1. About this Document

This document describes the streaming direct memory access (DMA) Accelerator Functional Unit (AFU) implementation using the Platform Designer.

1.1. Intended Audience

This document is intended for hardware or software developer who requires an Accelerator Function (AF) that accesses the data buffered in memory and provides it to an accelerator as a serial stream of data. Intel recommends you gain familiarity with Platform Designer before using this design example.

2. Streaming DMA AFU Description

The streaming DMA AFU design example shows how to transfer data between the memory and Avalon®-ST sources and sinks. Most commonly, a streaming DMA is utilized to transfer data from host memory into a hardware accelerator and stream the results back to host memory without using the local FPGA memory as a temporary buffer. These streams typically operate in parallel mode and reduce the latency of a hardware accelerator by removing the additional memory copy operations.

The streaming DMA AFU comprises the following sub-modules:

- Memory Properties Factory (MPF) Basic Building Block (BBB)
- Core Cache Interface (CCI-P) to Avalon-MM Adapter
- Streaming DMA Test System, which includes:
  - Memory-to-Stream (M2S) DMA BBB
  - Stream-to-Memory (S2M) DMA BBB
  - Streaming Pattern Checker and Generator

The streaming DMA AFU design example includes a user space driver as well as a host application that performs data transfer between host memory and the FPGA pattern checker and generator. You can use this design example as a starting point to implement streaming data transfers in your own AFU design by replacing the pattern checker and generator with your hardware accelerator and modifying the host application accordingly.

Both M2S and S2M DMA BBBS support packetized data, therefore the streaming data includes the start-of-packet (SOP), end-of-packet (EOP), and empty signals. You can use this packet support to transfer a hardware driven payload size. For example, a compression accelerator typically receives a known payload size; and the compression results have an unknown length until the accelerator completes this task. The compression accelerator simply issues a packet to the S2M DMA BBB and the driver provides the host application metadata that describes how much data can be transferred.

Related Information
Avalon Interface Specifications

2.1. Hardware Subsystems

The Streaming DMA AFU accesses the host memory through the FPGA Interface Unit (FIU) and the local SDRAM directly. In practice the streaming DMAs typically only need to be connect to the FIU to access host memory. The streaming DMAs can access up to 256 TB of local SDRAM.

You can use the streaming DMA AFU to perform the following data transfer:
• Host memory to FPGA stream
• FPGA stream to host memory
• Local FPGA memory to FPGA stream
• FPGA stream to local FPGA memory

The Platform Designer system implements most part of the streaming DMA AFU, M2S and S2M DMA BBBs.

The Streaming DMA AFU implemented in the Platform Designer system can be found in the following location:

```
$OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu/hw/rtl/<device>/
```

You can find the two DMA BBBs in the following location:

• S2M DMA BBB:

  ```
  $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu/hw/rtl/stream_to_memory_dma_bbb
  ```

• M2S DMA BBB:

  ```
  $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu/hw/rtl/memory_to_stream_dma_bbb
  ```

(1) Supported in a future release of the Intel Acceleration Stack.
2. Streaming DMA AFU Description

The streaming DMA AFU includes the following modules that connect to the FIU:

- Memory-Mapped IO (MMIO) Decode Logic—detects MMIO read and write transactions and separates them from the CCI-P RX channel 0 that they arrive from. This ensures that MMIO traffic never reaches the MPF BBB and is serviced by an independent MMIO command channel.

- MPF BBB—ensures that reads issued by the M2S DMA BBB are returned in the order that they were issued. The streaming DMA BBBS use the Avalon-MM protocol which requires the read data to return in-order.

- CCI-P to Avalon-MM Adapter—translates MMIO accesses to Avalon-MM read and write transactions. This module also receives Avalon-MM read and write transactions from the streaming DMA BBBS and converts them to CCI-P transactions that are issued to the host.

- Streaming DMA Test System—a wrapper around the two streaming DMA BBBS and includes pattern checker and generator components. This module exposes Avalon-MM master and slave interfaces that connect to the CCI-P to Avalon-MM adapter.
2.2. Streaming DMA Test System

The streaming DMA test system is a Platform Designer system that connects the streaming DMA BBBs to other IP in the system.

Figure 2. Streaming DMA Test System Block Diagram

The streaming DMA test system includes the following modules:

- **AFU DFH**—stores the 64-bit device feature header (DFH) for the streaming DMA AFU. The host driver scans the hardware that is searching for the AFU DFH and various BBBs used to identify the hardware. The AFU DFH is setup to point to the next DFH at offset 0x100.

- **M2S DMA BBB**—reads buffers from memory and provides the data as a serial stream to the Avalon-ST source port. In this design example, the streaming data is sent to the pattern checker.

- **S2M DMA BBB**—accepts a serial stream of data from its Avalon-ST port and writes the data to buffers in memory. In this design example, the streaming data is sent from the pattern generator.

- **Pattern Checker and Generator**—these modules are programmed by the host with an incrementing pattern. The supplied host software configures each component with a pattern that increments by one for every increasing byte.

- **Clock Crossing Bridge**—this module has been added between the streaming DMAs and the local FPGA external memory to operate the streaming DMA AFU in the pClk clock domain.
• Pipeline Bridge—this module has been added between the M2S DMA BBB and host read interface of the CCI-P to Avalon-MM adapter to improve the maximum operating frequency (Fmax) of the streaming DMA AFU.

• Far Reach Avalon-MM Bridge—this module has been added between the S2M DMA BBB and host write interface of the CCI-P to Avalon-MM adapter to improve the maximum operating frequency (Fmax). It also sends write responses from the CCI-P interface to the S2M DMA.

• Null DFH—A DFH with its last DFH field set to terminate the DFH list. This module helps you to add more DMA channels to the design and have a module to terminate the DFH list.

• Streaming Decimator—performs loopback testing that programmatically filters out streaming data. This block emulates a hardware accelerator that performs reduction operations (compression for example). It can also be configured for passthrough operation.

• Streaming Multiplexer/De-multiplexer—2:1 and 1:2 multiplexer and de-multiplexer that route the streaming data either to the pattern checker and generator or perform loopback testing between the M2S and S2M DMAs.

2.3. Memory-to-Stream DMA BBB

The Memory-to-Stream (M2S) DMA BBB reads data from a buffer stored in memory and converts it into an Avalon-ST source stream. The buffer must be aligned to 64 bytes. The M2S DMA BBB is configured to handle up to a 1 gigabyte (GB) transfer size, which requires buffer to be allocated with a 1 GB hugepage to ensure it resides in continuous physical memory. The M2S DMA BBB can also transfer payloads up to 4 KB and 2 MB of size depending on the page size used when allocating the pinned memory.

The M2S DMA BBB streaming interface supports packet generation by exposing the start-of-packet (SOP), end-of-packet (EOP), and empty signals. Your host application can optionally instruct the streaming DMA driver to generate packetized data. If you enable the packetized data, then the empty signal conveys the number of bytes at the end of a transfer that are in valid when the EOP signal is asserted. For example, a DMA transfer of 4100 bytes contains 65 beats of streaming data with SOP asserted during the first beat and EOP asserted during the last beat. The empty signal is set to 60 (0X3C) on the last streaming beat. Since the first 64 beats transfer 64 bytes each, the last beat only contains four valid bytes (first four bytes out of 64 are valid).
The components in the M2S DMA BBB Platform Designer system implement the following functions:
• M2S DMA BBB DFH—stores the 64-bit device feature header (DFH) for the M2S DMA BBB. The host driver scans the hardware that is searching for the AFU DFH and various BBBs used to identify the hardware. The M2S DMA BBB DFH is setup to point to the next DFH at offset 0x100.

• Dispatcher—buffers descriptors before issuing read transfer commands to the read master.

• Read Master—accepts commands from the dispatcher and reads from memory and converts the data to an Avalon-ST stream. The data leaving the streaming port can be accompanied by streaming sideband signaling for SOP, EOP, and empty signals. If you require the stream to support non-multiples of 64 bytes, then you must request the driver to send packetized data. Therefore, if the last beat is not 64 bytes in size, then the empty signal informs your downstream hardware about the invalid bytes. Only the last beat can contain invalid bytes, all other beats must be 64 bytes in size which is defined by the Avalon-ST specification.

• Pipeline Bridge—this component has been added between the Read Master and host/local FPGA memory to improve the maximum operating frequency (Fmax) of the M2S DMA BBB. If your design does not require the M2S DMA BBB to connect to local FPGA memory, then export that interface and ground all its master inputs. All the dispatcher slave interfaces connect to a pipeline bridge which spans an address range of 0x100. The pipeline bridge connects to all the Avalon slaves inside the DMA BBB (Descriptor Frontend, Dispatcher, DMA BBB DFH) and span an address range of 0x100.

• Descriptor Frontend—fetches transfer descriptors from the host memory and overwrites them with the status information after the transfer completes.

2.4. Stream-to-Memory DMA BBB

The Steam-to-Memory (S2M) DMA BBB accepts Avalon-ST data and transfers it to a buffer in memory. The buffer must be aligned to 64-bytes. The S2M DMA BBB is configured to handle up to a 1 GB transfer size, which requires buffer to be allocated with a 1 GB hugepage to ensure it resides in continuous physical memory.

The S2M DMA BBB streaming interface supports receiving packetized data by exposing the SOP, EOP, and empty signals. Your host application instructs the streaming DMA driver to use the packet signaling when it requests a streaming transfer. By using the packetized data, the hardware accelerator that provides the data can determine when transfer complete. For example, if a data compression engine is connected to the S2M DMA BBB, the host application does not know how much data might stream until the compression operation is complete. Instead of dividing this data into frames, your hardware accelerator simply notifies the start and end of the payload via asserting SOP and EOP respectively. The DMA transfers the entire payload to memory using one or more DMA transfers and DMA driver instructs the host application of the payload length of each transfer upon completion.
The components in the S2M DMA BBB Platform Designer system implement the following functions:

- **S2M DMA BBB DFH**—stores the 64-bit device feature header (DFH) for the S2M DMA BBB. The host driver scans the hardware that is searching for the AFU DFH and various BBBs used to identify the hardware. The S2M DMA DMA BBB DFH points to the next DFH at offset 0x100.

- **Dispatcher**—buffers descriptors before issuing read transfer commands to the read master.

- **Write Master**—accepts commands from the dispatcher and writes the data accepted by the Avalon-ST sink interface to memory. The data arriving at the streaming port can be accompanied by streaming sideband signaling for SOP, EOP, and empty signals.
• Pipeline Bridge—this component has been added between the write master and local FPGA memory to improve the maximum operating frequency (Fmax) of the S2M DMA BBB. If your design does not require the S2M DMA BBB to connect to local FPGA memory, then export that interface and ground all its master inputs. The pipeline bridge connects to all the Avalon slaves inside the DMA BBB (Descriptor Frontend, Dispatcher, DMA BBB DFH) and span an address range of 0x100.

• Far Reach Avalon-MM Bridge—this component has been added between the mSGDMA write master and host write interface of the CCI-P to Avalon-MM adapter to improve the maximum operating frequency (Fmax) of the S2M DMA BBB. It also forwards write responses to the write master.

• Descriptor Frontend—fetches transfer descriptors from the host memory and overwrites them with the status information after the transfer completes.

3. Memory Map and Address Spaces

The streaming DMA AFU has three memory views:

- **DMA view**
- **Host view**
- **DMA Descriptor view**

The DMA view supports a 49-bit address space. The lower half of the DMA view maps to the local FPGA memory. Only the streaming DMA BBBs have connectivity to the local FPGA memory, the host cannot access the local FPGA memory. The upper half of the DMA view maps to host memory.

The host view includes all the registers accessible through MMIO accesses such as DFH tables, and control/status registers of the various components that are used inside the streaming DMA AFU.

The DMA Descriptor view is a 48-bit address space that maps to the host memory. Because the DMA Fetch engine only access the host memory, it sees host memory at address 0x00 unlike the DMA view.

The MMIO registers in both streaming DMA BBBs and the streaming DMA AFU support 32- and 64-bit access. The streaming DMA AFU does not support 512-bit MMIO accesses. The dispatcher registers inside each streaming DMA BBB must be accessed using 32-bit accesses.

### 3.1. Streaming DMA AFU Memory Map

The streaming DMA register map provides the absolute addresses of all the locations within the unit. These registers are in the host view because only the host can access them.

</tr>
<tr>
<td>fpgaDMATransfer</td>
<td>Performs a DMA transfer.</td>
</tr>
</tbody>
</table>

For more information about the API, input, and output arguments, refer to the header file located at $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu/sw/fpga_dma.h

To know more about software driver use model, refer to the README file located at $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu/README
5. Running the AFU Example

Before you begin:

- Intel recommends you refer to the Quick Start Guide for your Intel FPGA PAC D5005 to be familiar with running similar examples. Before you proceed through the following steps, verify that the `OPAE_PLATFORM_ROOT` environment variable is set to the OPAE SDK installation directory.
- You must also set up two 1 GB hugepages to run the sample application using the instruction below:

  ```bash
  sudo sh -c "echo 2 > /sys/kernel/mm/hugepages/hugepages-1048576kB/nr_hugepages"
  ```

Perform the following steps to download the Streaming DMA Accelerator Function (AF) bitstream, to build the application and driver, and to run the design example:

1. Change to the Streaming DMA application and driver directory:

   ```bash
   cd $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu/sw
   ```

2. Build the driver and application:

   ```bash
   make
   ```

3. Download the streaming DMA AFU bitstream:

   ```bash
   fpgaconf ../bin/streaming_dma_afu.gbs
   ```

4. Execute the host application to transfer 100 MB in 1 MB portions from host memory to the FPGA pattern checker:

   ```bash
   ./fpga_dma_st_test -l off -s 104857600 -p 1048576 -r mtos -t fixed
   ```

5. Execute the host application to transfer 100 MB in 1 MB portions from the FPGA pattern generator to host memory:

   ```bash
   ./fpga_dma_st_test -l off -s 104857600 -p 1048576 -r stom -t fixed
   ```

6. Execute the host application to transfer 100 MB in 1 MB portions from host memory back to host memory in loopback mode:

   ```bash
   ./fpga_dma_st_test -l on -s 104857600 -p 1048576 -t fixed -f 0
   ```

5.1. Optimization for Improved DMA Performance

Implementation of NUMA (non-uniform memory access) optimization in the fpga_dma_st_test.c (application) allows processor to access its own local memory. This implementation is faster than accessing the non-local memory (memory local to another processor).

A typical NUMA configuration is shown in the diagram below. The orange arrow represents access from a core to memory local of the same core. The red arrow illustrates the path taken when a core on Node 0 access memory that resides in local memory of Node 1.

Figure 6. Typical NUMA Configuration

Use the following code to implement NUMA optimization in your test application:

```c
// Set up proper affinity if requested
if (cpu_affinity || memory_affinity) {
    unsigned dom = 0, bus = 0, dev = 0, func = 0;
    fpga_properties props;
    int retval;
    #if(FPGA_DMA_DEBUG)
    char str[4096];

    ON_ERR_GOTO(retval, out_destroy_tok, "hwloc_set_cpubind");
} 
} 
}
6. Compiling the Accelerator Function (AF)

To generate a synthesis build environment to compile an AF, use the `afu_synth_setup` command as following:

1. Change to the streaming DMA AFU sample directory:
   ```bash
cd $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu
   ```

2. Generate the design build directory:
   ```bash
   afu_synth_setup --source hw/rtl/filelist.txt build_synth
   ```

3. From the synthesis build directory generated by `afu_synth_setup`, enter the following commands from a terminal window to generate an AF for the target hardware platform:
   ```bash
   cd build_synth
   $OPAE_PLATFORM_ROOT/bin/run.sh
   ```

The `run.sh` AF generation script creates the AF image with the same base filename as the AFU's platform configuration file with a `.gbs` suffix at the location:

$OPAE_PLATFORM_ROOT/hw/samples/build_synth/streaming_dma_afu.gbs.
7. Simulating the AFU Example

Intel recommends you refer to the *Intel Accelerator Functional Unit (AFU) Simulation Environment (ASE) Quick Start Guide* for your Intel PAC to be familiar with simulating similar examples and to setup your environment. Before you proceed through the following steps, verify that the `OPAE_PLATFORM_ROOT` environment variable is set to the OPAE SDK installation directory.

Complete the following steps to setup the hardware simulator for the streaming DMA AFU:

1. Change to the streaming DMA AFU sample directory:
   
   ```
   cd $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu
   ```

2. Create an ASE environment in a new directory and configure it for simulating an AFU:
   
   ```
   afu_sim_setup --source hw/rtl/filelist.txt build_ase_dir
   ```

3. Change to the ASE build directory:
   
   ```
   cd build_ase_dir
   ```

4. Build the driver and application:
   
   ```
   make
   ```

5. make sim

Sample output from the hardware simulator:

```
[SIM]  ** ATTENTION : BEFORE running the software application **
[SIM]  Set env(ASE_WORKDIR) in terminal where application will run (copy-and-paste) =>
[SIM]  $SHELL   | Run:
[SIM]  ---------+---------------------------------------------------
[SIM]  bash/zsh | export ASE_WORKDIR=/mnt/Tools/ias/hw/samples/streaming_dma_afu/build_ase_dir/work
[SIM]  tcsh/csh | setenv ASE_WORKDIR /mnt/Tools/ias/hw/samples/streaming_dma_afu/build_ase_dir/work
[SIM]  For any other $SHELL, consult your Linux administrator
[SIM]  [SIM] Ready for simulation...
[SIM]  Press CTRL-C to close simulator...
```

Complete the following steps to compile and execute the streaming DMA AFU software in the simulation environment:

1. Open a new terminal window.
2. Change directory to:
   
   ```
   cd $OPAE_PLATFORM_ROOT/hw/samples/streaming_dma_afu/sw
   ```
3. Copy environment setup string (choose string appropriate for your shell) from the steps above in the hardware simulation to the terminal window. See the following lines in the sample output from the hardware simulator.

```
[SIM]  bash/zsh | export ASE_WORKDIR=/mnt/Tools/ias/hw/samples/streaming_dma_afu/build_ase_dir/work
[SIM]  tcsh/csh | setenv ASE_WORKDIR /mnt/Tools/ias/hw/samples/streaming_dma_afu/build_ase_dir/work
```

4. `make USE_ASE=1`

5. Execute the host application to transfer 4 KB in 1 KB portions from the host memory to the FPGA pattern checker:

```
./fpga_dma_st_test -l off -s 4096 -p 1024 -r mtos -t fixed
```

6. Execute the host application to transfer 4 KB in 1 KB portions from the FPGA pattern checker to the host memory:

```
./fpga_dma_st_test -l off -s 4096 -p 1024 -r stom -t fixed
```

7. Execute the host application to transfer 4 KB in 1 KB portions from the host memory back to host memory in the loopback mode:

```
./fpga_dma_st_test -l on -s 4096 -p 1024 -t fixed
```
