1 About the Intel® Stratix® 10 LL 100GbE IP Core

The Intel® Stratix® 10 Low Latency 100-Gbps Ethernet (Intel Stratix 10 LL 100GbE) IP core offers low round-trip latency and small size to implement the *IEEE 802.3ba High Speed Ethernet Standard*.

Note: The full product name, Intel Stratix 10 Low Latency 100-Gbps Ethernet IP core, is shortened to Intel Stratix 10 LL 100GbE IP core in this document.

Figure 1. Intel Stratix 10 LL 100GbE IP Core

Main blocks, internal connections, and external block requirements.

The MAC client side Avalon Streaming (Avalon-ST) interface data bus is 512 bits wide. The client-side data maps to four 25.78125 Gbps transceiver PHY links.

The FPGA serial transceivers are compliant with the IEEE 802.3ba standard CAUI-4 specification. You can connect the transceiver interfaces directly to an external physical medium dependent (PMD) optical module or to another device.

1.1 Intel Stratix 10 LL 100GbE IP Core Supported Features

The IP core is designed to the *IEEE 802.3ba-2010 High Speed Ethernet Standard* available on the IEEE website (www.ieee.org). The MAC provides cut-through frame processing to optimize latency, and supports full wire line speed with a 64-byte frame length and back-to-back or mixed length traffic with no dropped packets. All Intel Stratix 10 LL 100GbE IP core variations include both a MAC and a PHY, and all variations are in full-duplex mode. These IP core variations offer the following features:

- PHY features:
 - Soft PCS logic that interfaces seamlessly to Intel Intel Stratix 10 FPGA 25.78125 Gbps serial transceivers.
 - CAUI-4 external interface consisting of four FPGA hard serial transceiver lanes operating at 25.78125 Gbps.
 - Optional Reed-Solomon forward error correction RS-FEC(528,514). This feature is not yet fully tested in the Intel Quartus® Prime Pro Edition v17.1 software release.
- Frame structure control features:
 - Support for jumbo packets.
 - TX and RX CRC pass-through control.
 - Optional TX CRC generation and insertion.
 - RX and TX preamble pass-through options for applications that require proprietary user management information transfer.
 - TX automatic frame padding to meet the 64-byte minimum Ethernet frame length at the Intel Stratix 10 LL 100GbE Ethernet connection.
- Frame monitoring and statistics:
 - RX CRC checking and error reporting.
 - Optional RX strict SFD checking per IEEE specification.
 - RX malformed packet checking per IEEE specification.
 - Optional statistics counters.
- Debug and testability features:
 - Optional serial PMA loopback (TX to RX) at the serial transceiver for self-diagnostic testing.
 - Optional access to Altera Debug Master Endpoint (ADME) for debugging or monitoring PHY signal integrity.
- User system interfaces:
 - Avalon Memory-Mapped (Avalon-MM) management interface to access the IP core control and status registers.
 - Avalon-ST data path interface connects to client logic with the start of frame in the most significant byte (MSB). Interface has data width 512 bits, to ensure the data rate despite this RX client interface SOP alignment and RX and TX preamble passthrough option.
 - Hardware and software reset control.

For a detailed specification of the Ethernet protocol refer to the *IEEE 802.3ba-2010 High Speed Ethernet Standard*.

1.2 IP Core Device Family and Speed Grade Support

The following sections list the device family and device speed grade support offered by the Intel Stratix 10 LL 100GbE IP core:

[Intel Stratix 10 LL 100GbE IP Core Device Family Support](#) on page 6

[Intel Stratix 10 LL 100GbE IP Core Device Speed Grade Support](#) on page 7

1.2.1 Intel Stratix 10 LL 100GbE IP Core Device Family Support

Table 1. Intel FPGA IP Core Device Support Levels

Device Support Level	Definition
Advance	The IP core is available for simulation and compilation for this device family. Timing models include initial engineering estimates of delays based on early post-layout information. The timing models are subject to change as silicon testing improves the correlation between the actual silicon and the timing models. You can use this IP core for system architecture and resource utilization studies, simulation, pinout, system latency assessments, basic timing assessments (pipeline budgeting), and I/O transfer strategy (datapath width, burst depth, I/O standards tradeoffs).
Preliminary	The IP core is verified with preliminary timing models for this device family. The IP core meets all functional requirements, but might still be undergoing timing analysis for the device family. It can be used in production designs with caution.
Final	The IP core is verified with final timing models for this device family. The IP core meets all functional and timing requirements for the device family and can be used in production designs.

Table 2. Intel Stratix 10 LL 100GbE IP Core Device Family Support

Shows the level of support offered by the Intel Stratix 10 LL 100GbE IP core for each Intel FPGA device family.

Device Family	Support
Intel Stratix 10	Advance
Other device families	No support

[Timing and Power Models](#)

Reports the default device support levels in the current version of the Quartus Prime Pro Edition software.

1.2.2 Intel Stratix 10 LL 100GbE IP Core Device Speed Grade Support

Table 3. Slowest Supported Device Speed Grades

Lists the slowest supported device speed grades for the Intel Stratix 10 LL 100GbE IP core.

Device Family	Supported Speed Grades
Intel Stratix 10	E2

1.3 IP Core Verification

To ensure functional correctness of the Intel Stratix 10 LL 100GbE IP core, Intel performs extensive validation through both simulation and hardware testing. Before releasing a version of the Intel Stratix 10 LL 100GbE IP core, Intel runs comprehensive regression tests in the current or associated version of the Intel Quartus Prime software.

Related Links

- [Knowledge Base Errata for Intel Stratix 10 LL 100GbE IP core](#)
Exceptions to functional correctness that first manifest in software releases 17.1 and later are documented in the Intel Stratix 10 Low Latency 100GbE IP core errata.
- [Intel FPGA IP Release Notes: Intel Stratix 10 Low Latency 100-Gbps Ethernet IP Core Release Notes](#)
Changes to the Intel Stratix 10 LL 100GbE IP core in software releases 17.1 and later are noted in the Intel FPGA IP Release Notes.

1.3.1 Simulation Environment

Intel performs the following tests on the Intel Stratix 10 LL 100GbE IP core in the simulation environment using internal and third party standard bus functional models (BFM):

- Constrained random tests that cover randomized frame size and contents
- Randomized error injection tests that inject Frame Check Sequence (FCS) field errors, runt packets, and corrupt control characters, and then check for the proper response from the IP core
- Assertion based tests to confirm proper behavior of the IP core with respect to the specification
- Extensive coverage of our runtime configuration space and proper behavior in all possible modes of operation

1.3.2 Compilation Checking

Intel performs compilation testing on an extensive set of Intel Stratix 10 LL 100GbE IP core variations and designs that target different devices, to ensure the Intel Quartus Prime software places and routes the IP core ports correctly.

1.3.3 Hardware Testing

Intel performs hardware testing of the key functions of the Intel Stratix 10 LL 100GbE IP core using standard 100Gbps Ethernet network test equipment and optical modules. The Intel hardware tests of the Intel Stratix 10 LL 100GbE IP core also ensure reliable solution coverage for hardware related areas such as performance, link synchronization, and reset recovery.

1.4 Performance and Resource Utilization

Resource utilization changes depending on the parameter settings you specify in the Intel Stratix 10 LL 100GbE parameter editor. For example, if you turn on RS-FEC in the Intel Stratix 10 LL 100GbE parameter editor, the IP core requires additional resources to implement the additional functionality.

Table 4. IP Core Variation Encoding for Resource Utilization Tables

"On" indicates the parameter is turned on. The symbol "—" indicates the parameter is turned off or not available.

IP Core Variation	A	B	C	D	E
Parameter					
Enable RS-FEC	—	—	On	—	On
Enable TX CRC insertion	—	On	On	On	On
Enable preamble passthrough	—	—	—	On	On
Enable RX/TX statistics counters	—	On	On	On	On

Table 5. IP Core FPGA Resource Utilization

Lists the resources and expected performance for selected variations of the Intel Stratix 10 LL 100GbE IP core, from one compilation of each IP core variation. Your results may vary depending on your overall design.

These results were obtained using the Intel Quartus Prime Pro Edition v17.1 software.

Note: Resource utilization numbers for variations with RS-FEC enabled, reflect preliminary results for the RS-FEC feature. The resource utilization for this block might vary by up to 5% in the final implementation of this feature.

- The numbers of ALMs and logic registers are rounded up to the nearest 100.
- The numbers of ALMs, before rounding, are the **ALMs needed** numbers from the Intel Quartus Prime Fitter Report.

LL 100GbE Variation	ALMs	Dedicated Logic Registers	Memory M20K
A	24200	61400	40
B	29100	74800	40
C	55200	132500	101
D	29100	74500	40
E	55200	141700	101

2.1 Installing and Licensing Intel FPGA IP Cores

The Intel Quartus Prime software installation includes the Intel FPGA IP library. This library provides many useful IP cores for your production use without the need for an additional license. Some Intel FPGA IP cores require purchase of a separate license for production use. The Intel FPGA IP Evaluation Mode allows you to evaluate these licensed Intel FPGA IP cores in simulation and hardware, before deciding to purchase a full production IP core license. You only need to purchase a full production license for licensed Intel IP cores after you complete hardware testing and are ready to use the IP in production.

The Intel Quartus Prime software installs IP cores in the following locations by default:

Provides the licensing product codes for the IP core.

2.2 Specifying the IP Core Parameters and Options

The Intel Stratix 10 LL 100GbE parameter editor allows you to quickly configure your custom IP variation. Use the following steps to specify IP core options and parameters in the Intel Quartus Prime Pro Edition software.

1. If you do not already have an Intel Quartus Prime Pro Edition project in which to integrate your Intel Stratix 10 LL 100GbE IP core, you must create one.
 - a. In the Intel Quartus Prime Pro Edition, click **File > New Project Wizard** to create a new Quartus Prime project, or **File > Open Project** to open an existing Quartus Prime project. The wizard prompts you to specify a device.
 - b. Specify the device family **Intel Stratix 10** and select a device that meets all of these requirements:
 - i. Transceiver tile is L-tile or H-tile (any transceiver tile)
 - ii. Transceiver speed grade is 1 or 2
 - iii. Core speed grade is 1 or 2
 - iv. Device is not an 1SG280L ES1 device (part name 1SG280L...VGS1)
 - c. Click **Finish**.
2. In the IP Catalog, locate and select **Low Latency 100G Ethernet**. The **New IP Variation** window appears.
3. Specify a top-level name for your new custom IP variation. The parameter editor saves the IP variation settings in a file named <your_ip>.ip.
4. Click **OK**. The parameter editor appears.
5. Specify the parameters for your IP core variation. Refer to [IP Core Parameters](#) on page 19 for information about specific IP core parameters.
6. Optionally, to generate a simulation testbench or compilation and hardware design example, follow the instructions in the *Intel Stratix 10 Low Latency 100G Ethernet Design Example User Guide*.
7. Click **Generate HDL**. The **Generation** dialog box appears.
8. Specify output file generation options, and then click **Generate**. The IP variation files generate according to your specifications.

Note: A functional VHDL IP core is not available. Specify Verilog HDL only, for your IP core variation.

9. Click **Finish**. The parameter editor adds the top-level `.ip` file to the current project automatically. If you are prompted to manually add the `.ip` file to the project, click **Project ► Add/Remove Files in Project** to add the file.
10. After generating and instantiating your IP variation, make appropriate pin assignments to connect ports.

2.3 Generated File Structure

The Intel Quartus Prime Pro Edition software generates the following IP core output file structure.

For information about the file structure of the design example, refer to the *Intel Stratix 10 LL 100GbE Design Example User Guide*.

Figure 3. Intel Stratix 10 LL 100GbE IP Core Generated Files

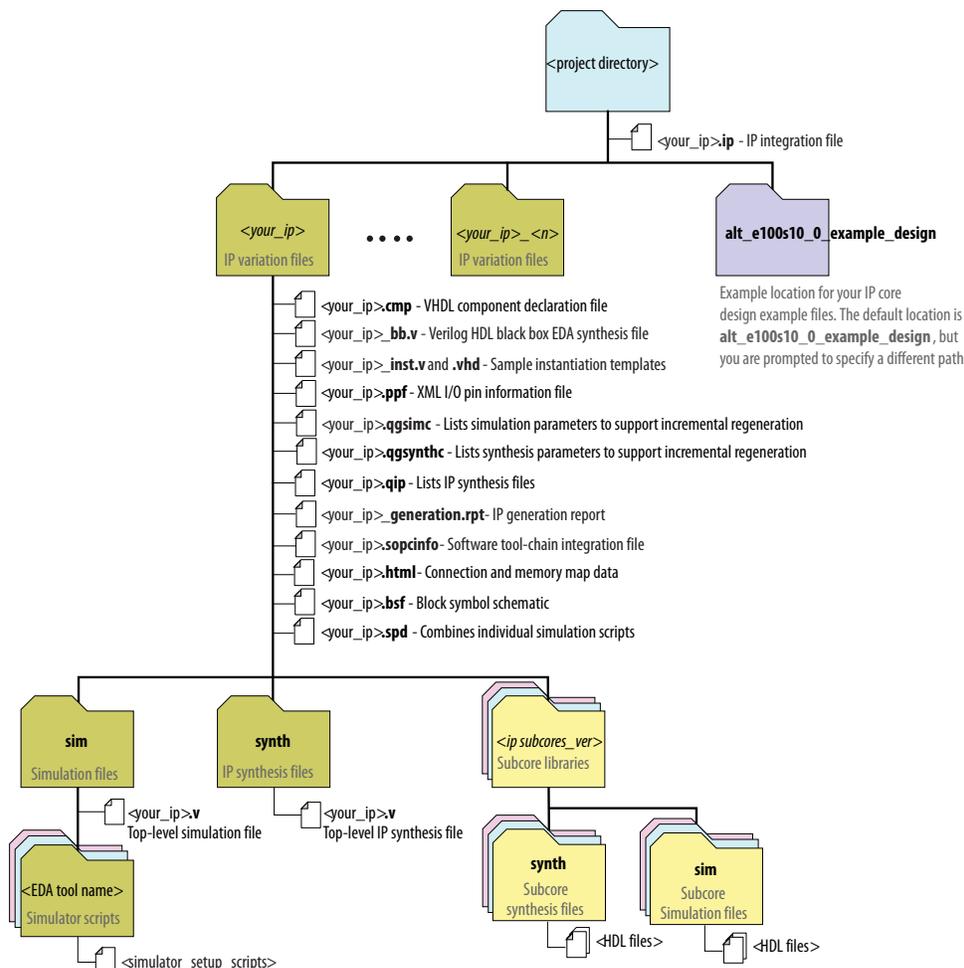

Table 8. IP Core Generated Files

File Name	Description
<your_ip>.ip	The Qsys system or top-level IP variation file. <your_ip> is the name that you give your IP variation.
<your_ip>.cmp	The VHDL Component Declaration (.cmp) file is a text file that contains local generic and port definitions that you can use in VHDL design files. This IP core does not support VHDL. However, the Intel Quartus Prime Pro Edition software generates this file.
<your_ip>.html	A report that contains connection information, a memory map showing the address of each slave with respect to each master to which it is connected, and parameter assignments.
<your_ip>.generation.rpt	IP or Qsys generation log file. A summary of the messages during IP generation.
<your_ip>.qgsimc	Lists simulation parameters to support incremental regeneration.
<your_ip>.qgsynthc	Lists synthesis parameters to support incremental regeneration.
<i>continued...</i>	

File Name	Description
<your_ip>.qip	Contains all the required information about the IP component to integrate and compile the IP component in the Intel Quartus Prime software.
<your_ip>.sopcinfo	Describes the connections and IP component parameterizations in your Qsys system. You can parse its contents to get requirements when you develop software drivers for IP components. Downstream tools such as the Nios® II tool chain use this file. The .sopcinfo file and the system.h file generated for the Nios II tool chain include address map information for each slave relative to each master that accesses the slave. Different masters may have a different address map to access a particular slave component.
<your_ip>.csv	Contains information about the upgrade status of the IP component.
<your_ip>.bsf	A Block Symbol File (.bsf) representation of the IP variation for use in Quartus Prime Block Diagram Files (.bdf).
<your_ip>.spd	Required input file for ip-make-simscript to generate simulation scripts for supported simulators. The .spd file contains a list of files generated for simulation, along with information about memories that you can initialize.
<your_ip>.ppf	The Pin Planner File (.ppf) stores the port and node assignments for IP components created for use with the Pin Planner.
<your_ip>_bb.v	You can use the Verilog black-box (_bb.v) file as an empty module declaration for use as a black box.
<your_ip>_inst.v or _inst.vhd	HDL example instantiation template. You can copy and paste the contents of this file into your HDL file to instantiate the IP variation. This IP core does not support VHDL. However, the Intel Quartus Prime Pro Edition software generates the _inst.vhd file.
<your_ip>.regmap	If IP contains register information, .regmap file generates. The .regmap file describes the register map information of master and slave interfaces. This file complements the .sopcinfo file by providing more detailed register information about the system. This enables register display views and user customizable statistics in the System Console.
<your_ip>.svd	Allows hard processor system (HPS) System Debug tools to view the register maps of peripherals connected to HPS within a Qsys system. During synthesis, the .svd files for slave interfaces visible to System Console masters are stored in the .sof file in the debug section. System Console reads this section, which Qsys can query for register map information. For system slaves, Qsys can access the registers by name.
<your_ip>.v	HDL files that instantiate each submodule or child IP core for synthesis or simulation.
mentor/	Contains a ModelSim script msim_setup.tcl to set up and run a simulation.
aldec/	Contains a Riviera-PRO script rivierapro_setup.tcl to setup and run a simulation.
synopsys/vcs/ synopsys/vcsmx/	Contains a shell script vcs_setup.sh to set up and run a VCS® simulation. Contains a shell script vcsmx_setup.sh and synopsys_sim.setup file to set up and run a VCS MX® simulation.
cadence/	Contains a shell script ncsim_setup.sh and other setup files to set up and run an NCSIM simulation.
submodules/	Contains HDL files for the IP core submodules.
<child IP cores>/	For each generated child IP core directory, Qsys generates synth/ andsim/ sub-directories.

2.4 Integrating Your IP Core in Your Design

When you integrate your IP core instance in your design, you must pay attention to the following items:

[Pin Assignments](#) on page 15

[Adding the Transceiver PLLs](#) on page 15

[Placement Settings for the Intel Stratix 10 LL 100GbE IP Core](#) on page 17

Related Links

[Stratix 10 Low Latency 100G Ethernet Design Example User Guide](#)

2.4.1 Pin Assignments

When you integrate your Intel Stratix 10 LL 100GbE IP core instance in your design, you must make appropriate pin assignments. You can create a virtual pin to avoid making specific pin assignments for top-level signals until you are ready to map the design to hardware.

Related Links

Information about constraints on transceiver configuration in Intel Stratix 10 devices.
- [Intel Stratix 10 GX 2800 L-Tile ES-1 Transceiver PHY User Guide](#)
Information about transceiver configuration in L-tile ES1 devices.

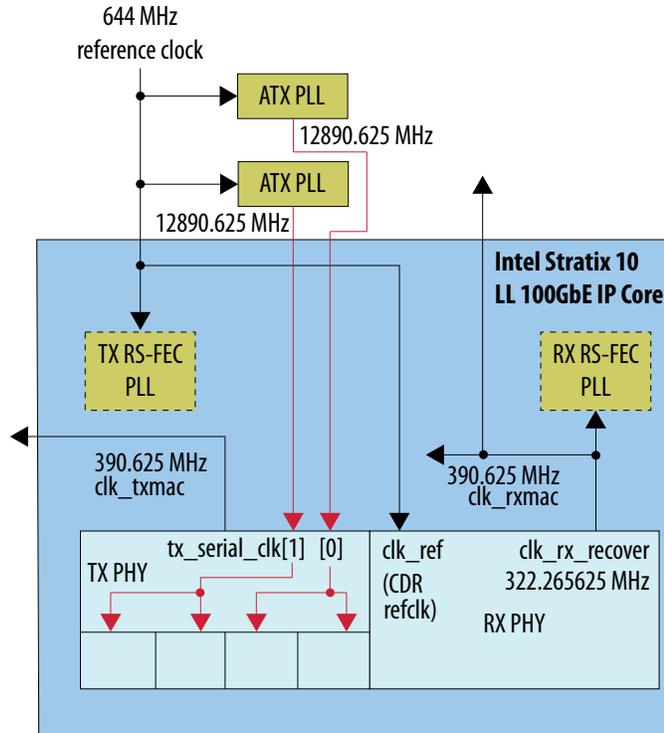

2.4.2 Adding the Transceiver PLLs

The Intel Stratix 10 LL 100GbE IP core requires two external TX transceiver PLLs to compile and to function correctly in hardware. On Stratix 10 devices, only the ATX PLL supports the required data rate.

The transceiver PLLs you configure are physically present on the device, but the Intel Stratix 10 LL 100GbE IP core does not configure and connect them. The required number of ATX PLLs is two. Each ATX PLL drives the clocks for two transceiver channels.

Figure 4. PLL Configuration Example

The TX transceiver PLLs are instantiated with two Stratix 10 ATX PLL IP cores. The TX transceiver PLLs must always be instantiated outside the Intel Stratix 10 LL 100GbE IP core.

You can use the IP Catalog to create a transceiver PLL.

- Select **Stratix 10 L-Tile/H-Tile Transceiver ATX PLL**.
- In the parameter editor, set the following parameter values:
 - Set **VCCR_GXB** and **VCCT_GXB** supply voltage for the Transceiver to **1_1V**.
 - Set **Primary PLL clock output buffer** to **GXT clock output buffer**.
 - Turn on **Enable GXT local clock output port (tx_serial_clk_gxt)**.
 - Set **GXT output clock source** to **Local ATX PLL**.
 - **PLL output frequency** to **12890.625 MHz**. The transceiver performs dual edge clocking, using both the rising and falling edges of the input clock from the PLL. Therefore, this PLL output frequency setting supports a 25.78125 Gbps data rate through the transceiver.
 - Set **PLL auto mode reference clock frequency** to **644.53125 MHz**.

When you generate a Intel Stratix 10 LL 100GbE IP core, the software also generates the HDL code for an ATX PLL, in the file `<variation_name>/atx_pll_s100.v`. However, the HDL code for the Intel Stratix 10 LL 100GbE IP core does not instantiate the ATX PLL. If you choose to use the ATX PLL provided with the Intel Stratix 10 LL 100GbE IP core, you must instantiate and connect the instances of the ATX PLL with the Intel Stratix 10 LL 100GbE IP core in user logic.

Note: If your design includes multiple instances of the Intel Stratix 10 LL 100GbE IP core, do not use the ATX PLL HDL code provided with the IP core. Instead, generate new TX PLL IP cores to connect in your design.

You must drive the reference clock input ports of the two PLLs with the same clock to minimize PMM differences. This clock can be but need not be the same as the clock that drives the Intel Stratix 10 LL 100GbE IP core reference clock.

Each PLL drives the `tx_serial_clk` input of two of the Intel Stratix 10 LL 100GbE IP core PHY links. You must connect the PLLs to the Intel Stratix 10 LL 100GbE IP core as follows:

PLL	PLL Signal	Intel Stratix 10 LL 100GbE IP Core Signal
A	<code>tx_serial_clk</code>	<code>tx_serial_clk[0]</code>
A	<code>pll_locked</code>	<code>tx_pll_locked[0]</code>
B	<code>tx_serial_clk</code>	<code>tx_serial_clk[1]</code>
B	<code>pll_locked</code>	<code>tx_pll_locked[1]</code>

Refer to the example compilation project or design example for working user logic that demonstrates one correct method to instantiate and connect the external PLLs.

Information about the Intel Stratix 10 LL 100GbE design example, which connects two external PLLs to the IP core PHY links.

2.4.3 Placement Settings for the Intel Stratix 10 LL 100GbE IP Core

The Quartus Prime software provides the options to specify design partitions and LogicLock® Plus regions for block-based design, to control placement on the device. To achieve timing closure for your design, you might need to provide floorplan guidelines using one or both of these features.

The appropriate floorplan is always design-specific, and depends on your full design.

2.5 IP Core Testbenches

Intel provides a compilation-only design example and a testbench with certain variations of the Intel Stratix 10 LL 100GbE IP core.

To generate the testbench, in the Intel Stratix 10 LL 100GbE parameter editor, you must first set the parameter values for the IP core variation you intend to generate in your end product. If you do not set the parameter values for your DUT to match the parameter values in your end product, the testbench you generate does not exercise the IP core variation you intend. If your IP core variation does not meet the criteria for a testbench, the parameter editor provides warnings and the design example generation process creates a testbench that does not function correctly.

The testbench demonstrates a basic test of the IP core. It is not intended to be a substitute for a full verification environment.

Information about generating and running the design example and testbench files for the Intel Stratix 10 LL 100GbE IP core. This testbench demonstrates a basic test of the IP core. It is not intended to be a substitute for a full verification environment.

2.6 Compiling the Full Design and Programming the FPGA

You can use the **Start Compilation** command on the Processing menu in the Intel Quartus Prime Pro Edition software to compile your design. After successfully compiling your design, program the targeted Intel device with the Programmer and verify the design in hardware.

Note: The Intel Stratix 10 LL 100GbE IP core design example synthesis directories include Synopsys Constraint (.sdc) files that you can copy and modify for your own design.

3 IP Core Parameters

The Intel Stratix 10 LL 100GbE parameter editor provides the parameters you can set to configure the Intel Stratix 10 LL 100GbE IP core and simulation and hardware design examples.

Intel Stratix 10 LL 100GbE parameter editor includes an **Example Design** tab. For information about that tab, refer to the *Stratix 10 Low Latency 100G Ethernet Design Example User Guide*.

Table 9. Intel Stratix 10 LL 100GbE Parameters: Main Tab

Describes the parameters for customizing the Intel Stratix 10 LL 100GbE IP core on the Main tab of the Intel Stratix 10 LL 100GbE parameter editor.

Parameter	Type	Range	Default Setting	Parameter Description
General Options				
Device family	String	Stratix 10	Stratix 10	Selects the device family.

4 Functional Description

The Intel FPGA Intel Stratix 10 LL 100GbE IP core implements an Ethernet MAC in accordance with the *IEEE 802.3 Ethernet Standard*. The IP core handles the frame encapsulation and flow of data between client logic and an Ethernet network through a 100-Gbps Ethernet PCS and PMA (PHY) .

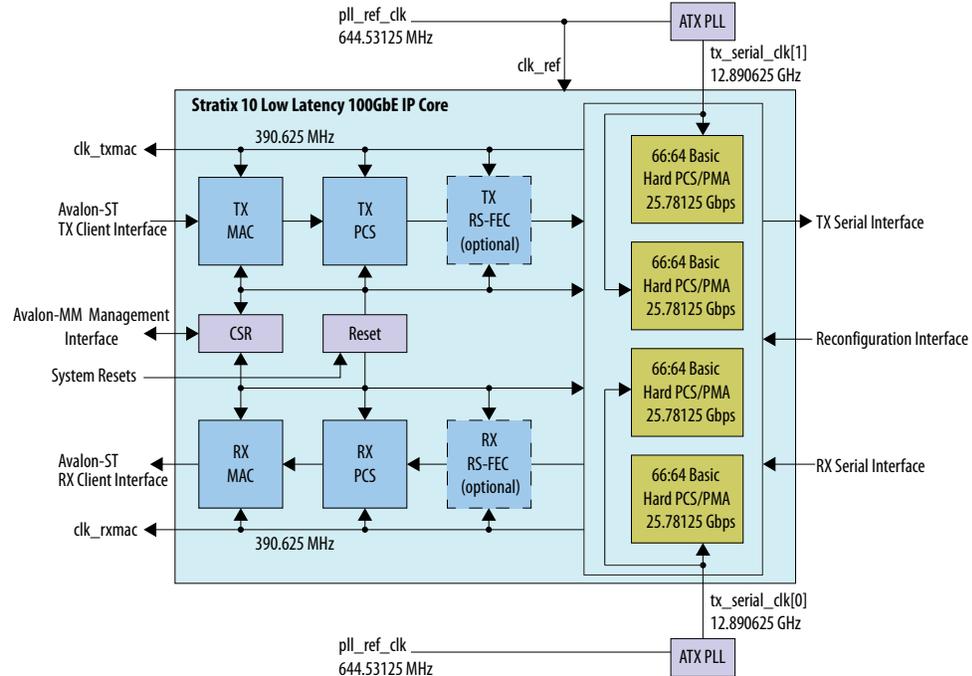

In the transmit direction, the MAC accepts client frames, and inserts inter-packet gap (IPG), preamble, start of frame delimiter (SFD), padding, and CRC bits before passing them to the PHY. The MAC also updates the TX statistics counters if they are present. The PHY encodes the MAC frame as required for reliable transmission over the media to the remote end.

In the receive direction, the PHY passes frames to the MAC. The MAC accepts frames from the PHY, performs checks, updates statistics counters if they are present, strips out the CRC, preamble, and SFD, and passes the rest of the frame to the client. In RX preamble pass-through mode, the MAC passes on the preamble and SFD to the client instead of stripping them out. In RX CRC pass-through mode (bit 1 of the CRC_CONFIG register has the value of 1), the MAC passes on the CRC bytes to the client and asserts the EOP signal in the same clock cycle with the final CRC byte.

4.1 High Level System Overview

Figure 5. Intel Stratix 10 LL 100GbE IP Core

Main blocks, internal connections, and external block requirements.

4.2 Intel Stratix 10 LL 100GbE IP Core TX Datapath

The TX MAC module receives the client payload data with the destination and source addresses and then adds, appends, or updates various header fields in accordance with the configuration specified. The MAC does not modify the destination address, the source address, or the payload received from the client. However, the TX MAC module adds a preamble (if the IP core is not configured to receive the preamble from user logic), pads the payload of frames greater than eight bytes to satisfy the minimum Ethernet frame payload of 46 bytes, and if you set **Enable TX CRC insertion**, calculates the CRC over the entire MAC frame. (If padding is added, it is also included in the CRC calculation. If you turn off **Enable TX CRC insertion**, the client must provide the CRC bytes and must provide frames that have a minimum size of 64 bytes and therefore do not require padding). The TX MAC module always inserts IDLE bytes to maintain an average IPG.

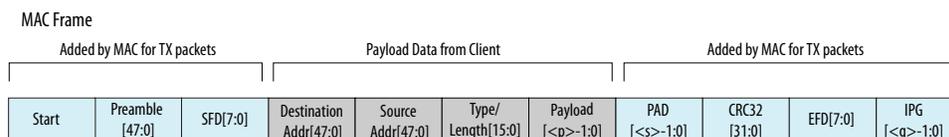

The Intel Stratix 10 LL 100GbE IP core does not process incoming frames of less than nine bytes correctly. You must ensure such frames do not reach the TX client interface.

Figure 6. Typical Client Frame at the Transmit Interface

Illustrates the changes that the TX MAC makes to the client frame when **Enable preamble passthrough** is turned off. This figure uses the following notational conventions:

- $\langle p \rangle$ = payload size, which is arbitrarily large.
- $\langle s \rangle$ = number of padding bits (0–46 bytes)
- $\langle g \rangle$ = number of IPG bits (full bytes)

The following sections describe the functions performed by the TX MAC:

[Preamble, Start, and SFD Insertion](#) on page 23

[Length/Type Field Processing](#) on page 23

[Frame Padding](#) on page 23

[Frame Check Sequence \(CRC-32\) Insertion](#) on page 24

[TX RSFEC](#) on page 24

4.2.1 Preamble, Start, and SFD Insertion

In the TX datapath the MAC appends an eight-byte preamble that begins with a Start byte (0xFB) to the client frame.

The source of the preamble depends on whether you turn on the preamble pass-through feature by turning on **Enable preamble passthrough** in the Intel Stratix 10 LL 100GbE parameter editor.

If the preamble pass-through feature is turned on, the client provides the eight-byte preamble (including Start byte) on the data bus. The client is responsible for providing the correct Start byte.

4.2.2 Length/Type Field Processing

This two-byte header represents either the length of the payload or the type of MAC frame. When the value of this field is equal to or greater than 1536 (0x600) it indicates a type field. Otherwise, this field provides the length of the payload data that ranges from 0–1500 bytes. The TX MAC does not modify this field before forwarding it to the network.

4.2.3 Frame Padding

When the length of client frame is less than 64 bytes (meaning the payload is less than 46 bytes) and greater than eight bytes, the TX MAC module inserts pad bytes (0x00) after the payload to create a frame length equal to the minimum size of 64 bytes.

Caution: The Intel Stratix 10 LL 100GbE IP core does not process incoming (egress) frames of less than nine bytes correctly. You must ensure such frames do not reach the TX client interface.

4.2.4 Frame Check Sequence (CRC-32) Insertion

The TX MAC computes and inserts a CRC32 checksum in the transmitted MAC frame. The frame check sequence (FCS) field contains a 32-bit CRC value. The MAC computes the CRC32 over the frame bytes that include the source address, destination address, length, data, and pad (if applicable). The CRC checksum computation excludes the preamble, SFD, and FCS. The encoding is defined by the following generating polynomial:

$$\text{FCS}(X) = X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

CRC bits are transmitted with MSB (X32) first.

You can configure your IP core TX MAC to implement TX CRC insertion or not, by turning **Enable TX CRC insertion** on or off in the Intel Stratix 10 LL 100GbE parameter editor. By default, the CRC insertion feature is enabled.

[Order of Transmission](#) on page 28

Illustrations of the byte order and octet transmission order on the Avalon-ST client interface.

4.2.5 TX RSFEC

If you turn on **Enable RS-FEC** in the Intel Stratix 10 LL 100GbE parameter editor, the IP core includes Reed-Solomon forward error correction (FEC) in both the receive and transmit datapaths.

The IP core implements Reed-Solomon FEC per Clause 91 of the IEEE Standard 802.3bj. The Reed-Solomon FEC algorithm includes the following modules:

- 64B/66B to 256B/257B Transcoding
- High-Speed Reed-Solomon Encoder

Caution: This feature is not yet fully tested in the Intel Quartus Prime Pro Edition v17.1 software release.

4.3 Intel Stratix 10 LL 100GbE IP Core RX Datapath

The Intel Stratix 10 LL 100GbE RX MAC receives Ethernet frames from the PHY and forwards the payload with relevant header bytes to the client after performing some MAC functions on header bytes.

Note: The Intel Stratix 10 LL 100GbE IP core does not yet support flow control. If the IP core receives a pause or PFC frame, it passes the frame through to the RX client interface.

Figure 7. Flow of Frame Through the MAC RX Without Preamble Pass-Through

Illustrates the typical flow of frame through the MAC RX when the preamble pass-through feature is turned off. In this figure, p is payload size, and s is the number of pad bits (0–46 bytes).

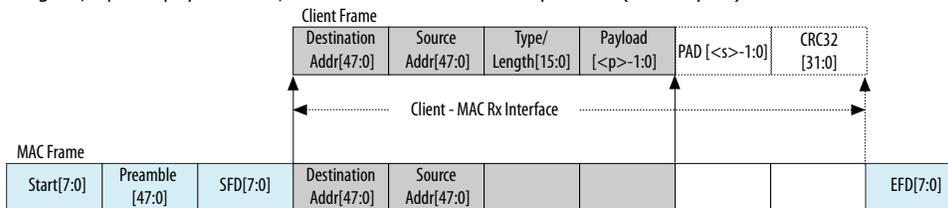

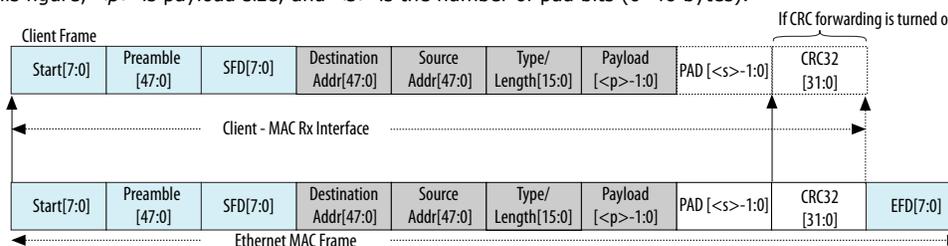

Figure 8. Flow of Frame Through the MAC RX With Preamble Pass-Through Turned On

Illustrates the typical flow of frame through the MAC RX when the preamble pass-through feature is turned on. In this figure, p is payload size, and s is the number of pad bits (0–46 bytes).

The following sections describe the functions performed by the RX MAC:

- [Intel Stratix 10 LL 100GbE IP Core Preamble Processing](#) on page 25
- [IP Core Strict SFD Checking](#) on page 26
- [Intel Stratix 10 LL 100GbE IP Core FCS \(CRC-32\) Removal](#) on page 26
- [Intel Stratix 10 LL 100GbE IP Core CRC Checking](#) on page 26
- [Intel Stratix 10 LL 100GbE IP Core Malformed Packet Handling](#) on page 26
- [RX CRC Forwarding](#) on page 27
- [Inter-Packet Gap](#) on page 27
- [RX RSFEC](#) on page 27

4.3.1 Intel Stratix 10 LL 100GbE IP Core Preamble Processing

The preamble sequence is Start, six preamble bytes, and SFD. The Start byte must be on receive lane 0 (most significant byte). The IP core uses the Start byte (0xFB) to identify the preamble. The MAC RX looks for the Start, six preamble bytes and SFD, depending on the strict SFD checking settings of the IP core.

By default, the MAC RX removes all Start, SFD, preamble, and IPG bytes from accepted frames. However, if you turn on **Enable preamble passthrough** in the Intel Stratix 10 LL 100GbE parameter editor, the MAC RX does not remove the eight-byte preamble sequence.

4.3.2 IP Core Strict SFD Checking

The Intel Stratix 10 LL 100GbE IP core RX MAC checks all incoming packets for a correct Start byte (0xFB). If you turn on **Enable Strict SFD check** in the Intel Stratix 10 LL 100GbE parameter editor, you enable the RX MAC to check the incoming preamble and SFD for the following values:

- SFD = 0xD5
- Preamble = 0x555555555555

The RX MAC checks one or both of these values depending on the values in bits [4:3] of the `RXMAC_CONTROL` register at offset 0x50A.

Table 10. Strict SFD Checking Configuration

Enable Strict SFD check	0x50A[4]: Preamble Check	0x50A[3]: SFD Check	Fields Checked	Behavior if Check Fails
Off	Don't Care	Don't Care	Start byte	IP core does not recognize a malformed Start byte as a Start byte
On	0	0	Start byte	
	0	1	Start byte and SFD	IP Core drops the packet
	1	0	Start byte and preamble	
1	1	1	Start byte and preamble and SFD	

4.3.3 Intel Stratix 10 LL 100GbE IP Core FCS (CRC-32) Removal

Independent user configuration register bits control FCS CRC removal at runtime. Bit 0 of the `MAC_CRC_CONFIG` register enables and disables CRC removal; by default, CRC removal is enabled.

In the user interface, the EOP signal (`18_rx_endofpacket`) indicates the end of CRC bytes if CRC is not removed. When CRC is removed, the EOP signal indicates the final byte of payload.

4.3.4 Intel Stratix 10 LL 100GbE IP Core CRC Checking

The 32-bit CRC field is received in the order: X32, X30, . . . X1, and X0, where X32 is the most significant bit of the FCS field and occupies the least significant bit position in the first FCS byte.

If the RX MAC detects a CRC32 error, it marks the frame invalid by asserting `18_rx_error[1]`.

4.3.5 Intel Stratix 10 LL 100GbE IP Core Malformed Packet Handling

The malformed packet handling feature ensures the client receives the expected SOP-EOP sequences on the RX client interface. While receiving an incoming packet from the Ethernet link, the Intel Stratix 10 LL 100GbE IP core expects to detect a terminate character at the end of the packet. When it detects an expected terminate character, the IP core generates an EOP on the client interface. However, sometimes the IP core

detects an unexpected control character when it expects a terminate character. The Intel Stratix 10 LL 100GbE IP core detects and handles the following forms of malformed packets:

- If the IP core detects an Error character, it generates an EOP and asserts a malformed packet error (`18_rx_error[0]`). If the IP core subsequently detects a terminate character, it does not generate another EOP indication.
- If the IP core detects any other control character (for example, an IDLE or Start character) when it is waiting for an EOP indication (terminate character), the IP core generates an EOP indication, asserts a malformed packet error (`18_rx_error[0]`), and asserts a CRC error (`18_rx_error[1]`). If the IP core subsequently detects a terminate character, it does not generate another EOP indication.

4.3.6 RX CRC Forwarding

The CRC-32 field is forwarded to the client interface after the final byte of data, if the CRC removal option is not enabled.

4.3.7 Inter-Packet Gap

The MAC RX removes all IPG octets received, and does not forward them to the client interface.

4.3.8 RX RSFEC

If you turn on **Enable RS-FEC** in the Intel Stratix 10 LL 100GbE parameter editor, the IP core includes Reed-Solomon forward error correction (FEC) in both the receive and transmit datapaths.

The IP core implements Reed-Solomon FEC per Clause 91 of the IEEE Standard 802.3bj. The Reed-Solomon FEC algorithm includes the following modules:

- Alignment marker lock
- High-speed Reed-Solomon decoder
- 256B/257B to 64B/66B Transcoding

Caution: This feature is not yet fully tested in the Intel Quartus Prime Pro Edition v17.1 software release.

4.4 User Interface to Ethernet Transmission

The IP core reverses the bit stream for transmission per Ethernet requirements. The transmitter handles the insertion of the inter-packet gap, frame delimiters, and padding with zeros as necessary. The transmitter also handles FCS computation and insertion.

The Ethernet MAC and PHY transmit complete packets. After transmission begins, it must complete with no IDLE insertions. Between the end of one packet and the beginning of the next packet, the data input is not considered and the transmitter sends IDLE characters. An unbounded number of IDLE characters can be sent between packets.

4.4.1 Order of Transmission

The IP core transmits bytes on the Ethernet link starting with the preamble and ending with the FCS in accordance with the IEEE 802.3 standard. On the transmit client interface, the IP core expects the client to send the most significant bytes of the frame first, and to send each byte in big-endian format. Similarly, on the receive client interface, the IP core sends the client the most significant bytes of the frame first, and orders each byte in big-endian format.

Figure 9. Byte Order on the Client Interface Lanes Without Preamble Pass-Through

Describes the byte order on the Avalon-ST interface when the preamble pass-through feature is turned off. Destination Address[40] is the broadcast/multicast bit (a type bit), and Destination Address[41] is a locally administered address bit.

	Destination Address (DA)						Source Address (SA)						Type/ Length (TL)		Data (D)		
Octet	5	4	3	2	1	0	5	4	3	2	1	0	1	0	00	...	NN
Bit	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]	[15:8]	[7:0]	MSB[7:0]	..	LSB[7:0]

For example, the destination MAC address includes the following six octets AC-DE-48-00-00-80. The first octet transmitted (octet 0 of the MAC address described in the 802.3 standard) is AC and the last octet transmitted (octet 7 of the MAC address) is 80. The first bit transmitted is the low-order bit of AC, a zero. The last bit transmitted is the high order bit of 80, a one.

The preceding table and the following figure show that in this example, 0xAC is driven on DA5 (DA[47:40]) and 0x80 is driven on DA0 (DA[7:0]).

Figure 10. Octet Transmission on the Avalon-ST Signals Without Preamble Pass-Through

Illustrates how the octets of the client frame are transferred over the TX datapath when preamble pass-through is turned off.

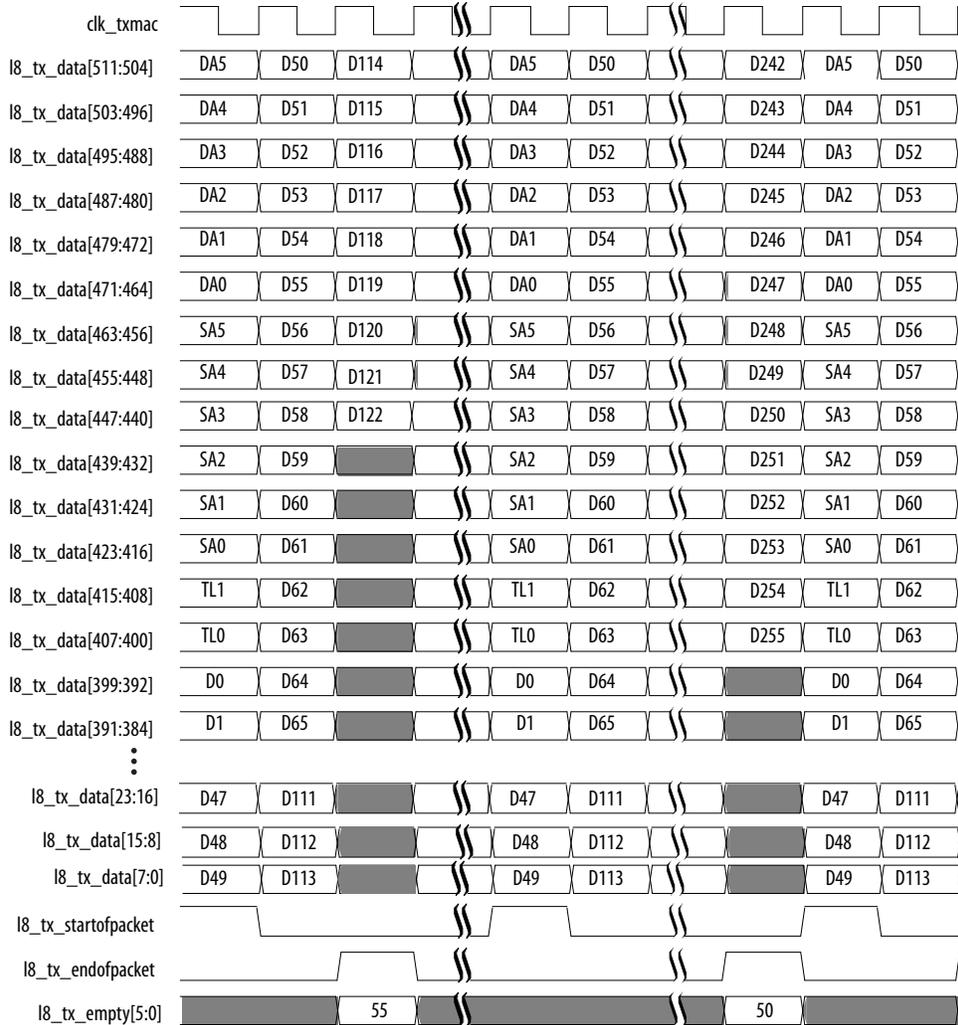

Figure 11. Byte Order on the Avalon-ST Interface Lanes With Preamble Pass-Through

Describes the byte order on the Avalon-ST interface when the preamble pass-through feature is turned on.

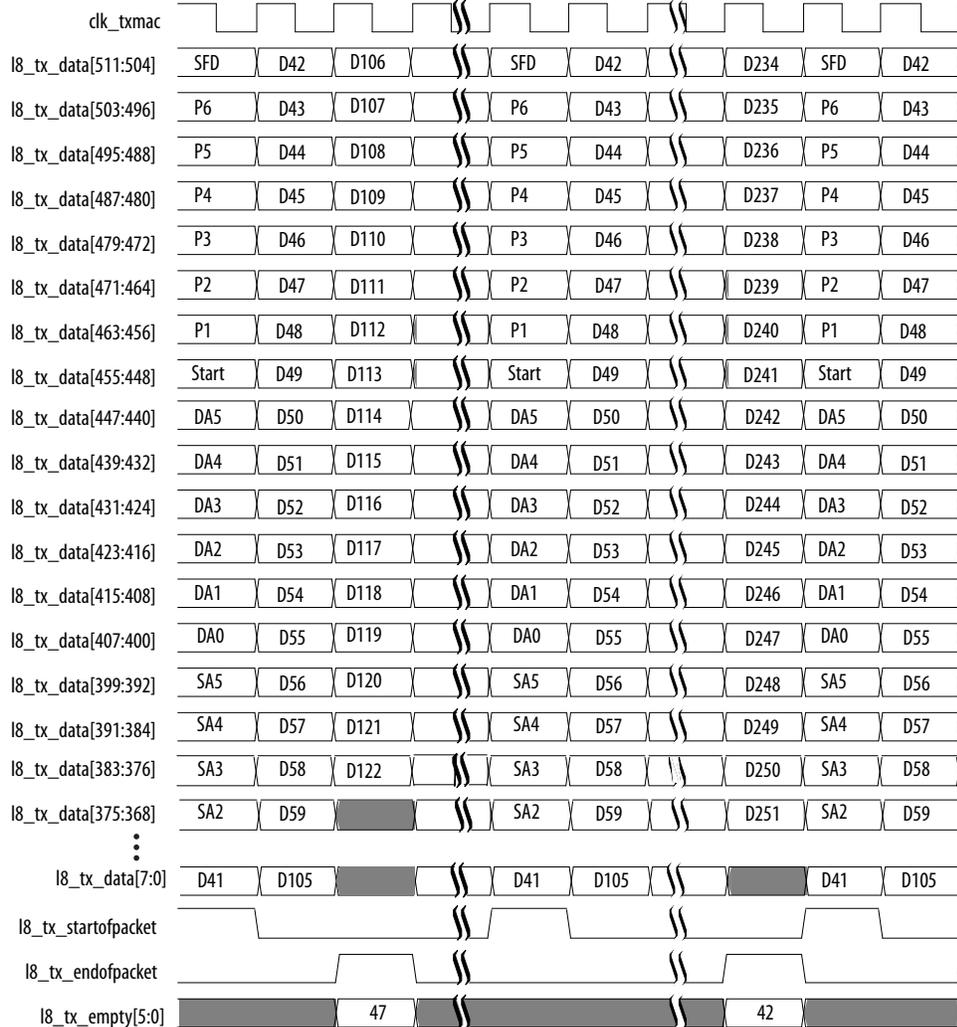

Destination Address[40] is the broadcast/multicast bit (a type bit), and Destination Address[41] is a locally administered address bit.

	SFD	Preamble						Start	Destination Address (DA)						Source Address (SA)						Type/Length		Data (D)		
Octet	7	6	5	4	3	2	1	0	5	4	3	2	1	0	5	4	3	2	1	0	1	0	00	...	NN
Bit	[63:56]	[55:48]	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]	[47:40]	[39:32]	[31:24]	[23:16]	[15:8]	[7:0]	[15:8]	[7:0]	MSB[7:0]	...	LSB[7:0]

Figure 12. Octet Transmission on the Avalon-ST Signals With Preamble Pass-Through

Illustrates how the octets of the client frame are transferred over the TX datapath when preamble pass-through is turned on. The eight preamble bytes precede the destination address bytes. The preamble bytes are reversed: the application must drive the Start byte on `l8_tx_data[455:448]` and the SFD byte on `l8_tx_data[511:504]`.

The destination address and source address bytes follow the preamble pass-through in the same order as in the case without preamble pass-through.

4.4.2 Bit Order For TX and RX Datapaths

The TX bit order matches the placement shown in the PCS lanes as illustrated in *IEEE Standard for Ethernet, Section 4, Figure 49-5*. The RX bit order matches the placement shown in *IEEE Standard for Ethernet, Section 4, Figure 49-6*.

[IEEE website](#)

The *IEEE Standard for Ethernet, Section 4* is available on the IEEE website.

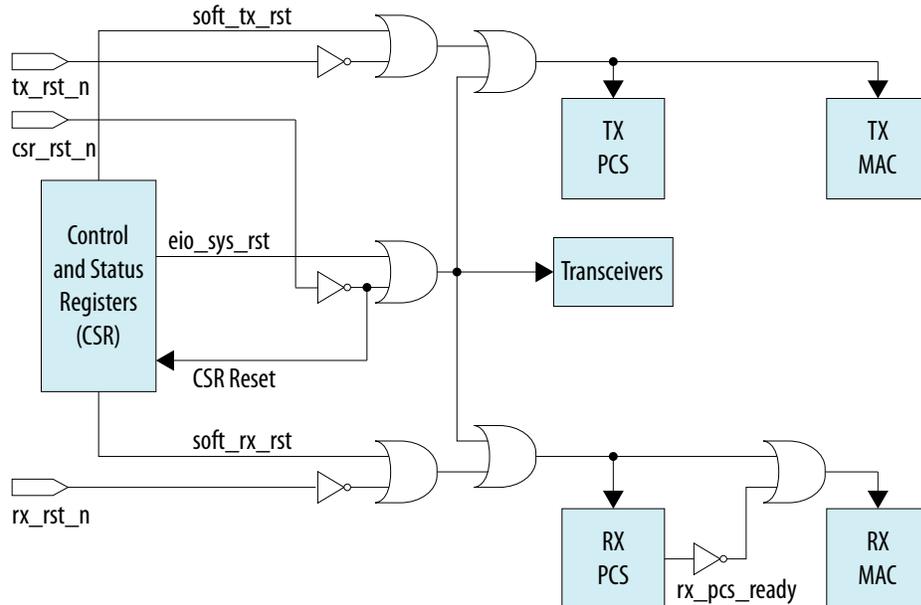

5 Reset

Control and Status registers control three parallel soft resets. These soft resets are not self-clearing. Software clears them by writing to the appropriate register. In addition, the IP core has three hard reset signals.

Asserting the external hard reset `csr_rst_n` returns all Control and Status registers to their original values, including the statistics counters. An additional dedicated reset signal resets the transceiver reconfiguration interface.

Figure 13. Conceptual Overview of General IP Core Reset Logic

The three hard resets are top-level ports. The three soft resets are internal signals which are outputs of the `PHY_CONFIG` register. Software writes the appropriate bit of the `PHY_CONFIG` to assert a soft reset.

The general reset signals reset the following functions:

- `soft_tx_rst`, `tx_rst_n`: Resets the IP core in the TX direction. Resets the TX PCS and TX MAC. This reset leads to deassertion of the `tx_lanes_stable` output signal.
- `soft_rx_rst`, `rx_rst_n`: Resets the IP core in the RX direction. Resets the RX PCS and RX MAC. This reset leads to deassertion of the `rx_pcs_ready` output signal.
- `sys_rst`, `csr_rst_n`: Resets the IP core. Resets the TX and RX MACs, PCS, and transceivers.

Note: `csr_rst_n` resets the Control and Status registers, including the statistics counters. `sys_rst` does not reset any Control and Status registers.

This reset leads to deassertion of the `tx_lanes_stable` and `rx_pcs_ready` output signals.

In addition, the synchronous `reconfig_reset` signal resets the IP core transceiver reconfiguration interface, an Avalon-MM interface. Associated clock is the `reconfig_clk`, which clocks the transceiver reconfiguration interface.

System Considerations

You should perform a system reset before beginning IP core operation, preferably by asserting the `csr_rst_n` signal.

If you assert the transmit reset when the downstream receiver is already aligned, the receiver loses alignment. Before the downstream receiver loses lock, it might receive some malformed frames.

If you assert the receive reset while the upstream transmitter is sending packets, the packets in transit are corrupted.

If the ATX PLL loses lock, the IP core forces a transmit side reset. After the ATX PLL acquires lock, the IP core deasserts the transmit reset.

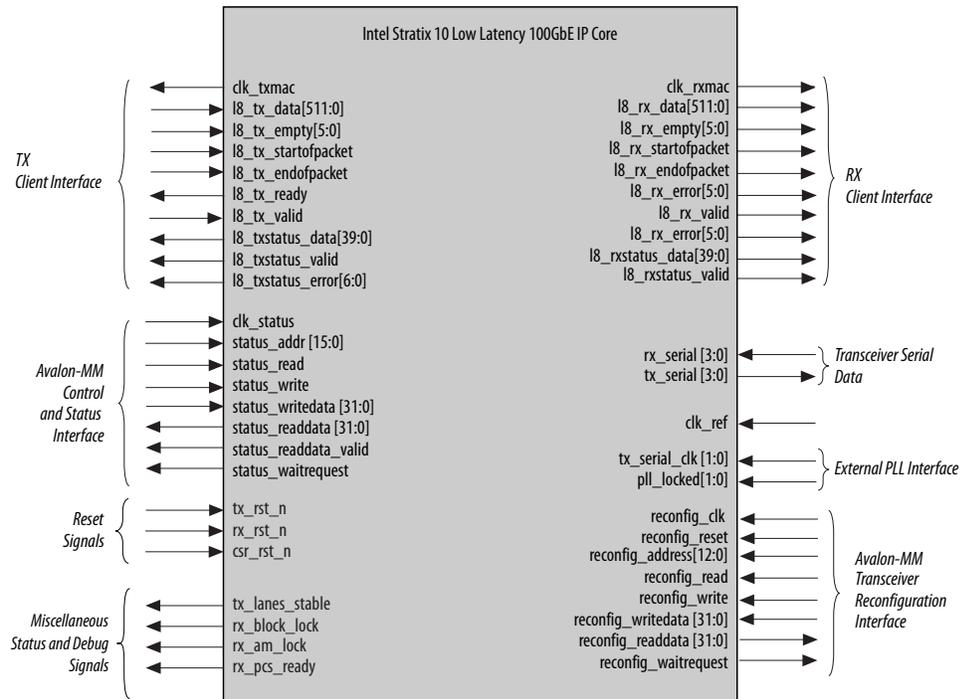

If the IP core suffers loss of signal on the serial links, it asserts the receive reset.

6 Interfaces and Signal Descriptions

Figure 14. Intel Stratix 10 LL 100GbE Signals and Interfaces

6.1 TX MAC Interface to User Logic

The Intel Stratix 10 LL 100GbE IP core TX client interface employs the Avalon-ST protocol. The Avalon-ST protocol is a synchronous point-to-point, unidirectional interface that connects the producer of a data stream (source) to a consumer of data (sink). The key properties of this interface include:

- Start of packet (SOP) and end of packet (EOP) signals delimit frame transfers.
- The SOP must always be in the MSB, simplifying the interpretation and processing of incoming data.
- A valid signal qualifies signals from source to sink.
- The sink applies backpressure to the source by using the ready signal. The source typically responds to the deassertion of the ready signal from the sink by driving the same data until the sink can accept it. The `readyLatency` defines the relationship between assertion and deassertion of the ready signal, and cycles which are considered to be `ready` for data transfer. The `readyLatency` on the TX client interface is zero cycles.

The client acts as a source and the TX MAC acts as a sink in the transmit direction.

Table 11. Signals of the Avalon-ST TX Client Interface

All interface signals are clocked by the `clk_txmac` clock.

Signal Name	Direction	Description
<code>clk_txmac</code>	Output	The TX clock for the IP core is <code>clk_txmac</code> . The frequency of this clock is 390.625 MHz.
<code>18_tx_data[511:0]</code>	Input	TX data. If the preamble pass-through feature is enabled, data begins with the preamble. The Intel Stratix 10 LL 100GbE IP core does not process incoming frames of less than nine bytes correctly. You must ensure such frames do not reach the TX client interface. You must send each TX data packet without intermediate IDLE cycles. Therefore, you must ensure your application can provide the data for a single packet in consecutive clock cycles. If data might not be available otherwise, you must buffer the data in your design and wait to assert <code>18_tx_startofpacket</code> when you are assured the packet data to send on <code>18_tx_data[511:0]</code> is available or will be available on time.
<code>18_tx_empty[5:0]</code>	Input	Indicates the number of empty bytes on <code>18_tx_data[511:0]</code> when <code>18_tx_endofpacket</code> is asserted.
<code>18_tx_startofpacket</code>	Input	When asserted, indicates the start of a packet. The packet starts on the MSB.
<code>18_tx_endofpacket</code>	Input	When asserted, indicates the end of packet.
<code>18_tx_ready</code>	Output	When asserted, the MAC is ready to receive data. The <code>18_tx_ready</code> signal acts as an acknowledge. The source drives <code>18_tx_valid</code> and <code>18_tx_data[511:0]</code> , then waits for the sink to assert <code>18_tx_ready</code> . The <code>readyLatency</code> is zero cycles, so that the IP core accepts valid data in the same cycle in which it asserts <code>18_tx_ready</code> . The <code>18_tx_ready</code> signal indicates the MAC is ready to receive data in normal operational mode. However, the <code>18_tx_ready</code> signal might not be an adequate indication following reset. To avoid sending packets before the Ethernet link is able to transmit them reliably, you should ensure that the application does not send packets on the TX client interface until after the <code>tx_lanes_stable</code> signal is asserted.
<code>18_tx_valid</code>	Input	When asserted <code>18_tx_data</code> is valid. This signal must be continuously asserted between the assertions of <code>18_tx_startofpacket</code> and <code>18_tx_endofpacket</code> for the same packet.
<code>18_tx_error</code>	Input	When asserted in an EOP cycle (while <code>18_tx_endofpacket</code> is asserted), directs the IP core to insert an error in the packet before sending it on the Ethernet link. <i>Note:</i> The Intel Quartus Prime v17.1 software release does not yet support this feature. You must tie this input signal to the value of 0.
<code>18_txstatus_valid</code>	Output	When asserted, indicates that <code>18_txstatus_data</code> and <code>18_txstatus_error[6:0]</code> are driving valid data.
<code>18_txstatus_data[39:0]</code>	Output	Specifies information about the transmit frame. The following fields are defined: <ul style="list-style-type: none"> [Bit 39]: When asserted, indicates a PFC frame [Bit 38]: When asserted, indicates a unicast frame Bit[37]: When asserted, indicates a multicast frame Bit[36]: When asserted, indicates a broadcast frame

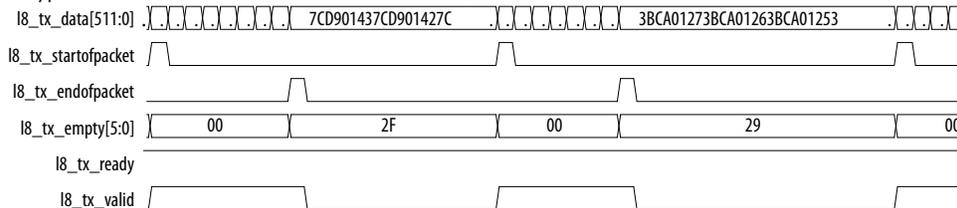

continued...

Signal Name	Direction	Description
		<ul style="list-style-type: none"> • Bit[35]: When asserted, indicates a pause frame • Bit[34]: When asserted, indicates a control frame • Bit[33]: When asserted, indicates a VLAN frame • Bit[32]: When asserted, indicates a stacked VLAN frame • Bits[31:16]: Specifies the frame length from the first byte of the destination address to the last byte of the FCS • Bits[15:0]: Specifies the payload length
l8_txstatus_error[6:0]	Output	Specifies the error type in the transmit frame. The following fields are defined: <ul style="list-style-type: none"> • Bits[6:3]: Reserved • Bit[2]: Payload length error • Bit[1]: Oversized frame • Bit[0]: Reserved. This signal is valid when l8_txstatus_valid is asserted.

6.2 RX MAC Interface to User Logic

The Intel Stratix 10 LL 100GbE IP core RX datapath employs the Avalon-ST protocol. The Avalon-ST protocol is a synchronous point-to-point, unidirectional interface that connects the producer of a data stream (source) to a consumer of data (sink). The key properties of this interface include:

- Start of packet (SOP) and end of packet (EOP) signals delimit frame transfers.
- The SOP must always be in the MSB, simplifying the interpretation and processing of data you receive on this interface.
- A valid signal qualifies signals from source to sink.

The RX MAC acts as a source and the client acts as a sink in the receive direction.

Table 12. Signals of the Avalon-ST RX Client Interface

All interface signals are clocked by the `clk_rxmac` clock.

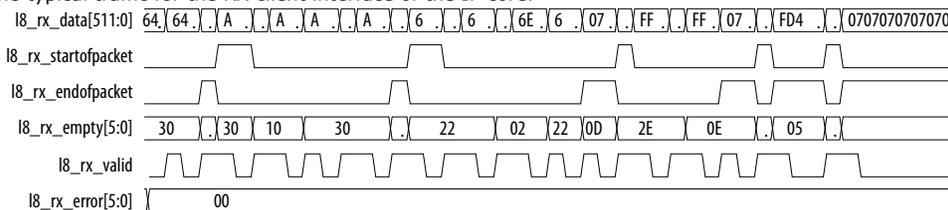

Name	Direction	Description
<code>clk_rxmac</code>	Output	The RX clock for the IP core is <code>clk_rxmac</code> . The IP core recovers this clock from the incoming data. This clock is guaranteed stable when <code>rx_pcs_ready</code> is asserted. The frequency of this clock is 390.625 MHz.
<code>l8_rx_data[511:0]</code>	Output	RX data. Bit 511 is the MSB and bit 0 is the LSB. Bytes are read in the usual left to right order. The IP core reverses the byte order to meet the requirements of the Ethernet standard.
<code>l8_rx_empty[5:0]</code>	Output	Indicates the number of empty bytes on <code>l8_rx_data[511:0]</code> when <code>l8_rx_endofpacket</code> is asserted, starting from the least significant byte (LSB).
<code>l8_rx_startofpacket</code>	Output	When asserted, indicates the start of a packet. The packet starts on the MSB.
<code>l8_rx_endofpacket</code>	Output	When asserted, indicates the end of packet. In the case of an undersized packet, or in the case of a packet that is exactly 64 bytes long, <code>l8_rx_startofpacket</code> and <code>l8_rx_endofpacket</code> are asserted in the same clock cycle.
<code>l8_rx_error[5:0]</code>	Output	Reports certain types of errors in the Ethernet frame whose contents are currently being transmitted on the client interface. This signal is valid in EOP cycles only. The individual bits report different types of errors: <ul style="list-style-type: none"> • Bit [0]: Malformed packet error. If this bit has the value of 1, the packet is malformed. The IP core identifies a malformed packet when it receives a control character that is not a terminate character, while receiving the packet. • Bit [1]: CRC error. If this bit has the value of 1, the IP core detected a CRC error in the frame. • Bit [2]: undersized payload. If this bit has the value of 1, the frame size is between nine and 63 bytes, inclusive. The IP core does not recognize an incoming frame of size eight bytes or less as a frame, and those cases are not reported here. The <code>l8_rx_error[1]</code> bit also signals an FCS error. • Bit [3]: oversized payload. If this bit has the value of 1, the frame size is greater than the maximum frame size programmed in the <code>RXMAC_SIZE_CONFIG</code> register at offset 0x506. • Bit [4]: payload length error. If this bit has the value of 1, the payload received in the frame did not match the length field value, and the value in the length field is less than 1536 bytes. • Bit [5]: Reserved.
<code>l8_rx_valid</code>	Output	When asserted, indicates that RX data is valid. Only valid between the <code>l8_rx_startofpacket</code> and <code>l8_rx_endofpacket</code> signals. This signal might be deasserted between the assertion of <code>l8_rx_startofpacket</code> and <code>l8_rx_endofpacket</code> .
<code>l8_rxstatus_valid</code>	Output	When asserted, indicates that <code>l8_rxstatus_data</code> is driving valid data. This signal behaves identically to the <code>l8_rx_endofpacket</code> signal.
<code>l8_rxstatus_data[39:0]</code>	Output	Specifies information about the received frame. The following fields are defined: <ul style="list-style-type: none"> • [Bit 39]: When asserted, indicates a PFC frame • [Bit 38]: When asserted, indicates a unicast frame • Bit[37]: When asserted, indicates a multicast frame • Bit[36]: When asserted, indicates a broadcast frame
<i>continued...</i>		

Name	Direction	Description
		<ul style="list-style-type: none"> Bit[35]: When asserted, indicates a pause frame Bit[34]: When asserted, indicates a control frame Bit[33]: When asserted, indicates a VLAN frame Bit[32]: When asserted, indicates a stacked VLAN frame Bits[31:16]: Specifies the frame length from the first byte of the destination address to the last byte of the FCS Bits[15:0]: Specifies the payload length

6.3 Transceivers

The transceivers implement four CAUI-4 physical lanes at 25.78125 MHz and require two separately instantiated advanced transmit (ATX) PLLs to generate the high speed serial clocks. On Stratix 10 devices, only the ATX PLL supports the required data rate.

Table 13. Transceiver Signals

Signal	Direction	Description
tx_serial[3:0]	Output	TX transceiver data. Each tx_serial bit becomes two physical pins that form a differential pair.
rx_serial[3:0]	Input	RX transceiver data. Each rx_serial bit becomes two physical pins that form a differential pair.
clk_ref	Input	The input clock clk_ref is the reference clock for the transceiver RX CDR PLL and the RS-FEC PLLs. This clock must have a frequency of 644.53125 MHz with a ±100 ppm accuracy per the <i>IEEE 802.3ba-2010 Ethernet Standard</i> . In addition, clk_ref must meet the jitter specification of the <i>IEEE 802.3ba-2010 Ethernet Standard</i> . The PLL and clock generation logic use this reference clock to derive the transceiver and PCS clocks. The input clock should be a high quality signal on the appropriate dedicated clock pin. Refer to the relevant device datasheet for transceiver reference clock phase noise specifications.
tx_serial_clk[1:0]	Input	High speed serial clocks driven by the two ATX PLLs. The frequency of these clocks is 12.890625 GHz.

continued...

Signal	Direction	Description
		You must drive these clocks from the two ATX PLLs that you configure separately from the Intel Stratix 10 LL 100GbE IP core.
tx_pll_locked[1:0]	Input	Lock signals from the two ATX PLLs. Each bit indicates the corresponding ATX PLL is locked.

6.4 Transceiver Reconfiguration Signals

You access the transceiver control and status registers using the transceiver reconfiguration interface. This is an Avalon-MM interface.

The Avalon-MM interface implements a standard memory-mapped protocol. You can connect an Avalon master to this bus to access the registers of the embedded Transceiver PHY IP core.

Table 14. Reconfiguration Interface Ports with Shared Native PHY Reconfiguration Interface

All interface signals are clocked by the `reconfig_clk` clock. These signals are provided by a four-channel Stratix 10 Native PHY IP core embedded in the Intel Stratix 10 LL 100GbE IP core.

Port Name	Direction	Description
<code>reconfig_clk</code>	Input	Avalon clock. The clock frequency is 100-125 MHz. All signals transceiver reconfiguration interface signals are synchronous to <code>reconfig_clk</code> .
<code>reconfig_reset</code>	Input	Resets the Avalon-MM interface and all of the registers to which it provides access.
<code>reconfig_write</code>	Input	Write request signal. Signal is active high.
<code>reconfig_read</code>	Input	Read request signal. Signal is active high.
<code>reconfig_address[13:0]</code>	Input	Address bus. Refer to the Refer to the <i>Intel Stratix 10 L- and H-Tile Transceiver PHY User Guide</i> for information about the address fields for the Native PHY four-channel configuration.
<code>reconfig_writedata[31:0]</code>	Input	A 32-bit data write bus. <code>reconfig_address</code> specifies the address.
<code>reconfig_readdata[31:0]</code>	Output	A 32-bit data read bus. Drives read data from the specified address. Signal is valid after <code>reconfig_waitrequest</code> is deasserted.
<code>reconfig_waitrequest</code>	Output	Indicates the Avalon-MM interface is busy. Keep the <code>reconfig_write</code> or <code>reconfig_read</code> asserted until <code>reconfig_waitrequest</code> is deasserted.

6.5 Avalon-MM Management Interface

You access control and status registers using an Avalon-MM management interface. The interface responds regardless of the link status. It also responds when the IP core is in a reset state driven by any reset signal or soft reset other than the `csr_rst_n` signal. Asserting the `csr_rst_n` signal resets all control and status registers except the statistics counters; while this reset is in process, the Avalon-MM management interface does not respond.

Note: This interface cannot handle multiple pending read transfers. Despite the presence of the `status_readdata_valid` signal, this Avalon-MM interface is non-pipelined with variable latency.

Table 15. Avalon-MM Management Interface

Signal	Direction	Description
<code>clk_status</code>	Input	The clock that drives the control and status registers. The frequency of this clock is 100-125 MHz.
<code>status_addr[15:0]</code>	Input	Drives the Avalon-MM register address.
<code>status_read</code>	Input	When asserted, specifies a read request.
<code>status_write</code>	Input	When asserted, specifies a write request.
<code>status_readdata[31:0]</code>	Output	Drives read data. Valid when <code>status_readdata_valid</code> is asserted.
<code>status_readdata_valid</code>	Output	When asserted, indicates that <code>status_read_data[31:0]</code> is valid.
<code>status_writedata[31:0]</code>	Input	Drives the write data.
<code>status_waitrequest</code>	Output	Indicates that the control and status interface is not ready to complete the transaction. <code>status_waitrequest</code> is only used for read transactions.

6.6 Miscellaneous Status and Debug Signals

The miscellaneous status and debug signals are asynchronous.

Table 16. Miscellaneous Status and Debug Signals

Signal	Direction	Description
<code>tx_lanes_stable</code>	Output	Asserted when all four physical TX lanes are stable and ready to transmit data.
<code>rx_block_lock</code>	Output	Asserted when all 20 virtual lanes have identified 66-bit block boundaries in the serial data stream.
<code>rx_am_lock</code>	Output	Asserted when all 20 incoming virtual lanes have been ordered.
<code>rx_pcs_ready</code>	Output	Asserted when the RX lanes are fully aligned and ready to receive data.

6.7 Reset Signals

The IP core has three external hard reset inputs. These resets are asynchronous and are internally synchronized. Assert resets for ten `clk_status` cycles or until you observe the effect of their specific reset. Asserting the external hard reset `csr_rst_n` returns control and status registers to their original values. `rx_pcs_ready` and `tx_lanes_stable` are asserted when the core has exited reset successfully.

Table 17. Reset Signals

Signal	Direction	Description
<code>tx_rst_n</code>	Input	Active low hard reset signal. Resets the TX interface, including the TX PCS and TX MAC. This reset leads to the deassertion of the <code>tx_lanes_stable</code> output signal.
<code>rx_rst_n</code>	Input	Active low hard reset signal. Resets the RX interface, including the RX PCS and RX MAC. This reset leads to the deassertion of the <code>rx_pcs_ready</code> output signal.
<code>csr_rst_n</code>	Input	Active low hard global reset. Resets the full IP core. Resets the TX MAC, RX MAC, TX PCS, RX PCS, transceivers, and control and status registers. This reset leads to the deassertion of the <code>tx_lanes_stable</code> and <code>rx_pcs_ready</code> output signals.

6.8 Clocks

You must set the transceiver reference clock (`clk_ref`) frequency to a value that the IP core supports. The Intel Stratix 10 LL 100GbE IP core supports a `clk_ref` frequency of 644.53125 MHz ± 100 ppm. The ± 100 ppm value is required for any clock source providing the transceiver reference clock.

Table 18. Clock Inputs

Describes the input clocks that you must provide.

Signal Name	Description
<code>clk_ref</code>	The input clock <code>clk_ref</code> is the reference clock for the transceiver RX CDR PLL and the RS-FEC PLLs. This clock must have a frequency of 644.53125 MHz with a ± 100 ppm accuracy per the <i>IEEE 802.3ba-2010 Ethernet Standard</i> . In addition, <code>clk_ref</code> must meet the jitter specification of the <i>IEEE 802.3ba-2010 Ethernet Standard</i> .

continued...

Signal Name	Description
	The PLL and clock generation logic use this reference clock to derive the transceiver and PCS clocks. The input clock should be a high quality signal on the appropriate dedicated clock pin. Refer to the relevant device datasheet for transceiver reference clock phase noise specifications.
tx_serial_clk[1:0]	These two input clocks are part of the external PLL interface. The IP core fans out each clock to target two of the four transceiver PHY links. You must drive these clocks from two ATX PLLs that you configure separately from the Intel Stratix 10 LL 100GbE IP core. The required frequency is 12.890625 GHz.
clk_status	Clocks the control and status interface. The clock quality and pin chosen are not critical. <code>clk_status</code> is expected to be a 100–125 MHz clock.
reconfig_clk	Clocks the transceiver reconfiguration interface. The clock quality and pin chosen are not critical. <code>reconfig_clk</code> is expected to be a 100–125 MHz clock.

Table 19. Clock Outputs

Describes the output clocks that the IP core provides. In most cases these clocks participate in internal clocking of the IP core as well.

Signal Name	Description
clk_txmac	The TX clock for the IP core is <code>clk_txmac</code> . The TX MAC clock frequency is 390.625 MHz. This clock is guaranteed stable when <code>tx_lanes_stable</code> is high.
clk_rxmac	The RX clock for the IP core is <code>clk_rxmac</code> . The RX MAC clock frequency is 390.625 MHz. This clock is only reliable when <code>rx_pcs_ready</code> has the value of 1. The IP core generates <code>clk_rxmac</code> from a recovered clock that relies on the presence of incoming RX data.

7 Registers

This section provides information about the memory-mapped registers. You access these registers using the IP core Avalon-MM control and status interface. The registers use 32-bit addresses; they are not byte addressable.

Write operations to a read-only register field have no effect. Read operations that address a Reserved register return an unspecified result. Write operations to Reserved registers have no effect. Accesses to registers that do not exist in your IP core variation, or to register bits that are not defined in your IP core variation, have an unspecified result. You should consider these registers and register bits Reserved. Although you can only access registers in 32-bit read and write operations, you should not attempt to write or ascribe meaning to values in undefined register bits.

Table 20. Intel Stratix 10 LL 100GbE IP Core Register Map Overview

Lists the main ranges of the memory mapped registers for the Intel Stratix 10 LL 100GbE IP core. Addresses are word addresses.

Word Offset	Register Category
0x300–0x3FF	PHY registers
0x400–0x4FF	TX MAC registers
0x500–0x5FF	RX MAC registers
0x800–0x8FF	TX statistics counters
0x900–0x9FF	RX statistics counters
0xC00–0xCFF	TX RS-FEC registers
0xD00–0xDFF	RX RS-FEC registers

0x304	PHY_NAME_2	Final characters of IP core variation identifier string, "pcs".	0x0070 6373	RO
0x310	PHY_CONFIG	PHY configuration registers. The following bit fields are defined: <ul style="list-style-type: none"> Bit[0]: : eio_sys_rst. Full system reset (except registers). Set this bit to initiate the internal reset sequence. Bit[1]: soft_txp_rst. TX soft reset. Bit[2]: soft_rxp_rst. RX soft reset. Bit[3]: Reserved. Bit[4]: set_ref_lock. Directs the RX CDR PLL to lock to the reference clock. Bit[5]: set_data_lock. Directs the RX CDR PLL to lock to data. Bits[31:6]: Reserved. The reset bits are not self-clearing. To force a reset, you can set and reset a reset bit in back-to-back register write operations.	0x0000 0000	RW
0x312	WORD_LOCK	Each of the 20 lower order bits, when asserted, indicates that the corresponding virtual channel has identified 66 bit block boundaries in the serial data stream. If Enable RS-FEC is turned on, the value is always zero.	0XXXX0 0000 (X= don't care)	RO
0x313	EIO_SLOOP	Serial PMA loopback. Setting a bit puts the corresponding transceiver in serial loopback mode. In serial loopback mode, the TX lane loops back to the RX lane on an internal loopback path.	0XXXXX XXX0	RW
0x314	EIO_FLAG_SEL	Supports indirect addressing of individual FIFO flags in the 10G PCS Native PHY IP core. Program this register with the encoding for a specific FIFO flag. The flag values (one per transceiver) are then accessible in the EIO_FLAGS register. The value in the EIO_FLAG_SEL register directs the IP core to make available the following FIFO flag: <ul style="list-style-type: none"> 3'b000: TX FIFO full 3'b001: TX FIFO empty 3b010: TX FIFO partially full 3'b011: TX FIFO partially empty 3b100: RX FIFO full 3b101: RX FIFO empty 3b110: RX FIFO partially full 3b111: RX FIFO partially empty 	29'bX_3'b000	RW
0x315	EIO_FLAGS	PCS indirect data. To read a FIFO flag, set the value in the EIO_FLAG_SEL register to indicate the flag you want to read. After you specify the flag in the EIO_FLAG_SEL register, each bit [n] in the EIO_FLAGS register has the value of that FIFO flag for the transceiver channel for lane [n].	0XXXXX XXX0	RO

continued...

Addr	Name	Description	Reset	Access
0x321	EIO_FREQ_LOCK	Each of the lower order four bits, when asserted, indicates that the corresponding lane RX clock data recovery (CDR) phase-locked loop (PLL) is locked.	0xXXXX XXX0	RO
0x322	PHY_CLK	The following encodings are defined: <ul style="list-style-type: none"> • Bit[0]: If set to 1, indicates the TX transceivers have completed reset. • Bit [1] : If set to 1, indicates the TX core clock is stable and if Enable RS-FEC is turned on, that the FEC TX PLL has acquired frequency lock. • Bit[2] : If set to 1, indicates the RX core clock is stable and if Enable RS-FEC is turned on, that the FEC RX PLL has acquired frequency lock. 	29'bX_3'b000	RO
0x323	FRM_ERR	Each of the 20 lower order bits, when asserted, indicates that the corresponding virtual lane has a frame error. You can read this register to determine if the IP core sustains a low number of frame errors, below the threshold to lose word lock. These bits are sticky, unless the virtual lane loses word lock. Write 1'b1 to the SCLR_FRM_ERR register to clear. If a virtual lane loses word lock, it clears the corresponding register bit. Each bit in this register has a valid value only if the corresponding bit in the WORD_LOCK register at offset 0x312 has the value of 1. If Enable RS-FEC is turned on, the value is always zero.	0xFFFF 0000	RO
0x324	SCLR_FRM_ERR	Synchronous clear for FRM_ERR register. Write 1'b1 to this register to clear the FRM_ERR register and bit [1] of the LANE_DESKEWED register. A single bit clears all sticky framing errors. This bit does not auto-clear. Write a 1'b0 to continue logging frame errors.	0x0000 0000	RW
0x325	EIO_RX_SOFT_PURGE_S	Set bit [0] to clear the RX FIFO for all four physical lanes.	31'bX_1'b0	RW
0x326	RX_PCS_FULLY_ALIGNED_S	Indicates the RX PCS is fully aligned and ready to accept traffic. <ul style="list-style-type: none"> • Bit[0] : RX PCS fully aligned status. • Bit[1]: RX PCS HI BER status. If Enable RS-FEC is turned on, the value is always zero.	30'bX_2'b00	RO
0x328	AM_LOCK	When bit [0] is asserted, indicates that the IP core has identified virtual lane alignment markers in the data stream of all 20 virtual lanes, and has ordered the virtual lanes. If Enable RS-FEC is turned on, the value is always zero.	0xXXXX XXX0	RO
0x329	LANE_DESKEWED	The following encodings are defined:	30'bX_2'b00	RO

0x400	TXMAC_REVID	TX MAC revision ID.	0x0809 2017	RO
0x401	TXMAC_SCRATCH	Scratch register available for testing.	0x0000 0000	RW
0x402	TXMAC_NAME_0	First 4 characters of module variation identifier string, "100gMACTxCSR".	0x3130 3067	RO
0x403	TXMAC_NAME_1	Next 4 characters of IP core variation identifier string, "MACT".	0x4D41 4354	RO
0x404	TXMAC_NAME_2	Final 4 characters of IP core variation identifier string, "xCSR".	0x7843 5352	RO
0x406	IPG_COL_REM	Specifies the number of IDLE columns to be removed in every Alignment Marker period to compensate for alignment marker insertion. You can program this register to a larger value than the default value, for clock compensation. The default value is 20 (decimal).. Bits [31:8] of this register are Reserved.	0xXXXX XX14	RW
0x407	MAX_TX_SIZE_CONFIG	Specifies the maximum TX frame length. Frames that are longer are considered oversized. However, the IP core does transmit them. If the IP core transmits an Ethernet frame of size greater than the number of bytes specified in this register, and the IP core includes statistics registers, the IP core increments the 64-bit <code>CNTR_TX_OVERSIZE</code> counter. The minimum value of this register is 64 (decimal). Bits [31:16] of this register are Reserved.	0xXXXX 2580	RW
0x40A	TX_MAC_CONTROL	TX MAC Control Register. A single bit is defined: <ul style="list-style-type: none"> Bit [1] – VLAN detection disabled. This bit is deasserted by default, implying VLAN detection is enabled. 	30'hX2'b0X	RW

7.3 RX MAC Registers

Table 23. RX MAC Registers

Addr	Name	Description	Reset	Access
0x500	RXMAC_REVID	RX MAC revision ID.	0x0809 2017	RO
0x501	RXMAC_SCRATCH	Scratch register available for testing.	0x0000 0000	RW
0x502	RXMAC_NAME_0	First 4 characters of IP core variation identifier string, "100gMACRxCSR".	0x3130 3067	RO
0x503	RXMAC_NAME_1	Next 4 characters of IP core variation identifier string, "100gMACRxCSR".	0x4D41 4352	RO
0x504	RXMAC_NAME_2	Final 4 characters of IP core variation identifier string, "100gMACRxCSR".	0x7843 5352	RO
0x506	RXMAC_SIZE_CONFIG	Specifies the maximum frame length available. The MAC asserts <code>l8_rx_error[3]</code> when the length of the received frame exceeds the value of this register. If the IP core receives an Ethernet frame of size greater than the number of bytes specified in this register, and the IP core includes statistics registers, the IP core increments the 64-bit <code>CNTR_RX_OVERSIZE</code> counter.	0xFFFF 2580	RW
0x507	MAC_CRC_CONFIG	The RX CRC forwarding configuration register. The following encodings are defined: <ul style="list-style-type: none"> 1'b0 : Remove RX CRC, do not forward it to the RX client interface 1'b1 : Retain RX CRC, forward it to the RX client interface In either case, the IP core checks the incoming RX CRC and flags errors.	31'hX1'b0	RW
0x50A	RXMAC_CONTROL	RX MAC Control Register. The following bits are defined: <ul style="list-style-type: none"> Bit[4] – Preamble check. Strict SFD checking option to compare each packet preamble to 0x555555555555. This field is available only if you turn on Enable Strict SFD check. Bit[3] – SFD check. Strict SFD checking option to compare each SFD byte to 0x5D. This field is available only if you turn on Enable Strict SFD check. Bit [1] – VLAN detection disabled. This bit is deasserted by default implying VLAN detection is enabled. 	27'h0_5'b11X0X	RW

7.4 Statistics Registers

The Intel Stratix 10 LL 100GbE statistics registers count Ethernet traffic and errors. The 64-bit statistics registers are designed to roll over, to ensure timing closure on the FPGA. However, these registers should never roll over if the link is functioning properly. The statistics registers check the size of frames, which includes the following fields:

- Size of the destination address
- Size of the source address
- Size of the data
- Four bytes of CRC

The statistics counters module is a synthesis option. The statistics registers are counters that are implemented inside the CSR. When you turn on the **Enable RX/TX statistics counters** parameter in the Intel Stratix 10 LL 100GbE parameter editor, the counters are implemented in the CSR. When you turn off the **Enable RX/TX statistics counters** parameter in the Intel Stratix 10 LL 100GbE parameter editor, the counters are not implemented in the CSR, and read access to the counters returns undefined results.

After system power-up, the statistics counters have random values. You must clear these registers and confirm the system is stable before using their values. You can clear the registers with the `csr_rst_n` input signal, or with the configuration registers at offsets 0x845 and 0x945.

The configuration register at offset 0x845 allows you to clear all of the TX statistics counters. The configuration register at offset 0x945 allows you to clear all of the RX statistics counters. If you exclude these registers, you can monitor the statistics counter increment vectors that the IP core provides at the client side interface and maintain your own counters.

Reading the value of a statistics register does not affect its value.

To ensure that the counters you read are consistent, you should issue a shadow request to create a snapshot of all of the TX or RX statistics registers, by setting bit [2] of the configuration register at offset 0x845 or 0x945, respectively. Until you reset this bit, the counters continue to increment but the readable values remain constant. You can read bit [1] of the status register at offset 0x846 or 0x946, respectively, to confirm your shadow request has been granted or released.

7.4.1 TX Statistics Registers

Table 24. Transmit Side Statistics Registers

The TX MAC does not check outgoing frames for FCS errors. Therefore, the TX statistics registers do not collect statistics for related categories: all FCS error-related registers should maintain the value of 0. In addition, the TX MAC does not check for undersized frames. Therefore, the `CNTR_TX_FRAGMENTS` and `CNTR_TX_RUNT` registers should maintain the value of 0.

Address	Name	Description	Access
0x800	CNTR_TX_FRAGMENT_S_LO	Number of transmitted frames less than 64 bytes and reporting a CRC error (lower 32 bits)	RO
0x801	CNTR_TX_FRAGMENT_S_HI	Number of transmitted frames less than 64 bytes and reporting a CRC error (upper 32 bits)	RO
0x802	CNTR_TX_JABBERS_LO	Number of transmitted oversized frames reporting a CRC error (lower 32 bits)	RO
0x803	CNTR_TX_JABBERS_HI	Number of transmitted oversized frames reporting a CRC error (upper 32 bits)	RO
0x804	CNTR_TX_FCS_LO	Number of transmitted packets with FCS errors. (lower 32 bits)	RO
0x805	CNTR_TX_FCS_HI	Number of transmitted packets with FCS errors. (upper 32 bits)	RO
0x806	CNTR_TX_CRCERR_LO	Number of transmitted frames with a frame of length at least 64 reporting a CRC error (lower 32 bits)	RO
0x807	CNTR_TX_CRCERR_HI	Number of transmitted frames with a frame of length at least 64 reporting a CRC error (upper 32 bits)	RO

Addr	Name	Bit	Description	Reset	Access
0xC00	REVID	[31:0]	Reed-Solomon FEC TX module revision ID.	0x0809 2017	RO
0xC01	TX_RSFECC_SCRATCH	[31:0]	Scratch register available for testing.	32'b0	RW
0xC02	TX_RSFECC_NAME_0	[31:0]	Final 4 characters of IP core variation identifier string, "100gRSFECCoTX".	0x436F 5458	RO
0xC03	TX_RSFECC_NAME_1	[31:0]	Middle 4 characters of IP core variation identifier string, "100gRSFECCoTX".	0x5253 4645	RO
0xC04	TX_RSFECC_NAME_2	[31:0]	Initial 4 characters of IP core variation identifier string, "100gRSFECCoTX".	0x3130 3067	RO
0xC05	ERR_INS_EN	[31:5]	Reserved.	0x00000000	RW
		[4]	When 1'b1, enables error insertion for single FEC codeword. This bit self-clears after the Reed-Solomon FEC transmitter inserts the error.		
		[3:1]	Reserved.		
		[0]	When 1'b1, enables error insertion for every FEC codeword. Specifies that the Reed-Solomon FEC transmitter should insert the error in every FEC codeword.		
0xC06	ERR_MASK	[31:25]	Reserved.	0x00000000	RW
		[24]	<i>SYM_32</i> : Each FEC codeword consists of 16 groups of 33 symbols. This register field specifies whether the RS-FEC transmitter corrupts symbol 32 (of symbols 0-32) in each corrupted group. Specifically, the value of 1 directs the IP core to corrupt symbol 32 according to <i>BIT_MASK</i> .		
		[23:18]	Reserved.		
		[17:8]	<i>BIT_MASK</i> : Specifies which of the ten bits the RS-FEC transmitter corrupts in each corrupted symbol. Specifically, the value of 1 in bit [n+8] directs the IP core to corrupt bit [n] in each corrupted symbol.

Addr	Name	Bit	Description	Reset	Access
		[7:4]	Reserved.		
		[3:0]	<p>GROUP_NUM: Each FEC codeword consists of 16 groups of 33 symbols. This register field specifies the single group of 33 symbols that the RS-FEC transmitter corrupts in the current FEC codeword.</p> <p>The following values are defined:</p> <ul style="list-style-type: none"> 4'b000: First group of 33 symbols (symbols 0-32) 4'b0001: Second group of symbols (symbols 33-65) ... 4'b1110: Second-to-final group of symbols (symbols 462-494) 4'b1111: Final group of symbols (symbols 495-527, or {chk[13:0],sym[514:495]}) <p>Continuous corruption of groups 0-3 might lead to strange behavior as a result of alignment marker corruption.</p>		
0xC07	SYMBOL_ERR_MASK	[31:0]	Each FEC codeword consists of 16 groups of 33 symbols. This register specifies which of the lower order 32 symbols in a group the RS-FEC transmitter corrupts. Specifically the value of 1 in bit [n] directs the IP core to corrupt symbol n.	32'b0	RW

7.6 RX Reed-Solomon FEC Registers

Table 27. RX Reed-Solomon FEC Registers

Addr	Name	Bit	Description	Reset	Access
0xD00	REVID	[31:0]	RSFEC RX module revision ID	0x0809 2017	RO
0xD01	RX_RSFEC_SCRATCH	[31:0]	Scratch register available for testing.	32'b0	RW
0xD02	RX_RSFEC_NAME0	[31:0]	Final 4 characters of IP core variation identifier string, "100gRSFECoRX".	0x436F 5258	RO
0xD03	RX_RSFEC_NAME1	[31:0]	Middle 4 characters of IP core variation identifier string, "100gRSFECoRX".	0x5253 4645	RO
0xD04	RX_RSFEC_NAME2	[31:0]	Initial 4 characters of IP core variation identifier string, "100gRSFECoRX".	0x3130 3067	RO
0xD05	BYPASS_RESTART	[4]	Restart state machines. When 1'b1, specifies the IP core restarts the FEC synchronization and alignment state machines. Bit self-clears after alignment marker synchronization is restarted. (Refer to Figure 91-8 and Figure 91-9 in <i>IEEE Standard 802.3bj-2014</i>).	0x0000 0000	RW
		[3:1]	Reserved.		

continued...

Addr	Name	Bit	Description	Reset	Access
		[0]	Bypass RS-FEC decoder. When 1'b1, specifies the IP core bypasses the RS-FEC decoder. When 1'b0, enables RS-FEC error correction.		
0xD06	RX_FEC_STATUS	[15:8]	fec_lane: Two bits per lane hold the FEC lane number when the corresponding amps_lock bit (in register bits [3:0]) has the value of 1. The following encodings are defined: <ul style="list-style-type: none"> • Bits[15:14]: fec_lane for lane 3 • Bits[13:12]: fec_lane for lane 2 • Bits[11:10]: fec_lane for lane 1 • Bits[9:8]: fec_lane for lane 0 	0x0000 0000	RO
		[7:5]	Reserved.		
		[4]	fec_align_status: Alignment marker lock status. When 1'b1, indicates all lanes are synchronized and aligned. When 1'b0, indicates the deskew process is not yet complete. (Refer to Figure 91-9 in <i>IEEE Standard 802.3bj-2014</i>).		
		[3:0]	amps_lock: Each bit indicates that the receiver has detected the location of the alignment marker payload sequence for the corresponding FEC lane. (Refer to Figure 91-8 in <i>IEEE Standard 802.3bj-2014</i>).		
0xD07	CORRECTED_CW	[31:0]	32-bit counter that contains the number of corrected FEC codewords processed. The value resets to zero upon read and holds at max count.	0x0000 0000	RC
0xD08	UNCORRECTED_CW	[31:0]	32-bit counter that contains the number of uncorrected FEC codewords processed. The value resets to zero upon read and holds at max count.	0x0000 0000	RC

8 Debugging the Link

Begin debugging your link at the most basic level, with word lock. Then, consider higher level issues.

The following steps should help you identify and resolve common problems that occur when bringing up a Intel Stratix 10 LL 100GbE IP core link:

1. Establish word lock—The RX lanes should be able to achieve word lock even in the presence of extreme bit error rates. If the IP core is unable to achieve word lock, check the transceiver clocking and data rate configuration. Check for cabling errors such as the reversal of the TX and RX lanes. Check the clock frequency monitors in the Control and Status registers.

To check for word lock: Clear the `FRM_ERR` register by writing the value of 1 followed by another write of 0 to the `SCLR_FRM_ERR` register at offset 0x324. Then read the `FRM_ERR` register at offset 0x323. If the value is zero, the core has word lock. If non-zero the status is indeterminate.

2. When having problems with word lock, check the `EIO_FREQ_LOCK` register at address 0x321. The values in this register define the status of the recovered clock. In normal operation, all the bits should be asserted. A non-asserted (value-0) or toggling logic value on the bit that corresponds to any lane, indicates a clock recovery problem. Clock recovery difficulties are typically caused by the following problems:
 - A high bit error rate (BER)
 - Failure to establish the link
 - Incorrect clock inputs to the IP core
3. Check the PMA FIFO levels by selecting appropriate bits in the `EIO_FLAG_SEL` register and reading the values in the `EIO_FLAGS` register. During normal operation, the TX and RX FIFOs should be nominally filled. Observing a the TX FIFO is either empty or full typically indicates a problem with clock frequencies. The RX FIFO should never be full, although an empty RX FIFO can be tolerated.
4. Establish lane integrity—When operating properly, the lanes should not experience bit errors at a rate greater than roughly one per hour per day. Bit errors within data packets are identified as FCS errors. Bit errors in control information, including IDLE frames, generally cause errors in XL/CGMII decoding.
5. If the IP core acquires word lock but the link is still not established, check the `AM_LOCK` register at offset 0x328 by reading it repeatedly. If it is deasserted or toggling, check the cables and connections.

6. If the IP core acquires alignment marker lock on all virtual lanes (bit [0] of the `AM_LOCK` has the consistent value of 1), but the link is still not established, check the `LANE_DESKEWED` register at offset 0x329. If this register remains at the value of 0, the skew is greater than the deskew limit.
7. Verify packet traffic—The Ethernet protocol includes automatic lane reordering so the higher levels should follow the PCS. If the PCS is locked, but higher level traffic is corrupted, there may be a problem with the remote transmitter virtual lane tags.
8. Tuning—You can adjust analog parameters to improve the bit error rate. IDLE traffic is representative for analog purposes.

In addition, your IP core can experience loss of signal on the Ethernet link after it is established. In this case, the TX functionality is unaffected, but the RX functionality is disrupted. The following symptoms indicate a loss of signal on the Ethernet link:

- The IP core deasserts the `rx_pcs_ready` signal, indicating the IP core has lost alignment marker lock.
- The IP core deasserts the RX PCS fully aligned status bit (bit [0]) of the `RX_PCS_FULLLY_ALIGNED_S` register at offset 0x326. This change is linked to the change in value of the `rx_pcs_ready` signal.
- The IP core triggers the RX digital reset process by asserting `soft_rxp_rst`.
