>
<td>Input</td>
<td>MEM_IF_DQS_WIDTH × DWIDTH_RATIO / 2</td>
<td>Doing read input. Indicates that the DDR or DDR2 SDRAM controller is currently performing a read operation.</td>
</tr>
</tbody>
</table>

The controller generates ctl_doing_rd to the ALTMEMPHY megafunction. The ctl_doing_rd signal is asserted for one phy_clk cycle for every read command it issues. If there are two read commands, ctl_doing_rd is asserted for two phy_clk cycles. The ctl_doing_rd signal also enables the capture registers and generates the ctl_mem_rdata_valid signal. The ctl_doing_rd signal should be issued at the same time the read command is sent to the ALTMEMPHY megafunction.

</table>

Notes to Table 5–7:
(1) The debug interface uses the simple Avalon-MM interface protocol.
(2) These ports exist in the Quartus II software, even though the debug interface is for Altera’s use only.

PHY-to-Controller Interfaces

The following section describes the typical modules that are connected to the ALTMEMPHY variation and the port name prefixes each module uses. This section also describes using a custom controller. This section describes the AFI.
The AFI standardizes and simplifies the interface between controller and PHY for all Altera memory designs, thus allowing you to easily interchange your own controller code with Altera’s high-performance controllers. The AFI includes an administration block that configures the memory for calibration and performs necessary mode registers accesses to configure the memory as required (these calibration processes are different). Figure 5–13 shows an overview of the connections between the PHY, the controller, and the memory device.

Altera recommends that you use the AFI for new designs.

**Figure 5–13. AFI PHY Connections**

For half-rate designs, the address and command signals in the ALTMEMPHY megafuction are asserted for one `mem_clk` cycle (1T addressing), such that there are two input bits per address and command pin in half-rate designs. If you require a more conservative 2T addressing, drive both input bits (of the address and command signal) identically in half-rate designs.

For DDR3 SDRAM with the AFI, the read and write control signals are on a per-DQS group basis. The controller can calibrate and use a subset of the available DDR3 SDRAM devices. For example, two devices out of a 64- or 72-bit DIMM, for better debugging mechanism.

For half-rate designs, the AFI allows the controller to issue reads and writes that are aligned to either half-cycle of the half-rate `phy_clk`, which means that the datapaths can support multiple data alignments—word-unaligned and word-aligned writes and reads. Figure 5–14 and Figure 5–15 display the half-rate write operation.
After calibration completes, the sequencer sends the write latency in number of clock cycles to the controller. After calibration completes, the sequencer sends the write latency in number of clock cycles to the controller.

Figure 5–16 shows a full-rate write. After calibration completes, the sequencer sends the write latency in number of clock cycles to the controller.

Figure 5–17 shows full-rate reads; Figure 5–18 shows half-rate reads. After calibration completes, the sequencer sends the write latency in number of clock cycles to the controller.
Figure 5–17. Full-Rate Reads

ctl_rlat = 9

1 2 3 4 5 6 7 8 9

Figure 5–18. Half-Rate Reads

ctl_rlat = 9

1 2 3 4 5 6 7 8 9
Figure 5–19 and Figure 5–20 show word-aligned writes and reads. In the following read and write examples the data is written to and read from the same address. In each example, ctl_rdata and ctl_wdata are aligned with controller clock (ctl_clk) cycles. All the data in the bit vector is valid at once. For comparison, refer Figure 5–21 and Figure 5–22 that show the word-unaligned writes and reads.

The ctl_doing_rd is represented as a half-rate signal when passed into the PHY. Therefore, the lower half of this bit vector represents one memory clock cycle and the upper half the next memory clock cycle. Figure 5–22 on page 5–44 shows separated word-unaligned reads as an example of two ctl_doing_rd bits are different. Therefore, for each x16 device, at least two ctl_doing_rd bits need to be driven, and two ctl_rdata_valid bits need to be interpreted.

The AFI has the following conventions:

- With the AFI, high and low signals are combined in one signal, so for a single chip select (ctl_cs_n) interface, ctl_cs_n[1:0], where location 0 appears on the memory bus on one mem_clk cycle and location 1 on the next mem_clk cycle.

  This convention is maintained for all signals so for an 8 bit memory interface, the write data (ctl_wdata) signal is ctl_wdata[31:0], where the first data on the DQ pins is ctl_wdata[7:0], then ctl_wdata[15:8], then ctl_wdata[23:16], then ctl_wdata[31:24].

- Word-aligned and word-unaligned reads and writes have the following definitions:

  Word-aligned for the single chip select is active (low) in location 1 (_L). ctl_cs_n[1:0] = 01 when a write occurs. This alignment is the easiest alignment to design with.

  Word-unaligned is the opposite, so ctl_cs_n[1:0] = 10 when a read or write occurs and the other control and data signals are distributed across consecutive ctl_clk cycles.

  The Altera high-performance controllers use word-aligned data only.

  The timing analysis script does not support word-unaligned reads and writes.

  Word-unaligned reads and writes are only supported on Stratix III and Stratix IV devices.

- Spaced reads and writes have the following definitions:

  Spaced writes—write commands separated by a gap of one controller clock (ctl_clk) cycle

  Spaced reads—read commands separated by a gap of one controller clock (ctl_clk) cycle
Figure 5–19 through Figure 5–22 assume the following general points:

- The burst length is four. A DDR2 SDRAM is used—the interface timing is identical for DDR3 devices.
- An 8-bit interface with one chip select.
- The data for one controller clock (ctl_clk) cycle represents data for two memory clock (mem_clk) cycles (half-rate interface).
Figure 5–19. Word-Aligned Writes

Notes to Figure 5–19:

(1) To show the even alignment of \(ctl\text{\_cs\_n}\), expand the signal (this convention applies for all other signals).

(2) The \(ctl\text{\_dqs\_burst}\) must go high one memory clock cycle before \(ctl\text{\_wdata\_valid}\). Compare with the word-unaligned case.

(3) The \(ctl\text{\_wdata\_valid}\) is asserted two \(ctl\text{\_wlat}\) controller clock \((ctl\text{\_clk})\) cycles after chip select \((ctl\text{\_cs\_n})\) is asserted. The \(ctl\text{\_wlat}\) indicates the required write latency in the system. The value is determined during calibration and is dependant upon the relative delays in the address and command path and the write datapath in both the PHY and the external DDR SDRAM subsystem. The controller must drive \(ctl\text{\_cs\_n}\) and then wait \(ctl\text{\_wlat}\) (two in this example) \(ctl\text{\_clk}\)s before driving \(ctl\text{\_wdata\_valid}\).

(4) Observe the ordering of write data \((ctl\text{\_wdata})\). Compare this to data on the \(mem\text{\_dq}\) signal.

(5) In all waveforms a command record is added that combines the memory pins \(ras\text{\_n}, cas\text{\_n}\) and \(we\text{\_n}\) into the current command that is issued. This command is registered by the memory when chip select \((mem\text{\_cs\_n})\) is low. The important commands in the presented waveforms are WR = write, ACT = activate.
**Figure 5–20.** Word-Aligned Reads

Notes to Figure 5–20:

1. For AFI, \(ctl\_doing\_rd\) is required to be asserted one memory clock cycle before chip select \((ctl\_cs\_n)\) is asserted. In the half-rate \(ctl\_clk\) domain, this requirement manifests as the controller driving 11 (as opposed to the 01) on \(ctl\_doing\_rd\).

2. AFI requires that \(ctl\_doing\_rd\) is driven for the duration of the read. In this example, it is driven to 11 for two half-rate \(ctl\_clks\), which equates to driving to 1, for the four memory clock cycles of this four-beat burst.

3. The \(ctl\_rdata\_valid\) returns 15 (\(ctl\_lat\)) controller clock (\(ctl\_clk\)) cycles after \(ctl\_doing\_rd\) is asserted. Returned is when the \(ctl\_rdata\_valid\) signal is observed at the output of a register within the controller. A controller can use the \(ctl\_lat\) value to determine when to register to returned data, but this is unnecessary as the \(ctl\_rdata\_valid\) is provided for the controller to use as an enable when registering read data.

4. Observe the alignment of returned read data with respect to data on the bus.
Figure 5–21 and Figure 5–22 show spaced word-unaligned writes and reads.

Figure 5–21. Word-Unaligned Writes

Notes to Figure 5–21:

1. Alternative word-unaligned chip select (ctl_cs_n).
2. As with word-aligned writes, ctl_dqs_burst is asserted one memory clock cycle before ctl_wdata_valid. You can see ctl_dqs_burst is 11 in the same cycle where ctl_wdata_valid is 10. The LSB of these two becomes the first value the signal takes in the mem_clk domain. You can see that ctl_dqs_burst has the necessary one mem_clk cycle lead on ctl_wdata_valid.
3. The latency between ctl_cs_n being asserted and ctl_wdata_valid going high is effectively ctl_wlat (in this example, two) controller clock (ctl_clk) cycles. This can be thought of in terms of relative memory clock (mem_clk) cycles, in which case the latency is four mem_clk cycles.
4. Only the upper half is valid (as the ctl_wdata_valid signal demonstrates, there is one ctl_wdata_valid bit to two 8-bit words). The write data bits go out on the bus in order, least significant byte first. So for a continuous burst of write data on the DQ pins, the most significant half of write data is used, which goes out on the bus last and is therefore contiguous with the following data. The converse is true for the end of the burst. Write data is spread across three controller clock (ctl_clk) cycles, but still only four memory clock (mem_clk) cycles. However, in relative memory clock cycles the latency is equivalent in the word-aligned and word-unaligned cases.
5. The 0504 here is residual from the previous clock cycle. In the same way that only the upper half of the write data is used for the first beat of the write, only the lower half of the write data is used in the last beat of the write. These upper bits can be driven to any value in this alignment.
Figure 5–22. Word-Unaligned Reads

Notes to Figure 5–22:

(1) Similar to word-aligned reads, `ctl_doing_rd` is asserted one memory clock cycle before chip select (`ctl_cs_n`) is asserted, which for a word-unaligned read is in the previous controller clock (`ctl_clk`) cycle. In this example the `ctl_doing_rd` signal is now spread over three controller clock cycles, the high bits in the sequence ‘10’, ‘11’, ‘01’, ‘10’, ‘11’, ‘01’ providing the required four memory clock cycles of assertion for `ctl_doing_rd` for the two 4-beat reads in the full-rate memory clock domain, ‘011110’, ‘011110’.

(2) The return pattern of `ctl_rdata_valid` is a delayed version of `ctl_doing_rd`. Advertised read latency (`ctl_rlat`) is the number of controller clock cycles delay inserted between `ctl_doing_rd` and `ctl_rdata_valid`.

(3) The read data (`ctl_rdata`) is spread over three controller clock cycles and in the pointed to vector only the upper half of the `ctl_rdata` bit vector is valid (denoted by `ctl_rdata_valid`).
Using a Custom Controller

The ALTMEMPHY megafunction can be integrated with your own controller. This section describes the interface requirement and the handshake mechanism for efficient read and write transactions.

Preliminary Steps
Perform the following steps to generate the ALTMEMPHY megafunction:

1. If you are creating a custom DDR or DDR2 SDRAM controller, generate the Altera High-Performance Controller MegaCore function targeting your chosen Altera memory devices.
2. Compile and verify the timing. This step is optional; refer to “Compile and Simulate” on page 4–1.
3. If targeting a DDR or DDR2 SDRAM device, simulate the high-performance controller design.
4. Integrate the top-level ALTMEMPHY design with your controller. If you started with the high-performance controller, the PHY variation name is <controller_name>_phy.v/.vhd. Details about integrating your controller with Altera’s ALTMEMPHY megafunction are described in the following sections.
5. Compile and simulate the whole interface to ensure that you are driving the PHY properly and that your commands are recognized by the memory device.

Design Considerations
This section discuss the important considerations for implementing your own controller with the ALTMEMPHY megafunction. This section describes the design considerations for AFI variants.

Simulating the high-performance controller is useful if you do not know how to drive the PHY signals.

Clocks and Resets
The ALTMEMPHY megafunction automatically generates a PLL instance, but you must still provide the reference clock input (pll_ref_clk) with a clock of the frequency that you specified in the MegaWizard Plug-In Manager. An active-low global reset input is also provided, which you can deassert asynchronously. The clock and reset management logic synchronizes this reset to the appropriate clock domains inside the ALTMEMPHY megafunction.

A clock output (half the memory clock frequency for a half-rate controller; the same as the memory clock for a full-rate controller) is provided and all inputs and outputs of the ALTMEMPHY megafunction are synchronous to this clock. For AFIIs, this signal is called ctl_clk.

There is also an active-low synchronous reset output signal provided, ctl_reset_n. This signal is synchronously de-asserted with respect to the ctl_clk or phy_clk clock domain and it can reset any additional user logic on that clock domain.
Calibration Process Requirements

When the global reset_n signal is released, the ALTMEMPHY handles the initialization and calibration sequence automatically. The sequencer calibrates memory interfaces by issuing reads to multiple ranks of DDR SDRAM (multiple chip select). Timing margins decrease as the number of ranks increases. It is impractical to supply one dedicated resynchronization clock for each rank of memory, as it consumes PLL resources for the relatively small benefit of improved timing margin. When calibration is complete, the ctl_cal_success signal goes high if successful; the ctl_cal_fail signal goes high if calibration fails. Calibration can be repeated by the controller using the soft_reset_n signal, which when asserted puts the sequencer into a reset state and when released the calibration process begins again.

You can ignore the following two warning and critical warning messages:

Warning: Timing Analysis for multiple chip select DDR/DDR2/DDR3-SDRAM configurations is preliminary (memory interface has a chip select width of 4)

Critical Warning: Read Capture and Write timing analyses may not be valid due to violated timing model assumptions

Other Local Interface Requirements

The memory burst length can be two, four, or eight for DDR SDRAM devices, and four or eight for DDR2 SDRAM devices. For a half-rate controller, the memory clock runs twice as fast as the clock provided to the local interface, so data buses on the local interface are four times as wide as the memory data bus. For a full-rate controller, the memory clock runs at the same speed as the clock provided to the local interface, so the data buses on the local interface are two times as wide as the memory data bus.

This section describes the DDR or DDR2 SDRAM high-performance controllers with the AFI.

Address and Command Interfacing

Address and command signals are automatically sized for 1T operation, such that for full-rate designs there is one input bit per pin (for example, one cs_n input per chip-select configured); for half-rate designs there are two. If you require a more conservative 2T address and command scheme, use a full-rate design and drive the address/command inputs for two clock cycles, or in a half-rate design drive both address/command bits for a given pin identically.

Although the PHY inherently supports 1T addressing, the high performance controllers support only 2T addressing, so PHY timing analysis is performed assuming 2T address and command signals.

Handshake Mechanism Between Read Commands and Read Data

When performing a read, a high-performance controller with the AFI asserts the ctl_doing_read signal to indicate that a read command is requested and the byte lanes that it expects valid data to return on. ALTMEMPHY uses the ctl_doing_read signal for the following actions:

- Control of the postamble circuit
- Generation of ctl_rdata_valid
Dynamic termination (Rt) control timing

The read latency, ctl_rlat, is advertised back to the controller. This signal indicates how long it takes in ctl_clk clock cycles from assertion of the ctl_doing_read signal to valid read data returning on ctl_rdata. The ctl_rlat signal is only valid when calibration has successfully completed and never changes values during normal user mode operation.

The ALTMEMPHY provides a signal, ctl_rdata_valid, to indicate that the data on read data bus is valid. The width of this signal varies between half-rate and full-rate designs to support the option to indicate that the read data is not word aligned. Figure 5–23 and Figure 5–24 show these relationships.

**Figure 5–23. Address and Command and Read-Path Timing—Full-Rate Design**

**Figure 5–24. Second Read Alignment—Half-Rate Design**

**Handshake Mechanism Between Write Commands and Write Data**

In the AFI, the ALTMEMPHY output ctl_wlat gives the number of ctl_clk cycles between the write command that is issued ctl_cs_n asserted and ctl_dqs_burst asserted. The ctl_wlat signal takes account of the following actions to provide a single value in ctl_clk clock cycles:

- CAS write latency
- Additive latency
- Datapath latencies and relative phases
- Board layout
- Address and command path latency and 1T register setting, which is dynamically setup to take into account any leveling effects
The `ctl_wlat` signal is only valid when the calibration has been successfully completed by the ALTMEMPHY sequencer and does not change at any point during normal user mode operation. Figure 5–25 shows the operation of `ctl_wlat` port.

**Figure 5–25.** Timing for `ctl_dqs_burst`, `ctl_wdata_valid`, Address, and Command—Half-Rate Design

For a half-rate design `ctl_cs_n` is 2 bits, not 1. Also the `ctl_dqs_burst` and `ctl_wdata_valid` waveforms indicate a half-rate design. This write results in a burst of 8 at the DDR. Where `ctl_cs_n` is driven 2'b01, the LSB (1) is the first value driven out of mem_cs_n, and the MSB (0) follows on the next mem_clk. Similarly, for `ctl_dqs_burst`, the LSB is driven out of mem_dqs first (0), then a 1 follows on the next clock cycle. This sequence produces the continuous DQS pulse as required. Finally, the `ctl_addr` bus is twice `MEM_IF_ADDR_WIDTH` bits wide and so the address is concatenated to result in an address phase two `mem_clk` cycles wide.

**Partial Write Operations**

As part of the DDR and DDR2 SDRAM memory specifications, you have the option for partial write operations by asserting the DM pins for part of the write signal.

For designs targeting the Stratix III device families, deassert the `ctl_wdata_valid` signal during partial writes, when the write data is invalid, to save power by not driving the DQ outputs.

For designs targeting other device families, use only the DM pins if you require partial writes. Assert the `ctl_dqs_burst` and `ctl_wdata_valid` signals as for full write operations, so that the DQ and DQS pins are driven during partial writes.

The I/O difference between Stratix III device families and other device families makes it only possible to use the `ctl_dqs_burst` signal for the DQS enable in Stratix III devices.
6. Functional Description—High-Performance Controller

The high-performance controller (HPC) architecture instantiates encrypted control logic and the ALTMEMPHY megafuncon. The controller accepts read and write requests from the user on its local interface, using either the Avalon-MM interface protocol or the native interface protocol. It converts these requests into the necessary SDRAM commands, including any required bank management commands. Each read or write request on the Avalon-MM or native interface maps to one SDRAM read or write command. Since the controller uses a memory burst length of 4, read and write requests are always of length 1 on the local interface if the controller is in half-rate mode. In full-rate mode, the controller accepts requests of size 1 or 2 on the local interface. Requests of size 2 on the local interface produce better throughput as whole memory burst is used.

The bank management logic in the controller keeps a row open in every bank in the memory system. For example, a controller configured for a double-sided, 4-bank DDR or DDR2 SDRAM DIMM keeps an open row in each of the 8 banks. The controller allows you to request an auto-precharge read or auto-precharge write, allowing control over whether to keep that row open after the request. You can achieve maximum efficiency when you issue reads and writes to the same bank, with the last access to that bank being an auto-precharge read or write. The controller does not do any access reordering.

Block Description

Figure 6–1 shows the top-level block diagram of the DDR or DDR2 SDRAM HPC.

Figure 6–1. DDR and DDR2 SDRAM HPC Block Diagram

![Block Diagram](image)

Note to Figure 6–1:
(1) For DDR2 SDRAM HPC only.
Figure 6–2 shows a block diagram of the DDR or DDR2 SDRAM high-performance controller architecture.

**Figure 6–2. DDR and DDR2 SDRAM High-Performance Controller Architecture Block Diagram**

The blocks in Figure 6–2 on page 6–2 are described in the following sections.

**Command FIFO Buffer**

This FIFO buffer allows the controller to buffer up to four consecutive read or write commands. It is built from logic elements, and stores the address, read or write flag, and burst count information. If this FIFO buffer fills up, the `local_ready` signal to the user is deasserted until the main state machine takes a command from the FIFO buffer.

**Write Data FIFO Buffer**

The write data FIFO buffer holds the write data from the user until the main state machine can send it to the ALTMEMPHY megafunction, which does not have a write data buffer. In the Avalon-MM interface mode, the user logic presents a write request, address, burst count, and one or more beats of data at the same time. The write data beats are placed into the FIFO buffer until they are needed. In the native interface mode, the user logic presents a write request, address, and burst count. The controller then requests the correct number of write data beats from the user via the `local_wdata_req` signal, and the user logic must return the write data in the clock cycle after the write data request signal.

This FIFO buffer is sized to be deeper than the command FIFO buffer to prevent it from filling up and interrupting streaming writes.
Write Data Tracking Logic

The write data tracking logic keeps track of the number of write data beats in the FIFO buffer. In the native interface mode, this logic manages how much more data to request from the user logic and issues the `local_wdata_req` signal.

Main State Machine

The main state machine decides what DDR commands to issue based on inputs from the command FIFO buffer, the bank management logic, and the timer logic.

Bank Management Logic

The bank management logic keeps track the current state of each bank. It can keep a row open in every bank in your memory system. The state machine uses the information provided by this logic to decide whether it needs to issue bank management commands before it reads or writes to the bank. The controller always leaves the bank open unless the user requests an auto-precharge read or write. The periodic refresh process also causes all the banks to be closed.

Timer Logic

The timer logic tracks whether the required minimum number of clock cycles has passed since the last relevant command was issued. For example, the timer logic records how many cycles have elapsed since the last activate command so that the state machine knows it is safe to issue a read or write command (tRCD). The timer logic also counts the number of clock cycles since the last periodic refresh command and sends a high priority alert to the state machine if the number of clock cycles has expired.

Initialization State Machine

The initialization state machine issues the appropriate sequence of command to initialize the memory devices. It is specific to DDR and DDR2 as each memory type requires a different sequence of initialization commands.

With the AFI, the ALTMEMPHY megafuction initializes the memory, otherwise the controller is responsible for initializing the memory.

Address and Command Decode

When the state machine wants to issue a command to the memory, it asserts a set of internal signals. The address and command decode logic turns these into the DDR-specific RAS, CAS, and WE commands.

PHY Interface Logic

When the main state machine issues a write command to the memory, the write data for that write burst has to be fetched from the write data FIFO buffer. The relationship between write command and write data depends on the memory type, ALTMEMPHY megafuction interface type, CAS latency, and the full-rate or half-rate setting. The PHY interface logic adjusts the timing of the write data FIFO read request signal so that the data arrives on the external memory interface DQ pins at the correct time.
ODT Generation Logic

The ODT generation logic (not shown) calculates when and for how long to enable the ODT outputs. It also decides which ODT bit to enable, based on the number of chip selects in the system.

- 1 DIMM (1 or 2 Chip Selects)
  In the case of a single DIMM, the ODT signal is only asserted during writes. The ODT signal on the DIMM at mem_cs[0] is always used, even if the write command on the bus is to mem_cs[1]. In other words, mem_odt[0] is always asserted even if there are two ODT signals.

- 2 or more DIMMs
  Table 6–1 shows which ODT signal on the adjacent DIMM is enabled.

<table>
<thead>
<tr>
<th>mem_cs[0] or cs[1]</th>
<th>mem_odt[2]</th>
</tr>
</thead>
</table>

Table 6–1. ODT

Low-Power Mode Logic

The low-power mode logic (not shown) monitors the local_powerdn_req and local_self_rfsh_req request signals. This logic also informs the user of the current low-power state via the local_powerdn_ack and local_self_rfsh_ack acknowledge signals.

Control Logic

Bus commands control SDRAM devices using combinations of the mem_ras_n, mem_cas_n, and mem_we_n signals. For example, on a clock cycle where all three signals are high, the associated command is a no operation (NOP). A NOP command is also indicated when the chip select signal is not asserted. Table 6–2 shows the standard SDRAM bus commands.

The DDR or DDR2 SDRAM HPC must open SDRAM banks before they access the addresses in that bank. The row and bank to be opened are registered at the same time as the active (ACT) command. The HPC closes the bank and opens it again if it needs to access a different row. The precharge (PCH) command closes only a bank.

The primary commands used to access SDRAM are read (RD) and write (WR). When the WR command is issued, the initial column address and data word is registered. When a RD command is issued, the initial address is registered. The initial data appears on the data bus 2 to 3 clock cycles later (3 to 5 for DDR2 SDRAM). This delay is the column address strobe (CAS) latency and is due to the time required to read the internal DRAM core and register the data on the bus. The CAS latency depends on the speed of the SDRAM and the frequency of the memory clock. In general, the faster the clock, the more cycles of CAS latency are required. After the initial RD or WR command, sequential reads and writes continue until the burst length is reached or a burst terminate (BT) command is issued. DDR and DDR2 SDRAM devices support burst lengths of 2, 4, or 8 data cycles. The auto-refresh command (ARF) is issued periodically to ensure data retention. This function is performed by the DDR or DDR2 SDRAM high-performance controller.

The load mode register command (LMR) configures the SDRAM mode register. This register stores the CAS latency, burst length, and burst type.

For more information, refer to the specification of the SDRAM that you are using.

**Error Correction Coding (ECC)**

The optional ECC comprises an encoder and a decoder-corrector, which can detect and correct single-bit errors and detect double-bit errors. The ECC uses an 8-bit ECC for each 64-bit message. The ECC has the following features:

- Hamming code ECC that encodes every 64-bits of data into 72-bits of codeword with 8-bits of Hamming code parity bits
- Latency:
  - Maximum of 1 or 2 clock delay during writes
  - Minimum 1 or 3 clock delay during reads
- Detects and corrects all single-bit errors. Also the ECC sends an interrupt when the user-defined threshold for a single-bit error is reached.
- Detects all double-bit errors. Also, the ECC counts the number of double-bit errors and sends an interrupt when the user-defined threshold for double-bit error is reached.
- Accepts partial writes
- Creates forced errors to check the functioning of the ECC
- Powers up to a ready state
Figure 6–3 shows the ECC block diagram.

The ECC comprises the following blocks:

- The encoder—encodes the 64-bit message to a 72-bit codeword
- The decoder-corrector—decodes and corrects the 72-bit codeword if possible
- The ECC logic—controls multiple encoder and decoder-correctors, so that the ECC can handle different bus widths. Also, it controls the following functions of the encoder and decoder-corrector:
  - Interrupts:
    - Detected and corrected single-bit error
    - Detected double-bit error
    - Single-bit error counter threshold exceeded
    - Double-bit error counter threshold exceeded
  - Configuration registers:
    - Single-bit error detection counter threshold
    - Double-bit error detection counter threshold
    - Capture status for first encountered error or most recent error
    - Enable deliberate corruption of ECC for test purposes
  - Status registers:
    - Error address
    - Error type: single-bit error or double-bit error
    - Respective byte error ECC syndrome
  - Error signal—an error signal corresponding to the data word is provided with the data and goes high if a double-bit error that cannot be corrected occurs in the return data word.
Counters:
- Detected and/or corrected single-bit errors
- Detected double-bit errors

The ECC can instantiate multiple encoders, each running in parallel, to encode any width of data words assuming they are integer multiples of 64.

The ECC operates between the local (native or Avalon-MM interface) and the memory controller.

The ECC has an $N \times 64$-bit (where $N$ is an integer) wide interface, between the local interface and the ECC, for receiving and returning data from the local interface. This interface can be a native interface or an Avalon-MM slave interface, you select the type of interface in the MegaWizard interface.

The ECC has a second interface between the local interface and the ECC, which is a 32-bit wide Avalon-MM slave to control and report the status of the operation of the ECC logic.

The encoded data from the ECC is sent to the memory controller using a $N \times 72$-bit wide Avalon-MM master interface, which is between the ECC and the memory controller.

When testing the DDR SDRAM high-performance controller, you can turn off the ECC.

Interrupts
The ECC issues an interrupt signal when one of the following scenarios occurs:
- The single-bit error counter reaches the set maximum single-bit error threshold value.
- The double-bit error counter reaches the set maximum double-bit error threshold value.

The error counters increment every time the respective event occurs for all $N$ parts of the return data word. This incremented value is compared with the maximum threshold and an interrupt signal is sent when the value is equal to the maximum threshold. The ECC clears the interrupts when you write a 1 to the respective status register. You can mask the interrupts from either of the counters using the control word.

Partial Writes
The ECC supports partial writes. Along with the address, data, and burst signals, the Avalon-MM interface also supports a signal vector that is responsible for byte-enable. Every bit of this signal vector represents a byte on the data-bus. Thus, a 0 on any of these bits is a signal for the controller not to write to that particular location—a partial write.

For partial writes, the ECC performs the following steps:
1. The ECC logic stalls further read or write commands from the Avalon-MM interface when it receives a partial write condition.
2. It simultaneously sends a self-generated read command, for the partial write address, to the memory controller.
3. Upon receiving the returned read data from the memory controller for the particular address, the decoder decodes the data, checks for errors, and then sends it to the ECC logic.

4. The ECC logic merges the corrected or correct datadword with the incoming information.

5. The ECC logic sends the updated datadword to the encoder for encoding, and then sends updated datadword to the memory controller with a write command.

6. The ECC logic stops stalling the commands from the Avalon-MM interface so that the logic can receive new commands.

The following corner cases can occur:

- A single-bit error during the read phase of the read-modify-write process. In this case, the single-bit error is corrected first, the single-bit error counter is incremented and then a partial write is performed to this corrected decoded data word.

- A double-bit error during the read phase of the read-modify-write process. In this case, the double-bit error counter is incremented and an interrupt is sent through the Avalon-MM interface. The new write word is not written to its location. A separate field in the interrupt status register highlights this condition.

Figure 6–4 and Figure 6–5 show the partial write operation for HPC in full-rate and half-rate mode. The full-rate HPC supports a local size of 1 and 2, and the half-rate HPC supports a local size of 1 only.

Partial Bursts

DIMMs that do not have the DM pins do not support partial bursts. A minimum of four words must be written to the memory at the same time.

Figure 6–6 shows the partial burst operation for HPC.

ECC Latency

Using the ECC results in the following latency changes:

- Local Burst Length 1
- Local Burst Length 2

Local Burst Length 1

For a local burst length of 1, the write latency increases by one clock cycle; the read latency increases by one clock cycle (including checking and correction).

A partial write results in a read followed by write in the ECC logic, so latency depends on the time the controller takes to fetch the data from the particular address.

Table 6–3 shows the relationship between burst lengths and rate.

Table 6–3. Burst Lengths and Rates

<table>
<thead>
<tr>

<th>Rate</th>
<th>Memory Burst Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Half</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>Full</td>
<td>4</td>
</tr>
</tbody>
</table>

Local Burst Length 2

For a local burst length of 2, the write latency increases by two clock cycles; the read latency increases by one clock cycle (including checking and correction).

A partial write results in a read followed by write in the ECC logic, so latency depends on the time the controller takes to fetch the data from the particular address.

For a single-bit error, the automatic correction of memory takes place without stalling the read cycle (if enabled), which stalls further commands to the ECC logic, while the correction takes place.

ECC Registers

Table 6–4 shows the ECC registers.

**Example Top-Level File**

The MegaWizard Plug-In Manager helps you create an example top-level file that shows you how to instantiate and connect the DDR or DDR2 SDRAM HPC. The example top-level file consists of the DDR or DDR2 SDRAM HPC, some driver logic to issue read and write requests to the controller, a PLL to create the necessary clocks, and a DLL (Stratix series only). The example top-level file is a working system that you can compile and use for both static timing checks and board tests.

**Figure 6–7** shows the testbench and the example top-level file.

**Example Design**

- Example Driver
- DDR SDRAM Controller
- ALTMEMPHY
- DLL
- PLL
- Control Logic

</tr>
</tbody>
</table>

There are two Altera-generated memory models available—associative-array memory model and full-array memory model.

The associative-array memory model (`<variation name>_mem_model.v`) allocates reduced set of memory addresses with a default depth of 2,048 or 2K address spaces. This allocation allows for a larger memory array compilation and simulation which enables you to easily reconfigure the depth of the associate array.

The full-array memory model (`<variation name>_full_mem_model.v`) allocates memory for all addresses accessible by the DDR cores. This allocation makes it impossible to simulate large memory (more than 2K address spaces) designs, because simulators need more memory than what is available on a typical system.

Both the memory models display similar behaviors and have the same calibration time.

The memory model, `<variation name>_test_component.v/vhd`, used in SOPC Builder designs, is actually a variation of the full-array memory model. To ensure your simulation works in SOPC Builder, use memory model with less than 512-Mbit capacity.

**Example Driver**

The example driver is a self-checking test pattern generator for the memory interface. It uses a state machine to write and read from the memory to verify that the interface is operating correctly.

It performs the following tests and loops back the tests indefinitely:

- Sequential addressing writes and reads
  
  The state machine writes pseudo-random data generated by a linear feedback shift register (LFSR) to a set of incrementing row, bank, and column addresses. The state machine then resets the LFSR, reads back the same set of addresses, and compares the data it receives against the expected data. You can adjust the length and pattern of the bursts that are written by changing the `MAX_ROW`, `MAX_BANK`, and `MAX_COL` constants in the example driver source code, and the entire memory space can be tested by adjusting these values. You can skip this test by setting the `test_seq_addr_on` signal to logic zero.
Incomplete write operation

The state machine issues a series of write requests that are less than the maximum burst size supported by your controller variation. The addresses are then read back to ensure that the controller has issued the correct signals to the memory. This test is only applicable in full-rate mode, when the local burst size is two. You can skip this test by setting the test_incomplete_writes_on signal to logic zero.

Byte enable/data mask pin operation

The state machine issues two sets of write commands, the first of which clears a range of addresses. The second set of write commands has only one byte enable bit asserted. The state machine then issues a read request to the same addresses and the data is verified. This test checks if the data mask pins are operating correctly. You can skip this test by setting the test_dm_pin_on signal to logic zero.

Address pin operation

The example driver generates a series of write and read requests starting with an all-zeros pattern, a walking-one pattern, a walking-zero pattern, and ending with an all-zeros pattern. This test checks to make sure that all the individual address bits are operating correctly. You can skip this test by setting the test_addr_pin_on signal to logic zero.

Low-power mode operation

The example driver requests that the controller place the memory into power-down and self-refresh states, and hold it in those states for the amount of time specified by the COUNTER_VALUE signal. You can vary this value to adjust the duration the memory is kept in the low-power states. This test is only available if your controller variation enables the low-power mode option.

The example driver has four outputs that allow you to observe which tests are currently running and if the tests are passing. The pass not fail (pnf) signal goes low once one or more errors occur and remains low. The pass not fail per byte (pnf_per_byte) signal goes low when there is incorrect data in a byte but goes back high again once correct data is observed in the following byte. The test_status signal indicates the test that is currently running, allowing you to determine which test has failed. The test_complete signal goes high for a single clock cycle at the end of the set of tests.

Table 6-11 shows the bit mapping for each test status.

### Table 6–13. Local Interface Signals (Part 2 of 4)

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local_be[]</td>
<td>Input</td>
<td>Byte-enable signal, which you use to mask off individual bytes during writes. local_be is active high; mem_dm is active low.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>To map local_wdata and local_be to mem_dq and mem_dm, consider a full-rate design with 32-bit local_wdata and 16-bit mem_dq.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Local_wdata = &lt;22334455&gt;&lt;667788AA&gt;&lt;BBCDDEE&gt; Local_be = &lt;1100&gt;&lt;0110&gt;&lt;1010&gt;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>These values map to: mem_dq = &lt;4455&gt;&lt;2233&gt;&lt;88AA&gt;&lt;6677&gt;&lt;DDEE&gt;&lt;BBCC&gt; mem_dm = &lt;11&gt;&lt;00&gt;&lt;01&gt;&lt;10&gt;&lt;01&gt;&lt;01&gt;</td>
</tr>
<tr>
<td>local_burstbegin</td>
<td>Input</td>
<td>The Avalon burst begin strobe, which indicates the beginning of an Avalon burst. This signal is only available when the local interface is an Avalon-MM interface and the memory burst length is greater than 2. Unlike all other Avalon-MM signals, the burst begin signal does not stay asserted if local_ready is deasserted. For write transactions, assert this signal at the beginning of each burst transfer and keep this signal high for one cycle per burst transfer, even if the slave has deasserted the local_ready signal. This signal is sampled at the rising edge of phy_clk when the local_write_req signal is asserted. After the slave deasserts the local_ready signal, the master keeps all the write request signals asserted until local_ready signal becomes high again. For read transactions, assert this signal for one clock cycle when read request is asserted and the local_address from which the data should be read is given to the memory. After the slave deasserts local_ready (waitrequest_n in Avalon interface), the master keeps all the read request signals asserted until the local_ready signal becomes high again.</td>
</tr>
<tr>
<td>local_read_req</td>
<td>Input</td>
<td>Read request signal. You cannot assert read request and write request signals at the same time.</td>
</tr>
<tr>
<td>local_refresh_req</td>
<td>Input</td>
<td>User-controlled refresh request. If Enable User Auto-Refresh Controls option is turned on, local_refresh_req becomes available and you are responsible for issuing sufficient refresh requests to meet the memory requirements. This option allows complete control over when refreshes are issued to the memory including ganging together multiple refresh commands. Refresh requests take priority over read and write requests unless they are already being processed.</td>
</tr>
<tr>
<td>local_size[]</td>
<td>Input</td>
<td>Controls the number of beats in the requested read or write access to memory, encoded as a binary number. The range of values depend on the memory burst length and whether you select full or half rate in the wizard. If you select a memory burst length 4 and half rate, the local burst length is 1 and so local_size should always be driven with 1. If you select a memory burst length 4 and full rate, the local burst length is 2 and you should set the local_size to either 1 or 2 for each read or write request.</td>
</tr>
<tr>
<td>local_wdata[]</td>
<td>Input</td>
<td>Write data bus. The width of local_wdata is twice that of the memory data bus for a full rate controller; four times the memory data bus for a half rate controller.</td>
</tr>
<tr>
<td>local_write_req</td>
<td>Input</td>
<td>Write request signal. You cannot assert read request and write request signals at the same time.</td>
</tr>
</tbody>
</table>
### Local Interface Signals (Part 3 of 4)

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local_autopch_req</td>
<td>Input</td>
<td>User control of precharge. If Enable Auto-Precharge Control is turned on, <code>local_autopch_req</code> becomes available and you can request the controller to issue an auto-precharge write or auto-precharge read command. These commands cause the memory to issue a precharge command to the current bank at the appropriate time without an explicit precharge command from the controller. This is particularly useful if you know the current read or write is the last one you intend to issue to the currently open row. The next time you need to use that bank, the access could be quicker as the controller does not need to precharge the bank before activating the row you wish to access.</td>
</tr>
<tr>
<td>local_powerdn_req</td>
<td>Input</td>
<td>User control of the power-down feature. If Enable Power Down Controls option is enabled, you can request that the controller place the memory devices into a power-down state as soon as it can without violating the relevant timing parameters and responds by asserting the <code>local_powerdn_ack</code> signal. You can hold the memory in the power-down state by keeping this signal asserted. The controller brings the memory out of the power-down state to issue periodic auto-refresh commands to the memory at the appropriate interval if you hold it in the power-down state. You can release the memory from the power-down state at any time by deasserting the <code>local_powerdn_ack</code> signal once it has successfully brought the memory out of the power-down state.</td>
</tr>
<tr>
<td>local_self_rfsh_req</td>
<td>Input</td>
<td>User control of the self-refresh feature. If Enable Self-Refresh Controls option is enabled, you can request that the controller place the memory devices into a self-refresh state by asserting this signal. The controller places the memory in the self-refresh state as soon as it can without violating the relevant timing parameters and responds by asserting the <code>local_self_rfsh_ack</code> signal. You can hold the memory in the self-refresh state by keeping this signal asserted. You can release the memory from the self-refresh state at any time by deasserting the <code>local_self_rfsh_req</code> signal and the controller responds by deasserting the <code>local_self_rfsh_ack</code> signal once it has successfully brought the memory out of the self-refresh state.</td>
</tr>
<tr>
<td>phy_clk</td>
<td>Output</td>
<td>The system clock that the ALTMEMPHY megafunction provides to the user. All user inputs to and outputs from the DDR high-performance controller must be synchronous to this clock.</td>
</tr>
<tr>
<td>reset_phy_clk_n</td>
<td>Output</td>
<td>The reset signal that the ALTMEMPHY megafunction provides to the user. It is asserted asynchronously and deasserted synchronously to the <code>phy_clk</code> clock domain.</td>
</tr>
<tr>
<td>aux_full_rate_clk</td>
<td>Output</td>
<td>An alternative clock that the ALTMEMPHY megafunction provides to the user. This clock always runs at the same frequency as the external memory interface. In half-rate mode, this clock is twice the frequency of the <code>phy_clk</code> and can be used whenever a 2x clock is required. In full-rate mode, this clock is driven by the same PLL output as the <code>phy_clk</code> signal.</td>
</tr>
<tr>
<td>aux_half_rate_clk</td>
<td>Output</td>
<td>An alternative clock that the ALTMEMPHY megafunction provides to the user. This clock always runs at half the frequency as the external memory interface. In full-rate mode, this clock is half the frequency of the <code>phy_clk</code> and can be used, for example to clock the user side of a half-rate bridge. In half-rate mode, this clock is driven by the same PLL output as the <code>phy_clk</code> signal.</td>
</tr>
<tr>
<td>dll_reference_clk</td>
<td>Output</td>
<td>Reference clock to feed to an externally instantiated DLL.</td>
</tr>
</tbody>
</table>
### Table 6–13. Local Interface Signals (Part 4 of 4)

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reset_request_n</td>
<td>Output</td>
<td>Reset request output that indicates when the PLL outputs are not locked. Use this signal as a reset request input to any system-level reset controller you may have. This signal is always low when the PLL is trying to lock, and so any reset logic using it is advised to detect a reset request on a falling edge rather than by level detection.</td>
</tr>
<tr>
<td>local_init_done</td>
<td>Output</td>
<td>When the memory initialization, training, and calibration are complete, the ALTMEMPHY sequencer asserts the ctrl_usr_mode_rdy signal to the memory controller, which then asserts this signal to indicate that the memory interface is ready to be used. Read and write requests are still accepted before local_init_done is asserted, however they are not issued to the memory until it is safe to do so. This signal does not indicate that the calibration is successful. To find out if the calibration is successful, look for the calibration signal, resynchronization_successful, or postamble_successful for Stratix IV devices.</td>
</tr>
<tr>
<td>local_rdata[]</td>
<td>Output</td>
<td>Read data bus. The width of local_rdata is twice that of the memory data bus for a full rate controller; four times the memory data bus for a half rate controller.</td>
</tr>
<tr>
<td>local_rdata_error</td>
<td>Output</td>
<td>Asserted if the current read data has an error. This signal is only available if the Enable Error Detection and Correction Logic option is turned on. This signal is asserted together with the local_rdata_valid signal. If the controller encounters double-bit errors, no correction is made and the controller asserts this signal.</td>
</tr>
<tr>
<td>local_rdata_valid</td>
<td>Output</td>
<td>Read data valid signal. The local_rdata_valid signal indicates that valid data is present on the read data bus.</td>
</tr>
<tr>
<td>local_ready</td>
<td>Output</td>
<td>The local_ready signal indicates that the DDR or DDR2 SDRAM high-performance controller is ready to accept request signals. If local_ready is asserted in the clock cycle that a read or write request is asserted, that request has been accepted. The local_ready signal is deasserted to indicate that the DDR or DDR2 SDRAM high-performance controller cannot accept any more requests. The controller is able to buffer four read or write requests.</td>
</tr>
<tr>
<td>local_refresh_ack</td>
<td>Output</td>
<td>Refresh request acknowledge, which is asserted for one clock cycle every time a refresh is issued. Even if the Enable User Auto-Refresh Controls option is not selected, local_refresh_ack still indicates to the local interface that the controller has just issued a refresh command.</td>
</tr>
<tr>
<td>local_wdata_req</td>
<td>Output</td>
<td>Write data request signal, which indicates to the local interface that it should present valid write data on the next clock edge. This signal is only required when the controller is operating in Native interface mode.</td>
</tr>
<tr>
<td>local_powerdn_ack</td>
<td>Output</td>
<td>Power-down request acknowledge signal. This signal is asserted and deasserted in response to the local_powerdn_req signal from the user.</td>
</tr>
<tr>
<td>local_self_rfsh_ack</td>
<td>Output</td>
<td>Self-refresh request acknowledge signal. This signal is asserted and deasserted in response to the local_self_rfsh_req signal from the user.</td>
</tr>
</tbody>
</table>

The high-performance controller II (HPC II) architecture is an upgraded controller with higher efficiency and more features than the HPC. HPC II is recommended for all new designs.

HPC II is pin-out compatible with your existing DDR high-performance designs. HPC II has the following additional features:

- Higher efficiency with in-order read and write commands, and out-of-order bank management command.
- Run-time programmability to configure the behavior of the controller.
- Half-rate bridge option to reduce memory access latency.
- Integrated burst adapter supporting a range of burst sizes on the local interface.
- Integrated ECC, supporting 40-bit and 72-bit interfaces with partial word writes and optional write back on error.
- Support for multi-rank UDIMMs and RDIMMs.

Upgrading from HPC to HPC II

If you want to migrate your designs from the existing HPC to the more efficient HPC II, you have to ensure that you do the following:

- In the Preset Editor dialog box, assign the following HPC II timing parameters to match your memory specification. Set these parameters according to the memory datasheet:
  - \( t_{FAW} \)
  - \( t_{RRD} \)
  - \( t_{RTP} \)
  
  For example, for Micron DDR3-800 datasheet, \( t_{FAW}=40 \) ns, \( t_{RRD}=10 \) ns, \( t_{RTP}=10 \) ns.
- If you are using the Avalon-MM interface, HPC II replaces the port interface level for the AFI and Avalon interface without requiring any top-level change.
- The side-band signals differ slightly for HPC II. If you use these signals, you need to perform the following steps.
  - local_refresh_req
    
    You need to drive an additional active high signal, local_refresh_chip, to control which chip to issue the user-refresh to.
  - local_powerdn_req

    The user-manual power signal is no longer supported in HPC II. Instead, you can select auto power-down on the Controller Settings tab in the MegaWizard Plug-In Manager, and specify the desired time-out (\( n \) cycles) after which the controller automatically powers down the memory.
Because HPC II only supports a specific memory burst length, you must update the memory burst length to match the controller settings in Table 7–1.

Table 7–1. Burst Length Support

<table>
<thead>
<tr>
<th>Controller</th>
<th>HPC</th>
<th>HPC II</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDR</td>
<td>Burst length of 2 and 4</td>
<td>Burst length of 4 in full-rate mode, and burst length of 8 in half-rate mode.</td>
</tr>
<tr>
<td>DDR2</td>
<td>Burst length of 4</td>
<td></td>
</tr>
</tbody>
</table>

Because HPC II supports arbitrary user burst length ranging from 1 to 64, you can adjust the max_local_size value in HPC II. Adjusting the maximum local size value changes the width of the local_size signal. The maximum local_size signal value is \(2^n-1\), where \(n\) is the width of the local_size signal. HP has a fixed local_size signal width of either 1 or 2.

Block Description

Figure 7–1 shows the top-level block diagram of the DDR or DDR2 SDRAM HPC II.

Note to Figure 7–1:
(1) For DDR2 SDRAM HPC II only.
Figure 7–2 shows a block diagram of the DDR or DDR2 SDRAM HPC II architecture.

**Avalon-MM Data Slave Interface**

The Avalon-MM data slave interface accepts read and write requests from the Avalon-MM master. The width of the data busses, `local_wdata` and `local_rdata`, is twice or four times the width of the external memory interface, depending on whether you choose full or half rate.
The local address width is sized based on the memory chip, row, bank, and column address widths. For example:

- For multiple chip selects:
  \[
  \text{width} = \text{chip bits} + \text{row bits} + \text{bank bits} + \text{column} - N
  \]

- For a single chip select:
  \[
  \text{width} = \text{row bits} + \text{bank bits} + \text{column} - N
  \]

Where \( N \) = 1 for full-rate controller and 2 for half-rate controller.

For every Avalon transaction, the number of read or write requests can go up to the maximum local burst count of 64. Altera recommends that you set this maximum burst count to match your system master’s supported burst count.

**Write Data FIFO Buffer**

The write data FIFO buffer holds the write data and byte-enable from the user logic until the data is needed by the main state machine. The `local_ready` signal is deasserted when either the command queue or write data FIFO buffer is full. The write data FIFO buffer is wide enough to store the write data and the byte-enable signals.

**Command Queue**

The command queue allows the controller to buffer up to eight consecutive reads or writes. The command queue presents the next 4, 6, or 6 accesses to the internal logic for the look-ahead bank management. The bank management is more efficient if the look-ahead is deeper, but a deeper queue consumes more resources, and may cause maximum frequency degradation.

Other than storing incoming commands, the command queue also maps the local address to memory address based on the address mapping option selected. By default, the command queue leverages bank interleaving scheme, where the address increment goes to the next bank instead of the next row to increase chances of page hit.

**Bank Management Logic**

The bank management logic keeps track of the current state in each bank across multiple chips. It can keep a row open in every bank in your memory system. When a command is issued by the state machine, the bank management logic is updated with the latest bank status. With the look-ahead capability, the main state machine is able to issue early bank management commands. With the auto-precharge feature, the controller supports an open page policy, where the last accessed row in each bank is kept open and a close page policy, where a bank is closed after it is used.

**Timer Logic**

The timer logic models the state of each bank in the memory interface. The timer logic models the internal behavior of each bank and provides status output signals to the state machine. The state machine then decides whether to issue the look-ahead bank management command based on the timer status signals.
**Command-Issuing State Machine**

The command-issuing state machine decides what DDR commands to issue based on the inputs from the command queue, the bank management logic, and the timer logic. The command-issuing state machine operates in two modes: full-rate or half-rate. The full-rate state machine supports 1T address and command, and always issues memory burst length of 4. The half-rate state machine supports 2T address and command, and always issues memory burst length of 8.

A longer memory burst length, in this case 8 beats, increases the command bandwidth by allowing more data cycles for the same amount of command cycles. A longer memory burst length also provides more command cycles that ensures a more effective look-ahead bank management. However, longer memory burst lengths are less efficient if the bursts you issue do not provide enough data to fill the burst.

This state machine accepts any local burst count of 1 to 64. The built-in burst adapter in this state machine maps the local burst count to the most efficient memory burst. The state machine also supports reads and writes that start on non-aligned memory burst boundary addresses. For effective command bus bandwidth, this state machine supports additive latency which issues reads and writes immediately after the ACT command. This state machine accepts additive latency values greater or equal to \( t_{RCD} - 1 \), in clock cycle unit (\( t_{CK} \)).

**Address and Command Decode Logic**

When the main state machine issues a command to the memory, it asserts a set of internal signals. The address and command decode logic turns these signals into AFI specific commands and address. This block generates the following signals:

- Clock enable and reset signals: \( \text{afi}_\text{cke}, \text{afi}_\text{rst}_\text{n} \)
- Command and address signals: \( \text{afi}_\text{cs}_\text{n}, \text{afi}_\text{ba}, \text{afi}_\text{addr}, \text{afi}_\text{ras}_\text{n}, \text{afi}_\text{cas}_\text{n}, \text{afi}_\text{we}_\text{n} \)

**Write and Read Datapath, and Write Data Timing Logic**

The write and read datapath, and the write data timing logic generate the AFI read and write control signals.

When the state machine issues a write command to the memory, the write data for that write burst has to be fetched from the write data FIFO buffer. The relationship between the write command and write data depends on the \( \text{afi}_\text{wlat} \) signal. This logic presents the write data FIFO read request signal so that the data arrives on the external memory interface DQ pins at the correct time.

During write, the following AFI signals are generated based on the state machine outputs and the \( \text{afi}_\text{wlat} \) signal:

- \( \text{afi}_\text{dqs}_\text{burst} \)
- \( \text{afi}_\text{wdata}_\text{valid} \)
- \( \text{afi}_\text{wdata} \)
- \( \text{afi}_\text{dm} \)
During read, the afi_doing_read signal generates the afi_rdata_valid signal and controls the ALTMEMPHY postamble circuit.

**ODT Generation Logic**

The ODT generation logic generates the necessary ODT signals for DDR2 memory devices, based on the scheme recommended by Altera.

Figure 7–2 shows which ODT signal on the adjacent DIMM is enabled for DDR2 SDRAM.

<table>
<thead>
<tr>
<th>Write or Read On</th>

<td>mem_odt[2]</td>
</tr>
<tr>
<td>mem_cs[2]</td>
<td>mem_odt[0]</td>
</tr>
</tbody>
</table>

**User-Controlled Side-Band Signals**

The user-controlled side-band signals consists of the following signals.

**User Auto-Precharge Commands**

The auto-precharge read and auto-precharge write commands allow you to indicate to the memory device that this read or write command is the last access to the currently open row. The memory device automatically closes or auto-precharges the page it is currently accessing so that the next access to the same bank is quicker.

This command is useful for applications that require fast random accesses. You can request an auto-precharge by asserting the local_autopch signal during a read or write request.

**User-Refresh Commands**

The user-refresh command enables the request to place the memory into refresh mode. The user-refresh control takes precedence over a read or write request. You can issue up to nine consecutive refresh commands to the memory.

**Multi-Cast Write**

The multi-cast write request signal allows you to ask the controller to send the current write requests to all the chip-selects. This means that the write data is written to all the ranks in the system. The multi-cast write feature is useful for tRC mitigation where you can cycle through chips to continuously read data without hitting tRC. The multi-cast write is not supported in ECC and RDIMM modes.

**Low-Power Mode Logic**

There are two types of low-power mode logic: user-controlled self-refresh logic and automatic power-down with programmable time-out logic.
**User-Controlled Self-Refresh Logic**

When you assert the `local_self_rfsh_req` signal, the controller completes all pending reads and writes before it places the memory into self-refresh mode. Once the controller places the memory into self-refresh mode, it responds by asserting the acknowledge signal, `local_self_rfsh_ack`. You can leave the memory in self-refresh mode for as long as you choose.

To bring the memory out of self-refresh mode, you must deassert the request signal, and the controller responds by deasserting the acknowledge signal when the memory is no longer in self-refresh mode.

**Automatic Power-Down with Programmable Time-Out**

The controller automatically places the memory in power-down mode to save power if the requested number of idle controller clock cycles is observed in the controller. The *Auto Power Down Cycles* parameter on the *Controller Settings* tab allows you to specify a range between 1 to 65,535 idle controller clock cycles. The counter for the programmable time-out starts when there are no user read or write requests in the command queue. Once the controller places the memory in power-down mode, it responds by asserting the acknowledge signal, `local_powerdown_ack`.

**Configuration and Status Register (CSR) Interface**

The configuration and status register interface is a 32-bit wide interface that uses the Avalon-MM interface standard. The CSR interface allows you to configure the timing parameters, address widths, and the behavior of the controller. If you do not need this feature, you can disable it and all the programmable settings are fixed to the values configured during the generation process. This interface is synchronous to the controller clock.

Refer to Table 7–9 through Table 7–23 on page 7–20 for detailed information about the register maps.

**Error Correction Coding (ECC)**

The optional ECC logic comprises an encoder and a decoder-corrector, which can detect and correct single-bit errors, and detect double-bit errors. The ECC logic is available in two widths: 64/72 bit and 32/40 bit. The ECC logic has the following features:

- **Hamming code ECC** that encodes every 64 or 32 bits of data into 72 or 40 bits of codeword.
- A latency increase of one clock for both writes and reads.
- Detects and corrects all single-bit errors.
- Detects all double-bit errors.
- Counts the number of single-bit and double-bit errors.
- Accepts partial writes, which trigger a read-modify-write cycle, for memory devices with `dm` pins.
- Is able to inject single-bit and double-bit errors to trigger ECC correction for testing and debugging purposes.
Generates an interrupt signal when an error occurs.

When a single-bit or double-bit error occurs, the ECC logic triggers the ecc_interrupt signal to inform you that an ECC error has occurred. When a single-bit error occurs, the ECC logic issues an internal read to the error address, and performs an internal write to write back the corrected data. When a double-bit error occurs, the ECC logic does not do any error correction but it asserts the local_rdata_error signal to indicate that the data is incorrect. The local_rdata_error signal follows the same timing as the local_rdata_valid signal.

Enabling auto-correction allows the ECC logic to hold off all controller pending activities until the correction is complete. You can choose to disable auto-correction and schedule the correction manually when the controller is idle to ensure better system efficiency. To manually correct ECC errors, do the following:

1. When an interrupt occurs, read out the SBE_ERROR register. When a single-bit error occurs, the SBE_ERROR register is equal to one.

2. Read out the ERR_ADDR register.

3. Correct the single-bit error by doing one of the following:
   - Issue a dummy write to the memory address stored in the ERR_ADDR register. A dummy write is a write request with the local_be signal zero, that triggers a partial write which is effectively a read-modify-write event. The partial write corrects the data at that address and writes it back.
   - Enable the ENABLE_AUTO_CORR register using the CSR interface and issue a read request to the memory address stored in the ERR_ADDR register. The read request triggers auto-error correction to the memory address stored in the ERR_ADDR register.

Partial Writes

The ECC logic supports partial writes. Along with the address, data, and burst signals, the Avalon-MM interface also supports a signal vector, local_be, that is responsible for byte-enable. Every bit of this signal vector represents a byte on the data-bus. Thus, a logic low on any of these bits instructs the controller not to write to that particular byte, resulting in a partial write. The ECC code is calculated on all bytes of the data-bus. If any bytes are changed, the ECC code must be recalculated and the new code must be written back to the memory.

For partial writes, the ECC logic performs the following steps:

1. The ECC logic sends a read command to the partial write address.
2. Upon receiving a return data from the memory for the particular address, the ECC logic decodes the data, checks for errors, and then merges the corrected or correct dataword with the incoming information.
3. The ECC logic issues a write to write back the updated data and the new ECC code.
The following corner cases can occur:

- A single-bit error during the read phase of the read-modify-write process. In this case, the single-bit error is corrected first, the single-bit error counter is incremented and then a partial write is performed to this corrected decoded data word.

- A double-bit error during the read phase of the read-modify-write process. In this case, the double-bit error counter is incremented and an interrupt is issued. A new write word is written back to the memory location. The ECC status register keeps track of the error information.

Figure 7–3 and Figure 7–4 show the partial write operation for HPC II.

**Partial Bursts**

DIMMs that do not have the DM pins do not support partial bursts. A minimum of four (half rate) or eight words (full rate) must be written to the memory at the same time.
Example Top-Level File

The MegaWizard Plug-In Manager helps you create an example top-level file that shows you how to instantiate and connect the DDR or DDR2 SDRAM HPC II. The example top-level file consists of the DDR or DDR2 SDRAM HPC II, some driver logic to issue read and write requests to the controller, a PLL to create the necessary clocks, and a DLL (Stratix series only). The example top-level file is a working system that you can compile and use for both static timing checks and board tests.

Figure 7–5 shows the partial burst operation for HPC II.

</tr>
</tbody>
</table>

There are two Altera-generated memory models available—associative-array memory model and full-array memory model.

The associative-array memory model (`<variation name>_mem_model.v`) allocates reduced set of memory addresses with a default depth of 2,048 or 2K address spaces. This allocation allows for a larger memory array compilation and simulation which enables you to easily reconfigure the depth of the associate array.

The full-array memory model (`<variation name>_mem_model_full.v`) allocates memory for all addresses accessible by the DDR cores. This allocation makes it impossible to simulate large memory designs.

Both the memory models display similar behaviors and have the same calibration time.

The memory model, `<variation name>_test_component.v` or `.vhd`, used in SOPC Builder designs, is actually a variation of the full-array memory model. To ensure your simulation works in SOPC Builder, use memory model with less than 512-Mbit capacity.
Example Driver

The example driver is a self-checking test pattern generator for the memory interface. It uses a state machine to write and read from the memory to verify that the interface is operating correctly.

The example driver performs the following tests and loops back the tests indefinitely:

- **Sequential addressing writes and reads**
  The state machine writes pseudo-random data generated by a linear feedback shift register (LFSR) to a set of incrementing row, bank, and column addresses. The state machine then resets the LFSR, reads back the same set of addresses, and compares the data it receives against the expected data. You can adjust the length and pattern of the bursts that are written by changing the `MAX_ROW`, `MAX_BANK`, and `MAX_COL` constants in the example driver source code, and the entire memory space can be tested by adjusting these values. You can skip this test by setting the `test_seq_addr_on` signal to logic zero.

- **Incomplete write operation**
  The state machine issues a series of write requests that are less than the maximum burst size supported by your controller variation. The addresses are then read back to ensure that the controller has issued the correct signals to the memory. This test is only applicable in full-rate mode, when the local burst size is two. You can skip this test by setting the `test_incomplete_writes_on` signal to logic zero.

- **Byte enable/data mask pin operation**
  The state machine issues two sets of write commands, the first of which clears a range of addresses. The second set of write commands has only one byte enable bit asserted. The state machine then issues a read request to the same addresses and the data is verified. This test checks if the data mask pins are operating correctly. You can skip this test by setting the `test_dm_pin_on` signal to logic zero.

- **Address pin operation**
  The example driver generates a series of write and read requests starting with an all-zeros pattern, a walking-one pattern, a walking-zero pattern, and ending with an all-zeros pattern. This test checks to make sure that all the individual address bits are operating correctly. You can skip this test by setting the `test_addr_pin_on` signal to logic zero.

- **Low-power mode operation**
  The example driver requests the controller to place the memory into power-down and self-refresh states, and hold it in those states for the amount of time specified by the `COUNTER_VALUE` signal. You can vary this value to adjust the duration the memory is kept in the low-power states. This test is only available if your controller variation enables the low-power mode option.
The example driver has four outputs that allow you to observe which tests are currently running and if the tests are passing. The pass not fail (pnf) signal goes low once one or more errors occur and remains low. The pass not fail per byte (pnf_per_byte) signal goes low when there is incorrect data in a byte but goes back high again once correct data is observed in the following byte. The test_status signal indicates the test that is currently running, allowing you to determine which test has failed. The test_complete signal goes high for a single clock cycle at the end of the set of tests.

Table 7–4 shows the bit mapping for each test status.

<tr>
<td>phy_clk</td>
<td>Output</td>
<td>The system clock that the ALTMEMPHY megafunction provides to the user. All user inputs to and outputs from the DDR HPC II must be synchronous to this clock.</td>
</tr>
<tr>
<td>reset_phy_clk_n</td>
<td>Output</td>
<td>The reset signal that the ALTMEMPHY megafunction provides to the user. It is asserted asynchronously and deasserted synchronously to phy_clk clock domain.</td>
</tr>
<tr>
<td>aux_full_rate_clk</td>
<td>Output</td>
<td>An alternative clock that the ALTMEMPHY megafunction provides to the user. This clock always runs at the same frequency as the external memory interface. In half-rate mode, this clock is twice the frequency of the phy_clk and can be used whenever a 2x clock is required. In full-rate mode, this clock is driven by the same PLL output as the phy_clk signal.</td>
</tr>
</tbody>
</table>
### aux_half_rate_clk
Output
An alternative clock that the ALTMEMPHY megafunction provides to the user. This clock always runs at half the frequency as the external memory interface. In full-rate mode, this clock is half the frequency of the phy_clk and can be used, for example, to clock the user side of a half-rate bridge. In half-rate mode, or if the **Enable Half Rate Bridge** option is turned on, this clock is driven by the same PLL output that drives the phy_clk signal.

### dll_reference_clk
Output
Reference clock to feed to an externally instantiated DLL.

### reset_request_n
Output
Reset request output that indicates when the PLL outputs are not locked. Use this signal as a reset request input to any system-level reset controller you may have. This signal is always low when the PLL is trying to lock, and so any reset logic using it is advised to detect a reset request on a falling edge rather than by level detection.

### soft_reset_n
Input
Edge detect reset input intended for SOPC Builder use or to be controlled by other system reset logic. It is asserted to cause a complete reset to the PHY, but not to the PLL used in the PHY.

### oct_ctl_rs_value
Input
ALTMEMPHY signal that specifies the serial termination value. Should be connected to the ALT_OCT megafunction output seriesterminationcontrol.

### oct_ctl_rt_value
Input
ALTMEMPHY signal that specifies the parallel termination value. Should be connected to the ALT_OCT megafunction output parallelterminationcontrol.

### dqs_delay_ctrl_import
Input
Allows the use of DLL in another ALTMEMPHY instance in this ALTMEMPHY instance. Connect the export port on the ALTMEMPHY instance with a DLL to the import port on the other ALTMEMPHY instance.
Table 7–6 shows the DDR and DDR2 SDRAM HPC II local interface signals.

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
</table>
| local_address[]     | Input     | Memory address at which the burst should start. By default, the local address is mapped to the bank interleaving scheme. You can change the ordering via the **Local-to-Memory Address Mapping** option in the **Controller Settings** page. The width of this bus is sized using the following equation:  
  - **Full rate controllers**  
    The width of this bus is sized using the following equation:  
    For one chip select:  
    width = row bits + bank bits + column bits – 1  
    For multiple chip selects:  
    width = chip bits + row bits + bank bits + column bits – 1  
    If the bank address is 2 bits wide, row is 13 bits wide and column is 10 bits wide, then the local address is 24 bits wide. To map `local_address` to bank, row and column address:  
    - `local_address` is 24 bits wide  
    - `local_address[23:11] = row address [12:0]`  
    - `local_address[10:9] = bank address [1:0]`  
    - `local_address[8:0] = column address [9:1]`  
    The least significant bit (LSB) of the column address (multiples of four) on the memory side is ignored, because the local data width is twice that of the memory data bus width.  
  - **Half rate controllers**  
    The width of this bus is sized using the following equation:  
    For one chip select:  
    width = row bits + bank bits + column bits – 2  
    For multiple chip selects:  
    width = chip bits + row bits + bank bits + column bits – 2  
    If the bank address is 2 bits wide, row is 13 bits wide and column is 10 bits wide, then the local address is 23 bits wide. To map `local_address` to bank, row and column address:  
    - `local_address` is 23 bits wide  
    - `local_address[22:10] = row address [12:0]`  
    - `local_address[9:8] = bank address [1:0]`  
    - `local_address[7:0] = column address [9:2]`  
    Two LSBs of the column address on the memory side are ignored, because the local data width is four times that of the memory data bus width. |
Top-level Signals Description

local_be[]

- Input
- Byte enable signal, which you use to mask off individual bytes during writes.
  - local_be is active high; mem_dm is active low.

  To map local_wdata and local_be to mem_dq and mem_dm, consider a full-rate design with 32-bit local_wdata and 16-bit mem_dq.

  Local_wdata = \langle 22334455 > \langle 667788AA > \langle BBCCDDEE >
  Local_be = \langle 1100 > \langle 0110 > \langle 1010 >

  These values map to:
  Mem_dq = \langle 4455 > \langle 2233 > \langle 88AA > \langle 6677 > \langle DDEE > \langle BBCC >
  Mem_dm = \langle 11 > \langle 00 > \langle 01 > \langle 10 > \langle 01 > \langle 01 >

local_burstbegin

- Input
- The Avalon burst begin strobe, which indicates the beginning of an Avalon burst. Unlike all other Avalon-MM signals, the burst begin signal does not stay asserted if local_ready is deasserted.

  For write transactions, assert this signal at the beginning of each burst transfer and keep this signal high for one cycle per burst transfer, even if the slave has deasserted the local_ready signal. This signal is sampled at the rising edge of phy_clk when the local_write_req signal is asserted.

  After the slave deasserts the local_ready signal, the master keeps all the write request signals asserted until local_ready signal becomes high again.

  For read transactions, assert this signal for one clock cycle when read request is asserted and the local_address from which the data should be read is given to the memory. After the slave deasserts local_ready (waitrequest_n in Avalon interface), the master keeps all the read request signals asserted until the local_ready signal becomes high again.

local_read_req

- Input
- Read request signal. You cannot assert read request and write request signal at the same time.

local_refresh_req

- Input
- User-controlled refresh request. If Enable User Auto-Refresh Controls option is turned on, local_refresh_req becomes available and you are responsible for issuing sufficient refresh requests to meet the memory requirements. This option allows complete control over when refreshes are issued to the memory including grouping together multiple refresh commands. Refresh requests take priority over read and write requests, unless the requests are already being processed.

local_refresh_chip

- Input
- Controls which chip to issue the user refresh to. This active high signal is used together with the local_refresh_req signal. This signal is as wide as the memory chip select. This signal asserts a high value to each bit that represents the refresh for the corresponding memory chip.

  For example: If the local_refresh_chip signal is assigned with a value of 4'b0101, the controller refreshes the memory chips 0 and 2, and memory chips 1 and 3 are not refreshed.

local_size[]

- Input
- Controls the number of beats in the requested read or write access to memory, encoded as a binary number. The range of supported Avalon burst lengths is 1 to 64. The width of this signal is derived based on the burst count specified in the Local Maximum Burst Count option. With the derived width, choose a value ranging from 1 to the local maximum burst count specified.

With the derived width, choose a value ranging from 1 to the local maximum burst count specified. |
### Top-level Signals Description

**local_wdata[]**
- **Input**
- Write data bus. The width of `local_wdata` is twice that of the memory data bus for a full rate controller; four times the memory data bus for a half rate controller.

**local_write_req**
- **Input**
- Write request signal. You cannot assert read request and write request signal at the same time.

**local_multicast**
- **Input**
- In-band multi-cast write request signal. This active high signal is used together with the `local_write_req` signal. When this signal is asserted high, data is written to all the memory chips available.

**local_autopch_req**
- **Input**
- User control of auto-precharge. If Enable Auto-Precharge Control option is turned on, the `local_autopch_req` signal becomes available, and you can request the controller to issue an auto-precharge write or auto-precharge read command. These commands cause the memory to issue a precharge command to the current bank at the appropriate time without an explicit precharge command from the controller. This is particularly useful if you know the current read or write is the last one you intend to issue to the currently open row. The next time you need to use that bank, the access could be quicker as the controller does not need to precharge the bank before activating the row you wish to access.

If you issue a local burst longer than the memory burst with the `local_autopch_req` signal asserted, the controller only issues auto-precharge with the last read or write command.

**local_self_rfsh_req**
- **Input**
- User control of the self-refresh feature. If Enable Self-Refresh Controls option is enabled, you can request that the controller place the memory devices into a self-refresh state by asserting this signal. The controller places the memory in the self-refresh state as soon as it can without violating the relevant timing parameters and responds by asserting the `local_self_rfsh_ack` signal. You can hold the memory in the self-refresh state by keeping this signal asserted. You can release the memory from the self-refresh state at any time by deasserting the `local_self_rfsh_req` signal and the controller responds by deasserting the `local_self_rfsh_ack` signal once it has successfully brought the memory out of the self-refresh state.

**local_init_done**
- **Output**
- When the memory initialization, training, and calibration are complete, the ALTMEMPHY sequencer asserts the `ctrl_usr_mode_rdy` signal to the memory controller, which then asserts this signal to indicate that the memory interface is ready to be used. Read and write requests are still accepted before `local_init_done` is asserted, however they are not issued to the memory until it is safe to do so. This signal does not indicate that the calibration is successful.

**local_rdata[]**
- **Output**
- Read data bus. The width of `local_rdata` is twice that of the memory data bus for a full rate controller; four times the memory data bus for a half rate controller.

**local_rdata_error**
- **Output**
- Asserted if the current read data has an error. This signal is only available if the Enable Error Detection and Correction Logic option is turned on. This signal is asserted together with the `local_rdata_valid` signal.

If the controller encounters double-bit errors, no correction is made and the controller asserts this signal.

**local_rdata_valid**
- **Output**
- Read data valid signal. The `local_rdata_valid` signal indicates that valid data is present on the read data bus.
The `local_ready` signal indicates that the DDR or DDR2 SDRAM HPC II is ready to accept request signals. If `local_ready` is asserted in the clock cycle that a read or write request is asserted, that request has been accepted. The `local_ready` signal is deasserted to indicate that the DDR or DDR2 SDRAM HPC II cannot accept any more requests. The DDR or DDR2 SDRAM HPC II is able to buffer eight read or write requests.

`local_refresh_ack` Output Refresh request acknowledge, which is asserted for one clock cycle every time a refresh is issued. Even if the `Enable User Auto-Refresh Controls` option is not selected, `local_refresh_ack` still indicates to the local interface that the controller has just issued a refresh command.

`local_self_rfsh_ack` Output Self-refresh request acknowledge feature. This signal is asserted and deasserted in response to the `local_self_rfsh_req` signal from the user.

`local_power_down_ack` Output Auto power-down acknowledge signal. This signal is asserted for one clock cycle every time auto power-down is issued.

`ecc_interrupt` Output Interrupt signal from the ECC logic. This signal is asserted when the ECC feature is turned on, and an error is detected. This signal remains asserted until the user logic clears the error through the CSR interface.

8. Latency

Latency is defined using the local (user) side frequency and absolute time (ns). There are two types of latencies that exists while designing with memory controllers—read and write latencies, which have the following definitions:

- Read latency—the amount of time it takes for the read data to appear at the local interface after initiating the read request.
- Write latency—the amount of time it takes for the write data to appear at the memory interface after initiating the write request.

For a half-rate controller, the local side frequency is half of the memory interface frequency. For a full-rate controller, the local side frequency is equal to the memory interface frequency.

Altera defines read and write latencies in terms of the local interface clock frequency and by the absolute time for the memory controllers. These latencies apply to supported device families (Table 1–1 on page 1–2) with the following memory controllers:

- Legacy DDR and DDR2 SDRAM controllers
- Half-rate HPC and HPC II
- Full-rate HPC and HPC II

The latency defined in this section uses the following assumptions:

- The row is already open, there is no extra bank management needed.
- The controller is idle, there is no queued transaction pending, indicated by the `local_ready` signal asserted high.
- No refresh cycles occur before the transaction.

The latency for the high-performance controllers comprises many different stages of the memory interface. Figure 8–1 on page 8–2 shows a typical memory interface read latency path showing read latency from the time a `local_read_req` signal assertion is detected by the controller up to data available to be read from the dual-port RAM (DPRAM) module.
Table 8–1 shows the different stages that make up the whole read and write latency that Figure 8–1 shows.

<table>
<thead>
<tr>
<th>Latency Number</th>
<th>Latency Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1</td>
<td>Controller</td>
<td>local_read_req or local_write_req signal assertion to ddr_cs_n signal assertion.</td>
</tr>
<tr>
<td>T2</td>
<td>Command Output</td>
<td>ddr_cs_n signal assertion to mem_cs_n signal assertion.</td>
</tr>
<tr>
<td>T3</td>
<td>CAS or WL</td>
<td>Read command to DQ data from the memory or write command to DQ data to the memory.</td>
</tr>
<tr>
<td>T4</td>
<td>ALTMEMPHY read data input</td>
<td>Read data appearing on the local interface.</td>
</tr>
<tr>
<td>T2 + T3</td>
<td>Write data latency</td>
<td>Write data appearing on the memory interface.</td>
</tr>
</tbody>
</table>

From Figure 8–1, the read latency in the high-performance controllers is made up of four components:

Read latency = controller latency + command output latency + CAS latency + PHY read data input latency = T1 + T2 + T3 + T4

Similarly, the write latency in the high-performance controllers is made up of three components:

Write latency = controller latency + write data latency = T1 + T2 + T3

You can separate the controller and ALTMEMPHY read data input latency into latency that occurred in the I/O element (IOE) and latency that occurred in the FPGA fabric.
Table 8–2 shows the minimum and maximum supported CAS latency for the DDR and DDR2 SDRAM high-performance controllers (HPC and HPC II).

<table>
<thead>
<tr>

<tr>
<td>Stratix IV</td>
<td>3.0</td>
<td>3.0</td>
</tr>
</tbody>
</table>

Note to Table 8–2:
(1) The registered DIMMs, where supported, effectively introduce one extra cycle of CAS latency. For the registered DIMMs, you need to subtract 1.0 from the CAS figures to determine the minimum supported CAS latency, and add 1.0 to the CAS figures to determine the maximum supported CAS latency.

Table 8–3 through Table 8–6 show a typical latency that can be achieved in Arria GX, Arria II GX, Cyclone III, Cyclone IV, Stratix IV, Stratix III, Stratix II, and Stratix II GX devices. The exact latency for your memory controller depends on your precise configuration. You can obtain precise latency from simulation, but this figure can vary slightly in hardware because of the automatic calibration process.

The actual memory CAS and write latencies shown are halved in half-rate designs as the latency calculation is based on the local clock.

The read latency also depends on your board trace delay. The latency found in simulation can be different from that found in board testing as functional simulation does not take into account the board trace delays. For a given design on a given board, the latency may change by one clock cycle (for full-rate designs) or two clock cycles (for half-rate designs) upon resetting the board. Different boards could also show different latencies even with the same design.

The CAS and write latencies are different between DDR and DDR2 SDRAM interfaces. To calculate latencies for DDR SDRAM interfaces, use the numbers from DDR2 SDRAM listed below and replace the CAS and write latency with the DDR SDRAM values.

Notes to Table 8–5:

1. These are typical latency values using the assumptions listed in the beginning of the section. Your actual latency may be different than shown. Perform your own simulation for your actual latency.
2. Numbers shown may have been rounded up to the nearest higher integer.
3. The controller latency value is from the Altera high-performance controller.
4. Memory write latency is per memory device specification. The latency from when you provide the command to write to when you need to provide data at the memory device.
5. Total write latency is the sum of controller, address and command, and memory write latencies.

To see the latency incurred in the IOE for both read and write paths for ALTMEMPHY variations in Stratix IV and Stratix III devices refer to the IOE figures in the *External Memory Interfaces in Stratix III Devices* chapter of the *Stratix III Device Handbook* and the *External Memory Interfaces in Stratix IV Devices* chapter of the *Stratix IV Device Handbook*. 
This chapter details the timing diagrams for the DDR and DDR2 SDRAM high-performance controllers (HPC) and high-performance controllers II (HPC II).

**DDR and DDR2 High-Performance Controllers**

This section discusses the following timing diagrams for HPC in AFI mode:

- “Auto-Precharge”
- “User Refresh”
- “Full-Rate Read”
- “Half-Rate Read”
- “Full-Rate Write”
- “Half Rate Write”
- “Initialization Timing”
- “Calibration Timing”
Auto-Precharge

The auto-precharge read and auto-precharge write commands allow you to indicate to the memory device that this read or write command is the last access to the currently open row. The memory device automatically closes (auto-precharges) the page it is currently accessing so that the next access to the same bank is quicker. This command is particularly useful for applications that require fast random accesses.

Figure 9–1. Auto-Precharge Operation for HPC

Notes to Figure 9–1:
(1) The auto-precharge request goes high.
(2) The local_ready signal is asserted and remains high until the auto-precharge request goes low.
(3) A new row address begins.
User Refresh

Figure 9–2 shows the user refresh control interface. This feature allows you to control when the controller issues refreshes to the memory. This feature allows better control of worst case latency and allows refreshes to be issued in bursts to take advantage of idle periods.

Figure 9–2. User-Refresh Operation for HPC

Notes to Figure 9–2:

1. The local refresh request signal is asserted.
2. The controller asserts the local_refresh_ack signal.
3. The auto-refresh (ARF) command on the command bus.
Full-Rate Read

Figure 9–3. Full-Rate Read Operation for HPC Using Native and Avalon-MM Interfaces
The following sequence corresponds with the numbered items in Figure 9–3:

1. The local read request signal is asserted.
2. The controller accepts the request, the `local_ready` signal is asserted.
3. The controller asserts the `ctl_doing_rd` to tell the PHY how many clock cycles of read data to expect.
4. The read command (RD) on the bus.
5. The `mem_dqs` signal has the read data.
6. These are the data to the controller with the valid signal.
7. The controller returns the valid read data to the user logic by asserting the `local_rdata_valid` signal when there is valid local read data.
Half-Rate Read

Figure 9–4. Half-Rate Read Operation for HPC Using Native and Avalon-MM Interfaces
The following sequence corresponds with the numbered items in Figure 9–4:

1. The local read request signal is asserted.
2. The controller accepts the request, the local_ready signal is asserted.
3. The controller asserts the ctl_doing_rd to tell the PHY how many clock cycles of read data to expect.
4. The read command (RD) on the bus.
5. The mem_dqs signal has the read data.
6. These are the data to the controller with the valid signal.
7. The controller returns the valid read data to the user logic by asserting the local_rdata_valid signal when there is valid local read data.
Full-Rate Write

The following sequence corresponds with the numbered items in Figure 9–5:
1. The local write request signal is asserted.
2. The local_ready signal is high at the time of the write request.
3. The date is written to the memory for this write command.
4. The write command (WR) on the command bus.
5. The valid write data on the \texttt{ctl\_wdata} signal. The \texttt{ctl\_wdata\_valid} is 1.
6. Data on the \texttt{mem\_dqs} signal goes to the controller.
Half Rate Write

Figure 9–6. Half-Rate Write Operation for HPC Using Native and Avalon-MM Interfaces
The following sequence corresponds with the numbered items in Figure 9–6:

1. The user logic requests write by asserting the `local_write_req` signal.
2. The `local_ready` signal is asserted, indicating that the controller has accepted the request.
3. The data written to the memory for the write command.
4. The controller requests the user logic for the write data and byte-enables for the write by asserting the `local_wdata_req` signal, (only for native interface).
5. The valid write data on the `ctl_wdata` signal.
6. The valid data on the `mem_dq` signal goes to the controller.
Initialization Timing

Figure 9–7. Initialization Timing for HPC
The following sequence corresponds with the numbered items in Figure 9–7:
1. The `pll_locked` signal goes high.
2. The `mem_cke` signal is asserted.
3. The first sequence of the initialization commands: PCH, LMR, PCH, ARF, LMR.
4. Write training data.
5. The first read command to read back training pattern.
Calibration Timing

Figure 9–8. Calibration Timing for HPC
The following sequence corresponds with the numbered items in Figure 9–8:

1. The first read calibration at zero degrees.
2. The PPL phase.
3. The second read calibration after the PLL phase.
4. The final read calibration and final PLL phase.
5. The burst of the PLL phase to center the clock.
6. The second initialization sequence (LMR) to load the settings.
7. The \texttt{ctl\_cal\_success} signal goes high.
8. The functional memory stage.
DDR and DDR2 High-Performance Controllers II

This section discusses the following timing diagrams for HPC II:

- “Half-Rate Read”
- “Half-Rate Write”
- “Full-Rate Read”
- “Full-Rate Write”
Half-Rate Read

Figure 9–9. Half-Rate Read Operation for HPC II
The following sequence corresponds with the numbered items in Figure 9–9:

1. The user logic requests the first read by asserting the `local_read_req` signal, and the size and address for this read. In this example, the request is a burst of length of 2 to the local address 0×000000. This local address is mapped to the following memory address in half-rate mode:
   
   ```
   mem_row_address = 0×000000
   mem_col_address = 0×0000
   mem_bank_address = 0×00
   ```

2. The user logic initiates a second read to a different memory column within the same row. The request for the second write is a burst length of 2. In this example, the user logic continues to accept commands until the command queue is full. When the command queue is full, the controller deasserts the `local_ready` signal. The starting local address 0x000002 is mapped to the following memory address in half-rate mode:
   
   ```
   mem_row_address = 0×0000
   mem_col_address = 0×0002<<2 = 0×0008
   mem_bank_address = 0×00
   ```

3. The controller issues the first read memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

4. The controller asserts the `afi_doing_rd` signal to indicate to the ALTMEMPHY megafunction the number of clock cycles of read data it must expect for the first read. The ALTMEMPHY megafunction uses the `afi_doing_rd` signal to enable its capture registers for the expected duration of memory burst.

5. The ALTMEMPHY megafunction issues the first read command to the memory and captures the read data from the memory.

6. The ALTMEMPHY megafunction returns the first data read to the controller after resynchronizing the data to the `phy_clk` domain, by asserting the `afi_rdata_valid` signal when there is valid read data on the `afi_rdata` bus.

7. The controller returns the first read data to the user by asserting the `local_rdata_valid` signal when there is valid read data on the `local_rdata` bus. If the ECC logic is disabled, there is no delay between the `afi_rdata` and the `local_rdata` buses. If there is ECC logic in the controller, there is one or three clock cycles of delay between the `afi_rdata` and `local_rdata` buses.
Half-Rate Write

Figure 9–10. Half-Rate Write Operation for HPC II
The following sequence corresponds with the numbered items in Figure 9–10:

1. The user logic asserts the first write request to row 0 so that row 0 is open before the next transaction.

2. The user logic asserts a second local_write_req signal with size of 2 and address of 0 (col = 0, row = 0, bank = 0, chip = 0). The local_ready signal is asserted along with the local_write_req signal, which indicates that the controller has accepted this request, and the user logic can request another read or write in the following clock cycle. If the local_ready signal was not asserted, the user logic must keep the write request, size, and address signals asserted until the local_ready signal is registered high.

3. The controller issues the necessary memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

4. The controller asserts the afi_wdata_valid signal to indicate to the ALTMEMPHY megafunction that valid write data and write data masks are present on the inputs to the ALTMEMPHY megafunction.

5. The controller asserts the afi_dqs_burst signals to control the timing of the DQS signal that the ALTMEMPHY megafunction issues to the memory.

6. The ALTMEMPHY megafucntion issues the write command, and sends the write data and write DQS to the memory.
Full-Rate Read

Figure 9–11. Full-Rate Read Operation for HPC II
The following sequence corresponds with the numbered items in Figure 9–11:

1. The user logic requests the first read by asserting the \texttt{local\_read\_req} signal, and the size and address for this read. In this example, the request is a burst length of 2 to a local address \texttt{0x000000}. This local address is mapped to the following memory address in full-rate mode:
   
   \begin{align*}
   \text{mem\_row\_address} &= 0\times0000 \\
   \text{mem\_col\_address} &= 0\times0000<<2 = 0\times0000 \\
   \text{mem\_bank\_address} &= 0\times00
   \end{align*}

2. The controller issues the first read memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

3. The controller asserts the \texttt{afi\_doing\_rd} signal to indicate to the ALTMEMPHY megafunction the number of clock cycles of read data it must expect for the first read. The ALTMEMPHY megafunction uses the \texttt{afi\_doing\_rd} signal to enable its capture registers for the expected duration of memory burst.

4. The ALTMEMPHY megafunction issues the first read command to the memory and captures the read data from the memory.

5. The ALTMEMPHY megafunction returns the first data read to the controller after resynchronizing the data to the \texttt{phy\_clk} domain, by asserting the \texttt{afi\_rdata\_valid} signal when there is valid read data on the \texttt{afi\_rdata} bus.

6. The controller returns the first read data to the user by asserting the \texttt{local\_rdata\_valid} signal when there is valid read data on the \texttt{local\_rdata} bus. If the ECC logic is disabled, there is no delay between the \texttt{afi\_rdata} and the \texttt{local\_rdata} buses. If there is ECC logic in the controller, there is one or three clock cycles of delay between the \texttt{afi\_rdata} and \texttt{local\_rdata} buses.
Full-Rate Write

Figure 9–12. Full-Rate Write Operation for HPC II
The following sequence corresponds with the numbered items in Figure 9–12:

1. The user logic asserts the first write request to row 0 so that row 0 is open before the next transaction.

2. The user logic asserts a second `local_write_req` signal with a size of 2 and address of 0 (col = 0, row = 0, bank = 0, chip = 0). The `local_ready` signal is asserted along with the `local_write_req` signal, which indicates that the controller has accepted this request, and the user logic can request another read or write in the following clock cycle. If the `local_ready` signal was not asserted, the user logic must keep the write request, size, and address signals asserted until the `local_ready` signal is registered high.

3. The controller issues the necessary memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

4. The controller asserts the `afi_wdata_valid` signal to indicate to the ALTMEMPHY megafunction that valid write data and write data masks are present on the inputs to the ALTMEMPHY megafunction.

5. The controller asserts the `afi_dqs_burst` signals to control the timing of the DQS signal that the ALTMEMPHY megafunction issues to the memory.

6. The ALTMEMPHY megafunction issues the write command, and sends the write data and write DQS to the memory.

1. About This IP

The Altera® DDR3 SDRAM High-Performance Controller MegaCore® function provides simplified interfaces to industry-standard DDR3 SDRAM. The ALTMEMPHY megafuction is an interface between a memory controller and the memory devices, and performs read and write operations to the memory. The MegaCore function works in conjunction with the Altera ALTMEMPHY megafuction.

The DDR3 SDRAM High-Performance Controller MegaCore function and ALTMEMPHY megafuction offer half-rate DDR3 SDRAM interfaces. The DDR3 SDRAM High-Performance Controller MegaCore function offers two controller architectures: the high-performance controller (HPC) and the high-performance controller II (HPC II). HPC II provides higher efficiency and more advanced features.

Figure 1–1 on page 1–1 shows a system-level diagram including the example top-level file that the DDR3 SDRAM High-Performance Controller MegaCore function creates for you.

**Figure 1–1. System-Level Diagram**

The MegaWizard™ Plug-In Manager generates an example top-level file, consisting of an example driver, and your DDR3 SDRAM high-performance controller custom variation. The controller instantiates an instance of the ALTMEMPHY megafuction which in turn instantiates a phase-locked loop (PLL) and DLL. You can optionally instantiate the DLL outside the ALTMEMPHY megafuction to share the DLL between multiple instances of the ALTMEMPHY megafuction. You cannot share a PLL between multiple instances of the ALTMEMPHY megafuction, but you may share some of the PLL clock outputs between these multiple instances.

The example top-level file is a fully-functional design that you can simulate, synthesize, and use in hardware. The example driver is a self-test module that issues read and write commands to the controller and checks the read data to produce the pass or fail, and test complete signals.
The ALTMEMPHY megafunction creates the datapath between the memory device and the memory controller. The megafunction is available as a stand-alone product or can be used in conjunction with Altera high-performance memory controllers. As a stand-alone product, use the ALTMEMPHY megafunction with either custom or third-party controllers.

### Release Information

Altera verifies that the current version of the Quartus® II software compiles the previous version of each MegaCore function. The MegaCore IP Library Release Notes and Errata report any exceptions to this verification. Altera does not verify compilation with MegaCore function versions older than one release. For information about issues on the ALTMEMPHY megafunction in a particular Quartus II version, refer to the Quartus II Software Release Notes.

### Device Family Support

The MegaCore functions provide either full or preliminary support for target Altera device families:

- Full support means the megafunction meets all functional and timing requirements for the device family and can be used in production designs.

- Preliminary support means the megafunction meets all functional requirements, but can still be undergoing timing analysis for the device family.
Table 1–2 shows the level of support offered by the DDR3 SDRAM high-performance controllers to each of the Altera device families.

### Features

The ALTMEMPHY megafuncon offers the following features:

- Simple setup
- Support for the Altera PHY Interface (AFI) for DDR3 SDRAM on all supported devices.
- Automated initial calibration eliminating complicated read data timing calculations
- VT tracking that guarantees maximum stable performance for DDR3 SDRAM interface
- Self-contained datapath that makes connection to an Altera controller or a third-party controller independent of the critical timing paths
- Easy-to-use MegaWizard interface

The ALTMEMPHY megafunction supports DDR3 SDRAM DIMMs with leveling and DDR3 SDRAM components without leveling:

- ALTMEMPHY with leveling is for unbuffered DIMMs (including SODIMM and MicroDIMM) or DDR3 SDRAM components up to 80-bit total data bus width with a layout like a DIMM that target Stratix III and Stratix IV devices:
  - Supports a fully-calibrated DDR3 SDRAM PHY for DDR3 SDRAM unbuffered DIMM with \( x4 \) and \( x8 \) devices with 300-MHz to 533-MHz frequency targets.
  - Deskew circuitry is enabled automatically for interfaces higher than 400 MHz
  - Supports single and multiple chip selects
- ALTMEMPHY supports DDR3 SDRAM components without leveling for Arria II GX, Stratix III, and Stratix IV devices using T-topology for clock, address, and command bus:
  - Supports multiple chip selects
- The DDR3 SDRAM PHY with leveling \( f_{\text{MAX}} \) is 533 MHz; without leveling \( f_{\text{MAX}} \) is 400 MHz for single chip selects.
- No support for data-mask (DM) pins for ×4 DDR3 SDRAM DIMMs or components, so select No for Drive DM pins from FPGA when using ×4 devices
- The ALTMEMPHY megafunction supports half-rate DDR3 SDRAM interfaces only.

Table 1–3 shows the features provided by the DDR3 SDRAM HPC and HPC II.

**Notes to Table 1–3:**

(1) HPC II supports additive latency values greater or equal to \( t_{RC} - 1 \), in clock cycle unit (t_{CK}).
Unsupported Features

The DDR3 SDRAM high-performance controllers do not support the following features:

- Timing simulation
- Partial burst and unaligned burst in ECC and non-ECC mode when DM pins are disabled.

MegaCore Verification

MegaCore verification includes simulation testing. Altera performs extensive random, directed tests with functional test coverage using industry-standard Denali models to ensure the functionality of the DDR3 SDRAM high-performance controllers.

Resource Utilization

The following sections show the resource utilization data for the ALTMEMPHY megafunction, and the high-performance controllers.

ALTMEMPHY Megafuction

Table 1–4 and Table 1–5 show the typical size of the ALTMEMPHY megafuction with the AFI in the Quartus II software version 9.1 for the following devices:

- Arria II GX (EP2AGX260FF35C4) devices
- Stratix III (EP3SL110F1152C2) devices
- Stratix IV (EP4SGX230HF35C2) devices

System Requirements

The DDR3 SDRAM High-Performance Controller MegaCore function is a part of the MegaCore IP Library, which is distributed with the Quartus II software and downloadable from the Altera website, www.altera.com.

For system requirements and installation instructions, refer to Altera Software Installation & Licensing.
Installation and Licensing

Figure 1–2 shows the directory structure after you install the DDR3 SDRAM High-Performance Controller MegaCore function, where <path> is the installation directory. The default installation directory on Windows is c:\altera\<version>; on Linux it is /opt/altera<version>.

Figure 1–2. Directory Structure

You need a license for the MegaCore function only when you are completely satisfied with its functionality and performance, and want to take your design to production.

To use the DDR3 SDRAM HPC, you can request a license file from the Altera web site at www.altera.com/licensing and install it on your computer. When you request a license file, Altera emails you a license.dat file. If you do not have Internet access, contact your local representative.

To use the DDR3 SDRAM HPC II, contact your local sales representative to order a license.

OpenCore Evaluation

Altera's OpenCore Plus evaluation feature is only applicable to the DDR3 SDRAM HPC. With the OpenCore Plus evaluation feature, you can perform the following actions:

- Simulate the behavior of a megafuction (Altera MegaCore function or AMPP™ megafuction) within your system
- Verify the functionality of your design, as well as evaluate its size and speed quickly and easily
- Generate time-limited device programming files for designs that include MegaCore functions
- Program a device and verify your design in hardware
OpenCore Plus Time-Out Behavior

OpenCore Plus hardware evaluation can support the following two modes of operation:

- Untethered—the design runs for a limited time
- Tethered—requires a connection between your board and the host computer. If tethered mode is supported by all megafuntions in a design, the device can operate for a longer time or indefinitely

All megafuntions in a device time-out simultaneously when the most restrictive evaluation time is reached. If there is more than one megafunction in a design, a specific megafunction’s time-out behavior may be masked by the time-out behavior of the other megafunctions.

For MegaCore functions, the untethered time-out is 1 hour; the tethered time-out value is indefinite.

Your design stops working after the hardware evaluation time expires and the local_ready output goes low.
You can implement the DDR3 SDRAM High-Performance Controller MegaCore function using either one of the following flows:
- SOPC Builder flow
- MegaWizard Plug-In Manager flow

You can only instantiate the ALTMEMPHY megafuction using the MegaWizard Plug-In Manager flow.

Figure 2–1 shows the stages for creating a system in the Quartus II software using either one of the flows.
The SOPC Builder flow offers the following advantages:

- Generates simulation environment
- Creates custom components and integrates them via the component wizard
- Interconnects all components with the Avalon-MM interface

The MegaWizard Plug-In Manager flow offers the following advantages:

- Allows you to design directly from the DDR3 SDRAM interface to peripheral device or devices
- Achieves higher-frequency operation

**SOPC Builder Flow**

The SOPC Builder flow allows you to add the DDR3 SDRAM high-performance controller directly to a new or existing SOPC Builder system.

You can also easily add other available components to quickly create an SOPC Builder system with the DDR3 SDRAM high-performance controller, such as the Nios II processor and scatter-gather direct memory access (DMA) controllers. SOPC Builder automatically creates the system interconnect logic and system simulation environment.

For more information about SOPC Builder, refer to volume 4 of the *Quartus II Handbook*. For more information about how to use controllers with SOPC Builder, refer to the *DDR, DDR2, and DDR3 SDRAM Design Tutorials* section in volume 6 of the *External Memory Interface Handbook*. For more information on the Quartus II software, refer to the Quartus II Help.

**Specify Parameters**

To specify the parameters for the DDR3 SDRAM high-performance controllers using the SOPC Builder flow, perform the following steps:

1. In the Quartus II software, create a new Quartus II project with the **New Project Wizard**.
2. On the Tools menu, click **SOPC Builder**.
3. For a new system, specify the system name and language.
4. Add **DDR3 SDRAM High-Performance Controller** to your system from the **System Contents** tab.

   - The **DDR3 SDRAM High-Performance Controller** is in the **SDRAM** folder under the **Memories and Memory Controllers** folder.

5. Specify the required parameters on all **s** in the **Parameter Settings** tab.

   - For detailed explanation of the parameters, refer to the “**Parameter Settings**” on page 3–1.

6. Click **Finish** to complete parameterizing the DDR3 SDRAM high-performance controller and add it to the system.
Complete the SOPC Builder System

To complete the SOPC Builder system, perform the following steps:

1. In the System Contents tab, select Nios II Processor and click Add.
2. On the Nios II Processor, in the Core Nios II tab, select altmemddr for Reset Vector and Exception Vector.
3. Change the Reset Vector Offset and the Exception Vector Offset to an Avalon address that is not written to by the ALTMEMPHY megafuction during its calibration process.

Caution: The ALTMEMPHY megafuction performs memory interface calibration every time it is reset, and in doing so, writes to a range of addresses. If you want your memory contents to remain intact through a system reset, you should avoid using these memory addresses. This step is not necessary if you reload your SDRAM memory contents from flash every time you reset your system.

If you are upgrading your Nios system design from version 8.1 or previous, ensure that you change the Reset Vector Offset and the Exception Vector Offset to AFI mode.

To calculate the Avalon-MM address equivalent of the memory address range 0×0 to 0×47, multiply the memory address by the width of the memory interface data bus in bytes. Refer to Table 2–1 for more Avalon-MM addresses.

<table>
<thead>
<tr>
<th>External Memory Interface Width</th>
<th>Reset Vector Offset</th>
<th>Exception Vector Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>0×60</td>
<td>0×80</td>
</tr>
<tr>
<td>16</td>
<td>0×A0</td>
<td>0×C0</td>
</tr>
<tr>
<td>32</td>
<td>0×120</td>
<td>0×140</td>
</tr>
<tr>
<td>64</td>
<td>0×240</td>
<td>0×260</td>
</tr>
</tbody>
</table>

4. Click Finish.
6. Select JTAG UART and click Add.
7. Click Finish.

If there are warnings about overlapping addresses, on the System menu, click Auto Assign Base Addresses.

If you enable ECC and there are warnings about overlapping IRQs, on the System menu click Auto Assign IRQs.

8. For this example system, ensure all the other modules are clocked on the altmemddr_sysclk, to avoid any unnecessary clock-domain crossing logic.
9. Click Generate.
Among the files generated by SOPC Builder is the Quartus II IP File (.qip). This file contains information about a generated IP core or system. In most cases, the .qip file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. Generally, a single .qip file is generated for each SOPC Builder system. However, some more complex SOPC Builder components generate a separate .qip file. In that case, the system .qip file references the component .qip file.

10. Compile your design, refer to “Compile and Simulate” on page 4–1.

**MegaWizard Plug-In Manager Flow**

The MegaWizard Plug-In Manager flow allows you to customize the DDR3 SDRAM high-performance controller or ALTMEMPHY megafunction, and manually integrate the function into your design.

You can alternatively use the IP Advisor to help you start your DDR3 SDRAM high-performance controller design. On the Quartus II Tools menu, point to Advisors, and then click IP Advisor. The IP Advisor guides you through a series of recommendations for selecting, parameterizing, evaluating, and instantiating a DDR3 SDRAM high-performance controller into your design. It then guides you through a complete Quartus II compilation of your project.

For more information about the MegaWizard Plug-In Manager and the IP Advisor, refer to the Quartus II Help.

**Specify Parameters**

To specify parameters using the MegaWizard Plug-In Manager flow, perform the following steps:

1. In the Quartus II software, create a new Quartus II project with the **New Project Wizard**.

2. On the Tools menu, click **MegaWizard Plug-In Manager** to start the MegaWizard Plug-In Manager.

   - The DDR3 SDRAM High-Performance Controller is in the **Interfaces** folder under the **External Memory** folder.
   - The ALTMEMPHY megafunction is in the **I/O** folder.

   The `<variation name>` must be a different name from the project name and the top-level design entity name.

3. Specify the parameters on all s in the **Parameter Settings** tab.

   For detailed explanation of the parameters, refer to the “Parameter Settings” on page 3–1.
4. On the **EDA** tab, turn on **Generate simulation model** to generate an IP functional simulation model for the MegaCore function in the selected language.

An IP functional simulation model is a cycle-accurate VHDL or Verilog HDL model produced by the Quartus II software.

⚠️ Use the simulation models only for simulation and not for synthesis or any other purposes. Using these models for synthesis creates a nonfunctional design.

Some third-party synthesis tools can use a netlist that contains only the structure of the MegaCore function, but not detailed logic, to optimize performance of the design that contains the MegaCore function. If your synthesis tool supports this feature, turn on **Generate netlist**.

When targeting a VHDL simulation model, the MegaWizard Plug-In Manager still generates the `<variation_name>_alt_mem_phy.v` file for the Quartus II synthesis. Do not use this file for simulation. Use the `<variation_name>.vho` file for simulation instead.

The ALTMEMPHY megafunction only supports functional simulation. You cannot perform timing or gate-level simulation when using the ALTMEMPHY megafunction.

5. On the **Summary** tab, select the files you want to generate. A gray checkmark indicates a file that is automatically generated. All other files are optional.

6. Click **Finish** to generate the MegaCore function and supporting files. A generation report appears.

7. If you generate the MegaCore function instance in a Quartus II project, you are prompted to add the `.qip` files to the current Quartus II project. When prompted to add the `.qip` files to your project, click **Yes**. The addition of the `.qip` files enables their visibility to Nativelink. Nativelink requires the `.qip` files to include libraries for simulation.

   The `.qip` file is generated by the MegaWizard interface, and contains information about the generated IP core. In most cases, the `.qip` file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. The MegaWizard interface generates a single `.qip` file for each MegaCore function.

8. After you review the generation report, click **Exit** to close the MegaWizard Plug-In Manager.

9. For the high-performance controller (HPC or HPC II), set the `<variation name>_example_top.v` or `.vhd` file to be the project top-level design file.
   a. On the File menu, click **Open**.
   b. Browse to `<variation name>_example_top` and click **Open**.
   c. On the Project menu, click **Set as Top-Level Entity**.
Table 2–2 shows the ALTMEMPHY generated files.

<table>
<thead>
<tr>
<th>File Name</th>
<th>Description</th>

</tbody>
</table>

Table 2–4 through Table 2–6 show the additional files generated by the high-performance controllers, that may be in your project directory. The names and types of files specified in the MegaWizard Plug-In Manager report vary based on whether you created your design with VHDL or Verilog HDL.

In addition to the files in Table 2–4 through Table 2–6, the MegaWizard also generates the ALTMEMPHY files in Table 2–2, but with a _phy prefix. For example, `<variation_name>_alt_mem_phy_delay.vhd` becomes `<variation_name>_phy_alt_mem_phy_delay.vhd`.

Table 2–4. Controller Generated Files—All High Performance Controllers (Part 1 of 2)

<table>
<thead>
<tr>
<th>Filename</th>
<th>Description</th>
</tr>

3. Parameter Settings

ALTMEMPHY Parameter Settings

The ALTMEMPHY Parameter Settings page in the ALTMEMPHY MegaWizard interface (Figure 3–1) allows you to parameterize the following settings:

- Memory Settings
- PHY Settings
- Board Settings
- Controller Interface Settings

Figure 3–1. ALTMEMPHY Parameter Settings Page
The text window at the bottom of the MegaWizard Plug-In Manager displays information about the memory interface, warnings, and errors if you are trying to create something that is not supported. The Finish button is disabled until you correct all the errors indicated in this window.

The following sections describe the four tabs of the Parameter Settings page in more detail.

**Memory Settings**

In the Memory Settings tab, you can select a particular memory device for your system and choose the frequency of operation for the device. Under General Settings, you can choose the device family, speed grade, and clock information. In the middle of the page (left-side), you can filter the available memory device listed on the right side of the Memory Presets page, refer to Figure 3–1. If you cannot find the exact device that you are using, choose a device that has the closest specifications, then manually modify the parameters to match your actual device by clicking Modify parameters, next to the Selected memory preset field.

Table 3–1 describes the General Settings available on the Memory Settings page of the ALTMEPHY MegaWizard interface.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Device family</td>
<td>Targets device family (for example, Stratix III). Table 1–2 on page 1–3 shows supported device families. The device family selected here must match the device family selected on the MegaWizard page 2a.</td>
</tr>
<tr>
<td>Speed grade</td>
<td>Selects a particular speed grade of the device (for example, 2, 3, or 4 for the Stratix III device family).</td>
</tr>
<tr>
<td>PLL reference clock frequency</td>
<td>Determines the clock frequency of the external input clock to the PLL. Ensure that you use three decimal points if the frequency is not a round number (for example, 166.667 MHz or 100 MHz) to avoid a functional simulation or a PLL locking problem.</td>
</tr>
<tr>
<td>Memory clock frequency</td>
<td>Determines the memory interface clock frequency. If you are operating a memory device below its maximum achievable frequency, ensure that you enter the actual frequency of operation rather than the maximum frequency achievable by the memory device. Also, ensure that you use three decimal points if the frequency is not a round number (for example, 333.333 MHz or 400 MHz) to avoid a functional simulation or a PLL locking issue.</td>
</tr>
<tr>
<td>Controller data rate</td>
<td>Selects the data rate for the memory controller. Sets the frequency of the controller to equal to either the memory interface frequency (full-rate) or half of the memory interface frequency (half-rate). The full-rate option is not available for DDR3 SDRAM devices.</td>
</tr>
<tr>
<td>Enable half rate bridge</td>
<td>This option is only available for HPC II full-rate controller. Turn on to keep the controller in the memory full clock domain while allowing the local side to run at half the memory clock speed, so that latency can be reduced.</td>
</tr>
<tr>
<td>Local interface clock frequency</td>
<td>Value that changes with the memory device that you choose from the Memory Presets list.</td>
</tr>
<tr>
<td>Local interface width</td>
<td>Value that depends on the memory clock frequency and controller data rate, and whether or not you turn on the Enable Half Rate Bridge option.</td>
</tr>
</tbody>
</table>
Table 3–2 describes the options available to filter the Memory Presets that are displayed. This set of options is where you indicate whether you are creating a datapath for DDR3 SDRAM.

Table 3–2. Memory Presets List

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory type</td>
<td>You can filter the type of memory to display, for example, DDR3 SDRAM.</td>
</tr>
<tr>
<td>Memory vendor</td>
<td>You can filter the memory types by vendor. JEDEC is also one of the options, allowing you to choose the JEDEC specifications. If your chosen vendor is not listed, you can choose JEDEC for the DDR3 SDRAM interfaces. Then, pick a device that has similar specifications to your chosen device and check the values of each parameter. Make sure you change the each parameter value to match your device specifications.</td>
</tr>
<tr>
<td>Memory format</td>
<td>You can filter the type of memory by format, for example, discrete devices or DIMM packages.</td>
</tr>
<tr>
<td>Maximum frequency</td>
<td>You can filter the type of memory by the maximum operating frequency.</td>
</tr>
</tbody>
</table>

Use the Preset Editor to Create a Custom Memory Preset

Pick a device in the Memory Presets list that is closest or the same as the actual memory device that you are using. Then, click the Modify Parameters button to parameterize the following settings in the Preset Editor dialog box:

- Memory attributes—These are the settings that determine your system’s number of DQ, DQ strobe (DQS), address, and memory clock pins.
- Memory initialization options—These settings are stored in the memory mode registers as part of the initialization process.
- Memory timing parameters—These are the parameters that create and time-constrain the PHY.

Even though the device you are using is listed in Memory Presets, ensure that the settings in the Preset Editor dialog box are accurate, as some parameters may have been updated in the memory device datasheets.

You can change the parameters with a white background to reflect your system. You can also change the parameters with a gray background so the device parameters match the device you are using. These parameters in gray background are characteristics of the chosen memory device and changing them creates a new custom memory preset. If you click Save As (at the bottom left of the page) and save the new settings in the `<quartus_install_dir>\quartus\common\ip\altera\altmemphy\lib` directory, you can use this new memory preset in other Quartus II projects created in the same version of the software.

When you click Save, the new memory preset appears at the bottom of the Memory Presets list in the Memory Settings tab.

If you save the new settings in a directory other than the default directory, click Load Preset in the Memory Settings tab to load the settings into the Memory Presets list.
Figure 3–2 shows the Preset Editor dialog box for a DDR3 SDRAM.

Figure 3–2. DDR3 SDRAM Preset Editor

The **Advanced** option is only available for Arria II GX and Stratix IV devices. This option shows the percentage of memory specification that is calibrated by the FPGA. The percentage values are estimated by Altera based on the process variation.
Table 3–3 through Table 3–5 describe the DDR3 SDRAM parameters available for memory attributes, initialization options, and timing parameters.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Range</th>
<th>Units</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Output clock pairs from FPGA</td>
<td>1–6</td>
<td>pairs</td>
<td>Defines the number of differential clock pairs driven from the FPGA to the memory. Memory clock pins use the signal splitter feature in Arria II GX, Stratix III and Stratix IV devices for differential signaling. The ALTMEMPHY MegaWizard Plug-In Manager displays an error on the bottom of the window if you choose more than one for DDR3 SDRAM interfaces.</td>
</tr>
<tr>
<td>Total Memory chip selects</td>
<td>1, 2, 4, or 8</td>
<td>bits</td>
<td>Sets the number of chip selects in your memory interface. The depth of your memory in terms of number of chips. You are limited to the range shown as the local side binary encodes the chip select address.</td>
</tr>
<tr>
<td>Memory interface DQ width</td>
<td>4–288</td>
<td>bits</td>
<td>Defines the total number of DQ pins on the memory interface. If you are interfacing with multiple devices, multiply the number of devices with the number of DQ pins per device. Even though the GUI allows you to choose 288-bit DQ width, DDR3 SDRAM variations are only supported up to 80-bit width due to restrictions in the board layout which affects timing at higher data width. Furthermore, the interface data width is limited by the number of pins on the device. For best performance, have the whole interface on one side of the device.</td>
</tr>
<tr>
<td>Mirror addressing</td>
<td></td>
<td></td>
<td>On multiple rank DDR3 SDRAM DIMMs address signals are routed differently to each rank (referred to in the JEDEC specification as address mirroring). Enter ranks with mirrored addresses in this field. There is one bit per chip select. For example, for four chip selects, enter 1011 to mirror the address on chip select #3, #1, and #0.</td>

<tr>
<td>t(_{MRD})</td>
<td>2–39 ns</td>
<td></td>
<td>Minimum load mode register command period. The controller waits for this period of time after issuing a load mode register command before issuing any other commands. t(<em>{MRD}) is specified in ns but in terms of t(</em>{CK}) cycles in Micron’s device datasheet. Convert t(<em>{MRD}) to ns by multiplying the number of cycles specified in the datasheet times t(</em>{CK}), where t(<em>{CK}) is the memory operation frequency and not the memory device’s t(</em>{CK}).</td>
</tr>
<tr>
<td>t(_{RAS})</td>
<td>8–200 ns</td>
<td></td>
<td>Minimum active to precharge time. The controller waits for this period of time after issuing an active command before issuing a precharge command to the same bank.</td>
</tr>
<tr>
<td>t(_{RED})</td>
<td>4–65 ns</td>
<td></td>
<td>Minimum active to read-write time. The controller does not issue read or write commands to a bank during this period of time after issuing an active command.</td>
</tr>
<tr>
<td>t(_{RP})</td>
<td>4–65 ns</td>
<td></td>
<td>Minimum precharge command period. The controller does not access the bank for this period of time after issuing a precharge command.</td>
</tr>
<tr>
<td>t(_{REFI})</td>
<td>1–65534 µs</td>
<td>µs</td>
<td>Maximum interval between refresh commands. The controller performs regular refresh at this interval unless user-controlled refresh is turned on.</td>
</tr>
<tr>
<td>t(_{RFC})</td>
<td>14–1651 ns</td>
<td></td>
<td>Minimum autorefresh command period. The length of time the controller waits before doing anything else after issuing an auto-refresh command.</td>
</tr>
<tr>
<td>t(_{WTR})</td>
<td>4–65 ns</td>
<td></td>
<td>Minimum write recovery time. The controller waits for this period of time after the end of a write transaction before issuing a precharge command.</td>
</tr>
<tr>
<td>t(_{WTR})</td>
<td>1–6 t(_{CK})</td>
<td></td>
<td>Minimum write-to-read command delay. The controller waits for this period of time after the end of a write command before issuing a subsequent read command to the same bank. This timing parameter is specified in clock cycles and the value is rounded off to the next integer.</td>
</tr>
<tr>
<td>t(_{AC})</td>
<td>0–750 ps</td>
<td></td>
<td>DQ output access time.</td>
</tr>
<tr>
<td>t(_{DQSCK})</td>
<td>50–750 ps</td>
<td></td>
<td>DQS output access time from CK/CK# signals.</td>
</tr>
<tr>
<td>t(_{DQS})</td>
<td>50–500 ps</td>
<td></td>
<td>The maximum DQS to DQ skew; DQS to last DQ valid, per group, per access.</td>
</tr>
<tr>
<td>t(_{DQS})</td>
<td>0–0.3 t(_{CK})</td>
<td></td>
<td>Positive DQS latching edge to associated clock edge.</td>
</tr>
<tr>
<td>t(_{DH})</td>
<td>10–600 ps</td>
<td></td>
<td>DQ and DM input hold time relative to DQS, which has a derated value depending on the slew rate of the differential DQS and DQ/DM signals. Ensure that you are using the correct number and that the value entered is referenced to V(<em>{REF})(dc), not V(</em>{IH})(dc) min or V(_{IL})(dc) max. Refer to “Derate Memory Setup and Hold Timing” on page 3–9 for more information about how to derate this specification.</td>
</tr>
</tbody>
</table>
Derate Memory Setup and Hold Timing

Because the base setup and hold time specifications from the memory device datasheet assume input slew rates that may not be true for Altera devices, derate and update the following memory device specifications in the Preset Editor dialog box:

- \( t_{DS} \)
- \( t_{DH} \)
- \( t_{IH} \)
- \( t_{IS} \)

For Arria II GX and Stratix IV devices, you need not derate using the Preset Editor. You only need to enter the parameters referenced to \( V_{REF} \), and the deration is done automatically when you enter the slew rate information on the Board Settings tab.

### Table 3–5. DDR3 SDRAM Timing Parameter Settings (Part 2 of 2) (Note 1)

<table>
<thead>
<tr>

</tr>
<tr>
<td>( t_{REP} )</td>
<td>2.06–64 ns</td>
<td></td>
<td>Read to precharge time.</td>
</tr>
</tbody>
</table>

Note to Table 3–5:
(1) See the memory device data sheet for the parameter range. Some of the parameters may be listed in a clock cycle \( (t_{CK}) \) unit. If the MegaWizard Plug-In Manager requires you to enter the value in a time unit (ps or ns), convert the number by multiplying it with the clock period of your interface (and not the maximum clock period listed in the memory data sheet).
After derating the values, you then need to normalize the derated value because Altera input and output timing specifications are referenced to $V_{REF}$. When the memory device setup and hold time numbers are derated and normalized to $V_{REF}$, update these values in the Preset Editor dialog box to ensure that your timing constraints are correct.

The following memory device specifications and update the Preset Editor dialog box with the derated value:

For example, according to JEDEC, 533-MHz DDR3 SDRAM has the following specifications, assuming 1V/ns DQ slew rate rising signal and 2V/ns DQS-DQSn slew rate:

- Base $t_{DS} = 25$
- Base $t_{DH} = 100$
- $V_{IH}(ac) = V_{REF} + 0.175 \text{ V}$
- $V_{IH}(dc) = V_{REF} + 0.100 \text{ V}$
- $V_{IL}(ac) = V_{REF} - 0.175 \text{ V}$
- $V_{IL}(dc) = V_{REF} - 0.100 \text{ V}$

The $V_{REF}$ referenced setup and hold signals for a rising edge are:

$t_{DS} (V_{REF}) = \text{Base } t_{DS} + \delta t_{DS} + (V_{IH}(ac) - V_{REF})/\text{slew\_rate} = 25 + 0 + 175 = 200 \text{ ps}$

$t_{DH} (V_{REF}) = \text{Base } t_{DH} + \delta t_{DH} + (V_{IH}(dc) - V_{REF})/\text{slew\_rate} = 100 + 0 + 100 = 200 \text{ ps}$

If the output slew rate of the write data is different from 1V/ns, you have to first derate the $t_{DS}$ and $t_{DH}$ values, then translate these AC/DC level specs to $V_{REF}$ specification.

For a 2V/ns DQ slew rate rising signal and 2V/ns DQS-DQSn slew rate:

$t_{DS} (V_{REF}) = \text{Base } t_{DS} + \delta t_{DS} + (V_{IH}(ac) - V_{REF})/\text{slew\_rate} = 25 + 88 + 87.5 = 200.5 \text{ ps}$

$t_{DH} (V_{REF}) = \text{Base } t_{DH} + \delta t_{DH} + (V_{IH}(dc) - V_{REF})/\text{slew\_rate} = 100 + 50 + 50 = 200 \text{ ps}$

For a 0.5V/ns DQ slew rate rising signal and 1V/ns DQS-DQSn slew rate:

$t_{DS} (V_{REF}) = \text{Base } t_{DS} + \delta t_{DS} + (V_{IH}(ac) - V_{REF})/\text{slew\_rate} = 25 + 5 + 350 = 380 \text{ ps}$

$t_{DH} (V_{REF}) = \text{Base } t_{DH} + \delta t_{DH} + (V_{IH}(dc) - V_{REF})/\text{slew\_rate} = 100 + 10 + 200 = 310 \text{ ps}$

**PHY Settings**

Click Next or the PHY Settings tab to set the options described in Table 3–6. The options are available if they apply to the target Altera device.
## Table 3-6. ALTMEMPHY PHY Settings (Part 1 of 2)

<table>
<thead>

<td>Stratix III and Stratix IV</td>
<td>This option provides I/O impedance matching and termination capabilities. The ALTMEMPHY megafuction enables parallel termination during reads and series termination during writes with this option checked. Only applicable for DDR3 SDRAM interfaces where DQ and DQS are bidirectional. Using the dynamic termination requires that you use the OCT calibration block, which may impose a restriction on your DQS/DQ pin placements depending on your R&lt;sub&gt;on&lt;/sub&gt;/R&lt;sub&gt;off&lt;/sub&gt; pin locations. For more information, refer to either the External Memory Interfaces in Stratix III Devices chapter in volume 1 of the Stratix III Device Handbook or the External Memory Interfaces in Stratix IV Devices chapter in volume 1 of the Stratix IV Device Handbook.</td>
</tr>
<tr>
<td>Clock phase</td>
<td>Arria II GX</td>
<td>Adjusting the address and command phase can improve the address and command setup and hold margins at the memory device to compensate for the propagation delays that vary with different loadings. You have a choice of 0°, 90°, 180°, and 270°, based on the rising and falling edge of the phy_clk and write_clk signals. In Stratix IV and Stratix III devices, the clock phase is set to dedicated.</td>
</tr>
<tr>
<td>Dedicated clock phase</td>
<td>Stratix III and Stratix IV</td>
<td>When you use a dedicated PLL output for address and command, you can choose any legal PLL phase shift to improve setup and hold for the address and command signals. You can set this value to between 180° and 359° (the default is 240°). However, generally PHY timing requires a value of greater than 240° for half-rate designs.</td>
</tr>
</tbody>
</table>
Board Settings

Click Next or the Board Settings tab to set the options described in Table 3–7. The board settings parameters are set to model the board level effects in the timing analysis. The options are available if you choose Arria II GX or Stratix IV device for your interface. Otherwise, the options are disabled.

DDR3 SDRAM High-Performance Controller Parameter Settings

The DDR3 SDRAM High-Performance Controller Parameter Settings page in the DDR3 SDRAM High-Performance Controller MegaWizard interface (Figure 3–3) allows you to parameterize the following settings:

- Memory Settings
- PHY Settings
- Board Settings
- Controller Settings

The Memory Settings, PHY Settings, and Board Settings tabs provide the same options as in the ALTMEMPHY Parameter Settings page.
Controller Settings

Table 3–8 shows the options provided on the Controller Settings tab.

<table>

<th>Controller Architecture</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable auto power down</td>
<td>HPC II</td>
<td>Turn on to enable the controller to automatically place the external memory device in power-down mode after a specified number of idle controller clock cycles is observed in the controller. You can specify the number of idle cycles after which the controller powers down the memory in the Auto Power Down Cycles field, refer to “Automatic Power-Down with Programmable Time-Out” on page 7–7.</td>
</tr>
<tr>
<td>Auto power down cycles</td>
<td>HPC II</td>
<td>Determines the desired number of idle controller clock cycles before the controller places the external memory device in a power-down mode. The legal range is 1 to 65,535. The auto power-down mode is disabled if you set the value to 0 clock cycles.</td>
</tr>
<tr>
<td>Enable user auto-refresh controls</td>
<td>Both</td>
<td>Turn on to enable the controller to allow you to have control on when to place the external memory device in refresh mode.</td>
</tr>
<tr>
<td>Enable auto-precharge control</td>
<td>Both</td>
<td>Turn on if you need fast random access.</td>
</tr>
</tbody>
</table>
| Local-to-memory address mapping  | HPC II                  | Allows you to control the mapping between the address bits on the Avalon interface and the chip, row, bank, and column bits on the memory interface.  
If your application issues bursts that are greater than the column size of the memory device, choose the Chip-Row-Bank-Column option. This option allows the controller to use its look-ahead bank management feature to hide the effect of changing the currently open row when the burst reaches the end of the column.  
On the other hand, if your application has several masters that each use separate areas of memory, choose the Chip-Bank-Row-Column option. This option allows you to use the top address bits to allocate a physical bank in the memory to each master. The physical bank allocation avoids different masters accessing the same bank which is likely to cause inefficiency, as the controller must then open and close rows in the same bank. |
<p>| Command queue look-ahead depth   | HPC II                  | This option allows you to select a command queue look-ahead depth value to control the number of read or writes requests the look-ahead bank management logic examines, refer to “Command Queue” on page 7–4. |
| Local maximum burst count        | HPC II                  | Specifies a burst count to configure the maximum Avalon burst count that the controller slave port accepts.                                                                                           |
| Enable configuration and status register interface | HPC II | Turn on to enable run-time configuration and status retrieval of the memory controller. Enabling this option adds an additional Avalon-MM slave port to the memory controller top level that allows run-time reconfiguration and status retrieving for memory timing parameters, memory address size and mode register settings, and controller features. If Error Detection and Correction Logic option is enabled, the same slave port also allows you to control and retrieve the status of this logic. Refer to “Configuration and Status Register (CSR) Interface” on page 7–7. |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Controller Architecture</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable error detection and correction logic</td>
<td>Both</td>
<td>Turn on to enable error correction coding (ECC) for single-bit error correction and double-bit error detection. Refer to “Error Correction Coding (ECC)” on page 6–5 for HPC, and “Error Correction Coding (ECC)” on page 7–7 for HPC II.</td>
</tr>
<tr>
<td>Enable auto error correction</td>
<td>HPC II</td>
<td>Turn on to allow the controller to perform auto correction when the ECC logic detects a single-bit error. Alternatively, you can turn off this option and schedule the error correction at a desired time for better system efficiency. Refer to “Error Correction Coding (ECC)” on page 7–7.</td>
</tr>
<tr>
<td>Enable multi-cast write control</td>
<td>HPC II</td>
<td>Turn on to enable the multi-cast write control on the controller top level. Asserting the multi-cast write control when requesting a write burst causes the write data to be written to all the chip selects in the memory system. Multi-cast write is not supported for registered DIMM interfaces or if the ECC logic is enabled.</td>
</tr>
<tr>
<td>Multiple controller clock sharing</td>
<td>Both</td>
<td>This option is only available in SOPC Builder Flow. Turn on to allow one controller to use the Avalon clock from another controller in the system that has a compatible PLL. This option allows you to create SOPC Builder systems that have two or more memory controllers that are synchronous to your master logic.</td>
</tr>
<tr>
<td>Local interface protocol</td>
<td>HPC</td>
<td>Specifies the local side interface between the user logic and the memory controller. The Avalon-MM interface allows you to easily connect to other Avalon-MM peripherals. The HPC II architecture supports only the Avalon-MM interface.</td>
</tr>
</tbody>
</table>
After setting the parameters for the MegaCore function, you can now integrate the MegaCore function variation into your design, and compile and simulate your design. The following sections detail the steps you need to perform to compile and simulate your design:

- Compile the Design
- Simulate the Design

## Compile the Design

Figure 4–1 shows the top-level view of the Altera high-performance controller design as an example of how your final design looks after you integrate the controller and the user logic.

![High-Performance Controller System-Level Diagram](image)

**Figure 4–1.** High-Performance Controller System-Level Diagram

### Note to Figure 4–1:

(1) When you choose **Instantiate DLL Externally**, DLL is instantiated outside the controller.

Before compiling a design with the ALTMEMPHY variation, you must edit some project settings, include the `.sdc` file, and make I/O assignments. I/O assignments include I/O standard, pin location, and other assignments, such as termination and drive strength settings. Some of these tasks are listed at the ALTMEMPHY Generation window. For most systems, Altera recommends that you use the Advanced I/O Timing feature by using the Board Trace Model command in the Quartus II software to set the termination and output pin loads for the device.
To compile the example top-level file in the Quartus II software and perform post-compilation timing analysis, perform the following steps:

1. Set up the TimeQuest timing analyzer:
   a. On the Assignments menu, click Timing Analysis Settings, select Use TimeQuest Timing Analyzer during compilation, and click OK.
   b. Add the Synopsys Design Constraints (.sdc) file, `<variation name>_phy_ddr_timing.sdc`, to your project. On the Project menu, click Add/Remove Files in Project and browse to select the file.
   c. Add the .sdc file for the example top-level design, `<variation name>_example_top.sdc`, to your project. This file is only required if you are using the example as the top-level design.

2. You can either use the `<variation name>_pin_assignments.tcl` or the `<variation name>.ppf` file to apply the I/O assignments generated by the MegaWizard Plug-In Manager. Using the .ppf file and the Pin Planner gives you the extra flexibility to add a prefix to your memory interface pin names. You can edit the assignments either in the Assignment Editor or Pin Planner. Use one of the following procedures to specify the I/O standard assignments for pins:
   - If you have a single SDRAM interface, and your top-level pins have default naming shown in the example top-level file, run `<variation name>_pin_assignments.tcl`.
   - Or
   - If your design contains pin names that do not match the design, edit the `<variation name>_pin_assignments.tcl` file before you run the script. To edit the .tcl file, perform the following steps:
     a. Open `<variation name>_pin_assignments.tcl` file.
     b. Based on the flow you are using, set the `sopc_mode` value to Yes or No.
        - SOPC Builder System flow:
          if {![info exists sopc_mode]} {set sopc_mode YES}
        - MegaWizard Plug-In Manager flow:
          if {![info exists sopc_mode]} {set sopc_mode NO}
     c. Type your preferred prefix in the `pin_prefix` variable. For example, to add the prefix `my_mem`, do the following:
       ```tcl
       if {![info exists set_prefix]}{set pin_prefix “my_mem_”}
       ```
       After setting the prefix, the pin names are expanded as shown in the following:
       - SOPC Builder System flow:
         ```tcl
         my_mem_cs_n_from_the_<your instance name>
         ```
       - MegaWizard Plug-In Manager flow:
         ```tcl
         my_mem_cs_n[0]
         ```
If your top-level design does not use single bit bus notation for the single-bit memory interface signals (for example, `mem_dqs` rather than `mem_dqs[0]`), in the Tcl script you should change `set single_bit {[0]}` to `set single_bit {}`.

or

Alternatively, to change the pin names that do not match the design, you can add a prefix to your pin names by performing the following steps:

a. On the Assignments menu, click Pin Planner.

b. On the Edit menu, click Create/Import Megafuntion.

c. Select Import an existing custom megafuntion and navigate to `<variation name>.ppf`.

d. Type the prefix you want to use in Instance name. For example, change `mem_addr` to `core1_mem_addr`.

3. Set the top-level entity to the top-level design.

a. On the File menu, click Open.

b. Browse to your SOPC Builder system top-level design or `<variation name>_example_top` if you are using MegaWizard Plug-In Manager, and click Open.

c. On the Project menu, click Set as Top-Level Entity.

4. Assign the DQ and DQS pin locations.

a. You should assign pin locations to the pins in your design, so the Quartus II software can perform fitting and timing analysis correctly.

b. Use either the Pin Planner or Assignment Editor to assign the clock source pin manually. Also choose which DQS pin groups should be used by assigning each DQS pin to the required pin. The Quartus II Fitter then automatically places the respective DQ signals onto suitable DQ pins within each group.

To avoid no-fit errors when you compile your design, ensure that you place the `mem_clk` pins to the same edge as the `mem_dq` and `mem_dqs` pins, and set an appropriate I/O standard for the non-memory interfaces, such as the clock source and the reset inputs, when assigning pins in your design. For example, for DDR3 SDRAM select 1.5 V. Also select in which bank or side of the device you want the Quartus II software to place them.

The ×4 DIMM has the following mapping between DQS and DQ pins:

- DQS[0] maps to DQ[3:0]
- DQS[10] maps to DQ[15:12]

The DQS pin index in other ×4 DIMM configurations typically increases sequentially with the DQ pin index (DQS[0]: DQ[3:0]; DQS[1]: DQ[7:4]; DQS[2]: DQ[11:8])
5. For Stratix III and Stratix IV designs, if you are using advanced I/O timing, specify board trace models in the **Device & Pin Options** dialog box. If you are using any other device and not using advanced I/O timing, specify the output pin loading for all memory interface pins.

6. Select your required I/O driver strength (derived from your board simulation) to ensure that you correctly drive each signal or ODT setting and do not suffer from overshoot or undershoot.

7. To compile the design, on the Processing menu, click **Start Compilation**. After you have compiled the example top-level file, you can perform RTL simulation or program your targeted Altera device to verify the example top-level file in hardware.

**Simulate the Design**

During system generation, SOPC Builder optionally generates a simulation model and testbench for the entire system, which you can use to easily simulate your system in any of Altera’s supported simulation tools. The MegaWizard also generates a set of ModelSim® Tcl scripts and macros that you can use to compile the testbench, IP functional simulation models, and plain-text RTL design files that describe your system in the ModelSim simulation software (refer to “Generated Files” on page 2–6).

For more information about simulating SOPC Builder systems, refer to volume 4 of the *Quartus II Handbook* and *AN 351: Simulating Nios II Embedded Processor Designs*. For more information about simulation, refer to the *Simulation* section in volume 4 of the *External Memory Interface Handbook*. For more information about how to include your board simulation results in the Quartus II software and how to assign pins using pin planners, refer to *DDR, DDR2, and DDR3 Design Tutorials* section in volume 6 of the *External Memory Interface Handbook*.

In ALTMEMPHY variations for DDR3 SDRAM with leveling and without leveling interfaces, you have the following three simulation options:

- **Skip calibration**—Performs a static setup of the ALTMEMPHY megafunction to skip calibration and go straight into user mode.

  Available for ×4 and ×8 DDR3 SDRAM. Skip calibration simulation is supported for 300 MHz through 533 MHz. There is no calibration in this simulation mode. As no phase calibration is performed, there must be no delays in the testbench.

  The ALTMEMPHY megafunction is statically configured to provide the correct write and read latencies. Skip calibration provides the fastest simulation time for DDR3 SDRAM interfaces. Use the generated or vendor DDR3 SDRAM simulation models for this simulation option.

  Skip calibration simulation between 300 MHz and 400 MHz supports CAS latency of 6 and a CAS write latency of 5. Skip calibration simulation between 400 MHz and 533 MHz supports CAS latency of 7 and a CAS write latency of 6.
Quick calibration—Performs a calibration on a single pin and chip select.
Available for ×4 and ×8 DDR3 SDRAM. In quick calibration simulation mode, the sequencer only does clock cycle calibration. So there must be no delays (DDR3 DIMM modeling for example) in the testbench, because no phase calibration is performed. Quick calibration mode can be used between 300 MHz and 533 MHz. Both the generated or vendor DDR3 SDRAM simulation models support burst length on-the-fly changes during the calibration sequence.

Full calibration—Across all pins and chip selects. This option allows for longer simulation time.
Available for ×4 and ×8 DDR3 SDRAM between 300 MHz and 533 MHz. You cannot use the wizard-generated memory model, if you select Full Calibration. You must use a memory-vendor provided memory model that supports write leveling calibration.

Simulating Using NativeLink
To set up simulation in the Quartus II software using NativeLink for the DDR3 high-performance controllers (HPC and HPC II), perform the following steps:
1. Create a custom variation with an IP functional simulation model, refer to step 4 in the “Specify Parameters” section on page 2–4.
2. Set the top-level entity to the example project.
   a. On the File menu, click Open.
   b. Browse to <variation name>_example_top and click Open.
   c. On the Project menu, click Set as Top-Level Entity.
3. Set up the Quartus II NativeLink.
   a. On the Assignments menu, click Settings. In the Category list, expand EDA Tool Settings and click Simulation.
   b. From the Tool name list, click on your preferred simulator.
   c. In NativeLink settings, select Compile test bench and click Test Benches.
   d. Click New at the Test Benches to create a testbench.
4. In the **New Test Bench Settings** dialog box, do the following:
   a. Enter a name for the **Test bench name**.
   b. In **Top level module in test bench**, enter the name of the automatically generated testbench, `<variation name>_example_top_tb`.
   c. In **Design instance in test bench**, enter the name of the top-level instance, `dut`.
   d. Under **Simulation period**, set **End simulation at** to 600 µs.
   e. Add the testbench files and automatically-generated memory model files. In the **File name** field, browse to the location of the memory model and the testbench, click **Open** and then click **Add**. The testbench is `<variation name>_example_top_tb.v`; memory model is `<variation name>_mem_model.v`.

   ![Note] The auto generated generic SDRAM model may be used as a placeholder for a specific memory vendor supplied model.

   f. Select the files and click **OK**.

5. On the **Processing** menu, point to **Start** and click **Start Analysis & Elaboration** to start analysis.

6. On the **Tools** menu, point to **Run EDA Simulation Tool** and click **EDA RTL Simulation**.

   ![Note] Ensure that the Quartus II EDA Tool Options are configured correctly for your simulation environment. On the Tools menu, click **Options**. In the **Category** list, click **EDA Tool Options** and verify the locations of the executable files.

   ![Note] If your Quartus II project appears to be configured correctly but the example testbench still fails, check the known issues on the Knowledge Database before filing a service request.
Chapter 4: Compile and Simulate

Simulate the Design

IP Functional Simulations

For VHDL simulations with IP functional simulation models, perform the following steps:

1. Create a directory in the `<project directory>	estbench` directory.
2. Launch your simulation tool from this directory and create the following libraries:
   - altera_mf
   - lpm
   - sgate
   - `<device name>`
   - altera
   - ALTGXB
   - `<device name>_hssi`
   - auk_ddr3_hp_user_lib
3. Compile the files into the appropriate library (AFI mode) as shown in Table 4–1. The files are in VHDL93 format.

Table 4–1. Files to Compile—VHDL IP Functional Simulation Models (Part 1 of 2)

<table>
<thead>
<tr>
<th>Library</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>altera_mf</td>
<td><code>&lt;QUARTUS ROOTDIR&gt;/eda/sim_lib/altera_mf.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;QUARTUS ROOTDIR&gt;/eda/sim_lib/altera_mf_components.vhd</code></td>
</tr>
<tr>
<td>lpm</td>
<td><code>/eda/sim_lib/220pack.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>/eda/sim_lib/220model.vhd</code></td>
</tr>
<tr>
<td>sgate</td>
<td><code>/eda/sim_lib/sgate_pack.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>/eda/sim_lib/sgate.vhd</code></td>
</tr>
<tr>
<td><code>&lt;device name&gt;</code></td>
<td><code>/eda/sim_lib/&lt;device name&gt;_atoms.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>/eda/sim_lib/&lt;device name&gt;_components.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>/eda/sim_lib/&lt;device name&gt;_hssi_atoms.vhd</code></td>
</tr>
<tr>
<td>altera</td>
<td><code>/eda/sim_lib/altera_primitives_components.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>/eda/sim_lib/altera_primitives.vhd</code></td>
</tr>
<tr>
<td>ALTGXB (1)</td>
<td><code>&lt;device name&gt;_mf.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;device name&gt;_mf_components.vhd</code></td>
</tr>
<tr>
<td><code>&lt;device name&gt;_hssi</code> (1)</td>
<td><code>&lt;device name&gt;_hssi_components.vhd</code></td>
</tr>
<tr>
<td></td>
<td><code>&lt;device name&gt;_hssi_atoms.vhd</code></td>
</tr>
</tbody>
</table>
If you are targeting Stratix IV devices, you need both the Stratix IV and Stratix III files (*stratixiv_atoms* and *stratixiii_atoms*) to simulate in your simulator, unless you are using NativeLink.

4. Load the testbench in your simulator with the timestep set to picoseconds.

For Verilog HDL simulations with IP functional simulation models, perform the following steps:

1. Create a directory in the `<project directory>	estbench` directory.
2. Launch your simulation tool from this directory and create the following libraries:
   - `altera_mf_ver`
   - `lpm_ver`
   - `sgate_ver`
   - `<device name>_ver`
   - `altera_ver`
   - `ALTGXB_ver`
   - `<device name>_hssi_ver`
   - `auk_ddr3_hp_user_lib`
3. Compile the files into the appropriate library (AFI mode) as shown in Table 4–2 on page 4–9.

### Table 4–1. Files to Compile—VHDL IP Functional Simulation Models (Part 2 of 2)

If you are targeting Stratix IV devices, you need both the Stratix IV and Stratix III files (stratixiv_atoms and stratixiii_atoms) to simulate in your simulator, unless you are using NativeLink.

Configure your simulator to use transport delays, a timestep of picoseconds, and to include all the libraries in Table 4–2.

5. Functional Description—ALTMEMPHY

The ALTMEMPHY megafunction creates the datapath between the memory device and the memory controller, and user logic in various Altera devices. The ALTMEMPHY megafunction GUI helps you configure multiple variations of a memory interface. You can then connect the ALTMEMPHY megafunction variation with either a user-designed controller or with an Altera high-performance controller. In addition, the ALTMEMPHY megafunction and the Altera high-performance controllers are available for half-rate DDR3 SDRAM interfaces.

If the ALTMEMPHY megafunction does not meet your requirements, you can also create your own memory interface datapath using the ALTDLL and ALTDQ_DQS megafunctions, available in the Quartus II software. However, you are then responsible for every aspect of the interface, including timing analysis and debugging.

This chapter describes the DDR3 SDRAM ALTMEMPHY megafunction, which uses AFI as the interface between the PHY and the controller.

**Block Description**

Figure 5–1 on page 5–2 shows the major blocks of the ALTMEMPHY megafunction and how it interfaces with the external memory device and the controller. The ALTPLL megafuction is instantiated inside the ALTMEMPHY megafunction, so that you do not need to generate the clock to any of the ALTMEMPHY blocks.
The ALTMEMPHY megafunction comprises the following blocks:

- Write datapath
- Address and command datapath
- Clock and reset management, including DLL and PLL
- Sequencer for calibration
- Read datapath

The major advantage of the ALTMEMPHY megafunction is that it supports an initial calibration sequence to remove process variations in both the Altera device and the memory device. In Arria series and Stratix series devices, the DDR3 SDRAM ALTMEMPHY calibration process centers the resynchronization clock phase into the middle of the captured data valid window to maximize the resynchronization setup and hold margin. During the user operation, the VT tracking mechanism eliminates the effects of VT variations on resynchronization timing margin.
Calibration

This section describes the calibration that the sequencer performs, to find the optimal clock phase for the memory interface. The calibration sequence is similar across families, but different depending on the following target memory interface:

- DDR3 SDRAM (without leveling)
- DDR3 SDRAM (with leveling)

**DDR3 SDRAM (without leveling)**

The calibration process for the DDR3 SDRAM without leveling PHY includes the following steps:

- “Step 1: Memory Device Initialization”
- “Step 2: Write Training Patterns”
- “Step 3: Read Resynchronization (Capture) Clock Phase”
- “Step 4: Read and Write Datapath Timing”
- “Step 5: Address and Command Clock Cycle”
- “Step 6: Postamble”
- “Step 7: Prepare for User Mode”

For detailed information on each calibration step, refer to the Debugging section in volume 4 of the *External Memory Interface Handbook*. 
Figure 5–2 shows the calibration flow.

Figure 5–2. Calibration Flow—Without Leveling

Step 1: Memory Device Initialization

This step initializes the memory device according to the DDR3 SDRAM specification. The initialization procedure includes resetting the memory device, specifying the mode registers and memory device ODT setting, and initializing the memory device DLL. Calibration requires overriding some of the user-specified mode register settings, which are reverted in “Step 7: Prepare for User Mode”.

Step 2: Write Training Patterns

In this step, a pattern is written to the memory to be read in later calibration stages. The matched trace lengths to DDR3 SDRAM devices mean that after memory initialization, write capture works. The pattern is 0x30F5 and comprises the following separately written patterns:

- All 0: ‘b0000 - DDIO high and low bits held at 0
- All 1: ‘b1111 - DDIO high and low bits held at 1
- Toggle: ‘b0101 - DDIO high bits held at 0 and DDIO low bits held at 1
Mixed: ‘b0011 - DDIO high and low bits have to toggle

Loading a mixed pattern is complex, because write latency is unknown at this time. Two sets of write and read operations (single pin resynchronization (capture) clock phase sweeps, (“Step 3: Read Resynchronization (Capture) Clock Phase”) are required to accurately write the mixed pattern to memory.

Memory bank 0, row 0, and column addresses 0 to 55 store calibration data.

**Step 3: Read Resynchronization (Capture) Clock Phase**

This step adjusts the phase of the resynchronization clock to determine the optimal phase that gives the greatest margin. The resynchronization clock captures the outputs of DQS capture registers (DQS is the capture clock).

To correctly calibrate resynchronization clock phase, based on a data valid window, requires 720° of phase sweep.

**Step 4: Read and Write Datapath Timing**

In this step, the sequencer calculates the calibrated write latency (the $ctl_wlat$ signal) between write commands and write data. The sequencer also calculates the calibrated read latency (the $ctl_rlat$ signal) between the issue of a read command and valid read data. Both read and write latencies are output to a controller. In addition to advertising the read latency, the sequencer calibrates a read data valid signal to the delay between a controller issuing a read command and read data returning. The controller can use the read data valid signal in place of the advertised read latency, to determine when the read data is valid.

**Step 5: Address and Command Clock Cycle**

This step optionally adds an additional memory clock cycle of delay from the address and command path. This delay aligns the write data to the memory commands given in the controller clock domain. If you require this delay, this step reruns the calibration (“Step 2: Write Training Patterns” to “Step 4: Read and Write Datapath Timing”) to calibrate to the new setting.

**Step 6: Postamble**

This step sets the correct clock cycle for the postamble path. The aim of the postamble path is to eliminate false DQ data capture because of postamble glitches on the DQS signal, through an override on DQS. This step ensures the correct clock cycle timing of the postamble enable (override) signal.

**Step 7: Prepare for User Mode**

In this step, the PHY applies user mode register settings and performs periodic VT tracking.

**VT Tracking**

VT tracking is a background process that tracks the voltage and temperature variations to maintain the relationship between the resynchronization or capture clock and the data valid window that are achieved at calibration.

When the data calibration phase is completed, the sequencer issues the mimic calibration sequence every 128 ms.
During initial calibration, the mimic path is sampled using the measure clock (measure_clk has a _1x or _2x suffix, depending whether the ALTMEMPHY is a full-rate or half-rate design). The sampled value is then stored by the sequencer. After a sample value is stored, the sequencer uses the PLL reconfiguration logic to change the phase of the measure clock by one VCO phase tap. The control sequencer then stores the sampled value for the new mimic path clock phase. This sequence continues until all mimic path clock phase steps are swept. After the control sequencer stores all the mimic path sample values, it calculates the phase which corresponds to the center of the high period of the mimic path waveform. This reference mimic path sampling phase is used during the VT tracking phase.

In user mode, the sequencer periodically performs a tracking operation as defined in the tracking calibration description. At the end of the tracking calibration operation, the sequencer compares the most recent optimum tracking phase against the reference sampling phase. If the sampling phases do not match, the mimic path delays have changed due to voltage and temperature variations.

When the sequencer detects that the mimic path reference and most recent sampling phases do not match, the sequencer uses the PLL reconfiguration logic to change the phase of the resynchronization clock by the VCO taps in the same direction. This allows the tracking process to maintain the near-optimum capture clock phase setup during data tracking calibration as voltage and temperature vary over time.

The relationship between the resynchronization or capture clock and the data valid window is maintained by measuring the mimic path variations due to the VT variations and applying the same variation to the resynchronization clock.

**Mimic Path**

The mimic path mimics the FPGA portion of the elements of the round-trip delay, which enables the calibration sequencer to track delay variation due to VT changes during the memory read and write transactions without interrupting the operation of the ALTMEMPHY megafunction.

The assumption made about the mimic path is that the VT variation on the round trip delay path that resides outside of the FPGA is accounted for in the board skew and memory parameters entered in the MegaWizard Plug-In Manager. For the write direction, any VT variation in the memory devices is accounted for by timing analysis.

Figure 5–3 shows the mimic path in Stratix II and Stratix II GX devices, which mimics the delay of the clock outputs to the memory as far as the pads of the FPGA and the delay from the input DQS pads to a register in the FPGA core. During the tracking operation, the sequencer measures the delay of the mimic path by varying the phase of the measure clock. Any change in the delay of the mimic path indicates a corresponding change in the round-trip delay, and a corresponding adjustment is made to the phase of the resynchronization or capture clock.

The mimic path in Arria II GX, Stratix III and Stratix IV devices is similar to Figure 5–3. The only difference is that the mem_clk[0] pin is generated by DDIO register; mem_clk_n[0] is generated by signal splitter.
DDDR3 SDRAM (with leveling)

The calibration process for the DDR3 SDRAM PHY (with leveling) assumes an interface in an unbuffered DIMM format, where the clock uses a fly-by termination, refer to Figure 5–4.

ALTMEMPHY does not support DDR3 SDRAM RDIMM.

With fly-by termination, each DDR3 SDRAM device on the DIMM sees the CK/CKn edges at different times. Therefore, the sequencer must adjust the clock to launch the DQS/DQSn and DQ signals so that it is appropriately aligned to the CK/CKn signals on each device.

The DDR3 SDRAM leveling sequencer during calibration writes to the following locations:

- Banks 0, 1, and 2
Row 0
All columns

Bank 0 is written to for the block training pattern and clock cycle calibration (DQ_1T and AC_1T). Bank 1 is written to for write deskew (DQ). Bank 2 is written to for write deskew (DM). For each bank, only row 0 is accessed. The number of columns accessed can vary, but you should avoid writing to all columns in these banks and row 0.

The calibration process for the DDR3 SDRAM PHY with leveling includes the following steps:

- “Step 1: Memory Device Initialization”
- “Step 2: Write Leveling”
- “Step 3: Write Training Patterns”
- “Step 4: Read Resynchronization”
- “Step 5: Address and Command Path Clock Cycle”
- “Step 7: Write Clock Path Setup”
- “Step 8: Prepare for User Mode”

No steps can be bypassed. Therefore, even if you are using only one DDR3 SDRAM DIMM, all the calibration sequences are performed.

The calibration assumes that the skew for all the DQS launch times is one clock period maximum.

The VT tracking portion of the DDR3 SDRAM sequencer is similar to that of the DDR or DDR2 SDRAM sequencer.
Step 1: Memory Device Initialization

This step initializes the memory device per the DDR3 SDRAM specification. The initialization procedure includes resetting the memory device, specifying the mode registers and memory device ODT setting, and initializing the memory device DLL. Some of these settings may be different to those you set; however, these are changed to the correct values (at the end of calibration) in “Step 8: Prepare for User Mode”.
On multiple rank DDR3 SDRAM DIMMs, address signals are routed differently to each rank (referred to in the JEDEC specification as address mirroring). Ranks with address mirroring can be specified in the memory Preset Editor in the Mirror addressing field.

RTL simulation of address mirroring is not currently supported by the memory model generated with the example testbench. To simulate successfully, you need a DDR3 DIMM model compatible with address mirroring.

**Step 2: Write Leveling**

This step aligns the DQS edge with the CK edge at each memory device in the DIMM, which includes calibrating the write-leveling delay chains, programmable output delay chain, and using the tDQSS-margin register in the DDR3 SDRAM to monitor the relationship between the DQS edge and the CK edge. The calibration uses one DQ pin per DQS group (prime DQ) for write leveling calibration.

**Step 3: Write Training Patterns**

This step only allows you to write a pattern to be read later to calibrate the read path. To satisfy the DDR3 SDRAM JEDEC specification, DQ is held constant during this step to ensure that there are no DQ timing violations. The DQS is then toggled, followed by a write command. A combination of burst length of four and burst length of eight operations ensure that it is correctly written. There are three different DQ patterns written in this step:

- All 0: 0×00, 0×00, 0×00, 0×00, 0×00, 0×00, 0×00, 0×00
- All 1: 0×FF, 0×FF, 0×FF, 0×FF, 0×FF, 0×FF, 0×FF, 0×FF
- Mixed: 0×00, 0×00, 0×00, 0×00, 0×FF, 0×FF, 0×FF, 0×FF

**Step 4: Read Resynchronization**

This step adjusts the phase of the resynchronization clock to determine the optimal clock phase that gives the most margin, similar to the resynchronization calibration done in DDR and DDR2 SDRAM PHYs.

This step uses the read-leveling delay chain and the PLL reconfigurable clock output to adjust the resynchronization clock phase for each DQS group.

**Step 5: Address and Command Path Clock Cycle**

This step word-aligns the read data within and between each DQS group so that data can be presented in one clock cycle.

**Step 6: Postamble**

This step sets the correct clock cycle and clock phase shift for the postamble path. With the read resynchronization process, the sequencer can approximate when the postamble enable must be asserted. The sequencer then tries to incrementally assert the postamble enable signal (per DQS group) earlier until there is a read failure. This ensures the optimal clock phase for the system’s postamble enable signal.
Step 7: Write Clock Path Setup

After the sequencer has the optimum settings for read capture and resynchronization setup, the sequencer calibrates the write datapath by configuring the alignment registers in the IOE and the DQ and DQS phase shift per DQS group. This step ensures that the write data can be presented on the same clock cycle from controller, but launched at the appropriate time for each DQS group to the DDR3 SDRAM memory devices.

Step 8: Prepare for User Mode

In this step, the sequencer sends the calibrated write latency between command and write data (the ctl_wlat signal) to the controller. The PHY then applies user mode register settings and performs setup for periodic VT tracking.

Deskew is automatically enabled above 400.000 MHz.

VT Tracking

For information on VT tracking for DDR3 SDRAM with leveling, refer to “VT Tracking” on page 5–5.

Mimic Path

For information on mimic path for DDR3 SDRAM with leveling, refer to “Mimic Path” on page 5–6.

Address and Command Datapath

This topic discusses the address and command datapath.

Arria II GX Devices

The address and command datapath is responsible for taking the address and command outputs from the controller and converting them from half-rate clock to full-rate clock. Two types of addressing are possible:

- 1T (full rate)—The duration of the address and command is a single memory clock cycle (mem_clk_2x, Figure 5–6). This applies to all address and command signals in full-rate designs or mem_cs_n, memcke, and mem_odt signals in half-rate designs.

- 2T (half rate)—The duration of the address and command is two memory clock cycles. For half-rate designs, the ALTMEMPHY megafuinction supports only a burst size of four, which means the burst size on the local interface is always set to 1. The size of the data is 4n-bits wide on the local side and is n-bits wide on the memory side. To transfer all the 4n-bits at the double data rate, two memory-clock cycles are required. The new address and command can be issued to memory every two clock cycles. This scheme applies to all address and command signals, except for mem_cs_n, memcke, and mem_odt signals in half-rate mode.

Refer to Table 5–1 on page 5–14 to see the frequency relationship of mem_clk_2x with the rest of the clocks.
Figure 5–6 shows a 1T chip select signal (mem_cs_n), which is active low, and disables the command in the memory device. All commands are masked when the chip-select signal is inactive. The mem_cs_n signal is considered part of the command code.

**Figure 5–6.** Arria II GX Address and Command Datapath

The command interface is made up of the signals mem_ras_n, mem_cas_n, mem_we_n, mem_cs_n, mem_cke, and mem_odt.

The waveform in Figure 5–6 shows a NOP command followed by five back-to-back write commands. The following sequence corresponds with the numbered items in Figure 5–6.

1. The commands are asserted either on the rising edge of ac_clk_2x. The ac_clk_2x clock is derived from either mem_clk_2x (0° or 180° phase shift) or write_clk_2x (270°), or the inverted variations of those two clocks (for 180° and 90° phase shifts). This depends on the setting of the address and command clock in the ALTMEMPHY MegaWizard Plug-In Manager. Refer to “Address and Command Datapath” on page 5–11 for illustrations of this clock in relation to the mem_clk_2x or write_clk_2x signals.

2. All address and command signals (except for mem_cs_n, mem_cke, and mem_odt signals) remain asserted on the bus for two clock cycles, allowing sufficient time for the signals to settle.

3. The mem_cs_n, mem_cke, and mem_odt signals are asserted during the second cycle of the address/command phase. By asserting the chip-select signal in alternative cycles, back-to-back read or write commands can be issued.

4. The address is incremented every other ac_clk_2x cycle.

- The ac_clk_2x clock is derived from either mem_clk_2x (when you choose 0° or 180° phase shift) or write_clk_2x (when you choose 90° or 270° phase shift).

- The address and command clock can be 0, 90, 180, or 270° from the system clock.
Stratix III and Stratix IV Devices

The address and command clock is one of the PLL dedicated clock outputs whose phase can be adjusted to meet the setup and hold requirements of the memory clock. The Stratix III address and command clock, ac_clk_1x, is half rate. The command and address pins use the DDIO output circuitry to launch commands from either the rising or falling edges of the clock. The chip select (mem_cs_n), clock enable (mem_cke), and mem_odt pins are enabled on one memory clock cycle basis and can be launched from either the rising or falling edge of the ac_clk_1x signal, while the address and other command pins are enabled for two memory clock cycles and can also be launched from either the rising or falling edge of ac_clk_1x signal. It is the responsibility of the controller to maintain the relative timing of the signals.

The DDR3 SDRAM PHY generates a write latency output ctl_wlat that indicates the number of ctl_clk cycles between the write command being issued, ctl_cs_n asserted, and ctl_dqs_burst being asserted. This ctl_wlat signal is only valid when calibration has been successfully completed by the ALTMEMPHY sequencer and does not change at any point during normal user mode operation. The value on ctl_wlat includes the effect of the following as determined during calibration:

- CAS write latency (CWL)
- Additive latency
- Datapath latencies and relative phases
- Board and memory module layout
- Address and command path latency and 1T register setting which is dynamically set up to take into account any leveling effects

Clock and Reset Management

The clocking and reset block is responsible for clock generation, reset management, and phase shifting of clocks. It also has control of clock network types that route the clocks, which is handled in the <variation_name>_alt_mem_phy_clk_reset module in the <variation_name>_alt_mem_phy.v/vhd file.

Clock Management

The clock management feature allows the ALTMEMPHY megafunction to work out the optimum phase during calibration, and to track voltage and temperature variation relies on phase shifting the clocks relative to each other.

Certain clocks require phase shifting during the ALTMEMPHY megafunction operation.

You can implement clock management circuitry using PLLs and DLLs.

The ALTMEMPHY MegaWizard Plug-In Manager automatically generates an ALTP PLL megafuction instance. The ALTP PLL megafuction generates the different clock frequencies and relevant phases used within the ALTMEMPHY megafuction.

The available device families have different PLL capabilities. The minimum PHY requirement is to have 16 phases of the highest frequency clock. The PLL uses With No Compensation to minimize jitter. Changing the PLL compensation to a different operation mode may result in inaccurate timing results.
The input clock to the PLL does not have any other fan-out to the PHY, so you do not have to use a global clock resource for the path between the clock input pin to the PLL. You must use the PLL located in the same device quadrant or side as the memory interface and the corresponding clock input pin for that PLL, to ensure optimal performance and accurate timing results from the Quartus II software.

You must choose a PLL and PLL input clock pin that are located on the same side of the device as the memory interface to ensure minimal jitter. Also, ensure that the input clock to the PLL is stable before the PLL locks; if it is not stable, you must perform a manual PLL reset (by driving the *global_reset_n* signal low) and relock the PLL to ensure that the phase relationship between all PLL outputs is properly set.

If the design cascades PLLs, the source (upstream) PLL should have a low-bandwidth setting, and the destination (downstream) PLL should have a high-bandwidth setting. Adjacent PLLs cascading is recommended to reduce clock jitter.

Cross-device cascading PLLs are only allowed in Stratix III devices with the following conditions:

- Upstream PLL: 0.59 MHz =< upstream PLL bandwidth < 1 MHz. The upstream PLL should use the With No Compensation operation mode.
- Downstream PLL: downstream PLL bandwidth > 2 MHz.

For more information about the VCO frequency range and the available phase shifts, refer to the Clock Networks and PLLs chapter in the respective device family handbook.

Table 5–1 shows the clock outputs that Arria II GX devices use.

</tbody>
</table>
The phase-shift inputs on the PLL perform the PLL reconfiguration. The PLL reconfiguration megafunction is not required.

**Reset Management**

Figure 5–8 and Figure 5–9 show the main features of the reset management block for the DDR3 SDRAM PHY. You can use the \texttt{pll\_ref\_clk} input to feed the optional \texttt{reset\_request\_n} edge detect and reset counter module. However, this requires the \texttt{pll\_ref\_clk} signal to use a global clock network resource.

There is a unique reset metastability protection circuit for the clock divider circuit because the \texttt{phy\_clk} domain reset metastability protection registers have fan-in from the \texttt{soft\_reset\_n} input so these registers cannot be used.

**Notes to Table 5–2:**

(1) In full-rate designs a \_1x clock may run at full-rate clock rate.

(2) This clock should be of the same clock network clock as the \texttt{resync\_clk\_lx} clock.

The phase-shift inputs on the PLL perform the PLL reconfiguration. The PLL reconfiguration megafunction is not required.
Read Datapath

This topic discusses the read datapath.

**Arria II GX Devices**

The read datapath logic captures data sent by the memory device and subsequently aligns the data back to the system clock domain. The read datapath for DDR3 SDRAM consists of the following three main blocks:

- Data capture
- Data resynchronization
- Data demultiplexing and alignment

As the DQS/DQS\(\overline{n}\) signal is not continuous, the PHY also has postamble protection logic to ensure that any glitches on the DQS input signals at the end of the read postamble time do not cause erroneous data to be captured as a result of postamble glitches.
Figure 5–9 shows the order of the functions performed by the read datapath and the frequency at which the read data is handled.

**Figure 5–9. DDR3 SDRAM Read Datapath in Arria II GX Devices**

---

**Data Capture and Resynchronization**

The data capture and resynchronization registers for Arria II GX devices are implemented in the I/O element (IOE) to achieve maximum performance. Data capture and resynchronization is the process of capturing the read data (DQ) with the DQS/DQSn strobes and resynchronizing the captured data to an internal free-running full-rate clock supplied by the enhanced PLL. The resynchronization clock is an intermediate clock whose phase shift is determined during the calibration stage. The captured data \(rdata_p\) and \(rdata_n\) is synchronized to the resynchronization clock \(resync_clk_2x\), refer to Figure 5–9. For Arria II GX devices, the ALTMEMPHY instances an ALTDQ_DQS megafunction that instantiates the required IOEs for all the DQ and DQS pins.

**Data Demultiplexing**

Data demultiplexing is the process of changing the SDR data into HDR data. Data demultiplexing is required to bring the frequency of the resynchronized data down to the frequency of the system clock, so that data from the external memory device can ultimately be brought into the FPGA controller clock domain. Before data capture, the data is DDR and \(n\)-bit wide. After data capture, the data is SDR and \(2n\)-bit wide. After data demuxing, the data is HDR of width \(4n\)-bits wide. The system clock frequency is half the frequency of the memory clock. Demultiplexing is achieved using a dual-port memory with a \(2n\)-bit wide write-port operating on the resynchronization clock (SDR) and a \(4n\)-bit wide read-port operating on the PHY clock (HDR). The basic principle of operation is that data is written to the memory at the SDR rate and read from the memory at the HDR rate while incrementing the read- and write-address pointers. As the SDR and HDR clocks are generated, the read and write pointers are continuously incremented by the same PLL, and the \(4n\)-bit wide read data follows the \(2n\)-bit wide write data with a constant latency.
Read Data Alignment

Data alignment is the process controlled by the sequencer to ensure the correct captured read data is present in the same half-rate clock cycle at the output of the read data DPRAM. Data alignment is implemented using memory blocks in the core of devices.

Postamble Protection

A dedicated postamble register controls the gating of the shifted DQS signal that clocks the DQ input registers at the end of a read operation. Any glitches on the DQS input signals at the end of the read postamble time do not cause erroneous data to be captured as a result of postamble glitches. The postamble path is also calibrated to determine the correct clock cycle, clock phase shift, and delay chain settings.

Stratix III and Stratix IV Devices

The DDR3 SDRAM controller asserts \texttt{ctl\_doing\_rd} to indicate that a read command is requested. The \texttt{ctl\_doing\_rd} signal is then used for the following purposes:

- Control of the postamble circuit
- Generation of \texttt{ctl\_rdata\_valid} from one bit to two bits
- Dynamic OCT control timing

The DDR3 SDRAM ALTMEMPHY then asserts the \texttt{ctl\_rdata\_valid} signal to indicate that the data on the read data bus is valid. The \texttt{ctl\_rdata\_valid} signal is two bits wide to allow controllers to issue reads and writes that are aligned to either the half-cycle of the half-rate clock.

When calibration is over, the read latency of the PHY (the \texttt{ctl\_rlat} signal) is sent back to the controller to indicate how long it takes in \texttt{ctl\_clk} clock cycles from assertion of the \texttt{ctl\_doing\_read} signal to the valid read data returning on the \texttt{ctl\_rdata} bus. The \texttt{ctl\_rlat} signal is only valid when calibration has successfully completed and never changes values during normal user mode operation.

The read datapath for DDR3 SDRAM consists of two main blocks:

- Read data capture, resynchronization, and demultiplexing (in the \texttt{dp\_io\_siii} module)
- Read data alignment logic (in the \texttt{read\_dp} module) to transfer data from the \texttt{resync\_clk\_2x} (half-rate resynchronization) clock domain to the \texttt{phy\_clk} clock domain.

As the DQS/DQS\textsubscript{n} signal is not continuous, the PHY also has postamble protection logic to ensure that any glitches on the DQS input signals at the end of the read postamble time do not cause erroneous data to be captured as a result of postamble glitches.
Figure 5–10 shows the order of the functions performed by the read datapath and the frequency at which the read data is handled.

**Data Capture, Resynchronization, and Demultiplexing**

The IOE in Stratix III and Stratix IV devices performs the following tasks during read operation:

- Captures the data
- Resynchronizes the captured data from the DQS domain to the resynchronization clock (resync_clk_1x) domain
- Converts the resynchronized data into HDR data

This operation is performed by feeding the resynchronized data into the HDR conversion block within the IOE, which is clocked by the half-rate resynchronization clock (resync_clk_1x). The resync_clk_1x signal is generated from the I/O clock divider module, based on the resync_clk_2x signal from the PLL.

**Read Data Storage Logic**

The read block performs the following two tasks:

- Transfers the captured read data (rdata[n]_1x) from the half-rate resynchronization clock (resync_clk_1x) domain to the half-rate system clock (phy_clk_1x) domain using DPRAM. Resynchronized data from the DPRAM is shown as ram_data_1x.
- Reorders the resynchronized data (ram_rdata_1x) into ctl_mem_rdata, to be presented in the user clock domain in the same clock cycle.
Postamble Protection

A dedicated postamble register controls the gating of the shifted DQS signal that clocks the DQ input registers at the end of a read operation. This ensures that any glitches on the DQS input signals at the end of the read postamble time do not cause erroneous data to be captured as a result of postamble glitches.

The postamble path is also calibrated to determine the correct clock cycle, clock phase shift, and delay chain settings. You can see the process in simulation if you choose Full calibration (long simulation time) mode in the MegaWizard Plug-In Manager.

Write Datapath

This topic discusses the write datapath.

Arria II GX Devices

The write datapath logic efficiently transfers data from the HDR memory controller to DDR3 SDRAM. The write datapath logic consists of:

- DQ and DQ output-enable logic
- DQS/DQSn and DQS/DQSn output-enable logic
- DM logic

The memory controller interface outputs 4n-bit wide data (ctl_wdata[4n]) at half-rate frequency. Figure 5-4 shows that the HDR write data (ctl_wdata[4n]) is clocked by the half-rate clock phy_clk_1x (ctl_clk) and is converted into SDR, which is represented by wdp_wdata_h and wdp_wdata_l and clocked by the full-rate clock write_clk_2x. The DQ IOEs convert 2n SDR bits to n-DDR bits.

Figure 5-11. DDR3 SDRAM Write Datapath in Arria II GX Devices
Stratix III and Stratix IV Devices

The memory controller interface outputs four \( n \)-bit wide data (\( \text{ctl_wdata} \)) at \( \text{phy_clk_1x} \) frequency. The write data is clocked by the system clock \( \text{phy_clk_1x} \) at half-data rate (HDR) and reordered into HDR of width four with \( n \)-bits each, represented in Figure 5–12 by \( \text{wpd_wdata3_1x} \), \( \text{wpd_wdata2_1x} \), \( \text{wpd_wdata1_1x} \), and \( \text{wpd_wdata0_1x} \).

Figure 5–12 shows the reordered or the reordered-and-delayed HDR data is then converted to DDR data within the IOE element using both the half-rate and full-rate clocks.

Figure 5–12. DDR3 SDRAM Write Datapath in Stratix IV and Stratix III Devices

The write datapath DDIO registers are clocked by the \( \text{phy_clk_1x} \) clock. The \( \text{write_clk_2x} \) signal then clocks the alignment registers.

For more information about the I/O structure, refer to the External Memory Interface chapter in the respective device family handbook.

Figure 5–13 shows how the write data, \( \text{ctl_wdata} \) signals should be aligned from the controller during a (half rate, normally aligned) write operation. The PHY then issues the write data as ABCD where \( a \) is the first data to be written to the memory. (ABCD represent two beats of data each.) The \( \text{ctl_wdata_valid} \) signal in Figure 5–13 shows the output enable for the DQ and DM pins.

Figure 5–13. Write Data Alignment from the DDR3 SDRAM Controller
This section describes the ALMEMPHY megafonction signals for DDR3 SDRAM variants. Table 5–3 through Table 5–5 show the signals.

Signals with the prefix `mem_` connect the PHY with the memory device; ports with the prefix `ctl_` connect the PHY with the controller.

The signal lists include the following signal groups:
- I/O interface to the SDRAM devices
- Clocks and resets
- External DLL signals
- User-mode calibration OCT control
- Write data interface
- Read data interface
- Address and command interface
- Calibration control and status interface
- Debug interface

The following section describes the typical modules that are connected to the ALTMEMPHY variation and the port name prefixes each module uses. This section also describes using a custom controller. This section describes the AFI.

The AFI standardizes and simplifies the interface between controller and PHY for all Altera memory designs, thus allowing you to easily interchange your own controller code with Altera’s high-performance controllers. The AFI PHY includes an administration block that configures the memory for calibration and performs necessary mode registers accesses to configure the memory as required (these calibration processes are different). Figure 5–14 shows an overview of the connections between the PHY, the controller, and the memory device.

Altera recommends that you use the AFI for new designs.

For half-rate designs, the address and command signals in the ALTMEMPHY megafuction are asserted for one mem_clk cycle (1T addressing), such that there are two input bits per address and command pin in half-rate designs. If you require a more conservative 2T addressing, drive both input bits (of the address and command signal) identically in half-rate designs.

**Table 5–6. Parameters (Part 2 of 2)**
For DDR3 SDRAM with the AFI, the read and write control signals are on a per-DQS group basis. The controller can calibrate and use a subset of the available DDR3 SDRAM devices. For example, the controller can calibrate and use two devices out of a 64- or 72-bit DIMM for better debugging mechanism.

For half-rate designs, the AFI allows the controller to issue reads and writes that are aligned to either half-cycle of the half-rate phy_clk, which means that the datapaths can support multiple data alignments—word-unaligned and word-aligned writes and reads. Figure 5–15 and Figure 5–16 display the half-rate write operation.

After calibration process is complete, the sequencer sends the write latency in number of clock cycles to the controller.
Figure 5–17 and Figure 5–18 show word-aligned writes and reads. In the following read and write examples the data is written to and read from the same address. In each example, \texttt{ctl_rdata} and \texttt{ctl_wdata} are aligned with controller clock (\texttt{ctl_clk}) cycles. All the data in the bit vector is valid at once. For comparison, refer Figure 5–19 and Figure 5–20 that show the word-unaligned writes and reads.

The \texttt{ctl\_doing\_rd} is represented as a half-rate signal when passed into the PHY. Therefore, the lower half of this bit vector represents one memory clock cycle and the upper half the next memory clock cycle. Figure 5–20 on page 5–38 shows separated word-unaligned reads as an example of two \texttt{ctl\_doing\_rd} bits are different. Therefore, for each x16 device, at least two \texttt{ctl\_doing\_rd} bits need to be driven, and two \texttt{ctl\_rdata\_valid} bits need to be interpreted.

The AFI has the following conventions:

- With the AFI, high and low signals are combined in one signal, so for a single chip select (\texttt{ctl\_cs\_n}) interface, \texttt{ctl\_cs\_n[1:0]}, where location 0 appears on the memory bus on one \texttt{mem\_clk} cycle and location 1 on the next \texttt{mem\_clk} cycle.

  This convention is maintained for all signals so for an 8 bit memory interface, the write data (\texttt{ctl\_wdata}) signal is \texttt{ctl\_wdata[31:0]}, where the first data on the DQ pins is \texttt{ctl\_wdata[7:0]}, then \texttt{ctl\_wdata[15:8]}, then \texttt{ctl\_wdata[23:16]}, then \texttt{ctl\_wdata[31:24]}.

- Word-aligned and word-unaligned reads and writes have the following definitions:
  - Word-aligned for the single chip select is active (low) in location 1 (\texttt{ctl\_cs\_n[1:0]} = 01) when a write occurs. This alignment is the easiest alignment to design with.
  - Word-unaligned is the opposite, so \texttt{ctl\_cs\_n[1:0]} = 10 when a read or write occurs and the other control and data signals are distributed across consecutive \texttt{ctl\_clk} cycles.

  The Altera high-performance controllers use word-aligned data only.

  The timing analysis script does not support word-unaligned reads and writes.

  Word-unaligned reads and writes are only supported on Stratix III and Stratix IV devices.

- Spaced reads and writes have the following definitions:
  - Spaced writes—write commands separated by a gap of one controller clock (\texttt{ctl\_clk}) cycle
  - Spaced reads—read commands separated by a gap of one controller clock (\texttt{ctl\_clk}) cycle
Figure 5–17 through Figure 5–20 assume the following general points:

- The burst length is four. A DDR2 SDRAM is used—the interface timing is identical for DDR3 devices.
- An 8-bit interface with one chip select.
- The data for one controller clock (ctl_clk) cycle represents data for two memory clock (mem_clk) cycles (half-rate interface).
**Notes to Figure 5–17:**

1. To show the even alignment of \( \text{ctl}_{\text{cs}} \_n \), expand the signal (this convention applies for all other signals).

2. The \( \text{ctl}_{\text{dqs}} \_\text{burst} \) must go high one memory clock cycle before \( \text{ctl}_{\text{wdata}} \_\text{valid} \). Compare with the word-unaligned case.

3. The \( \text{ctl}_{\text{wdata}} \_\text{valid} \) indicates the required write latency in the system. The value is determined during calibration and is dependant upon the relative delays in the address and command path and the write datapath in both the PHY and the external DDR SDRAM subsystem. The controller must drive \( \text{ctl}_{\text{cs}} \_n \) and then wait \( \text{ctl}_{\text{wlat}} \) (two in this example) \( \text{ctl}_{\text{clk}} \) before driving \( \text{ctl}_{\text{wdata}} \_\text{valid} \).

4. Observe the ordering of write data \( \text{ctl}_{\text{wdata}} \). Compare this to data on the \( \text{mem}_{\text{dq}} \) signal.

5. In all waveforms a command record is added that combines the memory pins \( \text{ras}_n \_\text{cas}_n \) and \( \text{we}_n \) into the current command that is issued. This command is registered by the memory when chip select \( \text{mem}_{\text{cs}} \_n \) is low. The important commands in the presented waveforms are \( \text{WR} = \text{write}, \text{ACT} = \text{activate} \).
Figure 5–18. Word-Aligned Reads

Notes to Figure 5–18:

1. For AFI, \texttt{ctl\_doing\_rd} is required to be asserted one memory clock cycle before chip select (\texttt{ctl\_cs\_n}) is asserted. In the half-rate \texttt{ctl\_clk} domain, this requirement manifests as the controller driving 11 (as opposed to the 01) on \texttt{ctl\_doing\_rd}.

2. AFI requires that \texttt{ctl\_doing\_rd} is driven for the duration of the read. In this example, it is driven to 11 for two half-rate \texttt{ctl\_clks}, which equates to driving to 1, for the four memory clock cycles of this four-beat burst.

3. The \texttt{ctl\_rdata\_valid} returns 15 (\texttt{ctl\_rlat}) controller clock (\texttt{ctl\_clk}) cycles after \texttt{ctl\_doing\_rd} is asserted. Returned is when the \texttt{ctl\_rdata\_valid} signal is observed at the output of a register within the controller. A controller can use the \texttt{ctl\_rlat} value to determine when to register to returned data, but this is unnecessary as the \texttt{ctl\_rdata\_valid} is provided for the controller to use as an enable when registering read data.

4. Observe the alignment of returned read data with respect to data on the bus.
Figure 5–19 and Figure 5–20 show spaced word-unaligned writes and reads.

**Figure 5–19.** Word-Unaligned Writes

Notes to Figure 5–19:

1. Alternative word-unaligned chip select (ctl_cs_n).
2. As with word-aligned writes, ctl_dqs_burst is asserted one memory clock cycle before ctl_wdata_valid. You can see that the LSB of these two becomes the first value the signal takes in the mem_clk domain. You can see that ctl_dqs_burst has the necessary one mem_clk cycle lead on ctl_wdata_valid.
3. The latency between ctl_cs_n being asserted and ctl_wdata_valid going high is effectively ctl_wlat (in this example, two) controller clock (ctl_clk) cycles. This can be thought of in terms of relative memory clock (mem_clk) cycles, in which case the latency is four mem_clk cycles.
4. Only the upper half is valid. Only the upper half of the write data is used for the first beat of the write, while the lower half of the write data is used in the last beat of the write. These upper bits can be driven to any value in this alignment.
Figure 5–20. Word-Unaligned Reads

Notes to Figure 5–20:

1. Similar to word-aligned reads, `ctl_doing_rd` is asserted one memory clock cycle before chip select (`ctl_cs_n`) is asserted, which for a word-unaligned read is in the previous controller clock (`ctl_clk`) cycle. In this example the `ctl_doing_rd` signal is now spread over three controller clock cycles, the high bits in the sequence '10','11','01','10','11','01' providing the required four memory clock cycles of assertion for `ctl_doing_rd` for the two 4-beat reads in the full-rate memory clock domain, '011110','011110'.

2. The return pattern of `ctl_rdata_valid` is a delayed version of `ctl_doing_rd`. Advertised read latency (`ctl_rlat`) is the number of controller clock cycles delay inserted between `ctl_doing_rd` and `ctl_rdata_valid`.

3. The read data (`ctl_rdata`) is spread over three controller clock cycles and in the pointed to vector only the upper half of the `ctl_rdata` bit vector is valid (denoted by `ctl_rdata_valid`).
Using a Custom Controller

The ALTMEMPHY megafunction can be integrated with your own controller. This section describes the interface requirement and the handshake mechanism for efficient read and write transactions.

Preliminary Steps

Perform the following steps to generate the ALTMEMPHY megafunction:

1. If you are creating a custom DDR3 SDRAM controller, generate the Altera high-performance controller targeting your chosen Altera and memory devices.
2. Compile and verify the timing. This step is optional; refer to “Compile and Simulate” on page 4–1.
3. If targeting a DDR3 SDRAM device, simulate the high-performance controller design so you can determine how to drive the PHY signals using your own controller.
4. Integrate the top-level ALTMEMPHY design with your controller. If you started with the high-performance controller, the PHY variation name is `<controller_name>_phy.v/vhd`. Details about integrating your controller with Altera’s ALTMEMPHY megafunction are described in the following sections.
5. Compile and simulate the whole interface to ensure that you are driving the PHY properly and that your commands are recognized by the memory device.

Design Considerations

This section discuss the important considerations for implementing your own controller with the ALTMEMPHY megafunction. This section describes the design considerations for AFI variants.

Simulating the high-performance controller is useful if you do not know how to drive the PHY signals.

Clocks and Resets

The ALTMEMPHY megafunction automatically generates a PLL instance, but you must still provide the reference clock input (pll_ref_clk) with a clock of the frequency that you specified in the MegaWizard Plug-In Manager. An active-low global reset input is also provided, which you can deassert asynchronously. The clock and reset management logic synchronizes this reset to the appropriate clock domains inside the ALTMEMPHY megafunction.

A clock output, half the memory clock frequency for a half-rate controller, is provided and all inputs and outputs of the ALTMEMPHY megafunction are synchronous to this clock. For AFIs, this signal is called ctl_clk.

There is also an active-low synchronous reset output signal provided, ctl_reset_n. This signal is synchronously de-asserted with respect to the ctl_clk or phy_clk clock domain and it can reset any additional user logic on that clock domain.
Calibration Process Requirements

When the global reset_n is released the ALTMEMPHY handles the initialization and calibration sequence automatically. The sequencer calibrates memory interfaces by issuing reads to multiple ranks of DDR3 SDRAM (multiple chip select). Timing margins decrease as the number of ranks increases. It is impractical to supply one dedicated resynchronization clock for each rank of memory, as it consumes PLL resources for the relatively small benefit of improved timing margin. When calibration is complete ctl_cal_success goes high if successful; ctl_cal_fail goes high if calibration fails. Calibration can be repeated by the controller using the soft_reset_n signal, which when asserted puts the sequencer into a reset state and when released the calibration process begins again.

Other Local Interface Requirements

The memory burst length for DDR3 SDRAM devices can be set at either four or eight; but when using the Altera high-performance controller, only burst length eight is supported. For a half-rate controller, the memory clock runs twice as fast as the clock provided to the local interface, so data buses on the local interface are four times as wide as the memory data bus.

Address and Command Interfacing

Address and command signals are automatically sized for 1T operation, such that for full-rate designs there is one input bit per pin (for example, one cs_n input per chip-select configured); for half-rate designs there are two. If you require a more conservative 2T address and command scheme, use a full-rate design and drive the address/command inputs for two clock cycles, or in a half-rate design drive both address/command bits for a given pin identically.

Although the PHY inherently supports 1T addressing, the high performance controllers support only 2T addressing, so PHY timing analysis is performed assuming 2T address and command signals.

Handshake Mechanism Between Read Commands and Read Data

When performing a read, a high-performance controller with the AFI asserts ctl_doing_read to indicate that a read command is requested and the byte lanes that it expects valid data to return on. ALTMEMPHY uses ctl_doing_read for the following actions:

- Control of the postamble circuit
- Generation of ctl_rdata_valid
- Dynamic termination (Rt) control timing

The read latency, ctl_rlat, is advertised back to the controller. This signal indicates how long it takes in ctl_clk clock cycles from assertion of ctl_doing_read to valid read data returning on ctl_rdata. The ctl_rlat signal is only valid when calibration has successfully completed and never changes values during normal user mode operation.

The ALTMEMPHY provides a signal, ctl_rdata_valid, to indicate that the data on read data bus is valid. The width of this signal varies between half-rate and full-rate designs to support the option to indicate that the read data is not word aligned.

Figure 5–21 and Figure 5–22 show these relationships.
Handshake Mechanism Between Write Commands and Write Data

In the AFI, the ALTMEMPHY output `ctl_wlat` gives the number of `ctl_clk` cycles between the write command that is issued `ctl_cs_n` asserted and `ctl_dqs_burst` asserted. The `ctl_wlat` signal considers the following actions to provide a single value in `ctl_clk` clock cycles:

- CAS write latency
- Additive latency
- Datapath latencies and relative phases
- Board layout
- Address and command path latency and 1T register setting, which is dynamically setup to take into account any leveling effects

The `ctl_wlat` signal is only valid when the calibration has been successfully completed by the ALTMEMPHY sequencer and does not change at any point during normal user mode operation. Figure 5–23 shows the operation of `ctl_wlat` port.
For a half-rate design, the `ctl_cs_n` is 2 bits, not 1. Also, the `ctl_dqs_burst` and `ctl_wdata_valid` waveforms indicate a half-rate design. This write results in a burst of 8 at the DDR. Where `ctl_cs_n` is driven `2'b01`, the LSB (1) is the first value driven out of `mem_cs_n`, and the MSB (0) follows on the next `mem_clk`. Similarly, for `ctl_dqs_burst`, the LSB is driven out of `mem_dqs` first (0), then a 1 follows on the next clock cycle. This sequence produces the continuous DQS pulse as required. Finally, the `ctl_addr` bus is twice `MEM_IF_ADDR_WIDTH` bits wide and so the address is concatenated to result in an address phase two `mem_clk` cycles wide.

**Partial Writes**

As part of the DDR3 SDRAM memory specifications, you have the option for partial write operations by asserting the DM pins for part of the write signal.

For designs targeting the Arria II and Stratix III devices, deassert the `ctl_wdata_valid` signal during partial writes, when the write data is invalid, to save power by not driving the DQ outputs.

For designs targeting other devices, use only the DM pins if you require partial writes. Assert the `ctl_dqs_burst` and `ctl_wdata_valid` signals as for full write operations, so that the DQ and DQS pins are driven during partial writes.

The I/O difference between Stratix III devices and other devices, and the preamble difference for DDR3 SDRAM on Arria II GX devices make it only possible to use the `ctl_dqs_burst` signal for the DQS enable in Stratix III devices.
The high-performance controller (HPC) architecture instantiates encrypted control logic and the ALTMEMPHY megafuction. The controller accepts read and write requests from the user on its local interface, using either the Avalon-MM interface protocol or the native interface protocol. It converts these requests into the necessary SDRAM commands, including any required bank management commands. Each read or write request on the Avalon-MM or native interface maps to one SDRAM read or write command.

The half-rate DDR3 SDRAM HPC accepts requests of size 1 or 2 on the local interface. If you request a burst size of 1, the controller issues a memory burst of 4 using the DDR3 SDRAM on-the-fly burst chop (waits for two cycles before issuing the next read or write command). If you request a burst size of 2, the controller issues a memory burst of 8 (issues the next read or write command back to back). Requests of size 2 on the local interface produce better throughput because DDR3 SDRAMs cannot accept back-to-back bursts of size 4.

The bank management logic in the controller keeps a row open in every bank in the memory system. For example, a controller configured for a dual-rank, 8-bank DDR3 SDRAM DIMM keeps an open row in each of the 16 banks. The controller allows you to request an auto-precharge read or auto-precharge write, allowing control over whether to keep that row open after the request. You can achieve maximum efficiency when you issue reads and writes to the same bank, with the last access to that bank being an auto-precharge read or write. The controller does not do any access reordering.
Block Description

Figure 6–1 on page 6–2 shows the top-level block diagram of the DDR3 SDRAM HPC.

Figure 6–2 shows a block diagram of the DDR3 SDRAM HPC architecture.

The blocks in Figure 6–2 on page 6–2 are described in the following sections.

Command FIFO Buffer

This FIFO buffer allows the controller to buffer up to four consecutive read or write commands. It is built from logic elements, and stores the address, read or write flag, and burst count information. If this FIFO buffer fills up, the local_ready signal to the user is deasserted until the main state machine takes a command from the FIFO buffer.
Chapter 6: Functional Description—High-Performance Controller

Block Description

Write Data FIFO Buffer

The write data FIFO buffer holds the write data from the user until the main state machine can send it to the ALTMEMPHY megafuction, which does not have a write data buffer. In the Avalon-MM interface mode, the user logic presents a write request, address, burst count, and one or more beats of data. The write data beats are placed into the FIFO buffer until they are needed. In the native interface mode, the user logic presents a write request, address, and burst count. The controller then requests the correct number of write data beats from the user via the `local_wdata_req` signal, and the user logic must return the write data in the clock cycle after the write data request signal.

This FIFO buffer is sized to be deeper than the command FIFO buffer to prevent it from filling up and interrupting streaming writes.

Write Data Tracking Logic

The write data tracking logic keeps track of the number of write data beats in the FIFO buffer. In native interface mode, this logic manages how much more data to request from the user logic and issues the `local_wdata_req` signal.

Main State Machine

The main state machine decides what DDR commands to issue based on inputs from the command FIFO buffer, the bank management logic, and the timer logic.

Bank Management Logic

The bank management logic keeps track the current state of each bank. It can keep a row open in every bank in your memory system. The state machine uses the information provided by this logic to decide whether it needs to issue bank management commands before it reads or writes to the bank. The controller always leaves the bank open unless the user requests an auto-precharge read or write. The periodic refresh process also causes all the banks to be closed.

Timer Logic

The timer logic tracks whether the required minimum number of clock cycles has passed since the last relevant command was issued. For example, the timer logic records how many cycles have elapsed since the last activate command so that the state machine knows it is safe to issue a read or write command (tRCD). The timer logic also counts the number of clock cycles since the last periodic refresh command and sends a high priority alert to the state machine if the number of clock cycles has expired.

Initialization State Machine

The initialization state machine issues the appropriate sequence of command to initialize the memory devices. It is specific to DDR3 as each memory type requires a different sequence of initialization commands.

With the AFI, the ALTMEMPHY megafuction initializes the memory, otherwise the controller is responsible for initializing the memory.
Address and Command Decode

When the state machine wants to issue a command to the memory, it asserts a set of internal signals. The address and command decode logic turns these into the DDR-specific RAS, CAS, and WE commands.

PHY Interface Logic

When the main state machine issues a write command to the memory, the write data for that write burst has to be fetched from the write data FIFO buffer. The relationship between write command and write data depends on the memory type, ALTMEMPHY interface type, CAS latency, and the full-rate or half-rate setting. The PHY interface logic adjusts the timing of the write data FIFO read request signal so that the data arrives on the external memory interface DQ pins at the correct time.

ODT Generation Logic

The ODT generation logic (not shown) calculates when and for how long to enable the ODT outputs. It also decides which ODT bit to enable, based on the number of chip selects in the system.

- 1 DIMM (1 or 2 Chip Selects)

  In the case of a single DIMM, the ODT signal is only asserted during writes. The ODT signal on the DIMM at mem_cs[0] is always used, even if the write command on the bus is to mem_cs[1]. In other words, mem_odt[0] is always asserted even if there are two ODT signals.

- 2 or more DIMMs

  In the multiple DIMM case, the appropriate ODT bit is asserted for both read and writes. Table 6-1 shows which ODT signal on the adjacent DIMM is enabled.

<table>

Low-Power Mode Logic

The low-power mode logic (not shown) monitors the local_powerdn_req and local_self_rfsh_req request signals. This logic also informs the user of the current low-power state via the local_powerdn_ack and local_self_rfsh_ack acknowledge signals.
Control Logic

Bus commands control SDRAM devices using combinations of the mem_ras_n, mem_cas_n, and mem_we_n signals. For example, on a clock cycle where all three signals are high, the associated command is a no operation (NOP). A NOP command is also indicated when the chip select signal is not asserted. Table 6–2 shows the standard SDRAM bus commands.

The DDR3 SDRAM HPC must open SDRAM banks before it accesses the addresses in that bank. The row and bank to be opened are registered at the same time as the active (ACT) command. The DDR3 SDRAM HPC closes the bank and opens it again if it needs to access a different row. The precharge (PCH) command closes only a bank.

The primary commands used to access SDRAM are read (RD) and write (WR). When the WR command is issued, the initial column address and data word is registered. When a RD command is issued, the initial address is registered. The initial data appears on the data bus 5 to 11 clock cycles later. This delay is the column address strobe (CAS) latency and is due to the time required to read the internal DRAM core and register the data on the bus. The CAS latency (of 6) depends on the speed of the SDRAM and the frequency of the memory clock. In general, the faster the clock, the more cycles of CAS latency are required. After the initial RD or WR command, sequential reads and writes continue until the burst length is reached. DDR3 SDRAM devices support fixed burst lengths of 4 or 8 data cycles or an on-the-fly mode where the controller can request a burst of 4 or 8 for each read or write command. This on-the-fly mode is the only mode supported. The auto-refresh command (ARF) is issued periodically to ensure data retention. This function is performed by the DDR3 SDRAM HPC.

The load mode register command (LMR) configures the SDRAM mode register. This register stores the CAS latency, burst length, and burst type.

For more information, refer to the specification of the SDRAM that you are using.

Error Correction Coding (ECC)

The optional ECC logic comprises an encoder and a decoder-corrector, which can detect and correct single-bit errors and detect double-bit errors. The ECC logic uses an 8-bit ECC for each 64-bit message. The ECC logic has the following features:

- Hamming code ECC logic that encodes every 64-bits of data into 72-bits of codeword with 8-bits of Hamming code parity bits
Latency:
- Maximum of 1 or 2 clock delay during writes
- Minimum 1 or 3 clock delay during reads

Detects and corrects all single-bit errors. Also, the ECC logic sends an interrupt when the user-defined threshold for a single-bit error is reached.

Detects all double-bit errors. Also, the ECC logic counts the number of double-bit errors and sends an interrupt when the user-defined threshold for double-bit error is reached.

Accepts partial writes

Creates forced errors to check the functioning of the ECC logic

Powers up to a ready state

Figure 6–3 shows the ECC block diagram.

Figure 6–3. ECC Block Diagram

The ECC comprises the following blocks:
- The encoder—encodes the 64-bit message to a 72-bit codeword
- The decoder-corrector—decodes and corrects the 72-bit codeword if possible
- The ECC controller—controls multiple encoder and decoder-correctors, so that the ECC can handle different bus widths. Also, it controls the following functions of the encoder and decoder-corrector:

  Interrupts:
  - Detected and corrected single-bit error
  - Detected double-bit error
  - Single-bit error counter threshold exceeded
  - Double-bit error counter threshold exceeded
Chapter 6: Functional Description—High-Performance Controller

■ Configuration registers:
  ■ Single-bit error detection counter threshold
  ■ Double-bit error detection counter threshold
  ■ Capture status for first encountered error or most recent error
  ■ Enable deliberate corruption of ECC for test purposes

■ Status registers:
  ■ Error address
  ■ Error type: single-bit error or double-bit error
  ■ Respective byte error ECC syndrome

■ Error signal—an error signal corresponding to the data word is provided with the data and goes high if a double-bit error that cannot be corrected occurs in the return data word.

■ Counters:
  ■ Detected and/or corrected single-bit errors
  ■ Detected double-bit errors

The ECC logic can instantiate multiple encoders, each running in parallel, to encode any width of data words assuming they are integer multiples of 64.

The ECC logic operates between the local (native or Avalon-MM interface) and the memory controller.

The ECC logic has an \( N \times 64 \)-bit (where \( N \) is an integer) wide interface, between the local interface and the ECC logic, for receiving and returning data from the local interface. This interface can be a native interface or an Avalon-MM slave interface, you select the type of interface in the MegaWizard interface.

The ECC logic has a second interface between the local interface and the ECC, which is a 32-bit wide Avalon-MM slave to control and report the status of the operation of the ECC controller.

The encoded data from the ECC logic is sent to the memory controller using a \( N \times 72 \)-bit wide Avalon-MM master interface, which is between the ECC logic and the memory controller.

When testing the DDR3 SDRAM HPC, you can turn off the ECC.

Interrupts
The ECC logic issues an interrupt signal when one of the following scenarios occurs:

■ The single-bit error counter reaches the set maximum single-bit error threshold value.

■ The double-bit error counter reaches the set maximum double-bit error threshold value.
The error counters increment every time the respective event occurs for all $N$ parts of the return data word. This incremented value is compared with the maximum threshold and an interrupt signal is sent when the value is equal to the maximum threshold. The ECC logic clears the interrupts when you write a 1 to the respective status register. You can mask the interrupts from either of the counters using the control word.

**Partial Writes**

The ECC logic supports partial writes. Along with the address, data, and burst signals, the Avalon-MM interface also supports a signal vector that is responsible for byte-enable. Every bit of this signal vector represents a byte on the data-bus. Thus, a 0 on any of these bits is a signal for the controller not to write to that particular location—a partial write.

For partial writes, the ECC logic performs the following steps:

1. The ECC logic stalls further read or write commands from the Avalon-MM interface when it receives a partial write condition.
2. It simultaneously sends a self-generated read command, for the partial write address, to the memory controller.
3. Upon receiving the returned read data from the memory controller for the particular address, the decoder decodes the data, checks for errors, and then sends it to the ECC logic.
4. The ECC logic merges the corrected or correct dataword with the incoming information.
5. The ECC logic sends the updated dataword to the encoder for encoding, and then sends updated dataword to the memory controller with a write command.
6. The ECC logic stops stalling the commands from the Avalon-MM interface so that the logic can receive new commands.

The following corner cases can occur:

- A single-bit error during the read phase of the read-modify-write process. In this case, the single-bit error is corrected first, the single-bit error counter is incremented and then a partial write is performed to this corrected decoded data word.
- A double-bit error during the read phase of the read-modify-write process. In this case, the double-bit error counter is incremented and an interrupt is sent through the Avalon-MM interface. The new write word is not written to its location. A separate field in the interrupt status register highlights this condition.
Figure 6–4 shows the partial write operation for HPC. The half-rate DDR3 SDRAM HPC supports a local size of 1 and 2.

![Partial Write for HPC](image)

**Note to Figure 6–4:**
1. R represents the internal read-back memory data during the read-modify-write process.

**Partial Bursts**

DIMMs that do not have the DM pins do not support partial bursts. A minimum of eight words must be written to the memory at the same time.

Figure 6–5 shows the partial burst operation for HPC.

![Partial Burst for HPC](image)

**ECC Latency**

Using the ECC results in the following latency changes:

- Local Burst Length 1
- Local Burst Length 2

**Local Burst Length 1**

For a local burst length of 1, the write latency increases by one clock cycle; the read latency increases by one clock cycle (including checking and correction).

A partial write results in a read followed by write in the ECC logic, so latency depends on the time the controller takes to fetch the data from the particular address.

Table 6–3 shows the relationship between burst lengths and rate.
Local Burst Length

For a local burst length of 2, the write latency increases by two clock cycles; the read latency increases by one clock cycle (including checking and correction).

A partial write results in a read followed by write in the ECC logic, so latency depends on the time the controller takes to fetch the data from the particular address.

For a single-bit error, the automatic correction of memory takes place without stalling the read cycle (if enabled), which stalls further commands to the ECC logic, while the correction takes place.

Example Top-Level File

The MegaWizard Plug-In Manager helps you create an example top-level file that shows you how to instantiate and connect the DDR3 SDRAM HPC. The example top-level file consists of the DDR3 HPC, some driver logic to issue read and write requests to the controller. The example top-level file is a working system that you can compile and use for both static timing checks and board tests.

Figure 6–6 shows the testbench and the example top-level file.
Table 6–10 describes the files that are associated with the example top-level file and the testbench.

<table>
<thead>
<tr>
<th>Filename</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;variation name&gt; _example_top_tb.v or .vhd</td>
<td>Testbench for the example top-level file.</td>
</tr>
<tr>
<td>&lt;variation name&gt; _example_top.v or .vhd</td>
<td>Example top-level file.</td>
</tr>
<tr>
<td>&lt;variation name&gt; _mem_model.v or .vhd</td>
<td>Associative-array memory model.</td>
</tr>
<tr>
<td>&lt;variation name&gt; _full_mem_model.v or .vhd</td>
<td>Full-array memory model.</td>

<td>Example driver.</td>
</tr>
<tr>
<td>&lt;variation name&gt; .v or .vhd</td>
<td>Top-level description of the custom MegaCore function.</td>
</tr>
<tr>
<td>&lt;variation name&gt; .qip</td>
<td>Contains Quartus II project information for your MegaCore function variations.</td>
</tr>
</tbody>
</table>

There are two Altera-generated memory models available—associative-array memory model and full-array memory model.

The associative-array memory model (<variation name> _mem_model.v) allocates reduced set of memory addresses with a default depth of 2,048 or 2K address spaces. This allocation allows for a larger memory array compilation and simulation which enables you to easily reconfigure the depth of the associate array.

The full-array memory model (<variation name> _full_mem_model.v) allocates memory for all addresses accessible by the DDR cores. This allocation makes it impossible to simulate large memory (more than 2K address spaces) designs, because simulators need more memory than what is available on a typical system.

Both the memory models display similar behaviors and have the same calibration time.

The memory model, <variation name> _test_component.v/vhd, used in SOPC Builder designs, is actually a variation of the full-array memory model. To ensure your simulation works in SOPC Builder, use memory model with less than 512-Mbit capacity.

**Example Driver**

The example driver is a self-checking test pattern generator for the memory interface. It uses a state machine to write and read from the memory to verify that the interface is operating correctly.

It performs the following tests and loops back the tests indefinitely:

- Sequential addressing writes and reads

  The state machine writes pseudo-random data generated by a linear feedback shift register (LFSR) to a set of incrementing row, bank, and column addresses. The state machine then resets the LFSR, reads back the same set of addresses, and compares the data it receives against the expected data. You can adjust the length and pattern of the bursts that are written by changing the MAX_ROW, MAX_BANK, and MAX_COL constants in the example driver source code, and the entire memory space can be tested by adjusting these values. You can skip this test by setting the test_seq_addr_on signal to logic zero.
Incomplete write operation

The state machine issues a series of write requests that are less than the maximum burst size supported by your controller variation. The addresses are then read back to ensure that the controller has issued the correct signals to the memory. This test is only applicable when the local burst size is two. You can skip this test by setting the `test_incomplete_writes_on` signal to logic zero.

Byte enable/data mask pin operation

The state machine issues two sets of write commands, the first of which clears a range of addresses. The second set of write commands has only one byte enable bit asserted. The state machine then issues a read request to the same addresses and the data is verified. This test checks if the data mask pins are operating correctly. You can skip this test by setting the `test_dm_pin_on` signal to logic zero.

Address pin operation

The example driver generates a series of write and read requests starting with an all-zeros pattern, a walking-one pattern, a walking-zero pattern, and ending with an all-zeros pattern. This test checks to make sure that all the individual address bits are operating correctly. You can skip this test by setting the `test_addr_pin_on` signal to logic zero.

Low-power mode operation

The example driver requests that the controller place the memory into power-down and self-refresh states, and hold it in those states for the amount of time specified by the `COUNTER_VALUE` signal. You can vary this value to adjust the duration the memory is kept in the low-power states. This test is only available if your controller variation enables the low-power mode option.

The example driver has four outputs that allow you to observe which tests are currently running and if the tests are passing. The pass not fail (pnf) signal goes low once one or more errors occur and remains low. The pass not fail per byte (pnf_per_byte) signal goes low when there is incorrect data in a byte but goes back high again once correct data is observed in the following byte. The `test_status` signal indicates the test that is currently running, allowing you to determine which test has failed. The `test_complete` signal goes high for a single clock cycle at the end of the set of tests.

Table 6–11 shows the bit mapping for each test status.

</tr>
<tr>
<td>local_refresh_req</td>
<td>Input</td>
<td>User-controlled refresh request. If Enable user auto-refresh controls is turned on, local_refresh_req becomes available and you are responsible for issuing sufficient refresh requests to meet the memory requirements. This option allows complete control over when refreshes are issued to the memory including ganging together multiple refresh commands. Refresh requests take priority over read and write requests unless they are already being processed.</td>
</tr>
<tr>
<td>local_size[]</td>
<td>Input</td>
<td>Controls the number of beats in the requested read or write access to memory, encoded as a binary number. The DDR3 SDRAM HPC supports burst lengths of 1 and 2 on the local side interface.</td>
</tr>
<tr>
<td>local_wdata[]</td>
<td>Input</td>
<td>Write data bus. The width of local_wdata is twice that of the memory data bus for a full rate controller; four times the memory data bus for a half rate controller.</td>
</tr>
<tr>
<td>local_write_req</td>
<td>Input</td>
<td>Write request signal. You cannot assert read request and write request signal at the same time.</td>
</tr>
<tr>
<td>local_autopch_req</td>
<td>Input</td>
<td>User control of precharge. If Enable Auto-Precharge Control is turned on, local_autopch_req becomes available and you can request the controller to issue an auto-precharge write or auto-precharge read command. These commands cause the memory to issue a precharge command to the current bank at the appropriate time without an explicit precharge command from the controller. This is particularly useful if you know the current read or write is the last one you intend to issue to the currently open row. The next time you need to use that bank, the access could be quicker as the controller does not need to precharge the bank before activating the row you wish to access.</td>
</tr>
<tr>
<td>local_powerdn_req</td>
<td>Input</td>
<td>User control of the power-down feature. If Enable Power Down Controls option is enabled, you can request that the controller place the memory devices into a power-down state as soon as it can without violating the relevant timing parameters and responds by asserting the local_powerdn_ack signal. You can hold the memory in the power-down state by keeping this signal asserted. The controller brings the memory out of the power-down state to issue periodic auto-refresh commands to the memory at the appropriate interval if you hold it in the power-down state. You can release the memory from the power-down state at any time by deasserting the local_powerdn_ack signal once it has successfully brought the memory out of the power-down state.</td>
</tr>
<tr>
<td>local_self_rfsh_req</td>
<td>Input</td>
<td>User control of the self-refresh feature. If Enable Self-Refresh Controls option is enabled, you can request that the controller place the memory devices into a self-refresh state by asserting this signal. The controller places the memory in the self-refresh state as soon as it can without violating the relevant timing parameters and responds by asserting the local_self_rfsh_ack signal. You can hold the memory in the self-refresh state by keeping this signal asserted. You can release the memory from the self-refresh state at any time by deasserting the local_self_rfsh_req signal and the controller responds by deasserting the local_self_rfsh_ack signal once it has successfully brought the memory out of the self-refresh state.</td>
</tr>

The high-performance controller II (HPC II) architecture is an upgraded controller with higher efficiency and more features than the HPC. HPC II is recommended for all new designs.

HPC II is pin-out compatible with your existing DDR high-performance designs. HPC II has the following additional features:

- Higher efficiency with in-order read and write commands, and out-of-order bank management commands.
- Run-time programmability to configure the behavior of the controller.
- Integrated burst adapter supporting a range of burst sizes on the local interface.
- Integrated ECC logic, supporting 40-bit and 72-bit interfaces with partial word writes and optional write back on error.
- Support for multi-rank UDIMM and RDIMM ports.

### Upgrading from HPC to HPC II

If you want to migrate your designs from the existing HPC to the more efficient HPC II, you must do the following:

- In the Preset Editor dialog box, assign the following HPC II timing parameters to match your memory specification. Set these parameters according to the memory datasheet:
  - $t_{FAW}$
  - $t_{RRD}$
  - $t_{RTP}$
  
  For example, for Micron DDR3-800 datasheet, $t_{FAW}$=40 ns, $t_{RRD}$=10 ns, $t_{RTP}$=10 ns.

- If you are using the Avalon-MM interface, HPC II replaces the port interface level for the AFI and Avalon interface without requiring any top-level change.

- The side-band signals differ slightly for HPC II. If you use these signals, you need to perform the following steps.

  - **local_refresh_req**
    
    You need to drive an additional active high signal, `local_refresh_chip`, to control which chip to issue the user-refresh to.

  - **local_powerdn_req**
    
    The user-manual power signal is no longer supported in HPC II. Instead, you can select auto power-down on the **Controller Settings** tab in the MegaWizard Plug-In Manager, and specify the desired time-out ($n$ cycles) after which the controller automatically powers down the memory.
Because HPC II only supports a specific memory burst length, you must update the memory burst length to match the controller settings. For DDR3, HPC II supports on-the-fly burst length in half-rate mode.

Because HPC II supports arbitrary user burst length ranging from 1 to 64, you can adjust the \texttt{max\_local\_size} value in HPC II. Adjusting the maximum local size value changes the width of the \texttt{local\_size} signal. The maximum \texttt{local\_size} signal value is \(2^n - 1\), where \(n\) is the width of the \texttt{local\_size} signal. HP has a fixed \texttt{local\_size} signal width of 2.

### Block Description

Figure 7–1 shows the top-level block diagram of the DDR3 SDRAM HPC II.

**Figure 7–1. DDR3 SDRAM HPC II Block Diagram**
Figure 7–2 shows a block diagram of the DDR3 SDRAM HPC II architecture.

**Avalon-MM Data Slave Interface**

The Avalon-MM data slave interface accepts read and write requests from the Avalon-MM master. The width of the data, `local_wdata` and `local_rdata`, is four times the width of the external memory.

The local address width is sized based on the memory chip, row, bank, and column address widths. For example:

- For multiple chip select:
  \[
  \text{width} = \text{chip bits} + \text{row bits} + \text{bank bits} + \text{column} - 2
  \]
For single chip select:

\[
\text{width} = \text{row bits} + \text{bank bits} + \text{column} - 2
\]

For every Avalon transaction, the number of read or write requests can go up to the maximum local burst count of 64. Altera recommends that you set this maximum burst count to match your system master’s supported burst count.

**Write Data FIFO Buffer**

The write data FIFO buffer holds the write data and byte-enable from the user logic until the data is needed by the main state machine. The `local_ready` signal is deasserted when either the command queue or write data FIFO buffer is full. The write data FIFO buffer is wide enough to store the write data and the byte-enable signals.

**Command Queue**

The command queue allows the controller to buffer up to eight consecutive reads or writes. The command queue presents the next 4, 6, or 8 accesses to the internal logic for the look-ahead bank management. The bank management is more efficient if the look-ahead is deeper, but a deeper queue consumes more resources, and may cause maximum frequency degradation.

Other than storing incoming commands, the command queue also maps the local address to memory address based on the address mapping option selected. By default, the command queue leverages bank interleaving scheme, where the address increment goes to the next bank instead of the next row to increase chances of page hit.

**Bank Management Logic**

The bank management logic keeps track of the current state in each bank across multiple chips. It can keep a row open in every bank in your memory system. When a command is issued by the state machine, the bank management logic is updated with the latest bank status. With the look-ahead capability, the main state machine is able to issue early bank management commands. With the auto precharge feature, the controller supports an open page policy, where the last accessed row in each bank is kept open and a close page policy, where a bank is closed after it is used.

**Timer Logic**

The timer logic models the state of each bank in the memory interface. The timer logic models the internal behavior of each bank and provides status output signals to the state machine. The state machine then decides whether to issue the look-ahead bank management command based on the timer status signals.

**Command-Issuing State Machine**

The command-issuing state machine decides what DDR commands to issue based on the inputs from the command queue, bank management logic, and timer logic. The DDR3 SDRAM provides half-rate command-issuing state machine. The half-rate state machine supports 2T address and command, and issues “on-the-fly” memory bursts.
A longer memory burst length, in this case 8 beats, increases the command bandwidth by allowing more data cycles for the same amount of command cycles. A longer memory burst length also provides more command cycles that ensures a more effective look-ahead bank management. However, longer memory burst lengths are less efficient if the bursts you issue do not provide enough data to fill the burst.

This state machine accepts any local burst count of 1 to 64. The built-in burst adapter in this state machine maps the local burst count to the most efficient memory burst. The state machine also supports reads and writes that start on non-aligned memory burst boundary addresses. For effective command bus bandwidth, this state machine supports additive latency which issues reads and writes immediately after the ACT command. This state machine accepts additive latency values greater or equal to \( t_{\text{RCD}} - 1 \), in clock cycle unit (tCK).

Address and Command Decode Logic

When the main state machine issues a command to the memory, it asserts a set of internal signals. The address and command decode logic turns these signals into AFI-specific commands and address. This block generates the following signals:

- Clock enable and reset signals: \( \text{afi}_\text{cke}, \text{afi}_\text{rst}_\text{n} \)
- Command and address signals: \( \text{afi}_\text{cs}_\text{n}, \text{afi}_\text{ba}, \text{afi}_\text{addr}, \text{afi}_\text{ras}_\text{n}, \text{afi}_\text{cas}_\text{n}, \text{afi}_\text{we}_\text{n} \)

Write and Read Datapath, and Write Data Timing Logic

The write and read datapath, and the write data timing logic generate the AFI read and write control signals.

When the state machine issues a write command to the memory, the write data for that write burst has to be fetched from the write data FIFO buffer. The relationship between the write command and write data depends on the \( \text{afi}_\text{wlat} \) signal. This logic presents the write data FIFO read request signal so that the data arrives on the external memory interface DQ pins at the correct time.

During write, the following AFI signals are generated based on the state machine outputs and the \( \text{afi}_\text{wlat} \) signal:

- \( \text{afi}_\text{dqs}_\text{burst} \)
- \( \text{afi}_\text{wdata}_\text{valid} \)
- \( \text{afi}_\text{wdata} \)
- \( \text{afi}_\text{dm} \)

During read, the \( \text{afi}_\text{doing_read} \) signal generates the \( \text{afi}_\text{rdata}_\text{valid} \) signal and controls the ALTMEMPHY postamble circuit.

ODT Generation Logic

The ODT generation logic generates the necessary ODT signals for DDR3 SDRAM HPC II memory devices, based on the scheme recommended by Altera.
Table 7–1 and Table 7–2 show which ODT signal on the adjacent DIMM is enabled.

#### User-Controlled Side-Band Signals

The user-controlled side-band signals consists of the following signals.

**User Auto-Precharge Commands**

The auto-precharge read and auto-precharge write commands allow you to indicate to the memory device that this read or write command is the last access to the currently open row. The memory device automatically closes or auto-precharges the page it is currently accessing so that the next access to the same bank is quicker.

This command is useful for applications that require fast random accesses. You can request an auto-precharge by asserting the `local_autopch` signal during a read or write request.

**User-Refresh Commands**

The user-refresh command enables the request to place the memory into refresh mode. The user-refresh control takes precedence over a read or write request. You can issue up to nine consecutive refresh commands to the memory.

**Multi-Cast Write**

The multi-cast write request signal allows you to ask the controller to send the current write requests to all the chip-selects. This means that the write data is written to all the ranks in the system. The multi-cast write feature is useful for tRC mitigation where you can cycle through chips to continuously read data without hitting tRC. The multi-cast write is not supported in ECC and RDIMM modes.

**Low-Power Mode Logic**

There are two types of low-power mode logic: the user-controlled self-refresh logic and automatic power-down with programmable time-out logic.
User-Controlled Self-Refresh Logic

When you assert the `local_self_rfsh_req` signal, the controller completes all pending reads and writes before it places the memory into self-refresh mode. Once the controller places the memory into self-refresh mode, it responds by asserting the acknowledge signal, `local_self_rfsh_ack`. You can leave the memory in self-refresh mode for as long as you choose.

To bring the memory out of self-refresh mode, you must deassert the request signal, and the controller responds by deasserting the acknowledge signal when the memory is no longer in self-refresh mode.

Automatic Power-Down with Programmable Time-Out

The controller automatically places the memory in power-down mode to save power if the requested number of idle controller clock cycles is observed in the controller. The `Auto Power Down Cycles` parameter on the `Controller Settings` tab allows you to specify a range between 1 to 65,535 idle controller clock cycles. The counter for the programmable time-out starts when there are no user read or write requests in the command queue. Once the controller places the memory in power-down mode, it responds by asserting the acknowledge signal, `local_powerdown_ack`.

Configuration and Status Register (CSR) Interface

The configuration and status register interface is a 32-bit wide interface that uses the Avalon-MM interface standard. The CSR interface allows you to configure the timing parameters, address widths, and the behavior of the controller. If you do not need this feature, you can disable it and all the programmable settings are fixed to the values configured during the generation process. This interface is synchronous to the controller clock.

Refer to Table 7–9 through Table 7–23 in page 7–18 for detailed information about the register maps.

Error Correction Coding (ECC)

The optional ECC logic comprises an encoder and a decoder-corrector, which can detect and correct single-bit errors, and detect double-bit errors. The ECC logic is available in two widths: 64/72 bit and 32/40 bit. The ECC logic has the following features:

- Hamming code ECC logic that encodes every 64 or 32 bits of data into 72 or 40 bits of codeword.
- A latency increase of one clock for both writes and reads.
- Detects and corrects all single-bit errors.
- Detects all double-bit errors.
- Counts the number of single-bit and double-bit errors.
- Accepts partial writes, which trigger a read-modify-write cycle, for memory devices with DM pins.
- Is able to inject single-bit and double-bit errors to trigger ECC correction for testing and debugging purposes.
Generates an interrupt signal when an error occurs.

When a single-bit or double-bit error occurs, the ECC logic triggers the `ecc_interrupt` signal to inform you that an ECC error has occurred. When a single-bit error occurs, the ECC logic issues an internal read to the error address, and performs an internal write to write back the corrected data. When a double-bit error occurs, the ECC logic does not do any error correction but it asserts the `local_rdata_error` signal to indicate that the data is incorrect. The first `local_rdata_error` signal follows the same timing as the `local_rdata_valid` signal.

Enabling auto-correction allows the ECC logic to hold off all controller pending activities until the correction is complete. You can choose to disable auto-correction and schedule the correction manually when the controller is idle to ensure better system efficiency. To manually correct ECC errors, do the following:

1. When an interrupt occurs, read out the `SBE_ERROR` register. When a single-bit error occurs, the `SBE_ERROR` register is equal to one.
2. Read out the `ERR_ADDR` register.
3. Correct the single-bit error by doing one of the following:
   - Issue a dummy write to the memory address stored in the `ERR_ADDR` register. A dummy write is a write request with the `local_be` signal zero, that triggers a partial write which is effectively a read-modify-write event. The partial write corrects the data at that address and writes it back.
   - Enable the `ENABLE_AUTO_CORR` register using the CSR interface and issue a read request to the memory address stored in the `ERR_ADDR` register. The read request triggers auto-error correction to the memory address stored in the `ERR_ADDR` register.

### Partial Writes

The ECC logic supports partial writes. Along with the address, data, and burst signals, the Avalon-MM interface also supports a signal vector, `local_be`, that is responsible for byte-enable. Every bit of this signal vector represents a byte on the data-bus. Thus, a logic low on any of these bits instructs the controller not to write to that particular byte, resulting in a partial write. The ECC code is calculated on all bytes of the data-bus. If any bytes are changed, the ECC code must be recalculated and the new code must be written back to the memory.

For partial writes, the ECC logic performs the following steps:

1. The ECC logic sends a read command to the partial write address.
2. Upon receiving a return data from the memory for the particular address, the ECC logic decodes the data, checks for errors, and then merges the corrected or correct data word with the incoming information.
3. The ECC logic issues a write to write back the updated data and the new ECC code.
The following corner cases can occur:

- A single-bit error during the read phase of the read-modify-write process. In this case, the single-bit error is corrected first, the single-bit error counter is incremented and then a partial write is performed to this corrected decoded data word.

- A double-bit error during the read phase of the read-modify-write process. In this case, the double-bit error counter is incremented and an interrupt is issued. A new write word is written to the location of the error. The ECC status register keeps track of the error information.

Figure 7–3 shows the partial write operation for HPC II.

**Figure 7–3.** Partial Write for HPC II

![Diagram of partial write operation]

**Note to Figure 7–3:**
(1) R represents the internal read-back memory data during the read-modify-write process.

**Partial Bursts**

DIMMs that do not have the DM pins do not support partial bursts. A minimum of eight words must be written to the memory at the same time.

Figure 7–4 shows the partial burst operation for HPC II.

**Figure 7–4.** Partial Burst for HPC II

![Diagram of partial burst operation]

**Example Top-Level File**

The MegaWizard Plug-In Manager helps you create an example top-level file that shows you how to instantiate and connect the DDR3 SDRAM HPC II. The example top-level file consists of the DDR3 SDRAM HPC II, some driver logic to issue read and write requests to the controller, a PLL to create the necessary clocks, and a DLL (Stratix series only). The example top-level file is a working system that you can compile and use for both static timing checks and board tests.
Figure 7–5 shows the testbench and the example top-level file.

**Figure 7–5. Testbench and Example Top-Level File**

</tr>
</tbody>
</table>

Table 7–3 describes the files that are associated with the example top-level file and the testbench.

There are two Altera-generated memory models available—associative-array memory model and full-array memory model.

The associative-array memory model (``<variation name>_mem_model.v``) allocates reduced set of memory addresses with a default depth of 2,048 or 2K address spaces. This allocation allows for a larger memory array compilation and simulation which enables you to easily reconfigure the depth of the associate array.

The full-array memory model (``<variation name>_mem_model_full.v``) allocates memory for all addresses accessible by the DDR cores. This allocation makes it impossible to simulate large memory designs.

Both the memory models display similar behaviors and have the same calibration time.

There is a notice about the memory model used in SOPC Builder designs. The memory model, `<variation name>_test_component.v`/`.vhd`, is actually a variation of the full-array memory model. To ensure your simulation works in SOPC Builder, use memory model with less than 512-Mbit capacity.
Example Driver

The example driver is a self-checking test pattern generator for the memory interface. It uses a state machine to write and read from the memory to verify that the interface is operating correctly.

The example driver performs the following tests and loops back the tests indefinitely:

- Sequential addressing writes and reads
  The state machine writes pseudo-random data generated by a linear feedback shift register (LFSR) to a set of incrementing row, bank, and column addresses. The state machine then resets the LFSR, reads back the same set of addresses, and compares the data it receives against the expected data. You can adjust the length and pattern of the bursts that are written by changing the MAX_ROW, MAX_BANK, and MAX_COL constants in the example driver source code, and the entire memory space can be tested by adjusting these values. You can skip this test by setting the test_seq_addr_on signal to logic zero.

- Incomplete write operation
  The state machine issues a series of write requests that are less than the maximum burst size supported by your controller variation. The addresses are then read back to ensure that the controller has issued the correct signals to the memory. This test is only applicable in full-rate mode, when the local burst size is two. You can skip this test by setting the test_incomplete_writes_on signal to logic zero.

- Byte enable/data mask pin operation
  The state machine issues two sets of write commands, the first of which clears a range of addresses. The second set of write commands has only one byte enable bit asserted. The state machine then issues a read request to the same addresses and the data is verified. This test checks if the data mask pins are operating correctly. You can skip this test by setting the test_dm_pin_on signal to logic zero.

- Address pin operation
  The example driver generates a series of write and read requests starting with an all-zeros pattern, a walking-one pattern, a walking-zero pattern, and ending with an all-zeros pattern. This test checks to make sure that all the individual address bits are operating correctly. You can skip this test by setting the test_addr_pin_on signal to logic zero.

- Low-power mode operation
  The example driver requests the controller to place the memory into power-down and self-refresh states, and hold it in those states for the amount of time specified by the COUNTER_VALUE signal. You can vary this value to adjust the duration the memory is kept in the low-power states. This test is only available if your controller variation enables the low-power mode option.
The example driver has four outputs that allow you to observe which tests are currently running and if the tests are passing. The pass not fail (pnf) signal goes low once one or more errors occur and remains low. The pass not fail per byte (pnf_per_byte) signal goes low when there is incorrect data in a byte but goes back high again once correct data is observed in the following byte. The test_status signal indicates the test that is currently running, allowing you to determine which test has failed. The test_complete signal goes high for a single clock cycle at the end of the set of tests.

Table 7–4 shows the bit mapping for each test status.

</tr>
<tr>
<td>phy_clk</td>
<td>Output</td>
<td>The system clock that the ALTMEMPHY megafunction provides to the user. All user inputs to and outputs from the DDR3 HPC II must be synchronous to this clock.</td>
</tr>
<tr>
<td>reset_phy_clk_n</td>
<td>Output</td>
<td>The reset signal that the ALTMEMPHY megafunction provides to the user. It is asserted asynchronously and deasserted synchronously to phy_clk clock domain.</td>
</tr>
<tr>
<td>aux_full_rate_clk</td>
<td>Output</td>
<td>An alternative clock that the ALTMEMPHY megafunction provides to the user. This clock always runs at the same frequency as the external memory interface. In half-rate mode, this clock is twice the frequency of the phy_clk and can be used whenever a 2x clock is required. In full-rate mode, this clock is driven by the same PLL output as the phy_clk signal.</td>
</tr>
</tbody>
</table>
Top-level Signals Description

- **aux_half_rate_clk**: Output
  An alternative clock that the ALTMEMPHY megafunction provides to the user. This clock always runs at half the frequency as the external memory interface. In full-rate mode, this clock is half the frequency of the `phy_clk` and can be used, for example, to clock the user side of a half-rate bridge. In half-rate mode, or if the **Enable Half Rate Bridge** option is turned on, this clock is driven by the same PLL output that drives the `phy_clk` signal.

- **dll_reference_clk**: Output
  Reference clock to feed to an externally instantiated DLL.

- **reset_request_n**: Output
  Reset request output that indicates when the PLL outputs are not locked. Use this signal as a reset request input to any system-level reset controller you may have. This signal is always low when the PLL is trying to lock, and so any reset logic using it is advised to detect a reset request on a falling edge rather than by level detection.

- **soft_reset_n**: Input
  Edge detect reset input intended for SOPC Builder use or to be controlled by other system reset logic. It is asserted to cause a complete reset to the PHY, but not to the PLL used in the PHY.

- **oct_ctl_rs_value**: Input
  ALTMEMPHY signal that specifies the serial termination value. Should be connected to the ALT_OCT megafunction output `seriesterminationcontrol`.

- **oct_ctl_rt_value**: Input
  ALTMEMPHY signal that specifies the parallel termination value. Should be connected to the ALT_OCT megafunction output `parallelterminationcontrol`.

- **dqs_delay_ctrl_import**: Input
  Allows the use of DLL in another ALTMEMPHY instance in this ALTMEMPHY instance. Connect the export port on the ALTMEMPHY instance with a DLL to the import port on the other ALTMEMPHY instance.

---

### Table 7-6. Local Interface Signals (Part 2 of 4)

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>local_burstbegin</td>
<td>Input</td>
<td>Avalon burst begin strobe, which indicates the beginning of an Avalon burst. Unlike all other Avalon-MM signals, the burst begin signal does not stay asserted if local_ready is deasserted. For write transactions, assert this signal at the beginning of each burst transfer and keep this signal high for one cycle per burst transfer, even if the slave has deasserted the local_ready signal. This signal is sampled at the rising edge of the phy_clk when the local_write_req signal is asserted. After the slave deasserts the local_ready signal, the master keeps all the write request signals asserted until the local_ready signal becomes high again. For read transactions, assert this signal for one clock cycle when read request is asserted and the local_address from which the data should be read is given to the memory. After the slave deasserts the local_ready signal (waitrequest_n in Avalon interface), the master keeps all the read request signals asserted until the local_ready signal becomes high again.</td>
</tr>
<tr>
<td>local_read_req</td>
<td>Input</td>
<td>Read request signal. You cannot assert read request and write request signals at the same time.</td>
</tr>
<tr>
<td>local_refresh_req</td>
<td>Input</td>
<td>User-controlled refresh request. If Enable User Auto-Refresh Controls option is turned on, local_refresh_req becomes available and you are responsible for issuing sufficient refresh requests to meet the memory requirements. This option allows complete control over when refreshes are issued to the memory including grouping together multiple refresh commands. Refresh requests take priority over read and write requests, unless the requests are already being processed.</td>
</tr>
<tr>
<td>local_refresh_chip</td>
<td>Input</td>
<td>Controls which chip to issue the user-refresh to. This active high signal is used together with the local_refresh_req signal. This signal is as wide as the memory chip select. This signal asserts a high value to each bit that represents the refresh for the corresponding memory chip. For example: If the local_refresh_chip signal is assigned with a value of 4'b0101, the controller refreshes the memory chips 0 and 2, and memory chips 1 and 3 are not refreshed.</td>
</tr>
<tr>
<td>local_size[]</td>
<td>Input</td>
<td>Controls the number of beats in the requested read or write access to memory, encoded as a binary number. The range of supported Avalon burst lengths is 1 to 64. The width of this signal is derived based on the burst count specified in the Local Maximum Burst Count option. With the derived width, you choose a value ranging from 1 to the local maximum burst count specified.</td>
</tr>
<tr>
<td>local_wdata[]</td>
<td>Input</td>
<td>Write data bus. The width of local_wdata is four times the memory data bus for a half rate controller.</td>
</tr>
<tr>
<td>local_write_req</td>
<td>Input</td>
<td>Write request signal. You cannot assert read request and write request signal at the same time.</td>
</tr>
<tr>
<td>local_multicast</td>
<td>Input</td>
<td>In-band multi-cast write request signal. This active high signal is used together with the local_write_req signal. When this signal is asserted high, data is written to all the memory chips available.</td>
</tr>
</tbody>
</table>
local_autopch_req | Input | User control of auto-precharge. If Enable Auto-Precharge Control option is turned on, the local_autopch_req signal becomes available and you can request the controller to issue an auto-precharge write or auto-precharge read command. These commands cause the memory to issue a precharge command to the current bank at the appropriate time without an explicit precharge command from the controller. This is particularly useful if you know the current read or write is the last one you intend to issue to the currently open row. The next time you need to use that bank, the access could be quicker as the controller does not need to precharge the bank before activating the row you wish to access.

If you issue a local burst longer than the memory burst with the local_autopch_req signal asserted, the controller only issues auto-precharge with the last read or write command.

local_self_rfsh_req | Input | User control of the self-refresh feature. If Enable Self-Refresh Controls option is enabled, you can request that the controller place the memory devices into a self-refresh state by asserting this signal. The controller places the memory in the self-refresh state as soon as it can without violating the relevant timing parameters and responds by asserting the local_self_rfsh_ack signal. You can hold the memory in the self-refresh state by keeping this signal asserted. You can release the memory from the self-refresh state at any time by deasserting the local_self_rfsh_req signal and the controller responds by deasserting the local_self_rfsh_ack signal once it has successfully brought the memory out of the self-refresh state.

local_init_done | Output | When the memory initialization, training, and calibration are complete, the ALTMEMPHY sequencer asserts the ctrl_usr_mode_rdy signal to the memory controller, which then asserts this signal to indicate that the memory interface is ready to be used.

Read and write requests are still accepted before local_init_done is asserted, however they are not issued to the memory until it is safe to do so.

This signal does not indicate that the calibration is successful.

local_rdata[] | Output | Read data bus. The width of local_rdata is twice that of the memory data bus for a full rate controller; four times the memory data bus for a half rate controller.

local_rdata_error | Output | Asserted if the current read data has an error. This signal is only available if the Enable Error Detection and Correction Logic option is turned on. This signal is asserted together with the local_rdata_valid signal.

If the controller encounters double-bit errors, no correction is made and the controller asserts this signal.

local_rdata_valid | Output | Read data valid signal. The local_rdata_valid signal indicates that valid data is present on the read data bus.

local_ready | Output | The local_ready signal indicates that the controller is ready to accept request signals. If the local_ready signal is asserted in the clock cycle that a read or write request is asserted, that request is accepted. The local_ready signal is deasserted to indicate that the controller cannot accept any more requests. The controller is able to buffer eight read or write requests.

<tr>
<td></td>
<td></td>
<td>occurred for a particular cycle.</td>
</tr>
</tbody>
</table>

Notes to Table 7–8:
(1) The mem_clk signals are output only signals from the FPGA. However, in the Quartus II software they must be defined as bidirectional (INOUT) I/Os to support the mimic path structure that the ALTMEMPHY megafunction uses.
(2) This signal is for Registered DIMMs only.

Register Maps Description

Table 7–10 through Table 7–23 show the register maps for the DDR3 SDRAM HPC II.

</tbody>
</table>
Latency is defined using the local (user) side frequency and absolute time (ns). There are two types of latencies that exist while designing with memory controllers—read and write latencies, which have the following definitions:

- **Read latency**—the amount of time it takes for the read data to appear at the local interface after initiating the read request.
- **Write latency**—the amount of time it takes for the write data to appear at the memory interface after initiating the write request.

For a half-rate controller, the local side frequency is half of the memory interface frequency.

Altera defines read and write latencies in terms of the local interface clock frequency and by the absolute time for the memory controllers. These latencies apply to supported device families with the half-rate DDR3 high-performance controllers (HPC and HPC II).

The latency defined in this section uses the following assumptions:

- The row is already open, there is no extra bank management needed.
- The controller is idle, there is no queued transaction pending, indicated by the `local_ready` signal asserted high.
- No refresh cycles occur before the transaction.

The latency for the high-performance controller comprises many different stages of the memory interface.
Figure 8–1 shows a typical memory interface read latency path showing read latency from the time a `local_read_req` assertion is detected by the controller up to data available to be read from the dual-port RAM (DPRAM) module.

**Figure 8–1. Typical Latency Path**

![Figure 8–1. Typical Latency Path](image)

Table 8–1 shows the different stages that make up the whole read and write latency that Figure 8–1 shows.

**Table 8–1. High Performance Controller Latency Stages and Descriptions**

<table>
<thead>
<tr>
<th>Latency Number</th>
<th>Latency Stage</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>T1</td>
<td>Controller</td>
<td><code>local_read_req</code> or <code>local_write_req</code> signal assertion to <code>ddr_cs_n</code> signal assertion.</td>
</tr>
<tr>
<td>T2</td>
<td>Command Output</td>
<td><code>ddr_cs_n</code> signal assertion to <code>mem_cs_n</code> signal assertion.</td>
</tr>
<tr>
<td>T3</td>
<td>CAS or WL</td>
<td>Read command to DQ data from the memory or write command to DQ data to the memory.</td>
</tr>
<tr>
<td>T4</td>
<td>ALTMEMPHY read data input</td>
<td>Read data appearing on the local interface.</td>
</tr>
<tr>
<td>T2 + T3</td>
<td>Write data latency</td>
<td>Write data appearing on the memory interface.</td>
</tr>
</tbody>
</table>

From Figure 8–1, the read latency in the high-performance controllers is made up of four components:

\[
\text{Read latency} = \text{controller latency} + \text{command output latency} + \text{CAS latency} + \text{PHY read data input latency} = T1 + T2 + T3 + T4
\]

Similarly, the write latency in the high-performance controllers is made up of three components:

\[
\text{Write latency} = \text{controller latency} + \text{write data latency} = T1 + T2 + T3
\]
You can separate the controller and ALTMEMPHY read data input latency into latency that occurred in the I/O element (IOE) and latency that occurred in the FPGA fabric.

Table 8–2 shows the read and write latency derived from the write and read latency definitions for half rate controller for Stratix III and Stratix IV devices.

The exact latency depends on your precise configuration. You should obtain precise latency from simulation, but this figure may vary in hardware because of the automatic calibration process.

### Table 8–2. Typical Latency

</table>

To see the latency incurred in the IOE for both read and write paths for ALTMEMPHY variations in Stratix IV and Stratix III devices refer to the IOE figures in the *External Memory Interfaces in Stratix III Devices* chapter of the *Stratix III Device Handbook* and the *External Memory Interfaces in Stratix IV Devices* chapter of the *Stratix IV Device Handbook*. 
This chapter details the timing diagrams for the DDR3 SDRAM high-performance controllers (HPC) and high-performance controllers II (HPC II).

**9. Timing Diagrams**

**DDR3 High-Performance Controllers**

This section discusses the following timing diagrams for HPC in AFI mode:

- “Auto-Precharge”
- “User Refresh”
- “Half-Rate Read for Avalon Interface”
- “Half-Rate Write for Avalon Interface”
- “Half Rate Write for Native Interface”
- “Initialization Timing for HPC”
- “Calibration Timing for HPC”
Auto-Precharge

The auto-precharge read and auto-precharge write commands allow you to indicate to the memory device that this read or write command is the last access to the currently open row. The memory device automatically closes (auto-precharges) the page it is currently accessing so that the next access to the same bank is quicker. This command is particularly useful for applications that require fast random accesses.

Figure 9–1. Auto-Precharge Operation for HPC

Notes to Figure 9–1:

(1) The auto-precharge request goes high.
(2) The local_ready signal is asserted and remains high until the auto-precharge request goes low.
(3) A new row address begins.
User Refresh

Figure 9–2 shows the user refresh control interface. This feature allows you to control when the controller issues refreshes to the memory. This feature allows better control of worst case latency and allows refreshes to be issued in bursts to take advantage of idle periods.

Figure 9–2. User-Refresh Operation for HPC

Notes to Figure 9–2:
(1) The local refresh request signal is asserted.
(2) The controller asserts the local_refresh_ack signal.
(3) The auto-refresh (ARF) command on the command bus.
Figure 9-3. Half-Rate Read Operation for HPC Using Avalon-MM Interface
The following sequence corresponds with the numbered items in Figure 9–3:

1. The local read request signal is asserted.
2. The controller accepts the request, the local_ready signal is asserted.
3. The controller asserts the ctl_doing_rd signal to tell the PHY how many clock cycles of read data to expect.
4. The read command (RD) on the command bus.
5. The mem_dqs signal has the read data from the controller.
6. These are the data to the controller with the valid signal.
7. The controller returns the valid read data to the user logic by asserting the local_rdata_valid signal when there is valid local read data.
Half-Rate Write for Avalon Interface

Figure 9–4. Half-Rate Write Operation for HPC Using Avalon Interface
The following sequence corresponds with the numbered items in Figure 9–4:

1. The user logic requests write by asserting the local_write_req signal.
2. The local_ready signal is asserted, indicating that the controller has accepted the request.
3. The data written to the memory for the write command.
4. The write (WR) command on the command bus.
5. The valid write data on the ctl_wdata signal.
6. The valid data on the mem_dq signal goes to the controller.
Half Rate Write for Native Interface

Figure 9–5. Half-Rate Write Operation for HPC Using Native Interface
The following sequence corresponds with the numbered items in Figure 9–5:

1. The user logic requests write by asserting the `local_write_req` signal.
2. The `local_ready` signal is asserted, indicating that the controller has accepted the request.
3. The data written to the memory for the write command.
4. The controller requests the user logic for the write data and byte-enables for the write by asserting the `local_wdata_req` signal.
5. The write (WR) command on the command bus.
6. The valid write data on the `ctl_wdata` signal.
7. The valid data on the `mem_dq` signal goes to the controller.
Initialization Timing

Figure 9–6. Initialization Timing for HPC
The following sequence corresponds with the numbered items in Figure 9–6:

1. The PHY initialization stage; wait for PLL to unlock.
2. The DRAM initialization stage; reset sequence.
3. Various SDRAM bus commands during the initialization sequence.
Calibration Timing

Figure 9–7. Calibration Timing for HPC
The following sequence corresponds with the numbered items in Figure 9–7:

1. The write leveling stage.
2. The write leveling coarse phase sweep.
3. Fine T9/T10 delay chain sweep.
4. The write burst training pattern.
5. Three training patterns available at different addresses—zeroes, ones, and mixed.
6. The read path setup starts with the first operation, read deskew.
7. The read path deskew increases capture margin.
8. The write deskew stage; patterns written to RAM and read back.
9. The write datapath setup; data written to DRAM to determine latency.
10. Advertise read and write latency stage.
11. Tracking setup stage to set up mimic window.
12. Calibration successful on user mode.
This section discusses the following timing diagrams for HPC II:

- “Half-Rate Read (Burst-Aligned Address)”
- “Half-Rate Write (Burst-Aligned Address)”
- “Half-Rate Read (Non Burst-Aligned Address)”
- “Half-Rate Write (Non Burst-Aligned Address)”
- “Half-Rate Read With Gaps”
- “Half-Rate Write With Gaps”
- “Half-Rate Write Operation (Merging Writes)”
- “Write-Read-Write-Read Operation”
Half-Rate Read (Burst-Aligned Address)

Figure 9–8. Half-Rate Read Operation for HPC II—Burst-Aligned Address
The following sequence corresponds with the numbered items in Figure 9–8:

1. The user logic requests the first read by asserting the \texttt{local\_read\_req} signal, and the size and address for this read. In this example, the request is a burst of length of 2 to the local address \texttt{0x000000}. This local address is mapped to the following memory address in half-rate mode:
   \begin{verbatim}
   mem\_row\_address = 0x000000
   mem\_col\_address = 0x0000
   mem\_bank\_address = 0x00
   \end{verbatim}

2. The user logic initiates a second read to a different memory column within the same row. The request for the second write is a burst length of 2. In this example, the user logic continues to accept commands until the command queue is full. When the command queue is full, the controller deasserts the \texttt{local\_ready} signal. The starting local address \texttt{0x000002} is mapped to the following memory address in half-rate mode:
   \begin{verbatim}
   mem\_row\_address = 0x0000
   mem\_col\_address = 0x0002<<2 = 0x0008
   mem\_bank\_address = 0x00
   \end{verbatim}

3. The controller issues the first read memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

4. The controller asserts the \texttt{afi\_doing\_rd} signal to indicate to the ALTMEMPHY megafunction the number of clock cycles of read data it must expect for the first read. The ALTMEMPHY megafunction uses the \texttt{afi\_doing\_rd} signal to enable its capture registers for the expected duration of memory burst.

5. The ALTMEMPHY megafunction issues the first read command to the memory and captures the read data from the memory.

6. The ALTMEMPHY megafunction returns the first data read to the controller after resynchronizing the data to the \texttt{phy\_clk} domain, by asserting the \texttt{afi\_rdata\_valid} signal when there is valid read data on the \texttt{afi\_rdata} bus.

7. The controller returns the first read data to the user by asserting the \texttt{local\_rdata\_valid} signal when there is valid read data on the \texttt{local\_rdata} bus. If the ECC logic is disabled, there is no delay between the \texttt{afi\_rdata} and the \texttt{local\_rdata} buses. If there is ECC logic in the controller, there is one or three clock cycles of delay between the \texttt{afi\_rdata} and \texttt{local\_rdata} buses.
Half-Rate Write (Burst-Aligned Address)

Figure 9–9. Half-Rate Write Operation for HPC II—Burst-Aligned Address
The following sequence corresponds with the numbered items in Figure 9–9:

1. The user logic asserts the first write request to row 0 so that row 0 is open before the next transaction.

2. The user logic asserts a second local_write_req signal with size of 2 and address of 0 (col = 0, row = 0, bank = 0, chip = 0). The local_ready signal is asserted along with the local_write_req signal, which indicates that the controller has accepted this request, and the user logic can request another read or write in the following clock cycle. If the local_ready signal was not asserted, the user logic must keep the write request, size, and address signals asserted until the local_ready signal is registered high.

3. The controller issues the necessary memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

4. The controller asserts the afi_wdata_valid signal to indicate to the ALTMEMPHY megafunction that valid write data and write data masks are present on the inputs to the ALTMEMPHY megafucntion.

5. The controller asserts the afi_dqs_burst signals to control the timing of the DQS signal that the ALTMEMPHY megafucntion issues to the memory.

6. The ALTMEMPHY megafucntion issues the write command, and sends the write data and write DQS to the memory.
Half-Rate Read (Non Burst-Aligned Address)

Figure 9–10. Half-Rate Read Operation for HPC II—Non Burst-Aligned Address
The following sequence corresponds with the numbered items in Figure 9–10:

1. The user logic requests the first read by asserting the `local_read_req` signal, and the size and address for this read. In this example, the request is a burst of length of 2 to the local address 0×000001. This local address is mapped to the following memory address in half-rate mode:

   mem_row_address = 0×0000
   mem_col_address = 0×0001<<2 = 0×0004
   mem_bank_address = 0×00

2. The controller issues the first read memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

3. The controller asserts the `afi_doing_rd` signal to indicate to the ALTMEMPHY megafunction the number of clock cycles of read data it must expect for the first read. The ALTMEMPHY megafunction uses the `afi_doing_rd` signal to enable its capture registers for the expected duration of memory burst.

4. The ALTMEMPHY megafunction issues the first read command to the memory and captures the read data from the memory.

5. The ALTMEMPHY megafunction returns the first data read to the controller after resynchronizing the data to the `phy_clk` domain, by asserting the `afi_rdata_valid` signal when there is valid read data on the `afi_rdata` bus.

6. The controller returns the first read data to the user by asserting the `local_rdata_valid` signal when there is valid read data on the `local_rdata` bus. If the ECC logic is disabled, there is no delay between the `afi_rdata` and the `local_rdata` buses. If there is ECC logic in the controller, there is one or three clock cycles of delay between the `afi_rdata` and `local_rdata` buses.
Half-Rate Write (Non Burst-Aligned Address)

Figure 9–11. Half-Rate Write Operation for HPC II—Non Burst-Aligned Address
The following sequence corresponds with the numbered items in Figure 9–11:

1. The user logic asserts the first `local_write_req` signal with a size of 2 and an address of 0x000001. The `local_ready` signal is asserted along with the `local_write_req` signal, which indicates that the controller has accepted this request, and the user logic can request another read or write in the following clock cycle. If the `local_ready` signal was not asserted, the user logic must keep the write request, size, and address signals asserted until the `local_ready` signal is registered high. The local address 0x000001 is mapped to the following memory address in half-rate mode:

   \[
   \begin{align*}
   \text{mem\_row\_address} &= 0\times0000 \\
   \text{mem\_col\_address} &= 0\times000001<<2 = 0\times000004 \\
   \text{mem\_bank\_address} &= 0\times00
   \end{align*}
   \]

2. The user logic asserts the second `local_write_req` signal with a size of 2 and an address of 0x000003. The local address 0x000003 is mapped to the following memory address in half-rate mode:

   \[
   \begin{align*}
   \text{mem\_row\_address} &= 0\times0000 \\
   \text{mem\_col\_address} &= 0\times000003<<2 = 0\times00000C \\
   \text{mem\_bank\_address} &= 0\times00
   \end{align*}
   \]

3. The controller issues the necessary memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

4. The controller asserts the `afi_wdata_valid` signal to indicate to the ALTMEMPHY megafunction that valid write data and write data masks are present on the inputs to the ALTMEMPHY megafunction.

5. The controller asserts the `afi_dqs_burst` signals to control the timing of the DQS signal that the ALTMEMPHY megafunction issues to the memory.

6. The ALTMEMPHY megafunction issues the write command, and sends the write data and write DQS to the memory.

7. The controller generates another write because the first write is to a non-aligned memory address, 0x0004. The controller performs the second write burst at the memory address of 0x0008.
Half-Rate Read With Gaps

Figure 9–12. Half-Rate Read Operation for HPC II—With Gaps
The following sequence corresponds with the numbered items in Figure 9–12:

1. The user logic requests the first read by asserting the `local_read_req` signal, and the size and address for this read. In this example, the request is a burst of length of 2 to the local address $0\times0000810$. This local address is mapped to the following memory address in half-rate mode:

   \[
   \begin{align*}
   &\text{mem\_row\_address} = 0\times0001 \\
   &\text{mem\_col\_address} = 0\times0010\ll2 = 0\times0040 \\
   &\text{mem\_bank\_address} = 0\times00
   \end{align*}
   \]

2. When the command queue is full, the controller deasserts the `local\_ready` signal to indicate that the controller has not accepted the command. The user logic must keep the read request, size, and address signal until the `local\_ready` signal is asserted again.

3. The user logic asserts a second `local\_read\_req` signal with a size of 2 and address of $0\times0000912$.

4. The controller issues the first read memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

5. The ALTMEMPHY megafunction issues the read command to the memory and captures the read data from the memory.
Half-Rate Write With Gaps

Figure 9–13. Half-Rate Write Operation for HPC II—With Gaps

The following sequence corresponds with the numbered items in Figure 9–13:

1. The user logic asserts a local_write_req signal with a size of 2 and an address of 0×0000F1C.
2. The controller issues the necessary memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.
3. The controller asserts the afi_wdata_valid signal to indicate to the ALTMEMPHY megafunction that valid write data and write data masks are present on the inputs to the ALTMEMPHY megafunction.
4. The controller asserts the afi_dqs_burst signals to control the timing of the DQS signal that the ALTMEMPHY megafunction issues to the memory.
5. The ALTMEMPHY megafunction issues the write command, and sends the write data and write DQS to the memory.
6. For transactions with a local size of two, the local_write_req and local_ready signals must be high for two clock cycles so that all the write data can be transferred to the controller.
Half-Rate Write Operation (Merging Writes)

Figure 9–14. Write Operation for HPC II—Merging Writes

The following sequence corresponds with the numbered items in Figure 9–14:

1. The user logic asserts the first `local_write_req` signal with a size of 1 and an address of `0x000000`. The `local_ready` signal is asserted along with the `local_write_req` signal, which indicates that the controller has accepted this request, and the user logic can request another read or write in the following clock cycle. If the `local_ready` signal was not asserted, the user logic must keep the write request, size, and address signals asserted until the `local_ready` signal is registered high. The local address `0x000000` is mapped to the following memory address in half-rate mode:

   \[
   \begin{align*}
   \text{mem_row_address} &= 0x000000 \\
   \text{mem_col_address} &= 0x000000 \\
   \text{mem_bank_address} &= 0x00
   \end{align*}
   \]

2. The user logic asserts a second `local_write_req` signal with a size of 1 and address of 1. The `local_ready` signal is asserted along with the `local_write_req` signal, which indicates that the controller has accepted this request. Since the second write request is to a sequential address (same row, same bank, and column increment by 1), this write and the first write can be merged at the memory transaction.

3. The controller issues the necessary memory command and address signals to the ALTMEMPHY megafuction for it to send to the memory device.
4. The controller asserts the `afi_wdata_valid` signal to indicate to the ALTMEMPHY megafuction that valid write data and write data masks are present on the inputs to the ALTMEMPHY megafunction.

5. The controller asserts the `afi_dqs_burst` signals to control the timing of the DQS signal that the ALTMEMPHY megafunction issues to the memory.

6. The ALTMEMPHY megafunction issues the write command, and sends the write data and write DQS to the memory.
Write-Read-Write-Read Operation

Figure 9–15. Write-Read Sequential Operation for HPC II

[Diagram of Write-Read-Write-Read Operation]
The following sequence corresponds with the numbered items in Figure 9–15:

1. The user logic requests the first write by asserting the `local_write_req` signal, and the size and address for this write. In this example, the request is a burst length of 1 to a local address `0x000002`. This local address is mapped to the following memory address in half-rate mode:

   ```plaintext
   mem_row_address = 0×0000
   mem_col_address = 0×0002<<2 = 0×0008
   mem_bank_address = 0×00
   ```

2. The user logic initiates the first read to the same address as the first write. The request for the read is a burst length of 1. The controller continues to accept commands until the command queue is full. When the command queue is full, the controller deasserts the `local_ready` signal. The starting local address `0x000002` is mapped to the following memory address in half-rate mode:

   ```plaintext
   mem_row_address = 0×0000
   mem_col_address = 0×0002<<2 = 0×0008
   mem_bank_address = 0×00
   ```

3. The user logic asserts a second `local_write_req` signal with a size of 1 and address of `0x000004`.

4. The user logic asserts a second `local_read_req` signal with a size of 1 and address of `0x000004`.

5. The controller issues the necessary memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

6. The controller asserts the `afi_wdata_valid` signal to indicate to the ALTMEMPHY megafunction that valid write data and write data masks are present on the inputs to the ALTMEMPHY megafunction.

7. The controller asserts the `afi_dqs_burst` signals to control the timing of the DQS signals that the ALTMEMPHY megafunction issues to the memory.

8. The controller issues the first read memory command and address signals to the ALTMEMPHY megafunction for it to send to the memory device.

9. The controller asserts the `afi_doing_rd` signal to indicate to the ALTMEMPHY megafunction the number of clock cycles of read data it must expect for the first read. The ALTMEMPHY megafunction uses the `afi_doing_rd` signal to enable its capture registers for the expected duration of memory burst.

10. The ALTMEMPHY megafunction issues the write command, and sends the write data and write DQS to the memory.

11. The ALTMEMPHY megafunction issues the first read command to the memory and captures the read data from the memory.

12. The ALTMEMPHY megafunction returns the first data read to the controller after resynchronizing the data to the `phy_clk` domain, by asserting the `afi_rdata_valid` signal when there is valid read data on the `afi_rdata` bus.
13. The controller returns the first read data to the user by asserting the \texttt{local\_rdata\_valid} signal when there is valid read data on the \texttt{local\_rdata} bus. If the ECC logic is disabled, there is no delay between the \texttt{afi\_rdata} and the \texttt{local\_rdata} buses. If there is ECC logic in the controller, there is one or three clock cycles of delay between the \texttt{afi\_rdata} and \texttt{local\_rdata} buses.

1. About This IP

The Altera QDR II and QDR II+ SRAM controllers with UniPHY provide simplified interfaces to industry-standard QDR II and QDR II+ SRAM.

The QDR II and QDR II+ SRAM controllers with UniPHY offer full-rate or half-rate QDR II and QDR II+ SRAM interfaces.

The MegaWizard Plug-In Manager generates an example top-level project, consisting of an example driver, and your QDR II and QDR II+ SRAM controller custom variation. The controller instantiates an instance of the UniPHY.

The example top-level project is a fully-functional design that you can simulate, synthesize, and use in hardware. The example driver is a self-test module that issues read and write commands to the controller and checks the read data to produce the pass or fail and test-complete signals.

The UniPHY IP is an interface between a memory controller and memory devices and performs read and write operations to the memory. The UniPHY IP creates the datapath between the memory device and the memory controller and user logic in various Altera devices.

For device families not supported by the UniPHY IP, use the Altera legacy integrated static datapath and controller MegaCore functions.

If the UniPHY IP does not suit your needs, you can create your own memory interface datapath using the ALTDLL and ALTDQ_DQS megafunctions, available in the Quartus II software, but you are then responsible for all of the aspects of the design including timing analysis and design constraints.

The UniPHY IP offers the Altera PHY interface (AFI). The AFI results in a simple connection between the PHY and controller.

Release Information

Table 1–1 provides information about this release of the QDR II and QDR II+ SRAM controllers with UniPHY.

<table>

Altera® verifies that the current version of the Quartus® II software compiles the previous version of each MegaCore function. The MegaCore IP Library Release Notes and Errata report any exceptions to this verification. Altera does not verify compilation with MegaCore function versions older than one release.
Device Family Support

Megafonctions provide either full or preliminary support for target Altera device families:

- Full support means the megafonction meets all functional and timing requirements for the device family and can be used in production designs.

- Preliminary support means the megafonction meets all functional requirements, but can still be undergoing timing analysis for the device family.

Table 1–2 shows the level of support offered by the QDR II and QDR II+ SRAM controller to each of the Altera device families.

For information about supported clock rates for external memory interfaces, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

The IP supports HardCopy III and HardCopy IV ASICs as companion devices to the Stratix III and Stratix IV target devices respectively.

Features

The QDR II and QDR II+ SRAM controller with UniPHY offers the following features:

- Supports all the features currently available from the main QDR II vendors

- Maximum frequency of 300 MHz (QDR II); maximum frequency of 400 MHz (QDR II+)

- ×9, ×18, ×36 memory organization

- ×36 emulation mode

- 2-word (QDR II only) or 4-word burst architecture

- Memory latency of 1.5 clocks (QDR II); memory latency 2 or 2.5 clocks (nonprogrammable for QDR II+)

- AFI between the PHY and the memory controller

- Full-rate or half-rate AFI—2-word burst is supported in QDR II full-rate designs only

- Support for timing simulation
MegaCore Verification

MegaCore verification involves simulation testing. Altera has carried out extensive random, directed tests with functional test coverage using industry-standard models to ensure the functionality of the QDR II and QDR II+ SRAM controllers with UniPHY.

Resource Utilization

Table 1–3 through Table 1–4 show the typical size of the QDR II and QDR II+ SRAM controllers with UniPHY in the Quartus II software version 9.1 for the following devices:

- Arria II GX devices
- Stratix III devices
- Stratix IV devices

System Requirements

The QDR II and QDR II+ SRAM controllers with UniPHY are part of the MegaCore IP Library, which is distributed with the Quartus II software.

For system requirements and installation instructions, refer to Quartus II Installation & Licensing for Windows and Linux Workstations.

Installation and Licensing

Figure 1–1 shows the directory structure after you install the QDR II and QDR II+ SRAM controllers with UniPHY, where <path> is the installation directory. The default installation directory on Windows is c:\altera\<version>; on Linux it is /opt/altera<version>.

Before you purchase a license, you can perform the following actions:

- Simulate the behavior of a megafunction (Altera MegaCore function or AMPSTM megafunction) within your system
- Verify the functionality of your design, as well as evaluate its size and speed quickly and easily
Generate device programming files for designs that include MegaCore functions

Program a device and verify your design in hardware

You need a license for the MegaCore function only when you want to take your design to production.

Contact your local Altera sales representative to order a license for the QDR II and QDR II+ SRAM controllers with UniPHY.
2. Getting Started

Design Flow

You can implement a QDR II or QDR II+ SRAM controller with UniPHY using either of the following flows:

- MegaWizard flow
- SOPC Builder flow

For information on the SOPC Builder flow, refer to *Volume 6: Design Flow Tutorials* of the *External Memory Interface Handbook*.

Figure 2–1. Design Flows

The MegaWizard flow offers the following advantages:

- Allows you to design directly from the QDR II and QDR II+ SRAM interface to peripheral device or devices
MegaWizard Plug-In Flow

The MegaWizard Plug-In flow allows you to customize the QDR II and QDR II+ SRAM controller with UniPHY and manually integrate the function into your design.

For more information about the MegaWizard Plug-In, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.

Specify Parameters

To specify parameters using the MegaWizard Plug-In flow, follow these steps:

1. In the Quartus II software, create a new Quartus II project with the New Project Wizard.

2. On the Tools menu, click MegaWizard Plug-In Manager and follow the steps to start the MegaWizard Plug-In Manager. The QDR II and QDR II+ SRAM controllers with UniPHY are in the Interfaces folder under the External Memory folder.

3. Click on the following tabs and set the parameters:
   - General settings
   - Memory parameters
   - Memory timing

   The text window at the bottom of the MegaWizard Plug-In displays information about the memory interface, warnings, and errors if you are trying to create something that is not supported. The Finish button is disabled until you fix all the errors indicated in this window.

   For more information about the parameters, click Info.

4. To select a memory preset, click the arrow to expand the presets list, select the preset and click Apply (Figure 2–2).

   If you select a preset, you may overwrite other settings.
5. Click **Finish** to generate the MegaCore function and supporting files.

   - Ignore the following warning at the end of the generated files list:

     ```plaintext
     WARNING: Files have same name.
     ```

     The wizard automatically generates an IP functional simulation model for VHDL designs.

   - Use the simulation models only for simulation and not for synthesis or any other purposes. Using these models for synthesis creates a nonfunctional design.

6. If you generate the MegaCore function instance in a Quartus II project, you are prompted to add the `.qip` files to the current Quartus II project. When prompted to add the `.qip` files to your project, click **Yes**. The addition of the `.qip` files enables their visibility to Nativelink. Nativelink requires the `.qip` files to include libraries for simulation.

   - The Quartus II IP File (.qip) contains information about the generated IP core. In most cases, the `.qip` file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. The MegaWizard interface generates a single `.qip` file for each MegaCore function.
7. After you review the generation report, click Exit to close the MegaWizard Plug-In Manager.

8. Add the example project files to your project:
   a. On the Project menu, click Add/Remove Files in Project.
   b. Browse to the `<variation_name>`\example_project directory.
   c. Select all of the files that start with `<variation name>`; do not select the mem_model.sv file. Click Open. Click OK.
   d. On the File menu, click Open.
   e. Browse to `<variation_name>_example_top.v` and click Open.
   f. On the Project menu, click Set as Top-Level Entity.

   ![You can look in the example_top.v file, to see how to instantiate the memory controller in your own design.]

**SOPC Builder Flow**

The SOPC Builder flow allows you to add the QDR II and QDR II+ SRAM controller with UniPHY directly to a new or existing SOPC Builder system.

You can easily add other available components to quickly create an SOPC Builder system with a QDR II and QDR II+ SRAM controller, such as the Nios II processor, external memory controllers, and scatter-gather DMA controllers. SOPC Builder automatically creates the system interconnect logic and system simulation environment.

For more information about SOPC Builder, refer to *volume 4* of the *Quartus II Handbook*. For more information about how to use controllers with SOPC Builder, refer to *Volume 6: Design Flow Tutorials* of the *External Memory Interface Handbook*. For more information on the Quartus II software, refer to the Quartus II Help.

**Specify Parameters**

To specify QDR II and QDR II+ SRAM controller with UniPHY parameters using the SOPC Builder flow, follow these steps:

1. In the Quartus II software, create a new Quartus II project with the New Project Wizard.
2. On the Tools menu, click SOPC Builder.
3. For a new system, specify the system name and language.
4. Add QDR II and QDR II+ SRAM Controller with UniPHY to your system from the System Contents tab. The QDR II and QDR II+ SRAM is in the Memories and Memory Controllers folder.
5. Click on the following tabs and set the parameters for the IP:
   - General settings
     - You must turn on Generate power of two bus widths.
   - Memory parameters
   - Memory timing

The text window at the bottom of the MegaWizard Plug-In displays information about the memory interface, warnings, and errors if you are trying to create something that is not supported. The Finish button is disabled until you correct all the errors indicated in this window.

For more information about the parameters, click Info.

6. Click Finish to complete the QDR II and QDR II+ SRAM controller with UniPHY and add it to the system.

**Complete the SOPC Builder System**

To complete the SOPC Builder system, follow these steps:

1. Select other components in the component library for your SOPC Builder system.
2. Click Generate.

   - The Quartus II IP File (.qip) contains information about a generated IP core or system. In most cases, the .qip file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. Generally, a single .qip file is generated for each SOPC Builder system. However, some more complex SOPC Builder components generate a separate .qip file. In that case, the system .qip file references the component .qip file.

3. Compile your design, refer to “Constraining and Compiling” on page 3–1.

**Simulate the System**

During system generation, SOPC Builder optionally generates a simulation model and testbench for the entire system, which you can use to easily simulate your system in any of Altera’s supported simulation tools. SOPC Builder also generates a set of ModelSim® Tcl scripts and macros that you can use to compile the testbench, IP functional simulation models, and plain-text RTL design files that describe your system in the ModelSim simulation software (refer to “Generated Files” on page 2–5).

For more information about simulating SOPC Builder systems, refer to volume 4 of the Quartus II Handbook and AN 351: Simulating Nios II Systems.

**Generated Files**

When you complete either flow, there are wizard-generated files in your project directory.
For information on the generated files, refer to the `readme.txt`.

The PLL parameters are statically defined in the `<variation name>_parameters.tcl` at generation time. To ensure timing constraints and timing reports are correct, when you make changes to the PLL component using the MegaWizard Plug-In, apply those changes to the PLL parameters in this file.

**Simulating the Design**

The wizard generates a testbench for simulation and generic memory model in the `rtl_sim` directory.

For more information about simulation, refer to the `Simulation` section in volume 4 of the **External Memory Interface Handbook**.
3. Constraining and Compiling

The wizard generates a Synopsis design constraint (.sdc) script and a pin assignment script, `<variation_name>_pin_assignments.tcl`. Both the .sdc and the `<variation name>_pin_assignments.tcl` support multiple instances. These scripts iterate through all instances of the core and apply the same constraints to all of them.

Add Pin and DQ Group Assignments

The pin assignment script, `<variation_name>_pin_assignments.tcl`, sets up the I/O standards and the input/output termination for the QDR II or QDR II+ SRAM controller with UniPHY. This script also helps to relate the DQ and QR pin groups together for the fitter to place them correctly in the Quartus II software.

The pin assignment script does not create a clock for the design. You need to create a clock for the design and provide pin assignments for the signals of both the example driver and testbench that the MegaCore variation generates.

Run the `<variation_name>_pin_assignments.tcl` to add the input and output termination, I/O standards, and DQ group assignments to the example design. To run the pin assignment script, follow these steps:

1. On Processing menu, point to Start, and click Start Analysis and Synthesis.
2. On the Tool menu click Tcl Scripts.
3. Specify the pin_assignments.tcl file and click Run.

The PLL input reference clock pin does not need to have the same I/O standard as the memory interface I/Os. However, you may see a no-fit as the bank in which the PLL input reference clock pin gets placed becomes unusable for placement of the memory interface I/Os (because of incompatible VCCIO levels). You should assign the same I/O standard to the PLL input reference clock pin.

Board Trace Model

Bus turnaround is not timing analyzed; consequently, the controller dead times are based on assumptions about the user board trace lengths. For timing analysis to be correct, board trace delays must be limited to 0.6 ns from FPGA to memory and from memory to FPGA.

For accurate I/O timing analysis, you must specify the board trace and loading information. You should derive and refine this information during your PCB development process of prelayout (line) simulation and finally postlayout (board) simulation.

For more information about how to include your board simulation results in the Quartus II software and how to assign pins using pin planners, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.
Compile the Design

To compile the design, on the Processing menu, click **Start Compilation**.

After you have compiled the top-level file, you can perform RTL simulation or program your targeted Altera device to verify the top-level file in hardware.

For more information about simulating, refer to the **Simulation** section in volume 4 of the *External Memory Interface Handbook*. 
4. Functional Description—Controller

The controller translates memory requests from the Avalon Memory-Mapped (Avalon-MM) interface to AFI, while satisfying timing requirements imposed by the memory configurations. QDR II and QDR II+ SRAM has unidirectional data buses, therefore read and write operations are highly independent of each other and each has its own interface and state machine.

Block Description

This topic describes the blocks in the IP. Figure 4–1 shows a block diagram of the QDR II and QDR II+ SRAM controller architecture.

Figure 4–1. QDR II and QDR II+ SRAM Controller Architecture Block Diagram

Avalon-MM Slave Read and Write Interfaces

The read and write blocks accept from the Avalon-MM interface read and write requests respectively. Each block has a simple state machine that represents the state of the command and address registers, which stores the command and address when a request arrives.

The read data passes through without the controller registering it, as the PHY takes care of read latency. The write data goes through a pipeline stage to delay for a fixed number of cycles as specified by the write latency. In the full-rate BL4 controller, the write data is also multiplexed into a burst of 2, which is then multiplexed again in the PHY to become a burst of 4 in DDR.

The user interface to the controller has separate read and write Avalon-MM interfaces because reads and writes are independent of each other in the memory device. The separate channels give efficient use of available bandwidth.

Command Issuing FSM

This full-state machine (FSM) has two states: INIT and INIT_COMPLETE. In the INIT_COMPLETE state, commands are issued immediately as requests arrive using combinational logic and do not require state transitions.
AFI

In the full-rate burst length of two configuration, the controller can issue both read and write commands in the same clock cycle. In the memory device, both commands are clocked on the positive edge, but the read address is clocked on the positive edge, while the write address is clocked on the negative edge. Care must be taken on how these signals are ordered in the AFI.

It is similar for the half-rate burst length of four configuration, except that the AFI width is doubled to fill two memory clocks per controller clock. As the controller only issues one write command and one read command per controller clock, the AFI read and write signals corresponding to the other memory cycle are tied to no operation (NOP).

Avalon-MM and Memory Data Width

Table 4–1 shows the data width ratio between the memory interface and the Avalon-MM interface. The half-rate controller does not support burst-of-2 devices because it under uses the available memory bandwidth. Regardless of full or half-rate decision and the device burst length, the Avalon-MM interface must supply all the data for the entire memory burst in a single clock cycle. Therefore the Avalon-MM data width of the full-rate controller with burst-of-4 devices is four times the memory data width.

### Table 4–1. Data Width Ratio

This chapter describes the PHY part of the QDR II and QDR II+ SRAM controller with UniPHY.

**Block Description**

The PHY comprises the following major functional units:

- Reset and Clock Generation
- Address and Command Datapath
- Write Datapath
- Read Datapath
- Sequencer

![PHY Block Diagram](image)

**Figure 5–1. PHY Block Diagram**

**I/O Pads**

The I/O pads contain all the I/O instantiations. The major I/O is the ALTDQ_DQS megafunction.
Reset and Clock Generation

The clocking operation in the PHY can be classified into two domains: the PHY-memory domain and the PHY-AFI domain. The PHY-memory domain interfaces with the external memory device and is always at full-rate. The PHY-AFI domain interfaces with the memory controller and can be either a full-rate or half-rate clock based on the choice of the controller. Table 5–1 lists the clocks required for half-rate designs.

Table 5–1. Clocks—Half-Rate Designs

</table>

The UniPHY uses an active-low, asynchronous assert and synchronous de-assert reset scheme. The global reset signal resets the PLL in the PHY and the rest of the system is held in reset until after the PLL is locked. The number of synchronization pipeline stages is set to 4.

Address and Command Datapath

The memory controller is responsible for controlling the read and write addresses and commands, to meet the memory specifications. The PHY simply passes the address and command received from the memory controller to the memory device. The PHY is also indifferent to address or command, the circuitry is the same for both.
The outputs of address and command datapath are connected to the inputs of the address and command I/Os. An ALTDDIO_OUT megafunction converts the addresses from single data rate to double data rate. An ALTDDIO_OUT megafunction with an ALTIOBUF megafunction deliver a pair of address and command clock to the memory.

Write Datapath

The write datapath passes write data from the memory controller to the I/O. The DQ pins are bidirectional and shared between read and write. The write data valid signal from the memory controller generates the output enable signal to control the output buffer. It is also generates the dynamic termination control signal, which selects between series (output mode) and parallel (input mode) termination. An ALT_OCT megafunction (instantiated in the top-level file) configures the termination values.

Read Datapath

The read data is captured in the input mode ALTDQ_DQS in the I/O. The captured data is then forwarded to the read datapath. The read datapath synchronizes read data from the read capture clock domain to the AFI clock domain and converts data from SDR to HDR (half-rate designs only).

In half-rate designs, the write side of the FIFO buffer should be double the size of the read side of the FIFO buffer. The read side only reads one entry after the write side has written into two entries, which effectively converts data from SDR to HDR. In full-rate designs, the size of the FIFO buffer is the same for both write and read as both sides operate at the same rate. The FIFO buffer size is 16 full rate entries.

Sequencer

The sequencer intercepts all the signals from the memory controller and takes control during calibration. The sequencer is a state machine that processes the calibration algorithm. Table 5–3 shows the states in the sequencer.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>
</tr>

</tr>
<tr>
<td>CALIB_FAIL</td>
<td>Calibration is not successful.</td>
</tr>
</tbody>
</table>

Interfaces

Figure 5–2 shows the major blocks of the UniPHY and how it interfaces with the external memory device and the controller.

Instantiating the delay-locked-loop (DLL) and the phase-locked loop (PLL) on the same level as the UNIPHY eases DLL and PLL sharing.
The following interfaces are on the UniPHY top-level file:

- AFI
- Memory interface
- DLL and PLL sharing interface
- OCT interface

### The Memory Interface

For more information on the memory interface, refer to “UniPHY Signals” on page 5-5.

### The DLL and PLL Sharing Interface

The UniPHY memory interface requires one PLL and one DLL to produce the clocks and delay codeword. The PLL and DLL can be shared using a master and slave scenario. The PLL and DLL output signals are defined as inputs and outputs in the top-level file and an additional parameter `PLL_DLL_MASTER` is also defined. If `PLL_DLL_MASTER` is 1, the RTL instantiates the PLL and DLL, which drives the clock and DLL codeword inputs and outputs. If the parameter is 0, the wires previously connected to the output of the PLL and DLL are assigned to the clock and DLL codeword input and outputs. During synthesis, the direction is automatically resolved to either input or output as they are either used strictly as inputs or outputs.

### UniPHY Signals

This section describes the UniPHY signals. Table 5-5 shows the clock and reset signals.

The QDR II and QDR II+ SRAM controllers with UniPHY use AFI. The AFI timing is identical to the DDR3 SDRAM AFI in the Quartus II software version 9.0. However, some signals have been renamed, some added, and others removed from the AFI definition. The AFI includes only signals that are part of the controller-to-PHY interface, clocks, and reset. All signals on the controller-to-PHY interface have the afi_ prefix to the signal name. Table 5–9 shows the renamed AFI signals and original (Quartus II software version 9.0) names.

This section describes the typical modules that are connected to the UniPHY PHY and the port name prefixes each module uses. This section describes using a custom controller and describes the AFI.

The AFI standardizes and simplifies the interface between controller and PHY for all Altera memory designs, thus allowing you to easily interchange your own controller code with Altera’s high-performance controllers. The AFI PHY includes an administration block that configures the memory for calibration and performs necessary accesses to mode registers that configure the memory as required (these calibration processes are different).

For half-rate designs, the address and command signals in the UniPHY are asserted for one `mem_clk` cycle (1T addressing), such that there are two input bits per address and command pin in half-rate designs. If you require a more conservative 2T addressing, drive both input bits (of the address and command signal) identically in half-rate designs.

**Figure 5–3** shows the half-rate write operation.

**Table 5–9. AFI New Signal Names**

**PHY-to-Controller Interfaces**

For half-rate designs, the address and command signals in the UniPHY are asserted for one `mem_clk` cycle (1T addressing), such that there are two input bits per address and command pin in half-rate designs. If you require a more conservative 2T addressing, drive both input bits (of the address and command signal) identically in half-rate designs.

**Figure 5–4** shows a full-rate write.
After calibration is completed, the sequencer sends the write latency in number of clock cycles to the controller.

Figure 5–5 shows full-rate reads; Figure 5–6 shows half-rate reads.

**Figure 5–4.** Full-Rate Write

**Figure 5–5.** Full-Rate Reads
Figure 5–6. Half-Rate Reads

afi_rlat = 9

afi_addr
afi_cs_n
afi_rdata_en
mem_dqs
mem_dq
afi_rdata_valid
afi_rdata

afi_addr = AX XA
afi_cs_n = 10
afi_rdata_en = 10 01
mem_dqs = 10 01
mem_dq = 10 01
afi_rdata_valid = DX XD
afi_rdata = DX XD
Figure 5–7 and Figure 5–8 show writes and reads, where the data is written to and read from the same address. In each example, afi_rdata and afi_wdata are aligned with controller clock (afi_clk) cycles. All the data in the bit vector is valid at once.

The AFI has the following conventions:

- With the AFI, high and low signals are combined in one signal, so for a single chip select (afi_cs_n) interface, afi_cs_n[1:0], where location 0 appears on the memory bus on one mem_clk cycle and location 1 on the next mem_clk cycle.

  This convention is maintained for all signals so for an 8 bit memory interface, the write data (afi_wdata) signal is afi_wdata[31:0], where the first data on the DQ pins is afi_wdata[7:0], then afi_wdata[15:8], then afi_wdata[23:16], then afi_wdata[31:24].

- Spaced reads and writes have the following definitions:
  - Spaced writes—write commands separated by a gap of one controller clock (afi_clk) cycle
  - Spaced reads—read commands separated by a gap of one controller clock (afi_clk) cycle

Figure 5–7 through Figure 5–8 assume the following general points:

- The burst length is four.
- An 8-bit interface with one chip select.
- The data for one controller clock (afi_clk) cycle represents data for two memory clock (mem_clk) cycles (half-rate interface).
Figure 5–7. Word-Aligned Writes

Notes to Figure 5–7:

1. To show the even alignment of \( \text{afi}\_\text{cs}_n \), expand the signal (this convention applies for all other signals).
2. The \( \text{afi}\_\text{dqs}\_\text{burst} \) must go high one memory clock cycle before \( \text{afi}\_\text{wdata}\_\text{valid} \). Compare with the word-unaligned case.
3. The \( \text{afi}\_\text{wdata}\_\text{valid} \) is asserted two \( \text{afi}\_\text{wlat} \) controller clock \( \text{afi}\_\text{clk} \) cycles after chip select \( \text{afi}\_\text{cs}_n \) is asserted. The \( \text{afi}\_\text{wlat} \) indicates the required write latency in the system. The value is determined during calibration and is dependant upon the relative delays in the address and command path and the write datapath in both the PHY and the external DDR SDRAM subsystem. The controller must drive \( \text{afi}\_\text{cs}_n \) and then wait \( \text{afi}\_\text{wlat} \) (two in this example) \( \text{afi}\_\text{clks} \) before driving \( \text{afi}\_\text{wdata}\_\text{valid} \).
4. Observe the ordering of write data \( \text{afi}\_\text{wdata} \). Compare this to data on the \( \text{mem}\_\text{dq} \) signal.
5. In all waveforms a command record is added that combines the memory pins \( \text{ras}_n, \text{cas}_n \) and \( \text{we}_n \) into the current command that is issued. This command is registered by the memory when chip select \( \text{mem}\_\text{cs}_n \) is low. The important commands in the presented waveforms are \( \text{WR} = \text{write}, \text{ACT} = \text{activate} \).
Figure 5–8. Word-Aligned Reads

Notes to Figure 5–8:

(1) For AFI, afi_rdata_en is required to be asserted one memory clock cycle before chip select (afi_cs_n) is asserted. In the half-rate afi_clk domain, this requirement manifests as the controller driving 11 (as opposed to the 01) on afi_rdata_en.

(2) AFI requires that afi_rdata_en is driven for the duration of the read. In this example, it is driven to 11 for two half-rate afi_clks, which equates to driving to 1, for the four memory clock cycles of this four-beat burst.

(3) The afi_rdata_valid returns 15 (afi_rlat) controller clock (afi_clk) cycles after afi_rdata_en is asserted. Returned is when the afi_rdata_valid signal is observed at the output of a register within the controller. A controller can use the afi_rlat value to determine when to register to returned data, but this is unnecessary as the afi_rdata_valid is provided for the controller to use as an enable when registering read data.

(4) Observe the alignment of returned read data with respect to data on the bus.
Using a Custom Controller

The `<variation name>` directory contains the `<variation name>_memphy_top.v` file, which is a module that is just the PHY portion with the parameter defaults set to the appropriate values given the current parameterization. This module can be used directly with a custom controller.
The MegaWizard Plug-In creates an example top-level project that shows you how to instantiate and connect the QDR II and QDR II+ SRAM controller.

The example top-level project contains a testbench, which is for use with Verilog HDL-only language simulators such as ModelSim-AE Verilog, and shows simple operation of the memory interface.

For a VHDL simulation, use the VHDL IP functional simulation model.

The testbench contains the following blocks:

- A synthesizable Avalon-MM example driver, which implements a pseudo-random pattern of reads and writes to a parameterized number of addresses. The driver also monitors the data read from the memory to ensure it is what is written and asserts a failure otherwise.

- An instance of the controller, which interfaces between the Avalon-MM interface and the API.

- The UniPHY, which serves as an interface between the memory controller and external memory device(s) to perform read and write operations to the memory.

- A memory model, which acts as a generic model that adheres to the memory protocol specifications. Memory vendors also provide simulation models for specific memory components that can be downloaded from their websites. This block is available in Verilog HDL only.

Figure 6–1 shows the testbench and the example top-level file.

Figure 6–1. Testbench and Example Top-Level File

The SystemVerilog VMM test bench is produced with the example top-level file and is for use with SystemVerilog simulators such as VCS and Questa. The testbench uses the Synopsys VMM libraries, which are freely available. The testbench file contains the following blocks:

- A UniPHY_env environment class that extends vmm_env and instantiates the test program.

- A test program that sends a variety of memory interface transactions to the Avalon-MM bus functional model.
Example Driver

The example driver for Avalon-MM memory interfaces generates Avalon-MM traffic on an Avalon-MM master interface. As the read and write traffic is generated, the expected read response is stored internally and compared to the read responses as they arrive. If all reads report their expected response then the pass signal is asserted, but if any read responds with unexpected data a fail is asserted.

Each operation generated by the driver is a single or block of writes followed by a single or block of reads to the same addresses, which allows the driver to determine exactly what data should be expected when the read data is returned by the memory interface. The driver comprises a traffic generation block, the Avalon-MM interface and a read compare block. The traffic generation block generates addresses and write data, which are then sent out over the Avalon-MM interface. The read compare block compares the read data received from the Avalon-MM interface to the write data generated from the traffic generator. If at any time the data received is not the expected data, the read compare signals that there is a failure and the driver enters a fail state. If all patterns have been generated and compared successfully, the driver enters a pass state.

Within the driver, there are the following five main states:

- Initialize
- Generation of individual read and writes
- Generation of block read and writes
- The pass state
- The fail state

Within each of the generation states there are the following three substates:

- The generation of sequentially address operations
- The generation of randomly selected address operations
- The interleave of random and sequentially generated address operations

For each of the six substates in both generate states, the number of operations generated for each substate is parameterizable. The sequential and random interleave substate takes in additions to the number of operations to generate. An additional parameter specifies the ratio of sequential to random addresses to generate randomly.
Read and Write Generation

There is individual or block read and write generation.

**Individual Read and Write Generation**

During the individual read and write generation stage of the driver, the traffic generation block generates individual write followed by individual read Avalon-MM transactions, where the address for the transactions are chosen according to the specific substate. The width of the Avalon-MM interface is a global parameter for the driver, but each substate can have a parameterizable range of burst lengths for each operation.

**Block Read and Write Generation**

During the block read and write generation state of the driver, the traffic generation block generates a parameterizable number of write operations followed by the same number of read operations. The specific addresses generated for the blocks are chosen by the specific substates. The burst length of each block operation can be parameterized by a range of acceptable burst lengths.

Address and Burst Length Generation

There is sequential or random addressing.

**Sequential Addressing**

The sequential addressing substate defines a traffic pattern where addresses are chosen in sequential order starting from a user definable address. The number of operations in this substate is parameterizable.

**Random Addressing**

The random addressing substate defines a traffic pattern where addresses are chosen randomly over a parameterizable range. The number of operations in this substate is parameterizable.

**Sequential and Random Interleaved Addressing**

The sequential and random interleaved addressing substate defines a traffic pattern where addresses are chosen to be either sequential or random based on a parameterizable ratio. The acceptable address range is parameterizable as is the number of operations to perform in this substate.
7. Latency

Altera defines read and write latencies in terms of the local interface clock frequency and by the absolute time in nanoseconds for the memory controllers. These latencies apply to supported device families (Table 1–2 on page 1–2). There are two types of latencies that exists while designing with memory controllers—read and write latencies, which have the following definitions:

- **Read latency**—the amount of time it takes for the read data to appear at the local interface after initiating the read request.
- **Write latency**—the amount of time it takes for the write data to appear at the memory interface after initiating the write request.

For a half-rate controller, the local side frequency is half of the memory interface frequency. For a full-rate controller, the local side frequency is equal to the memory interface frequency.

The QDR II and QDR II+ SRAM controller with UniPHY have the following latency for sending out the read command:

- 1 full-rate cycle for a flop stage between the controller and the I/O, to meet timing, for full-rate designs operating above 250 MHz
- 1 full rate cycle for DDR output registers

The QDR II and QDR II+ SRAM controller with UniPHY have the following latency for the read return path:

- 0.5 full-rate cycle for DDR input registers
- 1 full-rate cycle for writing data into the FIFO buffer
- 2 full-rate or half-rate cycles of guard band in the FIFO buffer for run time variations
- 1 full rate or half rate cycles for reading data out of the FIFO buffer

The latency for sending out the read and write commands is the same—one full-rate cycle for a flop stage between the controller and the I/O, to meet timing, for full-rate designs.

The latency between the write command and write data is 1 cycle.

Table 7–1 shows the latency in full rate clock cycles.

1. About This IP

The Altera RLDRAM II controller with UniPHY provides a simplified interface to industry-standard RLDRAM II.

The RLDRAM II controller with UniPHY offers full-rate or half-rate RLDRAM II interfaces.

The MegaWizard Plug-In Manager generates an example top-level project, consisting of an example driver, and your RLDRAM II controller custom variation. The controller instantiates an instance of the UniPHY.

The example top-level project is a fully-functional design that you can simulate, synthesize, and use in hardware. The example driver is a self-test module that issues read and write commands to the controller and checks the read data to produce the pass or fail and test-complete signals.

The UniPHY IP is an interface between a memory controller and memory devices and performs read and write operations to the memory. The UniPHY IP creates the datapath between the memory device and the memory controller and user logic in various Altera devices.

For device families not supported by the UniPHY IP, use the Altera legacy integrated static datapath and controller MegaCore functions.

If the UniPHY IP does not suit your needs, you can create your own memory interface datapath using the ALTDLL and ALTDQ_DQS megafunctions, available in the Quartus II software, but you are then responsible for all of the aspects of the design including timing analysis and design constraints.

The UniPHY IP offers the Altera PHY interface (AFI). The AFI results in a simple connection between the PHY and controller.

Release Information

Table 1–1 provides information about this release of the RLDRAM II controller with UniPHY.

<table>

Altera® verifies that the current version of the Quartus® II software compiles the previous version of each MegaCore function. The MegaCore IP Library Release Notes and Errata report any exceptions to this verification. Altera does not verify compilation with MegaCore function versions older than one release.
Device Family Support

Megafonctions provide either full or preliminary support for target Altera device families:

- Full support means the megafonction meets all functional and timing requirements for the device family and can be used in production designs.

- Preliminary support means the megafonction meets all functional requirements, but can still be undergoing timing analysis for the device family.

Table 1–2 shows the level of support offered by the RLDRAM II controller to each of the Altera device families.

For information about supported clock rates for external memory interfaces, refer to the External Memory Interface System Specifications section in volume 1 of the External Memory Interface Handbook.

The IP supports HardCopy III and HardCopy IV ASICs as companion devices to the Stratix III and Stratix IV target devices respectively.

Features

The RLDRAM II controller with UniPHY offers the following features:

- Support for ×9, ×18, and ×36 common I/O (CIO) devices
- Burst length of 2, 4, and 8
- All memory latency settings (3, 4, 5, 6, 8 cycles)
- Non-multiplexed addressing
- Multiple devices with a combined interface width of up to x72
- Avalon-MM user interface (with burst support up to 1,024 beats)
- Automatic periodic refresh
- AFI between the PHY and the memory controller
- Full-rate or half-rate AFI (does not support burst of 2 for half-rate designs)
- Support for timing simulation

Unsupported Features

The RLDRAM II controller with UniPHY does not support the following features:

- RLDRAM II SIO devices
MegaCore Verification

MegaCore verification involves simulation testing. Altera has carried out extensive random, directed tests with functional test coverage using industry-standard models to ensure the functionality of the RLDRAM II controller with UniPHY.

Resource Utilization

Table 1–3 shows the typical size of the RLDRAM II controller with UniPHY in the Quartus II software version 9.1 for Stratix III and Stratix IV devices.

Note to Table 1–3:
(1) Half-rate designs use the same amount of memory as full-rate designs, but the data is organized in a different way (half the width, double the depth) and the design may need more M9K resources.

System Requirements

The RLDRAM II controller with UniPHY is part of the MegaCore IP Library, which is distributed with the Quartus II software.

For system requirements and installation instructions, refer to Quartus II Installation & Licensing for Windows and Linux Workstations.

Installation and Licensing

Figure 1–1 shows the directory structure after you install the RLDRAM II controller with UniPHY, where <path> is the installation directory. The default installation directory on Windows is c:\altera\<version>; on Linux it is /opt/altera\<version>.
Before you purchase a license, you can perform the following actions:

- Simulate the behavior of a megafuction (Altera MegaCore function or AMPPSM megafuction) within your system
- Verify the functionality of your design, as well as evaluate its size and speed quickly and easily
- Generate device programming files for designs that include MegaCore functions
- Program a device and verify your design in hardware

You need a license for the MegaCore function only when you want to take your design to production.

Contact your local Altera sales representative to order a license for the RLDRAM II controller with UniPHY.
2. Getting Started

Design Flow

You can implement an RLDRAM II controller with UniPHY using either of the following flows:

- MegaWizard flow
- SOPC Builder flow

For information on the SOPC Builder flow, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.

Figure 2–1. Design Flows

The MegaWizard flow offers the following advantages:

- Allows you to design directly from the RLDRAM II interface to peripheral device or devices
Achieves higher-frequency operation

The SOPC Builder flow offers the following advantages:

- Generates simulation environment
- Creates custom components and integrates them via the component wizard
- Interconnects all components with the Avalon-MM interface

MegaWizard Plug-In Flow

The MegaWizard Plug-In flow allows you to customize the RLDRAM II controller with UniPHY and manually integrate the function into your design.

For more information about the MegaWizard Plug-In, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.

Specify Parameters

To specify parameters using the MegaWizard Plug-In flow, follow these steps:

1. In the Quartus II software, create a new Quartus II project with the New Project Wizard.

2. On the Tools menu, click MegaWizard Plug-In Manager and follow the steps to start the MegaWizard Plug-In Manager. The RLDRAM II controller with UniPHY is in the Interfaces folder under the External Memory folder.

3. Click on the following tabs and set the parameters:
   - General settings
   - Memory parameters
   - Memory timing

   The text window at the bottom of the MegaWizard Plug-In displays information about the memory interface, warnings, and errors if you are trying to create something that is not supported. The Finish button is disabled until you fix all the errors indicated in this window.

   For more information about the parameters, click Info.

4. To select a memory preset, click the arrow to expand the presets list, select the preset and click Apply (Figure 2–2).

   If you select a preset, you may overwrite other settings.
5. Click Finish to generate the MegaCore function and supporting files.

![Warning: Files have same name.]

WARNING: Files have same name.

The wizard automatically generates an IP functional simulation model for VHDL designs.

![Caution: Use simulation models only for simulation.]

CAUTION Use the simulation models only for simulation and not for synthesis or any other purposes. Using these models for synthesis creates a nonfunctional design.

6. If you generate the MegaCore function instance in a Quartus II project, you are prompted to add the .qip files to the current Quartus II project. When prompted to add the .qip files to your project, click Yes. The addition of the .qip files enables their visibility to Nativelink. Nativelink requires the .qip files to include libraries for simulation.
The Quartus II IP File (.qip) contains information about the generated IP core. In most cases, the .qip file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. The MegaWizard interface generates a single .qip file for each MegaCore function.

7. After you review the generation report, click Exit to close the MegaWizard Plug-In Manager.

8. Add the example project files to your project:
   a. On the Project menu, click Add/Remove Files in Project.
   b. Browse to the <variation_name>/example_project directory.
   c. Select all of the files that start with <variation name>; do not select the mem_model.sv file. Click Open. Click OK
   d. On the File menu, click Open.
   e. Browse to <variation_name>_example_top.v and click Open.
   f. On the Project menu, click Set as Top-Level Entity.

You can look in the example_top.v file, to see how to instantiate the memory controller in your own design.

**SOPC Builder Flow**

The SOPC Builder flow allows you to add the RLDRAM II controller with UniPHY directly to a new or existing SOPC Builder system.

You can easily add other available components to quickly create an SOPC Builder system with a RLDRAM II controller, such as the Nios II processor, external memory controllers, and scatter-gather DMA controllers. SOPC Builder automatically creates the system interconnect logic and system simulation environment.

For more information about SOPC Builder, refer to volume 4 of the Quartus II Handbook. For more information about how to use controllers with SOPC Builder, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook. For more information on the Quartus II software, refer to the Quartus II Help.

**Specify Parameters**

To specify RLDRAM II controller with UniPHY parameters using the SOPC Builder flow, follow these steps:

1. In the Quartus II software, create a new Quartus II project with the New Project Wizard.
2. On the Tools menu, click SOPC Builder.
3. For a new system, specify the system name and language.
4. Add RLDRAM II Controller with UniPHY to your system from the System Contents tab. The RLDRAM II is in the Memories and Memory Controllers folder.
5. Click on the following tabs and set the parameters for the IP:
   - General settings
     - You must turn on **Generate power of two bus widths**.
   - Memory parameters
   - Memory timing

   The text window at the bottom of the MegaWizard Plug-In displays information about the memory interface, warnings, and errors if you are trying to create something that is not supported. The **Finish** button is disabled until you correct all the errors indicated in this window.

   For more information about the parameters, click **Info**.

6. Click **Finish** to complete the RLDRAM II controller with UniPHY and add it to the system.

**Complete the SOPC Builder System**

To complete the SOPC Builder system, follow these steps:

1. Select other components in the component library for your SOPC Builder system.
2. Click **Generate**.

   - The Quartus II IP File (\*.qip) contains information about a generated IP core or system. In most cases, the \*.qip file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. Generally, a single \*.qip file is generated for each SOPC Builder system. However, some more complex SOPC Builder components generate a separate \*.qip file. In that case, the system \*.qip file references the component \*.qip file.

3. Compile your design, refer to “Constraining and Compiling” on page 3–1.

**Simulate the System**

During system generation, SOPC Builder optionally generates a simulation model and testbench for the entire system, which you can use to easily simulate your system in any of Altera’s supported simulation tools. SOPC Builder also generates a set of ModelSim® Tcl scripts and macros that you can use to compile the testbench, IP functional simulation models, and plain-text RTL design files that describe your system in the ModelSim simulation software (refer to “Generated Files” on page 2–5).

For more information about simulating SOPC Builder systems, refer to volume 4 of the *Quartus II Handbook* and *AN 351: Simulating Nios II Systems*.

**Generated Files**

When you complete either flow, there are wizard-generated files in your project directory.
The PLL parameters are statically defined in the `<variation name>_<parameters>.tcl` at generation time. To ensure timing constraints and timing reports are correct, when you make changes to the PLL component using the MegaWizard Plug-In, apply those changes to the PLL parameters in this file.

**Simulating the Design**

The wizard generates a testbench for simulation and generic memory model in the `rtl_sim` directory.

For more information about simulation, refer to the *Simulation* section in volume 4 of the *External Memory Interface Handbook*. 
3. Constraining and Compiling

The wizard generates a Synopsis design constraint (.sdc) script and a pin assignment script, `<variation_name>_pin_assignments.tcl`. Both the .sdc and the `<variation name>_pin_assignments.tcl` support multiple instances. These scripts iterate through all instances of the core and apply the same constraints to all of them.

### Add Pin and DQ Group Assignments

The pin assignment script, `<variation_name>_pin_assignments.tcl`, sets up the I/O standards and the input/output termination for the RLDRAM II controller with UniPHY. This script also helps to relate the DQ and QK pin groups together for the fitter to place them correctly in the Quartus II software.

The pin assignment script does not create a source clock for the design. You need to create a clock for the design and provide pin assignments for the signals of both the example driver and testbench that the MegaCore variation generates.

Run the `<variation_name>_pin_assignments.tcl` to add the input and output termination, I/O standards, and DQ group assignments to the example design. To run the pin assignment script, follow these steps:

1. On Processing menu, point to Start, and click **Start Analysis and Synthesis**.
2. On the Tool menu click **Tcl Scripts**.
3. Specify the `pin_assignments.tcl` file and click **Run**.

The PLL input reference clock pin does not need to have the same I/O standard as the memory interface I/Os. However, you may see a no-fit as the bank in which the PLL input reference clock pin gets placed becomes unusable for placement of the memory interface I/Os (because of incompatible VCCIO levels). You should assign the same I/O standard to the PLL input reference clock pin.

### Board Trace Model

Bus turnaround is not timing analyzed; consequently, the controller dead times are based on assumptions about the user board trace lengths. For timing analysis to be correct, board trace delays must be limited to 0.6 ns from FPGA to memory and from memory to FPGA.

For accurate I/O timing analysis, you must specify the board trace and loading information. You should derive and refine this information during your PCB development process of prelayout (line) simulation and finally postlayout (board) simulation.

For more information about how to include your board simulation results in the Quartus II software and how to assign pins using pin planners, refer to **Volume 6: Design Flow Tutorials** of the **External Memory Interface Handbook**.
Compile the Design

To compile the design, on the Processing menu, click **Start Compilation**.

After you have compiled the top-level file, you can perform RTL simulation or program your targeted Altera device to verify the top-level file in hardware.

For more information about simulating, refer to the **Simulation** section in volume 4 of the *External Memory Interface Handbook*. 
The controller translates memory requests from the Avalon Memory-Mapped (Avalon-MM) interface to AFI, while satisfying timing requirements imposed by the memory configurations.

**Block Description**

This topic describes the blocks in the IP. Figure 4–1 shows a block diagram of the RLDRAM II controller architecture.

**Figure 4–1. RLDRAM II Controller Architecture Block Diagram**

**Avalon-MM Slave Interface**

This Avalon-MM slave interface accepts read and write requests. A simple state machine represents the state of the command and address registers, which stores the command and address when a request arrives.

The Avalon-MM slave interface decomposes the Avalon-MM address to the memory bank, column, and row addresses. The IP automatically maps the bank address to the LSB of the Avalon address vector.

The Avalon-MM slave interface includes a burst adaptor, which has the following two parts:

- The first part is a read and write request combiner that groups requests to sequential addresses into the native memory burst. Given that the second request arrives within the read and write latency window of the first request, the controller can combine and satisfy both requests with a single memory transaction.
The second part is the burst divider in the front end of the Avalon-MM interface, which breaks long Avalon bursts into individual requests of sequential addresses, which is then passed on to the controller state machine.

**Write Data FIFO Buffer**

The write data FIFO buffer accepts write data from the Avalon-MM interface. The FIFO buffer write data is consumed at a later time controlled by the AFI.

**Command Issuing FSM**

The command issuing full-state machine (FSM) has three states. The controller is in the **INIT** state when the memory is being initialized by the PHY. Upon receiving the **afi_cal_success** signal, the state transitions to **INIT_COMPLETE**. If the calibration fails, **afi_cal_fail** is asserted and the state transitions to **INIT_FAIL**. Commands are issued to the PHY only in the **INIT_COMPLETE** state.

When a refresh request is presented to the state machine at the same time as a read or write request, the refresh request takes precedence. The read or write request is put on hold until there are no more refresh requests, and is issued immediately given that timing requirements are met.

**Refresh Timer**

With automatic refresh, the refresh timer periodically issues refresh requests to the command issuing FSM. The refresh interval can be set at generation.

**Bank Timer**

The bank timer contains one DQ timer and eight bank timers (one per bank). The DQ timer tracks how often read and write requests can be issued, to avoid bus contention. The bank timers track the cycle time (tRC).

The 8-bit wide output bus of the bank timer indicates to the command issuing FSM whether each bank can be issued a read, write, or refresh command.

**AFI**

For information on the AFI, refer to “Functional Description—UniPHY” on page 5–1.

**Avalon-MM and Memory Data Width**

Table 4–1 shows the data width ratio between the memory interface and the Avalon-MM interface. The half-rate controller does not support burst-of-2 devices because it under uses the available memory bandwidth.
Table 4-1. Data Width Ratio

This chapter describes the PHY part of the RLDRAM II controller with UniPHY.

**Block Description**

The PHY comprises the following major functional units:
- I/O Pads
- Reset and Clock Generation
- Address and Command Datapath
- Write Datapath
- Read Datapath
- Sequencer

Figure 5–1 shows the PHY block diagram.

**Figure 5–1. PHY Block Diagram**

---

**I/O Pads**

The I/O pads contain all the I/O instantiations. The major I/O is the ALTDQ_DQS megafunction.
Reset and Clock Generation

The clocking operation in the PHY can be classified into two domains: the PHY-memory domain and the PHY-AFI domain. The PHY-memory domain interfaces with the external memory device and is always at full-rate. The PHY-AFI domain interfaces with the memory controller and can be either a full-rate or half-rate clock based on the choice of the controller. Table 5–1 lists the clocks required for half-rate designs.

</table>

The UniPHY uses an active-low, asynchronous assert and synchronous de-assert reset scheme. The global reset signal resets the PLL in the PHY and the rest of the system is held in reset until after the PLL is locked. The number of synchronization pipeline stages is set to 4.

Address and Command Datapath

The memory controller is responsible for controlling the read and write addresses and commands, to meet the memory specifications. The PHY simply passes the address and command received from the memory controller to the memory device. The PHY is also indifferent to address or command, the circuitry is the same for both.
The address and command datapath outputs are connected to the inputs of the address and command I/Os. An ALTDDIO_OUT megafunction converts the addresses from SDR to DDR. An ALTDDIO_OUT megafunction with an ALTIOBUF megafunction deliver a pair of address and command clock to the memory.

**Write Datapath**

The write datapath passes write data from the memory controller to the I/O. The DQ pins are bidirectional and shared between read and write. The write data valid signal from the memory controller generates the output enable signal to control the output buffer. It is also generates the dynamic termination control signal, which selects between series (output mode) and parallel (input mode) termination. An ALT_OCT megafunction (instantiated in the top-level file) configures the termination values.

**Read Datapath**

The read data is captured in the input mode ALTDQ_DQS in the I/O. The captured data is then forwarded to the read datapath. The read datapath synchronizes read data from the read capture clock domain to the AFI clock domain and converts data from SDR to HDR (half-rate designs only).

In half-rate designs, the write side of the FIFO buffer should be double the size of the read side of the FIFO buffer. The read side only reads one entry after the write side has written into two entries, which effectively converts data from SDR to HDR. In full-rate designs, the size of the FIFO buffer is the same for both write and read as both sides operate at the same rate. The FIFO buffer size is 16 half-rate entries.

**Sequencer**

The sequencer intercepts all the signals from the memory controller and takes control during calibration. The sequencer is a state machine that processes the calibration algorithm. Table 5–3 shows the states in the sequencer.

<table>
<thead>
<tr>
<th>State</th>
<th>Description</th>

</tr>
<tr>
<td>L_COMPARE_READ_ONE</td>
<td>Check returned read data against expected data. If data is correct, go to L_REDUCE_LATENCY; otherwise go to L_ADD_MARGIN.</td>
</tr>
<tr>
<td>L_REDUCE_LATENCY</td>
<td>Reduce the latency counter by 1.</td>
</tr>
<tr>
<td>L_READ_FLUSH</td>
<td>Read from address 0 (expected data is all 0s), to flush the contents of the read data resynchronization FIFO buffer.</td>
</tr>
<tr>
<td>L_WAIT_READ_FLUSH</td>
<td>Wait until the whole FIFO buffer is flushed, then go back to L_READ and try again.</td>
</tr>
<tr>
<td>L_ADD_MARGIN</td>
<td>Increment latency counter by 3 (1 cycle to get the correct data, 2 more cycles of margin for run time variations). If latency counter value is smaller than predefined ideal condition minimum, then go to CALIB.FAIL.</td>
</tr>
<tr>
<td>CALIB_DONE</td>
<td>Calibration is successful.</td>
</tr>
<tr>
<td>CALIB_FAIL</td>
<td>Calibration is not successful.</td>
</tr>
</tbody>
</table>
The following interfaces are on the UniPHY top-level file:
- AFI
- Memory interface
- DLL and PLL sharing interface
- OCT interface

**The Memory Interface**

For more information on the memory interface, refer to “UniPHY Signals” on page 5–5.

**The DLL and PLL Sharing Interface**

The UniPHY memory interface requires one PLL and one DLL to produce the clocks and delay codeword. The PLL and DLL can be shared using a master and slave scenario. The PLL and DLL output signals are defined as inputs and outputs in the top-level file and an additional parameter `PLL_DLL_MASTER` is also defined. If `PLL_DLL_MASTER` is 1, the RTL instantiates the PLL and DLL, which drives the clock and DLL codeword inputs and outputs. If the parameter is 0, the wires previously connected to the output of the PLL and DLL are assigned to the clock and DLL codeword input and outputs. During synthesis, the direction is automatically resolved to either input or output as they are either used strictly as inputs or outputs.

**UniPHY Signals**

This section describes the UniPHY signals. Table 5–5 shows the clock and reset signals.

### AFI Signal Names

The RLDRAM II controller with UniPHY uses AFI.

The AFI timing is identical to the DDR3 SDRAM AFI in the Quartus II software version 9.0. However, some signals have been renamed, some added, and others removed from the AFI definition. The AFI includes only signals that are part of the controller-to-PHY interface, clocks, and reset. All signals on the controller-to-PHY interface have the `afi_` prefix to the signal name. Table 5–9 shows the renamed AFI signals and original (Quartus II software version 9.0) names.

<table>
<thead>
<tr>

**PHY-to-Controller Interfaces**

This section describes the typical modules that are connected to the UniPHY PHY and the port name prefixes each module uses. This section describes using a custom controller and describes the AFI.

The AFI standardizes and simplifies the interface between controller and PHY for all Altera memory designs, thus allowing you to easily interchange your own controller code with Altera’s high-performance controllers. The AFI PHY includes an administration block that configures the memory for calibration and performs necessary accesses to mode registers that configure the memory as required (these calibration processes are different).

For half-rate designs, the address and command signals in the UniPHY are asserted for one mem_clk cycle (1T addressing), such that there are two input bits per address and command pin in half-rate designs. If you require a more conservative 2T addressing, drive both input bits (of the address and command signal) identically in half-rate designs.

Figure 5–3 shows the half-rate write operation.

**Figure 5–3. Half-Rate Write with Word-Aligned Data**

Figure 5–4 shows a full-rate write.
After calibration is completed, the sequencer sends the write latency in number of clock cycles to the controller.

Figure 5–5 shows full-rate reads; Figure 5–6 shows half-rate reads.
Figure 5–6. Half-Rate Reads
Figure 5–7 and Figure 5–8 show writes and reads, where the data is written to and read from the same address. In each example, \( \text{afi}_r\text{data} \) and \( \text{afi}_w\text{data} \) are aligned with controller clock (\( \text{afi}_\text{clk} \)) cycles. All the data in the bit vector is valid at once.

The AFI has the following conventions:

- With the AFI, high and low signals are combined in one signal, so for a single chip select (\( \text{afi}_\text{cs}_n \)) interface, \( \text{afi}_\text{cs}_n[1:0] \), where location 0 appears on the memory bus on one \( \text{mem}_\text{clk} \) cycle and location 1 on the next \( \text{mem}_\text{clk} \) cycle.

This convention is maintained for all signals so for an 9-bit memory interface, the write data (\( \text{afi}_w\text{data} \)) signal is \( \text{afi}_w\text{data}[31:0] \), where the first data on the DQ pins is \( \text{afi}_w\text{data}[7:0] \), then \( \text{afi}_w\text{data}[15:8] \), then \( \text{afi}_w\text{data}[23:16] \), then \( \text{afi}_w\text{data}[31:24] \).

- Spaced reads and writes have the following definitions:
  - Spaced writes—write commands separated by a gap of one controller clock (\( \text{afi}_\text{clk} \)) cycle
  - Spaced reads—read commands separated by a gap of one controller clock (\( \text{afi}_\text{clk} \)) cycle

Figure 5–7 through Figure 5–8 assume the following general points:

- The burst length is four.
- An 9-bit interface with one chip select.
- The data for one controller clock (\( \text{afi}_\text{clk} \)) cycle represents data for two memory clock (\( \text{mem}_\text{clk} \)) cycles (half-rate interface).
Notes to Figure 5–7:
(1) To show the even alignment of \( \text{afi\_cs\_n} \), expand the signal (this convention applies for all other signals).
(2) The \( \text{afi\_dqs\_burst} \) must go high one memory clock cycle before \( \text{afi\_wdata\_valid} \). Compare with the word-unaligned case.
(3) The \( \text{afi\_wdata\_valid} \) is asserted two \( \text{afi\_wlat} \) controller clock (\( \text{afi\_clk} \)) cycles after chip select (\( \text{afi\_cs\_n} \)) is asserted. \( \text{afi\_wlat} \) indicates the required write latency in the system. The value is determined during calibration and is dependant upon the relative delays in the address and command path and the write datapath in both the PHY and the external DDR SDRAM subsystem. The controller must drive \( \text{afi\_cs\_n} \) and then wait \( \text{afi\_wlat} \) (two in this example) \( \text{afi\_clks} \) before driving \( \text{afi\_wdata\_valid} \).
(4) Observe the ordering of write data (\( \text{afi\_wdata} \)). Compare this to data on the \( \text{mem\_dq} \) signal.
(5) In all waveforms a command record is added that combines the memory pins \( \text{ras\_n}, \text{cas\_n} \) and \( \text{we\_n} \) into the current command that is issued. This command is registered by the memory when chip select (\( \text{mem\_cs\_n} \)) is low. The important commands in the presented waveforms are \( \text{WR} = \text{write}, \text{ACT} = \text{activate} \).
Figure 5–8. Word-Aligned Reads

Notes to Figure 5–8:

1. For AFI, $afi\_rdata\_en$ is required to be asserted one memory clock cycle before chip select ($afi\_cs\_n$) is asserted. In the half-rate $afi\_clk$ domain, this requirement manifests as the controller driving 11 (as opposed to the 01) on $afi\_rdata\_en$.

2. AFI requires that $afi\_rdata\_en$ is driven for the duration of the read. In this example, it is driven to 11 for two half-rate $afi\_clks$, which equates to driving to 1, for the four memory clock cycles of this four-beat burst.

3. The $afi\_rdata\_valid$ returns 15 ($afi\_rlat$) controller clock ($afi\_clk$) cycles after $afi\_rdata\_en$ is asserted. Returned is when the $afi\_rdata\_valid$ signal is observed at the output of a register within the controller. A controller can use the $afi\_rlat$ value to determine when to register to returned data, but this is unnecessary as the $afi\_rdata\_valid$ is provided for the controller to use as an enable when registering read data.

4. Observe the alignment of returned read data with respect to data on the bus.
Using a Custom Controller

The `<variation name>_rtl` directory contains the `<variation name>_memphy_top.v` file, which is a module that is just the PHY portion with the parameter defaults set to the appropriate values given the current parameterization. This module can be used directly with a custom controller.
The MegaWizard Plug-In creates an example top-level project that shows you how to instantiate and connect the RLDRAM II controller.

The example top-level project contains a testbench, which is for use with Verilog HDL only language simulators such as ModelSim-AE Verilog, and shows simple operation of the memory interface.

For a VHDL simulation, use the VHDL IP functional simulation model.

The testbench contains the following blocks:

- A synthesizable Avalon-MM example driver, which implements a pseudo-random pattern of reads and writes to a parameterized number of addresses. The driver also monitors the data read from the memory to ensure it is what is written and asserts a failure otherwise.

- An instance of the controller, which interfaces between the Avalon-MM interface and the API.

- The UniPHY, which serves as an interface between the memory controller and external memory device(s) to perform read and write operations to the memory.

- A memory model, which acts as a generic model that adheres to the memory protocol specifications. Memory vendors also provide simulation models for specific memory components that can be downloaded from their websites. This block is available in Verilog HDL only.

Figure 6–1 shows the testbench and the example top-level file.

**Figure 6–1. Testbench and Example Top-Level File**

The SystemVerilog VMM testbench is produced with the example top-level file and is for use with SystemVerilog simulators such as VCS and Questa. The testbench uses the Synopsys VMM libraries, which are freely available. The testbench file contains the following blocks:

- A `UniPHY_env` environment class that extends `vmm_env` and instantiates the test program.

- A test program that sends a variety of memory interface transactions to the Avalon-MM bus functional model.
A scoreboard class that compares the generated memory interface transactions against the ones produced by the memory model transactor.

An instance of the controller which interfaces between the Avalon-MM interface and the AFI.

The UniPHY, which serves as an interface between the memory controller and external memory device to perform read and write operations to the memory.

A memory model, which acts as a generic model that adheres to the memory protocol specifications. Memory vendors also provide simulation models for specific memory chips that can be downloaded from their websites.

### Example Driver

The example driver for Avalon-MM memory interfaces generates Avalon-MM traffic on an Avalon-MM master interface. As the read and write traffic is generated, the expected read response is stored internally and compared to the read responses as they arrive. If all reads report their expected response then the pass signal is asserted, but if any read responds with unexpected data a fail is asserted.

Each operation generated by the driver is a single or block of writes followed by a single or block of reads to the same addresses, which allows the driver to determine exactly what data should be expected when the read data is returned by the memory interface. The driver comprises a traffic generation block, the Avalon-MM interface and a read compare block. The traffic generation block generates addresses and write data, which are then sent out over the Avalon-MM interface. The read compare block compares the read data received from the Avalon-MM interface to the write data generated from the traffic generator. If at any time the data received is not the expected data, the read compare signals that there is a failure and the driver enters a fail state. If all patterns have been generated and compared successfully, the driver enters a pass state.

Within the driver, there are the following five main states:

- Initialize
- Generation of individual read and writes
- Generation of block read and writes
- The pass state
- The fail state

Within each of the generation states there are the following three substates:

- The generation of sequentially address operations
- The generation of randomly selected address operations
- The interleave of random and sequentially generated address operations

For each of the six substates in both generate states, the number of operations generated for each substate is parameterizable. The sequential and random interleave substate takes in additions to the number of operations to generate. An additional parameter specifies the ratio of sequential to random addresses to generate randomly.
Read and Write Generation

There is individual or block read and write generation.

Individual Read and Write Generation

During the individual read and write generation stage of the driver, the traffic generation block generates individual write followed by individual read Avalon-MM transactions, where the address for the transactions are chosen according to the specific substate. The width of the Avalon-MM interface is a global parameter for the driver, but each substate can have a parameterizable range of burst lengths for each operation.

Block Read and Write Generation

During the block read and write generation state of the driver, the traffic generation block generates a parameterizable number of write operations followed by the same number of read operations. The specific addresses generated for the blocks are chosen by the specific substates. The burst length of each block operation can be parameterized by a range of acceptable burst lengths.

Address and Burst Length Generation

There is sequential or random addressing.

Sequential Addressing

The sequential addressing substate defines a traffic pattern where addresses are chosen in sequential order starting from a user definable address. The number of operations in this substate is parameterizable.

Random Addressing

The random addressing substate defines a traffic pattern where addresses are chosen randomly over a parameterizable range. The number of operations in this substate is parameterizable.

Sequential and Random Interleaved Addressing

The sequential and random interleaved addressing substate defines a traffic pattern where addresses are chosen to be either sequential or random based on a parameterizable ratio. The acceptable address range is parameterizable as is the number of operations to perform in this substate.
Altera defines read and write latencies in terms of the local interface clock frequency and by the absolute time in nanoseconds for the memory controllers. These latencies apply to supported device families (Table 1–2 on page 1–2).

There are two types of latencies that exists while designing with memory controllers—read and write latencies, which have the following definitions:

- Read latency—the amount of time it takes for the read data to appear at the local interface after initiating the read request.
- Write latency—the amount of time it takes for the write data to appear at the memory interface after initiating the write request.

For a half-rate controller, the local side frequency is half of the memory interface frequency. For a full-rate controller, the local side frequency is equal to the memory interface frequency.

The RLDRAM II controller with UniPHY has the following latency for sending out the read command:

- 1 full-rate cycle for a flop stage between the controller and the I/O, to meet timing, for full-rate designs operating above 250 MHz
- 1 full rate cycle for DDR output registers

The RLDRAM II controller with UniPHY has the following latency for the read return path:

- 0.5 full-rate cycle for DDR input registers
- 1 full-rate cycle for writing data into the FIFO buffer
- 2 full-rate or half-rate cycles of guard band in the FIFO buffer for run time variations
- 1 full rate or half rate cycles for reading data out of the FIFO buffer

The latency for sending out the read and write commands is the same—one full-rate cycle for a flop stage between the controller and the I/O, to meet timing, for full-rate designs.

The latency between the write command and write data is 1 cycle.

Table 7–1 shows the latency in full rate clock cycles.

1. Simulation Walkthrough

For high-performance memory controllers, you can simulate the example top-level file with the MegaWizard-generated IP functional simulation models. The MegaWizard™ Plug-In generates a VHDL or Verilog HDL testbench for the example top-level file, which is in the \testbench directory of your project directory.

You can use the IP functional simulation model with any Altera-supported VHDL or Verilog HDL simulator. You can perform a simulation in a third-party simulation tool from within the Quartus II software, using NativeLink.

The ALTMEMPHY megafunktion cannot be simulated alone. To simulate the ALTMEMPHY megafunktion, you must use all of the following blocks:

- Memory controller
- Example driver (to initiate read and write transactions)
- Testbench and a suitable vendor memory model

Simulating the whole memory interface is a good way to determine the latency of your system. However, the latency found in simulation may be different than the latency found on the board because functional simulation does not take into account board trace delays and different process, voltage, and temperature scenarios. For a given design on a given board, the latency found may differ by one clock cycle (for full-rate designs) or two clock cycles (for half-rate designs) upon resetting the board. Different boards can also show different latencies even with the same design.

The ALTMEMPHY megafunktion only supports functional simulation; it does not support gate-level simulation, for the following reasons:

- The ALTMEMPHY is a calibrated interface. Therefore, gate-level simulation time can be very slow and take up to several hours to complete.
- Gate-level timing annotations, and the phase sweeping that the calibration uses, determine setup and hold violations. Because of the effect of X (unknown value) propagation within the atom simulation models, this action causes gate-level simulation failures in some cases.
- Memory interface timing methodology does not match the timing annotation that gate-level simulations use. Therefore the gate-level simulation does not accurately match real device behavior.

Altera recommends that you validate the functional operation of your design via RTL simulation, and the timing of your design using TimeQuest Timing Analysis.
Before Simulating

In general, you need the following files to simulate:

- Library files from the `<Quartus II install path>\quartus\eda\sim_lib\` directory:
  - `220model`
  - `altera_primitives`
  - `altera_mf`
  - `sgate`
  - `arriaii_atoms, stratixiv_atoms, stratixiii_atoms, cycloneiii_atoms, stratixii_atoms, stratixiigx_atoms` (device dependent)

If you are targeting Stratix IV devices, you need both the Stratix IV and Stratix III files (`stratixiv_atoms` and `stratixiii_atoms`) to simulate, unless you are using NativeLink.

- Sequencer wrapper file (in `.vo` or `.vho` format)
- PLL file (for example `<variation_name>_alt_mem_phy_pll.v` or `.vhd`)
- ALTMEMPHY modules (in the `<variation_name>_alt_mem_phy.v`)
- Top-level file
- User logic, or a driver for the PHY
- Testbench
- Vendor memory model

Preparing the Vendor Memory Model

If you are using a vendor memory model, instead of the MegaWizard-generated functional simulation model, you need to make some modifications to the vendor memory model and the testbench files by following these steps:

1. Make sure the IP functional simulation model is generated by turning on `Generate Simulation Model` during the instantiate PHY and controller design flow step.

2. Obtain and copy the vendor memory model to the `\testbench` directory. For example, obtain the `ddr2.v` and `ddr2_parameters.vh` simulation model files from the Micron website and save them in the testbench directory.

The auto-generated generic SDRAM model may be used as a placeholder for a specific vendor memory model.

Some vendor DIMM memory models do not use data mask (DM) pin operation, which can cause calibration failures. In these cases, use the vendor’s component simulation models directly.
3. Open the vendor memory model file in a text editor and specify the speed grade and device width at the top of the file. For example, you can add the following statements for a DDR2 SDRAM model file:

   'define sg25
   'define x8

   The first statement specifies the memory device speed grade as –25 (for 400 MHz operation). The second statement specifies the memory device width per DQS.

4. Check that the following statement is included in the vendor memory model file. If not, include it at the top of the file. This example is for a DDR2 SDRAM model file:

   `include "ddr2_parameters.vh"

5. Save the vendor memory model file.

6. Open the testbench in a text editor, delete the whole section between the START MEGAWIZARD INSERT MEMORY_ARRAY and END MEGAWIZARD INSERT MEMORY_ARRAY comments, instantiate the downloaded memory model, and connect its signals to the rest of the design.

7. Delete the START MEGAWIZARD INSERT MEMORY_ARRAY and END MEGAWIZARD INSERT MEMORY_ARRAY lines so that the wizard does not overwrite your changes if you use the wizard to regenerate the design.

8. Ensure that ports names and capitalization in the memory model match the portnames and capitalization in the testbench.

   The vendor memory model may use different pin names and capitalization than the MegaWizard-generated functional model.

9. Save the testbench file.

   The original instantiation may be similar to the following code:

   // << START MEGAWIZARD INSERT MEMORY_ARRAY
   // This will need updating to match the memory models you are using.
   // Instantiate a generated DDR memory model to match the datawidth & chipselect requirements
   ddr2_mem_model mem {
     .mem_dq       (mem_dq),
     .mem_dqs      (mem_dqs),
     .mem_dqs_n    (mem_dqs_n),
     .mem_addr     (a_delayed),
     .mem_ba       (ba_delayed),
     .mem_clk      (clk_to_ram),
     .mem_clk_n    (clk_to_ram_n),
     .mem_cke      (cke_delayed),
     .mem_cs_n     (cs_n_delayed),
     .mem_ras_n    (ras_n_delayed),
     .mem_cas_n    (cas_n_delayed),
   }
Replace with the following code:

```vhdl
ddr2 memory_0 (  .clk (clk_to_ram),  .clk_n (clk_to_ram_n),  .cke (cke_delayed),  .cs_n (cs_n_delayed),  .ras_n (ras_n_delayed),  .cas_n (cas_n_delayed),  .we_n (we_n_delayed),  .dm_q (dm_delayed[0]),  .ba (ba_delayed),  .addr (a_delayed),  .dq (mem_dq[7:0]),  .dqs (mem_dqs[0]),  .dqs_n (mem_dqs_n[0]),  .rdqs_n (),  .odt (odt_delayed) );

// << END MEGAWIZARD INSERT MEMORY_ARRAY
```

If you are interfacing with a DIMM or multiple memory components, you need to instantiate all the memory components in the testbench file.

---

**Simulating Using NativeLink**

To set up simulation in the Quartus® II software using NativeLink, follow these steps:

1. **Create a custom variation with an IP functional simulation model.**
2. **Set the top-level entity to the example project.**
   a. On the File menu, click **Open**.
   b. Browse to `<variation name>_example_top` and click **Open**.
   c. On the Project menu, click **Set as Top-Level Entity**.

---
3. Ensure that the Quartus II **EDA Tool Options** are configured correctly for your simulation environment.
   a. On the Tools menu, click **Options**.
   b. In the **Category** list, click **EDA Tool Options** and verify the locations of the executable files.

4. Set up the Quartus II NativeLink.
   a. On the Assignments menu, click **Settings**. In the **Category** list, expand **EDA Tool Settings** and click **Simulation**.
   b. From the **Tool name** list, click on your preferred simulator.
   c. In **NativeLink settings**, select **Compile test bench** and click **Test Benches**.
   d. Click **New** at the **Test Benches** page to create a testbench.

5. On the **New Test Bench Settings** dialog box:
   a. Type a name for the **Test bench name**, for example *<variation name>_example_top_tb*.
   b. In **Top level module in test bench**, type the name of the automatically generated testbench, *<variation name>_example_top_tb*.
   c. In **Design instance in test bench**, type the name of the top-level instance, *dut*.
   d. Under **Simulation period**, set **End simulation at** to 600 µs.
   e. Add the testbench files and automatically-generated memory model files. In the **File name** field, browse to the location of the memory model and the testbench, click **Open** and then click **Add**. The testbench is *<variation name>_example_top_tb.v*; memory model is *<variation name>_mem_model.v*.
   f. Select the files and click **OK**.

6. On the Processing menu, point to **Start** and click **Start Analysis & Elaboration** to start analysis.

7. On the Tools menu, point to **Run EDA Simulation Tool** and click **EDA RTL Simulation**.

If your Quartus II project appears to be configured correctly but the example testbench still fails, check the known issues on the **Knowledge Database** page before filing a service request.

For a complete MegaWizard Plug-In Manager system design example containing the DDR and DDR2 SDRAM high-performance controller MegaCore function, refer to **Volume 6: Design Flow Tutorials** of the **External Memory Interface Handbook**.

**IP Functional Simulations**

This topic discusses VHDL and Verilog HDL simulations with IP functional simulation models.
For VHDL simulations with IP functional simulation models, perform the following steps:

1. Create a directory in the `<project directory>\testbench` directory.
2. Launch your simulation tool from this directory and create the following libraries:
   - `altera_mf`
   - `lpm`
   - `sgate`
   - `<device name>`
   - `altera`
   - `ALTGXB`
   - `<device name>_hssi`
   - `auk_ddr_hp_user_lib`
3. Compile the files into the appropriate library (Table 1–1). The files are in VHDL93 format.

### Table 1–1. Files to Compile—VHDL IP Functional Simulation Models (Part 1 of 2)

<table>
<thead>
<tr>
<th>Library</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>altera_mf</code></td>
<td><code>&lt;QUARTUS ROOTDIR&gt;eda\sim_lib\altera_mf_components.vhd</code>&lt;br&gt;<code>&lt;QUARTUS ROOTDIR&gt;eda\sim_lib\altera_mf.vhd</code></td>
</tr>
<tr>
<td><code>lpm</code></td>
<td><code>\eda\sim_lib\220pack.vhd</code>&lt;br&gt;<code>\eda\sim_lib\220model.vhd</code></td>
</tr>
<tr>
<td><code>sgate</code></td>
<td><code>eda\sim_lib\sgate_pack.vhd</code>&lt;br&gt;<code>eda\sim_lib\sgate.vhd</code></td>
</tr>
<tr>
<td><code>&lt;device name&gt;</code></td>
<td><code>eda\sim_lib\&lt;device name&gt;_atoms.vhd</code>&lt;br&gt;<code>eda\sim_lib\&lt;device name&gt;_components.vhd</code>&lt;br&gt;<code>eda\sim_lib\&lt;device name&gt;_hssi_atoms.vhd (1)</code></td>
</tr>
<tr>
<td><code>altera</code></td>
<td><code>eda\sim_lib\altera_primitives_components.vhd</code>&lt;br&gt;<code>eda\sim_lib\altera_syn_attributes.vhd</code>&lt;br&gt;<code>eda\sim_lib\altera_primitives.vhd</code></td>
</tr>
<tr>
<td><code>ALTGXB (1)</code></td>
<td><code>&lt;device name&gt;_mf.vhd</code>&lt;br&gt;<code>&lt;device name&gt;_mf_components.vhd</code></td>
</tr>
<tr>
<td><code>&lt;device name&gt;_hssi (1)</code></td>
<td><code>&lt;device name&gt;_hssi_components.vhd</code>&lt;br&gt;<code>&lt;device name&gt;_hssi_atoms.vhd</code></td>
</tr>
</tbody>
</table>
If you are targeting a Stratix IV device, you need both the Stratix IV and Stratix III files (stratixiv_atoms and stratixiii_atoms) to simulate in your simulator, unless you are using NativeLink.

4. Load the testbench in your simulator with the timestep set to picoseconds.

5. Compile the testbench file.

**Verilog HDL**

For Verilog HDL simulations with IP functional simulation models, follow these steps:

1. Create a directory in the \<project directory>\testbench directory.

2. Launch your simulation tool from this directory and create the following libraries:
   - altera-mf_ver
   - lpm_ver
   - sgate_ver
   - \<device name>_ver
   - altera_ver
   - ALTGXB_ver
   - \<device name>_hssi_ver
   - auk_ddr_hp_user_lib

3. Compile the files into the appropriate library as shown in Table 1–2 on page 1–8.
If you are targeting a Stratix IV device, you need both the Stratix IV and Stratix III files (stratixiv_atoms and stratixiii_atoms) to simulate in your simulator, unless you are using NativeLink.

4. Configure your simulator to use transport delays, a timestep of picoseconds, and to include all the libraries in Table 1–2.

5. Compile the testbench file.

### Simulation Tips and Issues

This topic discusses simulation tips and issues.

Chapter 1: Simulation Walkthrough 1–9

Simulation Tips and Issues

Tips

The ALTMEMPHY datapath is in Verilog HDL; the sequencer is in VHDL. For ALTMEMPHY designs with the Altera PHY interface (AFI), to allow the Verilog HDL simulator to simulate the design after modifying the VHDL sequencer, follow these steps:

1. On the View menu, point to Utility Windows, and click TCL console.
2. Enter the following command in the console:

   quartus_map --read_settings_file=on --write_settings_file=off
   --source=<variation_name>_phy_alt_mem_phy_seq.vhd
   --source=<variation_name>_phy_alt_mem_phy_seq_wrapper.v --simgen
   --simgen_parameter=CBX_HDL_LANGUAGE=verilog
   <variation_name>_phy_alt_mem_phy_seq_wrapper -c
   <variation_name>_phy_alt_mem_phy_seq_wrapper

   The Quartus II software regenerates
   <variation_name>_phy_alt_mem_phy_seq_wrapper.vo and uses this file when the simulation runs.

DDR3 SDRAM (without Leveling) Warnings and Errors

You may see the following warning and error messages with skip calibration and quick calibration simulation:

- WARNING: 200 us is required before RST_N goes inactive
- WARNING: 500 us is required after RST_N goes inactive before CKE goes active

If these warning messages appear, change the values of the two parameters (tinit_tck and tinit_rst) in the following files to match the parameters in <variation_name>_phy_alt_mem_phy_seq_wrapper.v:

- <variation_name>_phy_alt_mem_phy_seq_wrapper.vo
- <variation_name>_phy_alt_mem_phy_seq_wrapper.vho files

You may see the following warning and error messages with full calibration simulation during write leveling, which you can ignore:

- Warning: tWLS violation on DQS bit 0 positive edge. Indeterminate CK capture is possible
- Warning: tWLH violation on DQS bit 0 positive edge. Indeterminate CK capture is possible.
- ERROR: tDQSH violation on DQS bit 0

You may see the following warning messages at time 0 (before reset) of simulation, which you can ignore:

- Warning: There is an 'U'|'X'|'W'|'Z'|'-' in an arithmetic operand, the result will be 'X'(es).
- Warning: NUMERIC_STD.TO_INTEGER: metavalue detected, returning 0

You may see the following warning and error messages during reset, which you can ignore:
■ Error: clock switches from 0/1 to X (Unknown value) on DLL instance

■ Warning: Duty Cycle violation DLL instance Warning: Input clock duty cycle violation.

1. Timing Analysis Methodology

Ensuring that your external memory interface meets the various timing requirements of today’s high-speed memory devices can be a challenge. Altera addresses this challenge by offering external memory physical layer (PHY) interface IP (the ALTMEMPHY megafuction), which employs a combination of source-synchronous and self-calibrating circuits to maximize system timing margins. This PHY interface is a plug-and-play solution that the Quartus® II TimeQuest Timing Analyzer timing constrains and analyzes. The ALTMEMPHY megafuction, and the numerous device features offered by Arria® II GX, Cyclone® III, Stratix® III, and Stratix IV, and FPGAs, greatly simplifies the implementation of an external memory interface. All the information presented in this document for Stratix III and Stratix IV devices is applicable to HardCopy® III and HardCopy IV devices, respectively.

This chapter details the various timing paths that determine overall external memory interface performance, and describes the timing constraints and assumptions that the PHY IP uses to analyze these paths.

This chapter focuses on timing constraints for external memory interfaces based on the ALTMEMPHY and UniPHY IP. For information about timing constraints and analysis of external memory interfaces and other source-synchronous interfaces based on the ALTDQ_DQS megafunction, refer to AN 433: Constraining and Analyzing Source Synchronous Interfaces. and the Quartus II TimeQuest Timing Analyzer chapter in volume 3 of the Quartus II Handbook.

External memory interface timing analysis is supported only by the TimeQuest timing analyzer, for the following reasons:

- The wizard-generated timing constraint scripts only support the TimeQuest timing analyzer.
- The Classic Timing Analyzer does not offer analysis of source-synchronous outputs. For example, write data, address, and command outputs.
- The Classic Timing Analyzer does not support detailed rise and fall delay analysis.

The performance of an FPGA interface to an external memory device is dependent on the following items:

- Read datapath timing
- Write datapath timing
- Address and command path timing
- Clock to strobe timing (tDQSS in DDR, DDR2, and DDR3 SDRAM, and tKHKH in QDR II and QDRII+ SRAM
- Read resynchronization path timing (applicable for DDR, DDR2, and DDR3 SDRAM in Arria II GX, Stratix III, and Stratix IV devices)
- Read postamble path timing (applicable for DDR, DDR2, and DDR3 SDRAM in Arria II GX, Stratix III, and Stratix IV devices)
Memory Interface Timing Components

Memory interface timing components can be categorized into source-synchronous timing paths, calibrated timing paths, internal FPGA timing paths, and other FPGA timing parameters.

Understanding the nature of timing paths enables you to use an appropriate timing analysis methodology and constraints. The following section examines these aspects of memory interface timing paths.

Source-Synchronous Paths

These are timing paths where clock and data signals are forwarded from the transmitting device to the receiving device.

An example of such a path is the FPGA-to-memory write datapath. The FPGA device transmits DQ output data signals to the memory along with a center-aligned DQS output strobe signal. The memory device uses the DQS signal to clock the data on the DQ pins into its internal registers.

For brevity in the remainder of this chapter, data signals and strobe and clock signals are referred to as DQ signals and DQS signals, respectively. While the terminology is formally correct only for DDR-type interfaces and does not match QDR II and RLDRAM II pin names, the behavior is similar enough that most timing properties and concepts apply to both. The clock that captures address and command signals is always referred to as CK/CK# too.

Calibrated Paths

These are timing paths where the clock used to capture data is dynamically positioned within the data valid window (DVW) to maximize timing margin.

For Stratix IV, Stratix III, and Arria II GX FPGAs interfacing with a DDR2 SDRAM component, the resynchronization of read data from the DQS-based capture registers to the FPGA system clock domain is implemented using a self-calibrating circuit. On initialization, the ALTMEMPHY sequencer block analyzes all path delays between the read capture and resynchronization registers to set up the resynchronization clock phase for optimal timing margin. The read postamble calibration process is implemented in a similar manner to the read resynchronization calibration. In addition, the ALTMEMPHY sequencer block calibrates a read data valid signal to the...
delay between a controller issuing a read command and read data returning to controller. For Stratix IV and Stratix III FPGAs interfacing with a DDR3 SDRAM DIMM, the write-leveling chains and programmable output delay chain are calibrated to align the DQS edge with the CK edge at each memory device in the DIMM. The ALTMEMPHY megafuction supports a fully-calibrated DDR3 SDRAM PHY for DDR3 SDRAM single-rank unbuffered DIMM with ×4 and ×8 devices using 300-MHz to 533-MHz frequency targets. Deskew circuitry is automatically enabled for interfaces higher than 400 MHz.

In Cyclone III FPGAs, the initial data capture from the memory device is performed by the ALTMEMPHY megafuction using a self-calibrating circuit. The DQS strobes from the memory are not used for capture. Instead, a dynamic PLL clock signal is used to capture DQ data signals into core LE registers.

**Internal FPGA Timing Paths**

Other timing paths that impact memory interface timing include FPGA internal f\(_{\text{MAX}}\) paths for PHY and controller logic. This timing analysis is common to all FPGA designs. With appropriate timing constraints on the design (such as clock settings), the TimeQuest Timing Analyzer reports the corresponding timing margins.

For more information about the TimeQuest Timing Analyzer, refer to the [Quartus II TimeQuest Timing Analyzer](#) chapter in volume 3 of the [Quartus II Handbook](#).

**Other FPGA Timing Parameters**

Some FPGA data sheet parameters, such as I/O toggle rate and output clock specifications, can limit memory interface performance.

I/O toggle rates vary based on speed grade, loading, and I/O bank location—top/bottom versus left/right. This toggle rate is also a function of the termination used (OCT or external termination) and other settings such as drive strength and slew rate.

Ensure you check the I/O performance in the overall system performance calculation. Altera recommends that you perform signal integrity analysis for the specified drive strength and output pin load combination.

For information about signal integrity, refer to the [Board Layout Guidelines](#) section in volume 2 of the [External Memory Interface Handbook](#) and [AN 476: Impact of I/O Settings on Signal Integrity in Stratix III Devices](#).

Output clock specifications include clock period jitter, half-period jitter, cycle-to-cycle jitter, and skew between FPGA clock outputs. You can obtain these specifications from the FPGA data sheet and must meet memory device requirements. You can use these specifications to determine the overall data valid window for signals transmitted between the memory and FPGA device.
### Timing Paths—ALTMEMPHY

Table 1–1 lists the timing paths for the ALTMEMPHY megafunction that are analyzed by the Report DDR in the TimeQuest Timing Analyzer.

FPGA Timing Paths

This topic describes the FPGA timing paths, the timing constraints examples, and the timing assumptions that the constraint scripts use.
In Arria II GX and Stratix IV devices, the margin for DDR2 and DDR3 SDRAM interfaces is reported based on a combination of the TimeQuest timing analyzer and further steps to account for calibration that occurs at runtime. First the TimeQuest timing analyzer returns the base setup and hold slacks, and then further processing adjusts the slacks to account for effects which cannot be modeled in TimeQuest. For DDR SDRAM, QDR II, QDR II+ SRAM, and RLDRAM II interfaces, the margin is entirely from the TimeQuest timing analyzer.

5. For output clock specifications, refer to the DC and Switching Characteristics chapter of the Stratix IV Device Handbook.

Cyclone III PHY Timing Paths

Table 1–5 categorizes the various timing paths in a Cyclone III memory interface. Cyclone III devices use a calibrated PLL output clock for data capture and ignore the DQS strobe from the memory. Therefore, read resynchronization and postamble timing paths are not applicable to Cyclone III designs. The read capture is implemented in LE registers specially placed next to the data pin with fixed routing, and data is transferred from the capture clock domain to the system clock domain using a FIFO block. Figure 1–3 shows the Cyclone III input datapath registers and circuit types.

Timing Margin Components

This section details the timing margins such as the read data and write data timing paths. Timing paths internal to the FPGA are either guaranteed by design and tested on silicon, or analyzed by the TimeQuest Timing Analyzer using corresponding timing constraints.

Timing margins for chip-to-chip data transfers can be defined as:

\[
\text{Margin} = \text{bit period} - \text{transmitter uncertainties} - \text{receiver requirements}
\]

where:

- Sum of all transmitter uncertainties = transmitter channel-to-channel skew (TCCS).
  The timing difference between the fastest and slowest output edges on data signals, including \( t_{CO} \) variation, clock skew, and jitter. The clock is included in the TCCS measurement and serves as the time reference.

- Sum of all receiver requirements = receiver sampling window (SW) requirement.
  The period of time during which the data must be valid to capture it correctly. The setup and hold times determine the ideal strobe position within the sampling window.

- Receiver skew margin (RSKM) = margin or slack at the receiver capture register.

For design guidelines about implementing and analyzing your external memory interface using the PHY in Stratix IV, Stratix III, or Cyclone III devices, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.

Figure 1–4 relates this terminology to a timing budget diagram.

**Figure 1–4. Sample Timing Budget Diagram**

The timing budget regions marked “½ × TCCS” represent the latest data valid time and earliest data invalid times for the data transmitter. The region marked sampling window is the time required by the receiver during which data must stay stable. This sampling window is made up of the following:

- Internal register setup and hold requirements
- Skew on the data and clock nets within the receiver device
- Jitter and uncertainty on the internal capture clock

The sampling window is not the capture margin or slack, but instead the requirement from the receiver. The margin available is denoted as RSKM.

The simple example illustrated in Figure 1–4 does not consider any board level uncertainties, assumes a center-aligned capture clock at the middle of the receiver sampling window region, and assumes an evenly distributed TCCS with respect to the transmitter clock pin. In this example, the left end of the bit period corresponds to time $t = 0$, and the right end of the bit period corresponds to time $t = TUI$ (where TUI stands for time unit interval). Therefore, the center-aligned capture clock at the receiver is best placed at time $t = TUI/2$.

Therefore:

$$\text{the total margin} = 2 \times \text{RSKM} = TUI – TCCS – SW.$$ 

Consider the case where the clock is not center-aligned within the bit period (clock phase shift = $P$), and the transmitter uncertainties are unbalanced ($\text{TCCS}_{\text{LEAD}} \neq \text{TCCS}_{\text{LAG}}$). $\text{TCCS}_{\text{LEAD}}$ is defined as the skew between the clock signal and latest data valid signal. $\text{TCCS}_{\text{LAG}}$ is defined as the skew between the clock signal and earliest data invalid signal. Also, the board level skew across data and clock traces are specified as $t_{\text{EXT}}$. For this condition, you should compute independent setup and hold margins at the receiver ($\text{RSKM}_{\text{SETUP}}$ and $\text{RSKM}_{\text{HOLD}}$). In this example, the sampling window requirement is split into a setup side requirement ($\text{SW}_{\text{SETUP}}$) and hold side ($\text{SW}_{\text{HOLD}}$) requirement. Figure 1–5 illustrates the timing budget for this condition. A timing budget similar to that shown in Figure 1–5 is used for Stratix IV and Stratix III FPGA read and write data timing paths.
Therefore:

\[
\text{Setup margin} = \text{RSKM}_{\text{SETUP}} = P - \text{TCCS}_{\text{LEAD}} - \text{SW}_{\text{SETUP}} - t_{\text{EXT}} \\
\text{Hold margin} = \text{RSKM}_{\text{HOLD}} = (T_{\text{UI}} - P) - \text{TCCS}_{\text{LAG}} - \text{SW}_{\text{HOLD}} - t_{\text{EXT}}
\]

The timing budget illustrated in Figure 1–4 with balanced timing parameters is applicable for calibrated paths where the clock is dynamically center-aligned within the data valid window. The timing budget illustrated in Figure 1–5 with unbalanced timing parameters is applicable for circuits that employ a static phase shift using a DLL or PLL to place the clock within the data valid window.

**Read Data Timing**

Memory devices provide edge-aligned DQ and DQS outputs to the FPGA during read operations. Stratix III FPGAs center-aligns the DQS strobe using static DLL-based delays, and the Cyclone III FPGAs use a calibrated PLL clock output to capture the read data in LE registers without using DQS. While Stratix III devices use a source synchronous circuit for data capture and Cyclone III devices use a calibrated circuit, the timing analysis methodology is quite similar, as shown in the following section.

When applying this methodology to read data timing, the memory device is the transmitter and the FPGA device is the receiver.

The transmitter channel-to-channel skew on outputs from the memory device can be obtained from the corresponding device data sheet. Let us examine the TCCS parameters for a DDR2 SDRAM component.

For DQS-based capture:

- The time between DQS strobe and latest data valid is defined as \( t_{\text{DQSQ}} \)
- The time between earliest data invalid and next strobe is defined as \( t_{\text{QHS}} \)
- Based on earlier definitions, \( \text{TCCS}_{\text{LEAD}} = t_{\text{DQSQ}} \) and \( \text{TCCS}_{\text{LAG}} = t_{\text{QHS}} \)

The sampling window at the receiver, the FPGA, includes several timing parameters:

- Capture register micro setup and micro hold time requirements
- DQS clock uncertainties because of DLL phase shift error and phase jitter
- Clock skew across the DQS bus feeding DQ capture registers
Data skew on DQ paths from pin to input register including package skew.

For TCCS and SW specifications, refer to the DC and Switching Characteristics chapter of the Stratix IV Device Handbook, the Stratix III Device Handbook, or the Cyclone III Device Handbook.

Figure 1–6 shows the timing budget for a read data timing path.

Table 1–6 details a read data timing analysis for a Stratix III –2 speed-grade device interfacing with a 400-MHz DDR2 SDRAM component.

Write Data Timing

During write operations, the FPGA generates a DQS strobe and a center-aligned DQ data bus using multiple PLL-driven clock outputs. The memory device receives these signals and captures them internally. The Stratix III and Cyclone III device families contain dedicated DDIO (double data rate I/O) blocks inside their IOEs. The timing analysis for these device families on the write datapath is identical.

For write operations, the FPGA device is the transmitter and the memory device is the receiver. The memory device’s data sheet specifies data setup and data hold time requirements based on the input slew rate on the DQ/DQS pins. These requirements make up the memory sampling window, and include all timing uncertainties internal to the memory.

Output skew across the DQ and DQS output pins on the FPGA make up the TCCS specification. TCCS includes contributions from numerous internal FPGA circuits, including:

- Location of the DQ and DQS output pins
- Width of the DQ group
- PLL clock uncertainties, including phase jitter between different output taps used to center-align DQS with respect to DQ
- Clock skew across the DQ output pins, and between DQ and DQS output pins
- Package skew on DQ and DQS output pins

Figure 1–7 illustrates the timing budget for a write data timing path.

**Figure 1–7. Timing Budget for Write Data Timing Path**

Table 1–9 details a write data timing analysis for a Stratix III –2 speed-grade device interfacing with a DDR2 SDRAM component at 400 MHz. This timing analysis assumes the use of a differential DQS strobe with 2.0-V/\text{ns} edge rates on DQS, and 1.0-V/\text{ns} edge rate on DQ output pins. Consult your memory device’s data sheet for derated setup and hold requirements based on the DQ/DQS output edge rates from your FPGA.

This section briefly describes the dynamic deskew and DQ-DQS offset timing calculations applied for Stratix III devices. The DQ-DQS offset scheme is applicable for a Stratix III device interfacing with DDR, DDR2 and DDR3 SDRAM components for frequencies of 400 MHz and below. For frequencies above 400 MHz, a dynamic deskew scheme improves the timing margins for a Stratix III device interfacing with a DDR3 SDRAM component.

This section does not apply to Cyclone III devices.

DQ-DQS Offset

At frequencies of 400 MHz and below, the ALTMEMPHY sequencer uses the delay chains in the IOE to shift the offset between DQ and DQS such that data setup and hold requirement are met at the memory device. The actual offsets employed are FPGA family, speed grade, and frequency dependent. The DQ-DQS offset is only applied to the write data timing path.

The mem_clk and mem_clk_n pins may have a D6 Delay assignment set to 2 inchesDDR3 SDRAM with leveling interfaces depending on the configuration of the DQ clocks generated by the write levelling delay chain.

Table 1–12 details a write timing analysis for a Stratix III –2 speed-grade device interfacing with a 400-MHz DDR3 SDRAM component.

Note to Table 1–13:
(1) At a frequency of 333 MHz, the DLL operates in 10-tap mode, resulting in a 72° output clock phase shift offset between the DQ and DQS pins.

Dynamic Deskew

For Stratix III devices interfacing with a DDR3 SDRAM component at frequencies above 400 MHz, the timing margins are too small to be fixed by the static DQ-DQS offset scheme. A dynamic scheme improves setup and hold margin at the memory device with the DLL set to 8-tap mode. The DDR3 SDRAM sequencer uses the configurable delay elements and delay-chains in the IOE to make an observation of the write window as seen in the DDR3 SDRAM components. This information is then used to configure the delays for each individual DQ and DM pin, to meet the memory device setup and hold requirements and reduce skew between DQ and DM pins in a DQS group.

Timing Analysis
For more information on deskew feature, refer to Calibration Techniques for High-Bandwidth Source-Synchronous Interfaces.

**DDR3 Deskew Effects on Timing Analysis Methodology**

This section briefly describes the DDR3 SDRAM deskew effects on the timing analysis methodology for external memory interfaces. The TCCS and SW specifications are updated for a Stratix III –2 speed-grade device interfacing with a DDR3 SDRAM component at a frequency range from 401 MHz to 533 MHz.

For more information on the TCCS and SW specifications, refer to the DC and Switching Characteristics chapter of the Stratix III Device Handbook.

With deskew circuitry and 8-tap phase offset, the board skew specifications are handled differently. When the board skew does not exceed the lead or lag thresholds, it does not affect timing performance. In contrast, the board skew can degrade timing margins if it exceeds the lead and the lag thresholds. The impacts are detailed in Table 1–14 and Table 1–15 by illustrating the timing analysis of different board skew settings for a Stratix III –2 speed-grade device interfacing with a 533-MHz DDR3 SDRAM component.

| Table 1–14. Write Data Timing Analysis for a 533-MHz DDR3 SDRAM Stratix III Device |
|-----------------|-------------------------------------------------|-----------------|-----------------|
| **Parameter** | **Specifications** | **Description** | **Value Based on 25ps Board Trace Skew (ps)** |
| Memory Specifications | t_HP Average half period as specified by the memory data sheet | 1875 |
| | t_DS Memory setup requirement | 200 |
| | t_DH Memory hold requirement | 200 |
| FPGA Specifications | TCCS_LEAD (2) FPGA transmitter channel-channel skew for dynamic deskew | 253 |
| | TCCS_LAG (2) | 262 |
| Timing Calculations | t_OUTPUT_CLOCK_OFFSET Output clock phase offset between DQ and DQS (90°) | 469 |
| | t_EXT_DELTA Amount (if any) by which board trace skew exceeds 20 ps FPGA skew threshold | 5 |
| | TX_DVW_LEAD Transmitter data valid window = t_OUTPUT_CLOCK_OFFSET - TCCS_LEAD | 216 |
| | TX_DVW_LAG Transmitter data valid window = t_HP - t_OUTPUT_CLOCK_OFFSET - TCCS_LAG | 207 |
| Results | Setup margin Margin = TX_DVW_LEAD * t_EXT_DELTA * t_DS | 11 |
| | Hold margin Margin = TX_DVW_LAG * t_EXT_DELTA * t_DH | 2 |

**Notes to Table 1–14:**

1. This sample calculation uses memory timing parameters from a 72-bit wide 1152-MB micron MT9JSF12872AY-1G1BZES 533-MHz DDR3 SDRAM DIMM.
2. The TCCS specifications used in this sample calculation are obtained from the Stratix III data sheet for a –2 speed-grade device and the SSTL-18 I/O standard.
The timing constraints differ for the ALTMEMPHY megafunction and the UniPHY IP.

### ALTMEMPHY Megafunction

To ensure a successful external memory interface operation, the ALTMEMPHY MegaWizard Plug-In generates the following files for timing constraints and reporting scripts:

- `<variation_name>_ddr_timing.sdc`
- `<variation_name>_timing.tcl`
- `<variation_name>_report_timing.tcl`
- `<variation_name>_report_timing_core.tcl`
- `<variation_name>_ddr_pins.tcl`

The Synopsys design constraint (.sdc) file is named `<controller_variation_name>_phy_ddr_timing.sdc` when the ALTMEMPHY megafuction is instantiated in the Altera memory controller, and named `<phy_variation_name>_ddr_timing.sdc` when the ALTMEMPHY megafuction is instantiated as a stand-alone design. You must add this .sdc to your Quartus II project to allow the Quartus II Fitter to use the timing driven compilation to optimize the timing margins. To add your .sdc, perform the following steps:

1. On the Assignments menu, click **Settings**.
2. In the **Settings** dialog box, under **Timing Analysis Settings**, select **TimeQuest Timing Analyzer**.

**Notes to Table 1–15:**

(1) This sample calculation uses memory timing parameters from a 72-bit wide 1152-MB micron MT9JSF12872AY-1G1BZES 533-MHz DDR3 SDRAM DIMM.

(2) The sampling window specifications used in this sample calculation are obtained from the Stratix III data sheet for a -2 speed-grade device and the SSTL-18 I/O standard.
3. Add the .sdc.

The timing margins for all ALTMEMPHY megafuction timing paths are analyzed by executing the Report DDR function in the TimeQuest timing analyzer, refer to the “Timing Analysis Description” on page 1–28. No timing constraints are required (or specified in the .sdc) for Cyclone III, Stratix IV, Stratix III, and Arria II GX devices read capture and write datapaths, because all DQ and DQS pins are pre-defined. The capture and output registers are built into the IOE, and the signals are using dedicated routing connections. Timing constraints have no impact on the read and write timing margins. However, the timing margins for these paths are analyzed using FPGA data sheet specifications and the user-specified memory data sheet parameters.

The ALTMEMPHY megafuction uses the following .sdc constraints for internal FPGA timing paths, address and command paths, and clock-to-strobe timing paths:

- Creating clocks on PLL inputs
- Creating generated clocks using derive_pll_clocks, which includes all full-rate and half-rate PLL outputs, PLL reconfiguration clock, and I/O scan clocks
- Calling derive_clock_uncertainty
- Cutting timing paths for DDR I/O, calibrated paths, and most reset paths
- Setting output delays on address and command outputs (versus CK/CK# outputs)
- Setting 2T or two clock-period multicycle setup for all half-rate address and command outputs, except nCS and on-die termination (ODT) (versus CK/CK# outputs)
- Setting output delays on DQS strobe outputs (versus CK/CK# outputs for DDR2 and DDR SDRAM)

The high-performance controller MegaWizard Plug-In generates an extra <variation_name>_example_top.sdc file for the example driver design. This file contains the timing constraints for the non-DDR specific parts of the project.

<variation_name>_timing.sdc

This script includes the memory interface and FPGA device timing parameters for your variation. It is included within <variation_name>_report_timing.tcl and <variation_name>_ddr_timing.sdc and run automatically during compilation. This script is run for every instance of the same variation.

<variation_name>_report_timing.tcl

This script reports the timing slacks for your variation. It is run automatically during compilation. You can also run this script with the Report DDR task in the TimeQuest Timing Analyzer window. This script is run for every instance of the same variation.

<variation_name>_report_timing_core.tcl

This script contains high-level procedures that <variation_name>_report_timing.tcl uses to compute the timing slacks for your variation. It is run automatically during compilation.
<variation_name>_ddr_pins.tcl

This script includes all the functions and procedures required by the <variation_name>_report_timing.tcl and <variation_name>_ddr_timing.sdc scripts. It is a library of useful functions to include at the top of an .sdc file. It finds all the variation instances in the design and the associated clock, register, and pin names of each instances. The results are saved in the same directory as the .sdc and <variation_name>_report_timing.tcl as <variation_name>_autodetectedpins.tcl.

Because this .tcl file traverses the design for the project pin names, you do not need to keep the same port names on the top level of the design.

UniPHY IP

To ensure a successful external memory interface operation, the wizards for the controllers with UniPHY generate the following files for timing constraints and reporting scripts:

- <variation_name>.sdc
- <variation_name>_timing.tcl
- <variation_name>_report_timing.tcl
- <variation_name>_pin_map.tcl
- <variation_name>_parameters.tcl

<variation_name>.sdc

The .sdc file <variation_name>.sdc is listed in the wizard-generated Quartus II IP (.qip) file. Including this file in the project allows the Quartus II Synthesis and Fitter to use the timing driven compilation to optimize the timing margins.

The timing margins for all UniPHY timing paths are analyzed by executing the Report DDR function in the TimeQuest timing analyzer.

The UniPHY IP uses the .sdc file to constrain internal FPGA timing paths, address and command paths, and clock-to-strobe timing paths, and more specifically:

- Creating clocks on PLL inputs
- Creating generated clocks
- Calling derive_clock_uncertainty
- Cutting timing paths for specific reset paths
- Setting input and output delays on DQ inputs and outputs
- Setting output delays on address and command outputs (versus CK/CK# outputs)

<variation_name>_timing.sdc

This script includes the memory interface and FPGA device timing parameters for your variation. It is included within <variation_name>_report_timing.tcl and <variation_name>.sdc. Avoid changing this file.
Timing Analysis Description

The following sections describe the timing analysis using the respective FPGA data sheet specifications and the user-specified memory data sheet parameters.

The timing slacks obtained from the TimeQuest timing analyzer include all the effects included with the Quartus II timing model such as die-to-die and within-die variations, aging, systematic skew, and operating condition variations. The TimeQuest timing analyzer reports do not include the effects of runtime calibration that occurs on some of the memory interface PHYs.

To account for the effects of calibration, the ALTMEMPHY includes additional scripts that are part of the <phy_variation_name>_report_timing.tcl and <phy_variation_name>_report_timing_core.tcl files that determine the timing margin after calibration. These scripts use the setup and hold slacks of individual pins to emulate what is occurring during calibration to obtain timing margins that are representative of calibrated PHYs. The effects that are considered as part of the calibrated timing analysis include improvements in margin because of calibration and calibration or quantization error and calibration uncertainty because of voltage and temperature changes after calibration.

Address and Command

Address and command signals are single data rate signals latched by the memory device using the FPGA output clock. Some of the address and command signals are half-rate data signals, while others, such as the chip select, are full-rate signals. The address and command timing paths are analyzed by the TimeQuest timing analyzer using the set_output_delay (max and min) constraints.
Arria II GX and Stratix IV Devices

For a 533-MHz DDR3 SDRAM component with Arria II GX and Stratix IV memory interface, Example 1–1 and Example 1–2 ensure optimum address and command timing margin.

Example 1–1. Optimum Address and Command Timing

```plaintext
set_output_delay -add_delay -clock $ckclock -max [round_3dp [expr ($off*$t(period) + $t(IS) + $t(board_skew) + $fpga_tCK_ADDR_CTRL_SETUP_ERROR + $t(additional_addresscmd_tpd))]] [concat $pins(addrcmd) $pins(addrcmd_2t)]
```

Example 1–2. Optimum Address and Command Timing

```plaintext
set_output_delay -add_delay -clock $ckclock -min [round_3dp [expr ($off*$t(period) - $t(IH) - $t(board_skew) - $fpga_tCK_ADDR_CTRL_HOLD_ERROR + $t(additional_addresscmd_tpd))]] [concat $pins(addrcmd) $pins(addrcmd_2t)]
```

Table 1–16 describes the terms for Arria II GX and Stratix IV address and command timing constraints in `<phy_variation_name>_ddr_timing.sdc`.

### Table 1–16. Description of Arria II GX and Stratix IV Address and Command Timing Constraints

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$off*$t(period)</td>
<td>For a Stratix III or Stratix IV device interfacing with a 533-MHz DDR3 SDRAM component, this offset is set to zero as the address and command interface is driven from a dedicated clock phase.</td>
</tr>
<tr>
<td>$t(IS)</td>
<td>The setup time for address and command pins at the memory side.</td>

<tr>
<td>$ISI(addresscmd_setup)</td>
<td>The intersymbol interference that reduces the address and command eye opening on the left side of the window.</td>
</tr>
<tr>
<td>$ISI(addresscmd_hold)</td>
<td>The intersymbol interference that reduces the address and command eye opening on the right side of the window.</td>
</tr>
<tr>
<td>$fpga_tCK_ADDR_CTRL_SETUP_ERROR</td>
<td>An uncertainty factor for HardCopy II designs. This factor is not needed for the Stratix III or Stratix IV family devices, and is set to zero.</td>
</tr>
<tr>
<td>$t(additional_addresscmd_tpd)</td>
<td>An extra offset parameter that can be set by modifying the assignment at the top of the <code>.sdc</code> file, allowing you to compensate for a longer address and command bus. If all the address and command traces are 0.500 ns longer than the clock traces, set this value to 0.500. This parameter is negative if the clock traces are longer than the address and command traces.</td>
</tr>
</tbody>
</table>

Stratix III Devices

For a 533-MHz DDR3 SDRAM component with Stratix III memory interface, Example 1–3 and Example 1–4 ensure optimum address and command timing margin.
Table 1–17 describes the terms for Stratix III address and command timing constraints in `<phy_variation_name>_ddr_timing.sdc`:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$off*$t(period)</td>
<td>For a Stratix III device interfacing with a 533-MHz DDR3 SDRAM component, this offset is set to zero as the address and command interface is driven from a dedicated clock phase.</td>

This parameter is negative if the clock traces are longer than the address and command traces.</td>
</tr>
</tbody>
</table>

**Read Capture**

Read capture timing analysis indicates the amount of slack on the DDR DQ signals that are latched by the FPGA using the DQS strobe output of the memory device. The read capture timing paths are analyzed by a combination of the TimeQuest timing analyzer using the set_input_delay (max and min), set_max_delay, and set_min_delay constraints, and further steps to account for calibration that occurs at runtime. The ALTMEMPHY megafunction includes timing constraints in the `<phy_variation_name>_ddr_timing.sdc` file, and further slack analysis in `<phy_variation_name>_report_timing.tcl` and `<phy_variation_name>_report_timing_core.tcl` files.

**Arria IV GX and Stratix IV Devices**

For a 533-MHz DDR3 SDRAM component with Stratix IV memory interface, Example 1–5 and Example 1–6 ensure optimum read capture timing.
Table 1–18 describes the terms for Arria GX and Stratix IV read capture timing equations in `<phy_variation_name>_report_timing.tcl`:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$t(DQS_{PSERR})$</td>
<td>The phase shift error in the DQS delay chain from what is specified.</td>
</tr>
<tr>
<td>$t(DQSQ)$</td>
<td>Memory uncertainty: DQS to DQ skew, per group.</td>
</tr>
<tr>
<td>$t(QH)$ (for DDR3 SDRAM only)</td>
<td>The memory output timing.</td>
</tr>
<tr>
<td>$\text{period} \times 0.5 - tQHS$ (for DDR/DDR2 SDRAM)</td>
<td></td>
</tr>
<tr>
<td>$t(\text{board_skew})$</td>
<td>The worst case difference in propagation delay between the clock pins and any address and command pins at the memory side.</td>
</tr>
<tr>
<td>$DQSpa\text{thjitter}$</td>
<td>The peak-to-peak jitter on the read capture paths that reduces the available timing margin.</td>
</tr>
<tr>
<td>$DQSpa\text{thjitter_setup_prop}$</td>
<td>The proportion of the jitter on the read capture paths that affects the setup margin.</td>
</tr>
<tr>
<td>$\text{fpga_tREAD_CAPTURE_SETUP_ERROR}$</td>
<td>Uncertainty factors for HardCopy designs. These factors are not needed for the Stratix IV or Arria II devices, and are set to zero.</td>
</tr>
<tr>
<td>$\text{fpga_tREAD_CAPTURE_HOLD_ERROR}$</td>
<td></td>
</tr>
<tr>
<td>$\text{SSN(\text{rel_pullin_i})}$</td>
<td>The timing pull-in because of simultaneous switching noise (SSN) on input pins caused by multiple DQ/DQS pins switching at the same time.</td>
</tr>
<tr>
<td>$\text{SSN(\text{rel_pushout_i})}$</td>
<td>The timing push-out because of SSN on input pins caused by multiple DQ/DQS pins switching at the same time.</td>
</tr>
</tbody>
</table>
Cyclone III

Cyclone III devices read data is captured using a PLL phase that is calibrated and tracked with the sequencer. The ALTMEMPHY megafuntion automatically calibrates the phase of a dedicated PLL read clock to center it in the read data valid window presented to all DQ capture registers. As DQS read strobes are ignored, read postamble path is not available for Cyclone III devices. The phase of the read clock is adjusted to account for voltage and temperature variations seen in the mimic path. Also, read resynchronization path is not applicable as the ALTMEMPHY clock domain is established using a dual-clock FIFO buffer.

For a DDR2 SDRAM component with Cyclone III memory interface, Example 1–7 ensures optimum read capture timing margin:

Example 1–7. Optimum Read Capture Timing Margin

```tcl
set su   [round_3dp [expr {0.25*$period - 0.5*$tDCD_total - $tAC - [lindex $tsw 0]/1000.0 - 0.5 * $board_skew}]]
set hold [round_3dp [expr {0.25*$period - 0.5*$tDCD_total - $tAC - [lindex $tsw 1]/1000.0 - 0.5 * $board_skew}]]
```

Table 1–19 describes the terms for a Cyclone III device read capture timing equation in `<phy_variation_name>_report_timing.tcl`:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.25*$period</td>
<td>Minimum setup/hold margin.</td>
</tr>
<tr>
<td>$tDCD_total</td>
<td>Total duty cycle distortion is split over both setup and hold margin.</td>
</tr>
<tr>
<td>$tAC</td>
<td>Data (DQ) output access time for a DDR2 SDRAM component.</td>
</tr>
<tr>
<td>$board_skew</td>
<td>The worst case difference in propagation delay between all DQ pins. It is split over both setup and hold margin.</td>
</tr>
<tr>
<td>[lindex $tsw 0]</td>
<td>Read sampling window (tSW_SETUP).</td>
</tr>
<tr>
<td>[lindex $tsw 1]</td>
<td>Read sampling window (tSW_HOLD).</td>
</tr>
</tbody>
</table>

Stratix III Devices

For a DDR3 SDRAM component with Stratix III memory interface, Example 1–8 and Example 1–9 ensure optimum read capture timing margin.

Example 1–8. Optimum Read Capture Timing Margin

```tcl
set su   [round_3dp [expr {$period*$dqs_phase/360.0 - [lindex $tsw 0]/1000.0 - $tDQSQ + $tmin_additional_dqs_variation - $read_board_skew}]]
```

Example 1–9. Optimum Read Capture Timing Margin

```tcl
set hold [round_3dp [expr {$tQH - $tmax_additional_dqs_variation - $period*$dqs_phase/360.0 - [lindex $tsw 1]/1000.0 - $read_board_skew}]]
```

The hold timing constraint for DDR and DDR2 SDRAM is different than DDR3 SDRAM.
For a Stratix III memory interface with DDR or DDR2 SDRAM, Example 1–10 and Example 1–11 ensure optimum read capture timing margin.

**Example 1–10.** Optimum Read Capture Timing Margin

```tcl
set su [round_3dp [expr {period*$dqs_phase/360.0 - [lindex $tsw 0]/1000.0 - $tDQSQ + $tmin_additional_dqs_variation - $read_board_skew}]]
```

**Example 1–11.** Optimum Read Capture Timing Margin

```tcl
set hold [round_3dp [expr {$period*(0.5 - $tDCD) - $tQHS - $tmax_additional_dqs_variation - $period*$dqs_phase/360.0 - [lindex $tsw 1]/1000.0 - $read_board_skew}]]
```

Table 1–20 describes the terms for a Stratix III read capture timing equation in `<phy_variation_name>_report_timing.tcl`:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$period*$dqs_phase/360.0</code></td>
<td>The DQS delay logic in the FPGA</td>
</tr>
<tr>
<td><code>$tDQSQ</code></td>
<td>Memory uncertainty</td>
</tr>
<tr>
<td><code>$board_skew</code></td>
<td>The worst case difference in propagation delay between the DQS strobe and any DQ pin in the same group</td>
</tr>
<tr>
<td><code>$tQHS</code> (for DDR3 SDRAM only)</td>
<td>The memory output timing</td>
</tr>
<tr>
<td>[lindex $tsw 0]</td>
<td>Read sampling window (tSW_SETUP)</td>
</tr>
<tr>
<td>[lindex $tsw 1]</td>
<td>Read sampling window (tSW_HOLD)</td>
</tr>
</tbody>
</table>

For a Stratix III memory interface with QDRII or QDRII+ SRAM, Example 1–12 and Example 1–13 ensure optimum read capture timing margin.

**Example 1–12.** QDR II and QDR II+ Read Capture Margin—Setup

```tcl
set su [round_3dp [expr {$tCYC*$dqs_phase/360.0 - [lindex $tsw 0]/1000.0 - $tCQD - $board_skew}]]
```

**Example 1–13.** QDR II and QDR II+ Read Capture Margin—Hold

```tcl
set hold [round_3dp [expr {$tCYC*(0.5 - $tDCD) - $tINTERNAL_JITTER + $tCQDOH - $tCYC*$dqs_phase/360.0 - [lindex $tsw 1]/1000.0 - $board_skew}]]
```

Table 1–21 describes the terms for a Stratix III read capture timing equation for QDR II and QDR II+ SRAM:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>$dqs_phase/360.0</code></td>
<td>Read phase shift as a percentage of the clock period.</td>
</tr>
<tr>
<td><code>$tCQD</code></td>
<td>Memory clock rise to data valid.</td>
</tr>
</tbody>
</table>
Write Capture

Write timing analysis indicates the amount of slack on the DDR DQ signals that are latched by the memory device using the DQS strobe output from the FPGA device. The write timing paths are analyzed by a combination of the TimeQuest timing analyzer using the set_output_delay (max and min) and further steps to account for calibration that occurs at runtime. The ALTMEMPHY megafunction includes timing constraints in the `<phy_variation_name>_ddr_timing.sdc` file, and further slack analysis in `<phy_variation_name>_report_timing.tcl` and `<phy_variation_name>_report_timing_core.tcl` files.

Arria IV GX and Stratix IV Devices

For a 533-MHz DDR3 SDRAM component with Stratix IV memory interface, Example 1–14 and Example 1–15 ensure optimum write timing margin:

```tcl
Example 1–14. Optimum Write Timing Margin

set su [round_3dp [expr {$period*$dq2dqs_output_phase_offset/360.0 - $write_board_skew - [lindex $tccs 0]/1000.0 - $tDS}]]
```

For a 400-MHz DDR3 SDRAM component with Stratix IV memory interface, Example 1–16 and Example 1–17 ensure optimum write timing margin:

```tcl
Example 1–16. Optimum Write Timing Margin

set su [round_3dp [expr {$period*$dq2dqs_output_phase_offset/360.0 - $write_board_skew - [lindex $tccs 0]/1000.0 - $tDS}]]
```

```tcl
Example 1–17. Optimum Write Timing Margin

set hold[round_3dp [expr {$period*(0.5 - $dq2dqs_output_phase_offset/360.0) - $write_board_skew - [lindex $tccs 1]/1000.0 - $tDH}]]
```

Table 1–22 describes the terms for a an Arria II GX or a Stratix IV timing equation in `<phy_variation_name>_report_timing.tcl`:

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>$tCQDOH</td>
<td>Memory hold after clock.</td>
</tr>
<tr>

### Read Resynchronization

In the DDR3, DDR2, and DDR SDRAM interfaces with Arria II GX and Stratix IV FPGAs, the resynchronization timing analysis concerns transferring read data that is captured with a DQS strobe to a clock domain under the control of the ALTMEMPHY. After calibration by a sequencer, a dedicated PLL phase tracks any movements in the data valid window of the captured data. The exact length of the DQS and CK traces does not affect the timing analysis. The calibration process centers the resynchronization clock phase in the middle of the captured data valid window to maximize the resynchronization setup and hold the margin, and removes any static offset from other timing paths. With the static offset removed, any remaining uncertainties are limited to voltage and temperature variation, jitter and skew.

### Arria II GX and Stratix IV Devices

For a DDR3 SDRAM component with Arria II GX or Stratix IV memory interface, Example 1–24 ensures optimum read capture timing margin.

**Example 1–24. Optimum Read Capture Timing Margin**

```plaintext
set resync_su [expr $period/2 - $dqsck - $jitper/2 - $resync_clock_jitter/2 - $dqs_clock_period_jitter/2 - $dqs_clock_skew/2 - $read_delay_VT_variation - $phy_uncertainty - $resync_clock_skew/2 - $quantization_error/2 - $::ssn(pushout_o) - $::ssn(pushout_i) - $resync_micro_tsu ]
set resync_hold [expr $period/2 - $dqsck - $jitper/2 - $resync_clock_jitter/2 - $dqs_clock_period_jitter/2 - $dqs_clock_skew/2 - $read_delay_VT_variation - $phy_uncertainty - $resync_clock_skew/2 - $quantization_error/2 - $::ssn(pullin_o) - $::ssn(pullin_i) - $resync_micro_th ]
```

The timing analysis consists of subtracting the following uncertainties from the nominal data valid window of one full-rate clock cycle.
Table 1–26 describes the terms for a Arria II GX or Stratix IV resynchronization timing equation in `<phy_variation_name>_report_timing.tcl`.

<tr>
<td>Resynchronization register micro th</td>
<td>resync_micro_th</td>
<td>Resynchronization register micro hold time requirements.</td>
</tr>
</tbody>
</table>
**Mimic Path**

The mimic path mimics the FPGA portion of the elements of the round-trip delay, which enables the calibration sequencer to track delay variations because of voltage and temperature changes during the memory read and write transactions without interrupting the operation of the ALTMEMPHY megafunction.

As the timing path register is integrated in the IOE, there is no timing constraint required for the Stratix IV and Arria II GX device families.

For Cyclone III devices, the mimic register is a register in the core and it is placed closer to the IOE by the fitter.

**DQS versus CK—Cyclone III Devices**

The DQS versus CK timing path indicates the skew requirement for the arrival time of the DQS strobe at the memory with respect to the arrival time of CK/CK# at the memory. Cyclone III devices require the DQS strobes and CK clocks to arrive edge aligned.

There are two timing constraints for DQS versus CK timing path to account for duty cycle distortion. The DQS/DQS# rising edge to CK/CK# rising edge ($t_{DQSS}$) requires the rising edge of DQS to align with the rising edge of CK to within 25% of a clock cycle, while the DQS/DQS# falling edge setup/hold time from CK/CK# rising edge ($t_{DSS}/t_{DSH}$) requires the falling edge of DQS to be more than 20% of a clock cycle away from the rising edge of CK.

The DQS vs CK timing paths are analyzed by the TimeQuest timing analyzer using the `set_output_delay` (max and min) constraints as shown below. For a DDR2 SDRAM component with Cyclone III memory interface, Example 1–26 ensure optimum DQS versus CK timing margin:

**Example 1–26. Optimum DQS versus CK Timing Margins**

```plaintext
set_output_delay -add_delay -clock $ckclock -max [round_3dp [expr {($off_tDQSS+1-$t(DQSS)) * $t(period) + $t(board_skew) + $fpga_tDQSS_SETUP_ERROR}] $dqspin
set_output_delay -add_delay -clock $ckclock -min [round_3dp [expr {($off_tDQSS+$t(DQSS)) * $t(period) - $t(board_skew) - $fpga_tDQSS_HOLD_ERROR}] $dqspin
set_output_delay -add_delay -clock $ckclock -max [round_3dp [expr {($off_tDSS+$t(DSS)) * $t(period) + $t(board_skew) + $fpga_tDSSH SETUP_ERROR}] $dqspin
set_output_delay -add_delay -clock $ckclock -min [round_3dp [expr {($off_tDSS-$t(DSH)) * $t(period) - $t(board_skew) - $fpga_tDSSH HOLD_ERROR}] $dqspin
```

**DDR3 SDRAM Write Leveling $t_{\text{DQSS}}$**

In DDR3 SDRAM interfaces, write leveling $t_{\text{DQSS}}$ timing is a calibrated path that details skew margin for the arrival time of the DQS strobe with respect to the arrival time of CK/CK# at the memory side. For proper write leveling configuration, DLL delay chain must be set to 8.

**Arria II GX or Stratix IV GX Devices**

For a DDR3 SDRAM component with Arria II GX or Stratix IV memory interface, **Example 29** ensures optimum write leveling $t_{\text{DQSS}}$ timing margin:

**Example 29. Optimum Write Leveling Timing Margin**

```tcl
set tdqss_setup [expr $tDQSS - $tWLH - $vt\_variation - $tJITper - $WL\_jitter/2 - $SSN(pushout\_o) - $SSN(pullin\_o)]
set tdqss_hold  [expr $tDQSS - $tWLS - $vt\_variation - $tJITper - $WL\_jitter/2 - $SSN(pushout\_o) - $SSN(pullin\_o) - $quantization\_error]
```

**Table 1–30** describes the terms for a Stratix IV write leveling $t_{\text{DQSS}}$ timing equation in `<phy\_variation\_name>_report\_timing.tcl`:

Timing Margin Report

The Report DDR task in the TimeQuest Timing Analyzer generates custom timing margin reports for all ALTMEMPHY and UniPHY instances in your design. This custom report is generated by the TimeQuest Timing Analyzer by sourcing the wizard-generated <variation>_report_timing.tcl script.

This <variation>_report_timing.tcl script reports the timing slacks on specific paths of the DDR SDRAM design for example, such as:

- Read capture
- Read resynchronization
- Mimic, address and command
- Core
- Core reset and removal
- Half-rate address and command
- DQS versus CK
- Write
- Write leveling ($t_{DQSS}$)
- Write leveling ($t_{DSS}/\t_{DSH}$)
The `<variation_name>_report_timing.tcl` script checks the design rules and assumptions as listed in "Timing Model Assumptions and Design Rules" on page 1–47. If you do not adhere to these assumptions and rules, you receive critical warnings when the TimeQuest Timing Analyzer is run during compilation or when you run the Report DDR task.

ALTMEMPHY-based memory interface designs do not support the use of report data sheet timing specifications for analyzing margins on DDR I/O timing paths (read and write datapaths). Instead, you must use Report DDR to perform I/O timing analysis with the TCCS and SW timing specifications described in the “Timing Margin Components” on page 1–14. Report data sheet results are based on the micro-timing model of the FPGA, and do not use the memory interface TCCS or SW specifications.

To generate a timing margin report, follow these steps:

1. Compile your design in the Quartus II software.
2. Launch the TimeQuest Timing Analyzer.
3. Double-click Report DDR from the Tasks pane, (Figure 1–8). This action automatically executes the Create Timing Netlist, Read SDC File, and Update Timing Netlist tasks for your project.

The .sdc file may not be applied correctly if the variation top-level file is the top-level file of the project. You must have the top-level file of the project instantiate the variation top-level file.

Figure 1–8. Generating the Report DDR Timing Report in the TimeQuest Tasks Pane

The Report DDR feature creates a new DDR folder in the TimeQuest Timing Analyzer Report pane. Expanding the DDR folder reveals the detailed timing information for each PHY timing path, in addition to an overall timing margin summary for the ALTMEMPHY instance, as shown in Figure 1–9 and Figure 1–10.
Timing Analysis

Chapter 1: Timing Analysis Methodology

Timing Margin Report

Figure 1–11 shows the timing margin report from the TimeQuest Timing Analyzer Console window. This is a command-line version of the report in Figure 1–10.

Figure 1–12 and Figure 1–13 show the read capture and write margin summary window generated by the Report DDR Task for a DDR3 core. It first shows the timing results calculated using the FPGA timing model. The <variation_name>_report_timing_core.tcl then adjusts these numbers to account for effects that are not modeled by either the timing model or by TimeQuest Timing Analyzer.
Timing Model Assumptions and Design Rules

External memory interfaces using Altera IP are optimized for highest performance, and use a high-performance timing model to analyze calibrated and source-synchronous, double-data rate I/O timing paths. This timing model is applicable to designs that adhere to a set of predefined assumptions. These timing model assumptions include memory interface pin-placement requirements, PLL and clock network usage, I/O assignments (including I/O standard, termination, and slew rate), and many others.

For example, the read and write datapath timing analysis is based on the FPGA pin-level $t_{TCCS}$ and $t_{SW}$ specifications, respectively. While calculating the read and write timing margins, the Quartus II software analyzes the design to ensure that all read and write timing model assumptions are valid for your variation instance.

When the Report DDR task or report_timing.tcl script is executed, the timing analysis assumptions checker is invoked with specific variation configuration information. If a particular design rule is not met, the Quartus II software reports the failing assumption as a Critical Warning message. Figure 2 shows a sample set of messages generated when the memory interface DQ, DQS, and CK/CK# pins are not placed in the same edge of the device.
Memory Clock Output Assumptions

To verify the quality of the FPGA clock output to the memory device (CK/CK# or K/K#), which affects FPGA performance and quality of the read clock/strobe used to read data from the memory device, the following assumptions are needed:

- The slew rate setting must be set to Fast or an on-chip termination (OCT) setting must be used.
- The output delay chains must all be set to 0 (the default value applied by the Quartus II software). These delay chains include the Cyclone III output register to pin delay chain and the Stratix III D5 and D6 output delay chains.
- The output open-drain parameter on the memory clock pin IO_OBUF atom must be set to Off. The Output Open Drain logic option must not be enabled.
- The weak pull-up on the CK and CK# pads must be set to Off. The Weak Pull-Up Resistor logic option must not be enabled.
- The bus hold on the CK and CK# pads must be set to Off. The Enable Bus-Hold Circuity logic option must not be enabled.
- All CK and CK# pins must be declared as output-only pins or bi-directional pins with the output enable set to VCC.

Arria II GX and Stratix IV Devices

For Arria II GX and Stratix IV devices the following additional memory clock assumptions are needed:
Chapter 1: Timing Analysis Methodology

Timing Model Assumptions and Design Rules

- All memory clock output pins must be placed on DIFFOUT pin pairs.
- In all DDR3 designs and DDR2 using differential DQS/DQS# strobes, (mem_clk[0] and mem_clk_n[0]) must be placed on DIFFIO_RX p- and n- pins for voltage and temperature tracking using the mimic path. The remaining memory output clock pins (mem_clk[i] and mem_clk_n[i], where i = 1 or greater), can be placed on the DIFFOUT p- and n- pins.
- For all other cases (including when the CK pin is a mimic pin, but the design does not use true differential DQS), the memory clock output pins must be placed on DIFFOUT p- and n- pins.
- The CK output pin must be fed by DDIO output registers.
- The CK# output pin must be fed by a signal splitter from its associated CK pin.
- All memory clock pins must be placed on the same edge of the device (top, bottom, left, or right).
- For DDR3 interfaces, the CK pins must be placed on FPGA output pins marked DQ, DQS, or DQSn.
- For DDR3 interfaces, the CK pin must be fed by an OUTPUT_PHASE_ALIGNMENT WYSIWYG with a 0° phase shift.
- For DDR3 interfaces, the PLL clock driving CK pins must be the same as the clock driving the DQS pins.
- The T4 (DDIO_MUX) delay chains must be set to 2.
- The memory output clock signals must be generated with the DDIO configuration shown in Figure 1–14, with a signal splitter to generate the n- pin pair and a regional clock network-to-clock to output DDIO block.

Figure 1–14. DIDO Configuration with Signal Splitter

Notes to Figure 1–14:
(1) The mem_clk[0] and mem_clk_n[0] pins for DDR3, DDR2, and DDR SDRAM interfaces use the I/O input buffer for feedback, therefore bidirectional I/O buffers are used for these pins. For memory interfaces using a differential DQS input, the input feedback buffer is configured as differential input; for memory interfaces using a single-ended DQS input, the input buffer is configured as a single-ended input. Using a single-ended input feedback buffer requires that the I/O standard’s VREF voltage is provided to that I/O bank’s VREF pins.
(2) Regional QCLK (quadrant) networks are required for memory output clock generation to minimize jitter.

Cyclone III Devices
For Cyclone III devices the following additional memory clock assumptions are needed:
The memory clock output pins must be fed by DDIO output registers and placed on DIFFIO p- and n- pin pairs.

The memory output clock signals must be generated using the DDIO configuration shown in Figure 1–15. In this configuration, the high register is strapped to $V_{CC}$ and the low register is strapped to GND.

**Figure 1–15. DDIO Configuration**

CK and CK# pins must be fed by a DDIO_OUT WYSIWYG with datainhi connected to GND and datainlo connected to $V_{CC}$.

CK or K pins must be fed by a DDIO_OUT with its clock input from the PLL inverted.

CK# or K# pins must be fed by a DDIO_OUT with its clock input from the PLL uninverted.

The I/O standard and current strength settings on the memory clock output pins must be as follows:

- SSTL-2 Class I and 12 mA, or SSTL-2 Class II and 16 mA for DDR SDRAM interfaces
- SSTL-18 Class I and 12 mA, or SSTL-18 Class II and 16 mA for DDR2 SDRAM interfaces

**Stratix III Devices**

For Stratix III devices the following additional memory clock assumptions are needed:

- All memory clock output pins must be placed on DIFFOUT pin pairs on the same edge of the device.
- In all DDR3 SDRAM and DDR2 SDRAM designs using differential DQS/DQS# strobes, (mem_clk[0] and mem_clk_n[0]) must be placed on DIFFIO_RX p- and n- pins for voltage and temperature tracking using the mimic path. The remaining memory output clock pins (mem_clk[i] and mem_clk_n[i], where i = 1 or greater), can be placed on the DIFFOUT p- and n- pins.
- For DDR SDRAM designs where the CK pin is a mimic pin, but the design does not use true differential DQS, the memory clock output pins must be placed on DIFFOUT p- and n- pins.
For DDR3 SDRAM interfaces:
- The CK pins must be placed on FPGA output pins marked DQ, DQS, or DQSn.
- The CK pin must be fed by an OUTPUT_PHASE_ALIGNMENT WYSIWYG with a 0° phase shift.
- The PLL clock driving CK pins must be the same as the clock driving the DQS pins.
- The T4 (DDIO_MUX) delay chains setting for the memory clock pins must be the same as the settings for the DQS pins.
- For non-DDR3 interfaces, the T4 (DDIO_MUX) delay chains setting for the memory clock pins must be greater than 0.
- The programmable rise and fall delay chain settings for all memory clock pins must be set to 0.
- The memory output clock signals must be generated with the DDIO configuration shown in Figure 1–16, with a signal splitter to generate the n- pin pair and a regional clock network-to-clock to output DDIO block.

**Figure 1–16. DIDO Configuration with Signal Splitter**

Notes to Figure 1–16:
(1) The mem_clk[0] and mem_clk_n[0] pins for DDR3, DDR2, and DDR SDRAM interfaces use the I/O input buffer for feedback, therefore bidirectional I/O buffers are used for these pins. For memory interfaces using a differential DQS input, the input feedback buffer is configured as differential input; for memory interfaces using a single-ended DQS input, the input buffer is configured as a single-ended input. Using a single-ended input feedback buffer requires that the I/O standard’s VREF voltage is provided to that I/O bank’s VREF pins.
(2) Regional GCLK (quadrant) networks are required for memory output clock generation to minimize jitter.

**Write Data Assumptions**

To verify that the ALTMEMPHY-based memory interface can use the FPGA TCCS output timing specifications, the following assumptions are needed:
- For QDRII, QDRII+, and RLDRAM II SIO memory interfaces, the write clock output pins (such as K/K# or DK/DK#) must be placed in DQS/DQSn pin pairs.
- The PLL clock used to generate the write-clock signals and the PLL clock used to generate the write-data signals must come from the same PLL.
- The slew rate for all write clocks and write data pins must be set to Fast or OCT must be used.
When auto deskew is not enabled (or not supported by the ALTMEMPHY configuration), the output delay chains and output enable delay chains must all be set to the default values applied by Quartus II. These delay chains include the Cyclone III output register and output enable register-to-pin delay chains, and the Stratix III D5 and D6 delay chains.

- The output open drain for all write clocks and write data pins’ IO_OBUF atom must be set to Off. The Output Open Drain logic option must not be enabled.
- The weak pull-up for all write clocks and write data pins must be set to Off. The Weak Pull-Up Resistor logic option must not be enabled.
- The Bus Hold for all write clocks and write data pins must be set to Off. The Enable Bus-Hold Circuitry logic option must not be enabled.

**Arria II GX and Stratix IV Devices**

For Arria II GX and Stratix IV devices the following additional write data assumptions are needed:

- Differential write clock signals (DQS/DQSn) must be generated using the signal splitter.
- The write data pins (DQ/DM/BWS#) must be placed in related DQ pins associated with the chosen DQS pin. The only exception to this rule is for QDRII and QDRII+ ×36 interfaces emulated using two ×18 DQ groups. For such interfaces, all of the write data pins must be placed on the same edge of the device (left, right, top, or bottom). Also, the write clock K/K# pin pair should be placed on one of the DQS/DQSn pin pairs on the same edge.
- All write clock pins must have similar circuit structure.
  - For DDR3 interfaces, all DQS/DQS# write strobes must be fed by DDIO output registers clocked by the write-leveling delay chain in the OUTPUT_PHASE_ALIGNMENT block.
  - For non-DDR3 memory interfaces, all write clock pins must be fed by DDIO output registers clocked by a global or regional clock network.
- All write data pins must have similar circuit structure.
  - For DDR3 interfaces, all write data pins must be fed by either DDIO output registers clocked by the OUTPUT_PHASE_ALIGNMENT block, VCC, or GND.
  - For non-DDR3 memory interfaces, all write data pins must be fed by either DDIO output registers clocked by a global or regional clock network, VCC, or GND.
- The write clock output must be 72°, 90°, or 108° more than the write data output.
  - For DDR3 interfaces, the write-leveling delay chain in the OUTPUT_PHASE_ALIGNMENT block must implement a phase shift of 72°, 90°, or 108° to center-align write clock with write data.
  - For non-DDR3 memory interfaces, the phase shift of the PLL clock used to clock the write clocks must be 72 to 108° more than the PLL clock used to clock the write data clocks to generated center-aligned clock and data.
- The T4 (DDIO_MUX) delay chains must all be set to 3. When differential DQS (using splitter) is used, T4 must be set to 2.
Table 1–35 lists I/O standards supported for the write clock and write data signals for each memory type and pin location.

### Cyclone III Devices

For Cyclone III devices the following additional write data assumptions are needed:

- Write data pins (including the DM pins) must be placed on DQ pins related to the selected DQS pins.
- All write clock pins (DQS/DQS#) must be fed by DDIO output registers.
- All write data pins must be fed by DDIO output registers, \( V_{CC} \) or GND.
- The phase shift of the PLL clock used to generate the write clocks must be 72° to 108° more than the PLL clock used to generate the write data (nominally 90° offset).
- The I/O standard and current strength settings on the write data- and clock-output pins must be as follows:
  - SSTL-2 Class I and 12 mA, or SSTL-2 Class II and 16 mA for DDR SDRAM interfaces
  - SSTL-18 Class I and 12 mA, or SSTL-18 Class II and 16 mA for DDR2 SDRAM interfaces

### Stratix III Devices

For Stratix III devices the following additional write data assumptions are needed:

- Differential write clock signals (DQS/DQSn) must be generated using the signal splitter.
The write data pins (including the DM pins) must be placed in related DQ pins associated with the chosen DQS pin. The only exception to this rule is for QDRII and QDRII+ ×36 interfaces emulated using two ×18 DQ groups. For such interfaces, all of the write data pins must be placed on the same edge of the device (left, right, top, or bottom). Also, the write clock K/K# pin pair should be placed on one of the DQS/DQSn pin pairs on the same edge.

All write clock pins must have similar circuit structure.

For DDR3 SDRAM with leveling interfaces, all DQS/DQS# write strobes must be fed by DDIO output registers clocked by the write-leveling delay chain in the OUTPUT_PHASE_ALIGNMENT block.

For DDR and DDR2 SDRAM interfaces, all write clock pins must be fed by DDIO output registers clocked by a global or regional clock network.

All write data pins must have similar circuit structure.

For DDR3 SDRAM interfaces, all write data pins must be fed by either DDIO output registers clocked by the OUTPUT_PHASE_ALIGNMENT block, VCC, or GND.

For DDR and DDR2 SDRAM interfaces, all write data pins must be fed by either DDIO output registers clocked by a global or regional clock network, VCC, or GND.

The write clock output must be 72°, 90°, or 108° more than the write data output.

For DDR3 SDRAM interfaces, the write-leveling delay chain in the OUTPUT_PHASE_ALIGNMENT block must implement a phase shift of 72°, 90°, or 108° to center-align write clock with write data.

For DDR and DDR2 SDRAM interfaces, the phase shift of the PLL clock used to clock the write clocks must be 72 to 108° more than the PLL clock used to clock the write data clocks to generated center-aligned clock and data.

The T4 (DDIO_MUX) delay chains must all be set to 3. When differential DQS (using splitter) is used, T4 must be set to 2.

The programmable rise and fall delay chain settings for all memory clock pins must be set to 0.

Table 1–36 lists I/O standards supported for the write clock and write data signals for each memory type and pin location.

</table>
To verify that the external memory interface can use the FPGA Sampling Window (SW) input timing specifications, the following assumptions are needed:

- The read clocks input pins must be placed on DQS pins. DQS/DQS# inputs must be placed on differential DQS/DQSn pins on the FPGA.
- Read data pins (DQ) must be placed on the DQ pins related to the selected DQS pins.
- For QDR II and QDR II+ SRAM interfaces, the complementary read clocks must have a single-ended I/O standard setting of HSTL-18 Class I or HSTL-15 Class I.
- For RLDRAM II interfaces, the differential read clocks must have a single ended I/O standard setting of HSTL 18 Class I or HSTL 15 Class I.

### Arriva II GX and Stratix IV Devices

For Arria II GX and Stratix IV devices the following additional read data and mimic pin assumptions are needed.

- For DDR3, DDR2, and DDR SDRAM interfaces, the read clock pin can only drive a DQS bus clocking a ×4 or ×9 DQ group.
- For QDRII, QDRII+, and RLDRAM II memory interfaces, the read clock pin can only drive a DQS bus clocking a ×9, ×18, or ×36 DQ group.
- For non-wraparound interfaces, the mimic pin, all read clock, and all read data pins must be placed on the same edge of the device (top, bottom, left, or right). For wraparound interfaces, these pins can be placed on adjacent row I/O and column I/O edges and operate at reduced frequencies. Wraparound interfaces are not supported in Stratix IV devices (all interface pins must be placed on the same edge).
- All read data pins and the mimic pin must feed DDIO_IN registers.
- DQS phase-shift setting must be either 72° or 90° (supports only one phase shift for each operating band and memory standard).
- All read clock pins must have the dqs_ctrl_latches_enable parameter of its DQS_DELAY_CHAIN WYSIWYG set to false.
Cyclone III Devices
For Cyclone III devices the following additional read data and mimic pin assumptions are needed:

- The I/O standard setting on read data and clock input pins must be as follows:
  - SSTL-2 Class I and Class II for DDR SDRAM interface
  - SSTL-18 Class I and Class II for DDR2 SDRAM interfaces

- The read data and mimic input registers (flip-flops fed by the read data pin’s input buffers) must be placed in the LAB adjacent to the read data pin. A read data pin can have 0 input registers.

- Specific routing lines from the IOE to core read data/mimic registers must be used. The Quartus II Fitter ensures proper routing unless user-defined placement constraints or LogicLock™ assignments force non-optimal routing. User assignments that prevent input registers from being placed in the LAB adjacent to the IOE must be removed.

- The read data and mimic input pin input pad to core/register delay chain must be set to 0.

- If all read data pins are on row I/Os or column I/Os, the mimic pin must be placed in the same type of I/O (row I/O for read-data row I/Os, column I/O for read-data column I/Os). For wraparound cases, the mimic pin can be placed anywhere.

Stratix III Devices
For Stratix III devices the following additional read data and mimic pin assumptions are needed:

- For DDR3, DDR2, and DDR SDRAM interfaces, the read clock pin can only drive a DQS bus clocking a ×4 or ×9 DQ group.

- For QDR II, QDR II+ SRAM, and RLDARM II interfaces, the read clock pin can only drive a DQS bus clocking a ×9, ×18, or ×36 DQ group.

- For non-wraparound DDR, DDR2, and DDR3 interfaces, the mimic pin, all read clock, and all read data pins must be placed on the same edge of the device (top, bottom, left, or right). For wraparound interfaces, these pins can be placed on adjacent row I/O and column I/O edges and operate at reduced frequencies.

- All read data pins and the mimic pin must feed DDIO_IN registers and their input delay chains D1, D2, and D3 set to the Quartus II default.

- DQS phase-shift setting must be either 72° or 90° (supports only one phase shift for each operating band and memory standard).

- All read clock pins must have the dqs_ctrl_latches_enable parameter of its DQS_DELAY_CHAIN WYSIWYG set to false.

- The read clocks pins must have their D4 delay chain set to the Quartus II default value of 0.

- The read data pins must have their T8 delay chain set to the Quartus II default value of 0.
When differential DQS strobes are used (DDR3 and DDR2 SDRAM), the mimic pin must feed a true differential input buffer. Placing the memory clock pin on a \texttt{DIFFIO\_RX} pin pair allows the mimic path to track timing variations on the DQS input path.

When single ended DQS strobes are used, the mimic pin must feed a single ended input buffer.

**Mimic Path Assumptions**

To verify that the ALTMEMPHY-based DDR, DDR2, or DDR3 SDRAM interface’s mimic path is configured correctly, the mimic path input must be placed on the \texttt{mem\_clk[0]} pin.

**Arria II GX, Stratix III and Stratix IV Devices**

To verify that the voltage and temperature tracking mimic path in ALTMEMPHY designs is set up correctly, the following assumptions are needed:

- When differential DQS strobes are used (DDR3 and DDR2), the mimic pin must feed a true-differential input buffer. Placing the memory clock pin on a \texttt{DIFFIO\_RX} pin pair allows the mimic path to track timing variations on the DQS input path.

- When single-ended DQS strobes are used, the mimic pin must feed a single-ended input buffer.

**DLL Assumptions**

The following DLL assumptions are needed:

These assumptions do not apply to Cyclone III devices.

- The DLL must directly feed its \texttt{delayctrlout[]} outputs to all DQS pins without intervening logic or inversions.

- The DLL must be in a valid frequency band of operation as defined in the corresponding device data sheet.

- The DLL must have jitter reduction mode and dual-phase comparators enabled.

**PLL and Clock Network Assumptions**

The PLL and clock network assumptions vary for each device family.

**Arria II GX, Stratix III, and Stratix IV Devices**

- The PLL that generates the memory output clock signals and write data and clock signals must be set to No compensation mode in Stratix IV devices to minimize output clock jitter.

- The reference input clock signal to the PLL must be driven by the dedicated clock input pin located adjacent to the PLL, or from the clock output signal from the adjacent PLL. To minimize output clock jitter, the reference input clock pin to the ALTMEMPHY PLL must not be routed through the core using global or regional clock networks. If the reference clock is cascaded from another PLL, that upstream PLL must be configured in No compensation mode and Low bandwidth mode.
For DDR3 and DDR2 SDRAM interfaces, use only regional or dual regional clock networks to route PLL outputs that are used to generate the write data, write clock, and memory output clock signals. This requirement ensures that the memory output clocks (CK/CK#) meet the memory device input clock jitter specifications, and that output timing variations or skews are minimized.

The same clock tree type (global, regional, or dual regional) is recommended for PLL clocks generating the write clock, write data, and memory clock signals to minimize timing variations or skew between these outputs.

**Cyclone III Devices**

To verify that the memory interface’s PLL is configured correctly, the following assumptions are needed:

- The PLL used to generate the memory output clock signals and write data/clock signals must be set to normal compensation mode in Cyclone III devices.
- PLL cascading is not supported.
- The reference input clock signal to the PLL must be driven by the dedicated clock input pin located adjacent to the PLL. The reference input clock pin must not be routed through the core using global or regional clock networks to minimize output clock jitter.
2. Timing Closure

This chapter describes common issues and how to optimize timing.

Common Issues

This topic describes potential timing closure issues that can occur when using the ALTMEMPHY. For possible timing closure issues with ALTMEMPHY variations, refer to the Quartus II Software Release Notes for the software version that you are using. You can solve some timing issues by moving registers or changing the project fitting setting to Standard (from Auto).

The Quartus II Software Release Notes list common timing issues that can be encountered in a particular version of the Quartus II software.

Missing Timing Margin Report

ALTMEMPHY timing margin reports may not be generated during compilation if the .sdc is not specified in the Quartus II project settings.

Timing margin reports are not generated if the ALTMEMPHY megafunction variation is specified as the top-level project entity. Instantiate the ALTMEMPHY variation as a lower level module in your user design or memory controller.

Incomplete Timing Margin Report

The timing report may be missing margin information for certain timing paths. This problem may occur when certain memory interface pins are optimized away during synthesis. Verify that all memory interface pins are listed in the <variation>_autodetectedpins.tcl file generated during compilation, and ensure they are connected to the I/O pins of the top-level FPGA design.

Read Capture Timing

In Stratix IV and Stratix III devices, read capture timing may fail if the DQS phase shift selected is not optimal or if the board skew specified is large.

- The effective DQS phase shift implemented by the DLL can be adjusted to balance setup and hold margins on the read timing path. The DQS phase shift can be adjusted in coarse PVT-compensated steps of 22.5°, 30°, 36°, or 45° by changing the number of delay buffers (range 1 to 4), or in fine steps using the DQS phase offset feature that supports uncompensated delay addition and subtraction in approximately 12 ps steps.
To adjust the coarse phase shift selection, determine the supported DLL modes for your chosen memory interface frequency by referencing the DLL and DQS Logic Block Specifications tables in the Switching Characteristics section of the device data sheet. For example, a 400 MHz DDR2 interface on a -2 speed grade device can use DLL mode 5 (resolution 36°, range 290 – 450 MHz) to implement a 72° phase shift, or DLL mode 6 (resolution 45°, range 360–560 MHz) to implement a 90° phase shift.

The phase_shift.tcl script and README files available for download with this application note can be used to adjust this DQS phase shift. The script only supports phase shift adjustments for Stratix IV and Stratix III devices.

In Cyclone III devices, the read capture is implemented using a calibrated clock and therefore, no clock phase-shift adjustment is possible. Additionally, the capture registers are routed to specific LE registers in the logic array blocks (LABs) adjacent to the IOE using predefined routing. Therefore, no timing optimization is possible for this path. Ensure that the correct memory device speed grade is selected for the FPGA speed grade and interface frequency.

Ensure that the appropriate board-skew parameter is specified in the ALTMEMPHY or the DDR, DDR2, and DDR3 SDRAM High-Performance Controller MegaWizard PHY Settings page. The default board trace length mismatch used is 20 ps.

**Write Timing**

Negative timing margins may be reported for write timing paths if the PLL phase shift used to generate the write data signals is not optimal. Adjust the PLL phase shift selection on the write clock PLL output using the PLL MegaWizard Plug-In Manager.

Regenerating the ALTMEMPHY or controller overwrites changes made using the PLL MegaWizard Plug-In Manager.

**Address and Command Timing**

Timing margins on the address and command timing path can be optimized by changing the PLL phase shift used to generate these signals. Modify the Dedicated Clock Phase setting in the PHY Settings page of the ALTMEMPHY or controller MegaWizard Plug-In.

Use the Pin Planner feature in the Quartus II software to accurately specify the board trace model information for all your address and command and memory clock output pins. The far-end load value and board trace delay differences between address and command and memory clock pins can result in timing failures if they are not accounted for during timing analysis.

Output delay chains on the address and command pins may not be optimally set by the Quartus II Fitter. To ensure that any PLL phase-shift adjustments are not negated by delay chain adjustments, create logic assignments using the Assignment Editor to set all address and command output pin D5 delay chains to 0.
For Stratix III, Stratix IV, HardCopy III, and HardCopy IV devices, some corner cases of device family and memory frequency may require an increase to the address and command clock phase to meet core timing. You can identify this situation, if the DDR timing report shows a PHY setup violation with the phy_clk launch clock, and the address and command latch clock—clock 0 (half-rate phy_clk) or 2 (full-rate phy_clk), and 6, respectively.

If you see this timing violation, you may fix it by advancing the address and command clock phase as required. For example, a 200-ps violation for a 400-MHz interface represents 8% of the clock period, or 28.8°. Therefore, advance the address and command phase from 270° to 300°. However, this action reduces the setup and hold margin at the DDR device.

**PHY Reset Recovery and Removal**

A common cause for reset timing violations in ALTMEMPHY designs is the selection of a global or regional clock network for a reset signal. ALTMEMPHY does not require any dedicated clock networks for reset signals. Only ALTMEMPHY PLL outputs require clock networks, and any other PHY signal using clock networks may result in timing violations.

Such timing violations can be corrected by:

- Setting the Global Signal logic assignment to Off for the problem path (via the Assignment Editor), or
- Adjusting the logic placement (via the Assignment Editor or Chip Editor)

**Clock-to-Strobe (for DDR and DDR2 SDRAM Only)**

Memory output clock signals and DQS strobes are generated using the same PLL output clock. Therefore, no timing optimization is possible for this path and positive timing margins are expected for interfaces running at or below the FPGA data sheet specifications.

For DDR3 interfaces, the timing margin for this path is reported as Write Leveling.

**Read Resynchronization, Postamble, and Write Leveling Timing (for SDRAM Only)**

These timing paths are only applicable to Arria II GX, Stratix IV, and Stratix III devices, and are implemented using calibrated clock signals driving dedicated IOE registers. Therefore, no timing optimization is possible for these paths, and positive timing margin is expected for interfaces running at or below the FPGA data sheet specifications.

Ensure that the correct memory device timing parameters (tDQCK, tDSS, tDSH) and board skew (tEXT) are specified in the ALTMEMPHY or High-Performance Controller MegaWizard Plug-In.

**Optimizing Timing**

For full-rate designs you may need to use some of the Quartus II advanced features, to meet core timing, by following these steps:
1. On the Assignments menu click **Settings**. In the **Category** list, click **Analysis & Synthesis Settings**. For **Optimization Technique** select **Speed** (see Figure 2–1).

**Figure 2–1. Optimization Technique**

2. In the **Category** list, click **Physical Synthesis Optimizations**. Specify the following options:

   - Turn on **Perform physical synthesis for combinational logic**.

     For more information on physical synthesis, refer to the *Netlist and Optimizations and Physical Synthesis* chapter in the *Quartus II Software Handbook*.

   - Turn on **Perform register retiming**

   - Turn on **Perform automatic asynchronous signal pipelining**

   - Turn on **Perform register duplication**

     You can initially select **Normal** for **Effort level**, then if the core timing is still not met, select **Extra** (see Figure 2–2).
Figure 2–2. Physical Synthesis Optimizations
3. Timing Deration Methodology for Multiple Chip Select DDR2 and DDR3 SDRAM Designs

This chapter explains two timing deration methodologies for multiple chip select DDR2 and DDR3 SDRAM designs. For Arria II GX and Stratix IV devices, the ALTMEMPHY and high-performance controller MegaWizard Plug-Ins have an option to select multiple chip select deration.

To perform multiple chip select timing deration for other Altera devices (for example Cyclone III and Stratix III devices), Altera provides an Excel-based calculator available from the Altera web site.

Timing deration in this chapter applies to either discrete components or DIMMs.

You can derate DDR SDRAM multiple chip select designs by using the DDR2 SDRAM section of the Excel-based calculator, but Altera does not guarantee the results.

This chapter assumes you know how to obtain data on PCB simulations for timing deration from HyperLynx or any other PCB simulator.

Background

A DIMM contains one or several RAM chips on a small PCB with pins that connect it to another system such as a motherboard or router.

Nonregistered (unbuffered) DIMMs (or UDIMMs) connect address and control buses directly from the module interface to the DRAM on the module.

Registered DIMMs (RDIMMs) improve signal integrity (and hence potentially clock rates and overall memory size) by electrically buffering the signals with a register, at a cost of an extra clock of increased latency. In addition, most RDIMMs come with error correction coding (ECC) as standard.

Multiple chip select configurations allow for one set of data pins (and address pins for UDIMMs) to be connected to two or more memory ranks. Multiple chip select configurations have a number of effects on the timing analysis including the intersymbol interference (ISI) effects, board effects, and calibration effects.

ISI Effects

With multiple chip selects and possible slots loading the far end of the pin, there may be ISI effects on a signal causing the eye openings for DQ, DQS, and address and command signals to be smaller than for single-rank designs (Figure 3–1). Figure 3–1 shows the eye shrinkage for DQ signal of a single rank system (top) and multiple chip select system (bottom). The ISI eye reductions reduce the timing window available for both the write path and the address and command path analysis. You must specify them as output delay constraints in the Synopsis design constraints file (.sdc) file.

Board trace models in the Quartus II software can account for the effects for a single rank, but cannot analyze effects caused by multiple chip selects.
Extra loading from the additional ranks causes the slew rate of signals from the FPGA to be reduced. This reduction in slew rate affects some of the memory parameters including data, address, command and control setup and hold times (tDS, tDH, tIS, and tIH).

**Figure 3–1.** Eye Shrinkage for DQ Signal

---

**Calibration Effects**

In addition to the SI effects, multiple chip select topologies change the way that the FPGA calibrates to the memories. In single rank situations with leveling, the calibration algorithms set delay chains in the FPGA such that specific DQ and DQS pin delays from the memory are equalized (only at 401 MHz and above) so that the write-leveling and resynchronization timing requirements are met. In single rank without leveling situations, the calibration algorithm centers the resynchronization or capture phase such that it is optimum for the single rank. When there are two or more ranks in a system, the calibration algorithms must calibrate to the average point of the ranks.

**Board Effects**

Unequal length PCB traces result in delays reducing timing margins. Furthermore, skews between different memory ranks can further reduce the timing margins in multiple chip select topologies. Board skews can also affect the extent to which the FPGA can calibrate to the different ranks. If the skew between various signals for different ranks is large enough, the timing margin on the fully calibrated paths such as write leveling and resynchronization changes.

To account for all these board effects for Arria II GX and Stratix IV GX devices, refer to the ALTMEMPHY wizard **Board Settings** tab.

To perform multiple chip select timing deration for other Altera devices (for example Cyclone III and Stratix III devices), use the Excel-based calculator available from the Altera web site.
Implementing Multiple Chip Selects in ALTMEMPHY-Based Designs

In a multiple chip select system, each individual rank has its own chip select signal. Consequently, you must change the **Total memory chip selects** in the **Preset Editor** of the ALTMEMPHY or the high performance controller wizard (Figure 3–2).

![Figure 3–2. Selecting Multiple Chip Select](image)

In the **Preset Editor**, you must leave the baseline non-derated \( t_{DS} \), \( t_{DH} \), \( t_{IS} \), \( t_{IH} \) values, because the settings on the **Board Settings** tab account for multiple chip select slew rate deration.

**Timing Deration using the Board Settings Tab (Arria II GX and Stratix IV Designs Only)**

When you target Arria II GX or Stratix IV devices, the ALTMEMPHY wizard includes the **Board Settings** tab, to automatically account for the timing deration caused by the multiple chip selects in your design.
If you are targeting Cyclone III or Stratix III devices you see the following warning:

"Warning: Calibration performed on all chip selects, timing analysis only performed on first chip select. Manual timing derating is required"

You must perform manual timing deration using the Excel-based calculator.

Figure 3–2 shows the **Board Settings** tab, which allows you to enter the parameters related to the board design including skews, signal integrity, and slew rates. The **Board Settings** tab also includes the board skew setting parameter, **Addr/Command to CK skew**, (previously on the **PHY Settings** tab).

**Figure 3–2. Board Settings Tab**

![Board Settings Tab](image)
Slew Rates

You can obtain the slew rates in one of the following ways:

- Altera performs PCB simulations on internal Altera boards to compute the output slew rate and ISI effects of various multiple chip select configurations. These simulation numbers are prepopulated in the Slew Rates based on the number of ranks selected. The address and command setup and hold times (tdS, tdH, tH, tI) are then computed from the slew rate values and the baseline nonderated tdS, tdH, tH numbers entered in the Preset Editor. The wizard shows the computed values in Slew Rates. If you do not have access to a simulator to obtain accurate slew rates for your specific system, Altera recommends that you use these prepopulated numbers for an approximate estimate of your actual board parameters.

- Alternatively, you can update these default values, if dedicated board simulation results are available for the slew rates. Custom slew rates cause the tdS, tdH, tH, tI values to be updated. Altera recommends performing board level simulations to calculate the slew rate numbers that accounts for accurate board-level effects for your board.

- You can modify the auto-calculated tdS, tdH, tH, tI values with more accurate dedicated results direct from the vendor data sheets, if available.

Intersymbol Interference

ISI parameters are similarly autopopulated based on the number of ranks you select with Altera’s PCB simulations. You can update these autopopulated typical values, if more accurate dedicated simulation results are available.

Altera recommends performing board-level simulations to calculate the slew rate and ISI deltas that account for accurate board level effects for your board. You can use HyperLynx or similar simulators to obtain these simulation numbers. The default values have been computed using HyperLynx simulations for Altera boards with multiple DDR2 and DDR3 SDRAM slots.

For DQ and DQS ISI there is one textbox for the total ISI, which assumes symmetric setup and hold. For address and command, there are two textboxes: one for ISI on the leading edge, and one for the lagging edge, to allow for asymmetric ISI.

The wizard writes these parameters for the slew rates and the ISI into the .sdc file and they are used during timing analysis.

Board Skews

Table 3–1 describes the six types of board skew.

<table>
<thead>
<tr>
<th>Board Skew</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Min CK/DQS skew to DIMM</td>
<td>The largest negative skew that exists between the CK signal and any DQS signal when arriving at any rank. This value affects the write leveling margin for DDR3 SDRAM DIMM interfaces in multiple chip select configurations only.</td>
</tr>
<tr>
<td>Max CK/DQS skew to DIMM</td>
<td>The maximum skew (or largest positive skew) between the CK signal and any DQS signal when arriving at any rank. This value affects the write leveling margin for DDR3 SDRAM DIMM interfaces in multiple chip select configurations.</td>
</tr>
</tbody>
</table>
To perform multiple chip select timing deration for other Altera devices (for example Stratix III and Cyclone III devices), use the Excel-based calculator, which is available from the Altera web site.

The Excel-based calculator requires data like the slew rate, eye reduction, and the board skews of your multiple chip select system as inputs and outputs the final result based on built-in formula.

The calculator requires the Quartus II timing results (report DDR section) from the single rank version of your system. Two simulations are also required for the slew rate and ISI information required by the calculator: a baseline single rank version of your system and your multiple chip select system. The calculator uses the timing deltas of these simulation results for the signals of interest (DQ, DQS, CK/CK#, address and command, and CS). You must enter board skews for your specific board. The calculator outputs the final derated timing margins, which provides a full analysis of your multiple chip select system’s performance.

The main assumption for this flow is that you have board trace models available for the single rank version of your system. If you have these board trace models, the Quartus II software automatically derates the effects for the single rank case correctly. Hence the Excel-based calculator provides the deration of the supported single-rank timing analysis, assuming that the single rank version has provided an accurate baseline.

You must ensure that the single rank board trace models are included in your Quartus II project so that the baseline timing analysis is accurate. If you do not have board trace models, follow the process described at the end of this section.

Before You Use the Excel-based Calculator for Timing Deration

Ensure you have the following items before you use the Excel-based calculator for timing deration:

1. A Quartus II project with your instantiated memory IP. Always use the latest version of the Quartus II software, for the most accurate timing models.
2. The board trace models for the single rank version of your system.

   If you do not have board trace models, refer to “Using the Excel-based Calculator for Timing Deration (Without Board Trace Models)” on page 3–10.

Using the Excel-Based Calculator

To obtain derated timing margins for multiple chip select designs using the Excel-based calculator, follow these steps:

1. Create a memory interface design in the Quartus II software.
2. Ensure board trace models are specified for your single rank system. Extract Quartus II reported timing margins into the Excel-based calculator.
3. Use the slow 85C model timing results (Figure 3–4).
   
   Use the worst-case values from all corners, which means that some values may come from different corners. For example, a setup value may come from the slow 85C model, while the hold value for the same metric may come from the fast 0C model. In most cases, using the slow 85C model should be accurate enough.

Figure 3–4. Quartus II Report DDR Section Timing Results for the Slow 85C Model

4. Enter the Report DDR results from Quartus II timing analysis into the Excel-based calculator (Figure 3–5).
5. Perform PCB SI simulations to get the following values:
   - Single rank eye width and topology eye width for data, strobe, and address and command signals.
   - Multiple chip select topology slew rates for clock, address and command, and data and strobe signals.

   Table 3–1 suggests the data rates and recommended stimulus patterns for various signals and memory interface types.

   Use a simulation tool (for example, HyperLynx), if you have access to the relevant input files that the tool requires, or use prelayout line simulations if the more accurate layout information is not available.

<table>
<thead>
<tr>
<th>Memory Interface</th>
<th>CLK and DQS Toggling Pattern (MHz)</th>
<th>DQ PRBS Pattern (MHz)</th>
<th>Address and Command PRBS Pattern (MHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td>DDR2 SDRAM (with a half-rate controller)</td>
<td>400</td>
<td>400</td>
<td>100</td>
</tr>
<tr>
<td>DDR2 SDRAM (with a full-rate controller)</td>
<td>300</td>
<td>300</td>
<td>150</td>
</tr>
<tr>
<td>DDR3 SDRAM (with a half-rate controller)</td>
<td>533</td>
<td>533</td>
<td>133</td>
</tr>
</tbody>
</table>

6. Calculate the deltas to enter into the Excel-based calculator. For example, if DQ for the single rank case is 853.682 ps and DQ for the dual rank case is 805.137 ps, enter 48 ps into the calculator (Figure 3–6).

For signals with multiple loads, look at the measurements at all the target locations and pick the worst case eye width in all cases. For example, for the address bus, if A7 is the worst case eye width from pins A0 to A14, use that measurement for the address signal.
Chapter 3: Timing Deration Methodology for Multiple Chip Select DDR2 and DDR3 SDRAM Designs

Implementing Multiple Chip Selects in ALTMEMPHY-Based Designs

7. Enter the topology slew rates into the slew rate deration section. The calculator calculates the extra tDS, tDH, tIS, tIH values.

8. Obtain the board skew numbers for your PCB from either your board simulation or from your PCB vendor and enter them into the calculator (Figure 3–7).

The Excel-based calculator then outputs the final derated numbers for your multiple chip select design.

These values are an accurate calculation of your multiple chip select design timing, assuming the simulation data you provided is correct. In this example, there is negative slack on some of the paths, so this design does not pass timing. You have the following four options available:

- Try to optimize margins and see if it improves timing (for example modify address and command phase setting)
- Lower the frequency of your design
- Lower the loading (change the topology of your interface to lower the loading and skew)
List

- Use a faster DIMM

**Using the Excel-based Calculator for Timing Deration (Without Board Trace Models)**

If board trace models are not available for any of the signals of the single rank system, follow these steps:

1. Create a new Quartus II Project with the Stratix III or Cyclone III device that you are targeting and instantiate a High-Performance SDRAM Controller for your memory interface.
2. Do not enter the board trace models (assumes a 0-pf load) and compile the Quartus II design.
3. Enter the Report DDR setup and hold slack numbers into the Excel-based calculator.
4. Perform a prelayout line simulation of a 0-pf load simulation and obtain eye width and slew rate numbers. Perform multiple chip select simulations of your topology and use the Excel-based calculator.
Section III. Debugging
## Revision History

The following table shows the revision history for this section.

<table>
<thead>
<tr>
<th>Date</th>
<th>Version</th>
<th>Changes Made</th>
</tr>
</thead>
<tbody>
<tr>
<td>January 2010</td>
<td>1.2</td>
<td>Corrected minor typos.</td>
</tr>

1. Verifying Functionality using the SignalTap II Logic Analyzer

The SignalTap® II logic analyzer shows read and write activity in the system.

For more information on using the SignalTap II logic analyzer, refer to Design Debugging Using the SignalTap II Embedded Logic Analyzer chapter in volume 3 of the Quartus II Software Handbook.

To add the SignalTap II logic analyzer, follow these steps:

1. On the Tools menu click SignalTap II Logic Analyzer.
2. In the Signal Configuration window next to the Clock box, click … (Browse Node Finder).
3. Type the memory interface system clock (typically *phy_clk) in the Named box, for Filter select SignalTap II: pre-synthesis and click List.
4. Select the memory interface system clock (<variation name>_example_top | <variation name>_inst | <variation name>_controller_phy:<variation name>_controller_phy_inst | phy_clk | phy_clk) in Nodes Found and click > to add the signal to Selected Nodes.
5. Click OK.
6. Under Signal Configuration, specify the following settings:
   - For Sample depth, select 512
   - For RAM type, select Auto
   - For Trigger flow control, select Sequential
   - For Trigger position, select Center trigger position
   - For Trigger conditions, select 1
7. On the Edit menu, click Add Nodes.
8. Search for specific nodes by typing *local* in the Named box, for Filter select SignalTap II: pre-synthesis and click List.
9. Select the following nodes in Nodes Found and click > to add to Selected Nodes:
   - local_address
   - local_rdata
   - local_rdata_valid
   - local_read_req
   - local_ready
   - local_wdata
   - local_wdata_req
   - local_write_req
   - pnf
   - pnf_per_byte
   - test_complete (trigger)
   - ctl_cal_success
   - ctl_cal_fail
   - ctl_wlat
   - ctl_rlat

   ![Note] Do not add any memory interface signals to the SignalTap II logic analyzer. The load on these signals increases and adversely affects the timing analysis.

10. Click OK.

11. To reduce the SignalTap II logic size, turn off Trigger Enable on the following bus signals:
   - local_address
   - local_rdata
   - local_wdata
   - pnf_per_byte
   - ctl_wlat
   - ctl_rlat

12. Right-click Trigger Conditions for the test_complete signal and select Rising Edge.

13. On the File menu, click Save, to save the SignalTap II .stp file to your project.

   ![Note] If you see the message Do you want to enable SignalTap II file “stp1.stp” for the current project, click Yes.

14. Once you add signals to the SignalTap II logic analyzer, recompile your design, on the Processing menu, click Start Compilation.
15. When the design compiles, ensure that TimeQuest timing analysis passes successfully. In addition to this FPGA timing analysis, check your PCB or system SDRAM timing. To run timing analysis, run the *_phy_report_timing.tcl script.
   a. On the Tools menu, click Tcl Scripts.
   b. Select <variation name>_phy_report_timing.tcl and click Run.

16. Connect the development board to your computer.

17. On the Tools menu, click SignalTap II Logic Analyzer.

18. Add the correct <your project name>.sof file to the SOF Manager:
   a. Click ... to open the Select Program Files dialog box.
   b. Select <your project name>.sof.
   c. Click Open.
   d. To download the file, click the Program Device button.

19. When the example design including SignalTap II successfully downloads to your development board, click Run Analysis to run once, or click Autorun Analysis to run continuously.
This chapter describes the process of debugging hardware and the tools to debug any external memory interface. The concepts contained discussed can be applied to any IP but focus on the debug of issues using the Altera DDR, DDR2, DDR3, QDRII, QDRII+, and RLDRAM II IP.

Use this document with the respective IP user guide and other sections in the *External Memory Interface Handbook*.

Increases in external memory interface frequency results in the following issues that increase the challenges of debugging interfaces:

- More complex memory protocols
- Increased features and functionality
- More critical timing
- Increased complexity of calibration algorithm

Before the in-depth debugging of any issue, gather and confirm all information regarding the issue.

### Debugging Checklist

The following checklist is a good starting point when debugging an external memory interface. This chapter discusses all of the items in the checklist.

<table>
<thead>
<tr>
<th>Check</th>
<th>Item</th>
</tr>
</thead>
<tbody>
<tr>
<td>☐</td>
<td>Try a different fit.</td>
</tr>
<tr>
<td>☐</td>
<td>Check IP parameters at the operating frequency (t\text{MRD}, t\text{WTR} for example).</td>
</tr>
<tr>
<td>☐</td>
<td>Check flexible timing model and timing deration.</td>
</tr>
<tr>
<td>☐</td>
<td>Simulate the design. If it fails in simulation, it will fail in hardware.</td>
</tr>
<tr>
<td>☐</td>
<td>Analyze timing.</td>
</tr>
<tr>
<td>☐</td>
<td>Place and assign R\text{UP} and R\text{DN} (OCT).</td>
</tr>
<tr>
<td>☐</td>
<td>Measure the power distribution network (PDN).</td>
</tr>
<tr>
<td>☐</td>
<td>Measure signal integrity.</td>
</tr>
<tr>
<td>☐</td>
<td>Measure setup and hold timing.</td>
</tr>
<tr>
<td>☐</td>
<td>Measure FPGA voltages.</td>
</tr>
<tr>
<td>☐</td>
<td>Vary voltages.</td>
</tr>
<tr>
<td>☐</td>
<td>Heat and cool the PCB.</td>
</tr>
<tr>
<td>☐</td>
<td>Operate at a lower or higher frequency.</td>
</tr>
<tr>
<td>☐</td>
<td>Check board timing and trace information.</td>
</tr>
<tr>
<td>☐</td>
<td>Check LVDS and clock sources, I/O voltages and termination.</td>
</tr>
<tr>
<td>☐</td>
<td>Check PLL clock source, specification, and jitter.</td>
</tr>
</tbody>
</table>
Debug issues may not be directly related to interface operation. Issues can also arise at the Quartus II Fitter stage, or complex designs may have timing analysis issues.

Quartus II Resource and Planning Issue Characteristics

Typically, single stand-alone interfaces should not present any Quartus II Fitter or timing issues. You may find that fitter, timing, and hardware operation can sometimes become a challenge, as multiple interfaces are combined into a single project, or as the device utilization increases. In such cases, the interface configuration is not the issue, the placement and total device resource requirements create problems.

Resource Issue Evaluation

External memory interfaces typically require the following resource types, which you must consider when trying to manually place, or perhaps use additional constraints to force the placement or location of external memory interface IP:

- Dedicated IOE DQS group resources and pins
- Dedicated DLL resources
- Specific PLL resources
- Specific global, regional, and dual-regional clock net resources

**Dedicated IOE DQS Group Resources and Pins**

Fitter issues can occur with even a single interface, if you do not size the interface to fit within the specified constraints and requirements. A typical requirement includes containing assignments for the interface within a single bank or possibly side of the chosen device.

Such a constraint requires that the chosen device meets the following conditions:

- Sufficient DQS groups and sizes to support the required number of common I/O (CIO) or separate I/O (SIO) data groups.
- Sufficient remaining pins to support the required number of address, command, and control pins.

Failure to evaluate these fundamental requirements can result in suboptimal interface design, if the chosen device cannot be modified. The resulting wraparound interfaces or suboptimal pseudo read and write data groups artificially limit the maximum operating frequency.

Multiple blocks of IP further complicate the issue, if other IP has either no specified location constraints or incompatible location constraints.
The Quartus II fitter may first place other components in a location required by your memory IP, then error at a later stage because of an I/O assignment conflict between the unconstrained IP and the constrained memory IP.

Your design may require that one instance of IP is placed anywhere on one side of the device, and that another instance of IP is placed at a specific location on the same side.

While the two individual instances may compile in isolation, and the physical number of pins may appear sufficient for both instances, issues can occur if the instance without placement constraints is placed before the instance with placement constraints.

In such circumstances, Altera recommends manually placing each individual pin, or at least try using more granular placement constraints.

For more information about the pin number and DQS group capabilities of your chosen device, refer to device data sheets or the Quartus II pin planner.

**Dedicated DLL Resources**

Altera devices typically use DLLs to enhance data capture at the FPGA.

While multiple external memory interfaces can usually share DLL resources, fitter issues can occur when there is insufficient planning before HDL coding. If DLL sharing is required, Altera gives the following recommendations for each instance of the IP that shares the DLL resources:

- Must have compatible DLL requirements—same frequency and mode.

- Exports its autogenerated DLL instance out of its own dedicated PHY hierarchy and into the top-level design file. This procedure allows easy comparison of the generated DLL’s mode, and allows you to explicitly show the required DLL sharing between two IP blocks in the HDL.

The Quartus II fitter does not dynamically merge DLL instances.

**Specific PLL Resources**

When only a single interface resides on one side or one quadrant of a device, PLL resources are typically not an issue. However if multiple interfaces or IP are required on a single side or quadrant, consider the specific PLL used by each IP, and the sharing of any PLL resources.

The Quartus II software automerges PLL resources, but not for any dynamically controlled PLL components. Use the following PLL resource rules:

- Ensure that the PLL located in the same bank or side of the device is available for your memory controller.

- If multiple PLLs are required for multiple controllers that cannot be shared, ensure that enough PLL resources are available within each quadrant to support your interface number requirements.

- Try to limit multiple interfaces to a single quadrant. For example, if two complete same size interfaces can fit on a single side of the device, constrain one interface entirely in one bank of that side, and the other controller in the other bank.
For more information about using multiple PHYs or controllers, refer to Volume 6: Design Flow Tutorials of the External Memory Interface Handbook.

Specific Global, Regional and Dual-Regional Clock Net Resources

Memory PHYs typically have specific clock resource requirements for each PLL clock output. For example because of characterization data, the PHY may require that the phy_clk is routed on a global clock net. The remaining clocks may all be routed on a global or a regional clock net. However, they must all be routed on the same type. Otherwise, the operating frequency of the interface is lowered, because of the increased uncertainty between two different types of clock nets. The design may still fit, but not meet timing.

Planning Issue Evaluation

Plan the total number of DQS groups and total number of other pins required in your shared area. Use the Pin Planner to assist with this activity.

Decide which PLLs or clock networks can be shared between IP blocks, then ensure that sufficient resources are available. For example, if an IP core requires a regional clock network, a PLL located on the opposite side of the device cannot be used.

Calculate the number of total clock networks and types required when trying to combine multiple instances of IP.

You must understand the number of quadrants that the IP uses and if this number can be reduced. For example, an interface may be autoplaced across an entire side of the device, but may actually be constrained to fit in a single bank.

Optimizing the physical placement ensures that when possible, regional clock networks are used as opposed to dual-regional clock networks, hence clock net resources are maintained and routing is simplified.

As device utilization increases, the Quartus II software may have difficulty placing the core. To optimize design utilization, follow these steps:

- Review any fitter warning messages in multiple IP designs to ensure that clock networks or PLL modes are not modified to achieve the desired fit.
- Use the Quartus II Fitter resource section to compare the types of resources used in a successful standalone IP implementation to those used in an unreliable multiple IP implementation.
- Use this information to better constrain the project to achieve the same results as the standalone project.
- Use the Chip Planner (Floorplan and Chip Editor) to compare the placement of the working stand-alone design to the multiple IP project. Then use LogicLock or Design Partitions to better guide the Quartus II software to the required results.
- When creating LogicLock regions, ensure that they encompass all required resources. For example, if constraining the read and write datapath hierarchy, ensure that your LogicLock region includes the IOE blocks used for your datapath pin out.
Performance, Efficiency, and Bottleneck Issues

This topic describes the performance ($f_{\text{MAX}}$), efficiency (latency and transaction efficiency) and bottleneck (the limiting factor) issues that you can encounter in any design.

Performance Issues

There are a large number of interface combinations and configurations possible in an Altera design, therefore it is impractical for Altera to explicitly state the achievable $f_{\text{MAX}}$ for every combination. Altera seeks to provide guidance on typical performance, but this data is subject to memory component timing characteristics, interface widths, depths directly affecting timing deration requirements, and the achieved skew and timing numbers for a specific PCB.

FPGA timing issues should generally not be affected by interface loading or layout characteristics. In general, the Altera performance figures for any given device family and speed-grade combination should usually be achievable.

Achievable interface timing (address and command, half-rate address and command, read and write capture) is directly affected by any layout issues (skew), loading issues (deration), signal integrity issues (crosstalk timing deration), and component speed grades (memory timing size and tolerance). Altera performance figures are typically stated for the default (single rank, unbuffered DIMM) case. Altera provides additional expected performance data where possible, but the $f_{\text{MAX}}$ is not achievable in all configurations. Altera recommends that you optimize the following items whenever interface timing issues occur:

- Improve PCB layout tolerances
- Use a faster speed grade of memory component
- Ensure that the interface is fully and correctly terminated
- Reduce the loading (reduce the deration factor)

Bottleneck and Efficiency Issues

Depending on the transaction types, efficiency issues can exist where the achieved data rate is lower than expected. Ideally, these issues should be assessed and resolved during the simulation stage because they are sometimes impossible to solve later without rearchitecting the product.

Any interface has a maximum theoretical data rate derived from the clock frequency, however, in practice this theoretical data rate can never be achieved continuously due to protocol overhead and bus turnaround times.

Simulate your desired configuration to ensure that you have specified a suitable external memory family and that your chosen controller configuration can achieve your required bandwidth.
Efficiency can be assessed in several different ways, and the primary requirement is an achievable continuous data rate. The local interface signals combined with the memory interface signals and a command decode trace should provide adequate visibility of the operation of the IP to understand whether your required data rate is sufficient and the cause of the efficiency issue.

To show if under ideal conditions the required data rate is possible in the chosen technology, follow these steps:

1. Use the memory vendor's own testbench and your own transaction engine.
2. Use either your own driver, or modify the provided example driver, to replicate the transaction types typical of your system.
3. Simulate this performance using your chosen memory controller and decide if the achieved performance is still acceptable.

Observe the following points that may cause efficiency or bottleneck issues at this stage:

- Identify the memory controller rate (full, half, or quarter) and commands, which may take two or four times longer than necessary
- Determine whether the memory controller is starved for data by observing the appropriate request signals.
- Determine whether the memory controller processor transactions at a rate sufficient to meet throughput requirements by observing appropriate signals, including the local ready signal.

Altera has several versions and types of memory controller, and where possible you can evaluate different configurations based on the results of the first tests.

Consider using either a faster interface, or a different memory type to better align your data rate requirements to the IP available directly from Altera.

Altera also provides stand-alone PHY configurations so that you may develop custom controllers or use third-party controllers designed specifically for your requirements.

**Functional Issues**

This topic discusses functional issues.

**Functional Issue Characteristics**

Functional issues occur at all frequencies (using the same conditions) and are not altered by speed grade, temperature, or PCB changes.

**Functional Issue Evaluation**

Functional issues should be evaluated using functional simulation.

The Altera IP includes the option to autogenerate a testbench specific to your IP configuration, which provides an easy route to functional verification.

The following issues should be considered when trying to debug functional issues in a simulation environment.
Correct Combination of the Quartus II Software and ModelSim-Altera Device Models

When running any simulations, ensure that you are using the correct combination of the Quartus II software and device models. Altera only tests each release of software and IP with the aligned release of device models. Failure to use the correct RTL and model combination may result in unstable simulation environments.

The ModelSim-Altera edition of the ModelSim simulator comes precompiled with the Altera device family libraries included. You must always install the correct release of ModelSim-Altera to align with your Quartus II software and IP release.

If you are using a full version of ModelSim-SE or PE, or any other supported simulation environment, ensure that you are compiling the current Quartus II supplied libraries. These libraries are located in the `<Quartus II install path>/quartus/eda/sim_lib/` directory.

Altera IP Memory Model

Altera memory IP autogenerates a generic simplified memory model that works in all cases. This simple read and write model is not designed or intended to verify all entered IP parameters or transaction requirements.

The Altera-generated memory model may be suitable to evaluate some limited functional issues, but it does not provide comprehensive functional simulation.

Vendor Memory Model

Contact the memory vendor directly as many additional models are available from the vendors support system.

When using memory vendor models, ensure that the model is correctly defined for the following characteristics:

- Speed grade
- Organization
- Memory allocation
- Maximum memory usage
- Number of ranks on a DIMM
- Buffering on the DIMM
- ECC

Refer to the `readme.txt` file supplied with the memory vendor model, for more information about how to define this information for your configuration.

During simulation vendor models output a wealth of information regarding any device violations that may occur because of incorrectly parameterized IP.

Refer to Transcript Window Messages, for more information.

Out of PC Memory Issues

If you are running the ModelSim-Altera simulator, the limitation on memory size, may mean that you have insufficient memory to run your simulation. Or, if you are using a 32-bit operating system, your PC may have insufficient memory.
Typical simulation tool errors include: "Iteration limit reached" or "Error out of memory".

When using either the Altera generic memory model, or a vendor specific model quite large memory depths can be required if you do not specify your simulation carefully.

For example, if you simulate an entire 4-GB DIMM interface, the hardware platform that performs that simulation requires at least this amount of memory just for the simulation contents storage.

Refer to Memory Allocation and Max Memory Usage in the vendor's readme.txt files for more information.

**Transcript Window Messages**

When debugging a functional issue in simulation, vendor models typically provide a much more detailed checks and feedback regarding the interface and their operational requirements than the Altera generic model.

In general, you should use a vendor-supplied model whenever one is available. Consider using second-source vendor models in preference to the Altera generic model.

Many issues can be traced to incorrectly configured IP for the specified memory components. Component data sheets usually contain settings information for several different speed grades of memory. Be aware data sheet specify parameters in fixed units of time, frequencies, or clock cycles.

The Altera generic memory model always matches the parameters specified in the IP, as it is generated using the same engine. Because vendor models are independent of the IP generation process, they offer a more robust IP parameterization check.

During simulation, review the transcript window messages and do not rely on the Simulation Passed message at the end of simulation. This message only indicates that the example driver successfully wrote and then read the correct data for a single test cycle.

Even if the interface functionally passes in simulation, the vendor model may report operational violations in the transcript window. These reported violations often specifically explain why an interface appears to pass in simulation, but fails in hardware.

Vendor models typically perform checks to ensure that the following types of parameters are correct:

- Burst length
- Burst order
- tMRD
- tMOD
- tRFC
- tREFPDEN
- tRP
- tRAS
If a vendor model can verify all these parameters are compatible with your chosen component values and transactions, it provides a specific insight into hardware interface failures.

**Simulation**

Passing simulation means that the interface calibrates and successfully completes a single test complete cycle without asserting pass not fail (pnf). It does not take into account any warning messages that you may receive during simulation. If you are debugging an interface issue, review and, if necessary, correct any warning messages from the transcript window before continuing.
2–10 Chapter 2: Debugging Hardware

Timing Issues

Modifying the Example Driver to Replicate the Failure

Often during debugging, you may discover that the example driver design works successfully, but that your custom logic is observing data errors. This information indicates that the issue is either:

- Related to the way that the local interface transactions are occurring. Altera recommends you probe and compare using the SignalTap II analyzer.
- Related to the types or format of transactions on the external memory interface. Altera recommends you modify the example design to replicate the issue.

Typical issues on the local interface side include:

- Incorrect local address to memory address translation causing the word order to be different than expected. Refer to Burst Definition in your memory vendor data sheet.
- Incorrect timing on the local interface. When your design requests a transaction, the local side must be ready to service that transaction as soon as it is accepted without any pause.

For more information, refer to the Avalon Interface Specification.

The default example driver only performs a limited set of transaction types, consequently potential bus contention or preamble and postamble issues can often be masked in its default operation. For successful debugging, isolate the custom logic transaction types that are causing the read and write failures and modify the example driver to demonstrate the same issue. Then, you can try to replicate the failure in RTL simulation with the modified driver.

An issue that you can replicate in RTL simulation indicates a potential bug in the IP. You should recheck the IP parameters. An issue that you can not replicate in RTL simulation indicates a timing issue on the PCB. You can try to replicate the issue on an Altera development platform to rule out a board issue.

Ensure that all PCB timing, loading, skew, and deration information is correctly defined in the Quartus II software, as the timing report is inaccurate if this initial data is not correct.

Functional simulation allows you to identify any issues with the configuration of either the Altera memory controller and or PHY. You can then easily check the operation against both the memory vendor data sheet and the respective Jedec specification. After you resolve functional issues, you can start testing hardware.

For more information about simulating, refer to the Simulation section in volume 4 of the External Memory Interface Handbook.

Timing Issues

The Altera PHY and controller combinations autogenerate timing constraint files to ensure that the PHY and external interface are fully constrained and that timing is analyzed during compilation. However, timing issues can still occur. This topic discusses how to identify and resolve any timing issues that you may encounter.
Timing Issue Characteristics

Timing issues typically fall into two distinct categories:

■ FPGA core timing reported issues
■ External memory interface timing issues in a specific mode of operation or on a specific PCB

TimeQuest reports timing issues in two categories: core to core and core to IOE transfers. These timing issues include the PHY and PHY reset sections in the TimeQuest Report DDR subsection of timing analysis. External memory interface timing issues are specifically reported in the TimeQuest Report DDR subsection, excluding the PHY and PHY reset. The Report DDR PHY and PHY reset sections only include the PHY, and specifically exclude the controller, core, PHY-to-controller and local interface. Quartus II timing issues should always be evaluated and corrected before proceeding to any hardware testing.

PCB timing issues are usually Quartus II timing issues, which are not reported in the Quartus II software, if incorrect or insufficient PCB topology and layout information is not supplied. PCB timing issues are typically characterized by calibration failure, or failures during user mode when the hardware is heated or cooled. Further PCB timing issues are typically hidden if the interface frequency is lowered.

Timing Issue Evaluation

Try to fix and identify timing issues in the Quartus II software. Consider the following issues when resolving timing issues.

FPGA Timing Issues

In general, you should not have any timing issues with Altera-provided IP unless you running the IP outside of Altera’s published performance range or are using a version of the Quartus II software with preliminary timing model support for new devices. However, timing issues can occur in the following circumstances:

■ The .sdc files are incorrectly added to the Quartus II project
■ Quartus II analysis and synthesis settings are not correct
■ Quartus II Fitter settings are not correct

For all of these issues, refer to the correct user guide for more information about recommended settings and follow these steps:

1. Ensure that the IP generated .sdc files are listed in the Quartus II TimeQuest Timing Analyzer files to include in the project window.
2. Ensure that Analysis and Synthesis Settings are set to Optimization Technique Speed.
3. Ensure that Fitter Settings are set to Fitter Effort Standard Fit.
4. Use TimeQuest Report Ignored Constraints, to ensure that .sdc files are successfully applied.
5. Use TimeQuest Report Unconstrained Paths, to ensure that all critical paths are correctly constrained.

More complex timing issues can occur if any of the following conditions are true:
- The design includes multiple PHY or core projects
- Devices where the resources are heavily used
- The design includes wide, distributed, maximum performance interfaces in large die sizes

Any of these conditions can lead to suboptimal placement results when the PHY or controller are distributed around the FPGA. To evaluate such issues, simplify the design to just the autogenerated example top-level file and determine if the core meets timing and you see a working interface. Failure implies that a more fundamental timing issue exists. If the standalone design passes core timing, evaluate how this placement and fit is different than your complete design.

Use LogicLock regions, or design partitions to better define the placement of your memory controllers. When you have your interface standalone placement, repeat for additional interfaces, combine, and finally add the rest of your design. Additionally, use fitter seeds and increase the placement and router effort multiplier.

**External Memory Interface Timing Issues**

External memory interface timing issues are not directly related to the FPGA timing but are actually derived from the FPGA input and output characteristics, PCB timing, and the memory component characteristics.

The FPGA input and output characteristics tend to be a predominately fixed value, as the IOE structure of the devices is fixed. Optimal PLL characteristics and clock routing characteristics do have an effect. Assuming the IP is correctly constrained with the autogenerated assignments, and you follow implementation rules, the design should reach the stated performance figures.

The memory component characteristics are fixed for any given component or DIMM. However, consider using faster components or DIMMs in marginal cases when PCB skew may be suboptimal, or your design includes multiple ranks when deration may be causing read capture or write timing challenges. Using faster memory components typically reduces the memory data output skew and uncertainty easing read capture, and lowering the memory’s input setup and hold requirement, which eases write timing.

Increased PCB skew reduces margins on address, command, read capture and write timing. If you are narrowly failing timing on these paths, consider reducing the board skew (if possible), or using faster memory. Address and command timing typically requires you to manually balance the reported setup and hold values with the dedicated address and command phase in the IP.

Refer to the respective IP user guide for more information.

Multiple-slot multiple-rank UDIMM interfaces can place considerable loading on the FPGA driver. Typically a quad rank interface can have thirty-six loads. In multiple-rank configurations, Altera’s stated maximum data rates are not likely to be achievable because of loading deration. Consider using different topologies, for example registered DIMMs, so that the loading is reduced.
Deration because of increased loading, or suboptimal layout may result in a lower than desired operating frequency meeting timing. You should close timing in the Quartus II software using your expected loading and layout rules before committing to PCB fabrication.

Ensure that any design with an Altera PHY is correctly constrained and meets timing in the Quartus II software. You must address any constraint or timing failures before testing hardware.

For more information about constraints, refer to Volume 3: Implementing Altera Memory Interface IP of the External Memory Interface Handbook.

Hardware Debugging in the Laboratory

Before starting to debug, confirm the design followed the Altera recommended design flow.

Refer to the Recommended Design Flow section in volume 1 of the External Memory Interface Handbook.

Always keep a record of tests, to avoid repeating the same tests later. To start debugging the design, perform the following initial steps.

Create a Simplified Design that Demonstrates the Same Issue

To help debugging create a simple design that replicates the issue. A simple design compiles faster and is much easier to understand. Altera’s external memory interface IP generates an example top-level file that is ideal for debugging. The example top-level file uses all the same parameters, pin-outs, and so on.

Measure Power Distribution Network

Ensure you take measurements of the various power supplies on their hardware development platform over a suitable time base and with a suitable trigger using an appropriate probe and grounding scheme. In addition, take the measurements directly on the pins or vias of the devices in question, and with the hardware operational.

Measure Signal Integrity and Setup and Hold Margin

Measure the signals on their PCB to ensure that everything looks correct. This information can be vital. When measuring any signal, consider the edge rate of the signal, not just its frequency. Modern FPGA devices have very fast edge rates, therefore you must use a suitable oscilloscope, probe, and grounding scheme when you measure the signals.

You can take measurements to capture the setup and hold time of key signal classes with respect to their clock or strobe. Ensure that the measured setup and hold margin is at least better than that reported in the Quartus II software. A worse margin indicates that a timing discrepancy exists somewhere in the project. However, this timing issue may not be the cause of your problem.
Vary Voltage

Try and vary the voltage of your system, if you suspect a marginality issue. Increasing the voltage typically causes devices to operate faster and also usually provides increased noise margin.

Use Freezer Spray and Heat Gun

If you have an intermittent marginal issue, cool or heat the interface to try and stress the issue. Cooling down ICs causes them to run faster, which makes timing easier. Conversely heating up ICs causes them to run slower, which makes timing more difficult.

If cooling or heating fixes the issue, you are probably looking at a timing issue.

Operate at a Lower Speed

Test the interface at a lower speed. If the interface works, the interface is correctly pinned out and functional. However, if the interface fails at a lower speed, determine if the test is valid. Many high-speed memory components have a minimal operating frequency, or require subtly different configurations when operating at a lower speeds.

For example, DDR, DDR2, or DDR3 SDRAM typically requires modification to the following parameters if you want operate the interface a lower speeds:
- t_{MRD}
- t_{WTR}
- CAS latency and CAS write latency

Find Out if the Issue Exists in Previous Versions of Software

Hardware that works before an update to either the Quartus II software or the memory IP indicates that the development platform is not the issue. However, the previous generation IP may be less susceptible to a PCB issue, masking the issue.

Find out if the Issue Exists in the Current Version of Software

Designs are often tested using previous generations of Altera software or IP. Projects do not always get upgraded for the following reasons:
- Multiple engineers are on the same project. To ensure compatibility, a common release of Altera software is used by all engineers for the duration of the product development. The design may be several releases behind the current Quartus II software version.
- Many companies delay before adopting a new release of software so that they can first monitor Internet forums to get a feel for how successful other users say the software is.
- Many companies never use the latest version of any software, preferring to wait until the first service pack is released that fixes the primary issues.
- Some users may only have a license for the older version of the software and can only use that version until their company makes the financial decision to upgrade.
The local interface specification from Altera IP to the customer’s logic sometimes changes from software release to software release. If you have already spent resources designing interface logic, you may be reluctant to repeat this exercise. If a block of code is already signed off, you may be reluctant to modify it to upgrade to newer IP from Altera.

In all of these scenarios, you must determine if the issue still exists in the latest version of the Altera software. Bugs are fixed and enhancements are added to the Altera IP every release. Depending on the nature of the bug or enhancement, it may not always be clearly documented in the release notes.

Finally, if the latest version of the software resolves the issue, it may be easier to debug the version of software that you are using.

Try A Different PCB

If you are using the same Altera IP on a number of different hardware platforms; find out if the issue occurs on all of these hardware platforms, or just one. Multiple instances of the same PCB, or multiple instances of the same interface, on physically different hardware platforms may exhibit different behavior. You can determine if the configuration is fundamentally not working, or if some form of marginality is involved in the issue.

Issues are often reported on the alpha build of a development platform. These are produced in very limited numbers and often have received limited BBT (bare board testing), or FT (functional testing). Hence, these early boards are often more unreliable than production quality PCBs.

Additionally, if the IP is from a previous project to help save development resources, find out if this specific IP configuration works on a previous platform.

Try Other Configurations

Designs are typically quite large, using multiple blocks of IP in many different combinations. Find out if any other configurations work correctly on the development platform. The full project may have multiple external memory controllers in the same device, or may have configurations where only half the memory width or frequency is required. Find out what does and does not work to help the debugging of the issue.

Catagorizing Hardware Issues

The following topic catagorizes issues. Identifying which category or groups of category an issue may be classified within allows you to focus on the cause of the issue.
Signal Integrity Issues

Many design issues, even ones that you find at the protocol layer, can often be traced back to signal integrity issues. Hence, you must check circuit board construction, power systems, command, and data signaling to determine if they meet specifications. If infrequent, random errors exist in the memory subsystem, product reliability suffers. As such, electrical verification is vital. Check the bare circuit board or PCB design file. Circuit board errors can cause poor signal integrity, signal loss, signal timing skew, and trace impedance mismatches. Differential traces with unbalanced lengths or signals that are routed too closely together can cause crosstalk.

Characteristics

Signal integrity issues often appear when the performance of the hardware design is marginal. The design may not always initialize and calibrate correctly, or may exhibit occasional bit errors in user mode. Severe signal integrity issues can result in total failure of an interface at certain data rates, and sporadic component failure because of electrical stress. PCB component variance and signal integrity issues often show up as failures on one PCB, but not on another identical board. Timing issues can have a similar characteristic. Multiple calibration windows or significant differences in the calibration results from one calibration to another can also indicate signal integrity issues.

Evaluating Signal Integrity Issues

Signal integrity issues can only really be evaluated in two ways, direct measurement using suitable test equipment like an oscilloscope and probe, or simulation using a tool like HyperLynx or Allegro PCB SI. Signals should be compared against the respective electrical specification. You should look for overshoot and undershoot, non-monotonicity, eye height and width, and crosstalk.

Skew

Ensure that all clocked signals, commands, addresses, and control signals arrive at the memory inputs at the same time. Trace length variations cause data valid window variations between the signals reducing margin. For example, DDR2-800 at 400 MHz has a data valid window that is smaller than 1,250 ps. Trace length skew or crosstalk can reduce this data valid window further, making it difficult to design a reliably operating memory interface. Ensure that the skew figure previously entered into the Altera IP matches that actually achieved on the PCB, otherwise Quartus II timing analysis of the interface is accurate.

Crosstalk

Crosstalk is another issue that is best evaluated early in the memory design phase. Check the clock-to-data strobes, as these are bi-directional. Measure the crosstalk at both ends of the line. Check the data strobes to clock, as the clocks are unidirectional, these only need checking at the memory end of the line.
Power System
Some memory interfaces tend to draw current in spikes from their power delivery system as SDRAMs are based on capacitive memory cells. Rows are read and refreshed one at a time, which causes dynamic currents that can stress any power distribution network (PDN). The various power rails should be checked either at or as close as possible to the SDRAM pins power pins. Ideally, a real-time oscilloscope set to fast glitch triggering should be used for this activity.

Clock Signals
The clock signal quality is important for any external memory system. Measurements include frequency, digital core design (DCD), high width, low width, amplitude, jitter, rise, and fall times.

Read Data Valid Window and Eye Diagram
The memory generates the read signals. Take measurements at the FPGA end of the line. To ease read diagram capture, modify the example driver to mask writes or modify the PHY to include a signal that you can trigger on when performing reads.

Write Data Valid Window and Eye Diagram
The FPGA generates the write signals. Take measurements at the memory device end of the line. To ease write diagram capture, modify the example driver to mask reads or modify the PHY export a signal that is asserted when performing writes.

OCT and ODT Usage
Modern external memory interface designs typically use OCT for the FPGA end of the line, and ODT for the memory component end of the line. If either the OCT or ODT are incorrectly configured or enabled, signal integrity issues exist. If the design is using OCT, RUP or RDN pins must be placed correctly for the OCT to work. If you do not place these pins, the Quartus II software allocates them automatically with the following warning:

Warning: No exact pin location assignment(s) for 2 pins of 110 total pins
Info: Pin termination_blk0~_rup_pad not assigned to an exact location on the device
Info: Pin termination_blk0~_rdn_pad not assigned to an exact location on the device

If you see these warnings, the RUP and RDN pins may have been allocated to a pin that does not have the required external resistor present on the board. This allocation renders the OCT circuit faulty, resulting in unreliable ALTMEMPHY calibration and or interface behavior. The pins with the required external resistor must be specified in the Quartus II software.

For the FPGA, ensure that follow these actions:

- Specify the RUP and RDN pins in either the projects HDL port list, or in the assignment editor (termination_blk0~_rup_pad/termination_blk0~_rdn_pad).
- Connect the RUP and RDN pins to the correct resistors and pull-up and pull-down voltage in the schematic or PCB.
Catagorizing Hardware Issues

- Contain the $R_{UP}$ and $R_{DN}$ pins within a bank of the device that is operating at the same VCCIO voltage as the interface that is terminated.
- Check that only the expected number of $R_{UP}$ and $R_{DN}$ pins exists in the project pin-out file. Look for `Info: Created on-chip termination` messages at the fitter stage for any calibration blocks not expected in your design.
- Review the Fitter Pin-Out file for $R_{UP}$ and $R_{DN}$ pins to ensure that they are on the correct pins, and that only the correct number of calibration blocks exists in your design.
- Check in the fitter report that the input, output, and bidirectional signals with calibrated OCT all have the termination control block applicable to the associated $R_{UP}$ and $R_{DN}$ pins.

For the memory components, ensure that you follow these actions:

- Connect the required resistor to the correct pin on each and every component, and ensure that it is pulled to the correct voltage.
- Place the required resistor close to the memory component.
- Correctly configure the IP to enable the desired termination at initialization time.
- Check that the speed grade of memory component supports the selected ODT setting.
- Check that the second source part that may have been fitted to the PCB, supports the same ODT settings as the original.

Hardware and Calibration Issues

When you resolve functional, timing, and signal integrity issues, assess the operation of the PHY and its interface calibration.

Hardware and Calibration Issue Characteristics

Hardware and calibration issues have the following definitions:

- Calibration issues result in calibration failing, which typically results in the design asserting the $ctl_{cal\_fail}$ signal.
- Hardware issues result in read and write failures, which typically results in the design asserting the pass not fail (pnf) signal

Ensure that functional, timing, and signal integrity issues are not the direct cause of your hardware issue, as functional, timing or signal integrity issues are usually the cause of any hardware issue.

Evaluating Hardware and Calibration Issues

Use the following methods to evaluate hardware and calibration issues:

- Evaluate hardware issues using the SignalTap II logic analyzer to monitor the local side read and write interface with the pass or fail or error signals as triggers.
- Evaluate calibration issues using the SignalTap II logic analyzer to monitor the various calibration, configuration with the pass or fail or error signals as triggers, but also use the debug toolkit and system consoles when available.
Refer to Chapter 4, *Debug Toolkit for DDR2 and DDR3 SDRAM High-Performance Controllers.*

Refer to the respective user guide for information on which signals you should use during debugging. Consider adding core noise to your design to aggravate margin timing and signal integrity issues. Steadily increase the stress on the interface in the following order:

1. Increase the interface utilization by modifying the example driver to focus on the types of transactions that exhibit the issue.
2. Increase the SNN or aggressiveness of the data pattern by modifying the example driver to output in synchronization PRBS data patterns, or hammer patterns.
3. Increase the stress on the PDN by adding more and more core noise to your system. Try sweeping the fundamental frequency of the core noise to help identify resonances in your power system.

Steadily increasing the stress on the external memory interface is an ideal way to assess and understand the cause of any previously intermittent failures that you may observe in your system. Using the SignalTap II probe tool can provide insights into the source or cause of operational failure in the system.

Additionally, steadily increasing stress on the external memory interface allows you to assess and understand the impact that such factors have on the amount of timing margin and resynchronization window. Take measurements with and without the additional stress factor to allow evaluation of the overall effect.

**Write Timing Margin**

Determine the write timing margin by phase sweeping the write clock from the PLL. Use sources and probes to dynamically control the PLL phase offset control, to increase and decrease the write clock phase adjustment so that the write window size may be ascertained.

Remember that when sweeping PLL clock phases, the following two factors may cause operational failure:

- The available write margin.
- The PLL phase in a multi-clock system.

The following code achieves this adjustment. You should use sources and probes to modify the respective output of the PLL. Ensure that the example driver is writing and reading from the memory while observing the `pnf_per_byte` signals to see when write failures occur:

```vhdl
/////////////////
wire [7:0] ProbeSig;
wire [5:0] SourceSig;
PhaseCount PhaseCounter (  
    .resetn (1'b1),  
    .clock (pll_ref_clk),  
    .step (SourceSig[5]),  
    .updown (SourceSig[4]),
```
Catagorizing Hardware Issues

Read Timing Margin

Similarly, assess the read timing margin by using sources and probes to manually control the DLL phase offset feature. Open the autogenerated DLL using ALT_DLL and add the additionally required offset control ports. This action allows control and observation of the following signals:

- dll_delayctrlout[5:0], // Phase output control from DLL to DQS pins (Gray Coded)
- dll_offset_ctrl_a_addnsub, // Input add or subtract the phase offset value
- dll_offset_ctrl_a_offset[5:0], // User Input controlled DLL offset value (Gray Coded)
- dll_aload, // User Input DLL load command
- dll_dqsupdate, // DLL Output update required signal.

In examples where the applied offset applied results in the maximum or minimum dll_delayctrlout[5:0] setting without reaching the end of the read capture window, regenerate the DLL in the next available phase setting, so that the full capture window is assessed.

Modify the example driver to constantly perform reads (mask writes). Observe the pnf_per_byte signals while the DLL capture phase is manually modified to see when failures begin, which indicates the edge of the window.
A resynchronization timing failure can indicate failure at that capture phase, and not a capture failure. You should recalibrate the PHY with the calculated phase offset to ensure that you are using the true read-capture margin.

**Address and Command Timing Margin**
You set the address and command clock phase directly in the IP. Assuming you enter the correct board trace model information into the Quartus II software, the timing analysis should be correct. However, if you want to evaluate the address and command timing margin, use the same process as in “Write Timing Margin”, only phase step the address and command PLL output (c6 ac_clk_1x). You can achieve this effect using the debug toolkit or system console.

Refer to Chapter 4, Debug Toolkit for DDR2 and DDR3 SDRAM High-Performance Controllers.

**Resynchronization Timing Margin**
Observe the size and margins, available for resynchronization using the debug toolkit or system console.

Refer to Chapter 4, Debug Toolkit for DDR2 and DDR3 SDRAM High-Performance Controllers.

Additionally for PHY configurations that use a dedicated PLL clock phase (as opposed to a resynchronization FIFO buffer), use the same process as described in “Write Timing Margin”, to dynamically sweep resynchronization margin (c4 resynch_clk_2x).

**Postamble Timing Issues and Margin**
The postamble timing is set by the PHY during calibration. You can diagnose postamble issues by viewing the pnf_per_byte signal from the example driver. Postamble timing issues mean only read data is corrupted during the last beat of any read request.

**Intermittent Issues**

Intermittent issues are typically the hardest type of issue to debug—they appear randomly and are hard to replicate.

**Intermittent Issue Evaluation**
Errors that occur during run-time indicate a data related issue, which you can identify by the following actions:

- Add the SignalTap II logic analyzer and trigger on the post-trigger pnf
- Use a stress pattern of data or transactions, to increase the probability of the issue
- Heat up or cool down the system
- Run the system at a slightly faster frequency

If adding the SignalTap II logic analyzer or modifying the project causes the issue to go away, the issue is likely to be placement or timing related.
Errors that occur at start-up indicate that the issue is related to calibration, which you can identify by the following actions:

- Modify the design to continually calibrate and reset in a loop until the error is observed
- Where possible, evaluate the calibration margin either from the debug toolkit or system console.

Refer to Chapter 4, Debug Toolkit for DDR2 and DDR3 SDRAM High-Performance Controllers

- Capture the calibration error stage or error code, and use this information with whatever specifically occurs at that stage of calibration to assist with your debug of the issue.

Monitoring Signals with the SignalTap II Logic Analyzer

The following sections detail the memory controller signals you should consider analyzing for different memory interfaces. The list is not exhaustive, but is a starting point.

For a description of each signal, refer to Volume 3: Implementing Altera Memory Interface IP of the External Memory Interface Handbook.

DDR, DDR2, and DDR3 ALTMEMPHY Designs

Monitor the following signals for DDR, DDR2, and DDR3 SDRAM ALTMEMPHY designs:

- Local_* -example_driver (all the local interface signals)
- Pnf -example_driver
- Pnf_per_byte -example_driver
- Test_complete -example_driver
- Test_status -example_driver
- Ctl_cal_req -phy_inst
- Ctl_init_fail -phy_inst
- Ctl_init_success -phy_inst
- Ctl_cal_fail -phy_inst
- Ctl_cal_success -phy_inst
- Cal_codvw_phase * -phy_inst

In all configurations, the noncalibrated address, command and control interfaces must be correctly constrained and meet timing.

If calibration fails at a specific stage, use this chapter to understand what functionally happens at that stage, to assist with the debug.

### Without Leveling

The ALTMEMPHY without leveling PHY performs the following calibration stages:

1. Enter Calibration (s_reset)
2. Initialize PHY (s_phy_initialize)
3. Initialize DRAM
4. Write Header Information in the internal RAM (s_write_ihi)
5. Load Training Patterns
6. Test More Pattern Writes
7. Calibrate Read Resynchronization Phase
8. Advertise Write Latency (s_was)
9. Calculate Read Latency (s_adv_rlat)
10. Output Write Latency (s_adv_wlat)
11. Calibrate Postamble (s_poa)
12. Set Up Address and Command Clock Cycle
13. Write User Mode Register Settings (s_prep_customer_mr_setup)
14. Voltage and Temperature Tracking

This chapter discusses these stages. Figure 3–1 on page 3–2 shows a flow chart of the calibration stages for the PHY without leveling.
Figure 3–1. Calibration Stages—Without Leveling
Enter Calibration (s_reset)

Calibration starts when the PHY reset signal is de-asserted and AFI signal \texttt{ctl_cal_req} is low.

Initialize PHY (s_phy_initialize)

This stage holds off calibration until the DLL has locked and (if debug toolkit is enabled) internal RAM contents are all reset to zero.

Initialize DRAM

Initializing the DRAM has the following two stages:

- Initialize DRAM Power Up Sequence (s_int_dram)
- Program Mode Registers for Calibration (s_prog_mr)

Initialize DRAM Power Up Sequence (s_int_dram)

This stage brings the SDRAM out of a reset state (from any previous state) through the initialization sequence specified in the JEDEC specification for each device type, up to but not including mode register set commands. At the end of this stage the SDRAM is ready to receive mode register load commands, which must occur (on each rank) before refreshes can occur.

This calibration stage is applied to all chip selects in parallel.

Program Mode Registers for Calibration (s_prog_mr)

Mode register set commands are issued on a per chip select basis, which allows you great flexibility to issue different mode register settings to different chip selects. When all chip selects have mode registers programmed (the initialization of that chip select is complete), refreshes are enabled.

The following overrides are applied to user settings:

- For DDR and DDR2 SDRAM:
  - DLL enable
  - Burst length 4
  - OCD calibration (DDR2 only)
- For DDR3 SDRAM:
  - DLL enable
  - Output buffer enable
  - Disable write leveling
  - Runtime burst length select
  - Test mode disabled
  - DLL reset

For DDR3 SDRAM this stage also includes a ZQ-cal long operation (refer to the JEDEC specification).
Write Header Information in the internal RAM (s_write_ihi)

In this stage, the internal header information in the first eight locations in the internal RAM is loaded with the parameterization of the PHY. The debug toolkit uses this information to provide the current PHY parameterization and IP version numbers.

This stage is only executed when the debug toolkit is enabled.

Refer to Chapter 4, Debug Toolkit for DDR2 and DDR3 SDRAM High-Performance Controllers

Load Training Patterns

In this stage, training patterns are written to the memory to be read in later calibration stages. Because of the matched trace lengths to DDR SDRAM components, after memory initialization, you can assume write capture works.

Training pattern writes are divided into the following two stages:

- Write Block Training Pattern (s_write_btp)
- Write More Training Patterns (s_write_mtp)

A further training pattern is written in the calibration of the write datapath, refer to Advertize Write Latency (s_was).

Write Block Training Pattern (s_write_btp)

This stage is used in read data valid alignment (s_rdv), advertise read latency (s_adv_rd_lat) and postamble calibration (s_poa). For these calibration stages a pattern of all 1s and all 0s is sufficient to setup the PHY.

Writing of these two patterns is trivial and requires all DDIO outputs (high and low phases (bits)) to be held at either 1 or 0, for all 1 and all 0 patterns, respectively. To write these patterns, the DDIO outputs are held low (or high) and DQS toggled for a predetermined length of time and a single write command is issued. A full range of memory write latencies are tested.

To support DDR3 SDRAM discrete components (burst of eight reads) eight memory locations are loaded with 1s and eight with 0s.

The following memory locations contain the following patterns:

- Locations [7:0], all 0s
- Locations [15:8], all 1s

Patterns of all 1s and all 0s are also needed for calibrating the read resynchronization phase.

Write More Training Patterns (s_write_mtp)

This stage is used in calculating the read resynchronization phase (s_rrp_sweep).

The pattern is 0x30F5 and comprises separately written patterns. This pattern is required to match the characterization behavior for nonDQS capture based schemes (for example, Cyclone III devices). All device families use the following pattern:
Chapter 3: ALTMEMPHY Calibration Stages

Without Leveling

- All 0: 'b0000 to DDIO high and low bits held at 0
- All 1: 'b1111 to DDIO high and low bits held at 1
- Toggle: 'b0101 to DDIO high bits held at 0 and DDIO low bits held at 1
- Mixed: 'b0011 to DDIO high and low bits have to toggle

While you can ensure that all zeros, all ones, or toggle are written into a burst of memory locations (output DDIO bits are held at constant values), it is challenging to ensure that a pattern of 0011 is written into memory. The challenge occurs because the write latency is unknown at this time. For example, if this pattern is repeated on DQ pins (0011 0011 0011) and a single write command issued (as for the other patterns), it is not known whether the memory location contains the pattern 0011 or 1100.

ALTMEMPHY provides a methodology to robustly write these patterns (Test More Pattern Writes). For this section two locations (X and Y) are populated with write data, one contains the pattern 0011; the other contains 1100.

The memory locations contain the following patterns:
- x30 alignment 0 to location (X): 23..16
- x30 alignment 1 to location (Y): 31..24
- xF5 to location: 39..32

These patterns are written in bursts of four beats, so in the pattern xF5, F is written separately to 5. Patterns F and 0 are written as a part of the writing of the block training pattern (Write Block Training Pattern (s_write_btp)).

**Test More Pattern Writes**

This stage comprises a number of calibration stages of the PHY, but the stage is described as one entity. This stage comprises:
- Initialize read resynchronization phase calculation (s_rrp_reset)
- Calculate read resynchronization phase (s_rrp_sweep)
- Calculate read data valid window (s_read_mtp)

The algorithm ensures the pattern 0011 is written to a known location in memory. The following assumptions and PHY settings apply to this stage:
- Assumptions:
  - Burst length of 4 writes
  - Write capture in the memory device works. Data can be safely written to memory. No write leveling is required. (Refer to JEDEC specification for more information on DDR3 SDRAM).
  - Writes are aligned on a clock cycle basis. You know which beats of DQ data to write on the low and high phases of DQS (ultimately DQ and DQS board delays are well matched).
Chapter 3: ALTMEMPHY Calibration Stages

Without Leveling

Settings:
- Address and command 1T setting. You can add additional latency to the address and command path (specified as a maximum of one memory clock cycles (t)). This setting aligns write data to address and command signals relative to the controller clock domain, where address and command signals are issued in a given alignment. This setting is not required (0t) for a full-rate PHY.
- Read data 1T alignment. Additional delay of captured read data to align with read commands in the half rate controller clock domain. The interpretation of 1T is the same as for address and command, but applied to read data. This setting does not apply to a full-rate PHY.
- Read resynchronization phase setting. This setting is the primary task of the training pattern to correctly set the resynchronization phase in the middle of data valid window for the read data (on DQ pins) to be captured.

From this algorithm, to determine PHY settings B and C, given that A is not set, follow these steps:

1. Try to write the pattern and indistinguishable variations of it to different memory locations. For example, write to different locations with the following two patterns on the DQ bus (timed to a local controller rate clock), refer to Write More Training Patterns (s_write_mtp):
   a. 0011 0011 0011 (try to write 0011) in location X
   b. 1100 1100 1100 (try to write 1100) in location Y

2. Perform two single-pin DQ pin and single-chip select read resynchronization phase calibrations using location X and location Y, as part of the larger training pattern (0x30F5). You do not know at this time which locations X and Y contain the pattern 0011. This stage iterates through the following stages:
   - Initialize read resynchronization phase calculation (s_rrp_reset)
   - Calculate read resynchronization phase (s_rrp_sweep)
   - Calculate read data valid window (s_read_mtp)

   Calculate read data valid window (s_read_mtp) is a special case of calibrate read resynchronization phase (s_rrp_sweep), refer to Calibrate Read Resynchronization Phase (s_rrp_sweep). This stage reports the size of the returned window without setting up the PLL phase or producing an error if no window is observed.

3. The single pin read resynchronization calibration (using pattern X or Y), which results in the largest data valid window, contains the optimal pattern. The read resynchronization calibration with the largest window indicates the location (X or Y) that contains the correct alignment (0011). Read resynchronization phase calibration uses this alignment (X or Y), to perform the full resynchronization phase calibration across all pins and chip selects.
During calibration of the read resynchronization phase, the DQ pin is captured using a free running clock, phase shifted through a given number of steps. You should try to match a training pattern against read data, for each phase shift, and a window of valid phases is composed.

In waveforms, you observe two resynchronization phase sweeps, over single pins, before the larger phase sweep. Except in fast simulation mode, where the duration of all three sweeps is equal. For half-rate interfaces, you may observe a total of six phase sweeps, where the entire calibration is repeated when the address and command 1T setting is toggled.

**Calibrate Read Resynchronization Phase**

This stage encompasses the following calibration stages:

- Initialize Read Resynchronisation Phase Calibration (s_rrp_reset)
- Calibrate Read Resynchronization Phase (s_rrp_sweep)
- Calculate Read Resynchronization Phase (s_rrp_seek)

This stage adjusts the phase of the resynchronization (or capture) clock to determine the optimal phase that gives the greatest margin. For DQS based capture schemes the resynchronization clock captures the outputs of DQS capture registers (DQS is the capture clock). In a non-DQS capture based scheme, the capture clock captures the input DQ pin data (the DQS signal is unused).

For all half-rate PHY interfaces, a 720° resynchronization or capture clock phase sweep is performed. For a half-rate PHY this sweep is effectively 360° of the half-rate clock, because resynchronization or capture clock is at the memory clock rate. A 720° sweep is required, so that read data can be presented to a controller aligned to one half-rate controller clock cycle.

For full-rate DQS based capture, because the DQ pins are captured using the DQS signal, in a 360° phase sweep, all resynchronization clock phases may pass. In this case the correct resynchronization phase to set cannot be determined. The correct phase is the one in the center of a valid window, where returned read data is correct. Thus a 720° phase sweep is performed. From 360 to 720°, a clock cycle of latency may be added to a 0 to 360° sweep. The returned read data is compared to a training pattern pseudo half-rate (at half the clock rate of the sequencer), so data can only be valid for 360° of the sweep. This method introduces edges to the data valid window such that a correct phase can be chosen.

For non-DQS capture in general, up to half (180°) of the swept capture clock phases can result in correct capture data, because the DDR to SDR conversion is performed by the capture clock, and thus high and low phases of DQ are captured in the incorrect alignment for half of the capture clock phases. Therefore, only 360° of capture clock need be swept for full-rate non-DQS capture based PHYs.

The pseudo half-rate case potentially adds one clock cycle of latency into the read datapath because of the 720° sweep. In ALTMEMPHY this occurrence is detected and the clock cycle of latency removed in the calculate read resynchronization phase (s_rrp_seek).
Initialize Read Resynchronisation Phase Calibration (s_rrp_reset)
This stage returns the PLL to a nominal zero phase shift.

Calibrate Read Resynchronization Phase (s_rrp_sweep)
This stage performs a sweep through a parameterised 360° or 720° of resynchronization clock phase. These results are optionally stored in the internal RAM.

The command has the following attributes:
- Single_pin to indicate just to sweep DQ pin 0 as for the use in testing the write more training patterns stage.
- mtp_alignment to say which location (X/Y) to use from the write more training patterns stage.

Calculate Read Resynchronization Phase (s_rrp_seek)
This stage calculates the size and center (in phase steps) of the largest data valid window found during the calibrate read resynchronization phase and sets PLL phase to the center phase.

Calculate read data valid window (s_read_mtp) is a special case of this stage which reports no errors for an invalid window (a failure is expected in one case) and does not setup the PLL.

Calculate Read Data Valid Window (s_rdv)
This stage sets the latency on a delayed version of the doing_rd signal, so that it is aligned with the rdata_valid signal for the read data it is incident with the read command for.

This stage has the following process:
1. Reads a continuous stream of 1s followed by one read of zeros. The sequencer only asserts doing_rd when read command for zeros is issued.
2. Checks for alignment of read data valid signal (delayed version of doing_rd) to the zeros (rdata = 0, rdata_valid = 1).
3. If not aligned, reduces latency between doing_rd and rdata_valid signal and loop.

   🔄 Read data valid latency is reset to a high value (before calibration) and then reduced until it matches the correct alignment.

Advertize Write Latency (s_was)
This stage writes a suitable pattern to the DRAM to calculate the write latency.

A write command is issued to a memory address 48 (Figure 3–2) while driving a count of frequency controller clock rate to the DQ pins (Figure 3–2), using the write datapath observed by the controller. For half-rate interfaces, each four beats of write data on DQ are identical. For full-rate interfaces, each two beats of write data are identical. In general, the write latency is written into addresses A... A + (n - 1), where n is two times the ratio of controller to memory clock rate and each n bits of write data must be identical. The pattern is written into memory locations 48 to 55.
Calculate Read Latency (s_adv_rlat)

In addition to read data valid window calculation (s_rdv), the advertised read latency is calculated in this stage in the following way:

- Issues a read command (with doing_rd) and starts a counter at PHY clock rate
- When rdata_valid returns, outputs the value of the counter to ctl_rlat signal.

This signal is redundant, because a controller can use the rdata_valid signal to determine when valid read data is returned.

The read data from the DRAM is not important here. The count is performed between the issue of doing_rd and rdata_valid returning.

Output Write Latency (s_adv_wlat)

To calibrate a PHY write datapath to a minimum latency, a robust process is required to determine the write latency (WL) between a memory controller write command and the associated write data. Factors that can contribute to WL are: the memory CAS latency, arbitrary additive delays in the PHY, and board trace lengths. The presented approach extends from calibrating a PHY, where the controller operates at the memory clock frequency, to controller operation at half or a quarter of the memory clock frequency.

After a predetermined maximum read latency clock cycles have passed, the contents of the chosen memory address (0x48 in Figure 3–2) are read to recover the write latency. The first n beats of read data contain the write latency.

While this method recovers the write latency it can determine the address and command 1T setting in half rate mode.
The returned read data, in the controller clock domain, should be equal across the first four read data beats, as aligned to the controller clock domain. For this check to work an alternate read location must be read immediately before and after that containing the write latency.

If read data is not correctly aligned then the address and command 1T setting is toggled and calibration is rerun from write training patterns stage.

**Calibrate Postamble (s_poa)**

This stage is only implemented for DQS capture based PHYs (not used for Cyclone III devices).

For this stage, the PHY reads the pattern \(0x30\) from memory, so that the de-assertion of the postamble protection signal \(\text{poa-enable}\) can be aligned to the 1's in this pattern.

This stage sets the correct clock cycle for the postamble path. The aim of the postamble path is to eliminate false DQ data capture because of postamble glitches on the DQS signal, through an override on DQS. This stage ensures the correct clock cycle timing of the postamble enable (override) signal.

The delay on the postamble enable signal starts off too large. It is then iteratively reduced until postamble enable de-asserts in the clock cycle before the last falling edge on DQS. **Figure 3–3** shows the calibration timing diagram.

**Figure 3–3. Calibration Timing**

![Calibration Timing Diagram](image)

**Note to Figure 3–3:**
1. The \(\text{poa-enable}\) signal is late, and the zeros on \(\text{mem_dq}\) after here are captured.
2. The \(\text{poa-enable}\) signal is aligned. Zeros following here are not captured and \(\text{rdata}\) remains at 1.

**Set Up Address and Command Clock Cycle**

For half-rate interfaces, this stage also optionally adds an additional memory clock cycle of delay from the address and command path. This stage aligns write data to memory commands given in the controller clock domain. You see this stage in the waveform as a rerun of calibration (from the writing of training patterns) to calibrate to the new setting.
This stage is detected in the advertise write latency stage ($s_{adv\_wlat}$)

Write User Mode Register Settings ($s_{prep\_customer\_mr\_setup}$)

User mode register settings are applied on a per chip select basis without the overrides in the program mode registers for calibration ($s_{prog\_mr}$) stage.

Voltage and Temperature Tracking

Voltage and temperature tracking is a background process that tracks the voltage and temperature variations to maintain the relationship between the resynchronization or capture clock and the data valid window that were achieved at calibration. When the data calibration phase completes, the sequencer issues the mimic calibration sequence every 128 ms (in user mode).

Setup the Mimic Window ($s_{tracking\_setup}$)

During initial calibration, the mimic path is sampled using the measure clock. The measure clk signal has a $\_1x$ or $\_2x$ suffix, depending whether the ALTMEMPHY is a full-rate or half-rate design. The sampled value is then stored by the sequencer. After a sample value is stored, the sequencer uses the PLL reconfiguration logic to change the phase of the measure clock by one voltage-controlled oscillator (VCO) phase tap. The sequencer then stores the sampled value for the new mimic path clock phase. This sequence continues until all mimic path clock phase steps are swept. After the sequencer stores all the mimic path sample values, it calculates the phase which corresponds to the center of the high period of the mimic path waveform. This reference mimic path sampling phase is used during the voltage and temperature tracking phase.

Perform Tracking ($s_{tracking}$)

In user mode, the sequencer periodically performs a tracking operation. At the end of the tracking calibration, the sequencer compares the most recent optimum tracking phase against the reference sampling phase. If the sampling phases do not match, the mimic path delays have changed because of voltage and temperature variations. When the sequencer detects that the mimic path reference and most recent sampling phases do not match, the sequencer uses the PLL reconfiguration logic to change the phase of the resynchronization clock by the VCO taps in the same direction. This procedure allows the tracking process to maintain the near-optimum capture clock phase setup during data tracking calibration as voltage and temperature vary over time. The relationship between the resynchronization or capture clock and the data valid window is maintained by measuring the mimic path variations because of the voltage and temperature variations and applying the same variation to the resynchronization clock.

With Leveling Calibration Stages

The ALTMEMPHY with leveling performs the following calibration stages:

1. Initialize
2. Perform Write Leveling
3. Write Block Training Patterns to Memory
4. Perform Read Deskew  
5. Calibrate Read Resynchronization Phase  
6. Calibrate Read Clock Cycle  
7. Perform Postamble Deskew  
8. Perform Write and DM Pin Deskew  
9. Set Up Write Datapath (for Nondeskedewed Datapath)  
10. Calibrate Write Clock Cycle  
11. Final Setup  
12. Tracking  
13. Idle (User Mode)

Figure 3–4 on page 3–13 shows a flow chart of the calibration stages for the PHY with leveling.

  - Calibrate Read Clock Cycle
  - Perform Postamble Deskew
  - Perform Write and DM Pin Deskew
  - Calibrate Write Clock Cycle
**Initialize**

Before DDR3 SDRAM calibration begins, the ALTMEMPHY sequencer is held in reset until the PLL locks. When the PLL locks, the sequencer starts the DDR3 SDRAM calibration sequence. The initialization stage performs the following operations:

- Initialize all internal ALTMEMPHY memories
- Initialize all DDR3 SDRAM interface I/O scanchains, including the individual DQ and DQS group I/O scanchains

   When initialization completes, all the following interface related settings are incorrect:

- Phase and delay settings for the generated clocks
- DQ, DQS, resynchronization and postamble clocks (MEM_CLK, DQS_CLK, RESYNC_CLK and POSTAMBLE_CLK)
- Read and write 1T settings per DQS group
- Set DDR3 SDRAM ODT settings and issue ZQCAL calibration command
- Set appropriate mode register settings for MR0, as per ALTMEMPHY GUI settings except:
  - Burst length configured to burst chop 4 or 8 on-the-fly
  - DLL reset
- Set appropriate mode register settings for MR0, as per ALTMEMPHY GUI settings except:
  - Enable DLL
  - Enable output buffer
  - Disable write leveling
- Set appropriate mode register settings for MR2 as GUI settings
- Set appropriate mode register settings for MR3 to all 0s

These mode register settings are specific to the DDR3 SDRAM calibration sequence and do not match the user mode register settings. These settings are setup in the mode register configuration stage, before entering user mode.

**Perform Write Leveling**

At ALTMEMPHY reset or FPGA power-up time the ALTMEMPHY sequencer initializes all DDR3 SDRAM I/O write and read clocks with a phase setting of 0° and delays of 0 ps across all DQS groups in the DDR3 SDRAM interface. The relationship of DQS and the memory clock at each DDR3 SDRAM component is unknown and violates the DDR3 SDRAM tDQSS timing parameter.

Write leveling determines and configures the required DQS phase and delay for each DQS signal, so that the DDR3 SDRAM tDQSS timing parameter functions correctly across PVT. Write leveling consists of the following stages:

- Gather data using the DDR3 SDRAM with write leveling
Process the data
Set up the appropriate I/O scanchain functions (phase and delay) based on the output of the processing stage

Write leveling is not confined to DDR3 SDRAM UDIMM interfaces. Write leveling and the DDR3 SDRAM calibration sequencer covers DDR3 SDRAM components where the memory clock, address and command signals are routed as per a DDR3 UDIMM in a fly-by topology.

This section provides a description of the following stages in write leveling:
- Gather write leveling phase data
- Process edge detect
- Set up scanchain
- Gather write leveling delay data
- Process edge detect
- Set up scanchain

During write leveling the DDR3 ALTMEMPHY sequencer determines the following optimal settings:
- Phase of the clock (DQS_CLK) to generate DQS
- Above 360 MHz, the DLL operates in 8-tap mode, providing 45° resolution
- At 360 MHz, the DLL operates in 10-tap mode, providing 36° resolution
- Delay applied to the DQS output pins

The write leveling calibration stage uses the write leveling of the DDR3 SDRAM components where the DQS signal samples the memory clock. The sampled value is then sent to the FPGA on the prime DQ pin within a DQS group. Write leveling is performed on all DQS groups in the DDR3 SDRAM interface.

**Gather Write Leveling Phase Data**

During the write leveling phase data gathering stage, all phases of the write leveling delay chain generated DQS clock (DQS_CLK) are swept through 360° using the leveling multiplex controlled by the DQS group I/O scanchains. For each phase tap tested, the sequencer toggles DQS from 0 to 1. The DQS is sampled by the memory clock and output on the prime DQ pin. The feedback value sampled from the prime DQ pin is stored in the main sequencer data storage RAM (internal RAM).

The prime DQ pin can be any pin or multiple pins within the DQS group.

When all DQS_CLK clock phases are swept through 360°, the internal RAM contains a window of the feedback and sampled DDR3 SDRAM clock values. The internal RAM now contains a mixture of 0s and 1s. The sampled values are stored per DQS group. The values stored in the internal RAM are a coarse result, because of the resolution of the write leveling delay chains compared with the delay chain resolution.
On starting write leveling, the prime DQ pin number is unknown. Therefore all DQ pins have to be considered prime, the feedback sampled result can be output on any DQ pin in a DQS group. The sequencer uses the fact that the non-prime DQ pins either drive the same sampled result or drive zero as sampling feedback is not supported on these pins. Therefore, when writing the sampled result into the internal RAM the results for each DQ within a DQS group are ORed together.

**Process Edge Detect**

During this stage the write leveling phase sweep results are read out of the internal RAM and are processed. For each DQS group the last phase tap value which returns 0 is determined. The next phase tap value should return a 1 value. As the write leveling calibration sequence is looking for a 0 to 1 transition per DQS group, the last phase returning a 0 needs to be determined to allow a fine grained delay to be applied during the subsequent calibration stages. The results of the processing stage are stored in the internal RAM.

**Set Up Scanchain**

During the scanchain setup stage each DQS_CLK clock phase per DQS group is set to the final phase, where 0 is returned as determined during the edge detect processing stage. The ALTMEMPHY sequencer writes to the DQS group scanchain, to setup the DQS_CLK clock phase. During this stage, the DQS phase has been coarsely setup to a phase tap resolution of either 45 or 35°. The next calibration stages describe the fine delay setup using the fine resolution delay chains.

**Gather Write Leveling Delay Data**

Now the fine 50 ps delay setting needs to be calibrated. As for the phase gathering stages, the delay chain is swept for each DQS pin in the DDR3 SDRAM interface. Again in a similar fashion to the phase gathering stages, the value returned on the prime DQ pin is stored in the sequencer internal RAM. The 50 ps delay sweep provides a more accurate DQS and memory clock relationship when write leveling calibration completes. For each phase tap tested, the sequencer toggles DQS from 0 to 1. The ALTMEMPHY sequencer internal RAM stores the sampled result.

**Process Edge Detect**

During this stage, the write leveling delay sweep results are read out of the internal RAM and are processed. For each DQS group the first delay tap value that returns 1 is determined. This delay for the configured phase tap per DQS group satisfies the write leveling calibration requirement where the DDR3 SDRAM tDQSS is met when a 0 to 1 transition is detected on the feedback and sampled signal.

**Set Up Scanchain**

During the scanchain setup stage each DQS_CLK clock delay per DQS group is set to the first delay where 1 is returned as determined during the edge detect processing stage. Figure 3–5 shows how to determine phase tap to use for delay calibration and that you should pick RHS most phase that returns 0 when next phase returns 1.
Multiple Chip Selects

When configured for multiple chip selects write leveling is performed once per chip select. The write leveling phase and delay results per chip select are written into separate internal RAM locations. When the write leveling gathering results are obtained for each chip select, the processing determines an average phase and delay setting for all chip selects.

Write Block Training Patterns to Memory

To perform DDR3 SDRAM interface calibration, the ALTMEMPHY sequencer reads back data patterns from the DDR3 SDRAM. At ALTMEMPHY reset or FPGA power-up time, the ALTMEMPHY has not established the following relationships:

- Write latency, address and command to write data
- DQS, address and command required
- DQ and DQS required

You cannot write toggling write DQ data into the DDR3 SDRAM to form a calibration training pattern. You can only write a DC pattern into the DDR3 SDRAM, as no data is toggling when DQS is toggling. To perform a block training pattern write, all DQs are held at a DC level for a period of time before the write DQS and are additionally held for a period of time after the write DQS, to avoid any setup or hold write memory write failures with respect to the toggling DQS signal.

The block training patterns that write into the DDR3 SDRAM are:

- \[ 11111111 \]
  - Eight consecutive ones, the ones pattern
- Write to address address 48
- Write as BL8
With Leveling Calibration Stages

- **00000000**
  - 8 consecutive zeroes, the ZEROS pattern
  - Write to address 16
  - Write as BL8

- **11110000**
  - Four consecutive ones, four consecutive zeroes, mixed pattern
  - Written to address 24
  - Write as BL8 and BC4

The calibration writes the ones and zeroes patterns as a continuous burst length 8 operation (BL8). The calibration writes the mixed pattern as a BL8 (zeros) and then overwrites with a burst chop 4 (BC4) operation (ones pattern). The following calibration stages use the block training patterns:

- Perform read deskew
- Calibrate read resynchronization phase
- Calibrate read clock cycle
- Perform postamble deskew

**Perform Read Deskew**

Dynamic read deskew is only active on Stratix III and Stratix IV designs above 400 MHz.

Dynamic read deskew is a calibration technique where the size and location of the read data valid window for each DQ pin is individually assessed. If necessary, the window position is shifted to guarantee that you see always a valid window across all possible operating conditions (voltage and temperature).

The following two mechanisms shift the position of the valid window:

- The T7 (D4) delay-chain in the DQS logic-block shifts an entire DQS group in one direction by increasing the delay on the DQS input path used for capture.
- The DQ T1 (D1, 2, and 3) delay-chains individually configure for each DQ pin. DQ T1 shifts the individual DQ pins in the opposite direction to the DQS logic-block T7 shift by increasing the input delay on the DQ pin.

When the calibration measures the size and position of the each DQ window, it applies an algorithm to pull the capture point more towards the center, if required by adjusting the DQS logic-block T7 and DQ T1 delay-chain settings appropriately.

Read deskew is a two-pass flow. In the first pass, the calibration uses the DDR3 in-built multipurpose register pattern (which may only return data on a single DQ pin per DDR3 SDRAM component). In the second pass, the calibration reads one of the block training patterns (11110000) from memory (which returns data on all DQ pins).

The first pass deskews and configures the interface sufficiently that the calibration can read the more aggressive block training pattern.
Gather Data
During the read deskew data gathering stage, the calibration sweeps all DQS logic-block T7 delay-chain values, while it holds all DQ T1 delay-chains at zero. Then the calibration sweeps all DQ T1 delay-chain values, while it holds all DQS T7 delay-chains at zero.

For each configured delay-chain settings, the calibration reads the appropriate pattern (multipurpose register or block training pattern) from external DRAM, with four-times over-sampling to mitigate the effects of jitter and capture the minimum size window. If the calibration successfully reads the pattern, the corresponding result bit in the internal RAM is set to 1, otherwise it is cleared. Different areas of the internal RAM store the multipurpose register and block training pattern results, the latter does not overwrite the former.

The calibration implements oversampling in the control-plane rather than the data-plane, a single read is performed at each of the configured T7/T1 delay-chain combinations and this entire process is then repeated four times (rather than performing four reads at each T7/T1 combination). Oversampling logically ANDs the DQ valid windows across the four reads.

Process Data
This stage reads the data gathering results from the internal RAM (the representation of the size of the DQ valid windows) and analyses the results to generate a deskew configuration (DQS logic-block T7 and DQ T1) that is then also written to the internal RAM.

The algorithm determines the center position for each DQ window, applies a clamp limit to this value (only allows the configuration to shift up to a certain amount from the nominal case) and stores the result, in terms of DQS logic-block T7 and DQ T1 settings, back to the internal RAM.

Set Up Scanchain
This stage reads the deskew configuration results from the internal RAM and applies these to the DQS logic-block T7 and DQ T1 delay-chains for all DQ pins in all DQS groups.

Calibrate Resynchronization (Multipurpose Register Pass only)
This stage (sweep phase, process data, set up, and 1T test or setup) configures the interface to successfully read the more aggressive block training pattern.

Calibrate Read Resynchronization Phase
The read resynchronization phase calibration has the following stages:

1. Resynchronization phase sweep. Collects pass and fail information for PLL phase settings over the range of 0 to 720° in increments of PLL phase steps (determined by the PLL megafunction at PHY generation).

2. Resynchronization process. Processes the results from the resynchronization phase sweep to determine the center of the passing window in PLL steps. Then converts to DLL taps by which to delay the resynchronization clock.
3. Resynchronization setup. The scanchain sets the delay (in DLL taps) in the I/O on the resynchronization clock.

**Training Pattern**

For resynchronization training to work, you need a pattern for which you can see a correct pattern in the half-rate clock domain. You can write before any setup of the write path (including deskew), therefore you are limited to the block training patterns. However, only having patterns of $8 \times$ zeros, $8 \times$ ones, or $4 \times$ zeros and $4 \times$ ones limits what you can do. Therefore, you must use the $11110000$ pattern, which is stored in address 24.

Although DDR3 SDRAM contains a hard-coded training pattern accessible through the multipurpose register, the pattern read back is always a toggling bit. This pattern is not suitable as a training pattern for resynchronization. If capture is successful, the bits representing the rising-edge captured data and the falling-edge captured data do not change. Therefore there are no transitions at the resynchronization registers and cannot use this pattern to calibrate.

**Assumptions**

Use the following assumptions:

- **Working capture.** At this point (after read deskew) assume that read capture is working. Because of the nature of the system, you cannot differentiate between capture or resynchronization failures, so assume that any failure is resynchronization. Failing read resynchronization may be because of read capture.

- **Unknown read alignment.** When you read a training pattern from memory, you do not know the latency of the entire read path, as a result you cannot predict in what cycle the read data returns. Also, because the timing for the resynchronization registers is so good, all phases in $360^\circ$ may pass. Therefore, check for data transitions in the half-rate clock domain. If you define one data alignment as correct; another alignment of data is incorrect. You can use this fact to measure a resynchronization window, so you need to sweep $720^\circ$ of PLL phases.

**Resynchronization Sweep**

The resynchronization sweep determines which resynchronization phases work and do not work. Because of the large step size of the resynchronization phases available from the PLL or DLL compensated delay chains, you may see that all phases work, as the setup and hold times and the uncertainties in the hard paths are so small in relation to phase step (PLL or DLL).

As the size of a PLL phase step is smaller than the size of the DLL compensated phase delay, measuring the resynchronization window in terms of PLL phase steps gives a more accurate measurement (two to three times the number of steps).

Because of the all phases valid problem and well matched paths (as they are hard), you need to compare over $720^\circ$ instead of $360^\circ$. Additionally, you define one alignment of read data as correct and the other as incorrect, so you see a $360^\circ$ passing window out of $720^\circ$. 

At this stage of calibration, you can only write the block training patterns, so you are limited in the patterns you can read back. The periodicity of the patterns you can read back means that the data only changes every two memory clock cycles. This situation is not ideal for the resynchronization window measurement, as bimodal jitter in the I/O may affect the measured margins.

As at this stage of calibration you have done nothing to determine the relevant delays for each group (address and command + memory = FPGA). It is more than likely that the read data comes back at different times, equating to a different phase and clock cycle for each group.

Use the following process:

- Activate the row and bank containing the mixed frequency block training pattern (11110000). Then read this address continuously.
- Bypass postamble circuitry and permanently enable.
- Start phase sweeping loop.
- Allow time to guarantee that read data has propagated from capture through resynchronization and into the core.
- Sample the read data and store the result (in internal RAM).
- Phase shift the PLL 1 step.
- If you have not done enough phase shifts ($2 \times \text{PLL\_PHASES\_PER\_TCK}$) go to loop start.
- Finish. Precharge the open row. Return postamble enable to normal.

One pin per DQS group is tested. The sweep is looped over all chip selects and the results collected with an AND operation, so that the final result is the worst case window across all chip selects.

**Resynchronization Process**

To maximize the setup and hold margin at the resynchronization registers, you employ a center of data valid window algorithm. In case there is a fringing effect on the edge of the window, you employ a center of largest data valid window approach.

The algorithm returns the center of the largest group of passing phases, which is implemented as a shift-register based bit-serial implementation for size and speed, and is designed to indicate errors on:

- No window (all fail)
- Continuous window (all pass)
- Multiple equally sized windows (2 or more passing regions with the same size)

This algorithm returns a value ranged between 0 and number of PLL steps (between 0 and 360°).

The result of the center of largest window operation above is scaled to the nearest DLL based value.

This stage is performed on a per DQS group basis.
Resynchronization Setup

The per-group (byte lane) scaled resynchronization value is programmed into the scanchains. However, as the processing function returns a value mod 360°, you have chosen the correct phase, but it may not be the correct clock cycle. As a result the clock cycle calibration is still required to ensure the correct work alignment for a half-rate PHY.

Additionally, to match the latency of each DQS group to compensate for leveling and use the read data valid flag, perform the read clock cycle calibration stage.

Data Storage

The resynchronization phase selection result header has the following format:

1 word : header

N words : one nibble per DQS group defining the resynchronization phase.

The resynchronization phase selection working dataset has the following format:

1 Word : header (ID code 17 in location [31:24])

N Words : 2 × PLL phase steps/32 words per DQS group

One bit per phase tested moving extending over the words.

(packed from LSB)

Table 3–1 shows the internal RAM data format.

Multiple Chip Selects

For multiple chip selects, the read resynchronization phase sweep process is iterated once per chip select. The calibration writes the results for sweep 1 (for chip select 0) into the internal RAM as normal. Subsequent sweeps (for chip selects 1, 2, ...) write into the internal RAM as a logical AND with the current internal RAM value. After a sweep of all windows, the stored internal RAM window is the intersection of windows for all chip selects (the worst case window). Processing and setup continues as for the single chip select case.

Calibrate Read Clock Cycle

This section describes the read datapath setup sequence for clock cycle calibration.
Set Up Postamble Clock Phase (Static)

The postamble clock phase leads the resynchronization clock phase by one read leveling delay chain tap, which is loaded into the I/O scanchains. This phase is a rough estimate for the required postamble clock phase, which is sufficient for clock cycle postamble calibration (postamble clock cycle calibration is done as the final part of read clock cycle calibration).

Test and Set Up Resynchronization 1T

This stage determines the read data alignment on a DQS group basis. As the phase of the half-rate resync_clk (DIV2 clock) per DQS group is unknown at the start of calibration, there can be a 1T memory clock difference in the alignment of the captured and resynchronized read data. If there is a 1T alignment problem for a given DQS group, each BL4 read is distributed across 2 DIV2 clock cycles. The requirement is that each BL4 read is aligned to a single DIV2 clock cycle.

The sequencer continuously reads the mixed block training pattern (11110000) from the DDR3 SDRAM as 2 contiguous BL4 reads. The captured read data is checked that each BL4 read is aligned to a single DIV2 clock cycle. The pass or fail result is stored in the sequencer internal RAM.

Next, the sequencer reads the resynchronization 1T test result from the internal RAM, to determine which DQS groups require the 1T input register to be dynamically switched in to align all captured read data. The read 1T register is controlled using the I/O scanchains.

Set Up Read Data Pattern Latency

Now that the captured read data is correctly aligned to the DIV2 clock on a DQS group basis, set up the read datapath so that all read data for a given read command appears at the ALTMEMPHY local interface in the same PHY_CLK clock cycle. The resynchronization 1T scanchain setup calibration stage may force the read data from the different DQS groups to be returned in different PHY_CLK clock cycles.

During this calibration stage the sequencer performs the following operations:

- Continuously read the 1s block training pattern
- Read the mixed block training pattern once
- Continuously read the 1s block training pattern

When the read data is returned the sequencer looks for the DQS group returning a PHY_CLK clock cycle of zeros with the highest latency from all DQS groups. The sequencer increases the latency through the read RAMs by 1 PHY_CLK clock cycle for all groups that do not have the same latency as the highest latency DQS group. This stage is repeated until all DQS groups return read zeros in the same PHY_CLK clock cycle.

Set Up Read Data Valid Pipe

This stage ensures the rdata_valid flag is asserted coincident with respect to the aligned read data at the ALTMEMPHY local interface. This stage performs the following operations:

- Continuously read the 1s block training pattern
- Read the mixed block training pattern once
- Continuously read the 1s block training pattern

When the aligned read data contains 0s, the rdata_valid flag is checked and adjusted until aligned with the read data. Rdata_valid is generated using a dual-port RAM where the input is the doing_rd flag. The sequencer decrements the latency through the dual-port RAM until it matches the latency of the read data.

**Set Up Postamble Clock Cycle (poa_cc_setup)**

When the read data is aligned to a single DIV2 clock cycle, the postamble clock cycle relationship needs to be calibrated. If the postamble clock cycle relationship is not setup correctly, the read data is not captured correctly. This stage performs the following operations:

- Continuously read the 1s block training pattern
- Read the mixed block training pattern once
- Continuously read the 1s block training pattern

The postamble control signal gates the DQS signal (to avoid a postamble glitch from resulting in incorrect data being captured). It is generated (per DQS group) by passing the doing_rd signal through a RAM (per DQS group). The latency through this RAM is decremented until a postamble failure associated with deasserting the postamble control signal too soon is detected (read data contains all 0s for two consecutive PHY clock cycles, indicating that the 1s from the mixed pattern are not captured).

When this postamble failure condition is reached for all DQS groups, the latency through each RAM for all the DQS groups is incremented by 1, so that the interface is left in a working state.

**Perform Postamble Deskew**

The postamble clock cycle calibration (part of the read clock cycle calibration), already sets up the postamble enable signal, to within a clock cycle of accuracy. Postamble deskew improves the accuracy of the postamble enable signal by adjusting the postamble clock phase and T11 delay.

**Sweep Postamble Phase**

The first stage of postamble deskew is the phase sweep. Each phase of the postamble clock phase is tested (using the same data pattern and checking as for postamble clock cycle setup). The pass or fail result for each phase is written into the internal RAM (on a per DQS group basis).

**Process Postamble Phase**

The phase sweep results are processed to find the passing to failing transition. The failing phase value at this transition point is stored in the internal RAM (on a per DQS group basis).

**Set Up Postamble Phase**

The phase result from the previous stage is read out of the internal RAM and the scanchains are programmed (on a per DQS group basis). At this point, the sequencer is setup such that each DQS group should be failing because of postamble, which is intentional, ready for the subsequent delay sweep.
Sweep Postamble Delay
Each T11 delay tap is tested (using the same data pattern and checking as for postamble clock cycle setup). The calibration writes the pass or fail result for each delay into the internal RAM (on a per DQS group basis).

Process Postamble Delay
The calibration processes the delay sweep results to find the first passing delay value (on a per DQS group basis). If the calibration finds a passing delay, it writes this result into the internal RAM. If it finds no passing delays, it sets the delay result to 0 and increments the phase result 1. Finally, 180° is added to the phase result to setup the postamble enable signal optimally.

Set Up Postamble Delay
The calibration reads the phase and delay results out of the internal RAM and the programs the scanchains accordingly.

Calibrate Postamble Clock Cycle
The final stage of postamble deskew is to repeat the clock cycle calibration, because the phase adjustments performed earlier may cause a clock cycle boundary crossing.

Perform Write and DM Pin Deskew
Dynamic write deskew is only active on Stratix III and Stratix IV designs above 400 MHz.

Dynamic write deskew is a calibration technique where the size and location of the write data valid window for each DQ and DM pin is individually assessed. If necessary, the window position is shifted to guarantee that you see always a valid window across all possible operating conditions (voltage and temperature).

The following two mechanisms are employed to shift the position of the window:

- The DQ/DM T9 (D5) delay-chains, which can be individually configured for each DQ or DM pin, can shift the pin in either direction (with respect to DQS) by increasing or decreasing the delay on the DQ or DM output pin. This action provides fine grain deskew control over a limited range.

- Only during the data gathering stage, the DQ write-leveling phase (part of the DQS logic-block) coarsely shifts all DQ and DM pins within a DQS group in either direction in steps sizes of 45°. Measurements are made in three phases; the nominal 90° DQ, DM, and DQS phase and the two adjacent phases (45° and 135°).

For each DQ and DM pin, the valid window information from all T9 (D5) delay-chain values from all three phases is combined to give an extended view of the windows. An algorithm is applied to pull the windows more towards the center if required.

Eight data patterns are used for write deskew, the calibration writes these to different areas of the external DDR3 SDRAM.

This section describes the differences in write deskew calibration for DQ and DM pins. The DM specific stages are not invoked if no DM pins are present in the PHY.
Gather Data

The calibration uses the following eight data patterns during write deskew:

- 10101010
- 01010101
- 00100010
- 01000100
- 11011101
- 10111011
- 11011011
- 11001100
- 11100000

Data gathering writes all of the patterns to external DDR3 SDRAM for all swept phase and delay-chain combinations. There are distinct calibration stages for DQ and DM writes.

The procedure for DQ is:

- Iterate through all eight write data patterns.
- For each data pattern, iterate through all three DQ and DQS phase settings.
- For each phase setting, iterate through all T9 (D5) delay-chain settings.
- For each delay setting, write the selected data pattern to external DRAM. Each data-pattern, phase, or delay combination uses a different address in memory, to perform discrimination when the success of the writes is later checked by reading.

No oversampling is performed for write deskew other than that inherent in using multiple data patterns and hence have multiple writes.

The procedure for DM is slightly different. As the function of DM pins is to mask or unmask writes, the relevant portion of external DRAM is first cleared using safe writes (writes with DQ and DM values held static).

However, the procedure is the same as for DQ with the following exceptions:

- The calibration holds all DQ pins at 1, so that the success of a write can be detected. A successful write changes the memory contents from the previously written 0, to a 1, whereas an unsuccessful write the previously written 0 persists.
- The eight data patterns are applied to the DM pins.

The next part of data gathering is to read back the results of the writes and thus build up a view of the DQ and DM write data valid windows. Again, there are distinct calibration stages for DQ and DM reads.

The following process is the same for DQ and DM:

- Perform memory reads for all of the addresses that correspond to all of the pattern, phase, or delay combinations used during the preceding data gathering write stages.
For each read, determine whether or not the corresponding write succeeded and update the write data gathering internal RAM result in a similar fashion as to read deskew.

- The results for all data-patterns for each DQ and DM pin are logically ANDed in a similar way to how read deskew over-sampling is handled.

### Process Data

This stage reads the data gathering results from the internal RAM (the representation of the size of the DQ and DM valid windows) and analyzes the results to generate a deskew configuration that the calibration then also writes to a different area of the internal RAM.

The algorithm determines the center position for each DQ and DM window, applies a clamp limit to value (only allows the configuration to shift up to a certain amount from the nominal case) and stores the result, in terms of DQ and DQS phase and DQ and DM T9 (D5) settings, back to the internal RAM.

The calibration sweeps three different phases during the data gathering stage. The processing stage combines the measured valid windows from all three phases to yield a wider view of the valid window. However the calibration always chooses the deskew result to be T9 (D5) tap within the nominal 90° phase.

### Set Up Scanchain

This stage is similar to read deskew and other setup stages. The DQS and DQ phase and DQ and DM T9 (D5) delay-chain results are read from internal RAM and set up on the appropriate scanchains.

### Set Up Write Datapath (for Nondeskewed Datapath)

To setup the DQ (and DM) versus DQS relationship, the sequencer writes to the appropriate scanchains to setup the following offsets:

- DQ phase = DQS phase – phase offset
  - 300 to 360 MHz phase offset is 72° (2 taps)
  - 360 to 400 MHz phase offset is 90° (2 taps)
  - >400 MHz. This stage is not run (write deskew is run)
- DQ T9 = DQS T9 + DQS T10 (D6) +/- static offset

T9 is given a positive or negative shift from the nominal value (DQS T10 +/- static offset), to balance the effect of the DQ and DQS phase shift, and for 10 tap DLL mode (below 360 MHz), to account for the phase shift of 72° rather than 90°.

- DM phase and T9 is also set in the same way as DQ.
- This static setup is for 300- to 400-MHz operation. Above 400 MHz, write deskew is run.
Calibrate Write Clock Cycle

This stage comprises write DQ 1T pattern, read DQ 1T pattern, setup DQ 1T pattern and finds the correct write data, DQ, 1T setting for each DQS group to help correct writes to memory. This stage ensures correct alignment of write DQ data against the memory clock cycle.

Write DQ 1T Pattern

The calibration writes a write data pattern, similar to the block training pattern, of 1111000011110000 to the DDR3 SDRAM. At this stage, the calibration uses the same technique of writing a DC value (four DQS edges for each DC value), which has a large setup and hold time, as the DQ and address and command clock cycle relationship is unknown.

Read DQ 1T Pattern

The calibration reads the data from the same address and the read 1T alignment is checked. The calibration writes the pass or fail result into the internal RAM. Read 1T alignment issues are detected when the expected read data is distributed across 2 DIV2 clock cycles.

Setup DQ 1T

If the internal RAM result indicates that the read 1T alignment is incorrect, the write datapath needs a write 1T register setting to be toggled on the failing DQS group. As the read datapath has already been configured any alignment issues can only occur if the write 1T settings are incorrect.

The write 1T registers are controlled using the DQS group scanchains.

Setup DQS 1T or 2T

This stage configures the DQS to be clock cycle correct in relation to the DQ and address and command path. This stage is a simple evaluation based on the phase of DQ, DQS, number of phases and the DQ 1T register setting. This stage determines the setting of the DQS 1T, and 2T register on a per group basis.

Set Up AC Latency

This stage performs the following operations:

- Sets up the write command and write DQ data relationship
- Calculates the number of PHY_CLK cycles between the DDR3 SDRAM controller providing the write command to the ALTMEMPHY and the write data to the ALTMEMPHY for a given write operation. This cycle is the write latency, CTL_WLAT.

The calibration writes an incrementing pattern, 0000111122223333444455556666.... pattern to the DDR3 SDRAM. Additionally, in the same clock cycle the 0000 is sent, a single write command is launched onto the address and command bus. The value read back represents the write latency.
When the sequencer reads back from the location written to the single write command, the result per DQS group is stored. If on reading back all the data the sequencer does not see four symbols that are the same \(0000\) or \(1111\), you can assume that there is an error in the \(DQ_{1T}\) setup. This error results in calibration stopping.

If the address and command latencies are the same for all DQS groups, this calibration stage completes successfully.

If the address and command latencies are off by one memory clock cycle for one or more DQS groups, the address and command \(1T\) setting is adjusted in the set \(AC_{1T}\) stage. You must then go back and perform the read path clock cycle setup again, and then repeat the write datapath address and command setup process again.

If the address and command latencies are off by one PHY clock cycle for one or more DQS groups, and it is the second time through this calibration stage, calibration fails and the state machine transitions to the \(cal\_failed\) state. User mode is not entered, as the calibration finds no valid configuration.

The calibration does not support a difference of more than one memory clock cycle between groups.

**Final Setup**

During this stage, the ALTMEMPHY sequencer programs the DDR3 SDRAM mode registers to the GUI values and tells the memory controller that the calibration sequence is complete. At this point the memory controller can start sending transactions to the attached DDR3 SDRAM components.

**Tracking**

Tracking maintains equal setup and hold times at the resynchronization registers in the I/O with respect to to the resynchronization clock, \(RESYNC\_CLK\). The optimal phase of \(RESYNC\_CLK\) is calibrated during the resynchronization calibration stage. As the voltage and temperature conditions of the FPGA device change, the delays on the paths associated with the capture and resynchronization stages varies. The phase of \(RESYNC\_CLK\) is no longer optimal, resulting in asymmetric setup and hold times at the I/O resynchronization registers. If the voltage and temperature variation is large enough from the initial voltage and temperature conditions at calibration time, the \(RESYNC\_CLK\) clock phase may drift outside of the resynchronization window. This situation results in invalid data resynchronized to the \(RESYNC\_CLK\) clock domain.

To preserve the calibrated setup and hold times the tracking process monitors a signal in the mimic path to determine how a reference point shifts as the voltage and temperature conditions change. As voltage and temperature conditions change, the ALTMEMPHY sequencer detects and changes the phase of \(RESYNC\_CLK\) accordingly.

Figure 3–6 shows the mimic path block.
Figure 3–6 shows the following points:

- The mimic path is formed by feeding back the memory clock, MEM_CLK inside the I/O cell.
- The feedback MEM_CLK is input to a DDIO_IN capture register.
- Unlike read capture the DDIO_IN is clocked by variable phase MEASURE_CLK from the PLL.
- The mimic path approximates the voltage and temperature variation on the FPGA memory clock and DQS input path.

Tracking is performed at the following times:

- At the end of the DDR3 SDRAM calibration sequence, before entering user mode.
- Periodically during user mode.

At the end of calibration the ALTMEMPHY sequencer requests a mimic operation where the mimic path logic takes successive samples of the feedback MEM_CLK for a given MEASURE_CLK phase. When the sampling process completes, the mimic path logic returns the sampled value to the ALTMEMPHY sequencer, where the sample value is stored in a register. The ALTMEMPHY sequencer then increments the phase of MEASURE_CLK using the dedicated phase shifting interface on the PLL and requests another mimic operation. This sequence continues until all PLL phases in a clock cycle are swept and the sampled value has been returned.

During this sampling process, the ALTMEMPHY sequencer looks to determine future tracking operations. When determined, the PLL phase tap reference point value is stored in the internal RAM. In user mode, tracking is performed periodically. The output again is the phase step that corresponds to the reference point of the feedback MEM_CLK. The sequencer compares the previous and current phase tap value stored in the internal RAM and updates the RESYNC_CLK phase accordingly if there is a difference between the two values. For example, if the previous tracking operation returns a PLL phase tap value of 2 and the current tracking operation returns a PLL phase tap value of 3 the sequencer increments the phase of RESYNC_CLK by +1 phase step.

**Idle (User Mode)**

When calibration is complete, you can enter user mode.
This chapter describes a debug toolkit for ALTMEMPHY-based high performance controllers. The debug toolkit uses a JTAG connection to a Windows PC. The debug toolkit supports the following Altera AFI-based IP:

- ALTMEMPHY megafucntion
- DDR2 and DDR3 SDRAM High-Performance Controller and High Performance Controller II—with leveling and without leveling interfaces

The debug toolkit does not support the QDR II and II+ SRAM, RLDRAM II with UniPHY controllers.

The debug toolkit provides detailed information regarding the calibration process. The debug toolkit and the SignalTap II logic analyzer can be run at the same time. However using **Autorun Analysis** in the SignalTap II logic analyzer slows down the JTAG communication with the debug toolkit.

This chapter provides the following information:

- “Debug Toolkit Overview”
- “Install the Debug Toolkit”
- “Modify the Example Top-Level File to use the Debug Toolkit”
- “Use the Debug Toolkit”
- “Interprete the Results”
- “Understand the Checksum and Failure Code”

The debug toolkit provides information on the failures and calibration results that assist and direct the hardware debug process. The debug toolkit does not fix a failing design. Before you use the debug toolkit, refer to Chapter 2, Debugging Hardware of the *External Memory Interfaces Handbook*.

### Debug Toolkit Overview

The debug TOOLKIT provides the following information:

- Lists the various calibration stages and indicates whether each stage was successful or not.
- States an error code specific to the exact type of calibration failure.
- Provides possible causes for calibration failures.
Provides graphics to visualize the following parameters:

- Resync clock phase setup (leveling = per DQ group, without leveling = per pin)
- Read deskew multipurpose registers (MPR) (prime DQ pins only)
- Read deskew block training pattern (per pin)
- Write deskew (per pin)
- Write leveling report

You can export a .doom file from the debug toolkit. This file provides a record of your calibration results and the ALTMEMPHY IOE configuration specific to your system, allowing you to refer to this data offline later.

Install the Debug Toolkit

To install the debug toolkit, follow these steps:

1. Download the debug toolkit, debug-toolkit.zip, file from Altera website.
2. Unzip the debug-toolkit.zip file.
3. To start the debug toolkit, navigate to the directory where you unzipped the .zip file and run debug-toolkit.exe.

To install the debug toolkit on a Quartus II production programming PC, follow these steps:

1. On a PC running the Windows OS, copy the debug-toolkit.zip file to your project directory or a common programming directory that you also use to program your test platform using a USB-Blaster™ download cable.
2. Unzip the debug-toolkit.zip file to either your project folder or a common programming folder.

Modify the Example Top-Level File to use the Debug Toolkit

Before you use the debug toolkit, you must modify your design’s example-top-level file, by following these steps:

- Verify the Design
- Regenerate the IP
- Instantiate the JTAG Avalon-MM port in to the Example-Top Level Project
- Add Additional Signals
- Add alt_jtagavalon.v to your Quartus II Project Settings Files List
- Recompile your Quartus II Test Design
- Program Hardware with Debug Enabled .sof

Your design must follow the recommended design flow, refer to the Recommended Design Flow section in volume 1 of the External Memory Interface Handbook.
Verify the Design

Ensure your design meets the following conditions:

- The parameters entered into the IP are correct for the memory and data rate.
- The design passes functional simulation.
- The Quartus II project has the correct board trace models specified for the PCB you are using.
- For Stratix III and Cyclone III devices, ensure that the `set (additional_addresscmd_tpd)` parameter is correctly specified in your `.sdc` file.
- For Stratix IV and Arria II GX devices, ensure that the `Address and Command to CK skew` parameter is correctly specified in the `Board Settings` tab of the IP wizard.
- The address and command clock phase is correct, to ensure optimum balanced setup and hold times.
- The Quartus II design successfully closes timing.
- The Quartus II project has the correct pin location assignments for the PCB that you are using.
- The autogenerated IP assignments are correctly applied to the example top-level file.
- The `.sdc` constraint files are correctly applied to the example top-level file.
- The Quartus II settings are correctly applied.
- The `R_up/rdn` pin locations are correctly specified in the example top-level file if required.
- The SignalTap II logic analyzer is added to the example top-level file.

Before you use the debug toolkit, follow these steps:

1. Edit the example top-level file to enable debugging:
   
a. Open the `<variation name>.v` or `.vhd` and find the `export_debug_port` private value.

   ```
   Do not edit this value in the file `<variation name>_phy.v` or `.vhd` file.
   ```

   The value is at the bottom of the file:

   ```
   // =========================================================
   // DDR3 High Performance Controller Wizard Data
   // --------------------------------------------------------
   // DO NOT EDIT FOLLOWING DATA
   // @Altera, IP Toolbench@
   ...
   ...
   ```
Regenerate the IP

To regenerate the IP, follow these steps:

1. Open the MegaWizard Plug In Manager, and select Edit an existing custom megafonction variation.
2. Select your modified high-performance controller.
3. Click Next to open the IP.
4. Click Finish to regenerate the IP.

You now have a version of the design with debug enabled. Seven new ports with the prefix `dbg_*` are added to the controller instance through the design hierarchy up to the `<variation name>_example_top.v` or `.vhd`.

Instantiate the JTAG Avalon-MM port in to the Example-Top Level Project

To instantiate the JTAG Avalon-MM port, follow these steps:

1. Declare the following wires in `<variation name>_example_top.v` or `.vhd`.
   
   ```
   wire [12: 0] av_address;
   wire av_write_n;
   wire [31: 0] av_writedata;
   wire av_read_n;
   wire av_waitrequest;
   wire [31: 0] av_readdata;
   ```

2. Add the following instances in `<variation name>_example_top.v` or `.vhd`.
   
   ```
   // inst jtag avalon:
   alt_jtagavalon alt_jtagavalon(
     .clk (phy_clk),
     .rst_n (reset_phy_clk_n),
     .av_address (av_address),
     .av_write_n (av_write_n),
     .av_writedata (av_writedata),
     .av_read_n (av_read_n),
     .av_readdata (av_readdata),
     .av_waitrequest (av_waitrequest)
   );
   defparam alt_jtagavalon.SLD_NODE_INFO = 203976192;
   defparam alt_jtagavalon.ADDR_WIDTH = 13;
   defparam alt_jtagavalon.DATA_WIDTH = 32;
   ```
defparam alt_jtagavalon.MODE_WIDTH = 3;

3. Update the following port connections in the DDR2 or DDR3 SDRAM instance in <variation name>_example_top.v or .vhd:

a. Locate the PHY or controller instance in the top-level file and locate the following debug port connections:

```vhdl```
//<< START MEGAWIZARD INSERT WRAPPER_NAME
<variation_name> <variation_name>_inst
  
  .dbg_addr (13'b0),
  .dbg_cs (1'b0),
  .dbg_rd (1'b0),
  .dbg_rd_data (dbg_rd_data_sig),
  .dbg_waitrequest (dbg_waitrequest_sig),
  .dbg_wr (1'b0),
  .dbg_wr_data (32'b0),
```

b. Change the following debug port connections to:

```vhdl```
//<< START MEGAWIZARD INSERT WRAPPER_NAME
<variation_name> <variation_name>_inst
  
  .dbg_addr (av_address),
  .dbg_cs (1'b1),
  .dbg_rd (~av_read_n),
  .dbg_rd_data (av_readdata),
  .dbg_waitrequest (av_waitrequest),
  .dbg_wr (~av_write_n),
  .dbg_wr_data (av_writedata),
```

The debug toolkit is added to your example top-level file.

### Add Additional Signals

In addition to the standard SignalTap II signals, you can add the following signals during debug to understand the following situations:

- Where calibration failed:
  - `*ctl_init_fail` -phy_inst
  - `*ctl_init_success` -phy_inst
  - `ctl_cal_fail` -phy_inst
  - `ctl_cal_success` -phy_inst
How much resynchronization margin is available:
- \( *cal\_codvw\_phase \times DT\_phy\_inst \)
- \( *cal\_codvw\_size \times DT\_phy\_inst \)
- \( *codvw\_trk\_shift \times DT\_phy\_inst \)

What the read and write latency is calibrated as:
- \( ctl\_rlat \times DT\_phy\_inst \)
- \( ctl\_wlat \times DT\_phy\_inst \)

If the PLL is locked and phase stepping as expected:
- Locked -altpll\_component
- Phasecounterselect -altpll\_component
- Phaseupdown -altpll\_component
- Phasestep -altpll\_component
- phasedone -altpll\_component
- dqs\_delay\_ctrl\_export \times DT\_phy\_inst

For signals marked with \( *DT \), disable trigger enable in the SignalTap II logic analyzer to reduce memory requirement.

Table 4–1 shows sequencer signals that you can also probe using the SignalTap II logic analyzer, to help you understand where calibration failure is occurring. The signals are in the `<variation_name>_alt_mem_phy_seq.vhd` file.

All signals are active high.

**Add alt_jtagavalon.v to your Quartus II Project Settings Files List**

Before you compile your design, you must add the `alt_jtagavalon.v` file to your projects file list. This `alt_jtagavalon.v` file is included with the debug toolkit.

**Recompile your Quartus II Test Design**

You must compile your modified design to generate a new .sof for testing that includes the debug toolkit code. Altera recommends you ensure that this modified design continues to pass timing analysis. Any timing failures should be assessed and corrected before using the debug toolkit.
**Program Hardware with Debug Enabled .sof**

To program hardware with the debug enabled .sof, program the device using the SignalTap II logic analyzer. Then click **Run Analysis** to run once. Typically, the SignalTap II logic analyzer is initially configured to trigger on the signal `test_complete`, which is fine for working designs.

For designs that are failing calibration, Altera recommends modifying the trigger based on the observed results. Combine this SignalTap II trigger fault isolation activity with use of the debug toolkit. For example:

1. Initially trigger on `test_complete`, if the interface works first time.
2. Trigger on `cal_fail`, if the PHY is failing calibration.
3. Trigger on the same `state.s_*` or error code that is reported as the calibration failure point in the debug toolkit.
4. Trigger on `init_fail`, if the memory is failing to initialize.
5. Trigger on `pll_locked`, if the PLL is operating incorrectly.

**Use the Debug Toolkit**

To use the debug toolkit, follow these steps:

1. Double-click `debug-toolkit.exe`.
2. On the File menu, click **Connect via JTAG** (Figure 4–1).

3. Navigate down the hierarchy and click on the Avalon-MM JTAG node (Figure 4–2).

   If you encounter connection problems, Altera recommends that you have a only a single USB-Blaster™ download cable rogramming adaptor connected to your PC.
4. If you receive a prompt stating the following message, verify you have the latest debug toolkit, and click Yes (Figure 4–3).

Hardware Version Number Mismatch –
this_debug_GUI_release_doesnt_match_the_altmemphy_version_used_in_generation

Interprete the Results

This topic discusses:

- Calibration Successful—Without Leveling
- Calibration Fails—Without Leveling
- Calibration Successful—With Leveling
- Calibration Fails—Without Leveling

Calibration Successful—Without Leveling

If calibration is successful, you see the following screen (Figure 4–4).
For optimum operation of the debug toolkit, ensure that you turn on Enable Debug (Figure 4–5).

Click internal RAM to display the calibration memory results (Figure 4–6).

This setting is not typically used.
The debug toolkit can dynamically alter the PLL clock phases (Figure 4–7).

This setting is not typically used.

The debug toolkit states the number of resynchronization clock phase steps that are valid at calibration time. For example, the resynchronization window size in PLL phase steps at calibration in Figure 4–7 is 26 PLL phase steps wide.

Click Visualization: resync clock phase setup (Figure 4–8) to show the PHY resynchronization pass and fail results in an expandable tree structure:

- For the whole interface including the chosen phase (black dot)
- On a DQS group basis
- On a per DQ pin basis
The debug toolkit additionally states the number of passing phase steps that it finds during calibration. Thus to calculate the resynchronization margin in this design, the resynchronization clock (C6) from the PLL has a phase-shift step resolution of 78.12 ps or 5.62 degrees. So 30 valid steps means that the window size = 2.343 ns or 168.6 degrees.

Click **PHY parameterization** (Figure 4–9), to show the exact calibration configuration of the generated IP.

**Figure 4–9. PHY Parameterization**

The debug toolkit additionally states the number of passing phase steps that it finds during calibration. Thus to calculate the resynchronization margin in this design, the resynchronization clock (C6) from the PLL has a phase-shift step resolution of 78.12 ps or 5.62 degrees. So 30 valid steps means that the window size = 2.343 ns or 168.6 degrees.

Click **PHY parameterization** (Figure 4–9), to show the exact calibration configuration of the generated IP.

**Calibration Fails—Without Leveling**

If calibration fails, you see the following screen (Figure 4–10).
The stage at which calibration fails is highlighted in red; the stages that have successfully passed are in green. When possible, the debug toolkit also provides a possible cause for the failure code.

This failure code is: 0x92177307, for more information on failure codes, refer to “Understand the Checksum and Failure Code” on page 4–23.

**Calibration Successful—With Leveling**

If calibration is successful, you see the following window (Figure 4–11).
For optimum operation of the debug toolkit, ensure that you turn on **Enable Debug** (Figure 4–12).

Click **IRAM** to display the calibration memory results (Figure 4–13).

This setting is not typically used.
The debug toolkit can dynamically alter the PLL clock phases (Figure 4–14).

This setting is not typically used.

The debug toolkit states the number of resynchronization clock phase steps that are valid at calibration time. For example, the resynchronization window size in PLL phase steps at calibration in Figure 4–14 is 20 PLL phase steps wide.

Click Visualization: resync clock phase setup (Figure 4–15), to show the PHY resynchronization pass and fail results in an expandable tree structure:

- For the whole interface including the chosen phase (black dot)
- On a DQS group basis

This feature is similar to the non-AFI PHY enable debug in system memory contents editor feature that allowed you to view the calibration results.
The interface level resynchronization calibration results may be 360 degrees offset when compared to the per pin results.

Figure 4–15. Visualization: Resynch Clock Phase Setup

The debug toolkit additionally states the number of passing phase steps that it finds during calibration. Thus to calculate the resynchronization margin in this design the resynchronization clock (C6) from the PLL has a phase-shift step resolution of 78.12 ps or 7.50 degrees, so 21 valid steps means that the window size is 1.64 ns or 157.5 degrees.

Click Visualization: Read Deskew (BTP) (Figure 4–16), which shows the PHY read deskew block training pattern pass and fail results in an expandable tree structure:

- For the whole interface including the chosen phase (black dot)
- On a DQS group basis
- On Per DQ pin basis
The debug toolkit additionally states the number of passing phase steps that it finds during calibration. Thus to calculate the read deskew margin in this design with a Stratix III device, the delay resolution is 50 ps, hence the margin is $17 \times 50 = 850$ ps or $+/-425$ ps.

Click Visualization: Read Deskew (MPR) (Figure 4–17), to show the PHY read deskew multi-purpose registers pass and fail results in an expandable tree structure:

- For the whole interface including the chosen delay (black dot)
- On a DQS group basis
- On Per DQ pin basis
This first phase of read deskew uses the prime DQ pin within each DQ group only. The debug toolkit additionally states the number of passing phase steps that it finds during calibration. Thus, to calculate the read deskew (MPR) margin, the delay resolution is 50 ps, hence the margin is $18 \times 50 = 900$ ps or $+/–450$ps.

Click Visualization: Write Deskew Pan (Figure 4–18), to show the PHY write deskew pass and fail results in an expandable tree structure:

- For the whole interface including the chosen delay (black dot)
- On a DQS group basis
- On Per DQ pin basis
The debug toolkit additionally states the number of passing phase steps that it finds during calibration. Thus to calculate the write deskew margin, the delay resolution is 50ps, hence the margin is $= 10 \times 50 = 500 \text{ ps or } +/–250\text{ps}$

Click **Write Leveling Report** (Figure 4–19), to show the results of the write leveling. This first calibration test may often be the stage that fails in an unreliable PHY. Write leveling is performed on a per rank basis, so results are for each chip select signal in the design.
Click PHY parameterization (Figure 4–20), to show the exact calibration configuration of the generated IP.

**Figure 4–20.** PHY Paremeterization

**Figure 4–19.** Write Leveling Report

Click PHY parameterization (Figure 4–20), to show the exact calibration configuration of the generated IP.

**Figure 4–20.** PHY Paremeterization

**Calibration Fails—With Leveling**

If calibration fails, you see the following screen (Figure 4–10).
Interpret the Results

The stage at which calibration fails is highlighted in red; the stages that have successfully passed are in green. When possible the debug toolkit also provides a possible cause for the failure code.

This failure code is: 0x92177307, for more information on failure codes, refer to “Understand the Checksum and Failure Code” on page 4–23.

In this example, the debug toolkit suggests One or more DDR3 Chips are being held in Reset. As this failure is reported at the write levelling stage, look at the write leveling report to see that DQS group 8 of the interface is not responding.

Save the Calibration Results

Often the calibration failure stage, the reported suggested failure cause, or the combined debug toolkit result and waveforms viewed in the SignalTap II logic analyzer provide enough detail to resolve the failure directly. However, you may wish to save your calibration results, so that you can refer to them later.
With your calibration process results still displayed on the File menu, click **Export** (Figure 4–22).

**Figure 4–22. Export**

In the **Save** dialog box (Figure 4–23), specify a file name and any comments to help with the identification and understanding of the controller configuration that you have evaluated, and details on what you may have tested.
You can save this .doom file with a Quartus II archive (.qar) file of the test design, and a copy of the captured SignalTap II waveform files, as a single design archive. This archive provides a record of your calibration results and the ALTMEMPHY IOE configuration specific to your system, so you can refer to this data at a later date.

**Understand the Checksum and Failure Code**

The debug toolkit checksum provides a direct correlation to the exact stage that calibration failed and the error code for that failure.

For example, the hexadecimal code in the format `0xAABBCCDD` represents the full 32-bit contents of the calibration status register.

During debug the code or the calibration stage and the subcode or the error code have the following definitions:

- The code and calibration stage is the first byte (DD) or `[7..0]`
- The subcode or the error code is the third byte (BB) or `[23..16]`

Take the hexadecimal value of each code and convert that to decimal. When you have these two numbers in decimal format, you can open the `failuremessages.csv` (levelling) or `failuremessages_nl.csv` (without-leveling) spreadsheet file and look up the likely causes of your calibration failure.

In a passing interface, these two numbers are zero.
For the ALTMEMPHY with leveling, Table 4–2 shows the codes that correspond to the indicated calibration stages.

You can find the same information from the SignalTap II logic analyzer if the
*_ctrl.command_err, *_ctrl.command_result *and state.s_* signals are
added. The command error and state signals identify which calibration stage
the interface fails The corresponding command result then includes the same
information as the suberror code.

For more information on the stages of calibration, refer to “ALTMEMPHY Calibration
Stages” on page 3–1.
How to Contact Altera

For the most up-to-date information about Altera® products, see the following table.

1. Creating a Custom PHY

This chapter describes the FPGA design flow to implement a memory interface datapath (PHY) using Stratix® III and Stratix IV devices and the ALTDLL and ALTDQ_DQS megafunctions. You can use this method as an alternative to using the available external memory interface IP. You can then connect this PHY with a custom memory controller to interface with other memory components.

Altera recommends using the available external memory IPs instead of using the ALTDLL and ALTDQ_DQS megafunctions whenever possible.

The ALTDLL megafunction implements the dedicated DQS circuitry, while the ALTDQ_DQS megafunction implements the read and write PHY required for the interface. For more information about these megafunctions, refer to the ALTDLL and ALTDQ_DQS Megafunctions User Guide.

You must constrain the timing of the PHY when using ALTDLL and ALTDQ_DQS megafunctions. This chapter does not cover details of the timing constraints; however, it includes information about timing analysis and board-level constraints that demonstrate and validate the interface.

The design flow steps in this chapter focus on the “Instantiate PHY and Controller” step of the Recommended Design Flow chapter of the External Memory Handbook. You can adapt the steps for a DDR2 SDRAM interface to create other types of memory interfaces.

After selecting the appropriate device and memory type, create a project in the Quartus II software that targets the device and memory type. When instantiating the datapath for DDR and DDR2 SDRAM interfaces in Stratix III and Stratix IV devices, Altera recommends using the ALTDLL and ALTDQ_DQS megafunctions for the datapath of custom external memory interfaces that are not supported by the ALTMEMPHY or UniPHY IP.

You use the following megafunctions to create a complete memory interface PHY:

- ALTDLL megafunction
- ALTDQ_DQS megafunction
- ALTPLL megafunction
- ALTIOBUF megafunction
- ALTIOCT megafunction

The following sections describe the work flow when you instantiate PHY via ALTDLL and ALTDQ_DQS megafunctions and your custom-designed controller in a Quartus II project:
Instantiate the ALTPLL Megafuntion

The ALTPLL instance provides the necessary clocking scheme for the custom PHY. Clocking schemes for the custom external memory interface are important. You must understand what clocks are required for a full-rate or half-rate interface. Both interfaces require different clocking schemes.

**Clocking Scheme Requirement for Full-Rate Interface**

Figure 1–1 on page 1–2 shows a sample full-rate interface.

**Figure 1–1. Example Full-Rate Interface**
The PLL instance should generate the following five clock outputs for the full-rate interface (refer to Figure 1–1):

- DLL Input clock
- Resynchronize postamble clock (resync_postamble_clk)
- Write Clock (write_clk)
- Memory clock (mem_clk)
- Address/command clock

The following sections describe each of the five clock outputs for the full-rate interface.

### DLL Input Clock

This clock toggles the DLL block. The DLL clock is equivalent to the full rate of the interface and has a 0° phase shift. You must connect the DLL block directly to a single dedicated PLL clock output.

### Resynchronize Postamble Clock (resync_postamble_clk)

The resync_postamble_clk clock is an optional clock. You can use this clock for two purposes:

- Clock the DQS enable control block. This block is used to disable the DQS input strobe when the strobe goes to Hi-Z (after a DDR read postamble). This is part of the DQS input path.
- Clock the INPUT_PHASE_ALIGN block. This block phase shifts the input signal and is primarily used to match the arrival delay of the DQS to the latest arrival delay of a DQS from the DDR or DDR2 DIMM. It is also used to resynchronize the data read from the DDIO_IN block. This is part of the DQ input path.

The resync_postamble_clk clock should be the full rate of the interface and have dynamic phase. You can set the dynamic phase capability for the PLL clock outputs with the ALTPLL megafunction. The correct resync_postamble_clk clock phase is crucial to correct data transfer. The ALTDQ_DQS megafunction cannot determine the phase that the resync_postamble_clk clock should have. Therefore, you must solve this with round-trip delay analysis or creating a custom data training circuitry to write and read back a training pattern to and from the memory device, and then dynamically adjust the resynchronization clock phase of the PLLs to find a good working phase.

### Write Clock (write_clk)

The write_clk clock clocks the DDIO_OUT block that is part of the DQ output path. The clock is used for writing data to the DQ pins and also to clock the FF (oe) block (refer to Figure 1–1 on page 1–2), which is part of the DQ OE path. The FF (oe) block acts as the output enable for the DQ output path.

The write_clk clock should be the full rate of the interface and have a –90° phase shift. This ensures the write DQ data is center-aligned with respect to the DQS write strobe.

### Memory Clock (mem_clk)

The mem_clk clocks the following blocks:
- DDIO_OUT block that is part of the DQS output path and
- DDIO_OUT blocks that generate the CK and CK# signals.
- DDIO_OE block that is part of the DQS OE path
- DDIO_OE (extended_rtena) block that is part of the dynamic termination for the DQS pin
- DDIO_OE (extended_rtena) block that is part of the dynamic termination for the DQ pin

The mem_clk should be the full rate of the interface and typically have 0° phase shift.

**Address/Command Clock**

The address/command clock is used to clock the DDIO_OUT blocks that are used for the address and command pins. Although not shown in Figure 1–1 on page 1–2, it is discussed further in “Create Controller Logic for Address and Command Pins” on page 1–21.

The address/command clock should be the full rate of the interface and have a 180° phase shift. The 180° value is dependent on the address/command/control signals being perfectly matched to the clock signals in time delay on the PCB. Typically, this is not the case, but it is ideal.

**Clocking Scheme Requirement for Half-Rate Interface**

Figure 1–2 shows a sample half-rate interface.
Figure 1–2. Example Half-Rate Interface
The PLL instance for a half-rate interface generates the following six clock outputs (refer to Figure 1–2):

- DLL input clock
- Resynchronize postamble clock (resync_postamble_clk)
- Write clock (write_clk)
- Memory clock (mem_clk)
- PHY Clock (PHY_clk)
- Address/command clock

The following sections describe the details of the six clock outputs for the half-rate interface.

**DLL Input Clock**

The DLL clock is used to toggle the DLL block. The DLL clock should be equivalent to the full rate of the interface and have a 0° phase shift. You must connect the DLL block directly to a single dedicated PLL clock output.

**Resynchronize Postamble Clock (resync_postamble_clk)**

The resync_postamble_clk clock is an optional clock. You can use this clock for three purposes:

- Clock the DQS enable control block. The DQS enable control block is used to disable the DQS input strobe after the strobe goes to Z (after a DDR read postamble). This is part of the DQS input path.
- Clock the INPUT_PHASE_ALIGN block. This block phase shifts the input signal and is primarily used to match the arrival delay of the DQS to the latest arrival delay of a DQS from the DDR or DDR2 DIMM. It is also used to resynchronize the data read from the DDIO_IN block.
- Feed the I/O clock divider block that is a part of the DQS input path. The I/O clock divider divides the clock by two (half-rate resync_clk) and uses it to clock the DDIO_OUT (half_rate_mode=TRUE) block that is part of the DQS input path. The DQS input path controls the DQS enable signal and also clocks the half-rate input block that is part of the DQ input path.

The resync_postamble_clk clock should be the full rate of the interface and have dynamic phase. You can set the dynamic phase capability for the PLL clock outputs with the ALTPPLL megafuction. The correct resync_postamble_clk clock phase is crucial to correct data transfer. The ALTDQ_DQS megafuction cannot determine the phase that the resync_postamble_clk should have. Therefore, you must solve this with RTD analysis or creating a custom data training circuitry to write and read back a training pattern to and from the memory device and then dynamically adjust the resynchronization clock phase of the PLLs to find a good working phase.

**Write Clock (write_clk)**

The write_clk clocks the DDIO_OUT block that is a part of the DQ output path. The DDIO_OUT block is used for writing data to the DQ pins and to clock the FF (oe) block that is a part of the DQ OE path. The FF (oe) block (refer to Figure 1–2) acts as the output enable for the DQ output path.
The **write_clk** should be the full rate of the interface and have about a ~90° phase shift. This requirement ensures the write DQ data is center-aligned with respect to the DQS write strobe.

### Memory Clock (mem_clk)

The **mem_clk** clocks the following blocks:

- DDIO_OUT block that is part of the DQS output path
  - The memory clock is also used to clock the DDIO_OUT blocks that generate the CK and CK# signals.
- DDIO_OE block that is part of the DQS OE path
- DDIO_OE (extended_rtena) block that is part of the dynamic termination for the DQS pin
- DDIO_OE (extended_rtena) block that is part of the dynamic termination for the DQ pin

The memory clock should be the full rate of the interface and have about a 0° phase shift.

### PHY Clock (PHY_clk)

The **PHY_clk** clocks the following blocks:

- Two DDIO_OUT (half_rate_mode=TRUE) blocks that are part of the DQS output path
- DDIO_OUT (half_rate_mode=TRUE) block that is part of the DQS OE path
- DDIO_OUT (half_rate_mode=TRUE) block that is part of the dynamic termination for the DQS pin
- Two DDIO_OUT (half_rate_mode=TRUE) blocks that are part of the DQ output path
- DDIO_OUT (half_rate_mode=TRUE) block that is part of the DQ OE path
- DDIO_OUT (half_rate_mode=TRUE) block that is part of the dynamic termination for the DQ pin

The **PHY_CLK** should be the half rate of the interface and have a 0° phase shift.

### Address and Command Clock

The address and command clock clocks the DDIO_OUT blocks that are used for the address and command pins. Although not shown in Figure 1–2 on page 1–5, it is discussed further in “Create Controller Logic for Address and Command Pins” on page 1–21.

The address and command clock should be the full rate of the interface and have a phase shift between 180° and 359°. The value is dependent on the address/command/control signals being perfectly matched to the clock signals in time delay on the PCB. Typically, this is not the case, but it is ideal.

For more information about using PLLs or other blocks, refer to the **ALTPLL Megafunction User Guide**.
After you decide on your clocking scheme as discussed in this section, you can proceed to the next step.

**Instantiate ALTDLL Megafunctions**

Using the MegaWizard Plus-In Manager, instantiate an ALTDLL megafunction that corresponds with the memory interface frequency. You must set the input frequency, delay chain length, and delay buffer mode for the DLL in the MegaWizard interface. Specify a DLL frequency mode that corresponds with the middle frequency range of the DLL frequency mode. This DLL frequency mode determines the delay buffer mode and delay chain length of interface. You can also specify a jitter reduction for the DLL offset control blocks.

Refer to the “DLL and DQS Logic Block Specifications” section of the the Stratix III Device Datasheet or the Stratix IV Device Datasheet.

For more information about the settings in this section, refer to the “MegaWizard Plug-In Manager Page Descriptions for the ALTDLL Megafunction” section of the ALTDLL and ALTDQ_DQS Megafuctions User Guide.

**Instantiate ALTDQ_DQS Megafunctions**

After configuring the DLL settings, you must set the dedicated circuitry settings for external memory interfaces with the ALTDQ_DQS megafunction.

A typical custom external memory interface consists of the following:

- Zero or one DQS I/O pin (read or write strobe/clock) with an optional DQSs I/O pin (differential strobe/clock), or a CQ and CQn I/O pair (complementary clock)
- One or more DQ I/O pins (read or write data)
- One DM/D pin (output-only data mask, write data, or both)

The ALTDQ_DQS megafunction allows you to instantiate a group of DQ pins (ranging from ×4 to ×36) along with their corresponding DQS block, or DQSs I/O (optional) block, or both (optional). The ALTDQ_DQS megafunction enables you to generate the necessary DQ/DQS circuitry to use with external memory interfaces. You can configure the DQS and DQSs I/O as input-only, output-only, or bidirectional pins. All bidir_dq I/O pins are identically configured. Similarly, all output_dq (output-only DQ/DM I/O pins) and input_dq I/O pins (input-only DQ pins) are identically configured. Hence, if delay chains or half-data rate blocks are used in a path, the configuration applies to all paths of the same type. The paths can be all-input paths, all-output paths, or bidirectional paths in the ALTDQ_DQS variation. The ALTDQ_DQS megafunction generates only one DQS I/O pin per instantiation. If you need a 72-bit data interface composed of ×9 data groups, you must generate a ×9 data group with the megafunction and then instantiate it eight times.

The following steps describe the general flow when using the ALTDQ_DQS megafunction:

1. Configure the general settings for the ALTDQ_DQS instances, which includes the number of input, output, and bidirectional DQ_DQS delay chain stages, DQS input frequency, use half-rate components, and use dynamic OCT path.
2. Configure the DQS input path, which includes using input delay chain (D1), using DQS delay chain, enabling DQS busout delay chain, enabling DQS enable block, enabling DQS enable control block, and enabling DQS enable block delay chain.

3. If you enable the DQS delay chain block to true, the **DQS Delay Chain Settings** dialog box appears. You must configure the DQS delay chain settings.

4. If you enable the DQS enable control to true, the **DQS Enable Control Settings** dialog box appears. You must configure the DQS enable control settings.

5. Configure the DQS output/OE path, which includes enabling DQS output delay chain 1 (D5), enabling DQS output delay chain 2 (D6), configuring DQS output registers, enabling DQS OE delay chain 1 (D5), enabling DQS OE delay chain 2 (D6), and configuring the DQS OE registers.

6. Configure the DQ input path, which includes configuring the DQ input registers, selecting the clock source for the DQ input register, enabling the DQ input phase alignment block, use the DQ half-rate dataoutbypass port, and enabling the DQ input delay chain (D1).

7. If you enable the DQ input phase alignment block to true, the **DQ Input Phase Alignment Block Settings** dialog box appears. You must configure the DQ input phase alignment block settings.

8. Configure the DQ output/OE path, which includes enabling DQ output delay chain 1 (D5), enabling DQ output delay chain 2 (D6), configuring the DQ output registers, enabling DQ OE delay chain 1 (D5), enabling DQ OE delay chain 2 (D6), and configuring the DQ OE registers.

9. Configure the half-rate components, which includes configuring the IO clock divider block, source clock, creating the **io_clock_divider_masterin** input port for chaining multiple **IO_CLOCK_DIVIDER** blocks, enabling the **io_clock_divider_clkout** output port for clocking core registers, enabling the **io_clock_divider_slaveout** output port for chaining multiple **IO_CLOCK_DIVIDER** blocks, and inverting the phase through this block.

10. Configure the Dynamic OCT components, which includes enabling OCT delay chain 1(D5 OCT), enabling OCT delay chain 2(D6 OCT), and configuring OCT register mode.

11. Configure the DQS/DQSn IO, which includes configuring the DQS/DQSn pair as a differential pair or complementary pair.

12. Configure the reset ports for the ALTDQ_DQS instance. The configuration enables the asynchronous and synchronous reset ports to all the registers in the DQS and DQ datapath.

Notes to Table 1–2:

(1) For more information about these options, refer to the “ALTDQ_DQS High-Level Configuration Settings” and “MegaWizard Plug-In Manager Page Descriptions for the ALTDQ_DQS Megafun” sections in the ALTDLL and ALTDQ_DQS Megafunctions User Guide.

(2) You can use differential or complementary mode instead of single-ended mode for the DQS IO.

(3) With dynamic OCT, you can enable the parallel termination (R_t) during reads from the DDR and DDR2 external memory, and disable the R_t during writes from the DDR and DDR2 external memory. This significantly reduces power consumption for external memory interfaces.

Table 1–3 shows the settings needed to achieve particular phase shifts for the DQS delay chain block mentioned in Table 1–2:

Setting the DQS delay chain phase is one of the most important parts of the ALTDQ_DQS megafun. It determines the necessary phase shift in the DQS delay chain that clocks the DDIO_IN block in the DQ input path. This requires a phase shift of 90° to center align the DQS strobe with the DQ data. Consider the following scenarios:

- **Scenario One**

  If you are using a Stratix III device with C3 speed grade, refer to the Stratix III Device Handbook for the appropriate settings.

  Because the DQS input frequency for the first scenario is 155 MHz, the device speed grade is C3, the DLL delay chain length is 12, delay buffer mode is low, and the intended phase shift is 90°. For these parameters, set the Stages of the DQS Delay Chain option to 3.

- **Scenario Two**

  For a particular DLL delay chain length, you might not get your intended phase setting.

  For example, set the DLL delay chain length to 10 and the DQS input frequency to 190 MHz. Your intended phase setting is 90°, but the closest available is a 72° phase shift, which is DQS delay stages setting of 2. Instantiate the DLL offset control blocks (ALTDLL) to introduce the necessary offset to the DQS delay chain to achieve the intended 90° phase shift.

Page 4 of the ALTDQ_DQS MegaWizard Plug-In Manager is the DQS IN Advanced Options page. Table 1–3 shows how to configure the DQS input path of the ALTDQ_DQS instance.

</tr>
<tr>
<td></td>
<td>This option is not applicable for full-rate interface.</td>
<td>■ DDIO_OUT (half_rate_mode=TRUE) block that is part of the DQS input path, which controls the DQS enable signal</td>
</tr>
<tr>
<td></td>
<td></td>
<td>■ Half-rate input block that is part of the DQ input path.</td>
</tr>
<tr>
<td>Create ‘io_clock_divider_masterin’ input port (2), (4)</td>
<td></td>
<td>Turn off this option. For this half-rate interface, there is only one ALTDQ_DQS instance. Therefore, I/O clock divider blocks are automatically chained in the instance depending on the amount of DQ pins. This is used for the I/O clock divider block.</td>
</tr>
<tr>
<td>Create ‘io_clock_divider_clkout’ output port (2), (5)</td>
<td>No. Not applicable for full-rate interface.</td>
<td>Turn on this option. This output should clock the core registers that are getting the half-rate DQ data from the half-rate registers.</td>
</tr>
<tr>
<td>Create ‘io_clock_divider_slaveout’ output port (2)</td>
<td></td>
<td>Turn off this option. For this half-rate interface, there is only one ALTDQ_DQS instance. Therefore, I/O clock divider blocks are automatically chained in the instance depending on the amount of DQ pins. This is used for the I/O clock divider block.</td>
</tr>
<tr>
<td><strong>IO Clock Divider Invert Phase (2)</strong></td>
<td></td>
<td>Select the Never option. This is used for the IO_Clock_Divider block.</td>
</tr>
</tbody>
</table>

### Notes to Table 1–7:

1. For more information about these options, refer to the “Configuring the DQS Input Path”, “I/O Clock Divider Primitive”, and “MegaWizard Plug-In Manager Page Descriptions for the ALTDQ_DQS Megafunction” sections in the ALTDLL and ALTDQ_DQS Megafunctions User Guide.

2. The I/O CLOCK_DIVIDER block represents a div-by-2 clock divider for transferring data to the core at one half the speed of the I/O input and output clock. Each divider can feed up to six pins (a x4 DQS group) in the device. To feed wider DQS groups, multiple clock dividers must be chained together by feeding the slaveout output of one divider to the masterin input of the neighboring pins’ divider. The phase settings for the INPUT_PHASE_ALIGN blocks must match the I/O clock divider block.

3. This is used to clock the IO_CLOCK_DIVIDER sub-block, which is used during half-rate operation.

4. If enabled, then the masterin input is used to synchronize this divider with another IO_CLOCK_DIVIDER sub-block. If disabled, then this divider operates independently (this mode is meant for the master divider for a group of dividers).

5. Enables the clock output signal divided by 2. It can be connected to the clock input of a half-rate input block or it can feed the FPGA core.

Page 9 of the ALTDQ_DQS MegaWizard Plug-In Manager is the **OCT Advanced Options** page. You can select options based on Table 1–8. This configures the OCT registers and delay chain settings of the ALTDQ_DQS instance.
Table 1–8. OCT Advanced Options Page

<table>
<thead>
<tr>

<td>Turn on this option. Turning on this option enables two D6 OCT blocks. This is part of the DQ OE Path. This is part of the DQ and DQS dynamic termination path.</td>
</tr>
</tbody>
</table>

DQ Output Path Options (OCT register mode)

<table>
<thead>
<tr>
<th>Options</th>
<th>Full-Rate Interface</th>
<th>Half-Rate Interface</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the DDIO option. This sets two blocks:</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DDIO_OE (extended_rtena) block that is part of the dynamic termination for the DQS pin</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DDIO_OE (extended_rtena) block that is part of the dynamic termination for the DQ pin</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Notes to Table 1–8:

(1) For more information about these options, refer to the “Configuring the DQ/DQS OCT Path” and “MegaWizard Plug-In Manager Page Descriptions for the ALTDQ_DQS Megafunction” sections in the ALTDLL and ALTDQ_DQS Megafuctures User Guide.

(2) The D5 OCT block is dynamic output delay chain 1 and the D6 OCT block is dynamic output delay chain 2. These delay chains are used together with the D5 block and D6 block. With Dynamic OCT, you can enable Rt during reads from the DDR and DDR2 external memory and disable Rr during writes from the DDR and DDR2 external memory. This has a benefit of significantly reducing power consumption for external memory interfaces. Hence the necessary usage of the D5 OCT block and D6 OCT block to synchronize during reads and writes from both DQ and DQS pins, and improve overall timing margins. For more information about delay chains, refer to the “Delay Chains For External Memory Interfaces” section in the ALTDLL and ALTDQ_DQS Megafuctures User Guide.

<td>Turn on this option. Turning on this option enables synchronous reset port for all registers in the DQ datapath.</td>
</tr>
</tbody>
</table>

This completes the settings for both full-rate and half-rate scenarios for the ALTDQ_DQS instance.

**Instaniate the ALTOCT Megafunction**

Use of the OCT scheme in Stratix III and Stratix IV devices eliminates the need for external series or parallel termination resistors and simplifies the design of a PCB. Stratix III and Stratix IV devices support calibrated on-chip series, parallel, and dynamic termination in all I/O banks for single-ended I/O standards. OCT calibration allows you to establish an optimal termination value that compensates for impedance change due to temperature and voltage fluctuation. You can calibrate Stratix III and Stratix IV devices with user-controlled signals during device operation, or by default during device configuration. For calibrated termination, use the ALTOCT megafunction to utilize the dedicated calibration blocks for termination available in the FPGA together with the dedicated OCT in the I/O buffers with the ALTIOBUF megafunction.

For custom external memory interfaces, there are significant advantages to using both dynamic OCT and calibrated termination:
OCT calibration allows you to establish an optimal termination value that compensates for impedance change due to temperature and voltage fluctuation.

Simplifies the design of a PCB.

Significant power consumption reduction for external memory interfaces. With dynamic OCT you can enable \( R_t \) during reads from the DDR and DDR2 external memory and disable \( R_t \) during writes from the DDR and DDR2 external memory and when the interface is idle.

You can use the ALTDLL and ALTDQ_DQS custom external memory interfaces to achieve these advantages.

For more information about using the dynamic calibration blocks for termination, refer to *Dynamic Calibrated On-Chip Termination (ALTOCT) Megafunction User Guide*.

For more information about using the dynamic OCT, refer to *I/O Buffer (ALTIOBUF) Megafunction User Guide*.

For more information about implementing calibrated dynamic OCT, refer to *AN 465: Implementing OCT Calibration in Stratix III Devices*.

### Create Controller Logic for the Read and Write Datapaths

Consider the following details when designing the controller for these signals:

- **General (applies to both full-rate and half-rate interfaces):**
  - The DQ signals are edge-aligned with the DQS signal during a read from the memory and are center-aligned with the DQS signal during a write to the memory.
  - The memory controller shifts the DQ signals by \(-90^\circ\) during a write operation to center-align the DQ and DQS signals. Center-align the PLL to the DQS signal with respect to the DQ signals during writes.
  - The memory controller delays the DQS signal during a read, to ensure that the DQ and DQS signals are center-align at the capture register. Use dedicated DQS phase-shift circuitry (ALTDLL and ALTDQ_DQS) to shift the incoming DQS signal during reads.
The DQS signal is generated on the positive edge of the system clock to meet the tDQSS requirement. The setup (tDS) and hold times (tDH) of the memory device for the write DQ and DM pins are relative to the edges of DQS write signals and not the CK or CK# clock.

DQ and DM signals use a clock shifted –90° from the system clock to ensure that the DQS edges are centered on the DQ or DM signals when they arrive at the DDR2 SDRAM.

DDR2 SDRAM uses the DM pins during a write operation. Driving the DM pins low shows that the write is valid. The memory masks the DQ signals if the DM pins are driven high. The timing requirements of the DM signal at the DDR2 SDRAM input are identical to those for DQ data. The Stratix III DDR registers, clocked by the –90° shifted clock, create the DM signals. While you can use any of the I/O pins in the same bank as the associated DQS and DQ pins to generate the DM signal, Altera recommends using the spare DQ pin in the same DQS group as the respective data to minimize skew.

Some DDR2 SDRAM DIMMs support error correction coding (ECC) to detect and automatically correct errors in data transmission. The 72-bit DDR2 SDRAM modules contain eight ECC pins in addition to 64-data pins. Connect the eight DDR2 SDRAM device ECC pins to a single DQS or DQ group.

The DQS, DQ, and DM board trace lengths must be tightly matched (20 ps).

The DQS is bidirectional. The DQSn pins in DDR2 SDRAM devices are optional but recommended for DDR2 SDRAM designs operating at more than 333 MHz.

The DQ pins are also bidirectional. Regardless of interface width, DDR SDRAM always operates in ×8 mode DQS groups. DDR2 SDRAM interfaces can operate in either ×4 or ×8 mode DQS groups, which is dependant on your chosen memory device or DIMM, and is also not related to the actual interface width. The ×4 and ×8 configurations use one pair of bidirectional data strobe signals, DQS and DQSn, to capture input data.

Two pairs of data strobes, UDQS and UDQS# (upper byte) and LDQS and LDQS# (lower byte), are required by the ×16 configuration devices. A group of DQ pins must remain associated with its respective DQS and DQSn pins.

Full-rate interface (refer to Figure 1–1 on page 1–2):

DQS, DQSn, DM, and DQ signals from FPGA core must be connected to the ALTDQ_DQS instance. The ALTDQ_DQS instance interfaces to the external memory (DDR and DDR2) for these pins.

Read data from the DQ input path should go through a dual-clock FIFO to transfer the data from the INPUT_PHASE_ALIGN blocks (resync_postamble_clk clock domain) to the FPGA core clock domain.

Controller has to ensure that the write data from core and DQS output path strobe are aligned to ensure that when writing data to external memory, the DQS strobe is center-aligned with the output DQ data to the external memory.
Create Controller Logic for Address and Command Pins

Because this is a custom external memory interface for DDR and DDR2 interface, you must design your own custom controller to control the address and command pins from the FPGA core.

Consider the following details when designing the controller for the \( CK \) and \( CK\# \) pins:

- DDR2 SDRAM components use \( CK \) and \( CK\# \) signals to clock the address and command signals into the memory. Furthermore, the memory uses these clock signals to generate the DQS signal during a read through the DLL inside the memory. The DDR2 SDRAM data sheet specifies the following timings:
  - \( t_{DQSCK} \) is the skew between the \( CK \) or \( CK\# \) signals and the DDR3 SDRAM-generated DQS signal
  - \( t_{DSH} \) is the DQS falling edge from \( CK \) rising edge hold time
  - \( t_{DSS} \) is the DQS falling edge from \( CK \) rising edge setup time
  - \( t_{DQSS} \) is the positive DQS latching edge to \( CK \) rising edge
  - \( t_{DQSCX} \) is the DQS output access time from \( CK \)

- The DDR2 SDRAM has a write requirement (\( t_{DQSS} \)) that states the positive edge of the DQS signal on writes must be \( \pm 25\% \) (\( \pm 90^\circ \)) of the positive edge of the DDR2 SDRAM clock input. Therefore, the memory controller should generate the \( CK \) and \( CK\# \) signals using the DDR registers in the IOE to match with the DQS signal and reduce any variations across process, voltage, and temperature. The positive edge of the DDR2 SDRAM clock, \( CK \), is aligned with the DQS write to satisfy \( t_{DQSS} \).
Consider the following details when designing the controller for the A (address), BA (bank address), CKE, CS#, RAS#, CAS#, WE#, and ODT pins:

1. Address and command signals in DDR2 SDRAM components are clocked into the memory device with the CK or CK# signal. These pins operate at a single data rate (SDR) using only one clock edge. The number of address pins depends on the DDR2 SDRAM device capacity. The address pins are multiplexed, so two clock cycles are required to send the row, column, and bank address. The CS, RAS, CAS, WE, CKE, and ODT pins are DDR2 SDRAM command and control pins. The DDR2 SDRAM address and command inputs do not have a symmetrical setup and hold time requirement with respect to the DDR2 SDRAM clocks, CK, and CK#.

2. In Stratix III and Stratix IV devices, the address and command clock should be one of the PLL dedicated clock outputs whose phase can be adjusted to meet the setup and hold requirements of the memory clock. The address and command clock is also typically half rate, although a full rate implementation can also be created. The command and address pins use the DDIO output circuitry to launch commands from either the rising or falling edges of the clock.

3. The chip selects (CS_N), clock enable (CKE), and ODT pins are only enabled for one memory clock cycle and can be launched from either the rising or falling edge of the address and command clock signal. The address and other command pins are enabled for two memory clock cycles and can also be launched from either the rising or falling edge of the address and command clock signal.

For more information about the timing requirements for the address and command pins during reading and writing operations, refer to the respective external memory device datasheet.

Create Controller Logic for the OCT Calibration Block

If calibrated series, parallel, or dynamic termination is used for the I/O in your design, your design requires a calibration block. This block requires a pair of RUP and RDN pins located in a bank that shares the same $V_{CCIO}$ voltage as your memory interface. This calibration block is not required to be in the same bank or side of the device as the IOEs it is serving. To use these capabilities in the FPGA, you must use the ALTOCT megafunction.

Consider the following details when designing the memory controller to be used with the ALTOCT megafunction:

- The RUP and RDN input ports of the ALTOCT instance must be connected to the respective RUP and RDN pins in the FPGA. Note that the RUP and RDN pins are dual-purpose pins and there are multiple pairs of RUP and RDN pins for each bank.

- The memory controller controls the calibration_request, s2pload, and calibration_wait input ports of this ALTOCT instance, to ensure that the termination is calibrated based on the PVT (process, voltage and temperature) variation requirements of the custom external memory interface.
The `calibration_busy` and `calibration_shift_busy` output ports of this ALTOCT instance must be used by the memory controller to determine when the calibration process of the termination is complete. This is important, because then only normal operations like reading to and writing from and to external memory can be performed. During termination calibration, the pins interfacing to the external memory must not be used for any operations.

The `seriesterminationcontrol` and `parallelterminationcontrol` output ports of this ALTOCT instance must be connected to the `ser_term_ctrl` and `par_term_ctrl` input ports of the ALTIOBUF instance, which interfaces with the external memory pins. This is to transfer the calibrated termination settings to the I/O buffers.

For more information about using these ports in the ALTOCT megafunction, refer to Dynamic Calibrated On-Chip Termination (ALTOCT) Megafunction User Guide.

For more information about implementing calibrated dynamic OCT in your designs, refer to AN 465: Implementing OCT Calibration in Stratix III Devices.

### Instantiate ALTIOBUF Megafunctions

All of the interface pins must be connected to I/O buffers via the ALTIOBUF megafunction. You must use this megafunction to enable differential capabilities for the I/O buffer which is connected to a differential DQS pin or to enable dynamic OCT capabilities for the respective interface pins.

Consider the following details when designing the memory controller to be used with the ALTIOBUF megafunction:

1. The `ser_term_ctrl` and `par_term_ctrl` input ports of this ALTIOBUF instance must be connected to the respective `seriesterminationcontrol` and `parallelterminationcontrol` output ports of the ALTOCT instance, which interfaces with the external memory pins. This is to transfer the calibrated termination settings to the I/O buffers.

2. The `dyn_term_ctrl` input ports of this ALTIOBUF instance must be connected. This port enables Rt during reads from the DDR and DDR2 external memory, and disables Rt during writes from the DDR and DDR2 external memory. This port must be connected to the output of the dynamic OCT DQ/DQS path in the ALTDQ_DQS instance. The input of this path in the ALTDQ_DQS instance should be connected to the memory controller, where it can determine when a read or write operation is done.

For more information about using these ports, refer to I/O Buffer Megafunction (ALTIOBUF) User Guide.

For more information about implementing calibrated dynamic OCT, refer to AN 465: Implementing OCT Calibration in Stratix III Devices.
Connect all Instances Used in Custom External Memory Interface

When all instances of ALTDLL, ALTPDLL, ALTDQ_DQS, ALTIOBUF, ALTOCT, and the custom memory controller are completed, you must connect them in the Quartus II software.

Add Constraints

The next step in the design flow is to add the timing, location, and physical constraints related to the external memory interface. These constraints include:

- Timing constraints
- Pin locations, DQ group assignments and I/O standards
- Pin loading, termination, and drive strength assignments

Unlike the ALTMEMPHY solution that automatically generates TCL scripts for timing constraints, I/O standard settings, and DQ group assignments, the ALTDLL and ALTDQ_DQS solution requires you to manually create these constraints via the Assignment Editor in the Quartus II software, and then source these assignments to a TCL script for reusability.

Timing Constraints

The ALTDLL and ALTDQ_DQS external memory solution only supports timing analysis using the TimeQuest timing analyzer with Synopsys Design Constraints (.sdc) assignments. These constraints are derived from the DDR2 and DDR SDRAM data sheet and tolerances from the board layout. The ALTDLL and ALTDQ_DQS external memory solution uses TimeQuest timing constraints and the timing driven fitter to achieve timing closure.

Consider the following details when performing timing analysis external on the memory interface:

- Read timing margins for DLL-based implementation
- Write data timing analysis
- Round-trip delay calculation
- DQS postamble timing

Because external memory interfaces are essentially source-synchronous interfaces, these are timing margins that you must verify:

- Address and command setup, and hold margin
- Half-rate address and command setup, and hold margin
- FPGA Core setup and hold margin
- FPGA Core reset and removal setup and hold margin
- Write setup and hold margin
- Read capture setup and hold margin

These are explained in detail in AN 433: Constraining and Analyzing Source-Synchronous Interfaces.
Plan Resources

This section describes planning resources.

Table 1–11 shows the pin placements that Altera recommends.

**Table 1–11. Stratix III DDR and DDR2 SDRAM Pin Placement Recommendations**

<table>
<thead>
<tr>
<th>Signal</th>
<th>Pin or FPGA</th>
<th>Pin on Memory Devices</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data (mem_dq)</td>
<td>DQ</td>
<td>DQ</td>
</tr>
<tr>
<td>Data mask (mem_dm)</td>
<td>DQ (1)</td>
<td>DM</td>
</tr>
<tr>
<td>Data strobe (mem_dqs)</td>
<td>DQS or DQS</td>
<td>DQS or DQS#</td>
</tr>
<tr>
<td>Memory clock (mem_clk)</td>
<td>DQ, or DQ, or DQSn</td>
<td>CK or CK#</td>
</tr>
<tr>
<td>Address</td>
<td>Any user I/O (2)</td>
<td>A or BA</td>
</tr>
<tr>
<td>Command</td>
<td>Any user I/O (2)</td>
<td>CS#, RAS#, CAS#, WE#, CKE, or ODT</td>
</tr>
</tbody>
</table>

**Notes to Table 1–11:**

(1) The DM pins must be in the DQ group.
(2) Ensure that address and command pins are placed on the same side of the device as the memory clock pins. If OCT is used, ensure that the RUP and RDN pins are assigned correctly.
The ALTDLL and ALTDQ_DQS external memory solution do not generate pin assignments for non-memory signals such as clock sources or pin location assignments for your design. Launch the Pin Planner to make these assignments to your design.

Advanced IO Timing

As part of I/O planning, especially with high-speed designs, you must take board-level signal integrity and timing into account. When adding an FPGA device with high-speed interfaces to a board design, the quality of the signal at the far end of the board route, and the propagation delay in getting there, are vital for proper system operation.

Perform RTL or Functional Simulation

After instantiating the SDRAM high-performance controller, it generates a design example and driver for testing the memory interface.

When using the ALTDLL and ALTDQ_DQS external memory solution, unlike the ALTMEMPHY solution, it does not use the SDRAM high-performance controller to generate an example design and driver for testing the memory interface. If you use this solution, you must create your own driver circuitry to test the custom-made controller logic with the datapath created via the ALTDLL, ALTDQ_DQS, ALTTOCT, ALTPLL, and ALTIOBUF megafunctions. This implies that you have to manually create your own testbench to verify the custom external memory interface.

To perform functional simulation with the ALTDLL and ALTDQ_DQS external memory solution, you must connect the simulation model of the driver, the simulation model of your design (which includes customized controller logic and ALTDLL and ALTDQ_DQS datapath), and the simulation model of their external memory in their functional simulation environment.

Compile Design and Verify Timing

After constraining your design, compile your design in the Quartus II software. Because the ALTDLL and ALTDQ_DQS external memory solution does not automatically generate timing reports to verify whether timing has been met, you must use SDC commands to manually compile the design.

After compiling your design in the Quartus II software, run the verifying timing script to produce the timing report for different paths, such as write data, read data, address and command, and core (entire interface) timing paths in your design.

The custom verifying timing script should report about margins on the following paths:

- Address and command setup and hold margin
- Half-rate address and command setup and hold margin
- Core setup and hold margin
- Core reset and removal setup and hold margin
- Write setup and hold margin
Read capture setup and hold margin

For more information about timing analysis and reporting using the ALTDLL and ALTDQ_DQS external memory solution, refer to AN 438: Constraining and Analyzing Timing for External Memory Interfaces.

**Adjust Constraints**

The timing report of your designs show the worst case setup and hold margin for the different paths in your design. If the setup and hold margin are unbalanced, achieve a balanced setup and hold margin by adjusting the phase setting of the clocks that clock these paths.

For example, for the address and command margin, the address and command outputs are clocked by an address and command clock that can be different with respect to the system clock, which is 0°. The system clock times the clock outputs going to the memory. If the report timing script indicates that using the default phase setting for the address and command clock results in more hold time than setup time, adjust the address and command clock to be less negative than the default phase setting with respect to the system clock to ensure that there is less hold margin. Similarly, adjust the address and command clock to be more negative than the default phase setting with respect to the system clock if there is more setup margin.
This chapter describes how to implement an 8-bit wide, 150-MHz, 300-Mbps DDR2 SDRAM full-rate interface using the ALTDLL and ALTDQ_DQS megafunctions.

This design example also provides some recommended settings, such as termination scheme and drive strength settings, to simplify your design. Although the design example is specifically for the DDR2 SDRAM interface, the design flow for a DDR SDRAM interface is the same.

At the end of this chapter, you create an example design similar to the one in www.altera.com/later/later, that targets the Stratix III FPGA Development Kit, which includes a component module (MT47H32M8BP-3:B). You can adapt this design to target any other board.

Software Requirements

This chapter assumes that you have experience with the Quartus II software. In addition, ensure that you have the Quartus II software version 9.0 or later installed.

Create a Quartus II Project and Specify a Target Device

Use the New Project wizard (File > New Project Wizard) to create a project in the Quartus II software that targets the EP3SL150F1152-C2ES device. This example design targets the EP3SL150F1152-C2 device targeting an 8-bit wide DDR2 SDRAM interface at 150 MHz. The design uses an 8-bit wide 256-MB Micron MT47H32M8BP-3:B 333-MHz DDR2 SDRAM component.

For detailed step-by-step instructions on how to create a Quartus II project, refer to the Tutorial in the Quartus II software. On the Help menu in the Quartus II window, click Tutorial.

Instantiate the PHY and Controller

This section describes the steps required to instantiate a custom PHY, implemented using the ALTDLL and ALTDQ_DQS megafunctions, as well as a custom designed controller. This design example is in Verilog HDL and consists of one top-level module or instance that connects 19 sub-modules or instances for a complete customized memory controller for DDR2. All these modules or instances are defined in the following sections.

Figure 2–1 shows the example interface between the Stratix III EP3SL150F1152-C2 device and an 8-bit wide 256-MB Micron MT47H32M8BP-3:B 333-MHz DDR2 SDRAM component.
The CK, CK_N, CK_E, CS_N, RAS_N, CAS_N, W_N, ODT, DM, BA[2:0], and ADDR[14:0] signals are output-only signals. DQ[7:0], DQS and DQS_N are bidirectional signals.

**Instantiate ALTPLLL MegafUNCTIONS**

This design example uses the ALTPLLL megafunction to implement two PLLs that clock the entire full-rate interface. Use the MegaWizard Plug-In Manager (Tools menu) to instantiate two variations of the ALTPLLL megafunction with the following parameters:

- **pll_1**:
  - in_clock = 50 MHz
  - mode = no compensation
  - c0 = 150 MHz, 0° phase shift. Used to clock the dll_1 instance. This PLL is dedicated to clock only the DLL

- **pll_2**:
  - in_clock = 50 MHz
  - mode = normal
  - c0 = 150 MHz, 0° phase shift. This is the mem_clk. It is used to clock the registers in the altdq_dqs_1 instance (the DQS output registers, the DQS OE registers, the DQS dynamic OCT registers, and DQ dynamic OCT registers), in the mem_clock_generate instance (the registers for generating CK and CK_N signals), the control_init_ddr instance (state machine for initialization of the DDR2), the control_write_ddr instance (state machine for writing data to the DDR2), the control_read_ddr instance (state machine for reading data from the DDR2), and the control_driver_ddr instance (state machine for driving
the control_init_ddr instance, control_write_ddr instance, and control_read_ddr instance). It is also used to clock the registers in the addr_cmd_generate and addr_cmd_generate_oe instances which are used to generate the ADDR[14:0], BA[2:0], CK_E, CS_N, RAS_N, CAS_N, WE_N, and ODT signals.

- \( c_1 = 150 \text{ MHz, } -90^\circ \text{ phase shift. This is the write_clk. It is used to clock the registers in the } altdq_dqs_1 \text{ instance (the DQ output registers and the DQ OE registers).}

### Instantiate the ALTDLL Megafunction

After deciding on the clocking scheme, you use the ALTDLL megafunction to instantiate a DLL of the correct operational frequency (DQS signal frequency) of the custom external memory. This frequency setting depends on the bandwidth you want.

Use the MegaWizard Plug-In Manager to instantiate a variations of the ALTPLL megafunction with the following parameters:

- \( \text{dll_1:}
- \quad \text{turn on jitter reduction} = \text{No}
- \quad \text{delay chain length} = 12
- \quad \text{delay buffer mode} = \text{low}
- \quad \text{DQS input frequency} = 150 \text{ MHz}
- \quad \text{Instantiate DLL offset control A} = \text{No}
- \quad \text{Instantiate DLL offset control B} = \text{No}
- \quad \text{create ‘dll_aload’ port} = \text{No}
- \quad \text{create ‘dll_dqsupdate’ port} = \text{Yes}

### Instantiate ALTDQ_DQS Megafunction

Next, you initialize the settings for the dedicated circuitry for external memory interfaces using the ALTDQ_DQS megafunction.

This custom DDR2 external memory interface consists of the following:

- One pair of differential DQS/DQSn I/O pin (read or write strobe/clock)
- Eight DQ I/O pins (read or write data)
- One DM pin (output-only data mask)

The following section describes how to instantiate a variation of the ALTDQ_DQS megafunction with the correct parameters.

### Specify altdq_dqs_1 Parameters

This section provides descriptions of the options that must be set for the altdq_dqs_1 instance on the individual pages of the ALTDQ_DQS MegaWizard Plug-In Manager for full-rate mode.
Page 3 of the ALTDQ_DQS MegaWizard Plug-In Manager is the **Parameter Settings** page. To configure the general settings for the ALTDQ_DQS instance, specify the options shown in **Table 2–1**.

This completes the parameter settings for the altdq_dqs_1 instance for this design example.

**Design Customized Memory Controller Datapath Logic**

Because this is a custom external memory interface for DDR2 interface, you must design the necessary datapath to control the CK, CK_N, ADDR[14:0], BA[2:0], CK_E, CS_N, RAS_N, CAS_N, WE_N, and ODT signals. Altera provides a design example that you can use to create your own logic.

In the Altera-provided design example, the datapath of the CK and CK_N signals are controlled by the mem_clock_generate instance. This instance consists of two DDIO_OUT blocks. For the CK signal, the inputs of the DDIO_OUT block are each tied to VCC and GND. For the CK_N signal, the inputs of the DDIO_OUT block are each tied to GND and VCC to reflect the inverse of the CK signal.

The addr_cmd_generate instance controls the datapath of the ADDR[14:0], BA[2:0], CK_E, CS_N, RAS_N, CAS_N, WE_N, and ODT signals. This addr_cmd_generate instance consists of 24 DDIO_OUT blocks to individually represent the 24 signals. For these signals, there are 24 DFF blocks to control their respective OE (output enable) signals. The OE signals are controlled by the addr_cmd_generate_oe instance. The inputs of these 48 blocks are fed accordingly with data, depending on the three state machines that act as the control path of the customized memory controller. The three state machines are as follows:

- control_init_ddr instance
- control_write_ddr instance

- control_driver_ddr instance

### Multiplexer Instances

There are two multiplexer instances: cmd_addr_mux_1 and dqs_dqsn_dq_dm_mux_1.

**cmd_addr_mux_1**

The cmd_addr_mux_1 instance is a 144-bit to 72-bit multiplexer with a 1-bit select signal. The cmd_addr_mux_1 instance multiplexes the CK_E, CK_N, RAS_N, CAS_N, WE_N, BA_OE, BA_DATA, ADDR_OE, ADDR_DATA and ODT signals from the following two control path state machines of the customized memory controller:

- control_init_ddr instance
- control_write_ddr instance

The output of the multiplexer is sent to the data path of the command and address instances, addr_cmd_generate and addr_cmd_generate_oe. For this multiplexer, the control_driver_ddr instance controls the 1-bit select.

**dqs_dqsn_dq_dm_mux_1**

The dqs_dqsn_dq_dm_mux_1 instance is a 66-bit to 33-bit multiplexer with a 1-bit select signal. The dqs_dqsn_dq_dm_mux_1 instance multiplexes the dm_oe, dm_data, dq_oe, dq_data, dqs_oe, dqs_data, dqsn_oe, and dqsn_data signals from the following two control path state machines of the customized memory controller:

- control_init_ddr instance
- control_write_ddr instance

The output of the multiplexer is sent to the data path of the DQS, DQSN, DQ, and DM (ALTDQ_DQS instance), which is the altdq_dqs_1 instance. The 1-bit select for this multiplexer is controlled by the control_driver_ddr instance.

This completes the steps for the customized memory controller datapath logic to generate the CK, CK#, ADDR[14:0], BA[2:0], CK_E, CS_N, RAS_N, CAS_N, WE_N, and ODT signals.

### Design Customized Memory Controller Control Path Logic

Because this is a custom external memory interface for the DDR and DDR2 interface, you must design control path logic to control the DQS, DQS_N, DQ, DM, A (address), BA (bank address), CK, CK#, CKE, CS#, RAS#, CAS#, WE#, and ODT signals from the FPGA core.

The design example contains three state machines to control these signals to enable proper operation of the external memory interface. These state machines are as follows:
 Instantiate the PHY and Controller

The control_init_ddr instance initializes the DDR2 component for the proper interface operation following the timing requirements as specified in the specific Micron DDR2 datasheet. Because the ALTMEMPHY megafonction does not support a burst length of 8, the customized memory controller in this design example initialized the DDR2 for this mode of operation.

The control_write_ddr instance writes a set of 8 data to the memory array in the DDR2 component following the timing requirements as specified in the specific Micron DDR2 datasheet.

The control_driver_ddr instance coordinates the two state machines (control_init_ddr and control_write_ddr instances) following the timing requirements as specified in the specific Micron DDR2 datasheet to enable proper operation of this design example. This includes sequentially enabling the following instances:

- The control_init_ddr instance state machine to initialize the DDR2 component
- The control_write_ddr instance state machine to write the data to the memory array in the DDR2 component

The state machine also controls the select signals of the two multiplexers (cmd_addr_mux_1 and dqsn_dq_dm_mux_1) depending on which of the two control path state machine is currently active.

Instantiate ALTIOBUF Megafunctions for Pins

For an external memory interface, the DQ, DQS, DQSn, DM, ADDR[14:0], BA[2:0], CK, CK_N, CK_E, CS_N, RAS_N, CAS_N, WE_N, and ODT pins must be connected to I/O buffers via the ALTIOBUF megafunction. There are 14 interface signals for this design example that need I/O buffers to be interfaced with the FPGA pins. These I/O buffers are contained in the dqs_io_buffer, ck_io_buffer, dq_io_buffer, dm_io_buffer, addr_io_buffer, ba_io_buffer, and cmd_io_buffer instances. There are 35 I/O buffers used in this instance.

Table 2–10 shows the requirements that must be set for these signals in the I/O buffer instances.

<table>

Add Constraints to Design Example

After instantiating the necessary instances to create a customized DDR2 memory controller from the “Instantiate PHY (via ALTDLL and ALTDQ_DQS) and (Custom-Designed) Controller in a Quartus II Project” stage, you must generate the constraints files for the design example. Apply these constraints to the design before compilation.

You must manually specify constraints because this design example does not use the ALTMEMPHY megafuction or the DDR2 SDRAM high-performance controller.

Add Timing Constraints

When you instantiate the customized DDR2 memory controller design, it does not automatically generate a timing constraint file (SDC file). You must manually create your own SDC file to constrain the timing on this design. This design example comes with a timing constraints file, `top_custom_ddr2_controller_phy_ddr_timing.sdc`.

The timing constraint file constrains the clocks on the customized DDR2 memory controller design.

To add timing constraints, perform the following steps:

1. On the Assignments menu, click Settings.
2. In the Category list, expand Timing Analysis Settings and select TimeQuest Timing Analyzer.
3. Select the `top_custom_ddr2_controller_phy_ddr_timing.sdc` file and click Add.
4. Click OK.

Set Top-Level Entity

Before compiling the design, set the top-level entity of the project. The design example top-level file is `top_custom_ddr2_controller.v`, which connects 13 other sub-modules or instances for a complete customized memory controller for DDR2.
To set the top-level file, perform the following steps:
1. Open the top-level entity file, `top_custom_ddr2_controller.v`.
2. On the Project menu, click Set as Top-Level Entity.

**Set Optimization Technique**

To ensure the remaining unconstrained paths are routed with the highest speed and efficiency, set the optimization technique to **Speed**. To set the optimization technique, perform the following steps:
1. On the Assignments menu, click **Settings**.
2. Select **Analysis & Synthesis Settings**.
4. Click OK.

**Set Fitter Effort**

To set the Fitter effort to Standard Fit, perform the following steps:
1. On the Assignments menu, click **Settings**.
2. Expand **Fitter Settings**.
3. Turn on **Optimize Hold Timing** and select **All Paths**.
4. Turn on **Optimize Fast Corner Timing**.
5. Under **Fitter Effort**, select **Standard Fit**.
6. Click OK.

**Enter Pin Location Assignments**

To enter the pin location assignments, perform the following steps:
1. On the Processing menu, point to Start, and click **Start Analysis and Synthesis**.
2. Assign all your pins, so the Quartus II software fits your design correctly and gives correct timing analysis. To assign pin locations for the Stratix III development kit, run the `top_custom_ddr2_controller_PinLocations.tcl` file, which is provided with the design example or manually assign pin locations with the Pin Planner using the Stratix III FPGA Development Kit at the Altera website.

If you are at the design exploration phase of your design cycle and do not have any PCB defined pin locations, you should still manually define an initial set of pin constraints, which can become more specific during your development process.
To manually assign pin locations, perform the following steps:

1. Open Pin Planner. On the Assignments menu, click **Pin Planner**.

2. Assign DQ and DQS pins.
   a. To select the device DQS pin groups that the design uses, assign each DQS pin in your design to the required DQS pin in the Pin Planner. The Quartus II Fitter then automatically places the respective DQ signals onto suitable DQ pins within each group. To see the DQS groups in Pin Planner, right-click, select **Show DQ/DQS Pins**, and click **In ×8/×9 Mode**. Pin Planner shows each DQS group in a different color and with a different legend: S = DQS pin, Sbar = DQSn pin, and Q = DQ pin.

   Most DDR2 SDRAM devices operate in ×8/×9 mode. However, some DDR2 SDRAM devices operate in ×4 mode. Refer to your specific memory device datasheet.

   b. Select the DQ mode to match the DQ group width (number of DQ pins/number of DQS pins) of your memory device. DQ mode is not related to the memory interface width.

   The DQ group order and DQ pin order in each group is not important. However, you must place DQ pins in the same group as their respective strobe pin.

3. Place DM pins in their respective DQ group.

4. Place address and control command pins on any spare I/O pins ideally in the same bank or side of the device as the CK and CK_N pins.

5. Ensure you place CK and CK_N pins on differential I/O pairs for the CK/CK# pin pair. To identify differential I/O pairs, right-click in Pin Planner and select **Show Differential Pin Pair Connections**. Pin pairs show a red line between each pin pair.

   You must place CK and CK_N on a DIFFIO_RX pin pair, if your design uses differential DQS signaling.

6. Place the clock_source pin on a dedicated PLL clock input pin with a direct connection to this design example’s PLL and DLL pair—usually on the same side of the device as your memory interface. This recommendation reduces PLL jitter, saves a global clock resource, and eases timing and fitter effort.

7. Place the global_reset pin (like any high fan-out signal) on a dedicated clock pin.

For more information about how to use the Quartus II Pin Planner, refer to the **I/O Management** chapter in volume 2 of the *Quartus II Handbook*. 
Board Trace Delay Models

For accurate I/O timing analysis, you must specify the board trace and loading information. This information should be derived and refined during your PCB development process of pre-layout (line) simulation and finally post-layout (board) simulation.

Perform RTL or Functional Simulation (Optional)

This section describes RTL and functional simulation. To set up simulation option, perform the following steps:

1. Unzip the top_custom_ddr2_controller_msim.zip file to any directory on your PC. Obtain and copy the vendors memory Verilog HDL simulation model to the directory where the previous zip file was uncompressed. This can be retrieved from the Micron website. Get the ddr2.v, ddr2_mcp.v, and ddr2_parameters.vh memory model files from the Micron website and save them in the directory of this design example.

2. Open the memory model file (ddr2.v) in a text editor and add the following define statements to the top of the file:

   'define sg3
   'define x8
   'define MAX_MEM

   The three define statements prepare the DDR2 SDRAM interface model.

   The first statement specifies the memory device speed grade as –3.

   The second statement specifies the memory device width per DQS.

   The third statement says to allocate memory for every address supported by the DDR2 model.

3. Open the testbench (tb_top_custom_ddr2_controller.v) from the directory in a text editor, instantiate the downloaded memory model, and connect its signals to the rest of the design.

4. Start the ModelSim® software.
   b. Select the folder in which you unzipped the files.
   c. On the Tools menu, click Execute Macro.
   d. Select the top_custom_ddr2_controller_msim.do file and click Open. This is a script file for the ModelSim-Altera software to automate the necessary settings for the simulation.
   e. Verify the results shown in the Wave window.

Compile Design and Verify Timing for Design Example

To compile the design, on the Processing menu, click Start Compilation.
After successfully compiling the design, run the TimeQuest timing analyzer to verify the timing based on the SDC file. For more information about the TimeQuest Timing Analyzer window, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

For more information about timing analysis, refer to the *Timing Analysis* section of the *External Memory Interfaces Handbook*.

**Adjust Constraints for this Design Example**

If the timing margin report shows negative hold time on the address and command datapath, adjusting the clock that is regulating the address and command output registers can improve the hold margin on the address and command datapath.

**Verifying Design on a Board**

You have the option to verify the customized DDR2 memory controller design example. You can implement the necessary debug logic to observe the read and write activity of the external memory interface during FPGA run-time.

For more information about using the SignalTap II logic analyzer, refer to *Design Debugging Using the SignalTap II Embedded Logic Analyzer* chapter in volume 3 of the *Quartus II Handbook*.
Additional Information

How to Contact Altera

For the most up-to-date information about Altera® products, see the following table.

<table>

This tutorial shows how to use your existing Native interface design with the high-performance controller II (HPC II) architecture. The HPC II architecture only supports the Avalon® Memory-Mapped (Avalon-MM) interface, and requires an adaptor to work with designs using the Native interface.

The HPC II architecture offers significantly more efficient memory access with better flexibility. As HPC II only supports the Avalon-MM interface, all Native interface designs migrating to HPC II architecture must adapt to the Avalon-MM interface. The only significant difference between the two interfaces is the write data timing. Using Avalon-MM interface, the user logic presents a write request, address, burst count, and the first beat of write data at the same time. The subsequent write data beats are placed into the FIFO buffer until they are needed. In the Native interface, the user logic presents a write request, address, and burst count. The controller then requests the correct number of write data beats by asserting the write data request signal.

This tutorial shows how you can compile and simulate using the native_to_avalon_adaptor design example.

The design example implements a 200-MHz, 8-bit DDR2 SDRAM memory interface with a full-rate DDR2 SDRAM HPC II.

To download the design example, native_to_avalon_adaptor.zip, go to the External Memory Interface Design Examples page.

**Functional Description**

Figure 1–1 shows the different components of the design example and how they are connected.

**Figure 1–1. Design Example Components**

The native_to_avalon_adaptor module in the design example enables designs with Native interface to work with the Avalon-MM interface of HPC II. The module registers all its outputs except these signals: ntv_ready, ntv_rdata, ntv_rdata_valid, and ntv_wdata_req.

The native_to_avalon_adaptor module indicates it is ready to accept commands on the Native interface by asserting the ntv_ready signal. The ntv_ready signal is not registered, so the signal is asserted at the same cycle as the avl_ready signal.
The Avalon read command is the same as the Native read command; so the Native interface signals are simply registered, and connected to the Avalon interface signals. The Avalon read data and valid signals are passed to the Native interface directly without being registered.

The write command and data adaptation is slightly more complicated. The native_to_avalon_adaptor module generates data requests to the Native interface master, when it sees a valid write command request by the master. The ntv_wdata_req signal path is combinatorial, so the native_to_avalon_adaptor module is able to generate the data requests on the same cycle as the command requests. A state machine tracks the outstanding write data requested by the native_to_avalon_adaptor module on the Native interface.

The module has a maximum count of write data cycles that can be tracked, and deasserts the ntv_ready signal when the maximum count is reached. The module only handles Native interface commands with a burst of 1 or 2.

**Performance**

The adaptor has a command latency of one cycle for both read and write commands. Figure 1–2 on page 1–3 and Figure 1–3 on page 1–4 show how a read or write command is presented on the Avalon-MM interface on the following cycle after the command is presented on the Native interface.
Figure 1–2. Read Commands
Figure 1–3. Write Commands

Native Interface

- clk
- ntv_ready
- ntv_read_req
- ntv_write_req
  - ntv_addr [208, 400, 402, 404, 406, 408, 600, 602]
  - ntv_be 3
  - ntv_size 0, 2
  - ntv_rdata
  - ntv_rdata_valid
  - ntv_wdata A0, B0, C0, D0, E0, F0, A1, B1, C1, D1, E1, F1, A2, B2
  - ntv_wdata_req

Avalon-MM Interface

- clk
- avl_ready
- avl_read_req
- avl_write_req
  - avl_addr [206, 208, 400, 402, 404, 406, 408, 600]
  - avl_be 3
  - avl_size 0, 2
  - avl_burstbegin
  - avl_rdata
  - avl_rdata_valid
  - avl_wdata 0, A0, B0, C0, D0, E0, F0, A1, B1, C1, D1, E1, F1, A2, B2
There are no latencies on the `ntv_rdata` and `ntv_rdata_valid` datapaths. Figure 1–4 shows that the data from a read command is presented on the Native interface, on the same cycle the data is presented on the Avalon-MM interface.

**Figure 1–4. Read Data Returned**

The adaptor asserts the `ntv_wdata_req` signal on the same cycle where the `ntv_write_req` signal is asserted. The Native interface master then presents the `ntv_wdata` signal on the subsequent cycle.
The adaptor uses a counter to keep track of outstanding write data beats that it needs to request on the Native interface. If the counter reaches a maximum value, the adaptor deasserts the `ntv_ready` signal to stop further commands on the Native interface. To increase the number of outstanding write data beats, increase the `NTV_SIZE_COUNTER_WIDTH` parameter to a sufficient value.

### Parameters

Table 1–1 shows the parameters for the native_to_avalon_adaptor module.

<table>
<thead>

Getting Started

This section discusses the requirements and related procedures to compile and simulate the design example. This section contains the following topics:

- Software Requirements
- Directory Structure
- Compile the Design
- Simulate the Design

Software Requirements

This design example requires the following software:

- Quartus® II software, version 9.1 or later
- ModelSim®-Altera® software, version 6.5b or later
- DDR2 High-Performance Controller MegaCore® function version 9.1

Directory Structure

Figure 1–5 shows the directory structure of the design example.

Compile the Design

To compile the design example, perform the following steps:

1. Launch the Quartus II software.
2. On the File menu, click Open Project, navigate to `<your project path>/native_to_avalon_adapter_ref_de/native_to_avalon_adapter_ref_de.qpf`, and click Open.
3. On the Processing menu, click Start Compilation.

Simulate the Design

To set up the simulation environment, and start the simulation, perform the following steps:

1. Launch ModelSim-Altera.
3. Select `<your project path>/native_to_avalon_adapter_ref_de/source/simulation/modelsim` and click OK.
4. On the Tools menu, click Tcl, then click Execute Macro. Select `native_example_top_run_msim_rtl_verilog.tcl`, and click Open to start the simulation.

Alternatively, you can run the script in the ModelSim transcript window by typing `source ./native_example_top_run_msim_rtl_verilog.tcl`, or in a terminal console by typing `vsim -do ./native_example_top_run_msim_rtl_verilog.tcl`.

Figure 1–5. Directory Structure

- `native_to_avalon_adapter_ref_de`
  - Contains the Quartus project files (.qpf).
- `source`
  - Contains the source files.
- `native_to_avalon_adapter`
  - Contains the Native interface to Avalon-MM interface adaptor code.
- `ddr2_hpII`
  - Contains the files for DDR2 SDRAM High-Performance Controller II.
- `native_design`
  - Contains the code for design example using Native interface.
- `testbench`
  - Contains the testbench code.
- `simulation`
  - Contains the ModelSim simulation script.
This tutorial describes how to use the design flow to design a 64-bit wide, 267-MHz, 533-Mbps DDR2 SDRAM interface, and a 16-bit wide, 300-MHz, 600-Mbps DDR3 SDRAM interface. The design examples provide some recommended settings, including termination scheme and drive strength settings, to simplify the design. You can also use the DDR2 SDRAM design example to design a DDR SDRAM interface.

The design examples target the Arria® II GX FPGA development kit, which includes a 64-bit wide 1-GB Micron MT8HTF12864HDY-800G1 400-MHz DDR2 SDRAM SODIMM, and a 16-bit wide 1-GB Micron MT41J64M16LA-15E DDR3 SDRAM component.

To download the design examples, emi_ddr2_aii.zip and emi_ddr3_aii.zip, go to the External Memory Interface Design Examples page.

For more information about the design flow, refer to the Recommended Design Flow section in volume 1 of the External Memory Interface Handbook.

System Requirements

This tutorial requires the following hardware and software:

- DDR2 SDRAM interface:
  - Quartus® II software version 9.1
  - DDR2 SDRAM High-Performance Controller MegaCore® version 9.1
  - Arria II GX FPGA Development Kit with the EP2AGX125EF35C5 device
- DDR3 SDRAM interface:
  - Quartus II software version 9.1
  - DDR3 SDRAM High-Performance Controller MegaCore version 9.1
  - Arria II GX FPGA Development Kit with the EP2AGX260FF35C4 device

Create a Quartus II Project

Create a project in the Quartus II software that targets the respective device; EP2AGX260FF35C5 for the DDR2 SDRAM interface or EP2AGX260FF35C4 for the DDR3 SDRAM interface.

For step-by-step instructions on how to create a Quartus II project, refer to the Quartus II software tutorial by clicking the Help menu in the Quartus II window and selecting PDF Tutorials.
Chapter 2: Using DDR, DDR2, and DDR3 SDRAM Devices in Arria II GX Devices

Instantiate and Parameterize a Controller

After creating a Quartus II project, you need to instantiate a controller and set its parameters.

Instantiate a Controller

To instantiate a controller, perform the following steps:

- DDR2 SDRAM controller
  a. Copy the memory parameters file, ArriaIIGX_DDR2_Kit(MT8HTF12864HDY-800G1).xml, to your <installation directory>\ip\ddr2_high_perf\lib directory.
  b. Launch the MegaWizard™ Plug-in Manager.
  c. In the MegaWizard Plug-In Manager, expand External Memory in the Interfaces folder and select the DDR2 SDRAM High Performance Controller.
  d. Enter ddr2_sodimm for the name of the DDR2 SDRAM high-performance controller.

- DDR3 SDRAM controller
  a. Copy the memory parameters file, ArriaIIGX_DDR3_Kit(MT41J64M16LA-15E).xml, to your <installation directory>\ip\ddr3_high_perf\lib directory.
  b. Launch the MegaWizard Plug-in Manager.
  c. In the MegaWizard Plug-In Manager, expand External Memory in the Interfaces folder and select the DDR3 SDRAM High Performance Controller.
  d. Enter ddr3 for the name of the DDR3 SDRAM high-performance controller.

Both the DDR2 and DDR3 design examples instantiate the ALTMEMPHY megafunction automatically.

Parameterize DDR2 SDRAM

To parameterize the DDR2 high-performance controller to interface with a 267-MHz 64-bit wide DDR2 SDRAM interface, perform the following steps:

1. In the Memory Setting tab, set Speed grade to 5.
2. For PLL reference clock frequency, enter 100 MHz. The input clock source, clock_source, supplies the PLL reference clock frequency.
3. For Memory clock frequency, enter 267 MHz. This value is the maximum frequency supported for the DDR2 SDRAM interface on Arria II GX devices.
4. For Memory Presets, select Micron ArriaIIGX_DDR2_Kit(MT8HTF12864HDY-800G1), which gives a 64-bit wide 1-GB 400-MHz DDR2 SODIMM.
5. To create or modify a memory preset, click Modify parameters. In the Preset Editor dialog box, modify the memory presets. Refer to Figure 2–1 on page 2–3.
6. Turn on the Enable Memory Chip Calibration in Timing Analysis option in the Advanced page. This option is required for Arria II GX devices, which need post-processing script to remove timing model pessimism.

7. In the PHY Settings tab, under Advanced PHY Settings, turn on the Use differential DQS option to enhance signal to noise ratio. Turn on this option if noise margin is a concern.

8. By default, Clock Phase is set to 90 for Address/Command Clock Settings.

The Auto-Calibration Simulation Options parameter is for RTL simulation only and is not applicable for gate-level simulation. ALTMEMPHY does not support gate-level timing simulation.
9. In the **Board Settings** tab, enter the following values for the parameters under **Slew Rates** and **Board Skews**:
   - CK/CK# slew rate (Differential) = 2.475 V/ns
   - Addr/Command slew rate = 0.859 V/ns
   - DQS/DQS# slew rate (Differential) = 1.386 V/ns
   - DQ slew rate = 2.665 V/ns
   
   These slew rates are obtained from a simulation using the default I/O standard and drive options.
   
   - Max skew within DQS group = 0.0339 ns
   - Max skew between DQS groups = 0.0824 ns
   - Addr/Command to CK skew = 0.0356 ns

   The Intersymbol Interference parameters are not applicable for single rank configurations. Set all these parameters to 0 ns.

10. In the **Controller Settings** tab, for **Controller Architecture**, select **High Performance Controller II** for higher efficiency and advanced features.

11. Under **Efficiency**, select the specified values for the following options:
   
   a. For **Command Queue Look-Ahead Depth**, select 6.
   
   b. For **Local-to-Memory Address Mapping**, select **CHIP-ROW-BANK-COL**.
   
   c. For **Local Maximum Burst Count**, select 8.

12. Click **Next**.

13. Turn on the **Generate simulation model** option to generate the simulation model for the RTL simulation.

14. Click **Finish** to generate your MegaCore function variation. The MegaWizard Plug-In Manager generates all the files necessary for your DDR2 SDRAM controller and a top-level design, which you use to test or verify the board operation.

For more information about the DDR_DDR2 SDRAM high-performance controller, refer to the **DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide** in volume 3 of the **External Memory Interface Handbook**.

**Parameterize DDR3 SDRAM**

To parameterize the DDR3 high-performance controller to interface with a 300-MHz, 16-bit wide, DDR3 SDRAM interface, perform the following steps:

1. In the **Memory Setting** tab, set **Speed grade** to 4.
2. For **PLL reference clock frequency**, enter 100 MHz, to match the on-board oscillator.
3. For **Memory clock frequency**, enter 300 MHz. This is the maximum frequency supported for DDR3 SDRAM interface on Arria II GX devices.
4. For Memory Presets, select Micron ArriaIIGX_DDR3_Kit(MT41J64M16LA-15E), which gives a 16-bit wide 1-GB 667-MHz DDR3 component. Refer to Figure 2–2.

Figure 2–2. Parameterize the DDR2 SDRAM High-Performance Controller

5. To create or modify a memory preset, click Modify parameters. In the Preset Editor dialog box, modify the memory presets (Figure 2–3 on page 2–6).
6. In Advanced page, turn on the Enable Memory Chip Calibration in Timing Analysis option. This option is required for Arria II GX devices, which need post-processing script to remove timing model pessimism.

7. Under Address/Command Clock Settings, use the default value of Clock Phase, which is 90.

8. In the Board Settings tab, set the following Slew Rates and Board Skews parameters to the specified values:
   - CK/CK# slew rate (Differential) = 4 V/ns
   - Addr/Command slew rate = 2 V/ns
   - DQS/DQS# slew rate (Differential) = 1.8 V/ns
   - DQ slew rate = 1.5 V/ns
These slew rates are obtained from simulation using the default I/O standard and drive options.

- Max skew within DQS group = 0.020 ns
- Max skew between DQS groups = 0.020 ns
- Addr/Command to CK skew = -0.045 ns

The Intersymbol Interference parameters are not applicable for single rank configurations. Set all these parameters to 0 ns.

9. In the Controller Settings table, for Controller Architecture, select High Performance Controller II for higher efficiency and advanced features.

10. Under Efficiency, select the specified values for the following options:
   a. For Command Queue Look-Ahead Depth, select 6.
   b. For Local-to-Memory Address Mapping, select CHIP-ROW-BANK-COL.
   c. For Local Maximum Burst Count, select 4.

11. Click Next.

12. Turn on the Generate simulation model option to generate the simulation model for the RTL simulation.

13. Click Finish to generate your MegaCore function variation. The MegaWizard Plug-In Manager generates all the files necessary for your DDR3 SDRAM controller and generates an example top-level design, which you use to test or verify board operation.

For more information about the DDR3 SDRAM high-performance controller, refer to the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide in volume 3 of the External Memory Interface Handbook.

Add Constraints

After instantiating the DDR2 or DDR3 SDRAM high-performance controller, the ALTMEMPHY megafuction generates the constraint files for the design example. You must apply these constraints to the design before compilation.

Set the Top-Level Entity

The top-level entity of the project must be set to the correct entity. The naming convention for an ALTMEMPHY megafuction entity is <variation_name>.phy.v or vhd; an SDRAM high-performance controller entity is <variation_name>.v or vhd.

To set the top-level file, perform the following steps:

1. Open the entity file, ddr2_sodimm_example_top.v or vhd for the DDR2 design example or ddr3_example_top.v or vhd for the DDR3 design example.

2. On the Project menu, click Set as Top-Level Entity.
Set the Optimization Technique

To ensure the remaining unconstrained paths are routed with the highest speed and efficiency, perform the following steps to set the optimization technique:

1. On the Assignments menu, click Settings.
2. Select Analysis & Synthesis Settings.
3. Select Speed under Optimization Technique. Click OK.

Set the Fitter Effort

To set the fitter effort, perform the following steps:

1. On the Assignments menu, click Settings.
2. Select Fitter Settings.
3. Turn on Optimize hold timing and select All Paths.
4. Turn on Optimize multi-corner timing.
5. Under Fitter effort, select Standard Fit (highest effort).
6. Click OK.

Add Timing Constraints

When you instantiate an SDRAM high-performance controller, it generates the timing constraints file <variation_name>_phy_ddr_timing.sdc, or <variation_name>_phy_ddr3_timing.sdc. The timing constraint file constrains the clock and input and output delay on the SDRAM high-performance controller.

To add the timing constraints, perform the following steps:

1. On the Assignments menu, click Settings.
2. In the Category list, expand Timing Analysis Settings and select TimeQuest Timing Analyzer.
3. Select the <variation_name>_phy_ddr_timing.sdc file for DDR2, or <variation_name>_phy_ddr3_timing.sdc file for DDR3 and click Add.
4. Click OK.

Add Pin and DQ Group Assignments

The pin assignment script, <variation_name>_pin_assignments.tcl, sets up the I/O standards for the memory interface.

This script does not create a clock for the design. You must create a clock for the design and provide pin assignments for the signals of both the example driver and testbench that the MegaCore variation generates.

To add the pin and I/O standards to the design example, perform the following steps:

1) On the Tools menu, click Tcl scripts.
2) Under Libraries, select <variation_name>_pin_assignments.tcl
3) Click Run.
Enter Pin Location Assignments

To enter the pin location assignments using the Pin Planner, perform the following steps:

1. Run analysis and synthesis. On the Processing menu, point to Start and click Start Analysis & Synthesis.

2. Assign all of your pins, so that the Quartus II software fits your design correctly and gives correct timing analysis. Manually assign the pin locations by using the Pin Planner or Assignment Editor. To assign the pin locations for the Arria II GX Development Kit, run the Altera®-provided ArriaIIGX_DDR2_PinLocations.tcl script for the DDR2 SDRAM interface design or the ArriaIIGX_DDR3_PinLocations.tcl script for the DDR3 SDRAM interface design.

If you are at the design exploration phase of your design cycle and do not have any PCB defined pin locations, you must still manually define an initial set of pin constraints, which can become more specific during your development process.

To manually assign pin locations using Pin Planner, perform the following steps:

1. On the Assignments menu, click Pin Planner.

2. Assign DQ and DQS pins.

   a. To select the device DQS pin groups that the design uses, assign each DQS pin in your design to the required DQS pin in the Pin Planner. The Quartus II Fitter then automatically places the respective DQ signals onto suitable DQ pins within each group. To see DQS groups in Pin Planner, right click, select Show DQ/DQS Pins, and click In ×8/×9 Mode. Pin Planner shows each DQS group in a different color and with a different legend: S = DQS pin, Sbar = DQSn pin and Q = DQ pin (refer to Figure 2–4).

   Most memory devices operate in ×8/×9 mode; however, as some memory devices operate in ×4 mode, refer to your specific memory device datasheet.

   b. Select the DQ mode to match the DQ group width (number of DQ pins/number of DQS pins) of your memory device. DQ mode is not related to the memory interface width.

   DQ group order and DQ pin order within each group is not important. However, you must place the DQ pins in the same group as their respective strobe pin.
3. Place the DM pins within their respective DQ group.

4. Place address and control command pins on any spare I/O pins, ideally in the same bank or side of the device as the mem_clk pins.

5. Ensure that you place mem_clk pins on differential I/O pairs for the CK/CK# pin pair. To identify the differential I/O pairs, right-click in the Pin Planner and select Show Differential Pin Pair Connections. The pin pairs show a red line between each pin pair.

6. Ensure that the mem_clk pins use any regular adjacent I/O pins; ideally the differential I/O pairs for the CK/CK# pin pair. To identify the differential I/O pairs, right-click in Pin Planner and select Show Differential Pin Pair Connections. Pin pairs show a red line between each pin pair.

7. Place the clock_source pin on a dedicated PLL clock input pin with a direct connection to the SDRAM controller PLL and DLL pair—usually on the same side of the device as your memory interface. This recommendation reduces PLL jitter, saves a global clock resource, and eases timing and fitter effort.

8. Place the global_reset_n pin (as any high fan-out signal) on a dedicated clock pin.

9. Ensure that you place the R_UP and R_DN pins, termination_blk0~_rdn_pad and termination_blk0~_rup_pad, at locations within the same V CCIO voltage bank.

For more information about how to use the Quartus II Pin Planner, refer to the I/O Management chapter in volume 2 of the Quartus II Handbook.
Assign I/O Standards

To assign the I/O standards, perform the following steps:

1. On the Assignments menu, click Assignment Editor.
2. Specify LVDS as the I/O standard for clock_source.
3. Specify 1.8 V for DDR2 SDRAM, or 1.5 V for DDR3 SDRAM as the I/O standard for global_reset_n and mem_odt[0].

Assign Virtual Pins

The example top-level design, which is auto-generated by the high-performance controller, includes an example driver to stimulate the interface. This example driver is not part of the SDRAM high-performance controller IP, but allows easy testing of the IP.

The example driver outputs several test signals to indicate its operation and the status of the stimulated memory interface. These signals are pnf, pnf_per_byte, test_complete, and test_status. These signals are not part of the memory interface, but are for testing. You must either take these signals to a debug header or set the signals to virtual pins using the Quartus II Assignment Editor. When using the example driver for testing, do not remove these signals from the top-level signal list; otherwise, the Quartus II software optimizes the driver away and the example driver fails.

To assign virtual pin assignments for the Arria II GX development board, run the Altera-provided ArriaIIGX_DDR2_exdriver_vpin.tcl file for the DDR2 SDRAM design example or ArriaIIGX_DDR3_exdriver_vpin.tcl file for DDR3 SDRAM design example, or manually assign the virtual pin assignments using the Assignment Editor.

Enter Board Trace Delay Models

For accurate I/O timing analysis, the Quartus II software must be aware of the board trace and loading information. This information must be derived and refined during your PCB development process of pre-layout (line) simulation through post-layout (board) simulation.

For external memory interfaces that use memory modules (DIMMs), the board trace and loading information must also include the trace and loading information of the module, which you can obtain from your memory vendor.

To enter board trace information, perform the following steps:

1. In the Pin Planner, select the pin or group of pins that you want to enter the information for.
2. Right-click and select Board Trace Model, as shown in Figure 2-5.
Figure 2–5. Board Trace Model

Table 2–1 shows the board trace model parameters for the Arria II GX development board.

Perform RTL or Functional Simulation (Optional)

After instantiating the DDR2 or DDR3 SDRAM high-performance controller, the Quartus II software generates a design example that includes driver, test bench, and memory model that allows you to perform functional simulation on your design.

The Verilog HDL or VHDL simulation model of the PHY, `<variation_name>_alt_mem_phy_sequencer_wrapper.vo/.vho` file, is located in your project directory.

To run the simulation with NativeLink, perform the following steps:

1. Set the absolute path to your third-party simulator executable file, by performing the following steps:
   a. On the Assignments menu, point to EDA Tool Settings.
   b. In the Category list, expand EDA Tool Settings and click Simulation.
   c. Under Tool name, select ModelSim.
   d. Under NativeLink settings, select Compile test bench and click Test Benches.
   e. Click New.
   f. Type the name of your testbench top-level module and simulation period.
   g. Click OK.

Note to Table 2–1:
(1) Addr = Addr, ba, we#, ras#, odt, and cas.
(2) The near (FPGA end of line) board trace model summary is not applicable for memory components configuration.

Note:
(1) Addr = Addr, ba, we#, ras#, odt, and cas.
(2) The near (FPGA end of line) board trace model summary is not applicable for memory components configuration.
2. To elaborate your design, on the Processing menu, point to Start and click Start Analysis & Elaboration.

3. On the Tools menu, point to the Run EDA Simulation Tool and click EDA RTL Simulation. This step creates the \simulation directory in your project directory and a script that compiles all necessary files and runs the simulation.

### Compile Design and Verify Timing

To compile the design, on the Processing menu, click Start Compilation. After successfully compiling the design, the Quartus II software automatically runs the verify timing script, which produces a timing report for the design together with the compilation report.

The report timing script provides information about the following margins and paths:

- Address and command setup and hold margin
- Core setup and hold margin
- Core reset, removal setup, and hold margin
- Read capture setup and hold margin
- Write setup and hold margin
- Read resync setup and hold margin
- DQS vs CK setup and hold margin

Figure 2–6 shows the timing margin report for a DDR2 SDRAM interface design in the message window in the Quartus II software.

You can also obtain the timing report by running the report timing script (ddr2_sodimm_phy_report_timing.tcl or ddr3_phy_report_timing.tcl) in the TimeQuest timing analyzer. To obtain the timing report in the TimeQuest Timing Analyzer window, perform the following steps:

1. In the Quartus II software, on the Tools menu, click TimeQuest Timing Analyzer.
2. On the Tasks pane, double-click Report DDR to run Update Timing Netlist, Create Timing Netlist, and Read SDC File. This command subsequently executes the report timing script to generate the timing margin report.

Figure 2–7 shows the timing margin report in the TimeQuest Timing Analyzer window after the report timing script runs. The results are the same as the Quartus II software results.
Chapter 2: Using DDR, DDR2, and DDR3 SDRAM Devices in Arria II GX Devices 2–15
Compile Design and Verify Timing

You must verify the timing on every corner of the timing model. You must run the timing report script with all available timing models—slow 0°C, slow 85°C, and fast 0°C—to ensure positive margins across process, voltage, and temperature. To analyze timing on a different corner, first double-click **Set Operating Conditions** in the left pane. Select a new timing corner, then go to the Script menu and rerun the `<variation name>_report_timing.tcl` script.

For designs that target Arria II GX devices, you must run a post-processing script to remove timing model pessimism on the write and read capture path margins. For example, refer to Figure 2–8 and Figure 2–9.

**Figure 2–7. Timing Margin Report in the TimeQuest Timing Analyzer**

![Timing Margin Report in the TimeQuest Timing Analyzer](image)

**Figure 2–8. Write Margin Summary**

<table>
<thead>
<tr>
<th>Operation</th>

<td>0.261</td>
</tr>
</tbody>
</table>
The standard write and read capture margins are initially calculated using the FPGA timing model and adjusted to account for the effects not modeled by either the timing model or TimeQuest timing analyzer. These effects include memory calibration, deskew topologies, quantization error and calibration uncertainties.

The final write and read capture margins are summarized in the Report DDR margin summary. Figure 2–10 shows an example of a Report DDR margin summary.

For more information about the TimeQuest Timing Analyzer window, refer to The Quartus II TimeQuest Timing Analyzer chapter in volume 7 of the Quartus II Handbook. For information about timing analysis, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.

Verify Design on a Board

The SignalTap® II Embedded Logic Analyzer shows read and write activity in the system.

For more information about using the SignalTap II Embedded Logic Analyzer, refer to the Design Debugging Using the SignalTap II Embedded Logic Analyzer chapter in the Quartus II Handbook, AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems and AN 446: Debugging Nios II Systems with the SignalTap II Embedded Logic Analyzer.

To add the SignalTap II Embedded Logic Analyzer, perform the following steps:

1. On the Tools menu, click SignalTap II Logic Analyzer.
2. Under Signal Configuration, next to the Clock box click ... (Browse Node Finder).
3. In the **Named** box, type `*phy_clk`.

4. For **Filter**, select **SignalTap II: pre-synthesis** and click **List**.

5. In **Nodes Found**, for a DDR2 SDRAM design, select
   `ddr2_sodimm_example_top|ddr2_sodimm:ddr2_sodimm_controller_phy:ddr2_sodimm_controller_phy_inst|phy_clk|phy_clk`, or for a DDR3 SDRAM design, select
   `ddr3_example_top|ddr3:ddr3_inst|ddr3_controller_phy:ddr3_controller_phy_inst|phy_clk|phy_clk`, and click > to add the signal to **Selected Nodes**.

6. Click **OK**.

7. Under **Signal Configuration**, specify the following settings:
   - For **Sample depth**, select **512**
   - For **RAM type**, select **Auto**
   - For **Trigger flow control**, select **Sequential**
   - For **Trigger position**, select **Center trigger position**
   - For **Trigger conditions**, select **1**

8. On the Edit menu, click **Add Nodes**.

9. In the **Named** box, search for specific nodes by typing `*local*`.

10. For **Filter**, select **SignalTap II: pre-synthesis** and click **List**.

11. Select the following nodes in **Nodes Found** and click > to add to **Selected Nodes**:
   - `local_address`
   - `local_rdata`
   - `local_rdata_valid`
   - `local_read_req`
   - `local_ready`
   - `local_wdata`
   - `local_wdata_req`
   - `local_write_req`
   - `pnf`
   - `pnf_per_byte`
   - `test_complete` (trigger)

   **Note**: Do not add any DDR2 SDRAM or DDR3 SDRAM interface signals to the SignalTap II Embedded Logic Analyzer. The load on these signals increases and adversely affects the timing analysis.

12. Click **OK**.
13. To reduce the SignalTap II logic size, turn off Trigger Enable on the following bus signals:
   - local_address
   - local_rdata
   - local_wdata
   - pnf_per_byte

14. Right-click Trigger Conditions for the test_complete signal and select Rising Edge.

15. On the File menu, click Save.

   If you see the message Do you want to enable SignalTap II file “stp1.stp” for the current project, click Yes.

Figure 2–11 shows the SignalTap II Embedded Logic Analyzer after you have completed the steps.

Figure 2–11. SignalTap II Embedded Logic Analyzer
Compile the Project

After you add signals to the SignalTap II Embedded Logic Analyzer, to recompile your design, on the Processing menu, click Start Compilation.

Verify Timing

After the design compiles, ensure that TimeQuest timing analysis passes successfully. In addition to this FPGA timing analysis, check your PCB or system SDRAM timing. To perform timing analysis, run the <variation name>_phy_report_timing.tcl script.
1. On the Tools menu, click Tcl Scripts.
2. Select <variation name>_phy_report_timing.tcl.
3. Click Run.

Download the Object File

To download the object file to the device, perform the following steps:
1. Connect the development board to your computer.
2. On the Tools menu, click SignalTap II Logic Analyzer. The SignalTap II dialog box appears.
3. Click ... to open the Select Program Files dialog box.
4. Select <your project name>.sof.
5. Click Open.
6. To download the file, click the Program Device button.

Test the Design Example in Hardware

When the design example including SignalTap II Embedded Logic Analyzer successfully downloads to your development board, click Run Analysis to run once, or click Autorun Analysis to run continuously. Figure 2–12 shows the design analysis.

Figure 2–12. SignalTap II Example DDR2 SDRAM Design Analysis
Verify Design on a Board
3. Using DDR and DDR2 SDRAM Devices in Cyclone III Devices

This tutorial shows how to use the design flow described in the preceding sections to design a 32-bit wide 167-MHz DDR2 SDRAM memory interface targeted for the Cyclone® III FPGA development kit. The design example also provides some recommended settings, including termination scheme and drive strength settings, to simplify your design flow. Although the design example is specifically for the DDR2 SDRAM memory interface, the design flow is identical to that for a DDR SDRAM memory interface.

This design example targets a memory interface frequency of 167 MHz because the targeted development kit uses an EP3C120F780 device. This device is available in –7 and –8 speed grades only. You can achieve a higher clock rate, up to 200 MHz, for DDR2 SDRAM if you select a –6 speed grade device from the Cyclone III family. This design example uses the DDR2 SDRAM high-performance controller and is compiled in the Quartus® II software version 9.0.

To download the design example, emi_ddr2_ciii.zip, go to the External Memory Interface Design Examples page.

Select the Device

Cyclone III devices support various data widths for DDR2 and DDR SDRAM memory interfaces. This walkthrough uses the Cyclone III EP3C120F780C7 device with 32-bit wide DDR2 SDRAM interface up to 167 MHz on the bottom I/O banks. The 32-bit wide interface uses four ×8 groups. For the DDR2 SDRAM memory device, select Micron’s 512-MB MT47H32M16CC-3 333-MHz DDR2 SDRAM device, because it is the device used on the development board.

Top/bottom DQ groups provide the fastest performance. The Quartus II software automatically uses the top/bottom DQ groups if they are available. Combining top/bottom DQ groups with left/right DQ groups for a single interface is not recommended and may result in a degraded performance.

For more information about the DQ/DQS bus groups for different Cyclone III densities, packages, and sides of the device, refer to the External Memory Interfaces in the Cyclone III Device Family chapter in volume 1 of the Cyclone III Device Handbook.

Instantiate PHY and Controller in a Quartus II Project

Create a project in the Quartus II software targeting the EP3C120F780C7 device. Figure 3–1 shows how to target this device in the New Project Wizard.
For detailed step-by-step instructions about how to create a Quartus II project, refer to the Quartus II software tutorial by clicking the Help menu in the Quartus II window and selecting PDF Tutorials.

After creating a Quartus II project, instantiate the DDR2 SDRAM controller. This example uses the DDR2 SDRAM high-performance controller, which instantiates the ALTMEMPHY megafunction automatically. Select the DDR2 SDRAM High-Performance Controller in the Interfaces section of the MegaWizard™ Plug-In Manager. Name the controller DDR2.

The subsequent files mentioned in this document that are generated by the MegaWizard Plug-In Manager and also other project files will have DDR2 as the prefix for the file names.

The rest of this subsection specifies the memory settings. Select the Cyclone III device with –7 speed grade. Then set the PLL reference clock frequency to 125 MHz and the memory clock frequency to 166.667 MHz. The 125 MHz PLL reference clock is provided by the on-board oscillator. Select the Micron MT47H32M16CC-3 333-MHz device. This 512-MB DDR2 device has a 16-bit data width. Figure 3–2 shows the memory settings panel after you make the selections.
The DDR2 SDRAM controller MegaWizard interface uses the default parameters for the memory when you instantiate the controller. The default parameters are based on the memory datasheets. You can customize your memory presets by modifying the parameters. Click the Modify parameters button to modify the memory attributes, memory initialization options, or memory timing parameters in the Preset Editor dialog box. In this design example, modify the memory interface DQ width to 32 to match the targeted memory width on the development kit. Figure 3–3 shows the Preset Editor dialog box after you perform the customization.
Figure 3–4 shows the PHY Settings tab. In the PHY Settings tab, under Board Timing Parameters, you must parameterize the Board Skew settings. The specified skew is across all memory interface signal types including data, strobe, clock, address and command, and is used to generate the PHY timing constraints for all paths. The default value is set to 20 ps. You must update this number based on your board specification, because this number is used to calculate the overall system timing margin.

The DDR2 SDRAM device uses the CK and CK# signals to clock the command and address signals into the memory. The controller names the CK and CK# signals mem_clk and mem_clk_n, respectively. The skew between the CK or CK# and the DDR2 SDRAM-generated DQS signal is the value of tDQSSCK in the DDR2 SDRAM data sheet.

The DDR2 SDRAM has a write requirement (tDQSS) that the positive edge of the DQS signal on writes be within ±25% (±90°) of the positive edge of the DDR2 SDRAM clock input. tDQSS is defined as the time between the DQS latching edge to its associated clock edge. The controller generates the mem_clk and mem_clk_n signals using the DDR registers in the input/output element (IOE) to match the DQS signal and reduce any variations across process, voltage, and temperature. The positive edge of the DDR2 SDRAM clock, mem_clk, is aligned with the DQS write to satisfy tDQSS.
The settings in the Auto-Calibration Simulation Options section are for RTL simulation only and are not applicable for gate-level simulation.
Figure 3–5 shows the Controller Settings panel.

**Figure 3–5. DDR2 SDRAM High-Performance Controller Settings**

Choose your local interface setting in the Controller Settings panel. Turn on the **Enable error detection and correction logic** option if you want to use error code correction (ECC). If you have your own refresh requirements, turn on **Enable user-controlled refresh**. Next, select the **Local Interface Protocol** for the memory interface. The default interface is the **Avalon Memory-Mapped Interface**. This interface allows you to easily connect to other Avalon® Memory-Mapped (Avalon-MM) peripherals.

**Figure 3–6 on page 3–7** shows the EDA panel. The MegaWizard can generate the simulation model for simulating the memory controller in either Verilog HDL or VHDL.
In the **Timing and Resource Estimation**, you can choose to generate a netlist if you are synthesizing your design with a third-party EDA synthesis tool.
Figure 3–7 shows the Summary panel.

For detailed step-by-step instructions about configuring the DDR2 SDRAM high-performance controller, refer to the DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section in volume 3 of the External Memory Interface Handbook.

Click Finish to generate the controller.

Perform RTL or Functional Simulation (Optional)

After instantiating the DDR2 SDRAM high-performance controller, the MegaWizard Plug-In Manager generates a design example and driver for testing the memory interface. Figure 3–8 shows a system-level diagram of the design example that the DDR2 SDRAM High-Performance Controller MegaWizard creates for you.
Figure 3–8. DDR2 SDRAM High-Performance Controller System-Level Diagram

Note to Figure 3–8:
(1) The ALTMEMPHY megafunction automatically generates the PLL. The PLL is part of the ALTMEMPHY megafunction.

For more information about the different files generated with the DDR2 SDRAM high-performance controller, refer to the *DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide* section and the *DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide* section in volume 3 of the *External Memory Interface Handbook*.

You can simulate the memory interface with the MegaWizard Plug-In Manager-generated IP functional simulation model. You should use this model in conjunction with your own driver or the testbench generated by the MegaWizard Plug-In Manager that issues read and write operations. The memory model file is also automatically generated by the MegaWizard Plug-In Manager in the testbench.

Use the functional simulation model with any Altera®-supported VHDL or Verilog HDL simulator. This walkthrough uses the Quartus II NativeLink feature to run the Altera-ModelSim® software to perform the simulation.

For more information about how to set up the simulation in Quartus II software using NativeLink, refer to the *Simulation Walkthrough* chapter in volume 4 of the *External Memory Interface Handbook*. 
Figure 3–9 shows an Altera-ModelSim RTL simulation.

Add Constraints

When you create your memory controller, the MegaWizard Plug-In Manager generates the following constraint files for timing constraint and pin assignment.

- **DDR2_phy_ddr_timing.sdc**
- **DDR2_pin_assignments.tcl**

The DDR2_phy_ddr_timing.sdc file is used to constrain the clock and input/output delays in the ALTMEMPHY megafunction. Enable the TimeQuest timing analyzer before compiling your design. To enable the TimeQuest timing analyzer, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. From the **Category** list, click **Timing Analysis Settings** and select **Use TimeQuest Timing Analyzer during compilation**.
3. Click **OK**.

Next, to add the timing constraints, perform the following steps:

1. On the **Settings** dialog box, click **Timing Analysis Settings** and select **TimeQuest Timing Analyzer**. The **TimeQuest Timing Analyzer** page appears.
2. Specify the SDC file and click **Add** (Figure 3–10).
3. Click OK.

Figure 3–10. Specifying the Timing Constraint SDC File for the Design Example

The DDR2_pin_assignments.tcl file specifies the I/O standard assignment for the memory interface pins. To run the Tcl file, on the Tools menu, click Tcl Scripts. Select the Tcl file and click Run (Figure 3–11 on page 3–12). Running the script adds the information into your Quartus II project. Alternatively, you can also use the Tcl Console to run the Tcl file.
After running the DDR2_pin_assignments.tcl file, you can assign the I/O locations based on your board design in the Assignment Editor or Pin Planner. In this design example, assign the I/O locations based on the Cyclone III FPGA development kit board. The 32-bit interface is located at the bottom I/O banks of the device.

### Compile Design and Verify Timing Closure

Before you compile the design, set the top level entity of the project to the design example created by the high-performance controller in the previous section, by performing the following steps:

1. On the File menu, click **Open**.
2. Browse to `<variation name>_example_top` and click **Open**.
3. On the Project menu, click **Set as Top-Level Entity**.

After you specify that the design example is the top level entity, set the Quartus II software to ensure the remaining unconstrained paths are routed with the highest speed and efficiency. To do so, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click **Analysis & Synthesis Settings**.
3. Define the **Optimization Technique** setting. The default setting is **Balanced** (Figure 3–12 on page 3–13).
Figure 3–12. Default Setting for Optimization Technique

4. In the Category list, click Fitter Settings, and set the Fitter effort. The default setting is Auto Fit (Figure 3–13 on page 3–14).
To compile your design, perform the following steps:

1. On the Processing menu, click **Start Compilation**.

2. After compilation is successful, on the Tools menu, select **TimeQuest Timing Analyzer**.

3. Generate the timing margin report for your memory interface design by executing the **Report DDR** function from the **Tasks** pane of the TimeQuest Timing Analyzer window (Figure 3–14).

Executing the Report DDR task automatically runs the `<variation_name>_phy_report_timing.tcl` timing margin report script generated by the MegaWizard Plug-In Manager when the megafunction variation was created.

For more information about the TimeQuest timing analyzer, refer to the **Quartus II TimeQuest Timing Analyzer** chapter in volume 3 of the **Quartus II Handbook**.
Figure 3–15 shows the output of the Report DDR task. The Report pane contains a new folder titled DDR with detailed timing information about the most critical paths, and a timing margin summary similar to the summary on the TimeQuest Console.
The report timing script provides information about the following margins and paths:

- Address/command setup and hold margin
- Half-rate address/command setup and hold margin
- Core setup and hold margin
- Core reset/removal setup and hold margin
- DQS vs CK setup and hold margin
- Mimic path
- Write setup and hold margin
- Read capture setup and hold margin
For more information about the timing analysis, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.

Adjust Constraints

Even if the MegaWizard Plug-In Manager generates the controller with the correct settings and you do not see any timing violation, you can manually adjust some of the constraints to improve the timing for your system. The timing margin report shows the address and command datapath with a 2.668 ns setup and 1.601 ns hold margin. Adjusting the clock that is regulating the address and command output registers can balance the setup and hold time better by decreasing the setup margin and increasing the hold margin on the address and command datapath. To determine the clock that is clocking the address and command registers, in TimeQuest timing analyzer, on the Report panel, click on the address/command report, and select the path for the setup or hold time for the address and command datapath as Path Summary (Figure 3–16) or in Waveform View (Figure 3–17).

Figure 3–16. Path Summary for the Address and Command Datapath
The report indicates that clk2 of the PLL is clocking the address and command registers. Edit PLL megafunction to change the phase setting of clk2. For this design, the initial phase setting of clk2 is –90° with reference to the system clock. By adjusting clk2 to later than –90° (specifying that the address and command launch later), the setup margin is decreased and the hold margin is increased.

Modify the clk2 phase setting to –55°, and recompile the design for the new PLL setting to take effect. Run the report timing script again. Figure 3–18 shows the timing margin reported in the Quartus II software after adjusting the phase setting of clk2. The address and command datapath now has a more balanced 2.117 ns setup and 2.128 ns hold margin.
Determine Board Design Constraints

The Cyclone III FPGA supports the series on-chip termination (OCT) to improve signal integrity and simplify the board design. The Cyclone III device supports OCT with or without calibration. In addition, you can choose the resistance value 25 Ω or 50 Ω, depending on the I/O standards you use for the memory interface and the termination scheme.

The DDR2 SDRAM supports dynamic parallel on-die termination (ODT). This feature allows you to turn on ODT when the FPGA is writing to the DDR2 SDRAM memory and turn off ODT when the FPGA is reading from the DDR2 SDRAM memory. The ODT features are available in settings of 150 Ω, 75 Ω, and 50 Ω. The 50-Ω setting is only available in DDR2 SDRAM with operating frequencies greater than 267 MHz.

Refer to the respective memory data sheet for additional information about the available settings for the ODT and the output driver impedance features, and the timing requirements for driving the ODT pin in DDR2 SDRAM.
For this design walkthrough, which targets the Cyclone III FPGA development kit, drive strength setting is used together with Class I termination. Using Class I termination allows a higher maximum DDR2 SDRAM clock frequency and reduces the number of external resistors required on the board. You can adjust the current strength of the output pin of the Cyclone III device according to your board setup. If the current strength is too high, you might see excessive overshoot and undershoot of your signal. Use the oscilloscope to check the signal overshoot and undershoot.

Figure 3–19 shows the setup for write operation to the DDR2 SDRAM memory with Class I termination together with the drive strength setting of the Cyclone III FPGA device. In this setup, the driver’s (FPGA) output impedance matches that of the transmission line, resulting in optimal signal transmission to the DDR2 SDRAM memory. On the receiver (DDR2 SDRAM memory) side, the receiving pin is properly terminated with matching impedance to the transmission line, through the external pull-up resistor to VTT, to eliminate any ringing or reflection.

If you choose not to use the drive strength setting, you can use the OCT feature of the Cyclone III FPGA device instead.

Finally, the loading seen by the FPGA during writes to the memory is different in a system using dual-inline memory modules (DIMMs) and a system using components. The additional loading from the DIMM connector can reduce the edge rates of the signals arriving at the memory, thus affecting available timing margin.

For more information about Cyclone III OCT, refer to the I/O Features in the Cyclone III Device Family chapter in volume 1 of the Cyclone III Device Handbook.
For detailed information about different effects on signal integrity design, refer to the *Board Layout Guidelines* section in volume 2 of the *External Memory Interface Handbook*. 

© February 2010 Altera Corporation
This tutorial describes how to use the design flow to design a 72-bit wide, 400-MHz, 800-Mbps DDR2 SDRAM interface with Stratix® III devices. This design example also provides some recommended settings, including termination scheme and drive strength setting, to simplify the design. Although the design example is specifically for the DDR2 SDRAM interface, the design flow for a DDR SDRAM interface is the same.

The design example targets the Stratix III FPGA development kit, which includes a 72-bit wide 1-GB Micron MT9HTF12872AY-800E 400-MHz DDR2 SDRAM DIMM. To download the design example, emi_ddr2_siii.zip, go to the External Memory Interface Design Examples page.

For more information about design flow, refer to the Recommended Design Flow section in volume 1 of the External Memory Interface Handbook.

Software Requirements

This tutorial assumes that you have experience with the Quartus® II software. This tutorial requires the following hardware and software:

- Quartus II software v9.0
- DDR and DDR2 SDRAM High-Performance Controller MegaCore® v9.0
- Stratix III FPGA development kit

Create a Quartus II Project

Create a project in the Quartus II software that targets the EP3SL150F1152-C2 device.

For detailed step-by-step instructions about how to create a Quartus II project, refer to the Quartus II software tutorial by clicking the Help menu in the Quartus II window and selecting PDF Tutorials.

Instantiate and Parameterize a Controller

After creating a Quartus II project, you need to instantiate a controller and its parameters.

Instantiate a Controller

To instantiate a controller, perform the following steps:

1. Start the MegaWizard™ Plug-In Manager.
2. In the MegaWizard Plug-In Manager, expand External Memory in the Interfaces folder and select the DDR2 SDRAM High Performance Controller.
3. Type ddr2_dimm for the name of the DDR2 SDRAM high-performance controller.
Parameterize DDR2 SDRAM with Stratix III

To parameterize the DDR2 SDRAM high-performance controller to interface with a 400-MHz, 72-bit wide DDR2 SDRAM interface.

1. In the Memory Setting tab, set Speed grade to 2.
2. For PLL reference clock frequency, type 50 MHz (to match the on-board oscillator).
3. For Memory clock frequency, type 400 MHz.
4. For the Memory Presets, select Micron MT9HTF12872AY-800, which gives a 72-bit wide 1-GB 400-MHz DDR2 DIMM.
5. To create or modify a memory preset, click Modify parameters. In the Preset Editor dialog box, you can modify the memory presets, see Figure 4–1.

Figure 4–1. Modify the Memory Presets to Create a Custom Memory

The $t_{	ext{tr}}$, $t_{	ext{th}}$, $t_{	ext{DS}}$, and $t_{	ext{DH}}$ parameters typically require slew rate derating.
For more information on slew rate derating and how to perform slew rate derating calculations, refer to the memory vendor datasheet.

Simulation and measurement show the following slew rate for the clock, address and command, DQ, and DQS pins on the Stratix III Development Board when using the default I/O standard and drive options:

- Address and command = 0.5 V/ns
- CLK and CLK# = 1.5 V/ns (differential)
- DQ = 1.5 V/ns
- DQS and DQSn = 2.8 V/ns (differential)

Hence, the correct tIS, tIH, tDS, and tDH values for this design are:

- tIS = tISb + \Delta tIS + (VIHAC – VREF)/address and command rising slew rate
  = 175 + (– 30) + 400 = 545 ps
- tIH = tIHb + \Delta tIH + (VREF – VILDC)/address and command rising slew rate
  = 250 + (– 95) + 250 = 405 ps
- tDS = tDSSa + \Delta tDS + (VIHAC – VREF)/DQ rising slew rate
  = 50 + 67 + 133 = 250 ps
- tDH = tDHa + \Delta tDH + (VREF – VILDC)/DQ rising slew rate
  = 125 + 42 + 83 = 250 ps

You should always simulate or measure your own design and topology to ensure accurate timing information and analysis.

For information about how to derate these numbers, refer to Derate Memory Setup and Hold Timing in the DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section in volume 3 of the External Memory Interface Handbook.

The DDR2 SDRAM has a write requirement (tDQSS) that states the positive edge of the DQS signal on writes must be within ± 25% (± 90°) of the positive edge of the DDR2 SDRAM clock input. To achieve this skew requirement, ALTMEMPHY-based designs always use DDR IOE registers to generate the CK and CK# signals.

6. In the PHY Settings tab, under Advanced PHY Settings turn on the Use differential DQS option to enhance signal to noise ratio. Turn on this option where noise margin is a concern. Differential DQS is recommended for DDR2 SDRAM interfaces operating at above 266 MHz and enhances signal to noise ratio. The Stratix III development board is routed for differential DQS.

7. Turn on the Enable dynamic parallel on-chip termination (OCT) option for this example. The Stratix III development board does not include discrete external termination on the DQ, DQS, or DM pins, as it was designed to use OCT.

8. Under Address/Command Clock Settings, for Dedicated clock phase type 240. Timing analysis shows that 240° is optimal for the Stratix III development board.
9. Under **Board Timing Parameters**, for **Board skew** type **20 ps**. This timing parameter is the board trace variation between the \texttt{DQ} and \texttt{DQS} pins. If your board can perform better or worse than this value, update it accordingly. The wizard uses this number to calculate the overall system timing margin. For this design example, type the value of 20 ps as the board skew tolerance target is 20 ps.

The **Auto-Calibration Simulation Options** parameter is for RTL simulation only and is not applicable for gate-level simulation.

10. Click **Next**.

11. Click **Next**.

12. Turn the **Generate simulation model** option.

13. Click **Finish** to generate your MegaCore function variation. The MegaWizard Plug-In generates all the files necessary for your DDR2 SDRAM controller, and generates an example top-level design, which you may use to test or verify board operation.

For detailed step-by-step instructions for parameterizing the DDR2 SDRAM high-performance controller, refer to **Volume 3: Implementing Altera Memory Interface IP** of the **External Memory Interface Handbook**.

### Perform RTL or Functional Simulation (Optional)

This section describes RTL and functional simulation.

#### Set Up Simulation Options

To set up simulation option, perform the following steps:

1. Obtain and copy the vendors memory model to a suitable location. For example, obtain the \texttt{ddr2.v} and \texttt{ddr2_parameters.vh} memory model files from the Micron website and save them in the testbench directory.

   Some vendor DIMM models do not use DM pin operation, which can cause calibration failures. In these cases, use the vendors component models directly.

2. Open the memory model file in a text editor and add the following define statements to the top of the file:

   \begin{verbatim}
   'define sg25
   'define x8
   \end{verbatim}

   The two define statements prepare the DDR2 SDRAM interface model.

   The first statement specifies the memory device speed grade as –25. The second statement specifies the memory device width per DQS.

3. Make sure the following statement is included in the model file:

   \begin{verbatim}
   `include "ddr2_parameters.vh"
   \end{verbatim}

4. Open the testbench in a text editor, instantiate the downloaded memory model, and connect its signals to the rest of the design.
5. Delete the whole section between the START and END MEGAWIZARD comments.

// << START MEGAWIZARD INSERT MEMORY_ARRAY
   // This will need updating to match the memory models you are using.
   // Instantiate a generated DDR memory model to match the datawidth & chipselect requirements

   ddr2_dimm_mem_model mem {
      .mem_dq (mem_dq),
      .mem_dqs (mem_dqs),
      .mem_dqs_n (mem_dqs_n),
      .mem_addr (a_delayed),
      .mem_ba (ba_delayed),
      .mem_clk (clk_to_ram),
      .mem_clk_n (clk_to_ram_n),
      .mem_cke (cke_delayed),
      .mem_cs_n (cs_n_delayed),
      .mem_ras_n (ras_n_delayed),
      .mem_cas_n (cas_n_delayed),
      .mem_we_n (we_n_delayed),
      .mem_dm (dm_delayed),
      .mem_odt (odt_delayed)
   };

   // << END MEGAWIZARD INSERT MEMORY_ARRAY

6. Instantiate the first instance of the DDR2 SDRAM model by editing the following section in the testbench file:

   ddr2 memory_0 {
      .clk (clk_to_ram),
      .clk_n (clk_to_ram_n),
      .cke (cke_delayed),
      .cs_n (cs_n_delayed),
      .ras_n (ras_n_delayed),
      .cas_n (cas_n_delayed),
      .we_n (we_n_delayed),
      .dm_rdqs (dm_delayed[0]),
      .ba (ba_delayed),
      .addr (a_delayed),
      .dq (mem_dq[7:0]),
      .dqs (mem_dqs[0]),
Make sure that port names in the memory model match with those in the testbench. Also the names and case of the names should be the same.

7. Similarly, create the other eight instances of the DDR2 module by changing the DQ, DQS, DQS_N, and DM bus indices, and the instance name memory_0. The following code shows the second ×8 memory instance of the DDR2 module:

```vhdl
ddr2 memory_1 (  .clk     (clk_to_ram),  .clk_n   (clk_to_ram_n),  .cke     (cke_delayed),  .cs_n    (cs_n_delayed),  .ras_n   (ras_n_delayed),  .cas_n   (cas_n_delayed),  .we_n    (we_n_delayed),  .dm_rdqs  (dm_delayed[1]),  .ba      (ba_delayed),  .addr    (a_delayed),  .dq      (mem_dq[15:8]),  .dqs     (mem_dqs[1]),  .dqs_n   (mem_dqs_n[1]),  .rdqs_n  (),  .odt     (odt_delayed) );
```

8. To launch the ModelSim® simulator from the Quartus II software, set the path to the ModelSim simulator in the Quartus II software:

   a. On the Tools menu click **Options**.
   b. Click **EDA Tools Options** in the **Category** list.
   c. Set the path to the simulator.
Run Simulation with NativeLink

To run the simulation with NativeLink, perform the following steps:

1. Set the absolute path to your third-party simulator executable file, by performing the following steps:
   a. On the Assignments menu, click EDA Tool Settings.
   b. In the Category list, expand EDA Tool Settings and click Simulation.
   c. Under Tool Name, select ModelSim-Altera.
   d. Under NativeLink settings, select Compile test bench and click Test Benches.
   e. Click New.

2. In the Edit Test Bench Settings dialog box, perform the following steps:
   a. Type the testbench name, testbench top-level module, design instance name, and simulation period.
   b. In the Test bench files field, include the testbench file and the memory model file (Figure 4–2).
   c. Click OK.

3. To elaborate your design, on the Processing menu, point to Start and click Start Analysis & Elaboration.

4. On the Tools menu, point to the Run EDA Simulation Tool and click EDA RTL Simulation. This step creates the \simulation directory in your project directory and a script that compiles all necessary files and runs the simulation.
For example timing diagrams, refer to Volume 3: Implementing Altera Memory Interface IP of the External Memory Interface Handbook.

Add Constraints

After instantiating the DDR2 SDRAM high-performance controller, the ALTMEMPHY megafunction generates the constraints files for the design example. Apply these constraints to the design before compilation.

Add Timing Constraints

When you instantiate an SDRAM high-performance controller, it generates a timing constraints file, <variation_name>_phy_ddr_timing.sdc. The timing constraint file constrains the clock and input and output delay on the SDRAM high-performance controller.

To add timing constraints, perform the following steps:

1. On the Assignments menu click Settings.
2. In the Category list, expand Timing Analysis Settings, and select TimeQuest Timing Analyzer.
3. Select the <variation_name>_phy_ddr_timing.sdc file and click Add.
4. Click OK.

Add Pin and DQ Group Assignments

The pin assignment script, <variation_name>_pin_assignments.tcl, sets up the I/O standards for the DDR2 SDRAM interface. It also launches the DQ group assignment script, <variation_name>_phy_assign_dq_groups.tcl, which relates the DQ and DQS pin groups together for the fitter to place them correctly in the Quartus II software.

This script does not create a clock for the design. You need to create a clock for the design and provide pin assignments for the signals of both the example driver and testbench that the MegaCore variation generates.

Run the <variation_name>_pin_assignments.tcl to add the pin, I/O standards, and DQ group assignments to the design example.

Set Top-Level Entity

Before compiling the design, set the top-level entity of the project to the correct entity. The ALTMEMPHY megafuntion entity is <variation_name>_phy.v or vhd; the SDRAM high-performance controller entity is <variation_name>.v or vhd.

The example top-level design, which instantiates the SDRAM high-performance controller and an example driver, is <variation_name>_example_top.v or vhd.

To set the top-level file, perform the following steps:

1. Open the top-level entity file, <variation_name>_example_top.v or vhd.
2. On the Project menu click Set as Top-Level Entity.
Set Optimization Technique

To ensure the remaining unconstrained paths are routed with the highest speed and efficiency, perform the following steps to set the optimization technique:

1. On the Assignments menu, click **Settings**.
2. Select **Analysis & Synthesis Settings**.
3. Select **Speed** under **Optimization Technique**. Click **OK**.

Set Fitter Effort

To set the fitter effort, perform the following steps:

1. On the Assignments menu, click **Settings**.
2. Expand **Fitter Settings**.
3. Turn on **Optimize hold timing** and select **All Paths**.
4. Turn on **Optimize multi-corner timing**.
5. Select **Standard Fit (highest effort)** under **Fitter effort**.
6. Click **OK**.

Enter Pin Location Assignments

To enter the pin location assignments, perform the following steps:

1. Run analysis and synthesis. On the Processing menu, point to **Start** and click **Start Analysis & Synthesis**.
2. Assign all of your pins, so the Quartus II software fits your design correctly and gives correct timing analysis. To assign pin locations for the Stratix III development board, run the Altera-provided **S3_Host_DDR2_PinLocations.tcl** file or manually assign pin locations by using the Pin Planner.

   > The SDRAM high-performance controller auto-generated scripts do not make any pin location assignments.

   If you are at the design exploration phase of your design cycle and do not have any PCB defined pin locations, you should still manually define an initial set of pin constraints, which can become more specific during your development process.

To manually assign pin locations using the Pin Planner, perform the following steps:

1. On the Assignments menu, click **Pin Planner**.
2. Assign DQ and DQS pins.
   a. To select the device DQS pin groups that the design uses, assign each DQS pin in your design to the required DQS pin in the Pin Planner. The Quartus II Fitter then automatically places the respective DQ signals onto suitable DQ pins within each group. To see DQS groups in the Pin Planner, right-click, select **Show DQ/DQS Pins**, and click **In x8/x9 Mode**. The Pin Planner shows each DQS group in a different color and with a different legend: S = DQS pin, Sbar = DQSn pin and Q = DQ pin, refer to Figure 4–3 on page 4–10.

   Most DDR2 SDRAM devices operate in ×8/×9 mode, however as some DDR2 SDRAM devices operate in ×4 mode, refer to your specific memory device datasheet.

   b. Select the DQ mode to match the DQ group width (number of DQ pins/number of DQS pins) of your memory device. DQ mode is not related to the memory interface width.

   DQ group order and DQ pin order within each group is not important. However, you must place the DQ pins in the same group as their respective strobe pin.

   **Figure 4–3.** Quartus II Pin Planner, Show DQ/DQS Pins, In x8/x9 Mode

3. Place the DM pins within their respective DQ group.
4. Place address and control command pins on any spare I/O pins ideally within the same bank or side of the device as the mem clk pins.

5. Ensure that you place mem clk pins on differential I/O pairs for the CK/CK# pin pair. To identify differential I/O pairs, right-click in the Pin Planner and select Show Differential Pin Pair Connections. The pin pairs show a red line between each pin pair.

You must place mem_clk[0] and mem_clk_n[0] on a DIFFIO_RX pin pair, if your design uses differential DQS signaling.

6. Ensure mem_clk pins use any regular adjacent I/O pins—ideally differential I/O pairs for the CK/CK# pin pair. To identify differential I/O pairs, right-click in the Pin Planner and select Show Differential Pin Pair Connections. The pin pairs show a red line between each pin pair.

7. Place the clock_source pin on a dedicated PLL clock input pin with a direct connection to the SDRAM controller PLL and DLL pair—usually on the same side of the device as your memory interface. This recommendation reduces PLL jitter, saves a global clock resource, and eases timing and fitter effort.

8. Place the global_reset_n pin (like any high fan-out signal) on a dedicated clock pin.

For more information on how to use the Quartus II Pin Planner, refer to the I/O Management chapter in volume 2 of the Quartus II Handbook.

Assign Virtual Pins

The example top-level design, which is auto-generated by the high-performance controller, includes an example driver to stimulate the interface. This example driver is not part of the SDRAM high-performance controller IP, but allows easy testing of the IP.

The example driver outputs several test signals to indicate its operation and the status of the stimulated memory interface. These signals are pnf, pnf_per_byte, and test_complete. These signals are not part of the memory interface, but are to facilitate testing. You should connect these signals to either a debug bus or assign the signals to virtual pins using the Quartus II Assignment Editor. When using the example driver for testing, do not remove these signals from the top-level signal list. If you remove these signals from the top-level module, the Quartus II software optimizes the driver away and the example driver fails.

To assign virtual pin assignments for the Stratix III development board, run the Altera-provided s3_Host_ddr2_edriver_vpin.tcl file or manually assign virtual pin assignments using the Assignment Editor.

Advanced I/O Timing

ALTMEMPHY-based designs assume that the memory address and command signals are matched length to the memory clock signals. Typically, this length match is not true for DIMM-based designs. You should verify the difference in your design. For the Stratix III development board fitted with the MT9HTF12872AY DIMM, the address and command signals remain asserted 750 ps longer than the clock signals.
To amend the TimeQuest .sdc file, `<variation name>`_phy_ddr_timing.sdc, to include this difference, perform the following steps:

1. Open the ddr2_dimm_phy_ddr_timing.sdc file in a text editor and find the following line (usually line 31):
   
   ```
   set t(additional_addresscmd_tpd) 0.000
   ```
   
2. Change the line to the following text:
   
   ```
   set t(additional_addresscmd_tpd) 0.750
   ```
   
3. Save the file.

If the DDR2 SDRAM controller .sdc file is regenerated, this change is lost and you must re-edit the file.

### Enter Board Trace Delay Models

For accurate I/O timing analysis, the Quartus II project must include the board trace and loading information. This information should be derived and refined during your PCB development process of prelayout (line) simulation and final post-layout (board) simulation. For external memory interfaces that use memory modules (DIMMs), this information should include the trace and loading information of the module in addition to the main and host platform. You can obtain the information from your memory vendor.

To enter board trace information, perform the following steps:

1. In the Pin Planner, select the pin or group of pins that you want to enter the information for.

2. Right-click and select **Board Trace Model**.

**Figure 4–4 through 4–14** show a typical board trace model for an address, memory clock, DQ, and DQS pin on the Stratix III development board including the data for the MT9HTF12872AY-800E memory module that is included with the kit.
Figure 4–4. Stratix III Development Board Address Signal Board Trace Model

![Stratix III Development Board Address Signal Board Trace Model](image1)

Figure 4–5. Stratix III Development Board Memory Clock Signal Board Trace Model

![Stratix III Development Board Memory Clock Signal Board Trace Model](image2)
Table 4–1 shows the board trace model parameters for the Stratix III development board.
Altera recommends you use the **Board Trace Model** assignment on all DDR and DDR2 SDRAM interface signals. To apply board trace model assignments for the Stratix III development board, run the Altera-provided **S3_Host_DDR2_BTModels.tcl** file or manually assign virtual pin assignments using the Quartus II Pin Planner.

The Stratix III development board has the following compensation capacitors fitted to its DDR2 SDRAM address and command, and CLK and CLK# signals:

- **Address and command** = 33 pF compensation capacitors
- **CLK and CLK#** = 7 pF (differential) compensation capacitors.

These capacitors are typically fitted to designs that use asymmetric DIMM designs. You should simulate your design to see if compensation capacitors are required. Stratix III devices have various programmable drive strength and OCT I/O options, so compensation capacitors should not usually be required. Fitting compensation capacitors reduces the edge rate of your signals, so you should observe memory vendor derating guidelines.

For more information on compensation capacitors, refer to *Micron Technical Note TN_47_01*.

### Compile Design and Verify Timing

To compile the design, on the Processing menu, click **Start Compilation**.

DDR, DDR2, and DDR3 SDRAM Design Tutorials © February 2010 Altera Corporation
For more information about the TimeQuest timing analyzer, refer to *The Quartus II TimeQuest Timing Analyzer* chapter in volume III of the Quartus II Handbook.

For information, refer to the *Timing Analysis* section in volume 4 of the *External Memory Interface Handbook*.

### Adjust Constraints

As the design meets timing, there is no need to adjust any constraints.

For information on timing closure, refer to the *Timing Analysis* section in volume 4 of the *External Memory Interface Handbook*.

### Determine Board Design Constraints and Perform Board-Level Simulations

Stratix III devices support both series and parallel OCT resistors to improve signal integrity. Another benefit of the Stratix III OCT resistors is eliminating the need for external termination resistors on the FPGA side. This feature simplifies board design and reduces overall board cost. You can dynamically switch between the series and parallel OCT resistor depending on whether the Stratix III devices are performing a write or a read operation. The OCT features offer user-mode calibration to compensate for any variation in voltage and temperature during normal operation to ensure that the OCT values remain constant. The parallel and series OCT features of the Stratix III devices are available in either a 25-Ω or 50-Ω setting.

Refer to the *Stratix III Device I/O Features* chapter of the *Stratix III Device Handbook*, for more information about the OCT features.

Refer to the respective memory data sheet, for more information about the available settings of the ODT and the output driver impedance features, and the timing requirements for driving the ODT pin in DDR2 SDRAM.

*Figure 4–10* illustrates the write operation to the DDR2 SDRAM with the ODT feature turned on and using the 50-Ω series OCT feature of the Stratix III FPGA device. In this setup, the transmitter (FPGA) is properly terminated with matching impedance to the transmission line, thus eliminating any ringing or reflection. The receiver (DDR2 SDRAM) is also properly terminated when the dynamic ODT setting is at 75 Ω.
4–18 Chapter 4: Using DDR and DDR2 SDRAM Devices in Stratix III and Stratix IV Devices

Adjust Termination and Drive Strength

Figure 4–10. Write Operation Using Parallel ODT and 50-Ω Series OCT of the Stratix III FPGA Device

Figure 4–11 illustrates the read operation from the DDR2 SDRAM using the parallel OCT feature of the Stratix III device. In this setup, the driver’s (DDR2 SDRAM) output impedance is not larger than 21 Ω. This impedance is in keeping with SSTL-18 JEDEC specification JESD79-2. Combined with an on dual-inline memory modules (DIMM) series resistor, the impedance matches that of the transmission line resulting in optimal signal transmission to the receiver (FPGA). On the receiver (FPGA) side, it is properly terminated with 50-Ω, which matches the impedance of the transmission line, thus eliminating any ringing or reflection.

Finally, the loading seen by the FPGA during writes to the memory is different between a system using DIMMs versus a system using components. The additional loading from the DIMM connector can reduce the edge rates of the signals arriving at the memory thus affecting available timing margin.

For more information about Stratix III devices signal integrity, refer to the Stratix III Device Signal and Power Integrity page.

Adjust Termination and Drive Strength

Due to the loading of the line, the Quartus II software may report that the default or chosen drive strength cannot drive the line to the specified toggle rate or minimum pulse width. If you encounter this error, use the stronger drive strength I/O standard. Ensure that you re-simulate your design with the new drive strength to ensure that signal quality is still acceptable.
Verify Design on a Board

The SignalTap® II Embedded Logic Analyzer shows read and write activity in the system.

For more information on using the SignalTap II Embedded Logic Analyzer, refer to the Design Debugging Using the SignalTap II Embedded Logic Analyzer chapter in the Quartus II Handbook, AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems and AN 446: Debugging Nios II Systems with the SignalTap II Logic Analyzer.

To add the SignalTap II Embedded Logic Analyzer, perform the following steps:

1. On the Tools menu, click SignalTap II Logic Analyzer.
2. In the Signal Configuration window next to the Clock box, click … (Browse Node Finder).
3. Type *phy_clk in the Named box, for Filter select SignalTap II: pre-synthesis and click List.
4. Select ddr2_dimm_example_top|ddr2_dimm:ddr2_dimm_inst|ddr2_dimm_controller_phy:ddr2_dimm_controller_phy_inst|phy_clk|phy_clk in Nodes Found and click > to add the signal to Selected Nodes.
5. Click OK.
6. Under Signal Configuration, specify the following settings:
   - For Sample depth, select 512
   - For RAM type, select Auto
   - For Trigger flow control, select Sequential
   - For Trigger position, select Center trigger position
   - For Trigger conditions, select 1
7. On the Edit menu, click Add Nodes.
8. Search for specific nodes by typing *local* in the Named box, for Filter select SignalTap II: pre-synthesis and click List.
9. Select the following nodes in Nodes Found and click > to add to Selected Nodes:
   - local_address
   - local_rdata
   - local_rdata_valid
   - local_read_req
   - local_ready
   - local_wdata
   - local_wdata_req
   - local_write_req
   - pnf
   - pnf_per_byte
   - test_complete (trigger)

   Do not add any DDR SDRAM interface signals to the SignalTap II Embedded Logic Analyzer. The load on these signals increases and adversely affects the timing analysis.

10. Click OK.

11. To reduce the SignalTap II logic size, turn off Trigger Enable on the following bus signals:
   - local_address
   - local_rdata
   - local_wdata
   - pnf_per_byte

12. Right-click Trigger Conditions for the test_complete signal and select Rising Edge.

   Figure 4–12 shows the completed SignalTap II Embedded Logic Analyzer.
13. On the File menu, click **Save**, to save the SignalTap II .stp file to your project.

   ![Image of SignalTap II Embedded Logic Analyzer](image)

   If you see the message **Do you want to enable SignalTap II file “stp1.stp” for the current project**, click **Yes**.

**Compile the Project**

Once you add signals to the SignalTap II Embedded Logic Analyzer, recompile your design, on the Processing menu, click **Start Compilation**.

**Verify Timing**

Once the design compiles, ensure that TimeQuest timing analysis passes successfully. In addition to this FPGA timing analysis, check your PCB or system SDRAM timing.

To run timing analysis, run the `<variation name>_phy_report_timing.tcl` script.

1. On the Tools menu, click **Tcl Scripts**.
2. Select `<variation name>_phy_report_timing.tcl` and click **Run**.

**Download the Object File**

To download the object file to the device, perform the following steps:

1. Connect the development board to your computer.
2. On the Tools menu, click **SignalTap II Logic Analyzer**. The SignalTap II dialog box appears.
3. Click ... to open the **Select Program Files** dialog box.
4. Select `<your project name>.sof`.
5. Click **Open**.
6. To download the file, click the **Program Device** button.

**Test the Design Example in Hardware**

When the design example including SignalTap II successfully downloads to your development board, click **Run Analysis** to run once, or click **Autorun Analysis** to run continuously. Figure 4–13 shows the design analysis.

**Figure 4–13.** SignalTap II Example DDR2 SDRAM Design Analysis
5. Using DDR3 SDRAM Devices in Stratix III and Stratix IV Devices

This tutorial describes how to use the design flow to implement a 64-bit wide, 533-MHz, 1,066-Mbps DDR3 SDRAM interface with Stratix® III devices, and a 72-bit wide, 400-MHz, 800-Mbps DDR3 SDRAM interface with Stratix IV devices. The design examples also provide some recommended settings to simplify the design.

The design examples target the Stratix III memory demonstration kit, which includes a 72-bit wide 1-GB Micron MT9JSF12872AY-1G1BZES 533-MHz DDR3 SDRAM DIMM, and the Stratix IV GX FPGA development kit, which includes four 16-bit wide 1-GB Micron MT41J64M16LA-187E 533-MHz DDR3 SDRAM devices.

To download the design examples, emi_ddr3_siii.zip and emi_ddr3_siv.zip, go to the External Memory Interface Design Examples page.

The Stratix III memory demonstration kit is not available for purchase. The early versions of the Stratix III memory demonstration kit include a MT16JTF25664AY-1G1D1 DDR3 SDRAM DIMM, which is a dual-rank DIMM and is not supported by ALTMEMPHY-based solutions. Make sure that the MT9JSF12872AY-1G1BZES DDR3 SDRAM DIMM is fitted.

For more information about the design flow, refer to the Recommended Design Flow section in volume 1 of the External Memory Interface Handbook.

System Requirements

This tutorial requires the following hardware and software for the DDR3 SDRAM interface with a Stratix III device:

- Quartus® II software version 9.1
- DDR3 SDRAM High-Performance Controller MegaCore® version 9.1
- Stratix III memory demonstration kit, with Micron MT9JSF12872AY-1G1BZES device

This tutorial requires the following hardware and software for the DDR3 SDRAM interface with a Stratix IV device:

- Quartus II software version 9.1
- DDR3 SDRAM High-Performance Controller MegaCore version 9.1
- Stratix IV GX FPGA development kit, with Micron MT41J64M16LA-187E device

Create a Quartus II Project

Create a project in the Quartus II software that targets the appropriate device; the EP3SL150F1152-C2ES device for the Stratix III device family or the EP4SGX230KF40C3ES device for the Stratix IV device family.
For step-by-step instructions to create a Quartus II project, refer to the Quartus II software tutorial by clicking the Help menu in the Quartus II window and selecting PDF Tutorials.

Instantiate and Parameterize a Controller

After you create a Quartus II project, you must instantiate a controller and its parameters.

Instantiate a Controller

To instantiate a controller, perform the following steps:

- DDR3 SDRAM controller with a Stratix III device:
  a. Copy the memory parameters files, S3MB1_Derated (Micron MT9JSF12872AY-1G1BZES).xml, to your <installation directory>\ip\ddr3_high_perf\lib directory.
  b. Start the MegaWizard™ Plug-In Manager.
  c. In the MegaWizard Plug-In Manager, expand External Memory in the Interfaces folder and select the DDR3 SDRAM High Performance Controller.
  d. Type ddr3_dimm for the name of the DDR3 SDRAM high-performance controller.

- DDR3 SDRAM controller with a Stratix IV device:
  a. Copy the memory parameters files, SD_PCIe_DDR3_Kit (4xMicron MT4J164M16LA-187E).xml, to your <installation directory>\ip\ddr3_high_perf\lib directory.
  b. Start the MegaWizard Plug-In Manager.
  c. In the MegaWizard Plug-In Manager, expand External Memory in the Interfaces folder and select the DDR3 SDRAM High Performance Controller.
  d. Type ddr3_bot_x64 for the name of the DDR3 SDRAM high-performance controller.

Both design examples instantiate the ALTMEMPHY megafunction automatically.

Parameterize DDR3 SDRAM with Stratix III

To parameterize the DDR3 SDRAM high-performance controller to interface with a 533-MHz, 72-bit wide DDR3 SDRAM interface, perform the following steps:

1. In the Memory Setting tab, set Speed grade to 2.
2. For PLL reference clock frequency, type 100 MHz (to match the on-board oscillator).
3. For Memory clock frequency, type 533 MHz (the maximum frequency supported for DDR3 SDRAM interfaces on Stratix III devices).
4. For Memory Presets, select S3MB1_Derated (Micron MT9JSF12872AY-1G1BZES), which gives a 72-bit wide, 1,152-Mbps 533-MHz DDR3 unbuffered DIMM.
5. To create or modify a memory preset, click **Modify parameters**. In the **Preset Editor** dialog box, you can modify the memory presets. Refer to Figure 5–1.

**Figure 5–1. Modify the Memory Presets to Create a Custom Memory**

The $t_{AC}$ and $t_{QHS}$ parameters are often not defined by memory vendors, as these values are only used in static RTD calculations and non-DQS capture mode. The wizard does not require these parameters, so use the default values.

The $t_{IS}$, $t_{IH}$, $t_{DS}$, and $t_{DH}$ parameters typically require slew rate derating.

Simulation and measurement show the following slew rate for the clock, address and command, and $DQ$ and $DQS$ pins on the Stratix III memory demonstration board when using the default I/O standard and drive options:

- Address and command = 1.5 V/\(\text{ns}\)
- $CLK$ and $CLK\# = 3$ V/\(\text{ns}\) (differential)
- $DQ = 2$ V/\(\text{ns}\)
- $DQS = 3$ V/\(\text{ns}\) (differential)

Hence, the correct $t_{IS}$, $t_{IH}$, $t_{DS}$, and $t_{DH}$ values for this design are:

- $t_{IS} = t_{ISb} + \Delta t_{IS} + (V_{IHAC} - V_{REF})/\text{address and command rising slew rate} = 125 + 59 + 175/1.5 = 301$ ps
- $t_{IH} = t_{IHb} + \Delta t_{IH} + (V_{REF} - V_{ILDC})/\text{address and command rising slew rate} = 200 + 34 + 100/1.5 = 301$ ps
- $t_{DS} = t_{DSb} + \Delta t_{DS} + (V_{IHAC} - V_{REF})/\text{DQ rising slew rate} = 25 + 88 + 175/2 = 201$ ps
\[ t_{DH} = t_{DHa} + \Delta t_{DH} + \frac{(V_{REF} - V_{IL})}{DQ \text{ rising slew rate}} \]
\[ = 100 + 50 + \frac{100}{2} = 200 \text{ ps} \]

For more information about how to derate these numbers, refer to Derate Memory Setup and Hold Timing in the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide in volume 3 of the External Memory Interface Handbook.

The DDR3 SDRAM has a write requirement \( t_{DQSS} \) that states the positive edge of the \( DQS \) signal on writes must be within \( \pm 25\% \) (\( \pm 90^\circ \)) of the positive edge of the DDR3 SDRAM clock input. To achieve this skew requirement, the ALTMEMPHY-based designs always use the DDR IOE registers to generate the \( CK \) and \( CK# \) signals.

6. To set the ODT settings for the DDR3 SDRAM interface on your board, in the Preset Editor dialog box, select Memory Initialization Options.

7. In the Memory Initialization Options dialog box, perform the following steps:
   a. For Output driver impedance, select \( RZQ/7 \) (which is 34).
   b. For Dynamic ODT (Rtt_WR) value, select Dynamic ODT off.
   c. For ODT Rtt nominal value, select \( RZQ/4 \) (which is 60).
   d. Click OK to apply the settings and exit the dialog box.

8. In the PHY Settings tab, under Advanced PHY Settings turn on the Enable dynamic parallel on-chip termination (OCT) option for this example.

9. Under Address/Command Clock Settings, for Dedicated clock phase type 240.

10. Under Board Timing Parameters, for Board skew type 20 ps. This timing parameter is the board trace variation between the \( CK, CK#, CAC, DQ, DQS, \) and \( DQS# \) pins. If your board can perform better or worse than this value, update it accordingly.

The Auto-Calibration Simulation Options parameter is for RTL simulation only and is not applicable for gate-level simulation.

11. In the Controller Settings tab, for Controller Architecture select High Performance Controller II for higher efficiency and advanced features.

12. Under Efficiency, select the specified values for the following options:
   a. For Command Queue Look-Ahead Depth, select 6.
   b. For Local-to-Memory Address Mapping, select CHIP-ROW-BANK-COL.
   c. For Local Maximum Burst Count, select 4.

13. Click Next.

14. Turn on the Generate simulation model option to generate the simulation model for the RTL simulation.

15. Click Finish to generate your MegaCore function variation. The MegaWizard Plug-In Manager generates all the files necessary for your DDR3 SDRAM controller, and generates an example top-level design, which you use to test or verify board operation.
Parameterize DDR3 SDRAM with Stratix IV

To parameterize the DDR3 SDRAM high-performance controller to interface with a 400-MHz, 64-bit wide DDR3 SDRAM interface, perform the following steps:

1. In the Memory Setting tab, set Speed grade to 3.
2. For PLL reference clock frequency, type 100 MHz to match the on-board oscillator.
3. For Memory clock frequency, type 400 MHz, the maximum frequency supported for DDR3 SDRAM interfaces on Stratix IV devices.
4. For Memory Presets, select SD_PCIE_DDR3_Kit (4xMicron MT41J64M16LA-187E), which is a 64-bit wide 512-MB 400-MHz DDR3 unbuffered DIMM.

The memory format in the SD_PCIE_DDR3_Kit (4xMicron MT41J64M16LA-187E).xml file is changed from discrete device to unbuffered DIMM to enable leveling functionality.

5. To create or modify a memory preset, click Modify parameters. In the Preset Editor dialog box, you can modify the memory presets.

The DDR3 SDRAM has a write requirement (tDQSS) that states the positive edge of the DQS signal on writes must be within ±25% (±90°) of the positive edge of the DDR3 SDRAM clock input. To achieve this skew requirement, the ALTMEMPHY-based designs always use the DDR IOE registers to generate the CK and CK# signals.

6. Turn on the Enable Memory Chip Calibration in Timing Analysis option on the Advanced page. This option is required for Stratix IV devices, which need post-processing script to remove timing model pessimism.
7. To specify the ODT settings for the DDR3 SDRAM interface on your board, in the Preset Editor dialog box, select Memory Initialization Options.

8. In the Memory Initialization Options dialog box, perform the following steps:
   a. For Output driver impedance, select RZQ/7 (which is 34).
   b. For Dynamic ODT (Rtt_WR) value, select RZQ/4 (which is 60).
   c. For ODT Rtt nominal value, select RZQ/4 (which is 60).
   d. Click OK to apply the settings and exit the dialog box.
9. In the PHY Settings tab, turn on the Enable dynamic parallel on-chip termination (OCT) option for this example. The Stratix IV GX FPGA development kit does not include discrete external termination on the DQ, DQS, DQS#, or DM pins as the board was designed to use OCT.
10. Under Address/Command Clock Settings, for Dedicated clock phase type 240.

The Auto-Calibration Simulation Options parameter is for RTL simulation only and is not applicable for gate-level simulation.
11. In the Board Settings tab, set the following Slew Rates and Board Skews parameters to the specified values:

- CK/CK# slew rate (Differential) = 4 V/ns
- Addr/Command slew rate = 1.5 V/ns
- DQS/DQS# slew rate (Differential) = 3 V/ns
- DQ slew rate = 1.5 V/ns

These slew rates are obtained from simulation using the default I/O standard and drive options.

- Max skew within DQS group = 0.015 ns
- Max skew between DQS groups = 0.128 ns
- Addr/Command to CK skew = - 0.05 ns

The Intersymbol Interference (ISI) parameters are not applicable for single rank configurations. Set these parameters to 0 ns.

12. In the Controller Settings tab, for Controller Architecture select High Performance Controller II for higher efficiency and advanced features.

13. Under Efficiency, select the specified values for the following options:

   a. For Command Queue Look-Ahead Depth, select 6.
   b. For Local-to-Memory Address Mapping, select CHIP-ROW-BANK-COL.
   c. For Local Maximum Burst Count, select 4.

14. Click Next.

15. Turn on the Generate simulation model option to generate the simulation model for the RTL simulation.

16. Click Finish to generate your MegaCore function variation. The MegaWizard Plug-In Manager generates all the files necessary for your DDR3 SDRAM controller, and an example top-level design, which you use to test or verify board operation.

For more information about the DDR3 SDRAM high-performance controller, refer to the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide in volume 3 of the External Memory Interface Handbook.

### Add Constraints

After instantiating the DDR3 SDRAM high-performance controller, the ALTMEMPHY megafuncon generates the constraints files for the design example. You must apply these constraints to the design before compilation.

### Set Top-Level Entity

The top-level entity of the project must be set to the correct entity. The naming convention for an ALTMEMPHY megafunction entity is <variation_name>_phy.v or vhd; an SDRAM high-performance controller entity is <variation_name>.v or vhd.
To set the top-level file, perform the following steps:
1. Open the entity file, `<variation_name>_example_top.v` or vhd.
2. On the Project menu, click **Set as Top-Level Entity**.

**Set Optimization Technique**

To ensure the remaining unconstrained paths are routed with the highest speed and efficiency, perform the following steps to set the optimization technique:
1. On the Assignments menu, click **Settings**.
2. Select **Analysis & Synthesis Settings**.
3. Select **Speed** under **Optimization Technique**. Click OK.

**Set Fitter Effort**

To set the fitter effort, perform the following steps:
1. On the Assignments menu, click **Settings**.
2. Select **Fitter Settings**.
3. Turn on **Optimize hold timing** and select **All Paths**.
4. Turn on **Optimize multi-corner timing**.
5. Select **Standard Fit (highest effort)** under **Fitter effort**.
6. Click OK.

**Add Timing Constraints**

When you instantiate an SDRAM high-performance controller, it generates a timing constraints file, `<variation_name>_phy_ddr_timing.sdc`. The timing constraint file constrains the clock, input, and output delay on the SDRAM high-performance controller.

To add timing constraints, perform the following steps:
1. On the Assignments menu click **Settings**.
2. In the **Category** list, expand **Timing Analysis Settings**, and select **TimeQuest Timing Analyzer**.
3. Select the `<variation_name>_phy_ddr_timing.sdc` file and click **Add**.
4. Click OK.

**Add Pin and DQ Group Assignments**

The pin assignment script, `<variation_name>_pin_assignments.tcl`, sets up the I/O standards for the DDR3 SDRAM interface. This script also launches the DQ group assignment script, `<variation_name>_phy_assign_dq_groups.tcl`, which relates the DQ and DQS pin groups together for the fitter to place them correctly in the Quartus II software.
This script does not create a clock for the design. You must create a clock for the design and provide pin assignments for the signals of both the example driver and testbench that the MegaCore variation generates.

To add the pin and I/O standards to the design example, perform the following steps:
1. On the Tools menu, click Tcl scripts.
2. Under Libraries, select `<variation_name>_pin_assignments.tcl`.
3. Click Run.

**Enter Pin Location Assignments**

To enter the pin location assignments using the Pin Planner, perform the following steps:
1. Run analysis and synthesis. On the Processing menu, point to Start and click Start Analysis & Synthesis.
2. Assign all of your pins, so the Quartus II software fits your design correctly and performs correct timing analysis. To assign pin locations for the Stratix III memory demonstration kit, run the Altera®-provided S3_MB1_DDR3_PinLocations.tcl file, and for the Stratix IV GX FPGA development kit, run the Altera-provided SIV_DDR3×64_PinLocations.tcl file, or manually assign the pin locations by using the Pin Planner.

The SDRAM high-performance controller auto-generated scripts do not make any pin location assignments.

If you are at the design exploration phase of your design cycle and do not have any PCB defined pin locations, you should manually define an initial set of pin constraints, which can become more specific during your development process.

To manually assign pin locations using the Pin Planner, perform the following steps:
1. On the Assignments menu, click Pin Planner.
2. Assign DQ and DQS pins.
   a. To select the device DQS pin groups that the design uses, assign each DQS pin in your design to the required DQS pin in the Pin Planner. The Quartus II Fitter automatically assigns the respective DQ signals to suitable DQ pins within each group. To view the DQS groups in the Pin Planner, right-click, select Show DQ/DQS Pins, and click In ×8/×9 Mode. The Pin Planner shows each DQS group in a different color and with a different legend: S = DQS pin, Sbar = DQSn pin and Q = DQ pin, as shown in Figure 5–2.

   Most DDR3 SDRAM devices operate in ×8/×9 mode. However, some DDR3 SDRAM devices operate in ×4 mode. Refer to your specific memory device datasheet.
   b. Select the DQ mode to match the DQ group width (number of DQ pins/number of DQS pins) of your memory device. DQ mode is not related to the memory interface width.
DQ group order and DQ pin order within each group is not important. However, you must place the DQ pins in the same group as their respective strobe pin.

3. Place the DM pins within their respective DQ group.

4. Place the address and control command pins on any spare I/O pins; ideally within the same bank or side of the device as the mem_clk pins.

5. Ensure that you place the mem_clk pins on differential I/O pairs for the CK/CK# pin pair. To identify differential I/O pairs, right-click in the Pin Planner and select Show Differential Pin Pair Connections. The pin pairs show a red line between each pin pair.

   You must place the mem_clk[0] and mem_clk_n[0] pins on an unused DQ or DQS pin pairs with DIFFIO_RX capability.

6. Place the clock_source pin on a dedicated PLL clock input pin with a direct connection to the SDRAM controller PLL and DLL pair—usually on the same side of the device as your memory interface. This recommendation reduces PLL jitter, saves a global clock resource, and eases timing and fitter effort.

7. Place the global_reset_n pin (like any high fan-out signal) on a dedicated clock pin.

8. Ensure that you place the R_UP and R_DN pins, termination_blk0~_rdn_pad and termination_blk0~_rup_pad, at locations within the same VCCIO voltage bank.
Assign I/O Standards

To assign the I/O standards, perform the following steps:

1. On the Assignments menu, click Assignment Editor.
2. Specify LVDS as the I/O standard for clock_source.
3. Specify 2.5 V as the I/O standard for global_reset_n.

Assign Virtual Pins

The example top-level design, which is auto-generated by the high-performance controller, includes an example driver to stimulate the interface. This example driver is not part of the SDRAM high-performance controller IP, but allows easy testing of the IP.

The example driver outputs several test signals to indicate its operation and the status of the stimulated memory interface. These signals are pnf, pnf_per_byte, and test_complete. These signals are not part of the memory interface, but are to facilitate testing. You must connect these signals to either a debug bus or assign the signals to virtual pins using the Quartus II Assignment Editor. When using the example driver for testing, do not remove these signals from the top-level signal list. If you remove these signals from the top-level module, the Quartus II software optimizes the driver away, and the example driver fails.

To assign virtual pin assignments for the Stratix III memory demonstration board, run the Altera-provided `s3_MB1_ddr3_exdriver_vpin.tcl` file, and for the Stratix IV GX FPGA development kit, run the Altera-provided `SIV_DDR3×64_exdriver_vpin.tcl` file, or manually assign the virtual pin assignments using the Assignment Editor.

The memory interface pins (DQ, DQS, DM, CK, CK#, address and command) cannot be assigned as virtual pins.

Advanced I/O Timing

The ALTMEMPHY-based Stratix III designs assume that the memory address and command signals are length-matched to the memory clock signals. Typically, this length match is not true for DIMM-based designs. You must verify the difference in your design. To edit the TimeQuest .sdc file, `<variation name>_phy_ddr_timing.sdc`, to include this difference, perform the following steps:

1. Open the `ddr3_dimm_phy_ddr_timing.sdc` file in a text editor and find the following command line (usually line 31):

   ```
   set t(additional_addresscmd_tpd) 0.000
   ```

   and change to the following command line:

   ```
   set t(additional_addresscmd_tpd) -0.300
   ```

2. Save the file.
If the DDR3 SDRAM controller .sdc file is regenerated, this change is lost and you must edit the file again.

Enter Board Trace Delay Models

For accurate I/O timing analysis, the Quartus II software must include the board trace and loading information. This information should be derived and refined during your PCB development process of prelayout (line) simulation and final post-layout (board) simulation.

For external memory interfaces that use memory modules (DIMMs), the board trace and loading information must also include the trace and loading information of the module. You can obtain these information from your memory vendor.

To enter board trace information, perform the following steps:

1. In the Pin Planner, select the pin or group of pins that you want to enter the information for.
2. Right-click and select Board Trace Model. Figure 5–3 shows the board trace model.

**Figure 5–3.** Board Trace Model for Stratix IV

Table 5–1 shows the board trace model parameters for the Stratix III and Stratix IV GX development boards.
Altera recommends you to use the Board Trace Model assignment for all DDR3 SDRAM interface signals. To apply the board trace model assignments for the Stratix III memory demonstration board, run the Altera-provided S3_MB1_DDR3_BTModels.tcl script, and for the Stratix IV GX FPGA development kit, run the Altera-provided SIV_DDR3×64_BoardTraceModels.tcl script, or manually assign the virtual pin assignments using the Quartus II Pin Planner.

The Stratix III demonstration board has the 7 pF (differential) compensation capacitors fitted to its DDR3 SDRAM CL, CK, and CK# signals. These capacitors are typically fitted to designs that use asymmetric DIMM designs. Simulate your design to check if the compensation capacitors are required. Stratix III devices have various programmable drive strength and OCT I/O options, so compensation capacitors are not usually required. Because fitting compensation capacitors reduces the edge rate of your signals, you should observe the memory vendor derating guidelines.

For more information on compensation capacitors, refer to Micron Technical Note TN_47_01.

**Notes to Table 5–1:**

1. Addr = Addr, ba, we#, ras#, odt, and cas.
2. $C_{\text{n}}$ value of 4.6 pF comprises 7 pF on memory demonstration board plus 2.2 pF on the DIMM, which is 9.2 pF differential or 4.6 pF SE.
Perform RTL or Functional Simulation (Optional)

After instantiating the DDR3 SDRAM high-performance controller, the MegaWizard Plug-In Manager generates a design example that includes a driver, a test bench, and a memory model that allows you to perform functional simulation on your design.

The Verilog HDL or VHDL simulation model of the PHY, `<variation_name>_alt_mem_phy_sequencer_wrapper.vo/.vho` file, is located in your project directory.

To run the simulation with NativeLink, perform the following steps:

1. Set the absolute path to your third-party simulator executable file by performing the following steps:
   a. On the Assignments menu, click EDA Tool Settings.
   b. In the Category list, expand EDA Tool Settings and click Simulation.
   c. Under Tool name, select ModelSim-Altera.
   d. Under NativeLink settings, select Compile test bench and click Test Benches.
   e. Click New.
   f. Type the name of your testbench top-level module and simulation period.
   g. Click OK.

2. To elaborate your design, on the Processing menu, point to Start and click Start Analysis & Elaboration.

3. On the Tools menu, point to the Run EDA Simulation Tool and click EDA RTL Simulation. This step creates the `\simulation` directory in your project directory and a script that compiles all necessary files and runs the simulation.

For example timing diagrams, refer to the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide in volume 3 of the External Memory Interface Handbook.

Compile Design and Verify Timing

To compile the design, on the Processing menu, click Start Compilation. After successfully compiling the design, the Quartus II software automatically runs the verify timing script, `<variation_name>_timing.tcl`, which produces a timing report for the design together with the compilation report.

Figure 5–4 shows the timing margin report in the message window in the Quartus II software.
You can also obtain the timing report by running the report timing script, `<variation_name>_timing.tcl`, in the TimeQuest Timing Analyzer window. To obtain the timing report in the TimeQuest Timing Analyzer window, perform the following steps:

1. On the Tools menu, click **TimeQuest Timing Analyzer**.

2. On the **Tasks** pane, double-click on **Report DDR** to run **Update Timing Netlist**, **Create Timing Netlist**, and **Read SDC File**. This command subsequently executes the report timing script to generate the timing margin report.

Figure 5–5 shows the timing margin report in the TimeQuest Timing Analyzer window after running the report timing script. The results are the same as those obtained from the Quartus II software directly.
You must verify the timing at every corner of the timing model. You must run the timing report script with all available timing models—slow 0°C, slow 85°C, and fast 0°C—to ensure positive margins across the process, voltage, and temperature variations. To analyze timing on a different corner, double-click Set Operating Conditions in the left pane. Select a new timing corner, then go to the Script menu and rerun the <variation_name>_report_timing.tcl script.

The Stratix IV devices need post-processing script to remove timing model pessimism on the write and read capture path margins, refer to Figure 5–6 and Figure 5–7.

**Figure 5–6. Write Margin Summary**

<table>
<thead>

</table>
The standard write and read capture margins are initially calculated using the FPGA timing model and adjusted to account for the effects not modeled by either the timing model or TimeQuest timing analyzer. These effects include memory calibration, deskew topologies, quantization error and calibration uncertainties.

The final write and read capture margins are summarized in the Report DDR margin summary, refer to Figure 5–8.

For more information about the TimeQuest timing analyzer, refer to The Quartus II TimeQuest Timing Analyzer chapter in volume 7 of the Quartus II Handbook. For information about timing analysis, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.

**Determine Board Design Constraints and Perform Board-Level Simulations**

The Stratix III and Stratix IV devices support both series and parallel OCT resistors to improve signal integrity. The Stratix III and Stratix IV OCT resistors also eliminate the need for external termination resistors on the FPGA. This feature simplifies board design and reduces overall board cost. The series ODT features are available in settings of 34 Ω and 40 Ω. Although 40 Ω is not supported by all vendors.

All DDR3 SDRAM interfaces use the following two classes of signal type:

- **Unidirectional class I** terminated signals, which include clocks, and address and command signals.
- **Bidirectional class II** terminated signals, which include DQS, DQ, and DM signals.
For bidirectional signals, Class II termination is recommended to ensure proper termination for the following operation:

- Reads from the memory component, termination at the Stratix III or Stratix IV GX FPGA side.
- Writes to the memory component, termination at the memory side.

The Stratix III and Stratix IV devices include on-chip series and parallel termination. So generally, discrete termination at the FPGA end of the line is not required. The DDR3 SDRAM devices support dynamic parallel ODT at the memory end of the line. So typically, discrete termination is not required. For these reasons, Class I termination are used for bidirectional signals in this tutorial.

To understand better about the different effects on signal integrity design, refer to the Board Layout Guidelines section in volume 2 of the External Memory Interface Handbook. For more information about the signal integrity of the Stratix III and Stratix IV devices, refer to Stratix III Device Signal and Power Integrity and Stratix IV FPGA Signal and Power Integrity pages.

**Verify Design on a Board**

The SignalTap® II Embedded Logic Analyzer shows read and write activity in the system.

For more information about using the SignalTap II Embedded Logic Analyzer, refer to the Design Debugging Using the SignalTap II Embedded Logic Analyzer chapter in the Quartus II Handbook, AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems and AN 446: Debugging Nios II Systems with the SignalTap II Logic Analyzer.

To add the SignalTap II Embedded Logic Analyzer, perform the following steps:

1. On the Tools menu, click SignalTap II Logic Analyzer.
2. Under Signal Configuration, next to the Clock box click ... (Browse Node Finder).
3. Type *phy_clk in the Named box, for Filter select SignalTap II: pre-synthesis and click List.
4. Select ddr3_dimm|ddr3_dimm_inst|phy_clk for a Stratix III design, or ddr3_bot_x64_example_top|ddr3_bot_x64:ddr3_bot_x64|phy_clk for a Stratix IV design, in Nodes Found and click > to add the signal to Selected Nodes.
5. Click OK.
6. Under **Signal Configuration**, specify the following settings:
   - For **Sample depth**, select 512
   - For **RAM type**, select Auto
   - For **Trigger flow control**, select Sequential
   - For **Trigger position**, select Center trigger position
   - For **Trigger conditions**, select 1

7. On the Edit menu, click **Add Nodes**.

8. Search for specific nodes by typing *local* in the **Named** box, for **Filter** select **SignalTap II: pre-synthesis** and click **List**.

9. Select the following nodes in **Nodes Found** and click > to add to **Selected Nodes**:
   - local_address
   - local_rdata
   - local_rdata_valid
   - local_read_req
   - local_ready
   - local_wdata
   - local_wdata_req
   - local_write_req
   - pnf
   - pnf_per_byte
   - test_complete (trigger)
   - ctl_cal_success
   - ctl_cal_fail
   - ctl_wlat
   - ctl_rlat

   **Tip** Do not add any DDR3 SDRAM interface signals to the SignalTap II Embedded Logic Analyzer. The load on these signals increases and adversely affects the timing analysis.

10. Click **OK**.
11. To reduce the SignalTap II logic size, turn off Trigger Enable on the following bus signals:
   - local_address
   - local_rdata
   - local_wdata
   - pnf_per_byte
   - ctl_wlat
   - ctl_rlat

12. Right-click Trigger Conditions for the test_complete signal and select Rising Edge.
Figure 5–9 shows the completed SignalTap II Embedded Logic Analyzer.

![SignalTap II Embedded Logic Analyzer](image)

13. On the File menu, click **Save**, to save the SignalTap II .stp file to your project.

   If you see the message **Do you want to enable SignalTap II file “stp1.stp” for the current project**, click **Yes**.

### Compile the Project

After you add signals to the SignalTap II Embedded Logic Analyzer, to recompile your design, on the Processing menu, click **Start Compilation**.

### Verify Timing

After the design compiles, ensure that TimeQuest timing analysis passes successfully. In addition to this FPGA timing analysis, check your PCB or system SDRAM timing. To run timing analysis, perform the following steps to run the `<variation name> Phy_report_timing.tcl` script:

1. On the Tools menu, click **Tcl Scripts**.
2. Select `<variation name> Phy_report_timing.tcl`.
3. Click **Run**.
Download the Object File

To download the object file to the device, perform the following steps:

1. Connect the development board to your computer.
2. On the Tools menu, click SignalTap II Logic Analyzer. The SignalTap II dialog box appears.
3. Click ... to open the Select Program Files dialog box.
4. Select <your project name>.sof.
5. Click Open.
6. To download the file, click the Program Device button.

Test the Design Example in Hardware

When the design example including SignalTap II successfully downloads to your development board, click Run Analysis to run once, or click Autorun Analysis to run continuously. Figure 5–10 shows the design analysis.

Figure 5–10. SignalTap II Example DDR3 SDRAM Design Analysis
6. Using High-Performance DDR, DDR2, and DDR3 SDRAM with SOPC Builder

The Altera® DDR, DDR2, and DDR3 SDRAM High-Performance Controller MegaCore® functions version 9.1 support SOPC Builder, enabling you to instantiate a DDR, DDR2, or DDR3 SDRAM high-performance controller in an SOPC Builder system.

This walkthrough discusses the following topics:

- Consider SOPC Builder system interconnect fabric and performance implications:
  - High-performance controller (HPC) or high-performance controller II (HPC II)
  - Full- or half-rate SDRAM high-performance controller
  - System and component clock selection, and half-rate bridges
  - Burst reads and writes
  - Latency and how to optimize read or write addressing

- Implement a DDR2 SDRAM high-performance controller in SOPC Builder

- Incorporate a Nios® II Processor and other peripherals

- Compile the design and generate the programming file

- Download the design to a development board and run sample code on your design to test read and write transactions

The design in this walkthrough ensures an optimum SOPC Builder Avalon® Memory-Mapped (Avalon-MM) architecture and demonstrates how a simple Nios II C program, when combined with a SignalTap® II Embedded Logic Analyzer, can verify both hardware and software operation.

For more information on functional simulation of an SOPC Builder system, refer to AN 351: Simulating Nios II Embedded Processor Designs. For more information about the DDR, DDR2, and DDR3 SDRAM high-performance controllers, refer to the DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section and the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section in volume 3 of the External Memory Interface Handbook.
SOPC Builder System Considerations

Always consider the following caveats and limitations when integrating a DDR, DDR2, or DDR3 SDRAM high-performance controller in SOPC Builder:

- High-Performance Controller (HPC) or High-Performance Controller II (HPC II)
- Full- or Half-Rate SDRAM High-Performance Controller
- Clock Selection and Clock Crossing Bridges
- Burst Reads and Writes
- Multimasters
- Direct Memory Access (DMA) Controller
- Read and Write Addressing and Latency

High-Performance Controller (HPC) or High-Performance Controller II (HPC II)

Select either HPC or HPC II based on your system design. HPC II is an enhanced version of HPC with higher efficiency, and provides the following features:

- Supports higher efficiency look-ahead bank management with in-order read and write, out of order management.
- Supports bank interleaving with additive latency and auto precharge to provide higher efficiency.
- Provides optional run-time programmability to configure the behavior of the controller such as memory timing, size and mode register settings, allowing you to reconfigure and read the controller parameters in user mode, and reduce compilation time.
- Has half-bridge integrated in the controller to reduce the memory access latency.
- Supports multi-cast write to mitigate \( t_{\text{RC}} \).
- Has integrated flexible built-in burst adapter to automatically split or merge user burst request to match memory’s native burst length, allowing you to set a maximum of 64 beats at the local side.
- Supports integrated error correction coding (ECC), which supports 40-bit and 72-bit interfaces with sub-word writes, and optional automatic write-back on error.
- Supports Avalon-MM interface.

For more information about HPC II, the DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section and the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section in volume 3 of the External Memory Interface Handbook.

Altera recommends that you use the HPC II, which provides more flexibility and higher efficiency.
Full- or Half-Rate SDRAM High-Performance Controller

Full- or half-rate SDRAM high-performance controllers have the following definitions:

- Full-rate controllers present data to the local interface at twice the width of the actual SDRAM interface at the full SDRAM clock rate.
- Half-rate controllers present data to the local interface at four times the width of the actual SDRAM interface at half the SDRAM clock rate.

Implementing the SDRAM high-performance controllers in half-rate mode gives the highest possible SDRAM clock frequency while allowing the more complex core logic to operate at half this frequency. You can simplify the complexity of your design by permitting your Nios II processor to run at the slower, half-rate memory speed while still achieving the required SDRAM bandwidth per I/O pin.

However, where possible it is generally more optimal to configure the controller in full-rate mode with the core operating at the same clock frequency as your SOPC Builder system.

Full-Rate Versus Half-Rate Command Operation

Commands can be slower using a half-rate controller. For example, a DDR SDRAM device can have a number of banks open at once. Each bank has a currently selected row. Changing the column within the selected row of an open bank requires no additional bank management commands to be issued. Changing the row in an active bank, or changing the bank both incur a protocol penalty that requires the precharge (PCH) command closes the active row or bank, and the active (ACT) command then opens or activates the new row or bank combination.

The duration of this penalty is a function of the controller clock frequency, the memory clock frequency, and the memory device characteristics. Calculating the impact of a change of memory and controller configuration on a given system is not a trivial task, as it depends on the nature of the accesses that are performed.

In this example each command takes a single clock cycle in a full-rate controller, but two clock cycles in a half-rate controller. The bank is not available for the subsequent ACT command until \( t_{RP} \) after the PCH. So the issuing of commands can be slower using a half-rate controller, even if the respective memory timing parameters remain the same.

Time-Specified Memory Parameters

For a half-rate SDRAM high-performance controller, the control circuitry is clocked at half rate and so control operations are slower than in full-rate mode. However, the memory’s clock frequency and physical properties are not affected.

When you use half-rate mode, any time-specified memory parameters in the controller are modified.
For example, if:
\[ t_{\text{RCD,min}} = 20 \text{ ns} \]

For a 133-MHz controller:
\[ t_{\text{CK}} = 7.5 \text{ ns} \]
\[ \frac{20}{7.5} = 2.666 \text{ rounded up to 3 clock cycles (22.5ns)}. \]

For a half-rate 66-MHz controller:
\[ t_{\text{CK}} = 15 \text{ ns} \]
\[ \frac{20}{15} = 1.33 \text{ rounded up to 2 clock cycles (30ns)}. \]

Thus bank and row changes are slower in half-rate mode, but are not twice as slow. The easiest way to measure this effect for your chosen memory device and interface clock speed is to simulate both half-rate and full-rate designs and record the increased latency when switching rows. Typically a full-rate controller is around 14% more efficient when switching rows within a bank. As a half-rate controller has less read latency and if the masters in your system do not cause bank switching to occur often, the half-rate controller still gives higher performance. In SOPC Builder, you can alter arbitration shares to prevent masters from switching memory banks, thus creating a more optimal system.

**Clock Selection and Clock Crossing Bridges**

Ideally every component in the SOPC Builder system should be clocked using the same clock, to prevent SOPC Builder automatically adding clock domain crossing logic, which adds latency. The SDRAM high-performance controllers already include a PLL, so you should set the SOPC Builder system clock to `altmemddr.sysclk`, which is the clock the controller and local interface logic use. SOPC Builder only shows the input clock to the controller PLL, not the interface clock, refer to Figure 6–1 on page 6–5.
If a different Avalon-MM clock is specified for connected components and a clock crossing bridge is not used, SOPC Builder automatically adds clock crossing adapters between any data masters of your SOPC Builder system and the SDRAM high-performance controller slave interface. Clock crossing adapters provide robust and safe transactions between different clock domains, however they increase latency and limit total bandwidth.

To prevent SOPC Builder from auto-inserting clock adapters:

- If the connected SOPC Builder components and SDRAM high-performance controller operate at the same frequency, use \texttt{altmemddr.sysclk} as the clock for the rest of your system. No clock domain crossing adapters are added by SOPC Builder.

- If the connected SOPC Builder components and SDRAM high-performance controller operate at different frequencies, manually insert an Avalon-MM clock crossing bridge between the SDRAM high-performance controller and the other SOPC Builder components.

- If the connected SOPC Builder components and SDRAM high-performance controller operate at different frequencies but are in the same clock phase, manually insert an Avalon-MM DDR memory half-rate bridge between the SDRAM high-performance controller and the other SOPC Builder components. Alternatively, turn on the Enable Half Rate Bridge option on the Memory Settings tab to use the embedded half-rate bridge in HPC II.
To use the Avalon-MM clock crossing bridge or the Avalon-MM DDR memory half-rate bridge, set the slave clock to your SOPC Builder system clock, and the master clock to \texttt{altmemddr.sysclk}.

For more information about the Avalon-MM clock crossing bridge and Avalon-MM DDR memory half-rate bridge, refer to the \textit{Avalon Memory-Mapped Bridges} chapter in volume 4 of the \textit{Quartus II Handbook}.

The Avalon-MM clock crossing bridge also works when you are using two different clocks at the same frequency but with different phases. However, the Avalon-MM DDR memory half-rate bridge must meet the following requirements:

- The clock frequency of the memory-side master must be in the same phase and twice of the processor-side slave frequency.
- The memory-side master is half as wide as the processor-side slave.

Use either the Avalon-MM clock crossing bridge or the Avalon-MM DDR memory half-rate bridge to allow a full-rate controller to connect to a half-rate SOPC builder design. As the memory controller still operates at full rate, twice the Nios II frequency, the memory interface commands operate at the faster rate.

The Avalon-MM DDR memory half-rate bridge has the same functionality as the Avalon-MM clock crossing bridge but provides lower latency. Altera recommends you use the Avalon-MM DDR memory half-rate bridge for Nios II Processors that require low latency access to high-speed memory.

Figure 6–2 shows a block diagram of how to use an Avalon-MM clock crossing bridge or an Avalon-MM DDR memory half-rate bridge.

\textbf{Figure 6–2. Clock Crossing Bridge}
Figure 6–3 shows a block diagram of how a half-rate bridge is embedded in HPC II.

Figure 6–3. Half-Rate Bridge in DDR SDRAM High-Performance Controller II

**Burst Reads and Writes**

Burst reads and writes differ in the following ways:

- In half-rate designs, the Avalon-MM slave interface is four times the width of the SDRAM device. Hence four transactions are performed on the SDRAM for every single Avalon-MM transaction. Avalon-MM burst requests on the local side serve no purpose as the memory interface is already using the maximum supported memory burst size for every single Avalon-MM transaction.

- In full-rate designs, you can use Avalon-MM bursts of one or two with the SDRAM high-performance controller, as each Avalon-MM transaction results in only two SDRAM transactions. So two Avalon-MM burst transactions may be combined to support the four supported on the SDRAM high-performance controller.

   When a burst capable master supports larger burst lengths than the slave, SOPC Builder automatically places a burst length adapter into the path.

To obtain performance advantages, ensure that the data widths of master and slave pairs are matched in SOPC Builder. Whenever a master port is connected to a slave port of a different width, SOPC Builder automatically inserts adapter logic to convert between the different data widths.

Ideally, the data size of an Avalon-MM interface is 32 bits for a Nios II processor:

- For a full-rate SDRAM high-performance controller, the double-data rate stage doubles the data width, thus a 16-bit external memory width is best.

- For a half-rate SDRAM high-performance controller, the double-data rate and half-rate stages both double the data width, thus an 8-bit external memory width is best.
Ideally, match the following data cache line sizes to the memory controller burst length:

- 4-byte line = bursts of 1 (32-bit word)
- 16-byte line = bursts of 4
- 32-byte line = bursts of 8

You can set the data bus arbitration priority to avoid using the burst signal.

Table 6–1 and Table 6–2 show the burst length support for each type of DDR SDRAM HPC and HPC II.

### Table 6–1. Burst Length Support for DDR SDRAM HPC

HPC II consists of a built-in burst adapter that automatically splits or merges burst request to match the memory’s native burst length. This built-in adapter allows the Nios II processor to request any burst length and maps the burst length to the most efficient memory burst. HPC II accepts up to 64 burst count.

### Multimasters

To achieve best throughput and latency of the SDRAM, you should connect the controller to the smallest number of masters and share those masters with the smallest number of slaves. Fewer connections reduce the complexity of the SOPC Builder auto-inserted data multiplexers and increase the $f_{\text{MAX}}$ of the Avalon-MM interface.

If the Avalon-MM interface $f_{\text{MAX}}$ becomes the limiting factor, insert pipeline bridges to increase $f_{\text{MAX}}$ the (at the expense of latency).

Master and slave pairs are locked for the whole duration of a burst—no other master is granted access to the slave target of a burst until the burst is completed. You should isolate critical memory connections from the rest of the system.

One master may lock an SDRAM high-performance controller until a write burst is completed, which may take several cycles of time, during which the SDRAM high-performance controller cannot accept any other request. The write burst command is complete when all burst data is passed to the SDRAM high-performance controller. For a read burst, the controller quickly transfers back the whole burst at full bandwidth and becomes immediately available for new requests.
**Direct Memory Access (DMA) Controller**

The DMA controller enables the memory data transfer directly without being preformed through the processor to achieve better performance and parallelism between operations. By enabling the direct transfer, the processor can perform other tasks in parallel.

For more information, refer to the *DMA Controller Core* chapter in volume 5 of the *Quartus II Handbook*.

The DMA controller can perform bulk data transfers, reading data from a source address range and writing data to a different address range. The DMA controller boosts the memory band-width and alleviates the multimaster bottleneck. With the use of a DMA controller, you can reduce the number of masters that access the memory. *Figure 6–4* shows an example where there are multiple masters access to the memory. This increases the complexity of the connection and latency to the system.

![Figure 6–4. Multiple Masters Accessing a Single Memory](image1)

You can use the DMA controller to reduce the bottleneck for the multimaster access to the memory. The DMA controller acts as the only master that accesses the memory but as a slave for other components that wants access to the memory. DMA controller uses interrupt request to notify the masters of other components that the transfers are completed without wasting time with polling. *Figure 6–5* shows an example of how DMA controller is used to enhance the memory bandwidth for multimaster.

![Figure 6–5. A Single Master Accessing Memory with DMA Controller](image2)
**Read and Write Addressing and Latency**

Systems with deterministic access patterns can minimize the number of bank and row changes. For example, by suitably arranging the memory map. In systems with more random access patterns (often typical in embedded SOPC Builder-type systems), minimizing bank and row changes is more difficult and the increased latency (by constantly changing the row in an active bank, or changing the bank) has a greater effect. Non-optimal cache implementations can waste cycles with half-rate controllers.

You should always consider the following actions:

- Match controller Avalon-MM interface width to Avalon-MM master interface width.
- Minimize non-sequential addressing to reduce row addressing time.
- Match the Nios II cache line size to memory burst length.
- Set arbitration priorities correctly.
- Insert bridges to increase f_{MAX} at the expense of latency.
- Minimize multimaster designs where arbitration stalls may take place.

In multi-mastering designs, the memory is not available to all masters concurrently.

Setting the arbitration priorities correctly prevents unnecessary memory accesses. For example, always set the Nios II instruction master arbitration priority to eight, because it always tries to access eight sequential addresses. Set the data master arbitration priorities depending on the cache line size; do not leave the arbitration priority value as default.

**DDR2 SDRAM High-Performance Controller with SOPC Builder Walkthrough**

This walkthrough shows how to use the SOPC Builder design flow to design a 8-bit wide, 150-MHz, 300-Mbps DDR2 SDRAM interface. The design example also provides some recommended settings to simplify the design. Although the design example is specifically for the DDR2 SDRAM interface, the design flow for DDR and DDR3 SDRAM interfaces are the same.

The design example targets the Cyclone® III FPGA development kit with four MT47H32M16CC-3 components and an 8-bit wide 512-MB Micron MT47H32M16CC-3 333-MHz DDR2 SDRAM component.

**System Requirement**

This application note assumes that you are familiar with the Quartus® II software and SOPC Builder. This tutorial requires the following hardware and software:

- Quartus II software version 9.1
- ModelSim®-SE 6.5b or higher
- DDR2 SDRAM High-Performance Controller MegaCore function version 9.1
- Nios II Embedded Design Suite (EDS) version 9.1
The design is targeted to the Cyclone® III FPGA development kit. You can target other supported device families or development kits.

Create Your Example Project

This section shows you how to create a new Quartus II project and an SOPC Builder system.

Create a New Quartus II Project

In the Quartus II software, create a new project with the New Project Wizard, ensure that the device type is set to Cyclone III, EP3C120F780C7.

Ensure that your project path does not include any spaces or extended characters.

Create the SOPC Builder System

To create an SOPC Builder system, perform the following steps:

1. On the Tools menu, click SOPC Builder.
2. In the Create New System dialog box, type sopc_top for the System Name. In the Target HDL, select Verilog, then click OK.
3. In the System Contents tab, under Component Library, expand Memories and Memory Controllers. Expand SDRAM. Select DDR2 SDRAM High Performance Controller and click Add. The DDR2 SDRAM high-performance controller wizard opens, refer to Figure 6–6 on page 6–12.
4. In the DDR2 High Performance Controller wizard interface, select 7 for the Speed grade to match the chosen device.

5. For the PLL reference clock frequency, type 50 MHz, to match signal CLKin50.

6. For the Memory clock frequency, type 150 MHz.

150 MHz is the maximum supported frequency for DDR2, SSTL-18 class I, in top and bottom I/O, in a C7 speed grade Cyclone III device.

7. For the Controller data rate, select Full. Full-rate frequency is selected because the half-rate bridge is used in HPC II to reduce latency by driving the PHY and controller to work faster.

The Enable Half Rate Bridge option is only available with the full-rate memory controllers.

8. For the Memory vendor, select Micron.

9. For the Memory format, select Discrete Device.

10. For the Memory Presets, select Micron MT47H32M16CC-3 x4 + MT47H32M8BP-3 x1, refer to Figure 6–7 on page 6–13.
This memory preset has been included by Altera in the DDR2 SDRAM high-performance controller as it matches the exact configuration that both the Cyclone III development board and the Stratix® II GX PCIe development kit use.

Figure 6–7. Memory Settings
11. Click **Modify parameters** and ensure that you change the following parameters:

- **Output clock pairs from FPGA**, select **1 pair**
- **Total Memory interface DQ width**, select **8 bits**, to give in an Avalon-MM width of 32 bits, which is ideal to connect to a Nios II processor
- **Memory drive strength setting**, select **Reduced** (DQ are low load point-to-point connections)
- **Memory on-die termination (ODT) setting**, select **Disabled** (discrete class I termination is already fitted to the development board)
- **Memory CAS latency setting**, select **3.0 cycles** (this DDR2 SDRAM supports CAS = 3 for frequencies of 200 MHz or lower)

12. Click **OK**, then click **Finish** in the DDR2 SDRAM high-performance controller interface.

![Figure 6–8. Preset Editor](image)

If you are using a device that requires timing model pessimism removal, ensure that you turn on the **Enable Memory Chip Calibration in Timing Analysis** option on the **Advanced** page. This option is not supported by Cyclone III devices.
Because Cyclone III devices do not support flexible timing methodology, ignore the board settings. If you are using devices that support flexible timing methodology, ensure that you fill in the **Board Settings** parameters based on your board simulation results to achieve accurate timing analysis.

For more information about timing model pessimism removal, refer to the **Timing Analysis** section in volume 4 of the *External Memory Interface Handbook*.

13. In the **Controller Settings** tab, select **High-Performance Controller II**.
15. For **Local-to-Memory Address Mapping**, select **CHIP-ROW-BANK-COL**.
16. For **Local Maximum Burst Count**, select 1, refer to Figure 6–10.

Set the maximum burst count based on the burst count of the core logic system.
If you are using multiple controllers, turn on the **Use clocks from another controller** option under **Multiple Controller Clock Sharing** to save clock resources, and improve system efficiency and latency. This option allows the controllers to share the static PHY clocks between multiple controllers that run on the same frequency and share the same PLL reference clock.

For more information about how to share the clock for multiple memory interfaces, refer to the **Implementing Multiple Memory Interfaces** section in volume 6 of the *External Memory Interface Handbook*.

17. Click the **Memory Settings** tab, and turn on the **Enable Half Rate Bridge** option.

18. Click **Finish**.
Add SOPC Builder Components

To add components from the System Contents tab, perform the following steps:

1. Under Component Library, expand Memories and Memory Controllers and expand On-Chip. Select On-Chip Memory (RAM or ROM), and click Add.
   a. For Total memory size type 64 KBs.
   b. Click Finish.

2. Select On-Chip Memory again, click Add.
   a. Set Total memory size to 4096 Bytes.
   b. Click Finish.
   c. Right click on this second on-chip memory, click Rename and type dma_read_memory and press Enter.

   a. Select Nios II/s.
   b. For Reset Vector Memory and Exception Vector Memory, select onchip_memory. If the local on-chip memory holds the Nios II instruction code, less arbitration is required to the SDRAM interface resulting in a more optimal Avalon-MM structure.
   c. Change Reset Vector Offset to 0x20 and Exception Vector Offset to 0x40.

   If you select SDRAM as reset and exception vector, the controller performs memory interface calibration every time it is reset and in doing so writes to addresses 0x00 to 0x1f. If you want your memory contents to remain intact through a system reset, you should avoid using the memory addresses below 0x20. This step is not necessary, if you reload your SDRAM contents from flash every time you reset.
   d. Click Finish.

5. Expand Interface Protocols and expand Serial, select JTAG UART and click Add.
   a. In the Configuration tab, under Write FIFO and Read FIFO, for the Buffer depth (bytes) select 64 and for IRQ threshold type 8.
   b. In the Simulation tab, select Create Modelsim alias to open an interactive stimulus/response window, to open the interactive display window during simulation.
   c. Click Finish.

6. Expand Peripherals and expand Microcontroller Peripherals, select PIO (Parallel I/O), click Add.
   a. For the Width type 8 bits.
   b. For Direction select Output ports only.
   c. Click Finish.
7. Expand **Memories and Memory Controllers** and expand DMA, select DMA Controller and click Add.
   a. In the DMA Parameters tab, turn on **Enable burst transfers**, and for the **Maximum burst size** select 512 words.
   b. In the **Advanced** tab, turn off byte, halfword, doubleword and quadword.
   c. Click **Finish**.

   Do not add a PLL component to your SOPC Builder design as the DDR2 SDRAM high-performance controller includes one.

8. Set the bus links, refer to Figure 6–11 on page 6–19.
   a. Connect the DMA **read_master** and **write_master** to both the **altmemddr** and the **dma_read_memory**.

   If there are warnings about overlapping addresses, on the System menu click **Auto-Assign Base Addresses**.

   If there are warnings about overlapping IRQ, on the System menu click **Auto-Assign IRQs**.

   b. Ensure that **altmemddr** is clocked on the external clock **clk** and that the frequency matches the external oscillator (50 MHz for the Cyclone III development board).

   c. Ensure that all other modules are clocked on the **altmemddr_sysclk**, to avoid any unnecessary clock-domain crossing logic.

   For more information on SOPC Builder system interconnect fabric, refer to the **System Interconnect Fabric for Memory-Mapped Interfaces** chapter in the Quartus II Handbook.
To generate the SOPC Builder System:

1. In SOPC Builder, click Next.
2. Turn on the Simulation. Create simulator project files option.
3. In SOPC Builder, click Generate. Click Save. When the generation is completed, the following message appears:
   Success: System generation completed.
4. In SOPC Builder, click Exit.

For more information on SOPC simulation and testbench options, refer to Volume 4: SOPC Builder of the Quartus II Handbook and AN 351: Simulating Nios II Systems.

Create the Top-Level Design File

Conceptually, you can consider the SOPC Builder system as component in your design. It can be the only component; or one of many components. Hence, when your SOPC Builder system is complete, you must add it to your top-level design.

The top-level design can be in your preferred HDL language, or simply a .bdf schematic design.
In this walkthrough, the top-level design is a simple wrapper file around the SOPC Builder system with no additional components. The top-level design file just defines the pin naming convention and port connections. Figure 6–12 shows the SOPC Builder top-level block diagram.

The SDRAM high-performance controller must make assignments to the top-level memory interface pins. These assignments are applied with the auto-generated script and constraint files. To ensure the constraints work, you must ensure the pin names and pin group assignments match, otherwise you get a no fit when you compile your design. The pin names default to `mem_*`. You can see the expected default pin names in the generated `altmemddr_example_top` file. You may optionally apply a prefix to the default pin naming convention.

All the SDRAM high-performance controllers generate the standalone design example `altmemddr_example_top`. This file only includes the controller and an example driver, refer to Figure 6–13. This file does not instantiate your SOPC Builder system but you can use the file in one of the following ways:

- Identify the default memory controller pin names
- Use as a starting point for the rest of the design
You can create a HDL top-level design using the `altmemddr_example_top` as a template. You may edit the pin names (if required) in the `altmemddr_example_top` file only with the addition of a prefix. You must replace the example driver and the DDR2 SDRAM high-performance controller and instantiate your SOPC Builder-generated system.

As a reference, Altera provides an example .bdf top-level design with the correct pin names, refer to Figure 6–14. The `mem_clk[0]` and `mem_clk_n[0]` pins are bidirectional because of the mimic path in the ALTMEMPHY megafunction.

**Figure 6–14.** Quartus II Top-Level Project

To create a top-level design for your SOPC Builder system using a Quartus II .bdf schematic, perform the following steps:

1. In the Quartus II software, on the File menu click **New**.
2. Select **Block Diagram/Schematic File** and click **OK**. A blank .bdf, Block1.bdf, opens.
3. On the File menu click **Save As**. In the **Save As** dialog window, click **Save**. The Quartus II software automatically sets the .bdf file name to your project name.
4. Right-click in the blank .bdf, point to **Insert** and click **Symbol** to open the Symbol dialog box.
5. Expand **Project**, under **Libraries** select **sopc_top**, click **OK**.
6. Position the SOPC Builder system component outline in the `<project>.bdf` and left-click.
7. Right-click on the SOPC Builder system component and click **Generate Pins for Symbol Ports**, to automatically add pins and nets to the schematic symbol.
The SOPC Builder system includes the following signals, which are not required for this design example and can be disconnected:

- altmemddr_phy_clk_out
- local_init_done_from_the_altmemddr
- local_refresh_ack_from_the_altmemddr
- local_wdata_req_from_the_altmemddr
- reset_phy_clk_n_from_the_altmemddr
- altmemddr_aux_full_rate_clk_out
- altmemddr_aux_half_rate_clk_out

The following single vector signals must have a [0] vectored pin name, otherwise the simulation may fail:

- mem_dm
- mem_dqs
- mem_clk
- mem_cke
- mem_cs_n
- mem_odt

The altmemddr_aux_full_rate_clk_out and altmemddr_aux_half_rate_clk_out clock signals instantiate the full-rate (altmemddr_auxfull) and half-rate (altmemddr_auxhalf) clocks that are exported from the DDR2 SDRAM high-performance controller to the top level of SOPC Builder. These two clocks are used to clock the half-rate bridge if the half-rate bridge is instantiated externally. These clocks are also used to clock other components within the system.

8. The SOPC Builder system has two reset inputs, reset_n and global_reset_n_to_the_altmemddr. Connect both these signals to a single pin, global_reset_n.

9. Ensure that you rename the clock signal as clock_source.

For more information on the signals, refer to the DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section and the DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide section in volume 3 of the External Memory Interface Handbook.

10. Rename out_port_from_the_Led_pio[7...0] to pio[7...0].

11. On the File menu, click Save, to save your changes.

12. On the Project menu, click Set as Top-Level Entity.
Add Constraints

After generating the DDR2 SDRAM high-performance controller, the ALTMEMPHY megafuntion generates the constraint files for the design. You need to apply these constraints to the design before compilation.

Device Settings

Set the unused pin and device voltage correctly before adding the constraint and pin assignment. Perform the following steps to set the device voltage and unused pin:

1. In the Category list, select Device and click Device and Pin Options.
2. Click the Unused Pins tab, and for Reserve all unused pins select As input tri-stated with weak pull-up resistor.
3. Click the Voltage tab, and for Default I/O standard select the same VCCIO voltage as the chosen SDRAM interface; for DDR2 SDRAM select 1.8 V.
4. Click OK.

Add Timing Constraints

When you instantiate an SDRAM high-performance controller, it automatically generates a timing constraints file, altemeddr_phy_ddr_timing.sdc. The timing constraint file constrains the clock, and the input and output delay on the SDRAM high-performance controller.

To add timing constraints, perform the following steps:

1. On the Assignments menu, click Settings.
2. In the Category list, expand Timing Analysis Settings, and select TimeQuest Timing Analyzer.
3. Select the altemeddr_phy_ddr_timing.sdc, altera_avalon_half_rate_bridge_constraints.sdc cpu.sdc, and cycloneIII_3c120_generic.sdc files and click Add.

   Add derive_pll_clocks command in the altera_avalon_half_rate_bridge_constraints.sdc file before you add this file.

4. Click OK.

Set Optimization Technique

To ensure that the remaining unconstrained paths are routed with the highest speed and efficiency, set the optimization technique. To set the optimization technique, perform the following steps:

1. On the Assignments menu, click Settings.
2. Select Analysis & Synthesis Settings.
3. Select Speed under Optimization Technique.
4. Click OK.
Set Fitter Effort
To set the Fitter effort, perform the following steps:
1. On the Assignments menu click **Settings**.
2. In the **Category** list, expand **Fitter Settings**.
3. Turn on **Optimize Hold Timing** and select **All Paths**.
4. Turn on **Optimize Multi-Corner Timing**.
5. Select **Standard Fit** under **Fitter Effort**.
6. Click **OK**.

Add Pin, DQ Group, and I/O Standard Assignments
The pin assignment script, `altmemddr_pin_assignments.tcl`, sets up the I/O standards for the DDR2 SDRAM interface. It also does the DQ group assignment for the Fitter to place them correctly. However, the pin assignment does not create a clock for the design. You need to create the clock for the design.

To run the `altmemddr_pin_assignments.tcl` script to add the pin, I/O standards, and DQ group assignments to the design example, perform the following steps:
1. On the Tools menu, click **Tcl Scripts**.
2. Select `altmemddr_pin_assignments.tcl`.
3. Click **Run**.

If you require pin name changes (prefix changes only), then in the Quartus II Pin Planner, perform the following steps:
1. On the Assignment menu, click **Pin Planner**.
2. Right-click in any area under **Node Name** and select **Create/Import Megafunction**, refer to Figure 6–15.
3. Select **Import an existing custom megafunction** and select the `<variation name>.ppf` file.
4. In the **Instance name** field, type the prefix that you want to use, refer to Figure 6–16 on page 6–25.
Alternatively, you may edit the altmemddr_pin_assignments.tcl file to change the prefix by following these steps:

1. Open the altmemddr_pin_assignments.tcl file.
2. To create assignments that do not match the SOPC Builder top-level pin names, change to the following code:
   
   ```tcl
   if {![info exists sopc_mode]} {set sopc_mode YES}
   to
   if {![info exists sopc_mode]} {set sopc_mode NO}
   ```
3. To change the prefix name to `mem_`, change to the following code:
   
   ```tcl
   if {![info exists pin_prefix]} {set pin_prefix "mem_"}
   ```
4. Save the altmemddr_pin_assignments.tcl file.
5. Run the .tcl script.

For more information about the DDR, DDR2, and DDR3 SDRAM High Performance Controllers pin naming, refer to the *DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide* and the *DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide* in volume 3 of the *External Memory Interface Handbook*.

**Pin Location Assignments**

To assign pin locations, perform the following steps:

1. On the Processing menu, point to **Start** and click **Start & Synthesis**.
2. Assign all of your pins, so the Quartus II software fits your design correctly and gives correct timing analysis. To assign pin locations for the Cyclone III development board, run the Altera-provided **C3_Dev_DDR2_Sopc_Pin_Location.tcl** file or manually assign pin locations by using either the Pin Planner or Assignment Editor.

The SDRAM high-performance controller auto-generated scripts do not make any pin location assignments.

If you are at the design exploration phase of your design cycle and do not have any PCB defined pin locations, you should still manually define an initial set of pin constraints, which can become more specific during your development process.

To manually assign pin locations in the Pin Planner, perform the following steps:

1. On the Assignments menu, click **Pin Planner**.
2. Assign DQ and DQS pins.
   a. To select the device DQS pin groups that the design uses, assign each DQS pin in your design to the required DQS pin in the Pin Planner. The Quartus II Fitter then automatically places the respective DQ signals onto suitable DQ pins within each group. To see DQS groups in the Pin Planner, right click, select **Show DQ/DQS Pins**, and click **In x8/x9 Mode**. The Pin Planner shows each DQS group in a different color and with a different legend: S = DQS pin, Sbar = DQSn pin and Q = DQ pin, refer to Figure 6–17 on page 6–27.

Most DDR2 SDRAM devices operate in x8/x9 mode, however as some DDR2 SDRAM devices operate in x4 mode, refer to your specific memory device datasheet.

b. Select the DQ mode to match the DQ group width (number of DQ pins/number of DQS pins) of your memory device. DQ mode is not related to the memory interface width.

DQ group order and DQ pin order within each group is not important. However, you must place DQ pins in the same group as their respective strobe pin.
3. Place the DM pins within their respective DQ group.

4. Place the address and control/command pins on any spare I/O pins ideally within the same bank or side of the device as the mem_clk pins.

5. Ensure the mem_clk pins use any regular adjacent I/O pins—ideally differential I/O pairs for the CK/CK# pin pair. To identify differential I/O pairs, right-click in Pin Planner and select Show Differential Pin Pair Connections (DIFFIO in Pin Planner). Pin pairs show a red line between each pin pair.

   - For Cyclone III and Cyclone IV devices, the mem_clk[0] pin cannot be located in the same row and column pad group as any of the interfacing DQ pins.

   - The DDR2 SDRAM in Stratix III and Stratix IV devices with differential DQS mode require the mem_clk[0]/mem_clk_n[0] pin on a DIFFIO_RX capable pin pair. The DDR3 SDRAM interfaces in Stratix III and Stratix IV devices require the mem_clk[0]/mem_clk_n[0] pin in any DQ or DQS pin pair with DIFFIO_RX capability.

   - For more information about memory clock pin placement and external memory pin selection, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.
6. Place the `clock_source` pin on a dedicated PLL clock input pin with a direct connection to the SDRAM controller PLL/DLL pair—usually on the same side of the device as your memory interface. This recommendation reduces PLL jitter, saves a global clock resource, and eases timing and fitter effort.

7. Place the `global_reset_n` pin (like any high fan-out signal) on a dedicated clock pin.

For more information on how to use the Quartus II Pin Planner, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*. For more information on Cyclone III external memory pin selection, refer to the *External Memory Interface in Cyclone III Devices* chapter in the *Cyclone III Device Handbook*.

**Enter Board Trace Delay Model**

For accurate I/O timing analysis, the Quartus II must be aware of the board trace and loading information. This information should be derived and refined during your PCB development process of prelayout (line) simulation and finally post-layout (board) simulation. For the external memory interfaces that use memory modules (DIMMs), the board trace and loading information should include the trace and loading information of the module in addition to the main and host platform, which you can obtain from your memory vendor.

To include the board trace information, perform the following steps:

1. In the Pin Planner, select the pin or group of pins that you want to enter the information for.

2. Right-click and select **Board Trace Model**.

*Figure 6–18 on page 6–28 shows the board trace model. Enter the values such as the trace length, capacitance/length, inductance/length, pull-up, pull-down and others based on your board.*

*Figure 6–18. Board Trace Model*
Table 6–3 shows the board trace model parameters for the Cyclone III development board.

### Table 6–3. Cyclone III Development Board Trace Model Summary

<table>
<thead>
<tr>
<th>Net</th>
<th>Near (FPGA End of Line)</th>
<th>Far (Memory End of Line)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Length</td>
<td>C_Per</td>
</tr>
<tr>
<td>Address</td>
<td>1.764</td>
<td>3.8p</td>
</tr>
<tr>
<td>CLK</td>
<td>1.872</td>
<td>3.4p</td>
</tr>
<tr>
<td>CKE/CSn</td>
<td>1.862</td>
<td>3.7p</td>
</tr>
<tr>
<td>ODT</td>
<td>1.527</td>
<td>3.8p</td>
</tr>
<tr>
<td>DQS (2)</td>
<td>1.165</td>
<td>3.6p</td>
</tr>
</tbody>
</table>

**Note to Table 6–3:**

1. Address = addr, ba, we#, ras#, and cas.
2. DQS = DM, DQ, and DQS pins.

Altera recommends you use the **Board Trace Model** assignment for all DDR, DDR2 and DDR3 SDRAM interface signals. To apply board trace model assignments for the Cyclone III development board, run the Altera-provided C3_Dev_DDR2_BTModels.tcl file or manually assign virtual pin assignments using the Quartus II Pin Planner.
Compile the Design

To compile the design, on the Processing menu, click **Start Compilation**.

After successfully compiling the design, the Quartus II software automatically runs the **altmemddr_phy_report_timing.tcl** file, which produces a timing report for the design together with the compilation report.

Figure 6–19 shows the timing margin report in the message window in the Quartus II software.

![Timing Margin Report in the Quartus II Software](image)

You may also run the report timing script in the TimeQuest Timing Analyzer window, To run the timing script, perform the following steps:

1. On the Tools menu, click **TimeQuest Timing Analyzer**.
2. Double-click **Update Timing Netlist** in the Tasks pane, which automatically runs **Create Timing Netlist** and **Read SDC File**. After a task is executed, it turns green.
3. After completing the tasks, run the report timing script by going to the Script menu and clicking **Run Tcl Script**.

Alternatively, you can directly double-click on **Report DDR** in the Tasks pane to get the timing report.
Chapter 6: Using High-Performance DDR, DDR2, and DDR3 SDRAM with SOPC Builder  6–31

**Figure 6–20** shows the timing margin report in the TimeQuest Timing Analyzer window after running the report timing script. The results are the same as the Quartus II software results.

**Figure 6–20.** Timing Margin Report in the TimeQuest Timing Analyzer

---

Incorporate the Nios II IDE

You can now add test code to the project’s Nios II processor and use this program to run some simple tests.

When doing memory tests, you must read and write from the external DDR SDRAM and not from cached memory. The following three methods avoid using Nios II cached memory:

- Use a Nios II processor that does not have cache memory, like the Nios II/s used in this example project.
- Use the alt_remap_uncached function.

**Launch the Nios II IDE**

To launch the Nios II IDE, perform the following steps:

1. One the Windows Start menu, point to All Programs, Altera, Nios II EDS <version>, Legacy Nios II Tools, and then click Nios II <version> IDE.

   If it is the first time you have run the IDE, click Workbench.
2. On the File menu, click **Switch Workspace** and select your project directory.

3. On the File menu, point to **New** and click **Project**.

4. Expand Altera Nios II select Nios II C/C++ Application and click **Next**.

5. Select **Blank Project** under Select Project Templates and click **Next**.

6. Ensure that SOPC Builder System .ptf is `<your project path>/your sopc top>.ptf`.

7. Click **Next** and click **Finish**.

8. In Windows Explorer, drag Altera-supplied DDR_TEST.c to the `blank_project_0` directory.

To see the DDR_TEST.c example test program, refer to “Example DDR_TEST.c Test Program File” on page 6–44.

This program consists of a simple loop that takes commands from the JTAG UART and executes them. Table 6–4 shows the commands that are sent to the Nios II C code.

The commands must be in the following format and the switches A, B, C, and D must be entered in upper case. Both address and data strings must always be 8 characters long.

<table>
<thead>
<tr>
<th>Command</th>
<th>Format</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Switch A</td>
<td>Switch</td>
<td>Data</td>
<td>Controls the LEDs.</td>
</tr>
<tr>
<td>Switch B</td>
<td>Switch</td>
<td>Address</td>
<td>Data</td>
</tr>
<tr>
<td>Switch C</td>
<td>Switch</td>
<td>Address</td>
<td>Performs a single read to an address offset location in memory.</td>
</tr>
<tr>
<td>Switch D</td>
<td>Switch</td>
<td>From Address</td>
<td>To Address</td>
</tr>
</tbody>
</table>
You can read the SOPC Builder component address locations directly from the SOPC Builder Window, refer to Figure 6–21.

**Figure 6–21.** SOPC Builder Component Address

---

**Set Up the Project Settings**

To set up the Nios II project settings, perform the following steps:

1. In the **Nios II C/C++ Projects** tab, right-click **blank_project_0** and click **System Library Properties**.
2. Click **System Library** in the list on the left side of the **Properties** dialog box.
3. To optimize the footprint size of the library project, under **System Library Contents**, turn on **Reduced device drivers**.
4. Under **Linker Script**, for all the memory options select **onchip_mem**. The on-chip memory is the target memory space for the executable file.
5. To reduce the memory size allocated for the system library, for **Max file descriptors** type 4.
6. Click OK.

**Perform RTL or Functional Simulation (Optional) with Nios II**

Perform the following steps to run RTL or functional simulation using the Nios II processor:

1. From the Nios II IDE, on the Run menu click RUN.
2. Under Nios II ModelSim, select **blank_project_0**.
3. Specify your ModelSim installation path in **ModelSim Path**.
4. Click Run. ModelSim is launched.
5. Type `s` in the ModelSim Transcript window to run the `s` macro to load the design.
6. Type `w` in the ModelSim Transcript window to run the `w` macro to display the waveform.
7. Type `jtag_uart_drive` to launch the interactive terminal.
8. Type `Run -all` to run the design.
9. In the interactive terminal, type your desired operation, data, and address, refer to Figure 6–23.
Figure 6–23. The JTAG UART Interactive Terminal

Figure 6–24 shows a single write operation where data 00000001 is written to address 00000001.

Figure 6–24. Waveform for Single Write Operation
Verify Design on a Development Platform

The SignalTap II Embedded Logic Analyzer shows read and write activity in the system.

For more information about using the SignalTap II Embedded Logic Analyzer, refer to the Design Debugging Using the SignalTap II Embedded Logic Analyzer chapter in the Quartus II Handbook, AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems and AN 446: Debugging Nios II Systems with the SignalTap II Logic Analyzer.

To add the SignalTap II Embedded Logic Analyzer, perform the following steps:

1. On the Tools menu, click SignalTap II Logic Analyzer.
2. In the Signal Configuration window next to the Clock box, click … (Browse Node Finder).
3. Type *phy_clk in the Named box, for Filter select SignalTap II: pre-synthesis and click List.
4. Select sopc_top:inst|altmemddr|the_altmemddr|phy_clk in Nodes Found and click > to add the signal to Selected Nodes.
5. Click OK.
6. Under Signal Configuration, specify the following settings:
   - For Sample depth, select 512
   - For RAM type, select Auto
   - For Trigger flow control, select Sequential
   - For Trigger position, select Center trigger position
   - For Trigger conditions, select 1
7. On the Edit menu, click Add Nodes.
8. Search for specific nodes by typing *local* in the Named box, for Filter select SignalTap II: pre-synthesis and click List.
9. In Nodes Found, select the following nodes and click > to add to Selected Nodes:
   - local_address
   - local_rdata
   - local_rdata_valid (alternative trigger to compare read/write data)
   - local_read_req
   - local_ready
   - local_wdata
   - local_write_req (trigger)

Do not add any DDR SDRAM interface signals to the SignalTap II Embedded Logic Analyzer. The load on these signals increases and adversely affects the timing analysis.
10. Click OK.

11. To reduce the SignalTap II logic size, turn off Trigger Enable on the following bus signals:
   - local_address
   - local_rdata
   - local_wdata

12. Right-click Trigger Conditions for the local_write_req signal and select Rising Edge.

   Figure 6–25 shows the completed SignalTap II Embedded Logic Analyzer.

   ![SignalTap II Embedded Logic Analyzer](image)

13. On the File menu, click Save, to save the SignalTap II .stp file to your project.

   ![Message icon] If you get the message Do you want to enable SignalTap II file “stp1.stp” for the current project, click Yes.

**Compile the Project**

Once you add signals to the SignalTap II Embedded Logic Analyzer, recompile your design, on the Processing menu, click Start Compilation.
Verify Timing
Once the design compiles, ensure that the TimeQuest timing analysis passes successfully. In addition to this FPGA timing analysis, check your PCB or system SDRAM timing.

To run timing analysis, run the `<variation name >_phy_report_timing.tcl` script by performing the following steps:
1. On the Tools menu, click Tcl Scripts.
2. Select `<variation name >_phy_report_timing.tcl` and click Run.

Connect the Development Board
Connect the Cyclone III development board to your computer.

For more information on the Cyclone III development board, refer to the *Cyclone III Development Kit User Guide*.

Download the Object File
On the Tools menu, click SignalTap II Logic Analyzer. The SignalTap II dialog box appears.

The SRAM Object File (SOF) Manager should contain the `<your project name >.sof` file. To add the correct file to the SOF Manager, perform the following steps:
1. Click ... to open the Select Program Files dialog box, refer to Figure 6–25.
2. Select `<your project name >.sof`.
3. Click Open.
4. To download the file, click the Program Device button.

**Figure 6–26.** Install the SRAM Object File in the SignalTap II Dialog Box

Verify Design with Nios II
Right-click on `blank_project_0`, point to Run As, and click Nios II Hardware for the the Nios II C/C++ IDE to compile the example test program.
If you have more than one JTAG download cable connected to your computer you may see an JTAG error. If you receive a JTAG error, perform the following steps:

1. From the Nios II IDE, on the Run menu click RUN. Click the Target Connection tab and correct the JTAG cable connection, refer to Figure 6–27.

2. Right click on blank_project_0, point to Run As, and click Nios II Hardware.

**Figure 6–27. JTAG Download Target Connection Settings**

---

**Test the System**

Perform the following tests to verify your system is operating correctly.

**Set SignalTap II Trigger to local_write_req**

Use the SignalTap II Embedded Logic Analyzer to capture write activity. To show write activity, perform the following steps:

1. In the Setup tab, select to trigger on a rising edge of local_write_req, refer to Figure 6–28.
2. Click **Run Once Analysis** to capture the write request.

3. Type the following command in the Nios II command console:
   
   \[B0000000010000001\]
   
4. Return to the SignalTap II Embedded Logic Analyzer window and check that at time 0 (refer to Figure 6–29):
   - **local_write_req** signal goes high for a single cycle
   - **local_wdata** shows \[00000001\]h
   - **local_address** shows \[000001\]h

**Figure 6–29. Waveform for Write Request**

---

2. Set **SignalTap II Trigger to local_write_req Signal**

   **Set SignalTap II Trigger to local_read_req**

   Use the SignalTap II Embedded Logic Analyzer to capture read activity. To show read activity, perform the following steps:

   1. In the **Setup** tab, select to trigger on a rising edge of **local_read_req**, refer to Figure 6–30.
2. Click **Run Once Analysis** to capture the read request
3. Type the following command in the Nios II command console:
   
   $ \text{C00000001}$

4. Return to the SignalTap II Embedded Logic Analyzer window and check that at time 0 (refer to Figure 6–22):
   - **local_read_req** signal goes high
   - **local_address** shows 000001h

   Several clock cycles later, depending on the system read latency:
   - **local_rdata_valid** goes high for one cycle
   - **local_rdata** shows 00000001h

   **Figure 6–30. Set Trigger for local_read_req Signal**

**Test Burst Write Operation**

Use the SignalTap II Embedded Logic Analyzer to capture write activity. To show write activity, perform the following steps:

1. In the **Setup** tab, select to trigger on a rising edge of **local_write_req**, refer to Figure 6–32.
2. Click **Run Once Analysis** to capture the write request.

3. Type the following command in the Nios II command console:

   D0200000000000000

4. Return to the SignalTap II Embedded Logic Analyzer window and check that at time 0 (refer to Figure 6–22):
   - The **local_write_req** signal goes high for multiple cycles
   - The **local_wdata** shows 03020100h followed by 07060504h and so on
   - The **local_address** shows 000000h followed by 000002h and so on

   *The write data is first to last, most significant byte (MSB) to the least significant byte (LSB) count format. For example, a count of 00, 01, 02, 03 = 03020100h.*

---

**Test Burst Read Operation**

Performing a burst read operation is similar to performing a burst write operation (refer to “Test Burst Write Operation” on page 6–41), but with the memory locations swapped. To perform a burst read operation, perform the following steps:

1. In the **Setup** tab, set to trigger on a rising edge of **local_read_req**.
2. Click **Run Once Analysis** to capture the read request:
3. Type the following command in the Nios II command console:
Example DDR_TEST.c Test Program File

```c
#include<stdio.h>
#include"sys/alt_dma.h"
#include "sys/alt_cache.h"
#include "system.h"
#include "altera_avalon_dma_regs.h"
define length 512
int to_hex(char* pkt)
{
    unsigned int value[8];
    unsigned int value1=0;
    unsigned int q;
    for (q=0;q<=7;q++)
    {
        value[q]=(pkt[q]>0x39)?(pkt[q]-0x37):(pkt[q]-0x30);
        if (q==0)
        {
            value1=(value1+value[q]);
        }
        else
        {
            value1=((value1<<4)+value[q]);
        }
    }
    return value1;
}

Many systems and applications use external memory interfaces as data storage or buffer mechanisms. As system applications require increasing bandwidth, become more complex, and devices get more expensive, designers prefer to have multiple memory interfaces in a single device to save cost and space on the board, along with removing partitioning complexity. To implement multiple memory interfaces on the same device that are efficient and optimized for the device architecture, designers must pay attention to the device and the physical interface (PHY) features.

This chapter describes the steps to implement multiple memory interfaces where there are independent memory transactions, but the interfaces are operating at the same frequency. Such implementations require multiple instantiations of the PHY, which in turn may necessitate device resource sharing, such as the delay-locked loops (DLLs) and clock networks, and may require extra steps to create the interfaces in a Quartus® II project. Multiple memory interfaces may also involve different types of memory standards, for example, if you have DDR2 SDRAM and RLDRAM II interfaces in a single Stratix® IV device. Width and depth expansion of a memory interface are not covered in this document as they are natively supported by the PHY. The memory interfaces described in this chapter use the ALTMEMPHY megafuntion.

While you may not be to share one PLL between multiple ALTMEMPHY-based controllers, you may be able to share the static clocks to reduce the number of clock networks used in the design.

You cannot merge dynamic clocks of the ALTMEMPHY megafuntion or high-performance controllers. The Quartus II software may not give a warning, but this merging does not work in the hardware.

This chapter assumes that you are familiar with the ALTMEMPHY megafuntion and Altera® FPGA resources. There is no design example associated with this tutorial.

Before Creating a Design in the Quartus II Software

When creating multiple memory interfaces to be fitted in a single device, first ensure that there are enough device resources for the different interfaces. These device resources include the number of pins, DLLs, PLLs, and clock networks, where applicable. The DLLs, PLLs, and clock network resources from the clock and reset management block can be shared between multiple memory interfaces, but there are sharing limitations that you need to pay close attention to.

For more information about selecting a device, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook.

The following different scenarios exist for the resources sharing DLL and PLL static clocks:
Multiple controllers with no sharing. You need to check the number of PLLs and DLLs that available in the targeted device and the number of PLLs and DLLs that needed in your design. If you have enough resources for the controllers, you do not need to share the DLL and PLL static clocks.

Multiple controllers sharing DLL only. If you have enough resources on PLL clocks output and only need to share DLL, ensure that the controllers are running at the same memory clock frequency.

Multiple controllers sharing PLL static clocks only. Ensure that all the controllers sharing the PLL static clocks are located in the same half of the device, as ALTMEMPHY requires the use of regional and dual-regional clocks, instead of global clocks. Each controller can have their own DLL as the DLL can only access the adjacent sides from its location.

Multiple controllers sharing DLL and PLL static clocks. The PLL static clocks and DLL can be shared when the controllers are on the same side or adjacent side of the device and provided they are running at the same memory-clock frequency.

After understanding the device resource limitations, determine the resources to share for your multiple controller design. You can use this as a framework for your Quartus II design constraints. If you also have a PCI interface in your design, you need to leave at least one bank (either on the top or the bottom of the device) for the PCI interface. For this particular example interface, you may need to share a DLL.

Creating PHY and Controller in a Quartus II Project

You can instantiate multiple controllers using either one of the following flows:

- **"SOPC Builder Flow"**
- **"MegaWizard Plug-In Manager Flow"**

The SOPC Builder flow provides useful validation and automatically generates all the wiring in SOPC Builder system and assignment. For the MegaWizard™ Plug-In Manager flow, you must manually set the assignment for the PLL static clock sharing but this flow gives you more flexibility.

SOPC Builder Flow

The SOPC Builder in version 8.1 and onwards of the Quartus II software allows you to add multiple controllers directly to a new or existing SOPC Builder system. The SOPC Builder supports sharing static PHY clocks between multiple controllers in the SOPC Builder that are running on the same frequency and sharing the same PLL reference clock. To share the static clocks, you must turn on the Clock source from another controller option in the Controller Settings page of the DDR, DDR2, or DDR3 SDRAM High Performance Controller wizard. This option must be turned on for the slave controllers. Turning on this option adds a new clock input connection point to the slave controller named shared_sys_clk. You must connect the sys_clk signal from the master controller to the shared_sys_clk signal of the slave controller (Figure 7–1). The Force Merging of PLL Clock Fanouts assignment is automatically assigned in the Quartus II software.
After the system generation, you must add the .sdc file and run the pin assignment Tcl scripts as usual.

When an SOPC Builder multiple controllers system does not share the sys_clk, SOPC Builder inadvertently inserts clock-crossing adaptors between the controller and the Nios II processor. In this situation, the system cannot achieve the maximum performance for both controllers.

SOPC Builder checks all the conditions listed in the regulation section and prevents you from generating the system when they are not met.

For more information on DDR, DDR2, and DDR3 SDRAM High Performance Controllers, refer to the *DDR and DDR2 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide* section and the *DDR3 SDRAM High-Performance Controller and ALTMEMPHY IP User Guide* section in volume 3 of the *External Memory Interface Handbook*.

For more information on simulating SOPC Builder systems, refer to *AN 351: Simulating Nios II Systems*.

**MegaWizard Plug-In Manager Flow**

If you are creating multiple instances of the same controller with the same parameters (frequency of operation, data width, burst mode, etc.), you only need to generate the controller once. You can then instantiate this controller variation multiple times in your top-level design file. If you are using controllers with different parameters, or you plan on modifying the RTL generated by the MegaWizard Plug-In Manager (as required for resource sharing in some cases), then you need to generate each variation of the memory controller individually.
If the controllers are generated individually Altera recommends you generate each controller’s files in a separate directory. However, you may get compilation errors if you add all the .qip files to the project. You may remove the following line in all the .qip files except for one to remove the compilation error:

```vhdl
set_global_assignment -name VHDL_FILE [file join $::quartus(qip_path) "auk_ddr3_hp_controller.vhd"]
```

The high-performance memory controller is generated with a top-level design called `<variation_name>_example_top.v` or `.vhd`, where `variation_name` is the name of the memory controller that you entered in the first page of the MegaWizard Plug-In Manager. This example top-level file instantiates the memory controller `<variation_name>.v` or `.vhd` and an example driver, which performs a comparison test after reading back data that was written to the memory. You can also generate simulation files for each high-performance controller or ALTMEMPHY megafuction.

When creating a multiple memory interface design, you have the option to combine certain aspects of the design flow. For example:

- You can use one of the top-level designs to instantiate all the memory controllers in the design, or create a new top-level design.
- You can either modify one of the example drivers to test all the memory interfaces in the design, or instantiate an example driver with each memory controller.
- You can simulate each memory interface separately, or create a testbench which combines all the memory interfaces in the design.

### Sharing DLLs

If the controllers are sharing a DLL, ensure that the Instantiate DLL externally option is turned on in the PHY Settings page of the DDR3/DDR2/DDR SDRAM High-Performance Controller or the ALTMEMPHY MegaWizard Plug-In Manager. This option must be turned on for every interface that is sharing a DLL.

When you turn on Instantiate DLL externally, the MegaWizard Plug-In Manager generates a file called `<variation_name>_phy_alt_mem_phy_dll_<device_family>.v/.vhd`, where `<device_family>` is:

- siii when targeting HardCopy® III, HardCopy IV, Stratix III, or Stratix IV devices
- aii when targeting Arria® II GX devices

The example top-level file then instantiates the DLL in addition to instantiating the memory controller and the example driver. You can then instantiate the other memory controllers for the design and either modify the example driver to create the test pattern for all controllers or create another design example for each controller instantiated.

If you do not need to share any PLL static clocks, you can continue to “Adding Constraints to the Design” on page 7–9.
Sharing PLL Clock Outputs or Clock Networks

The ALTMEMPHY sources a system clock, for use in your design, to clock your ALTMEMPHY interface. This same clock is used by Altera High-Performance controllers, SOPC Builder systems, and the Avalon® Memory-Mapped (Avalon-MM) interface connected to the memory controller. If you use more than one similarly configured ALTMEMPHY in a design, you can share these system clocks, which allows the ALTMEMPHY interfaces to operate synchronously to each other. PLL static clock sharing has the following benefits:

- Although a PLL instance is used for each ALTMEMPHY instance, the static clocks are shared, which uses fewer clocking resources
- The multiple ALTMEMPHYs operate on the same system clock so can be directly connected to logic on the same clock (for example, Avalon-MM interface) without any clock domain crossing logic required, which causes an increase in logic usage and read latency

PLL static clock sharing reduces the required number of clocks by up to four clock networks, which are used in the memory interface logic to clock the controller and generate DQ, DQS, CK/CK#, and address and command signals. Figure 7–2 shows a diagram of the connection between the DLL and the PLL for this scheme.

Figure 7–2. Two Controllers Static Clocks with Separate Resynchronization Clocks from Different PLLs

The maximum number of interfaces that can be shared in this scheme is limited by the number of PLLs and the number of pins available in the device. ALTMEMPHY-based memory interfaces may share static clocks between multiple controllers when the following rules are observed:
All ALTMEMPHYs are full-rate or all half-rate designs

All ALTMEMPHYs have the same PLL input and output frequencies

The ALTMEMPHY memory types are compatible. DDR and DDR2 SDRAM can be mixed in the same system; DDR3 SDRAM controllers may be compatible with DDR or DDR2 SDRAM if the static clock phases are identical.

- DDR3 with and without levelling implementations have different static clock phases. Check for the ALTMEMPHY static clock phase compatibility in the clocking tables of the appropriate device and memory interface standard.

- The `ref_clk` input of each ALTMEMPHY PLL must be connected to a clock signal derived from a single clock source. You can use a clock fanout buffer to create separate PLL reference clocks from a single clock source.

- All of the memory controller's circuitry is located in the same two device quadrants

- All of the clocks can be routed as required by their **Global Network Clock Type**. To see the global clocks, look in the Fitter Report > Resource selection > Global and other fast signals.

- The general routing rules defined in the relevant memory standard layout section are met.

Static clocks which can be shared are divided into two categories:

- Static clocks with a fixed phase in the IP (all static clocks except the address and command clock `ac_clk_1x`)

- Static clocks where the phase is set in the IP (the address and command clock `ac_clk_1x`)

Static clocks with a fixed phase in the IP do not require each controller's interface PCB traces to have the same delays. Static clocks with the phase set in the IP have several options where they may be shared between multiple controllers:

- The address and command clock traces all have the same respective delays from the FPGA to each device

- The TPD delay between the address and command signals and the memory clock of each of the interfaces is the same to all devices

- The TPD delay between the address and command signals and the memory clock of each of the interfaces is similar and the optimal address and command phase for each separate interface is within one to two PLL phase steps. Most designs should be able to use a single `ac_clk_1x` clock shared between all controllers and accept less margin.

For multiple controllers, where not all of the memory interface pins are on the same device edge, evaluating whether you can share static clocks is a complex process and there are many possible combinations of pin outs. In this case, you must evaluate the skews between signals across all controllers and factor this into the rules above for sharing clocks.
When static clocks are to be shared select which controller is to be the master. The slave controllers are made to share the master’s static clocks by using the **Force Merging of PLL Clock Fanouts** assignments. You need to manually add the two PLL merging assignments using the Assignment Editor or directly update the .qsf file.

The **Force Merging of PLL Clock Fanouts** option requires both the master and slave PLL to have the same input reference clock in the RTL. This option limits the placement of the controllers to be only on the same side where one input clock can provide the reference clock for both center PLLs. If your multiple memory controllers’ PLLs cannot share the same input reference clock pin, you need to manually connect the clocks together via RTL, instead of using this assignment.

If you are not sharing the address and command clocks, generate the slave controller address and command clocks from the master controller’s PLL spare outputs. Create these in the PLL wizard. Modify the PHY source code to bring these clocks out to the top-level file and then modify the slave controllers to connect in the new address and command clock.

Table 7–1 shows a list of PLL merging assignments.

</table>
To check that the Quartus II software has applied the assignments, read the Compilation Report - PLL Usage (available only if the fitter step is successful), which shows the two clocks merged. This report allows you to compare the PLL usage before PLL merging and after PLL merging.

If the report does not show the clocks merged as expected you should check the **FORCE_MERGE_PLL_FANOUTS** assignment carefully for incorrect clock names. You can also open your `<projectname>_fit.rpt` file and look for Merged PLL.
Adding Constraints to the Design

The MegaWizard Plug-In Manager generates an .sdc file for timing constraints and .tcl scripts for I/O standard and DQS/DQ grouping constraints of each controller. TimeQuest™ is the default timing analyzer for the Arria GX, Stratix III, and Cyclone III device families. To optimize timing with the Quartus II compiler and to use the timing report script created by the MegaWizard Plug-In Manager manually, you must enable the TimeQuest Timing Analyzer.

You must then add the .sdc file for each controller. If you are using two or more different memory controller variations, then you need to add the .sdc files generated for each variation. If, however, your design consists of multiple instantiations of the same controller, you only need to add the .sdc file once without modification. The Quartus II software is able to apply the .sdc file for all the interfaces using the same variation.

The High-Performance Memory Controller MegaWizard Plug-In Manager also generates two .tcl scripts per variation to set the I/O standard, output enable grouping, termination, and current strength for the memory interface pins. These .tcl scripts use the default MegaWizard Plug-In Manager names; for example, `mem_dq[71..0]`, `local_ready`, and `mem_ras_n`. Every variation of the high-performance memory controller uses this naming convention. However, if there are multiple memory controllers in the design, you must change the names of the interface pins in the top-level file to differentiate each controller. You can add prefixes to the controller pin names in the Quartus II Pin Planner by following these steps:

1. Open the Assignment menu and click on Pin Planner.
2. Right-click in any area under Node Name, and select Create/Import Megafunction (Figure 7–3).
3. Turn on the Import an existing custom megafunction radio button and choose the `<variation_name>.ppf` file.

4. Type the prefix that you want to use under the Instance name (Figure 7–4).

You may also want to set the default I/O standard for your design in the Voltage section of the Device and Pin Options, by navigating to Assignment and clicking Setting (Figure 7–5).
Be aware of the number of available pins per I/O bank to ensure that the Quartus II software can successfully compile the design.

Compiling the Design to Generate a Timing Report

During design compilation, the Quartus II software analyzes the timing margins for the memory controllers across the three timing model corners. As an alternative, you can also open the Tools menu and click TimeQuest Timing Analyzer. Double click on Report DDR to get the timing report for all ALTMEMPHY-based memory controllers in the design for the timing model that you select in the TimeQuest timing analyzer.

For more information about analyzing memory interface timing in Stratix III and Cyclone III devices, refer to the Timing Analysis section in volume 4 of the External Memory Interface Handbook.

Timing Closure

You may encounter some of the following timing failures:

- If read capture setup time is negative, you need to decrease the delay chain used in the DQ pins by setting the Input Delay from Pin to Input Register to 0 or a lower number than the current setting in the Assignment Editor. However, if hold time is negative, you need to do the opposite; increment the Input Delay from Pin to Input Register setting to a higher number than the current setting in the Assignment Editor.
- If you are experiencing any write and address/command timing failures, you may be able to resolve them by setting:

  ```
  set_instance_assignment -name CLOCK_TO_OUTPUT_DELAY 0 -to <address/command/CK/CK# pin>
  ```

- If the resynchronization path is not meeting timing, you must move the resynchronization registers closer to the IOE. Report DDR shows information messages with the names of the source and destination registers of the worst case setup path. You must copy the name of the destination register from the message and move it as close as possible to the source register using the Assignment Editor. Similarly, if the postamble path is not meeting recovery timing, move the postamble registers closer to the IOE.

- Setup failures for transfers from the measure clock \( (\text{clk}5) \) to the PHY clock \( (\text{clk}0 \text{ for half-rate interfaces or clk}1 \text{ for full-rate interfaces}) \) should be ignored. Due to the dynamic nature of the measure clock these should be treated as asynchronous transfers.

For more information about other issues that may cause timing failures in your design, refer to the latest version of the *Quartus II Release Notes.*

This tutorial describes how to use the design flow to implement an 18-bit wide, 400-MHz, 1600-Mbps QDR II+ SRAM controller with UniPHY interface using Stratix® III devices, and an 18-bit wide, 350-MHz, 1400-Mbps QDR II+ SRAM controller with UniPHY interface using Stratix IV devices. This tutorial also provides some recommended settings to simplify the design.

The design flow is also applicable for a QDR II SRAM controller with UniPHY interface.

The design examples target the Stratix III FPGA development kit, which includes an 18-bit wide, 36-Mb, 4-word burst, Cypress CY7C1263V18 400-MHz QDR II+ SRAM memory component, and the Stratix IV GX FPGA development kit, which includes an 18-bit wide, 72-Mb, 4-word burst, Cypress CY7C1563V18 400-MHz QDR II+ SRAM memory component. These design examples are also applicable to Arria® II GX devices.

To download the design examples, emi_qdrii_siii.zip and emi_qdrii_siv.zip, go to the External Memory Interface Design Examples page.

For more information about the design flow, refer to the Recommended Design Flow section in volume 1 of the External Memory Interface Handbook. For more information about the QDR II and QDR II+ SRAM controller with UniPHY, refer to the QDR II and QDR II+ SRAM Controller with UniPHY section in volume 3 of the External Memory Interface Handbook.

System Requirements

This tutorial assumes that you have experience with the Quartus® II software. This tutorial requires the following software:

- Quartus II software version 9.1 SP1 or later
- QDR II and QDR II+ SRAM Controller with UniPHY MegaCore® version 9.1
- ModelSim®-Altera® version 6.5b or later

Create a Quartus II Project

Create a project in the Quartus II software that targets the respective device: a EP3SL150F1152C2 device for the Stratix III device family, or a EP4SGX230KF40C3ES device for the Stratix IV GX device family.

For detailed step-by-step instructions to create a Quartus II project, refer to the Quartus II software tutorial by clicking the Help menu in the Quartus II window and selecting PDF Tutorials.
Instantiate and Parameterize a Controller

After creating a Quartus II project, instantiate the QDR II and QDR II+ SRAM controller with UniPHY and its parameters.

Instantiate a Controller

To instantiate the controller with UniPHY, perform the following steps:

1. Start the MegaWizard™ Plug-In Manager.
2. In the MegaWizard Plug-In Manager, expand External Memory in the Interfaces folder and select QDR II and QDR II+ SRAM Controller with UniPHY v9.1.
3. Type qdr_uniphy for the name of the QDR II and QDR II+ SRAM controller with UniPHY.

Parameterize QDR II+ SRAM Controller with UniPHY Interface

To parameterize the QDR II and QDR II+ SRAM controller with UniPHY for a 400-MHz, 18-bit wide QDR II+ SRAM interface with Stratix III devices, and a 350-MHz, 18-bit wide QDR II+ SRAM interface with Stratix IV devices, perform the following steps:

1. In the Presets list, select a memory preset from the list of presets that matches your memory based on your memory device specifications. If your memory device is not available in preset list, you have to modify the parameters based on your memory datasheet. Select CY7C1263V18-400 from the preset list for Stratix III design, or choose a memory device that suits the requirements on the CY7C1563V18-400 datasheet for the Stratix IV design, if the CY7C1563V18 is not in the preset list.

2. In the General Settings tab, under Clocks, for Memory clock frequency, type 400 MHz for Stratix III design, or 350 MHz for Stratix IV design as the system frequency.
3. For PLL reference clock frequency, type 125 MHz for Stratix III design, or 50 MHz for Stratix IV design.
4. For Full or half rate on Avalon-MM interface, select Half.
5. For Additional address/command clock phase, select 0.

If you are using the SOPC Builder system, turn on Generate power-of-2 bus widths under Advanced Settings.

6. For I/O standard, select 1.8-V HSTL for Stratix III design, or 1.5-V HSTL for Stratix IV design.
7. For Maximum Avalon-MM burst length, specify the burst length based on your system. For example, if your system only generates up to 64 beats, then select 64.
8. Turn on **Master for PLL/DLL sharing** if you want the UniPHY to instantiate its own PLL. If the **Master for PLL/DLL sharing** option is disabled, the PLL clock shares with other identical UniPHY core.

9. Turn off the **×36 emulated mode** option. Both Stratix III and Stratix IV designs use ×18 mode.

   For more information about ×36 emulated mode, refer to the *Device and Pin Planning* section in volume 2 of the *External Memory Interface Handbook*.

10. Under **Example Testbench Simulation Options**, turn on **Skip memory initialization**. Enabling this option allows you to skip the memory initialization sequence during simulation.

11. In the **Memory Parameters** tab, set the parameters based on the CY7C1563V18-400 datasheet if you are using the Stratix IV design.

12. In the **Memory Timing** tab, for the **Maximum board skew (data)** and **Maximum board skew (address and control)** options, select 20 ps.

   For more accurate timing analysis, assign the board trace delay model for every single pin. The board skew values are used to calculate the overall system timing margin. Change these values based on the performance of your board if you are not using the board trace delay model, or if you cannot accurately assign the board trace model for each pin. Refer to “Enter Board Trace Delay Models” on page 1–6 for more information about board trace delay models.

13. Click **Finish** to generate your MegaCore function variation. The MegaWizard Plug-In generates all the files necessary for your QDR II and QDR II+ SRAM controller with UniPHY, and an example top-level design, which you may use to test or verify board operation.

### Add Constraints

When you instantiate a QDR II and QDR II+ SRAM controller with UniPHY, the Quartus II software generates the constraints files for the design example. Apply these constraints to the design before compilation.

### Add Example Project

Add the example project files to your project by performing the following steps:

1. On the Project menu, click **Add/Remove Files in Project**.
2. Browse to the `<variation_name>`\example_project directory.
3. Select all the files with the `<variation_name>` prefix, except for the `<variation_name>_mem_model.sv` file, and click **Open**.
4. Click **OK**.
Set Top-Level Entity

The top-level entity of the project must be set to the correct entity. To set the top-level file, perform the following steps:

1. On the File menu, click Open.
2. Browse to the `<variation_name>_example_top.v or .vhd` file and click Open.
3. On the Project menu, click Set as Top-Level Entity.

Add Pin and DQ Group Assignments

The pin assignment script, `<variation_name>_pin_assignments.tcl`, sets up the I/O standards for the QDR II+ SRAM with UniPHY interface. This script does not include the assignment for the design’s PLL input clock. You must create a PLL input clock for the design and provide pin assignments for the signals of both the example driver and testbench that the MegaCore variation generates.

Run the `<variation_name>_pin_assignments.tcl` script to add the pin, I/O standards, and DQ group assignments to the design example.

The PLL input clock I/O does not need to have the same I/O standard as the memory interface I/Os. However, you may see a no-fit error as the bank in which the PLL input clock I/O gets placed becomes unusable for placement of the memory interface I/Os because of the incompatible VCCIO levels. Altera recommends that you assign the same I/O standard to the PLL input clock I/O.

Enter Pin Location Assignments

To enter the pin location assignments, assign all of your pins, so the Quartus II software fits your design correctly and gives correct timing analysis. To assign the pin locations, run the Altera-provided `SIII_qdrii_pin_location.tcl` file for the Stratix III FPGA development kit, and `SIV_GX_qdrii_pin_location.tcl` file for the Stratix IV GX FPGA development kit.

Alternatively, to manually assign the pin locations in the Pin Planner, perform the following steps:

1. On the Assignments menu, click Pin Planner.
2. To view the DQS groups in the Pin Planner, right click, select Show DQ/DQS Pins, and click In x16/x18 Mode. The Pin Planner shows each DQS group in a different color and with a different legend: S = DQS pin, Sbar = DQSn pin and Q = DQ pin, as shown in Figure 1–1.
3. To identify the differential I/O pairs in the Pin Planner, right-click and select **Show Differential Pin Pair Connections**. The pin pairs show a red line between each pin pair.

For more information about pin location assignments, refer to the **Device and Pin Planning** section in volume 2 of the **External Memory Interface Handbook**.

**Assign Virtual Pins**

The example top-level design, which is auto-generated by the QDR II and QDR II+ SRAM controller with UniPHY, includes an example driver to stimulate the interface. This example driver is not part of the QDR II and QDR II+ SRAM controller with UniPHY IP, but allows easy testing of the IP.
The example driver outputs several test signals to indicate its operation and the status of the stimulated memory interface. These signals are `afi_cal_success`, `afi_cal_fail`, `pass`, `fail`, and `test_complete`. These signals are not part of the memory interface, but are to facilitate testing. You must connect these signals to a debug bus or assign the signals to virtual pins using the Quartus II Assignment Editor. When using the example driver for testing, do not remove these signals from the top-level signal list. If you remove these signals from the top-level module, the Quartus II software optimizes the driver away, and the example driver fails.

To assign the virtual pins for the Stratix III FPGA development kit, run the Altera-provided `s3_qdr2_exdriver_vpin.tcl` file, and for the Stratix IV GX FPGA development kit, run the Altera-provided `s4_GX_qdr2_exdriver_vpin.tcl` file, or manually assign the virtual pins using the Assignment Editor.

**Enter Board Trace Delay Models**

For accurate I/O timing analysis, the Quartus II software must be aware of the board trace and loading information. This information should be derived and refined during your PCB development process of prelayout (line) simulation and final post-layout (board) simulation. For external memory interfaces that use memory modules (DIMMs), this information should include the trace and loading information of the module in addition to the main and host platform, which you can obtain from your memory vendor.

To enter the board trace information, perform the following steps:

1. In the Pin Planner, select the pin or group of pins for which you want to enter board trace parameters.
2. Right-click and select **Board Trace Model**.

Altera recommends that you use the board trace model assignment on all QDR II and QDR II+ SRAM interface signals. To apply the board trace model assignments for the Stratix III FPGA development kit, run the Altera-provided `S3_QDR2_BTModels.tcl` file, and for the Stratix IV GX FPGA development kit, run the Altera-provided `S4_GX_QDR2_BTModels.tcl` file. You can also manually assign the board trace model values using the Pin Planner.
Perform RTL Simulation (Optional)

This section describes RTL (functional) simulation.

To perform the functional simulation of your memory interface, use the functional model of the UniPHY generated by the MegaWizard Plug-In Manager. You must use this model along with your own driver or testbench that issues the read and write operations, and a memory model.

This design example includes the driver, testbench, and the memory model that allows you to perform functional simulation on the design. Use the ModelSim-Altera simulator to perform the functional simulation. This design example also includes a script file that directs the simulator to perform the necessary compilation and simulation.

To run the RTL simulation with NativeLink, perform the following steps:

1. Set the absolute path to your third-party simulator executable file, by performing the following steps:
   a. On the Tools menu, click Options.
   b. In the Category list, select EDA Tools Options and set the default path for ModelSim-Altera to C:\<version>\modelsim_ae\win32aloem.
   c. Click OK.

2. On the Assignments menu, click EDA Tool Settings.

3. In the Category list, expand EDA Tool Settings and click Simulation.

Table 1–1 shows the board trace model parameters for the Stratix III FPGA and Stratix IV GX FPGA development kits.

| Table 1–1. QDR II+ SRAM Board Trace Model Summary for Stratix III and Stratix IV GX FPGA Development Kits |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| Net | Near (FPGA End of Line) | Far (Memory End of Line) |
| Add_Cntl | Length (in) | C_per_length (pF/in) | L_per_length (nH/in) | Cn (pF) | Rns (Ω) | Rnh (Ω) | Length (in) | C_per_length (pF/in) | L_per_length (nH/in) | Cf (pF) | Rfh (Ω) |
| Stratix III | 3.456 | 3.36 | 7.77 | — | — | — | 5 | 56 |

© February 2010  Altera Corporation  QDR II, QDR II+ SRAM, and RLDRAM II Design Tutorials
5. Under **NativeLink settings**, select **Compile test bench** and click **Test Benches**.

6. Click **New**.

7. In the **Edit Test Bench Settings** dialog box, perform the following steps:
   a. Type the testbench name, `qdrii_uniphy_rtl_sim`.
   b. Type the top-level module file name, `qdrii_uniphy_example_top_tb.v`.
   c. Type the design instance name, `dut`.
   d. Select **Run simulation until all vector stimuli are used**.
   e. In the **Test bench files** field, include the testbench file, `<variation name>_example_top_tb.v`, and the memory model file, `<variation name>_mem_model.sv` (Figure 1–2).
   f. Click **OK**.

8. To elaborate your design, on the Processing menu, point to **Start** and click **Start Analysis & Elaboration**.

9. On the Tools menu, point to the **Run EDA Simulation Tool** and click **EDA RTL Simulation**. This step creates the `simulation` directory in your project directory and a script that compiles all necessary files and runs the simulation.

**Compile Design and Verify Timing**

To compile the design, on the Processing menu, click **Start Compilation**.

After successfully compiling the design, Quartus II software automatically runs the verify timing script, `<variation name>_report_timing.tcl`, which produces a timing report for the design together with the compilation report.
Figure 1–3 shows the timing margin report in the message window in the Quartus II software.

The report timing script performs the following tasks:

1. Creates a timing netlist.
2. Reads the `<variation_name>.sdc` file.
3. Updates the timing netlist.

You can also obtain the timing report by running the report timing script, `<variation_name>_timing.tcl`, in the TimeQuest timing analyzer. To obtain the timing report in the TimeQuest Timing Analyzer window, perform the following steps:

1. On the Tools menu, click TimeQuest Timing Analyzer.
2. On the Tasks pane, double-click Report DDR to run Update Timing Netlist, Create Timing Netlist, and Read SDC File. This command subsequently executes the report timing script to generate the timing margin report.
Figure 1–4 shows the timing margin report in the TimeQuest Timing Analyzer window after running the report timing script. The results are the same as the Quartus II software results.

**Figure 1–4. Timing Margin Report in the TimeQuest Timing Analyzer**

For more information about the TimeQuest timing analyzer, refer to *The Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Software Handbook*. For information timing analysis, refer to the *Timing Analysis* section in volume 4 of the *External Memory Interface Handbook*.

**Verify FPGA Functionality**

The SignalTap® II Embedded Logic Analyzer shows read and write activity in the system.

For more information about using the SignalTap II Embedded Logic Analyzer, refer to the following documents:

- *Design Debugging Using the SignalTap II Embedded Logic Analyzer* chapter in volume 3 of the *Quartus II Handbook*
- *AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems*
- *AN 446: Debugging Nios II Systems with the SignalTap II Embedded Logic Analyzer*
To add the SignalTap II Embedded Logic Analyzer to your Quartus II project, perform the following steps:

1. On the Tools menu, click **SignalTap II Logic Analyzer**.
2. Under **Signal Configuration** next to the **Clock** box, click ![…](Browse Node Finder).
3. Type *afi_clk* in the **Named** box, for **Filter** select **SignalTap II: pre-synthesis** and click **List**.
4. Select `<variation_name>:mem_if|afi_clk` in **Nodes Found** and click > to add the signal to **Selected Nodes**.
5. Click **OK**.
6. Under **Signal Configuration**, specify the following settings:
   - For **Sample depth**, select **512**
   - For **RAM type**, select **Auto**
   - For **Trigger flow control**, select **Sequential**
   - For **Trigger position**, select **Center trigger position**
   - For **Trigger conditions**, select **1**
7. On the Edit menu, click **Add Nodes**.
8. In the **Named** box, search for specific nodes by typing *avl*, for **Filter** select **SignalTap II: pre-synthesis** and click **List**.
9. In **Nodes Found**, select the following nodes and click > to add to **Selected Nodes**:
   - avl_addr
   - avl_read_req
   - avl_ready
   - avl_write_req
   - fail
   - pass
   - afi_cal_fail
   - afi_cal_success
   - test_complete
   - be_reg
   - pnf_per_bit
   - rdata_reg
   - rdata_valid_reg
   - data_out

   Do not add any QDR II+ SRAM interface signals to the SignalTap II Embedded Logic Analyzer. The load on these signals increases and adversely affects the timing analysis.
10. Click OK.

11. To reduce the SignalTap II logic size, turn off Trigger Enable on the following bus signals:
   - avl_addr
   - data_out
   - pnf_per_bit
   - rdata_reg
   - be_reg

12. Right-click Trigger Conditions for the test_complete signal and select Rising Edge.

13. On the File menu, click Save to save the SignalTap .stp file to your project.

   If you see the message Do you want to enable SignalTap II file “stp1.stp” for the current project?, click Yes.

   Figure 1–5 shows the completed SignalTap II Embedded Logic Analyzer after you perform all the steps.

**Figure 1–5. SignalTap II Embedded Logic Analyzer**

---

**Compile the Project**

After you add signals to the SignalTap II Embedded Logic Analyzer, to recompile your design, on the Processing menu, click Start Compilation.
Verify Timing

After the design compiles, ensure that the TimeQuest timing analysis passes successfully. In addition to this FPGA timing analysis, check your PCB or system SDRAM timing. To perform timing analysis, run the `<variation name>_report_timing.tcl` script by performing the following steps:

1. On the Tools menu, click Tcl Scripts.
2. Select `<variation name>_report_timing.tcl`.
3. Click Run.

Download the Object File

To download the object file to the device, perform the following steps:

1. Connect the development board to your computer.
2. On the Tools menu, click SignalTap II Logic Analyzer. The SignalTap II dialog box appears.
3. Click ... to open the Select Program Files dialog box.
4. Select `<your project name>.sof`.
5. Click Open.
6. To download the file, click the Program Device button.

Test the Design Example in Hardware

When the design example including SignalTap II Embedded Logic Analyzer successfully downloads to your development board, click Run Analysis to run once, or click Autorun Analysis to run continuously.

The design analysis in Figure 1–6 shows the `pnf_per_bit` and `pass` signals going high indicating that the test passes in hardware.

Figure 1–6. SignalTap II Example QDR II and QDR II+ SRAM Design Analysis

The design analysis in Figure 1–7 shows the data comparison between `rdata_reg[71:0]` and `data_out[71:0]` when the `rdata_valid_reg` and `data_out[79:72]` signals are high.
The `data_out[79:72]` signal that acts as byte-enable signal, selects certain x9 groups to compare the data. For this example, the `data_out[79:72]` signal is `1'b00110000`, which indicates that the fifth and sixth x9 groups in the `data_out[71:0]` signal are selected for data comparison.
2. Using RLDRAM II Controller with UniPHY in Stratix III and Stratix IV Devices

This tutorial describes how to use the design flow to implement a 36-bit wide, 400-MHz, 800-Mbps RLDRAM II controller with UniPHY interface. This tutorial also provides some recommended settings, including termination schemes and drive strength settings, to simplify the design.

The design examples target Stratix® III memory demonstration board and Stratix IV FPGA development board, which include a 36-bit wide 576-Mb Micron MT49H16M36-18 533-MHz component.

The Stratix III demonstration board is for internal use only.

To download the design examples, emi_rldramii_siii.zip and emi_rldramii_siv.zip, go to the External Memory Interface Design Examples page.

For more information about the design flow, refer to the Recommended Design Flow section in volume 1 of the External Memory Interface Handbook. For more information about the RLDRAM II SRAM controller with UniPHY, refer to the RLDRAM II Controller with UniPHY section in volume 3 of the External Memory Interface Handbook.

System Requirements

This tutorial requires the following hardware and software for the RLDRAM II controller with UniPHY using a Stratix III device:

- Quartus® II software version 9.1 SP1
- RLDRAM II Controller with UniPHY MegaCore® version 9.1
- ModelSim®-Altera® version 6.5b or later
- Stratix III FPGA memory demonstration board with EP3SL150F1152C2ES device

This tutorial requires the following hardware and software for the RLDRAM II controller with UniPHY using a Stratix IV device:

- Quartus II software version 9.1 SP1
- RLDRAM II Controller with UniPHY MegaCore version 9.1
- ModelSim-Altera version 6.5b or later
- Stratix IV FPGA development board with EP4SE530H35C2ES device

If you use a Quartus II software version later than 9.1 SP1, you must regenerate the MegaCore function in the design example.

Create a Quartus II Project

Create a project in the Quartus II software that targets the respective device; EP3SL150F1152C2ES device for the Stratix III device family, or EP4SE530H35C2ES device for the Stratix IV GX device family.
For detailed step-by-step instructions to create a Quartus II project, refer to the Quartus II software tutorial by clicking the Help menu in the Quartus II window and selecting PDF Tutorials.

**Instantiate and Parameterize a Controller**

After creating a Quartus II project, instantiate the RLDRAM II controller with UniPHY and its parameters.

**Instantiate a Controller**

To instantiate the controller with UniPHY, perform the following steps:

1. Start the MegaWizard™ Plug-In Manager.
2. In the MegaWizard Plug-In Manager, expand **External Memory** in the Interfaces folder and select **RLDRAM II Controller with UniPHY v9.1**.
3. Type `rldram` for the name of the RLDRAM II controller with UniPHY.

**Parameterize a Controller**

To parameterize the RLDRAM II controller with UniPHY to interface with a 400-MHz, 36-bit wide RLDRAM II interface, perform the following steps:

1. In the **Presets** list, select `MT49H16M36-18` and click **Apply**. The memory parameters are set automatically based on the memory preset settings you choose. You may change the parameters to suit your design requirements.
   
   Selecting a new memory preset overwrites your existing settings. You need to enter the settings again.

2. In the **General Settings** tab, under **Clocks**, for **Memory clock frequency**, type **400 MHz** as the system frequency.
3. For **PLL reference clock frequency**, type **100 MHz** for Stratix III design, or **50 MHz** for Stratix IV design to match the on-board oscillator.
4. For **Full or half rate on Avalon-MM interface**, select **Half**. This option allows you to choose between the full-rate and half-rate controller, and define the bus data width between the controller and the PHY.

   For more information about selecting half-rate or full-rate controller, refer to the **Device and Pin Planning** section in volume 2 of the **External Memory Interface Handbook**.

5. For **Additional address/command clock phase**, select **0**.

   If you are using the SOPC Builder system, turn on **Generate power-of-2 bus widths** under **Advanced Settings**.

6. For **I/O standard**, select **1.8-V HSTL**.
7. For **Maximum Avalon-MM burst length**, specify the burst length based on the burst count sent from the core fabric. For both design examples, select **128**.
8. Turn on **Master for PLL/DLL sharing** if you want the UniPHY to instantiate its own PLL. If the **Master for PLL/DLL sharing** option is disabled, the PLL clock shares with other identical UniPHY core.

9. Under **Example Testbench Simulation Options**, turn on **Skip memory initialization**. Enabling this option allows you to skip the memory initialization sequence during simulation so that you can reduce the simulation time.

10. In the **Memory Parameters** tab, for **Memory Mode Register Configuration**, select \( t_{RC}=6, t_{RL}=6, t_{WL}=7, f=400-175\text{MHz} \).

11. In the **Memory Timing** tab, for the **Maximum board skew (data)** and **Maximum board skew (address and control)** options, select 20 ps.

   For more accurate timing analysis, assign the board trace delay model for every single pin. The board skew values are used to calculate the overall system timing margin. Change these values based on the performance of your board if you are not using the board trace delay model, or if you cannot accurately assign the board trace model for each pin. Refer to “**Enter Board Trace Delay Models**” on page 2–7 for more information about board trace delay model.

12. Click **Finish** to generate your MegaCore function variation. The MegaWizard Plug-In generates all the files necessary for your RLDRAM II controller with UniPHY, and an example top-level design, which you may use to test or verify the board operation.

13. If you generate the MegaCore function instance in a Quartus II project, you are prompted to add the `.qip` files to the current Quartus II project. When prompted to add the `.qip` files to your project, click **Yes**. The NativeLink requires the `.qip` files to include libraries for simulation.

   The `.qip` file is generated by the MegaWizard interface, and contains information about the generated IP core. In most cases, the `.qip` file contains all of the necessary assignments and information required to process the MegaCore function or system in the Quartus II compiler. The MegaWizard interface generates a single `.qip` file for each MegaCore function.

14. Click **Exit** to close the MegaWizard Plug-In Manager after you have reviewed the generation report.

   For detailed step-by-step instructions for parameterizing the RLDRAM II controller with UniPHY, refer to **Volume 3: Implementing Altera Memory Interface IP** of the **External Memory Interface Handbook**.

---

### Add Constraints

After instantiating the RLDRAM II controller with UniPHY, the Quartus II software generates the constraints files for the design example. Apply these constraints to the design before compilation.
Add Example Project

Add the example project files to your project, by performing the following steps:

1. On the Project menu, click Add/Remove Files in Project.
2. Browse to the `<variation_name>`\example_project directory.
3. Select all the files with the `<variation_name>` prefix, except for the `<variation_name>mem_model.sv` file, and click Open.
4. Click OK.

Set Top-Level Entity

The top-level entity of the project must be set to the correct entity. To set the top-level file, perform the following steps:

1. On the File menu, click Open.
2. Browse to the `<variation_name>example_top.v` or `.vhd` file and click Open.
3. On the Project menu, click Set as Top-Level Entity.

Refer to the `<variation_name>example_top.v` or `.vhd` file to instantiate the memory controller in your own design.

Add Pin and DQ Group Assignments

The pin assignment script, `<variation_name>_pin_assignments.tcl`, sets up the I/O standards and the input/output termination for the RLDRAM II with UniPHY interface. This script also helps to relate the DQ and QK pin groups together for the Fitter to place them correctly in the Quartus II software.

This script does not create a clock for the design. You need to create a clock for the design and provide pin assignments for the signals of both the example driver and testbench that the MegaCore variation generates.

Run the `<variation_name>_pin_assignments.tcl` script to add the input/output termination, I/O standards, and DQ group assignments to the design example. To run the pin assignment script, perform the following steps:

1. On the Processing menu, point to Start and click Start Analysis & Synthesis.
2. In the Tools menu, click Tcl Scripts.
3. Locate the `<variation_name>_pin_assignments.tcl` file.
4. Click Run.

The PLL input clock I/O does not need to have the same I/O standard as the memory interface I/Os. However, you may see a no-fit error as the bank in which the PLL input clock I/O gets placed becomes unusable for placement of the memory interface I/Os because of the incompatible VCCIO levels. Altera recommends that you assign the same I/O standard to the PLL input clock I/O.
Chapter 2: Using RLDRAM II Controller with UniPHY in Stratix III and Stratix IV Devices

Add Constraints

Enter Pin Location Assignments

To enter the pin location assignments, assign all of your pins, so the Quartus II software fits your design correctly and performs correct timing analysis. To assign the pin locations for the Stratix III demonstration board, run the Altera-provided S3_Memory_RLDRAM_PinLocations.tcl file, and for the Stratix IV GX FPGA development board, run the Altera-provided S4_Host_RLDRAM_PinLocations.tcl file.

If you are at the design exploration phase of your design cycle and do not have any PCB defined pin locations, you must still manually define an initial set of pin constraints, which can become more specific during your development process.

Alternatively, to manually assign the pin locations, perform the following steps:

1. Open the Pin Planner. On the Assignments menu, click Pin Planner.
2. Assign DQ, DK, DKn, QK, and QKn pins.
   a. Assign each QK and QKn pin in your design to the required DQS and DQSn pin in the Pin Planner. The Quartus II Fitter then automatically places the respective DQ signals onto suitable DQ pins within each group. To view the DQS groups in Pin Planner, right click, select Show DQ/DQS Pins, and click In ×16/×18 Mode. The Pin Planner shows each DQS group in a different color and with a different legend: S = DQS pin, Sbar = DQSn pin and Q = DQ pin, as shown in Figure 2–1.

   In the ×36 CIO RLDRAM II interface, two ×16/×18 DQS groups are used. Select the DQ mode to match the DQ group width (number of DQ pins/number of DQS pins) of your memory device. DQ mode is not related to the memory interface width. DQ group order and DQ pin order within each group is not important. However, you must place DQ pins in the same group as their respective strobe pin.

   b. Assign the DK and DKn pins to an unused DQ pins in the DQS group, where the QK pin is assigned, or in adjacent DQS group, or in the same bank as the address and command pins.
3. Place the DM pin to an unused DQ pin in the DQS group where the QK pin is assigned.

4. Place the address and control command pins on any spare I/O pins, ideally within the same bank or side of the device as the mem_clk, DQ, QK, and DM pins.

5. Ensure you place the mem_clk pins on differential I/O pairs for the CK/CK# pin pair. To identify differential I/O pairs, right-click in the Pin Planner and select Show Differential Pin Pair Connections. The Pin Planner shows a red line between each pin pair. The mem_clk pins must be placed on the same side of the device as the address and command pins.

6. Assign the oct_rup and oct_rdn pins to the pull-up and pull-down resistance pins on the board.

7. Place the pll_ref_clk pin on a dedicated PLL clock input pin with a direct connection to the UniPHY PLL and DLL pair—usually on the same side of the device as your memory interface. This recommendation reduces PLL jitter, saves a global clock resource, and eases timing and Fitter effort.
8. Place the `global_reset_n` pin, like any high fan-out signal, on a dedicated clock pin.

For more information about how to assign the pin for the RLDRAM II CIO, refer to the Device and Pin Planning section in volume 2 of the External Memory Interface Handbook. For more information about how to use the Quartus II Pin Planner, refer to the I/O Management chapter in volume 2 of the Quartus II Handbook.

### Assign Virtual Pins

For debugging purposes, the `reset_request_n`, `afi_cal_success`, and `afi_cal_fail` signals are routed from the internal PHY to the top level of the design so that the signals can be monitored externally. When the PLL is out of lock, the `reset_request_n` signal goes high and when the PLL is locked, the `reset_request_n` signal goes low. The `afi_cal_success` and `afi_cal_fail` signals are used to check the calibration status of the sequencer. If the sequencer calibrates successfully, the `afi_cal_success` signal goes high and the `afi_cal_fail` signal goes low.

The example top-level design, which is auto-generated by the RLDRAM II controller with UniPHY, includes an example driver to stimulate the interface. This example driver is not part of the RLDRAM II controller with UniPHY IP, but allows easy testing of the IP.

The example driver outputs several test signals to indicate its operation and the status of the stimulated memory interface. These signals are `pass`, `fail`, and `test_complete`. These signals are not part of the memory interface, but are to facilitate testing. You must either connect these signals to a debug bus or assign the signals to virtual pins using the Quartus II Assignment Editor. When using the example driver for testing, do not remove these signals from the top-level signal list. If you remove these signals from the top-level module, the Quartus II software optimizes the driver away, and the example driver fails.

Use the Assignment Editor to assign these virtual pins.

### Enter Board Trace Delay Models

For accurate I/O timing analysis, the Quartus II software must be aware of the board trace and loading information. This information should be derived and refined during your PCB development process of prelayout (line) simulation and finally post-layout (board) simulation.

To enter board trace information, perform the following steps:

1. In Pin Planner, select the pin or group of pins for which you want to enter board trace parameters.
2. Right-click and select **Board Trace Model**.
3. Enter the board values based on the trace length, capacitance length, inductance length, pull-up, pull-down and so on based on your board.
Figure 2–2 shows a typical board trace model.

**Figure 2–2.** Stratix IV Development Board Address Signal Board Trace Model
Perform RTL or Functional Simulation (Optional)

This section describes RTL simulation. The RLDRAM II controller with UniPHY automatically generates the RTL simulation memory model files, `<variation name>_<mem_model>.sv`, and testbench top-level files, `<variation name>_<example_top_tb>.v`, located in the `rtl_sim` folders. You can use these files to verify your designs.

To run the RTL simulation with NativeLink, perform the following steps:

1. Set the absolute path to your third-party simulator executable, by performing the following steps:
   a. On the Tools menu, click Options.
   b. In the Category list, select EDA Tools Options and set the default path for ModelSim-Altera to C:\<version>\modelsim_ae\win32aloem.
   c. Click OK.
2. On the Assignments menu, click EDA Tool Settings.
3. In the Category list, expand EDA Tool Settings and click Simulation.
4. Under Tool name, select ModelSim.
5. Under NativeLink settings, select Compile test bench and click Test Benches.
6. Click New.

Table 2–1 shows the board trace model parameters for the Stratix III demonstration board and Stratix IV GX FPGA development board.

<table>
<thead>
<tr>

<td>1.897</td>
<td>2.9</td>
</tr>
</tbody>
</table>

Note to Table 2–1:

(1) Addr = Addr, ba, cs_n, ref_n, and we_n.
7. In the **Edit Test Bench Settings** dialog box, perform the following steps:
   a. Type the testbench name, testbench top-level module, design instance name, and simulation period.
   b. In the **Test bench files** field, include the testbench file, `<variation name>_example_top_tb.v`, and the memory model file, `<variation name>_mem_model.sv`. (Figure 2–3).
   c. Click **OK**.

   ![Figure 2–3. Testbench Settings](image)

8. To elaborate your design, on the Processing menu, point to **Start** and click **Start Analysis & Elaboration**.

9. On the Tools menu, point to the **Run EDA Simulation Tool** and click **EDA RTL Simulation**. This step creates the `\simulation` directory in your project directory and a script that compiles all necessary files and runs the simulation.

### Compile Design and Verify Timing

To compile the design, on the Processing menu, click **Start Compilation**. After successfully compiling the design, the Quartus II software automatically runs the verify timing script, `<variation_name>_report_timing.tcl`, which produces a timing report for the design together with the compilation report.

Figure 2–4 shows the timing margin report in the message window in the Quartus II software.
The report timing script performs the following tasks:

1. Creates a timing netlist.
2. Reads the .sdc file.
3. Updates the timing netlist.

You can also obtain the timing report by running the report timing script in the TimeQuest timing analyzer. To obtain the timing report in the TimeQuest Timing Analyzer window, perform the following steps:

1. In the Quartus II software, on the Tools menu, click TimeQuest Timing Analyzer.
2. On the Tasks pane, double-click Update Timing Netlist, which automatically runs Create Timing Netlist and Read SDC. After a task is executed, it turns green.
3. After completing the tasks, run the report timing script by going to the Script menu and clicking Run Tcl Script.

Alternatively, you can directly double-click on Report DDR on the Tasks pane to get the timing report.

Figure 2–5 shows the timing margin report in the TimeQuest Timing Analyzer window after running the report timing script. The results are the same as the Quartus II software results.
Verify Design on a Board

The SignalTap® II Embedded Logic Analyzer shows read and write activity in the system.

For more information on using the SignalTap II Embedded Logic Analyzer, refer to the following documents:

- Design Debugging Using the SignalTap II Embedded Logic Analyzer chapter in volume 3 of the Quartus II Handbook
- AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems
- AN 446: Debugging Nios II Systems with the SignalTap II Embedded Logic Analyzer
To add the SignalTap II Embedded Logic Analyzer, perform the following steps:

1. On the Tools menu, click **SignalTap II Logic Analyzer**.
2. Under **Signal Configuration** next to the **Clock** box, click … (Browse Node Finder).
3. Type *afi_clk* in the **Named** box, for **Filter** select **SignalTap II: pre-synthesis** and click **List**.
4. Select <variation_name>:mem_if|afi_clk in **Nodes Found** and click > to add the signal to **Selected Nodes**.
5. Click **OK**.
6. Under **Signal Configuration**, specify the following settings:
   - For **Sample depth**, select **128**
   - For **RAM type**, select **Auto**
   - For **Trigger flow control**, select **Sequential**
   - For **Trigger position**, select **Center trigger position**
   - For **Trigger conditions**, select **1**
7. On the Edit menu, click **Add Nodes**.
8. Search for specific nodes by typing *av1* in the **Named** box, for **Filter** select **SignalTap II: pre-synthesis** and click **List**.
9. In **Nodes Found**, select the following nodes and click > to add to **Selected Nodes**:
   - av1_addr
   - av1_rdata
   - av1_rdata_valid
   - av1_read_req
   - av1_ready
   - av1_wdata
   - av1_write_req
   - fail
   - pass
   - afi_cal_fail
   - afi_cal_success
   - test_complete (trigger)
   - pnf_per_bit
   - rdata_valid
   - rdata_valid_reg
   - data_out
   - data_in
Do not add any RLDRAM II interface signals to the SignalTap II Embedded Logic Analyzer. The load on these signals increases and adversely affects the timing analysis.

10. Click **OK**.

11. To reduce the SignalTap II logic size, turn off **Trigger Enable** on the following bus signals:
   - `avl_addr`
   - `avl_rdata`
   - `avl_wdata`
   - `data_out`
   - `data_in`

12. Right-click **Trigger Conditions** for the `test_complete` signal and select **Rising Edge**.

   Figure 2–6 shows the completed SignalTap II Embedded Logic Analyzer.

![SignalTap II Embedded Logic Analyzer](image-url)
13. On the File menu, click Save, to save the SignalTap II .stp file to your project.

   If you see the message Do you want to enable SignalTap II file “stp1.stp” for the current project?, click Yes.

**Compile the Project**

Once you add signals to the SignalTap II Embedded Logic Analyzer, recompile your design, and on the Processing menu, click Start Compilation.

**Verify Timing**

Once the design compiles, ensure that the TimeQuest timing analysis passes successfully. In addition to this FPGA timing analysis, check your PCB or system SDRAM timing. To run timing analysis, run the `<variation name>_report_timing.tcl` script.

1. On the Tools menu, click Tcl Scripts.
2. Select `<variation name>_report_timing.tcl` and click Run.

**Connect the Development Board**

Connect the development board to your computer.

**Download the Object File**

On the Tools menu, click SignalTap II Logic Analyzer. The SignalTap II dialog box appears.

The SOF Manager should contain the `<your project name>.sof` file. To add the correct file to the SOF Manager, perform the following steps:

1. Click ... to open the Select Program Files dialog box.
2. Select `<your project name>.sof`.
3. Click Open.
4. To download the file, click the Program Device button.

**Test the Design Example in Hardware**

When the design example including SignalTap II successfully downloads to your development board, click Run Analysis to run once, or click Autorun Analysis to run continuously.

Figure 2–7 on page 2–16 shows the design analysis. The example driver performs self verification by comparing the written out data, `data_out` with the read back data, `rdata_reg` when the `rdata_valid_reg` signal goes high.
Figure 2–7. SignalTap II Example RLDRAM II Design Analysis
How to Contact Altera

Typographic Conventions

The following table shows the typographic conventions that this document uses.

<table>
<thead>
<tr>
<th>Visual Cue</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bold Type with Initial Capital Letters</strong></td>
<td>Indicates command names, dialog box titles, dialog box options, and other GUI labels. For example, <strong>Save As</strong> dialog box. For GUI elements, capitalization matches the GUI.</td>
</tr>
<tr>
<td><strong>bold type</strong></td>
<td>Indicates directory names, project names, disk drive names, file names, file name extensions, dialog box options, software utility names, and other GUI labels. For example, <code>&lt;qdesigns&gt;</code> directory, <code>d:</code> drive, and <code>&lt;chiptrip.gdf&gt;</code> file.</td>
</tr>
<tr>
<td><strong>Italic Type with Initial Capital Letters</strong></td>
<td>Indicates document titles. For example, <em>AN 519: Stratix IV Design Guidelines.</em></td>
</tr>
<tr>
<td><strong>Italic type</strong></td>
<td>Indicates variables. For example, <code>n + 1</code>. Variable names are enclosed in angle brackets (<code>&lt; &gt;</code>). For example, <code>&lt;file name&gt;</code> and <code>&lt;project name&gt;.pof</code> file.</td>
</tr>
<tr>
<td>Initial Capital Letters</td>
<td>Indicates keyboard keys and menu names. For example, Delete key and the Options menu.</td>
</tr>
<tr>
<td>“Subheading Title”</td>
<td>Quotation marks indicate references to sections within a document and titles of Quartus II Help topics. For example, “Typographic Conventions.”</td>
</tr>
<tr>
<td><strong>Courier type</strong></td>
<td>Indicates signal, port, register, bit, block, and primitive names. For example, <code>data1</code>, <code>tdi</code>, and <code>input</code>. Active-low signals are denoted by suffix <code>n</code>. For example, <code>resetn</code>.</td>
</tr>
<tr>
<td></td>
<td>Indicates command line commands and anything that must be typed exactly as it appears. For example, <code>c:\qdesigns\tutorial\chiptrip.gdf</code>. Also indicates sections of an actual file, such as a Report File, references to parts of files (for example, the AHDL keyword <code>SUBDESIGN</code>), and logic function names (for example, <code>TRI</code>).</td>
</tr>
</tbody>
</table>
## Typographic Conventions
