1. Overview

Configuration via Protocol (CvP) is a configuration scheme supported in Arria® V, Cyclone® V, Stratix® V, Intel® Arria 10, Intel Stratix 10, and Intel Cyclone 10 GX device families. The CvP configuration scheme creates separate images for the periphery and core logic. You can store the periphery image in a local configuration device and the core image in host memory, reducing system costs and increasing the security for the proprietary core image. CvP configures the Intel FPGA fabric through the PCI Express* (PCIe*) link, and is available for Endpoint variants only. This document describes the CvP configuration scheme for Intel Stratix 10 device family.

- [Additional Clock Requirements for Transceivers, HPS, PCIe, High Bandwidth Memory \(HBM2\) and SmartVID](#)

1.1. Benefits of Using CvP

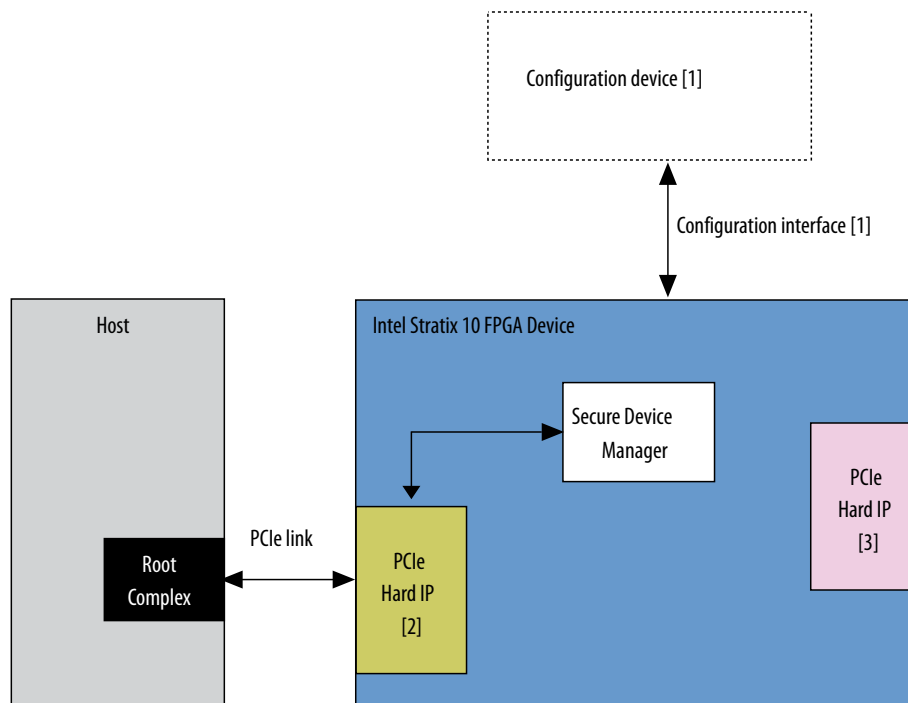

The CvP configuration scheme has the following advantages:

- Reduces system costs by reducing the size of the local flash device that stores the configuration data. The smallest EPCQ-L device is large enough for all Intel Stratix 10 periphery images.
- Allows update of the FPGA without reprogramming the flash.
- Enables dynamic core updates without requiring a system power down. CvP allows you to update the FPGA core fabric through the PCIe link without a host reboot or FPGA full chip reinitialization.
- Provides a simpler software model for configuration. A smart host can use the PCIe protocol and the application topology to initialize and update the FPGA core fabric.
- Allows quick update of your design for changing application loads.

1.2. CvP System

A CvP system typically consists of an FPGA, a PCIe host, and a configuration device.

Figure 1. CvP Block Diagram

1. The FPGA connects to the configuration device using the Active Serial x4 (fast mode) configuration scheme.
2. CvP and other applications use the PCIe Hard IP block (bottom left).
 - Many Intel Stratix 10 FPGAs include more than one Hard IP block for PCI Express. The CvP configuration scheme can only utilize the bottom left PCIe Hard IP block on each device. You must configure this as an Endpoint.
3. You can use other PCIe Hard IP blocks for PCIe applications and cannot use the blocks for CvP.

Note: To avoid configuration failure, you must provide a free running and stable reference clock source to PCIe IP core before you start the configuration.

1.3. CvP Modes

The CvP configuration scheme supports the following modes:

- CvP Initialization mode
- CvP Update mode

CvP Initialization Mode

This mode configures the CvP PCIe core using the peripheral image of the FPGA through the on-board configuration device. Subsequently, configures the core fabric and all GPIOs through PCIe link.

Benefits of using CvP Initialization mode include:

- Satisfying the PCIe wake-up time requirement
- Saving cost by storing the core image in the host memory

CvP Update Mode

In the CvP update mode, you reconfigure the entire device except the CvP PCIe core after the device enters the user mode through full chip configuration or CvP initialization. The subsequent core image updates use the PCIe link (the periphery must not change during CvP update).

The CvP update mode uses the same process as root partition reuse in block-based design, which allows you to reuse the device periphery.

Choose this mode if you want to update the core image for any of the following reasons:

- To change core algorithms logic blocks
- To perform standard updates as part of a release process
- To customize core processing for different components that are part of a complex system

Note: The CvP update mode is available after the FPGA enters user mode. In user mode, the PCIe link is available for normal PCIe applications as well as to perform an FPGA core image update.

Table 1. CvP Support for Intel Stratix 10 Device Family

PCIe Version	Supported CvP Modes
Gen 1 / Gen 2 / Gen 3	CvP Initialization, CvP Update

[Reusing Root Partitions](#)

1.3.1. CvP Limitations and Restrictions

The Intel Stratix 10 CvP implementation has the following limitations and restrictions in the current version of the Intel Quartus® Prime software:

- Only MemWR transactions can be used to write fabric configuration data to the CvP data register. ConfigWR transactions are not supported.
- When you poll the CVP_CREDIT bits from the CvP credit register, you must write the next 4KB of fabric configuration data to the CvP data register within 50 ms of receiving an additional credit. Failure to send the data results in configuration failure.
- The CvP response time is variable and depends on different conditions. The typical delay time is 5 sec and it is safe to wait till 1 min. So the driver should poll status in credit register to decide on driver timeout.
- In CvP initialization and update mode, when FPGA fabric is not programmed, the PCIe features that uses FPGA fabric are not accessible.
- To generate the update image in the CvP update mode, you must use the same version of the Intel Quartus Prime software that you use to generate the base image.

1.3.1.1. CvP Error Recovery

This section describes expected behavior during different error situations.

Table 2. Intel Stratix 10 CvP Error Events and Suggested Recovery Methods

Error Events	Suggested Recovery Method
A bitstream is corrupted within the first 168KB of data.	The CVP_CONFIG_ERROR bit in the CvP status register goes high. Go through the Teardown sequence prior to sending another bitstream.
A bitstream is corrupted after the first 168KB of data.	The CVP_CONFIG_ERROR bit in the CvP status register goes high. To recover the system, you must power-cycle the targeted Intel Stratix 10 device.
PCIe bus error during CvP	System is unrecoverable and you must power-cycle the system.
PCIe bus error results in PERST assert.	System is unrecoverable and you must power-cycle the system.
CvP operation requests to abort	Unsupported. Aborting configuration after requesting CvP operation is not supported. Intel recommends to power-cycle the system.
A bitstream is provided from a Intel Quartus Prime version other than the one used to generate configuration firmware currently running in the device.	The CVP_CONFIG_ERROR bit in the CvP status register goes high. Go through the Teardown sequence prior to sending another bitstream. Mixing bitstreams from different Quartus versions is not supported.

2. CvP Description

2.1. Configuration Images

In CvP, you split your bitstream into two images: periphery image and core image.

You use the Intel Quartus Prime Pro Edition software to generate the images:

- Periphery image (*.periph.jic) — contains all of the periphery. The entire periphery image is static and cannot be reconfigured.
- Core image (*.core.rbf) — contains all of the core components of the design.

2.2. CvP Modes

2.2.1. CvP Initialization Mode

In this mode, an external configuration device stores the periphery image and it loads into the FPGA through the Active Serial x4 (Fast mode) configuration scheme. The host memory stores the core image and it loads into the FPGA through the PCIe link.

After the periphery image configuration is complete, the CONF_DONE signal goes high and the FPGA starts PCIe link training. When PCIe link training is complete, the PCIe link transitions to L0 state and then allows the host to complete PCIe enumeration of the link. The PCIe host then initiates the core image configuration through the PCIe link. The PCIe REFCLK needs to be running prior to sending the periphery image.

After the core image configuration is complete, the CvP_CONF_DONE pin (if enabled) goes high, indicating the FPGA is fully configured.

After the FPGA is fully configured, the FPGA enters user mode. If the INIT_DONE signal is enabled, the INIT_DONE signal goes high after initialization is complete and the FPGA enters the user mode.

In user mode, the PCIe links are available for normal PCIe applications.

2.2.2. CvP Update Mode

CvP update mode is a reconfiguration scheme that allows a host device to deliver an updated bitstream to a target FPGA device after the device enters user mode. In this mode, the FPGA device initializes by loading the full configuration image from the external local configuration device to the FPGA or after CvP initialization.

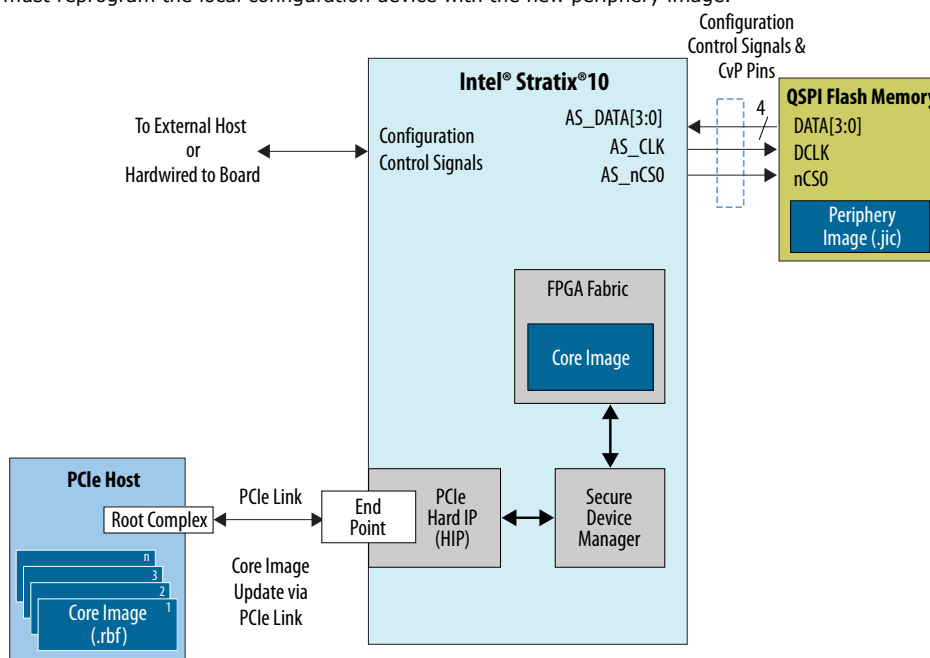

You can perform CvP update on a device that you originally configure using CvP initialization or any other configuration scheme. CvP initialization is not a prerequisite for performing CvP update.

In user mode, the PCIe links are available for normal PCIe applications. You can use the CvP PCIe link to perform an FPGA core image update. To perform the FPGA core image update, you can create one or more FPGA core images in the Intel Quartus Prime Pro Edition software that have identical connections to the periphery image.

Figure 2. Periphery and Core Image Storage Arrangement for CvP Core Image Update

The periphery image remains the same for different core image updates. If you change the periphery image, you must reprogram the local configuration device with the new periphery image.

2.3. Compression Features

Data Compression

The Intel Quartus Prime Pro Edition software compresses all Intel Stratix 10 bitstreams to reduce the storage requirement and increase bitstream processing speed. The periphery and core images are both compressed.

2.4. Pin Description

The following table lists the CvP pin descriptions and connection guidelines:

Table 3. CvP Pin Descriptions and Connection Guidelines

Pin Name	Pin Type	Pin Description	Pin Connection
CvP_CONFDONE	Output	The CvP_CONFDONE pin is driven low during configuration. When configuration via PCIe is complete, this signal is actively driven high.	If this pin is set as dedicated output, the VCCIO_SDM power supply must meet the input voltage specification of the receiving side. You can assign SDM_IO0, SDM_IO10, SDM_IO11, SDM_IO12, SDM_IO13,

continued...

Pin Name	Pin Type	Pin Description	Pin Connection
		During FPGA configuration in CvP initialization and update mode, you may observe this pin after the CONF_DONE pin goes high to determine if the FPGA is successfully configured.	SDM_IO14, SDM_IO15 or SDM_IO16 as CvP_CONF_DONE in Intel Quartus Prime Pro Edition software
INIT_DONE	Output	The INIT_DONE pin goes high indicating the device has entered user mode upon completion of configuration.	Intel recommends using SDM_IO0 pin for implementing the INIT_DONE function, provided that this function is enabled in the Intel Quartus Prime Pro Edition software. This pin has a weak pull-down for the correct function during power up. The INIT_DONE function can also be implemented using other unused SDM I/O pins (with a weak pull-down).
CONF_DONE	Output	For normal configuration mode, the CONF_DONE pin drives low before and during configuration. After all configuration data is received without error and the initialization cycle starts, CONF_DONE is driven high. In CvP initialization mode, CONF_DONE goes high after the periphery is configured.	Intel recommends using SDM_IO16 pin implementing the CONF_DONE function, provided that this function is enabled in the Intel Quartus Prime Pro Edition software.
nPERST[L,R] [0:2]	Input	The nPERST pin is only available when you use PCI Express hard IP. When the PCIe hard IP on a side (left or right) is enabled, then nPERST pins on that side cannot be used as general-purpose I/Os (GPIOs). In this case, connect the nPERST pin to the system PCIe nPERST signal to ensure that both ends of the link start link-training at the same time. The nPERST pins on a side are available as GPIOs only when the PCIe hard IP on that side is not enabled. When this pin is low, the transceivers are in reset. When this pin is high, the transceivers are out of reset. When you do not use this pin as the fundamental reset, you can use this pin as a user I/O pin	Connect this pin as defined in the Intel Quartus Prime Pro Edition software. For more details, refer to <i>Intel Stratix 10 Avalon[®]-MM/ST Interface for PCIe Solutions User Guide</i> . This pin is powered by the VCCIO3V supply. When you connect a 3.0-V supply to VCCIO3V, you must use a diode to clamp the 3.3V LVTTTL PCIe input signal to the VCCIO3V power of the device. When VCCIO3V is connected to any voltage other than 3.0V, you must use a level translator to shift down the voltage from 3.3V LVTTTL to the corresponding voltage level powering the VCCIO3V pin. Only one nPERST pin is used per PCIe hard IP. The Intel Stratix 10 device components may have all six pins listed even when the specific component might only have 1 or 2 PCIe hard IPs: <ul style="list-style-type: none"> nPERSTL0 = Bottom Left PCIe hard IP & CvP nPERSTL1 = Middle Left PCIe hard IP (When available) nPERSTL2 Top Left PCIe hard IP (When available)

continued...

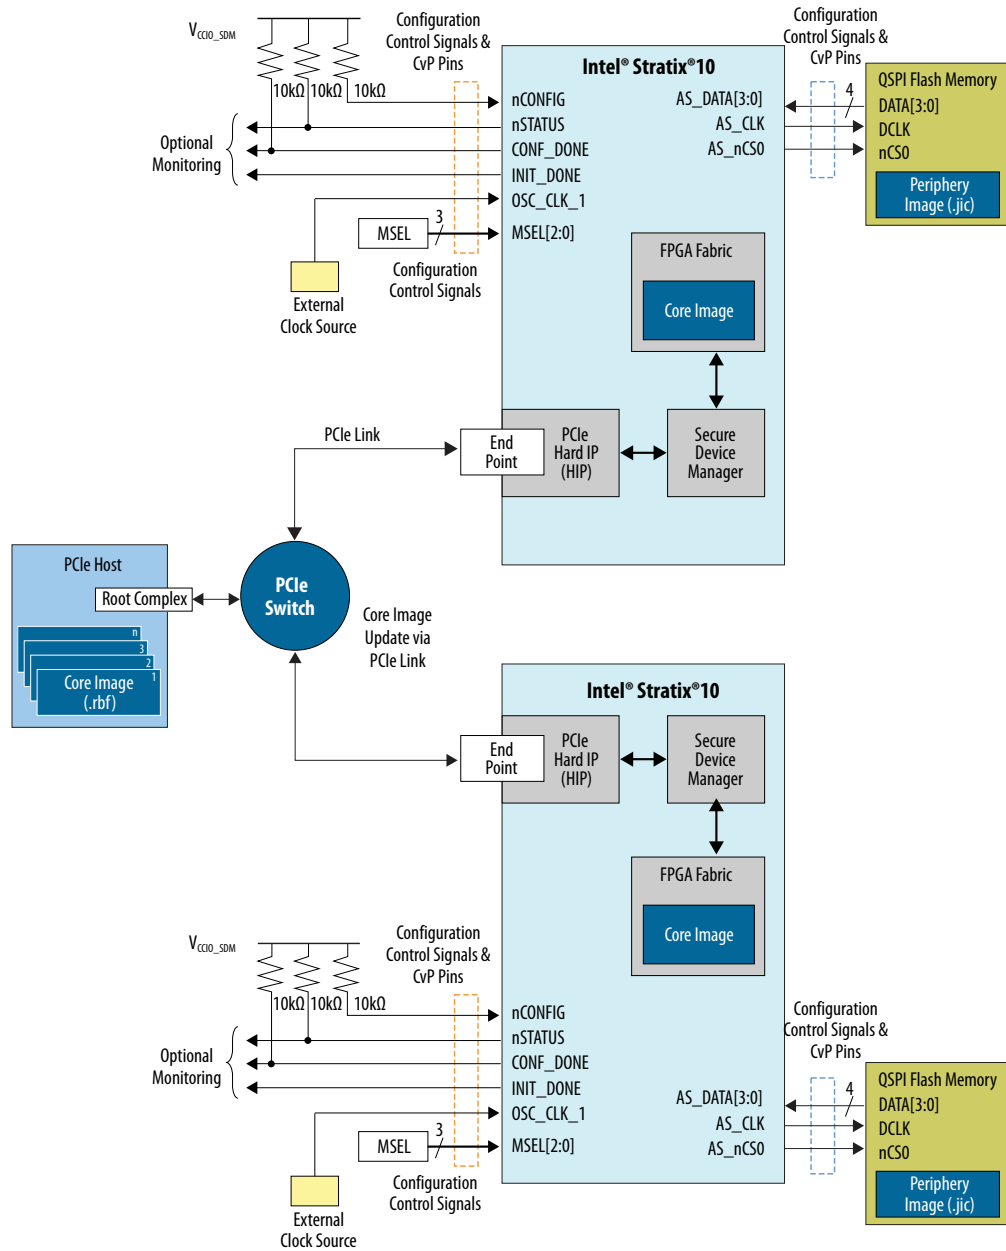

Pin Name	Pin Type	Pin Description	Pin Connection
			<ul style="list-style-type: none"> • nPERSTR0 = Bottom Right PCIe hard IP (When available) • nPERSTR1 = Middle Right PCIe hard IP (When available) • nPERSTR2 = Top Right PCIe hard IP (When available) <p><i>Note:</i> For maximum compatibility, always use the bottom left PCIe Hard IP first, as this is the only location that supports Configuration via Protocol (CvP) using the PCIe link.</p>

Figure 4. Multiple Endpoints Topology

4. Design Considerations

4.1. Designing CvP for an Open System

Follow these guidelines when designing an open CvP system where you do not have complete control of both ends of the PCIe link.

4.1.1. FPGA Power Supplies Ramp Time Requirement

For an open system, you must ensure that your design adheres to the FPGA power supplies ramp-up time requirement.

The power-on reset (POR) circuitry keeps the FPGA in the reset state until the power supply outputs are in the recommended operating range. A POR event occurs from when you power up the FPGA until the power supplies reach the recommended operating range within the maximum power supply ramp time, t_{RAMP} . If t_{RAMP} is not met, the device I/O pins and programming registers remain tri-stated, during which device configuration could fail.

To meet the PCIe link up time for CvP, the total t_{RAMP} must be less than 10 ms, from the first power supply ramp-up to the last power supply ramp-up. You must select ASx4 fast mode for MSEL settings to make sure the shortest POR delay.

Figure 5. Power Supplies Ramp-Up Time and POR

Related Information

[Intel Stratix 10 Power Management User Guide](#)

4.1.2. PCIe Wake-Up Time Requirement

For an open system, you must ensure that the PCIe link meets the PCIe wake-up time requirement as defined in the *PCI Express CARD Electromechanical Specification*. The transition from power-on to the link active (L0) state for the PCIe wake-up timing specification must be within 200 ms. The timing from FPGA power-up until the Hard IP for PCI Express IP Core in the FPGA is ready for link training must be within 120 ms.

Related Information

[PCI Express Card Electromechanical 3.0 Specification](#)

4.1.2.1. For CvP Initialization Mode

To meet the 120 ms wake-up time requirement for the PCIe Hard IP in CvP initialization mode, you need to use periphery image because the configuration time for periphery image is significantly less than the full FPGA configuration time. You must use the Active Serial x4 (fast mode) configuration scheme for the periphery image configuration.

To ensure successful configuration, all POR-monitored power supplies must ramp up monotonically to the operating range within the 10 ms ramp-up time. The `PERST#` signal indicates when the FPGA power supplies are within their specified voltage tolerances and the `REFCLK` is stable⁽¹⁾. The embedded hard reset controller triggers after the internal status signal indicates that the periphery image has been loaded. This reset does not trigger off of `PERST#`. For CvP Initialization mode, the PCIe link supports the FPGA core image configuration and subsequent PCIe applications in user mode.

Note: For Gen 2/Gen 3 capable Endpoints, after loading the core bitstream (`core.rbf`), Intel recommends to verify that the link has been trained to the expected Gen 2/Gen3 rate. If the link is not operating at Gen 2/Gen3, software can trigger the Endpoint to retrain.

⁽¹⁾ `REFCLK` must be stable 80 ms after the power supplies are stable in order to achieve the 145 ms link training complete time

Figure 6. PCIe Timing Sequence in CvP Initialization Mode

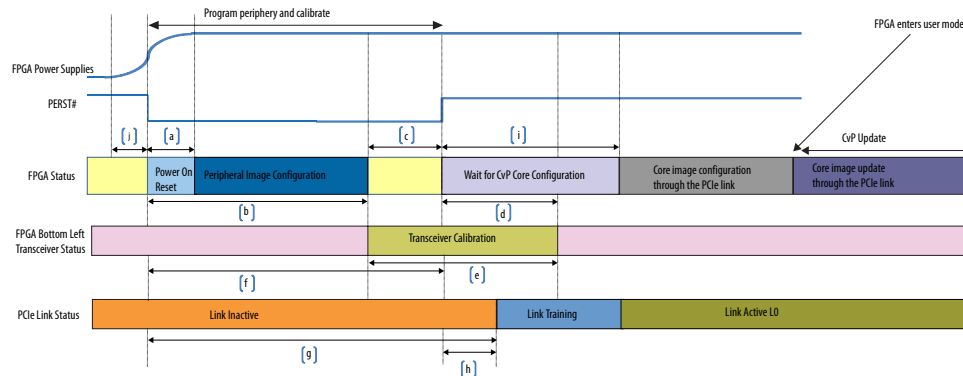

Table 4. Power-Up Sequence Timing in CvP Initialization Mode

Timing Sequence	Timing Range (ms)	Description
a	2-6.5	FPGA POR delay time (AS Fast Mode)
b	80	Maximum time from the FPGA power up to the end of periphery configuration in CvP initialization mode (before transceiver calibration)
c	20	Minimum calibration time before PERST# is deasserted
d	60	Minimum transceiver calibration window
e	80	Typical transceiver calibration window
f	100	Minimum PERST# signal active from the host
g	120	Maximum time from the FPGA power up to the end of periphery configuration in CvP initialization mode (include transceiver calibration)
h	20	Maximum PERST# signal inactive time from the host before the PCIe link enters training state
i	100	Maximum time PCIe device must enter L0 after PERST# is deasserted <i>Note:</i> 100 ms timing range is only applicable to PCIe Gen1/Gen2. PCIe Gen 3 does not need to meet 100 ms timing requirement.
j	10	Maximum ramp-up time requirement for all POR-monitored power supplies in the FPGA to reach their respective operating range

4.1.2.2. For CvP Update Mode

Before you perform CvP update mode, the device must be in user mode.

Note: For Gen 2/Gen 3 capable Endpoints, in user mode, Intel recommends to verify that the link has been trained to the expected Gen 2/Gen 3 rate. If the link is not operating at Gen 2/Gen3, software can trigger the Endpoint to retrain.

4.2. Designing CvP for a Closed System

While designing CvP for a closed system where you control both ends of the PCIe link, estimate the periphery configuration time for CvP Initialization mode or full FPGA configuration time for CvP update mode. You must ensure that the estimated

4. Design Considerations

UG-20045 | 2019.01.17

configuration time is within the time allowed by the PCIe host. Your driver can poll the USERMODE bit of the CvP Status Register to determine if the FPGA enters the user mode.

Related Information

[CvP Status Register](#) on page 21

5. CvP Driver and Registers

5.1. CvP Driver Support

You can develop your own custom CvP driver for Linux using the sample Linux driver source code provided by Intel.

Note: The Linux driver provided by Intel is not a production driver. You must adapt this driver to your design's strategy.

Related Information

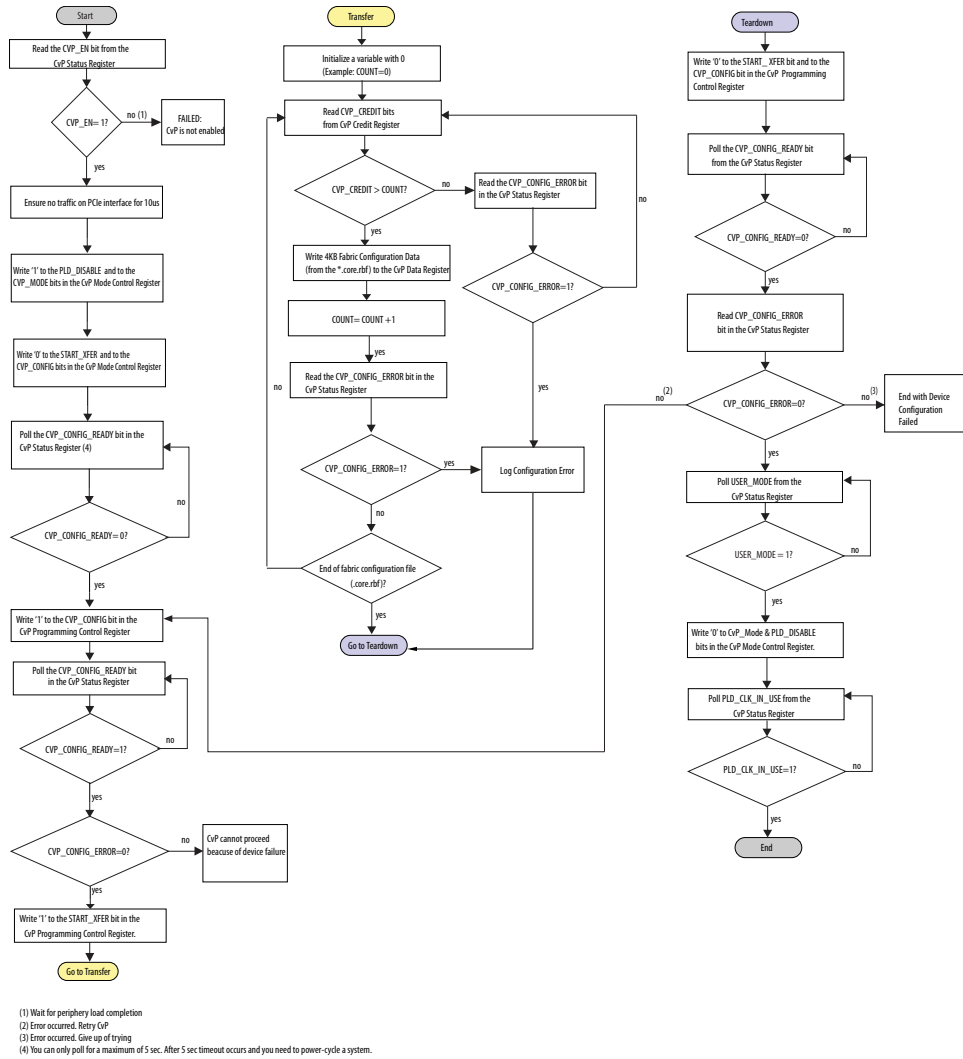

[Download the OpenSource Linux CvP Driver](#)

5.2. CvP Driver Flow

The CvP driver flow assumes that the FPGA is powered up and the SDM control block has already configured the FPGA with the peripheral image, which is indicated by the CVP_EN bit in the CvP status register.

Figure 7. CvP Driver Flow

5.3. VSEC Registers for CvP

The Vendor Specific Extended Capability (VSEC) registers occupy byte offsets 0xB80 to 0xBC0 in the PCIe Configuration Space. The PCIe host uses these registers to communicate with the FPGA control block. The following table shows the VSEC register map. Subsequent tables provide the fields and descriptions of each register.

Table 5. VSEC Registers for CvP

Byte Offset	Register Name
0xB80	Vendor Specific Capability Header
0xB84	Vendor Specific Header
0xB88	Intel Marker

continued...

Byte Offset	Register Name
0xB8C:0xB98	Reserved
0xB9C	User Configurable Device/Board ID
0xB9E	CvP Status
0xBA0	CvP Mode Control
0xBA4	CvP Data 2 ⁽²⁾
0xBA8	CvP Data
0xBAC	CvP Programming Control
0xBB0:0xBC4	Reserved
0xBC8	CvP Credit Register

5.3.1. Vendor Specific Capability Header Register

Table 6. Vendor Specific Capability Header Register (Byte Offset: 0xB80)

Bits	Name	Reset Value	Access	Description
[15:0]	PCI Express Extended Capability ID	0x000B	RO	PCIe specification defined value for VSEC Capability ID.
[19:16]	Version	0x1	RO	PCIe specification defined value for VSEC version.
[31:20]	Next Capability Offset	Variable	RO	Starting address of the next Capability Structure implemented, if any.

5.3.2. Vendor Specific Header Register

Table 7. Vendor Specific Header Register (Byte Offset: 0xB84)

Bits	Name	Reset Value	Access	Description
[15:0]	VSEC ID	0x1172	RO	A user configurable VSEC ID.
[19:16]	VSEC Revision	0	RO	A user configurable VSEC revision.
[31:20]	VSEC Length	0x05C	RO	Total length of this structure in bytes.

5.3.3. Intel Marker Register

Table 8. Intel Marker Register (Byte Offset: 0xB88)

Bits	Name	Reset Value	Access	Description
[31:0]	Intel Marker	0x41721172	RO	An additional marker.

(2) This register is no longer functional in Intel Stratix 10 devices.

5.3.4. User Configurable Device/Board ID Register

Table 9. User Configurable Device/Board ID Register (Byte Offset: 0xB9C)

Bits	Name	Reset Value	Access	Description
[15:0]	User Configurable Device/Board ID	0x00	RO	Helps user to select the correct programming file.

5.3.5. CvP Status Register

Table 10. CvP Status Register (Byte Offset: 0xB9E)

Bits	Name	Reset Value	Access	Description
[15:11]	—	Variable	RO	Reserved.
[10]	CVP_CONFIG_SUCCESS	Variable	RO	Status bit set by the device to indicate that the core image configuration was successful.
[9]	—	Variable	RO	Reserved.
[8]	PLD_CLK_IN_USE	Variable	RO	From clock switch module to fabric. You can use this bit for debug.
[7]	CVP_CONFIG_DONE	Variable	RO	Indicates that the device has completed the device configuration via CvP and there were no errors.
[6]	—	Variable	RO	Reserved.
[5]	USERMODE	Variable	RO	Indicates if the configurable FPGA fabric is in user mode.
[4]	CVP_EN	Variable	RO	Indicates if the device has enabled CvP mode.
[3]	CVP_CONFIG_ERROR	Variable	RO	Reflects the value of this signal from the device, checked by software to determine if there was an error during configuration.
[2]	CVP_CONFIG_READY	0x0	RO	Reflects the value of this signal from the device, checked by software during programming algorithm to determine the device is ready for configuration.
[1:0]	—	Variable	RO	Reserved.

5.3.6. CvP Mode Control Register

Table 11. CvP Mode Control Register (Byte Offset: 0xBA0)

Bits	Name	Reset Value	Access	Description
[31:3]	—	0x0000	RO	Reserved.
[2]	—	0x0000	RW	Reserved ⁽³⁾ .
[1]	PLD_DISABLE	1'b0	RW/RO	Enables/disables the PLD interface. This allows Host driver to switch the PLD interface out before USER MODE deasserts,

continued...

⁽³⁾ Intel recommends to set the reserved bit to 0 for write operation. For read operations, the PCIe IP always generates 0 as the output.

Bits	Name	Reset Value	Access	Description
				<p>and to switch the PLD interface back in only after USER MODE has been asserted. This helps to prevent any glitches or race conditions during the USER MODE switching.</p> <ul style="list-style-type: none"> 1: Disable the application layer interface. 0: Enable the application layer interface. <p>Only change the value of this signal when there has been no other TLP's to or from the HIP for 10 us. There should be no TLP's issued to the HIP for 10 us after this value changes. When entering CVP, this bit should be set before CVP_MODE is set. When exiting CVP, it should be cleared after CVP_MODE is clears. This ensures that there is no PLD switching during CVP. This field is RW when cvp_en=1, and RO when cvp_en=0.</p>
[0]	CVP_MODE	1'b0	RW	<p>Controls whether the Hard IP for PCI Express is in CVP_MODE or normal mode.</p> <ul style="list-style-type: none"> 1: CVP_MODE is active. Signals to the SDM active and all TLPs are route to the Configuration Space. This CVP_MODE cannot be enabled if CVP_EN = 0. 0: The IP core is in normal mode and TLPs are route to the FPGA fabric.

5.3.7. CvP Data Registers

Table 12. CvP Data Register (Byte Offsets: 0xBA4 - 0xBA8)

Bits	Name	Reset Value	Access	Description
[31:0]	CVP_DATA	0x00000000	RW	<p>Write the configuration data to this register. The data is transferred to the SDM to configure the device.</p> <p>Software must ensure that all bytes in the memory write dword are enabled. You can access this register using configuration writes. Alternatively, when in CvP mode, this register can also be written by a memory write to any address defined by a memory space BAR for this device. Using memory writes are higher throughput than configuration writes.</p>

5.3.8. CvP Programming Control Register

Table 13. CvP Programming Control Register (Byte Offset: 0x22C)

Bits	Name	Reset Value	Access	Description
[31:2]	—	0x0000	RO	Reserved.
[1]	START_XFER	1'b0	RW	Sets the CvP output to the FPGA control block indicating the start of a transfer.
[0]	CVP_CONFIG	1'b0	RW	When set to 1, the FPGA control block begins a transfer via CvP.

5.3.9. CvP Credit Register

The credit registers slow down the transmission of the CvP data to handle back pressure when there is no buffer space available within the configuration system. The crediting mechanism handles the back pressure from the configuration system. The total credits register increments each time an additional 4k buffer is available.

Table 14. CvP Credits Register (Byte Offset: 0xBC8)

Bits	Reset Value	Access	Description
[31:16]	0x00	RO	Reserved.
[15:8]	0x00	RO	Least significant 8 bits of the total number of 4k credits granted.
[7:0]	0x00	RO	Reserved.

6. Understanding the Design Steps for CvP Initialization and Update Mode in Intel Stratix 10

6.1. Implementation of CvP Initialization Mode

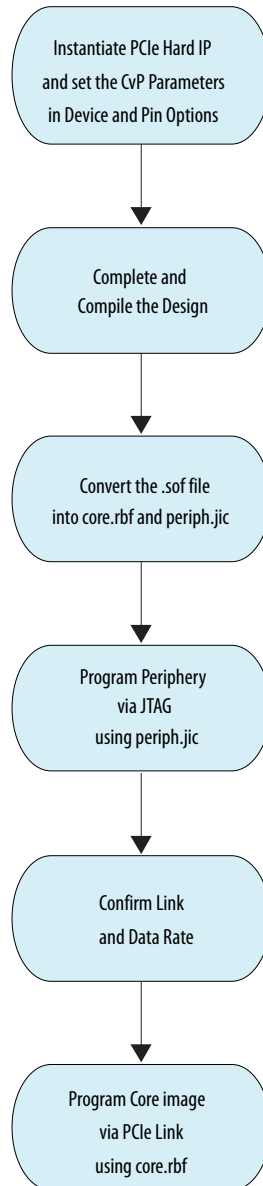

CvP Initialization mode splits the bitstream into periphery and core images. The periphery image is stored in a local flash device on the PCB. The core image is stored in host memory. You must download the core image to the FPGA using the PCI Express link.

You must specify CvP Initialization mode in the Intel Quartus Prime Pro Edition software by selecting the CvP Settings **Initialization and Update** and you must also instantiate the **Avalon-ST Intel Stratix 10 Hard IP for PCI Express**⁽⁴⁾.

(4) CvP also supports Avalon-MM.

Figure 8. Example Implementation Flow for CvP Initialization

The CvP Initialization demonstration (based on the Intel Stratix 10 FPGA Development Kit) walkthrough includes the following steps:

- [Generating the Synthesis HDL files for Avalon-ST Intel Stratix 10 Hard IP for PCI Express](#) on page 26
- [Setting up the CvP Parameters in Device and Pin Options](#) on page 27
- [Compiling the Design](#) on page 28
- [Converting the SOF File](#) on page 28
- [Bringing up the Hardware](#) on page 30

[Intel Stratix 10 GX FPGA Development Kit User Guide](#)

6.1.1. Generating the Synthesis HDL files for Avalon-ST Intel Stratix 10 Hard IP for PCI Express

Follow these steps to generate the synthesis HDL files with CvP enabled:

1. Open the Intel Quartus Prime Pro Edition software.
2. On the Tools menu, click **Platform Designer**. The **Open System** window appears.
3. For **System**, click + and specify a **File Name** to create a new platform designer system. Click **Create**.
4. On the **System Contents** tab, delete the `clock_in` and `reset_in` components that appear by default.
5. In the IP Catalog locate and double-click **Avalon-ST Intel Stratix 10 Hard IP for PCI Express**. The new window appears.
6. On the **IP Settings** tab, specify the parameters and options for your design variation.
7. On the **Example Designs** tab, select the **Simulation** option to generate the testbench, and select the **Synthesis** option to generate the hardware design example.
8. For **Generated file format**, only **Verilog** is available.
9. For **Target Development Kit**, select the board of your choice.
10. Click the **Generate Example Design** button. The **Select Example Design Directory** dialog box appears. Click **OK**. The software generates Intel Quartus Prime project files for PCI Express reference design. Click **Close** when generation completes. An example design `pcie_s10_hip_ast_0_example_design` is created in your project directory.
11. Click **Finish**. Close your current project and open the generated PCI Express example design (`pcie_example_design.qpf`).
12. Complete your CvP design by adding any desired top-level design and any other required modules. Pin assignments already being assigned properly based on the target development kit that user specified earlier.

Alternatively, you can download the complete Intel Stratix 10 CvP Initialization reference design from the link below.

Note: Reference design for CvP update is not available in the current version of the Intel Quartus Prime software.

- [Download the OpenSource Linux CvP Driver](#)

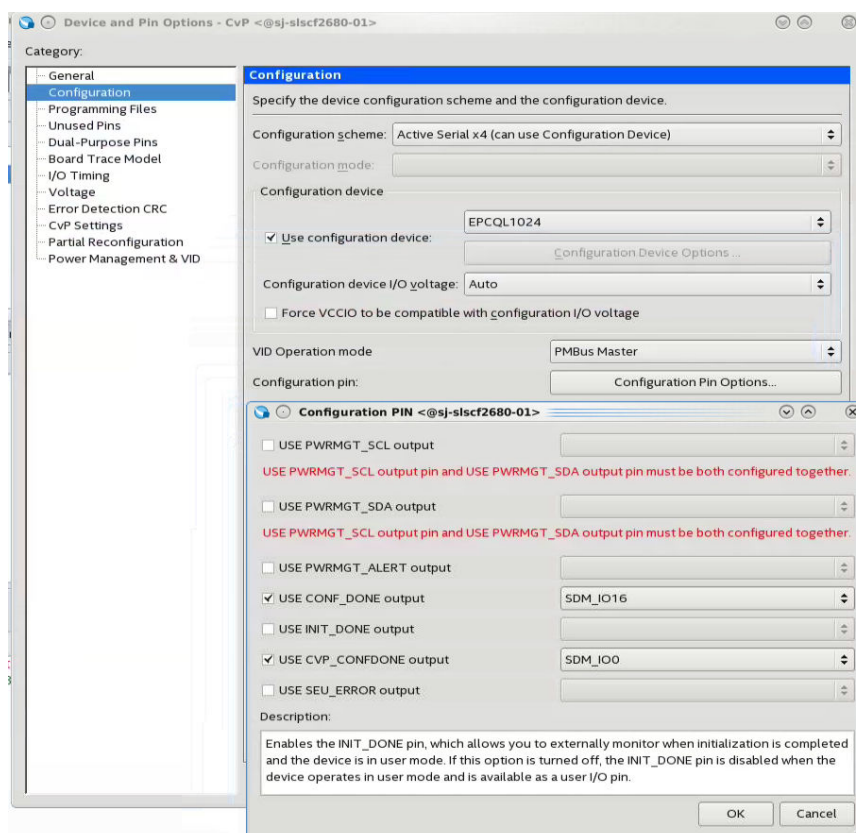

6.1.2. Setting up the CvP Parameters in Device and Pin Options

Follow these steps to specify CvP parameters:

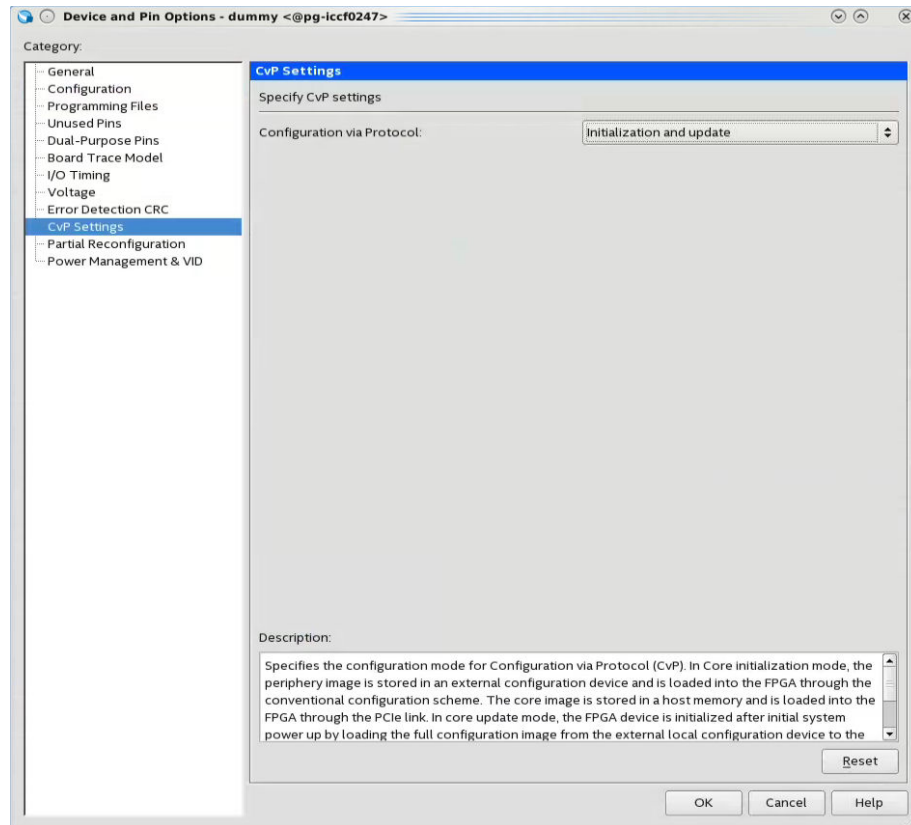

1. On the Intel Quartus Prime Assignment menu, select **Device**, and then click **Device and Pin Options**.
2. Under **Category**, select **Configuration** and then enable the following options:
 - a. For **Configuration scheme**, select **Active Serial x4 (can use Configuration Device)**.
 - b. For **Use configuration device**, select **EPCQL1024**.
 - c. For **Configuration pin**, click **Configuration Pin Options** and then turn on **USE CONF_DONE output** and **USE CVP_CONFDONE output**. Click **OK**.

Figure 9. CvP Parameters in Configuration Tab

3. Under **Category**, select **CvP Settings** to specify CvP settings. For **Configuration via Protocol**, select **Initialization and update** option. Click **OK**.

Figure 10. CvP Parameters in CvP Settings Tab

4. Click **OK**.

6.1.3. Compiling the Design

To compile the design, on the **Processing** menu, select **Start Compilation** to create the .sof file.

6.1.4. Converting the SOF File

Follow these steps to convert your .sof file into separate images for the periphery and core logic.

1. After the .sof file is generated, under **File** menu, select **Convert Programming Files**. The new window appears.
2. Under **Output programming file** section, specify the following parameters:

Table 15. Parameters: Output Programming File Tab

Parameter	Value
Programming file type	JTAG Indirect Configuration File (.jic)
Configuration device	EPCQL1024
Mode	Active Serial x4

continued...

Parameter	Value
File name	cvp_init.jic
Create Memory Map File (Generate output_file.map)	Turn this option on.
Create CvP files (Generate cvp_init.periph.jic and cvp_init.core.rbf)	Turn this option on. This option is only available when you specify the SOF Data file under Input files to convert .

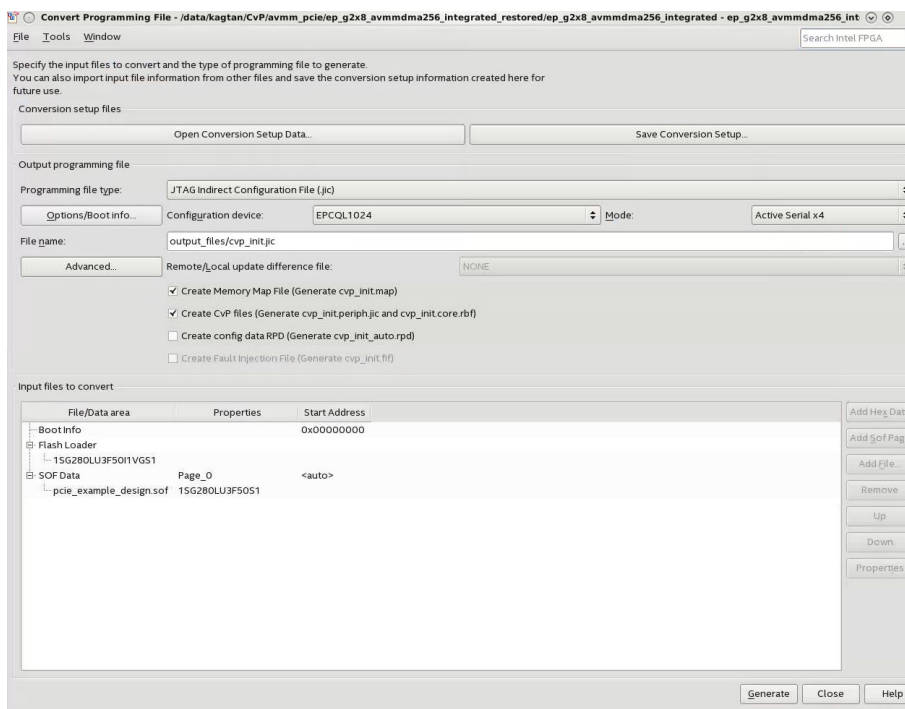

Note: Make sure to turn on the Create CvP files option. If you do not select this option, the Intel Quartus Prime software does not create separate files for the periphery and core images.

- Under **Input files to convert**, specify the following parameters:

Table 16. Parameters: Input Files to Convert Tab

Parameter	Value
Flash Loader	First click Flash Loader . Click Add Device , under Device family , select Stratix 10 and then for Device name select 1SG280LU3F50S1 . Click OK .
SOF Data	First click SOF Data . Click Add File and then select *.sof.

Figure 11. Illustrating the above Specified Options in the Convert Programming File GUI

- Click **Generate** to create *.periph.jic and *.core.rbf files.

6.1.5. Bringing up the Hardware

Before testing the design in hardware, you must install the CvP driver in your DUT system. You can also install RW Utilities or other system verification tools to monitor the link status of the Endpoint and to observe traffic on the link. You can download these utilities for free from many web sites.

Note: You can develop your own custom CvP driver for Linux using the sample Linux driver source code provided by Intel.

The test setup includes the following components:

1. Intel Stratix 10 FPGA Development Kit
2. Intel FPGA Download Cable
3. A DUT PC with PCI Express slot to plug in the FPGA Development Kit
4. A PC running the Intel Quartus Prime software to program the periphery image, .sof or .pof file.

Related Information

[Intel Stratix 10 GX FPGA Development Kit User Guide](#)

6.1.5.1. Installing Open Source CvP Driver in Linux Systems

1. Download the open source Linux CvP driver from the [CvP Driver](#).
2. Navigate to the driver directory.
3. Unzip the drive by typing the following command:

```
tar -zxvf <driver>.gz
```

4. Run the installation by typing the following command:

```
sudo make
sudo make install
```

5. Once the installation completed successfully, it generates the altera_cvp file under directory /dev/altera_cvp.

6.1.5.2. Modifying MSEL/DIP switch on Intel Stratix 10 FPGA Development Kit

The MSEL/DIP switch labeled SW1 at the front part of the Intel Stratix 10 FPGA Development Kit. Select Active Serial x4 (Fast mode) for CvP operation.

Table 17. MSEL Pin Settings for Each Configuration Scheme of Intel Stratix 10 Devices

Configuration Scheme	MSEL[2:0]
AS (Fast mode - for CvP) ⁽⁵⁾	001

⁽⁵⁾ To support AS fast mode, the V_{CCIO_SDM} of Intel Stratix 10 device must be fully ramped-up within 10ms to the recommended operating conditions. The delay between the device exiting POR and the SDM Boot-up is shorter for the fast mode compared to the normal mode. Therefore, AS fast mode is the recommended configuration scheme for CvP because the device can conform to the PCIe 100ms power-up-to-active time requirement.

Related Information

[Intel Stratix 10 Device Family Pin Connection Guidelines](#)

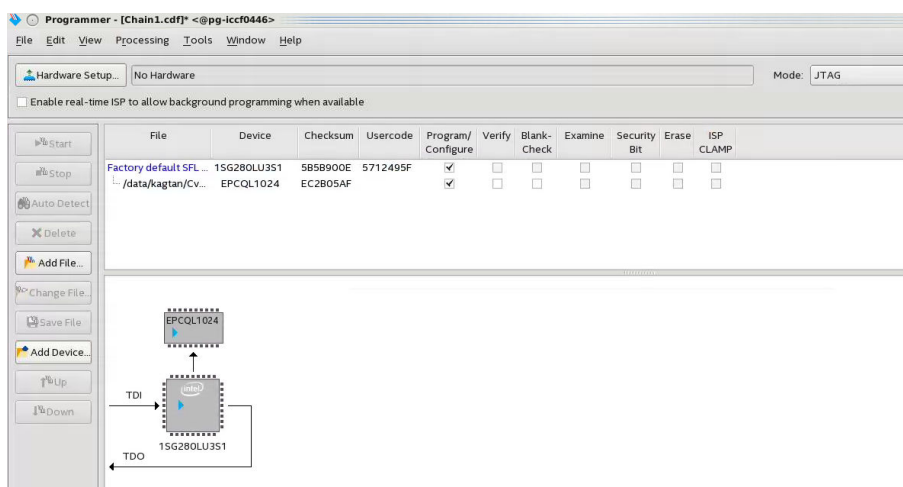

6.1.5.3. Programming CvP Images

You must program the periphery image (.periph.jic) into your AS configuration device and then download the core image (.core.rbf) using the PCIe Link. You can use Active Serial x4 (Fast mode) to load .periph.jic into your selected CvP initialization enabled Intel Stratix 10 device.

After loading the periphery image, the Intel Stratix 10 is triggered to reconfigure from AS to load it. The link should reach the expected data rate and link width. You can confirm the PCIe link status using the RW Utilities. Follow these steps to program and test the CvP functionality:

1. Plug the Intel Stratix 10 FPGA Development Kit into the PCI Express slot of the DUT PC and power it ON. It is recommended to use the ATX power supply that the development kit includes.
2. Open the Intel Quartus Prime **Tools** menu and select **Programmer**.
3. Click **Auto Detect** to verify that the Intel FPGA Download Cable recognizes the Intel Stratix 10 FPGA.
4. Follow these steps to program the periphery image:
 - a. Select **Stratix 10** device, and then right click **None** under **File** column and select **Change File**.
 - b. Navigate to .periph.jic file and click **Open**.
 - c. Under **Program/Configure** column, select the respective devices. For example, **1SG280LU3S1** and **EPCQL1024**.
 - d. Click **Start** to program the periphery image into **EPCQL1024** flash.

Figure 12. Illustrating the Specified Options to the Program Periphery Image

5. After the .periph.jic is programmed, the FPGA must be powered cycle to allow the new peripheral image to load from the on-board flash into the FPGA. To force the DUT PC to re-enumerate the link with the new image, power cycle the DUT PC and the Intel Stratix 10 FPGA Development Kit.

6. You can use RW Utilities or another system software driver to verify the link status. You can also confirm expected link speed and width.
7. Follow these steps to program the core image:
 - a. Copy the `.core.rbf` file to your working directory.
 - b. Open a console in Linux. Change the directory to the same mentioned above where the file is copied.
 - c. Program the core image by typing the following command:

```
cp *.core.rbf /dev/altera_cvp
```
8. You can see your core image running on the Intel Stratix 10 FPGA Development Kit. Alternatively, print out the kernel message using the `dmesg` to ensure the CvP is completed successfully.

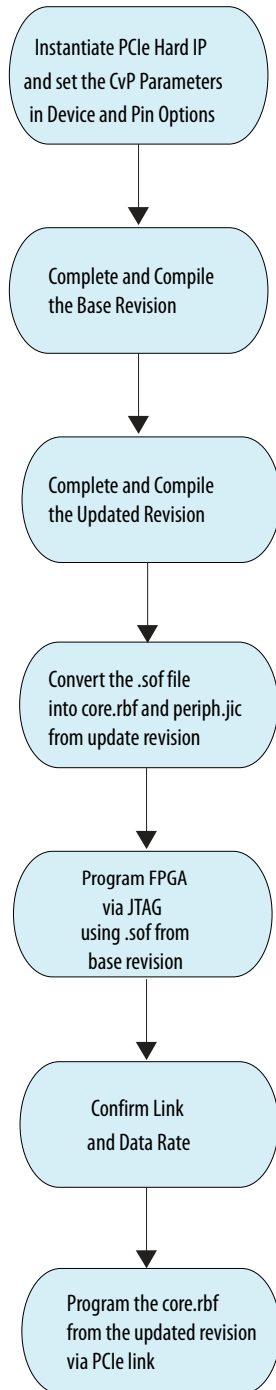

6.2. Implementation of CvP Update Mode

CvP update mode is a reconfiguration scheme to deliver an updated bitstream to a target device after the device enters user mode.

You must specify this mode in the Intel Quartus Prime Pro Edition software by selecting the CvP Settings **Initialization and Update**. The following figure provides the high-level steps for CvP update mode.

Figure 13. Example Implementation Flow for CvP Update

The CvP update mode demonstration walkthrough includes the following steps:

- [Instantiating the PCIe Hard IP](#) on page 34
- [Setting Up the CvP Parameters](#) on page 34
- [Setting up the Base Revision](#) on page 34
- [Setting up and Compile the Updated Revision](#) on page 37
- [Converting the SOF file of the Updated Revision](#) on page 39
- [Programming the FPGA using the Base Revision SOF File](#) on page 40

6.2.1. Instantiating the PCIe Hard IP

Follow the steps from [Generating the Synthesis HDL files for Avalon-ST Intel Stratix 10 Hard IP for PCI Express](#) on page 26 section to instantiate PCIe Hard IP and generate the synthesis HDL files with CvP enabled.

6.2.2. Setting Up the CvP Parameters

Specify the CvP parameters in Device and Pin options using the instructions in the [Setting up the CvP Parameters in Device and Pin Options](#) on page 27 section.

6.2.3. Setting up the Base Revision

To set up the base revision, you must create a periphery reuse core partition, define a logic lock region and then compile the base revision. After compilation, you need to export the root partition.

Related Information

[Reusing Root Partitions](#)

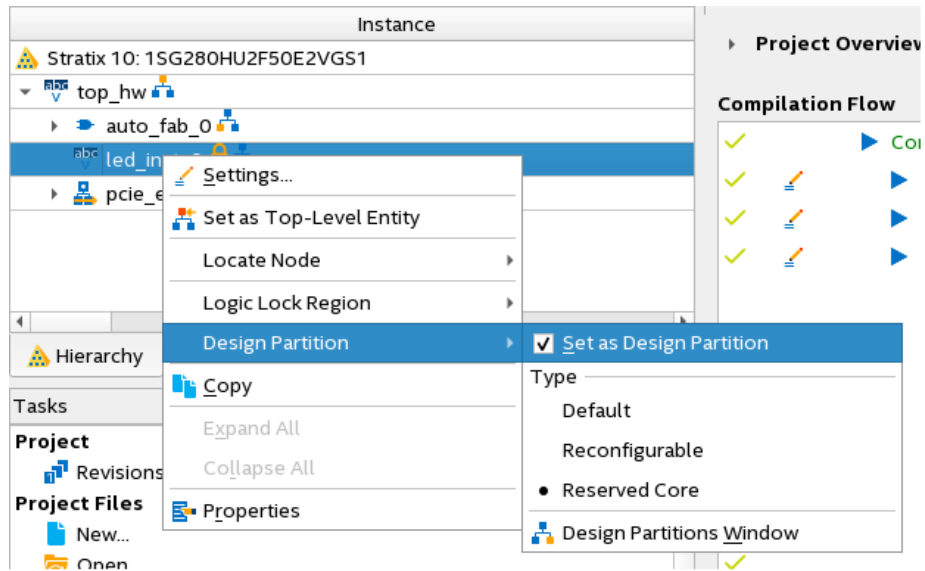

6.2.3.1. Creating a Reserved Core Partition

The following instructions are for creating a reserved core partition from the base revision:

1. To elaborate the hierarchy of the design, click **Processing** ► **Start** ► **Start Analysis & Synthesis**.
2. Right-click an instance in the **Project Navigator** and click **Design Partition** ► **Set as Design Partition**. A design partition icon appears next to each instance you assign.

Figure 14. Creating Design Partition from Project Navigator

This setting corresponds to the following assignment in the .qsf:

```
set_instance_assignment -name PARTITION <name> \
    -to <partition hierarchical path>
```

- When defining the partition, select **Reserved Core** for the partition **Type**. Ensure that all other partition options are set to default values.

This setting corresponds to the following assignment in the .qsf:

```
set_instance_assignment -name RESERVED CORE ON -to \
    <partition hierarchical path>
```

- To export the finalized static region from this base revision compile and to use in subsequent CvP update revision compile, in the **Post Final Export File** cell, double-click the entry for **root_partition** and type **root_partition.qdb**.

Figure 15. Design Partitions Window

Partition Name	Hierarchy Path	Type	Preservation Level	Empty	Partition Database File	Entity Re-binding	Color	Post Synthesis Export File	Post Final Export File
<<new>>									
root_partition									
green_led	led_inst_0	Reserved Core	Not Set	No					root_partition.qdb

This setting corresponds to the following assignment in the .qsf:

```
set_instance_assignment -name EXPORT_PARTITION_SNAPSHOT_FINAL \
    root_partition -to | -entity top
```

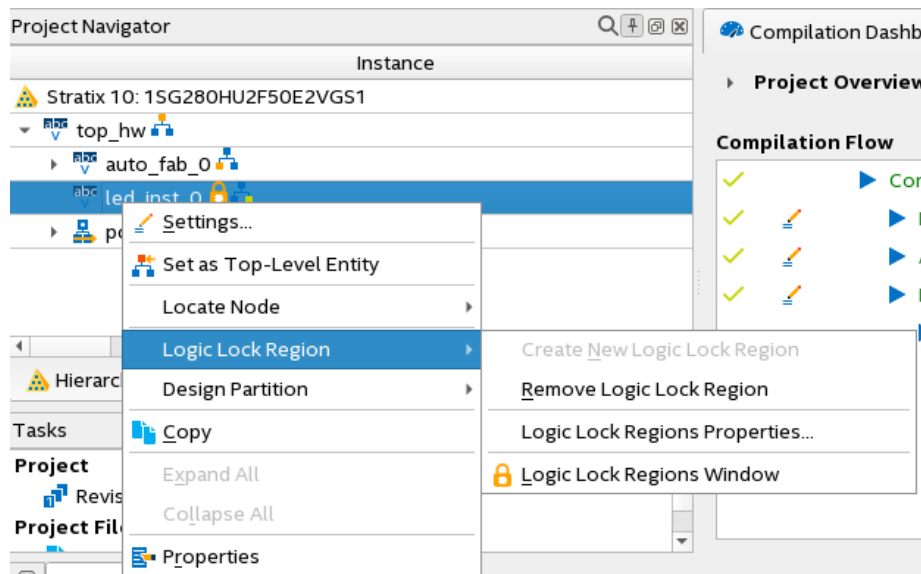

6.2.3.2. Defining a Logic Lock Region

To reserve core resources in an updated revision for the reserved core partition, you must define a fixed size and location, core-only, reserved Logic Lock region. The updated revision uses this area for core development, and the area can contain only core logic. Ensure that the reserved placement region is large enough to contain all core logic in the updated revision.

Follow these steps to define a Logic Lock region for core base revision:

1. Right-click the design instance in the **Project Navigator** and click **Logic Lock Region** ► **Create New Logic Lock Region**. The region appears in the Logic Lock Regions Window. You can also verify the region in the Chip Planner (**Locate Node** ► **Locate in Chip Planner**).

Figure 16. Creating Logic Lock Region from Project Navigator

2. In the Logic Lock Regions window, specify the **Width**, **Height** and the placement region co-ordinates in the **Origin** column.
3. Enable the **Reserved** and **Core-Only** options.
4. For **Size/State**, select **Fixed/Locked**.
5. Double-click the **Routing Region** cell. The **Logic Lock Routing Region Settings** dialog box appears.

Figure 17. Logic Lock Regions Window

Region Name	Members	Width	Height	Origin	Reserved	Core-Only	Size/State	Routing Region
Logic Lock Regions								
led_inst_0	led_inst_0	20	20	X169_Y140	On	On	Fixed/Locked	Fixed with expansion 1
<<new>>								

Annotations in the image point to: 'Specify Core-Only as On' (Core-Only column), 'Specify the Routing Region Type and Expansion Length' (Routing Region column), 'Specify Height and Width' (Height and Width columns), 'Specify Origin Coordinates' (Origin column), and 'Specify Reserved as On' (Reserved column).

6. Specify **Fixed with expansion** with **Expansion Length** of **1** for the **Routing Type**.
7. Click **OK**.
8. Click **File** ► **Save Project**.

6.2.3.3. Compiling and Exporting the Root Partition

To compile the base revision and export the root partition:

1. To compile the base revision, click **Processing > Start Compilation**
2. The base revision provides the exported `.qdb` file and any optional `.sdc` files for the periphery reuse core to the new revision.

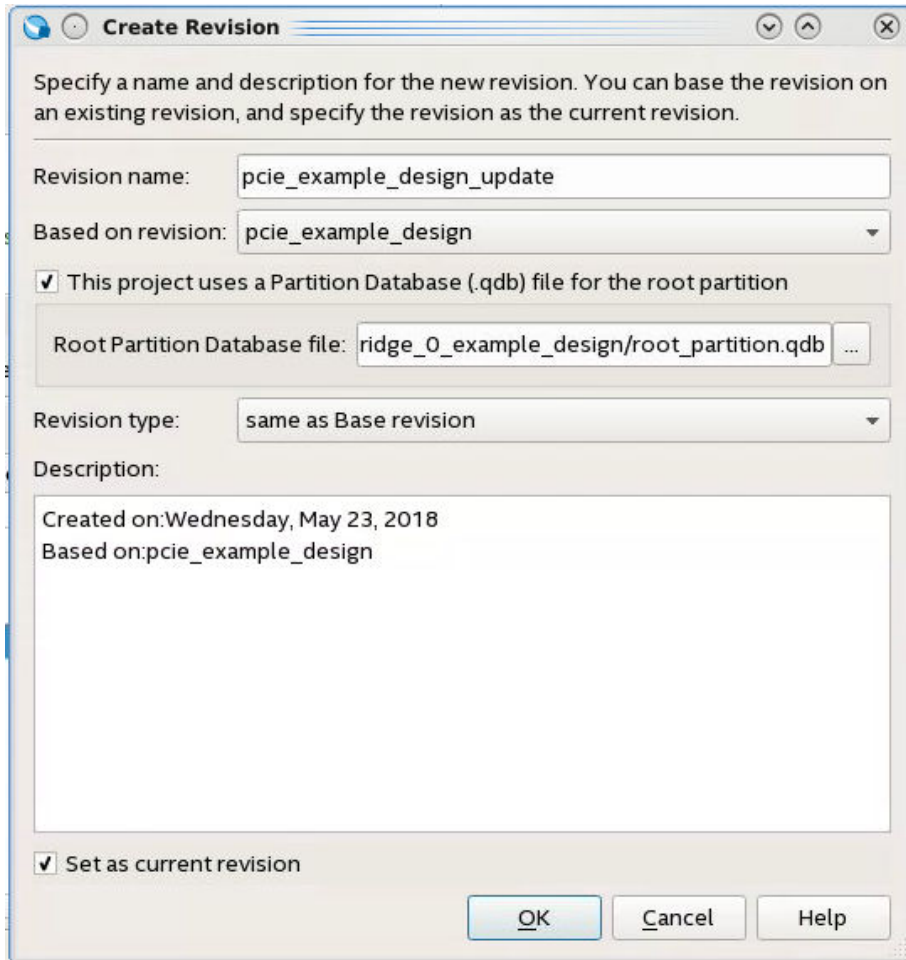

6.2.4. Setting up and Compile the Updated Revision

In this section, you create a new revision that serves as the updated revision of the base design. The new revision reuses the root partition that is exported from the base revision. However, it uses a new core logic.

Perform the following steps to create and compile an updated revision:

1. To create a new revision, Click **Project > Revisions**.
2. The new **Revision** window appears. To create a new revision, double-click **<<new revision>>**.
3. Specify the revision name in **Revision name** field.
4. For the **Revision Type**, select **same as Base revision**.
5. Enable **This project uses a Partition Database (.qdb) file for the root partition**. This setting is also present in the Design Partitions window.

Figure 18. Creating Revisions

6. Use entity rebinding assignment in design partitions window to change the logic associated with the reserved core partition.

For example, First you use `green_led` as the logic within reserved core partition. Now you change the `green_led` logic to `red_led` via entity rebinding, which replaces the `green_led` instance with a `red_led` instance.

Figure 19. Design Partitions Window

Partition Name	Hierarchy Path	Type	Preservation Level	Empty	Partition Database File	Entity Re-binding	Color	Post Synthesis Export File	Post Final Export File
<<new>>									
root_partition					root_partition.qdb				
green_led	led_inst_0	Reserved Core	Not Set	No		red_led	■		

Ensure that your Intel Quartus Prime project includes source files associated with updated Reserved Core partition logic in Intel Quartus Prime.

7. To run compilation, click **Processing** ► **Start Compilation**.

6.2.5. Converting the SOF file of the Updated Revision

Follow these steps to convert your `.sof` file of the updated revision into periphery and core images for CvP update mode.

1. On the **File** menu, select **Convert Programming Files**.
2. Under **Output programming file** section, specify the following parameters:

Table 18. Parameters: Output Programming File Tab

Parameter	Value
Programming file type	JTAG Indirect Configuration File (.jic)
Configuration device	EPCQL1024
Mode	Active Serial x4
File name	cvp_init.jic
Create Memory Map File (Generate output_file.map)	Turn this option on.
Create CvP files (Generate cvp_init.periph.jic and cvp_init.core.rbf)	Turn this option on. This option is only available when you specify the SOE Data file under Input files to convert .

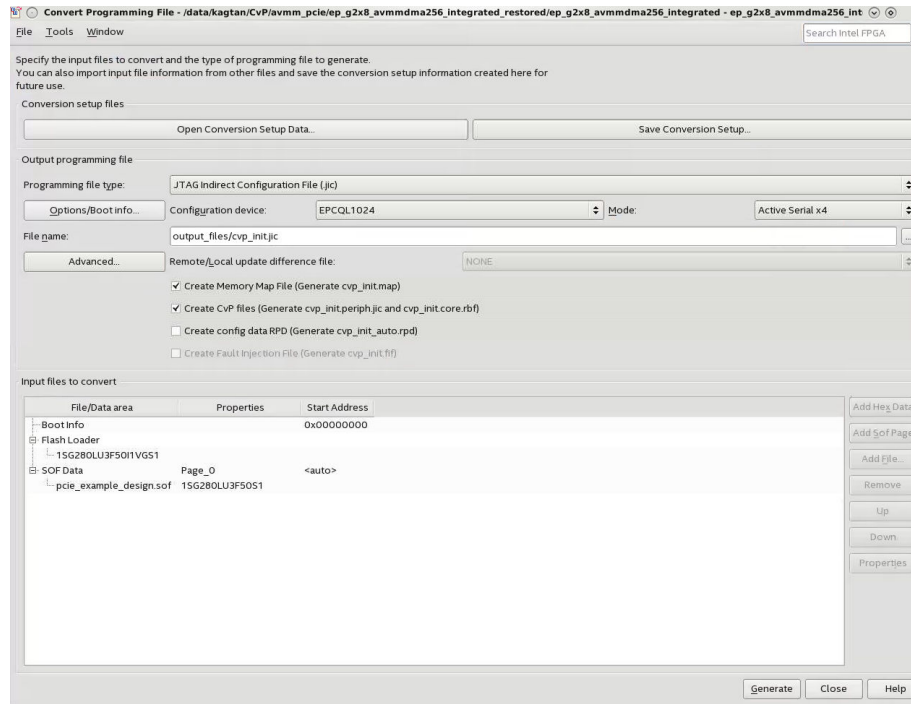

Note: Make sure to turn on the Create CvP files option. If you do not select this option, the Intel Quartus Prime software does not create separate files for the periphery and core images.

3. Under **Input files to convert**, specify the following parameters:

Table 19. Parameters: Input Files to Convert Tab

Parameter	Value
Flash Loader	First click Flash Loader . Click Add Device , under Device family , select Stratix 10 and then for Device name select 1SG280LU3F50I1VGS1 . Click OK .
SOE Data	First click SOE Data . Click Add File and then select <code>*.sof</code> .

Figure 20. Illustrating the above Specified Options in the Convert Programming File GUI

4. Click **Generate** to create *.periph.jic and *.core.rbf files.

6.2.6. Programming the FPGA using the Base Revision SOF File

For CvP update mode, you must program the FPGA using the base revision .sof file. After programming completes the FPGA enters user mode.

Before you begin:

- Connect the Intel FPGA Download Cable II between your PC USB port and the USB port on the Intel Stratix 10 FPGA Development Kit.
- You must install the altera_cvp driver in your DUT PC system. You can download the open source Linux CvP driver from the [CvP Driver](#).

Note: The Linux driver provided by Intel is not a production driver.

- Set the MSEL switches of the Intel Stratix 10 FPGA Development Kit to JTAG mode for CvP update operation.

Follow these steps to program and test CvP update functionality:

1. Plug the Intel Stratix 10 FPGA Development Kit into the PCI Express slot of the DUT PC and power it ON. It is recommended to use the ATX power supply that the development kit includes.
2. Open the Intel Quartus Prime Pro Edition software and click **Tools ► Programmer**.
3. Click **Auto Detect** to verify that the Intel FPGA Download Cable II recognizes the Intel Stratix 10 FPGA.
4. Follow these steps to program the base revision .sof file:

- a. Select **Stratix 10** device, and then right click **None** under **File** column and select **Change File**.
- b. Navigate to *.sof file generated from the base revision and click **Open**.
- c. Under **Program/Configure** column, select the device. For example, **1SG280LU3S1**.
- d. Click **Start**. The progress bar reaches 100% when device configuration is complete. The device is fully configured and in operation.
- e. After the .sof file is programmed, perform the soft reset on the PC.
- f. Once PC has completed soft rebooting, type the following command in a terminal window to make sure the PCIe link is up and running: `lspci -vvvd1172`.
- g. At this time, the FPGA enters into user mode with a functional PCIe link to the DUT PC and you are ready to use the `altera_cvp` driver to perform the CvP update.
- h. Follow these steps to program the `core.rbf`:
 - i. Type `lspci -vvvd1172` in a terminal window to make sure that you have an active PCIe link.
 - j. Program the `core.rbf` generated from the updated revision by typing the following command: `cp <new core.rbf file> /dev/altera_cvp`.

7. Intel Stratix 10 Configuration via Protocol (CvP) Implementation User Guide Archives

If an IP core version is not listed, the user guide for the previous IP core version applies.
