Interlaken is a high-speed serial communication protocol for chip-to-chip packet transfers. The Altera® 100G Interlaken MegaCore® function implements the Interlaken Protocol Specification, Revision 1.2. It supports specific combinations of number of lanes (12 or 24) and lane rates from 6.25 gigabits per second (Gbps) to 12.5 Gbps, on Stratix® V, Arria® V GZ, and Arria 10 devices, providing raw bandwidth of 123.75 Gbps to 150 Gbps.

Interlaken provides low I/O count compared to earlier protocols, supporting scalability in both number of lanes and lane speed. Other key features include flow control, low overhead framing, and extensive integrity checking. The 100G Interlaken MegaCore function incorporates a physical coding sublayer (PCS), a physical media attachment (PMA), and a media access control (MAC) block.

### Features

The 100G Interlaken MegaCore function has the following features:

- Compliant with the *Interlaken Protocol Specification, Revision 1.2*.
- Supports 12 and 24 serial lanes in configurations that provide up to 150 Gbps raw bandwidth.
- Supports per-lane data rates of 6.25, 10.3125, and 12.5 Gbps using Altera on-chip high-speed transceivers.
- Supports dynamically configurable BurstMax and BurstMin values.
- Supports Packet mode and Interleaved (Segmented) mode for user data transfer.
- Supports dual segment mode for efficient user data transfer.
- Supports up to 256 logical channels in out-of-the-box configuration.
- Supports optional user-controlled in-band flow control with 1, 2, 4, 8, or 16 16-bit calendar pages.
- Supports optional out-of-band flow control blocks.
- Supports memory block ECC in Stratix V and Arria 10 devices.

IP Core Verification

Before releasing a version of the 100G Interlaken IP core, Altera runs comprehensive regression tests in the current version of the Quartus® Prime software. These tests use standalone methods. These files are tested in simulation and hardware to confirm functionality. Altera tests and verifies the 100G Interlaken IP core in hardware for different platforms and environments.
Constrained random techniques generate appropriate stimulus for the functional verification of the IP core. Functional coverage metrics measure the quality of the random stimulus, and ensure that all important features are verified.

**Performance and Resource Utilization**

Table 1-5: 100G Interlaken MegaCore Function FPGA Resource Utilization

Lists the resources and expected performance for selected variations of the 100G Interlaken IP core using the Quartus II software v13.1 and v13.1 Arria 10 edition releases for the following devices:

- Arria 10 device 10AX115S2F45I2SGES
- Arria V GZ device 5AGZE1H2F35I3
- Stratix V GX device 5SGXMA7N2F45I3
- Stratix V GT device 5SGTMC7K3F40I2

The results in this table do not include the out-of-band flow control block.

The numbers of ALMs and logic registers are rounded up to the nearest 100. The numbers of ALMs, before rounding, are the **ALMs needed** numbers from the Quartus II Fitter Report.

Device Speed Grade Support

Table 1-6: Minimum Recommended FPGA Fabric Speed Grades

For each device family the 100G Interlaken IP core supports, Altera recommends that you configure the 100G Interlaken IP core only in the FPGA fabric speed grades listed in the table, and any faster (lower numbered) FPGA fabric speed grades that are available. Altera does not support configuration of this IP core in slower speed grades.

Altera verifies that the current version of the Quartus Prime software compiles the previous version of each MegaCore function, if this MegaCore function was included in the previous release. Altera reports any exceptions to this verification in the *Altera IP Release Notes* or clarifies them in the Quartus Prime IP Update tool. Altera does not verify compilation with IP core versions older than the previous release.

A 100G Interlaken IP core with optimized feature set or low resource utilization is available by request.

**Related Information**

*Altera IP Release Notes*
The following sections explain how to install, parameterize, simulate, and initialize the 100G Interlaken IP core.

**Installing and Licensing Intel FPGA IP Cores** on page 2-2
The Intel® Quartus Prime software installation includes the Intel FPGA IP library. This library provides many useful IP cores for your production use without the need for an additional license. Some Intel FPGA IP cores require purchase of a separate license for production use. The Intel FPGA IP Evaluation Mode allows you to evaluate these licensed Intel FPGA IP cores in simulation and hardware, before deciding to purchase a full production IP core license. You only need to purchase a full production license for licensed Altera® IP cores after you complete hardware testing and are ready to use the IP in production.

**Specifying the 100G Interlaken IP Core Parameters and Options** on page 2-5
The 100G Interlaken parameter editor allows you to quickly configure your custom IP variation. You specify IP core options and parameters in the Quartus Prime software.

**Files Generated for Arria V GZ and Stratix V Variations** on page 2-6

**Files Generated for Arria 10 Variations** on page 2-7

**Simulating the 100G Interlaken IP Core** on page 2-8

**Integrating Your IP Core in Your Design** on page 2-8

**Compiling the Full Design and Programming the FPGA** on page 2-17

**Creating a Signal Tap Debug File to Match Your Design Hierarchy** on page 2-17
For Intel Arria 10 and Intel Cyclone® 10 GX devices, the Intel Quartus Prime software generates two files, `build_stp.tcl` and `<ip_core_name>.xml`. You can use these files to generate a Signal Tap file with probe points matching your design hierarchy.

**Related Information**
- **Introduction to Altera IP Cores**
  Provides general information about all Altera FPGA IP cores, including parameterizing, generating, upgrading, and simulating IP cores.
- **Creating Version-Independent IP and Qsys Simulation Scripts**
  Create simulation scripts that do not require manual updates for software or IP version upgrades.
- **Project Management Best Practices**
  Guidelines for efficient management and portability of your project and IP files.
Installing and Licensing Intel® FPGA IP Cores

The Intel® Quartus Prime software installation includes the Intel FPGA IP library. This library provides many useful IP cores for your production use without the need for an additional license. Some Intel FPGA IP cores require purchase of a separate license for production use. The Intel FPGA IP Evaluation Mode allows you to evaluate these licensed Intel FPGA IP cores in simulation and hardware, before deciding to purchase a full production IP core license. You only need to purchase a full production license for licensed Altera® IP cores after you complete hardware testing and are ready to use the IP in production.

The Intel Quartus Prime software installs IP cores in the following locations by default:

**Figure 2-1: IP Core Installation Path**

```
intelfpga(_pro)
  -quartus - Contains the Intel Quartus Prime software
  -ip - Contains the Intel FPGA IP library and third-party IP cores
  -altera - Contains the Intel FPGA IP library source code
  <IP name> - Contains the Intel FPGA IP source files
```

**Intel FPGA IP Evaluation Mode**

The free Intel FPGA IP Evaluation Mode allows you to evaluate licensed Intel FPGA IP cores in simulation and hardware before purchase. Intel FPGA IP Evaluation Mode supports the following evaluations without additional license:

- Simulate the behavior of a licensed Intel FPGA IP core in your system.
- Verify the functionality, size, and speed of the IP core quickly and easily.
- Generate time-limited device programming files for designs that include IP cores.
- Program a device with your IP core and verify your design in hardware.
Intel FPGA IP Evaluation Mode supports the following operation modes:

- **Tethered**—Allows running the design containing the licensed Intel FPGA IP indefinitely with a connection between your board and the host computer. Tethered mode requires a serial joint test action group (JTAG) cable connected between the JTAG port on your board and the host computer, which is running the Intel Quartus Prime Programmer for the duration of the hardware evaluation period. The Programmer only requires a minimum installation of the Intel Quartus Prime software, and requires no Intel Quartus Prime license. The host computer controls the evaluation time by sending a periodic signal to the device via the JTAG port. If all licensed IP cores in the design support tethered mode, the evaluation time runs until any IP core evaluation expires. If all of the IP cores support unlimited evaluation time, the device does not time-out.

- **Untethered**—Allows running the design containing the licensed IP for a limited time. The IP core reverts to untethered mode if the device disconnects from the host computer running the Intel Quartus Prime software. The IP core also reverts to untethered mode if any other licensed IP core in the design does not support tethered mode.

When the evaluation time expires for any licensed Intel FPGA IP in the design, the design stops functioning. All IP cores that use the Intel FPGA IP Evaluation Mode time out simultaneously when any IP core in the design times out. When the evaluation time expires, you must reprogram the FPGA device before continuing hardware verification. To extend use of the IP core for production, purchase a full production license for the IP core.

You must purchase the license and generate a full production license key before you can generate an unrestricted device programming file. During Intel FPGA IP Evaluation Mode, the Compiler only generates a time-limited device programming file (\(<project\ name>_time\_limited.sof\) that expires at the time limit.
**Note:** Refer to each IP core's user guide for parameterization steps and implementation details.

Altera licenses IP cores on a per-seat, perpetual basis. The license fee includes first-year maintenance and support. You must renew the maintenance contract to receive updates, bug fixes, and technical support beyond the first year. You must purchase a full production license for Intel FPGA IP cores that require a production license, before generating programming files that you may use for an unlimited time. During Intel FPGA IP Evaluation Mode, the Compiler only generates a time-limited device programming file (<project name>_time_limited.sof) that expires at the time limit. To obtain your production license keys, visit the **Self-Service Licensing Center** or contact your local Intel FPGA representative.

The **Altera FPGA Software License Agreements** govern the installation and use of licensed IP cores, the Intel Quartus Prime design software, and all unlicensed IP cores.

Specifying the 100G Interlaken IP Core Parameters and Options

The 100G Interlaken parameter editor allows you to quickly configure your custom IP variation. You specify IP core options and parameters in the Quartus Prime software.

The 100G Interlaken IP core is not supported in Qsys. You must use the IP Catalog accessible from the Quartus Prime Tools menu.

The 100G Interlaken IP core does not support VHDL simulation models. Altera recommends that you specify the Verilog HDL for both synthesis and simulation models.

1. In the IP Catalog (Tools > IP Catalog), locate and double-click the name of the IP core to customize. The parameter editor appears.

2. Specify a top-level name for your custom IP variation. The parameter editor saves the IP variation settings in a file named <your_ip>.qsys. Click OK.

   Note: For Arria V GZ and Stratix V variations, you are prompted to specify an IP variation file type.

   To generate the demonstration testbench and example design, you must select the Verilog HDL and specify the Verilog file extension (.v).

3. Specify the parameters and options for your IP variation in the parameter editor, including one or more of the following. Refer to 100G Interlaken IP Core Parameter Settings for information about specific IP core parameters.

   - Specify parameters defining the IP core functionality, port configurations, and device-specific features.
   - Specify options for processing the IP core files in other EDA tools.

4. For Arria 10 variations, follow these steps:
   a. Click Generate HDL. The Generation dialog box appears.
   b. Specify output file generation options, and then click Generate. The IP variation files generate according to your specifications.

      Note: To generate the demonstration testbench and example design, you must specify Verilog HDL for both synthesis and simulation models.
   c. Optionally, click the Generate Example Design button in the parameter editor to generate a testbench and a hardware example design that targets the Arria 10 Transceiver Signal Integrity Development Kit.
   d. Click Finish. The parameter editor adds the top-level .qsys file to the current project automatically. If you are prompted to manually add the .qsys file to the project, click Project > Add/Remove Files in Project to add the file.

5. For Arria V GZ and Stratix V variations, follow these steps:
   a. Click Finish. The Generation dialog box appears.
   b. If you want to generate a demonstration testbench and example design for your IP core variation, turn on Generate example design.
   c. Click Generate.
   d. Click Exit. The parameter editor adds the top-level .qsys file to the current project automatically. If you are prompted to manually add the .qsys file to the project, click Project > Add/Remove Files in Project to add the file.

6. After generating and instantiating your IP variation, make appropriate pin assignments to connect ports.
Files Generated for Arria V GZ and Stratix V Variations

The Quartus Prime software generates multiple files during generation of your 100G Interlaken IP core Arria V GZ or Stratix V variation.

**Figure 2-3: IP Core Generated Files**

For 100G Interlaken IP cores that target a non-Arria 10 device, if you select the Verilog HDL for synthesis and simulation models and turn on **Generate example design**, the demonstration testbench and example design files are located in `<your_ip>_testbench/ilk_core/testbench`.
Files Generated for Arria 10 Variations

The Quartus Prime software generates multiple files during generation of your 100G Interlaken IP core Arria 10 variation.

Figure 2-4: IP Core Generated Files

In the Quartus Prime software v15.1 release, generating a 100G Interlaken IP core that targets an Arria 10 device does not generate a demonstration testbench. To generate the Verilog HDL testbench and example design files in this release, you must click the Generate Example Design button in the 100G Interlaken
parameter editor. When you do so, you are prompted to specify the location of the Verilog HDL demonstration testbench and example design files.

Simulating the 100G Interlaken IP Core

You can simulate your 100G Interlaken MegaCore function variation using any of the vendor-specific IEEE encrypted functional simulation models which are generated in the new `<instance name>_sim` or `<instance name>/sim` subdirectory of your project directory.

The 100G Interlaken MegaCore function supports the Synopsys VCS, Cadence NC Sim, and Mentor Graphics Modelsim-SE simulators.

The 100G Interlaken IP core generates only a Verilog HDL simulation model and testbench. The IP core parameter editor appears to offer you the option of generating a VHDL simulation model, but this IP core does not support a VHDL simulation model or testbench.

For more information about functional simulation models for Altera IP cores, refer to the Simulating Altera Designs chapter in volume 3 of the Quartus Prime Handbook.

For non-Arria 10 variations with Verilog HDL models, if you turn on Generate example design when you generate the IP core, the Quartus Prime software generates a testbench. This testbench demonstrates the resetting, clocking, and toggling of the 100G Interlaken IP core user interfaces in simulation. For Arria 10 variations, you can generate both this testbench and a hardware example design by clicking Generate Example Design in the 100G Interlaken parameter editor.

Integrating Your IP Core in Your Design

After you generate your 100G Interlaken IP core variation, you can instantiate it in the RTL for your design. When you integrate your IP core instance in your design, you must pay attention to the following items.

**Pin Assignments**

When you integrate your 100G Interlaken MegaCore function instance in your design, you must make appropriate pin assignments. You do not need to specify pin assignments for simulation. However, you should make the pin assignments before you compile, to provide direction to the Quartus Prime Fitter and to specify the signals that should be assigned to device pins.

You can create a virtual pin to avoid making specific pin assignments for top-level signals while you are simulating and not ready to map the design to hardware. Do not create virtual pins for clock or Interlaken link data signals.
For the Arria 10 device family, you must configure a PLL external to the 100G Interlaken IP core. The required number of PLLs depends on the distribution of your Interlaken lane data pins in the different A10 transceiver blocks.

Related Information
- Adding the External PLL on page 2-15
- Quartus Prime Help
  For information about the Quartus Prime software, including virtual pins.

Transceiver Logical Channel Numbering

In Arria V and Stratix V devices, logical channel numbering starts from zero. The logical channel numbering starts at the bottom of the die with logical channel 0 and continues in physical pin order through the four ordered transceiver blocks on the same side of the device. Each data channel and TX PLL has its own dedicated reconfiguration interface with an assigned logical channel.

In Arria 10 devices, you control the mapping of Interlaken lanes directly in the Arria 10 Native PHY IP core that is included in the 100G Interlaken IP core.

In Arria V and Stratix V devices, you can control the logical channel assignments in the IP core. You typically assign lanes to match the logical channel numbering. However, you can map the twelve Interlaken lanes in a 12-lane variation to any two adjacent transceiver blocks on the same side of the device. You can use the information in the following table to map the lanes to their default logical channel numbering. The logical channel numbering always starts at the bottom of a transceiver block.

For example, in an Arria V or Stratix V device, to change the VOD setting for lane 9, you write logical channel 10 to the Reconfiguration Controller.

**Related Information**

*Altera Transceiver PHY IP User Guide*
Background information to better understand logical channel numbering.

**Adding the Reconfiguration Controller**

100G Interlaken IP core variations that target an Arria V or a Stratix V device require an external reconfiguration controller to function correctly in hardware. 100G Interlaken IP core variations that target an Arria 10 device include a reconfiguration controller block and do not require an external reconfiguration controller.

Keeping the Reconfiguration Controller external to the IP core in Arria V and Stratix V devices provides the flexibility to share the Reconfiguration Controller among multiple IP cores and to accommodate FPGA transceiver layouts based on the usage model of your application. In Arria 10 devices, you can configure individual transceiver channels flexibly through an Avalon-MM Arria 10 transceiver reconfiguration interface.
The following simple instructions show you how to instantiate an Altera Transceiver Reconfiguration Controller and how to connect the design blocks:

**Generating the Reconfiguration Controller**

You can use the IP Catalog to generate an Altera Transceiver Reconfiguration Controller.

In the Transceiver Reconfiguration Controller parameter editor, you select the features of the transceiver that can be dynamically reconfigured. However, you must ensure that the following two features are turned on:

1. **Enable PLL calibration**
2. **Enable Analog controls**

You must also set the value of the **Number of reconfiguration interfaces** parameter. Each TX PLL requires its own reconfiguration interface, whether or not you intend to reconfigure it. The following formula determines the correct number of reconfiguration interfaces:

\[
\text{NUMBER_OF_RECONFIGURATION_INTERFACES} = \text{NUMBER_OF_LANES} + \text{NUMBER_OF_TX_PLLs}
\]

where

- **NUMBER_OF_LANES** is the total number of physical lanes used in your implemented design.
- **NUMBER_OF_TX_PLLs** is the total number of transceiver blocks (number of TX PLLs) used in your design.

For example, for a design that includes a 12-lane Interlaken variation that is configured in two transceiver blocks, you must set **Number of reconfiguration interfaces** to the value of 14.

**Connecting the Reconfiguration Controller to the IP Core**

The Reconfiguration Controller communicates with the 100G Interlaken IP core on two busses:

- reconfig_to_xcvr (output)
- reconfig_from_xcvr (input)

Each of these busses connects to the bus of the same name in the 100G Interlaken IP core.

You must also connect the following signals:

- mgmt_clk_clk: Reconfiguration Controller clock (input)
- mgmt_rst_reset: Reconfiguration Controller reset (input)
- reconfig_busy: Reconfiguration Controller busy indication (output)
Altera recommends that you set the Reconfiguration Controller input clock frequency in the range of 100 MHz to 125 MHz. Refer to the Altera Transceiver PHY IP Core User Guide for frequency range requirements specific to the device family.

The Reconfiguration Controller reset input should be asserted high during power up and remain asserted until its clock input becomes stable. Upon power up, the Reconfiguration Controller asserts reconfig_busy output high. The reconfig_busy signal remains asserted until the Reconfiguration Controller completes the configuration of all transceivers.

Altera Transceiver PHY IP Core User Guide

Adding the External PLL

100G Interlaken IP core variations that target an Arria 10 device require an external transceiver PLL to function correctly in hardware. 100G Interlaken IP core variations that target an Arria V or Stratix V device include the transceiver PLLs and do not require that you configure any additional PLLs.

You can use the IP Catalog to generate an external PLL IP core that configures a TX PLL on the device.

- Select **Arria 10 Transceiver ATX PLL**, **Arria 10 Transceiver CMU PLL**, or **Arria 10 FPLL**.
- In the parameter editor, set the following parameter values:
  - **PLL output frequency** to one half the per-lane data rate of the IP core variation. The transceiver performs dual edge clocking, using both the rising and falling edges of the input clock from the PLL. Therefore, this PLL output frequency setting drives the transceiver with the correct clock for the Interlaken lanes.
  - **PLL reference clock frequency** to a frequency at which you can drive the TX PLL input reference clock. You must drive the external PLL reference clock input signal at the frequency you specify for this parameter.

The number of external PLLs you must define depends on the distribution of your Interlaken TX serial lines across physical transceiver channels. You specify the clock network to which each PLL output connects by setting the clock network in the PLL parameter editor.
You must connect the external PLL signals and the Arria 10 100G Interlaken IP core transceiver Tx PLL interface signals according to the following rules:

- Connect the `tx_serial_clk` input pin for each Interlaken lane to the output port of the same name in the corresponding external PLL.
- Connect the `tx_pll_locked` input pin of the 100G Interlaken IP core to the logical AND of the `pll_locked` output signals of the external PLLs for all of the Interlaken lanes and the inverse of each of the `pll_cal_busy` signals from the external PLLs.
- Connect the `tx_pll_powerdown` output pin of the 100G Interlaken IP core to the `pll_powerdown` reset pin of the external PLLs for all of the Interlaken lanes.

User logic must provide the AND function and connections. The following figure provides an example of one correct method, among many, to implement connection logic. You can also refer to the example design for example working user logic including one correct method to instantiate and connect an external PLL.

**Figure 2-6: Example Connection of ATX PLL with 100G Interlaken IP Core Using Arria 10 xN Clock Network**

• **Arria 10 Transceiver PHY User Guide**
  Information about the correspondence between PLLs and transceiver channels, and information about how to configure an external PLL for your own design. You specify the clock network to which the PLL output connects by setting the clock network in the PLL parameter editor.

## Compiling the Full Design and Programming the FPGA

You can use the **Start Compilation** command on the Processing menu in the Quartus Prime software to compile your design. After successfully compiling your design, program the targeted Altera device with the Programmer and verify the design in hardware.

**Related Information**

- Incremental Compilation for Hierarchical and Team-Based Design
- Programming Altera Devices

## Creating a Signal Tap Debug File to Match Your Design Hierarchy

For Intel Arria 10 and Intel Cyclone® 10 GX devices, the Intel Quartus Prime software generates two files, `build_stp.tcl` and `<ip_core_name>.xml`. You can use these files to generate a Signal Tap file with probe points matching your design hierarchy.

The Intel Quartus Prime software stores these files in the `<IP core directory>/synth/debug/stp/` directory.

**Before you begin**

Synthesize your design using the Intel Quartus Prime software.

1. To open the Tcl console, click **View > Utility Windows > Tcl Console**.
2. Type the following command in the Tcl console:
   ```
   source <IP core directory>/synth/debug/stp/build_stp.tcl
   ```
3. To generate the STP file, type the following command:
   ```
   main -stp_file <output stp file name>.stp -xml_file <input xml_file name>.xml -mode build
   ```
4. To add this Signal Tap file (.stp) to your project, select **Project > Add/Remove Files in Project**. Then, compile your design.
5. To program the FPGA, click **Tools > Programmer**.
6. To start the Signal Tap Logic Analyzer, click **Quartus Prime > Tools > Signal Tap Logic Analyzer**.
   The software generation script may not assign the Signal Tap acquisition clock in `<output stp file name>.stp`. Consequently, the Intel Quartus Prime software automatically creates a clock pin called `auto_stp_external_clock`. You may need to manually substitute the appropriate clock signal as the Signal Tap sampling clock for each STP instance.
7. Recompile your design.
8. To observe the state of your IP core, click **Run Analysis**.
   You may see signals or Signal Tap instances that are red, indicating they are not available in your design. In most cases, you can safely ignore these signals and instances. They are present because software generates wider buses and some instances that your design does not include.
You customize the 100G Interlaken IP core by specifying parameters in the 100G Interlaken parameter editor, which you access from the Quartus Prime IP Catalog.

This chapter describes the parameters and how they affect the behavior of the IP core. To customize your 100G Interlaken IP core, you can modify parameters to specify the following properties:

- **Number of Lanes** on page 3-1
- **Meta Frame Length in Words** on page 3-2
- **Data Rate** on page 3-2
- **Transceiver Reference Clock Frequency** on page 3-2
- **Include Advanced Error Reporting and Handling** on page 3-3
- **Enable M20K ECC Support** on page 3-4
- **Include Diagnostic Features** on page 3-4
- **Enable Native XCVR PHY ADME** on page 3-5
- **Include In-Band Flow Control Block** on page 3-5
- **Number of Calendar Pages** on page 3-6
- **TX Scrambler Seed** on page 3-6
- **Transfer Mode Selection** on page 3-6
- **Data Format** on page 3-7

**Number of Lanes**

The **Number of lanes** parameter specifies the number of lanes available for Interlaken communication. The supported values are 12 and 24.

The default value of the **Number of lanes** parameter is 12.

The 100G Interlaken MegaCore function supports various combinations of number of lanes and lane rates. Ensure that your parameter settings specify a supported combination.
Table 3-1: 100G Interlaken IP Core Supported Combinations of Number of Lanes and Data Rate

<table>
<thead>
<tr>
<th>Number of Lanes</th>
<th>Lane Rate (Gbps)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>6.25</td>
</tr>
<tr>
<td>12</td>
<td>—</td>
</tr>
<tr>
<td>24</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Yes indicates a supported combination.

Meta Frame Length in Words

The Meta frame length in words parameter specifies the length of the meta frame, in 64-bit (8-byte) words. In the Interlaken specification, this parameter is called the MetaFrameLength parameter.

Smaller values for this parameter shorten the time to achieve lock. Larger values reduce overhead while transferring data, after lock is achieved.

For simulation, you can set the Meta frame length in words parameter to the value of 128 for fast lane locking. For hardware testing, Altera recommends that you set the Meta frame length in words parameter to the value of 2048.

The default value of the Meta frame length in words parameter is 2048.

Data Rate

The Data Rate parameter specifies the data rate on each lane. All lanes have the same data rate (lane rate).

The default value of the Data Rate parameter is 10312.5 Mbps (10.3125 Gbps).

The 100G Interlaken MegaCore function supports various combinations of number of lanes and lane rates. Ensure that your parameter settings specify a supported combination.

Table 3-2: 100G Interlaken IP Core Supported Combinations of Number of Lanes and Data Rate

<table>
<thead>
<tr>
<th>Number of Lanes</th>
<th>Lane Rate (Gbps)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>6.25</td>
</tr>
<tr>
<td>12</td>
<td>—</td>
</tr>
<tr>
<td>24</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Transceiver Reference Clock Frequency

The Transceiver reference clock frequency parameter specifies the expected frequency of the pll_ref_clk input clock.
If the actual frequency of the `pll_ref_clk` input clock does not match the value you specify for this parameter, the design fails in both simulation and hardware.

Table 3-3: 100G Interlaken IP Core Supported `pll_ref_clk` Frequencies

The sets of valid frequencies vary with the per-lane data rate of the transceivers.

<table>
<thead>
<tr>
<th>Per-Lane Data Rate</th>
<th>Valid <code>pll_ref_clk</code> Frequencies (MHz)</th>
</tr>
</thead>
<tbody>
<tr>
<td>10.3125</td>
<td>206.25, 257.8125, 322.265625, 412.5, 515.625, 644.53125</td>
</tr>
<tr>
<td>12.5, 6.25</td>
<td>156.25, 195.3125, 250, 312.5, 390.625, 500, 625</td>
</tr>
</tbody>
</table>

The default value of the `Transceiver reference clock frequency` parameter is 412.5 MHz.

Related Information

- 100G Interlaken IP Core Clock Interface Signals on page 5-1

Include Advanced Error Reporting and Handling

The `Include advanced error reporting and handling` parameter specifies whether your 100G Interlaken MegaCore function checks the integrity of incoming packets on the Interlaken link and reports the packet corruption errors it detects.

If you turn on `Include advanced error reporting and handling`, the `irx_err` signal reflects CRC24 errors that are associated with data and control words in a burst. Some CRC24 errors might be an indication of one of the following conditions:

- Loss of lane alignment
- Illegal control word
- Illegal framing pattern
- Missing SOP or EOP indicator

If you turn off `Include advanced error reporting and handling`, the value on the `irx_err` signal is not valid. If you turn it on, the `irx_err` signal is valid in clock cycles when `irx_eob` is asserted.

Your IP core calculates and inserts CRC24 bits in outgoing Interlaken communication, and checks incoming Interlaken communication for CRC24 errors in the control, data, and Idle words, whether or not you turn on this parameter. The IP core reports these errors in real time on the `crc24_err` output signal. However, the IP core reports all CRC24 errors it encounters on this signal, whether or not it is able to associate them with a specific burst. The `irx_err` signal, if enabled, provides a better indication of the location of actual errors in incoming communication on the Interlaken link.

If you turn this parameter on, your IP core reports certain incoming packet corruption errors, increasing system robustness. If you turn the parameter off your IP core has lower latency and requires fewer resources on the device.

A checkmark in the check box to the left of the parameter turns this parameter on, specifying that the IP core include this feature. A check box with no checkmark indicates that the option is turned off, and the IP core does not include the feature.

By default, the `Include advanced error reporting and handling` parameter is turned off.
Enable M20K ECC Support

The Enable M20K ECC support parameter specifies whether your 100G Interlaken MegaCore function variation supports the ECC feature in the Stratix V and Arria 10 M20K memory blocks that are configured as part of the IP core. This parameter is relevant only for IP core variations that target a Stratix V device or an Arria 10 device.

You can turn this parameter on to enable single-error correct, double-adjacent-error correct, and triple-adjacent-error detect ECC functionality in the M20K memory blocks configured in your IP core. You can turn this parameter off to decrease IP core latency and save resources on the device. If you turn on this feature, you enhance data reliability but increase latency and resource utilization. Without the ECC feature, a single M20K memory block can support a data path width of 40 bits. With the ECC feature, eight of those bits are dedicated to the ECC, and an M20K memory block can support a maximum data path width of 32 bits. Therefore, to support the same data bus width, the Quartus Prime Fitter must configure additional M20K blocks. The ECC check adds latency to the path through the memory block, and increases the amount of device memory used by your IP core.

A checkmark in the check box to the left of the parameter turns this parameter on, specifying that the IP core supports this feature. A check box with no checkmark indicates that the option is turned off, and the IP core does not support this feature.

By default, the Enable M20K ECC support parameter is turned off.

  Information about the built-in ECC feature in Stratix V devices.
- Embedded Memory Blocks in Arria 10 Devices
  Information about the built-in ECC feature in Arria 10 devices.

Include Diagnostic Features

The Include diagnostic features parameter enables the following diagnostic modes for initial board bring-up and for system testing in the factory and in the field:

- CRC error counters
- CRC32 error injection on the Interlaken link
- PRBS generation and checking
- Factory test features

You can turn this parameter on to enable this IP core functionality, or turn it off to save resources on the device. If you turn this parameter on, you control the diagnostic modes by accessing 100G Interlaken IP core registers.

A checkmark in the check box to the left of the parameter turns this parameter on, specifying that the IP core has this additional functionality. A check box with no checkmark indicates that the option is turned off, and the IP core does not have this functionality.

By default, the Include diagnostic features parameter is turned off.
Enable Native XCVR PHY ADME

The Enable Native XCVR PHY ADME parameter specifies whether your Arria 10 100G Interlaken IP core variation supports the ADME feature.

This parameter exposes debugging features of the Arria 10 Native PHY IP core that specifies the transceiver settings in the 100G Interlaken IP core. You can turn this parameter on to enable the following Arria 10 Native PHY IP core features:

- Enable Altera Debug Master Endpoint (ADME)
- Enable capability registers
- Enable prbs soft accumulators
- Enable odi acceleration logic

A checkmark in the check box to the left of the parameter turns this parameter on. When the parameter is turned on, the IP core include these transceiver reconfiguration capabilities. A check box with no checkmark indicates that the option is turned off, and the IP core does not support these features.

By default, the Enable native XCVR PHY ADME parameter is turned off.

This parameter is available only for 100G Interlaken IP core variations that target an Arria 10 device.

Related Information
Arria 10 Transceiver PHY User Guide
The Implementing Protocols in Arria 10 Transceivers chapter explains these Arria 10 Native PHY IP core parameters.

Include In-Band Flow Control Block

The Include in-band flow control functionality parameter specifies whether your 100G Interlaken MegaCore function includes an in-band flow control block.

You can turn this parameter on to include in-band flow control functionality in your IP core, or turn it off to save resources on the device. If you turn on the parameter, you can specify the number of calendar pages the IP core supports.

A checkmark in the check box to the left of the parameter turns this parameter on, specifying that the IP core include the in-band flow control block. A check box with no checkmark indicates that the option is turned off, and the IP core does not include an in-band flow control block.

By default, the Include in-band flow control functionality parameter is turned off.

Related Information

- 100G Interlaken IP Core In-Band Calendar Bits on Transmit Side on page 4-17
- In-Band Calendar Bits on the 100G Interlaken IP Core Receiver User Data Interface on page 4-26
**Number of Calendar Pages**

When **Include in-band flow control functionality** is turned on, the **Number of calendar pages** parameter specifies the number of 16-bit pages of in-band flow control data that your 100G Interlaken MegaCore function supports. The supported values are 1, 2, 4, 8, and 16.

Each 16-bit calendar page includes 16 in-band flow control bits. The application determines the interpretation of the in-band flow control bits. The IP core supports a maximum of 256 channels with in-band flow control.

If your design requires a different number of pages, select the lowest supported number of pages which is larger than the number required, and ignore any unused pages. For example, if your configuration requires three in-band flow control calendar pages, you can set **Number of Calendar pages** to 4 and use pages 3, 2, and 1 while ignoring page 0.

The default value of the **Number of calendar pages** parameter is 1.

**TX Scrambler Seed**

The **TX scrambler seed** parameter specifies the initial scrambler state.

If a single 100G Interlaken IP Core is configured on your device, you can use the default value of this parameter.

If multiple 100G Interlaken IP Cores are configured on your device, you must use a different initial scrambler state for each IP core to reduce crosstalk. Try to select random values for each 100G Interlaken IP core, such that they have an approximately even mix of ones and zeros and differ from the other scramblers in multiple spread out bit positions.

The default value of this parameter is 58’hdeadbeef123.

**Transfer Mode Selection**

The **Transfer mode selection** parameter specifies whether the 100G Interlaken transmitter expects incoming traffic to the TX user data transfer interface to be interleaved or packet based. The supported values are **Interleaved** and **Packet**. Interleaved mode is also called Segmented mode. The value of this parameter cannot be modified dynamically; it is determined when you generate the IP core.

If the value of this parameter is **Packet**, the 100G Interlaken transmitter expects incoming traffic to the TX user data transfer interface to be packet based. This setting enables the internal enhanced scheduler and causes the IP core to send data on the Interlaken link based on the programmed **BurstMax** and **BurstMin** parameter settings.

If the value of this parameter is **Interleaved**, the 100G Interlaken transmitter expects you to provide Start of Burst (SOB) and End of Burst (EOB) indications with the data on the TX user data transfer interface. In Interleaved mode, you can send either packet-based traffic or interleaved traffic, but you must provide the correct SOB and EOB signals even when sending non-interleaved packets. In this mode, the IP core does not implement the enhanced scheduler. The IP core ignores the **BurstMax** and **BurstMin** values.

**BurstShort** is still in effect. To avoid overflowing the transmit FIFO, you should not send a burst that is longer than 1024 bytes.

If packets are always sent contiguously in your application, Altera recommends that you set this parameter to the value of **Packet**. This setting enables simpler transfers on the user data transfer interface, and enables the 100G Interlaken IP core to perform enhanced scheduling based on the **BurstMax** and **BurstMin** values.
BurstMin settings. If the data bursts that arrive on the TX application interface might be interleaved between channels, then you must set Transfer mode selection to the value of Interleaved.

The default value of the Transfer mode selection parameter is Interleaved.

Related Information
Interleaved and Packet Modes on page 4-7

Data Format

The Data format parameter specifies whether the 100G Interlaken IP core opportunistically generates dual segment mode output to the RX user data transfer interface and handles dual segment mode input to the TX user data transfer interface. The supported parameter values are Single segment and Dual segment.

This parameter affects both the RX user data transfer interface and the TX user data transfer interface. The 100G Interlaken IP core can accept dual segment input from the application on the TX user data transfer interface only if you specify the value of Dual segment for the Data format parameter.

The default value of the Data format parameter is Single segment (single segment mode).

Enabling the 100G Interlaken IP core to send dual segment mode output to the RX user data transfer interface improves bandwidth by decreasing idle bytes in outgoing communication. Likewise, enabling the IP core to receive dual segment mode input on the TX user data transfer interface improves system bandwidth by decreasing idle bytes in incoming communication. However, if you turn on this feature, you must ensure your application can process data sent in dual segment format. In addition, enabling dual segment mode configures more complex logic in the IP core, impacting resource utilization.

Related Information
Dual Segment Mode on page 4-8
The 100G Interlaken MegaCore function provides the functionality described in the Interlaken Protocol Specification, Revision 1.2.

Interlaken Protocol Specification, Revision 1.2

Interfaces Overview
The Altera 100G Interlaken MegaCore function supports the following interfaces:

Application Interface on page 4-1
Interlaken Interface on page 4-1
Out-of-Band Flow Control Interface on page 4-2
Management Interface on page 4-2
Transceiver Control Interfaces on page 4-2

Application Interface
The application interface, also called the user data transfer interface, provides up to 256 channels of communication to and from the Interlaken link.

Related Information
- High Level Block Diagram on page 4-4
  The figure lists the major application interface signals.
- 100G Interlaken IP Core User Data Transfer Interface Signals on page 5-4
  Comprehensive list of application interface signals and information about required signal behavior.

Interlaken Interface
The Interlaken interface complies with the Interlaken Protocol Specification, Revision 1.2. It provides a high-speed transceiver interface to an Interlaken link.
The 100G Interlaken MegaCore function value for the Interlaken BurstMax parameter is determined by the value you specify on the `burst_max_in` input signal. The 100G Interlaken MegaCore function supports three values for BurstMax, 128 bytes, 256, and 512 bytes.

**Note:** You should only modify the value of the `burst_max_in` signal when no traffic is present.

You can configure your 100G Interlaken MegaCore function to use 1, 2, 4, 8, or 16 pages of 16 calendar bits. The application determines the use of the in-band flow control bits that the MegaCore function receives on the incoming Interlaken link, and the application is responsible for specifying the values of the in-band flow control bits the MegaCore function transmits on the outgoing Interlaken link.

**Related Information**
- [100G Interlaken IP Core Interlaken Link and Miscellaneous Interface Signals](#) on page 5-9
  Information about setting the BurstMax and BurstShort values, including the encoding of your desired value on the `burst_max_in` or `burst_short_in` input signal.

### Out-of-Band Flow Control Interface

The optional out-of-band flow control interface conforms to the out-of-band requirements in Section 5.3.4.2, Out-of-Band Flow Control, of the Interlaken Protocol Specification, Revision 1.2.

**Related Information**
- [Out-of-Band Flow Control in the 100G Interlaken MegaCore Function](#) on page 9-1
- [Interlaken Protocol Specification, Revision 1.2](#)

### Management Interface

The management interface provides access to the 100G Interlaken IP core internal status and control registers. This interface does not provide access to the hard PCS registers on the device.

The management interface complies with the Avalon Memory-Mapped (Avalon-MM) specification defined in the Avalon Interface Specifications.

**Related Information**
- [Avalon Interface Specifications](#)

### Transceiver Control Interfaces

The 100G Interlaken IP core provides several interfaces to control the transceiver. The transceiver control interfaces in your 100G Interlaken IP core variation depend on the device family the variation targets.

The 100G Interlaken IP core supports the following transceiver control interfaces:

- [Transceiver Reconfiguration Controller Interface](#) on page 4-3
- [Arria 10 External PLL Interface](#) on page 4-3
Transceiver Reconfiguration Controller Interface

100G Interlaken IP core variations that target an Arria V or a Stratix V device require an external reconfiguration controller to function correctly in hardware. 100G Interlaken IP core variations that target an Arria 10 device include a reconfiguration controller block and do not require an external reconfiguration controller.

Related Information

Arria 10 Transceiver Reconfiguration Interface

The Arria 10 transceiver reconfiguration interface provides access to the registers in the embedded Arria 10 Native PHY IP core. This interface provides direct access to the hard PCS registers on the device.

This interface is available only in variations that target an Arria 10 device. In variations that target an Arria V device or a Stratix V device, user logic reconfigures the transceivers through the transceiver reconfiguration controller, an external block that you must instantiate in your design outside the 100G Interlaken IP core.

The Arria 10 transceiver reconfiguration interface complies with the Avalon Memory-Mapped (Avalon-MM) specification defined in the Avalon Interface Specifications.

**IP Core Reset**

The 100G Interlaken IP core variations have a single asynchronous reset, the reset_n signal. The 100G Interlaken IP core manages the initialization sequence internally. After you de-assert reset_n (raise it after asserting it low), the IP core automatically goes through the entire reset sequence.

**Note:** Altera recommends that you hold the reset_n signal low for at least the duration of two mm_clk cycles, to ensure the reset sequence proceeds correctly.
The internal initialization sequence implemented by the reset controller included in the 100G Interlaken IP core. In Arria 10 devices, the \texttt{pll\_locked} signal originates in the external PLL. In other devices, it originates in the 100G Interlaken IP core itself.

Following completion of the reset sequence internally, the 100G Interlaken IP core begins link initialization. If your 100G Interlaken IP core and its Interlaken link partner initialize the link successfully, you can observe the assertion of the lane and link status signals according to the Interlaken specification. For example, you can monitor the \texttt{tx\_lanes\_aligned}, \texttt{sync\_locked}, \texttt{word\_locked}, and \texttt{rx\_lanes\_aligned} output status signals.

In Arria V GZ and Stratix V devices, after you de-assert the \texttt{reset\_n} signal, you must wait a certain number of \texttt{mm\_clk} cycles before you can successfully access the 100G Interlaken IP core registers using the IP core management interface.

- In hardware, you must wait $2^{20}$ \texttt{mm\_clk} cycles.
- In simulation, you must wait $2^6$ \texttt{mm\_clk} cycles.

In Arria 10 devices, the required wait time from de-asserting the \texttt{reset\_n} signal to safely accessing the IP core registers is a function of the internal reset controller. The IP core instantiates an Altera Transceiver PHY Reset Controller in Arria 10 variations.
Related Information

- **IP Core Reset Sequence with the Reconfiguration Controller** on page 4-7
  You must wait until the required Altera Transceiver Reconfiguration Controller completes configuration of the transceivers before you assert the reset_n signal.

  For more information about the Altera Transceiver PHY Reset Controller that is included in Arria 10 variations of the 100G Interlaken IP core, refer to the Transceiver Reset Control in Arria 10 Devices chapter.

IP Core Reset Sequence with the Reconfiguration Controller

If your 100G Interlaken IP core targets an Arria V device or a Stratix V device, you must connect the 100G Interlaken IP core to an Altera Reconfiguration Controller. At power up, the Reconfiguration Controller configures the transceivers. After power up, upon completion of the transceiver configuration process, the Reconfiguration Controller returns control of the reset to your application. You must wait until the Reconfiguration Controller completes configuration of the transceivers before you assert the reset_n signal.

The Reconfiguration Controller indicates the end of the configuration cycle by deasserting the reconfig_busy signal. After reconfig_busy is deasserted, you can assert reset_n. Altera recommends that you hold the reset_n signal low for at least the duration of two mm_clk cycles, to ensure the reset sequence proceeds correctly.

**Figure 4-3: Reset Sequence With the Reconfiguration Controller**

Indicates when you can safely assert the reset_n signal of the 100G Interlaken MegaCore IP core.

You must wait at least $2^{23}$ mm_clk cycles (or $2^9$ mm_clk cycles in simulation) after the mgmt_clk locks before you deassert the mgmt_rst_reset input signal to the reconfiguration controller.

Interleaved and Packet Modes

You can configure the 100G Interlaken IP core to accept interleaved data transfers from the application on the TX user data transfer interface, or to not accept interleaved data transfers on this interface. If the IP core can accept interleaved data transfers, it is in Interleaved mode, sometimes also called Segmented...
mode. If the IP core does not accept interleaved data transfers, it is in Packet mode. The value you specify for the **Transfer mode selection** parameter in the 100G Interlaken parameter editor determines the IP core transmit mode.

In Packet mode, the 100G Interlaken IP Core performs Optional Scheduling Enhancement based on Section 5.3.2.1.1 of the *Interlaken Protocol Specification, Revision 1.2*. The IP core ignores the itx_sob and itx_eob signals. Instead, the IP core performs optional enhanced scheduling based on the settings of BurstMax, BurstMin, and BurstShort.

In Interleaved mode, the 100G Interlaken IP Core inserts burst control words on the Interlaken link based on the itx_sob and itx_eob inputs. The internal optional enhanced scheduling is disabled and the BurstMax and BurstMin values are ignored. BurstShort is still in effect. To avoid overflowing the transmit FIFO, you should not send a burst that is longer than 1024 bytes.

In Interleaved mode or in Packet mode, the 100G Interlaken IP core is capable of accepting non-interleaved data on the TX user data transfer interface (itx_din_words). However, if the IP core is in Interleaved mode, the application must drive the itx_sob and itx_eob inputs correctly.

In Interleaved mode or in Packet mode, the 100G Interlaken IP core can generate interleaved data transfers on the RX user data transfer interface (irx_dout_words). The application must be able to accept interleaved data transfers if the Interlaken link partner transmits them on the Interlaken link. In this case, the Interlaken link partner must send traffic in Interleaved mode that conforms with the 100G Interlaken IP core BurstShort value.

**Note:** The transmitter (link partner) must only send packets with a minimum packet size of 64 bytes.

**Related Information**
- **Transfer Mode Selection** on page 3-6
- **100G Interlaken IP Core User Data Transfer Interface Signals** on page 5-4
- **Interlaken Protocol Specification, Revision 1.2**

**Dual Segment Mode**

In dual segment mode, the 100G Interlaken IP core can minimize wasted bandwidth on the user data transfer interface by starting a packet transfer at Byte 31 (Word 3) of the data bus (irx_dout_words[511:0]), if the previous packet ended with four or fewer 64-bit words transferred in the current rx_usr_clk cycle.

In dual segment mode, the IP core is capable of accepting dual segment input on the TX user data transfer interface (itx_din_words[511:0]). However, the application can control IP core input signals to specify that the current incoming data transfer does not use dual segment mode. In addition, if you tie the relevant input signals (itx_sob[0], itx_sop[0], and itx_num_valid[3:0]) permanently low in your design, the Quartus Prime Fitter compiles away the IP core logic that generates dual segment output from the IP core.
You must enforce the following additional constraints in sending dual segment traffic to the TX user data transfer interface:

- The application can start a packet or burst transfer in a single cycle on only one of the most significant byte (Byte 63) or the middle position (Byte 31) in the 512-bit data symbol. Therefore, the application can assert only one of ITX_SOP[1] and ITX_SOP[0], and only one of ITX_SOB[1] and ITX_SOB[0], in a given cycle. This constraint ensures that the minimum number of idle and data bytes between consecutive starts of packet or burst is at least 64.
- The application can end a packet or burst transfer only once in a single cycle. Therefore, the minimum number of idle and data bytes between consecutive ends of packet or burst must be at least 64.

The same constraints apply to dual segment traffic on the RX user data transfer interface: the minimum number of idle and data bytes between consecutive starts of packet or burst must be at least 64, and the minimum number of idle and data bytes between consecutive ends of packet or burst must be at least 64. The 100G Interlaken IP core enforces these constraints on the RX user data transfer interface.

Figure 4-4: Dual Segment Data Transfer

In a dual segment data transfer, the end of one data burst and the start of another can appear in the same clock cycle. In this example, each column represents a single 512-bit data symbol, divided into 64-bit words, and each color represents a separate data burst. The second and third data bursts are dual segment transfers.

M20K ECC Support

If you turn on Enable M20K ECC support in your Stratix V or Arria 10 100G Interlaken IP core variation, the IP core takes advantage of the built-in device support for ECC checking in all M20K blocks configured in the IP core on the device. The feature performs single-error correct, double-adjacent-error correct, and triple-adjacent-error detect ECC functionality in the M20K memory blocks configured in your IP core. The IP core reports ECC error statistics in the registers CNT_ERR_TX, CNT_UNCOR_TX, CNT_ERR_RX, and CNT_UNCOR_RX at offsets 0x122 through 0x125.

This feature enhances data reliability but increases latency and resource utilization. Without the ECC feature, a single M20K memory block can support a data path width of 40 bits. With the ECC feature, eight of those bits are dedicated to the ECC, and an M20K memory block can support a maximum data path width of 32 bits. Therefore, when M20K ECC support is turned on the IP core configures additional M20K memory blocks. The ECC check adds latency to the path through the memory block, and increases the amount of device memory used by your IP core.

100G Interlaken IP Core Transmit Path

The 100G Interlaken MegaCore function accepts application data from up to 256 channels and combines it into a single data stream in which data is labeled with its source channel. The 100G Interlaken TX MAC and PCS blocks format the data into protocol-compliant bursts and insert Idle words where required.

100G Interlaken IP Core Transmit User Data Interface Examples

The following examples illustrate how to use the Altera 100G Interlaken IP core TX user data interface:

- 100G Interlaken IP Core Interleaved Mode (Segmented Mode) Example on page 4-10
- 100G Interlaken IP Core Packet Mode Operation Example on page 4-12
- 100G Interlaken IP Core Back-Pressured Packet Transfer Example on page 4-13
- 100G Interlaken IP Core Dual Segment Interleaved Data Transfer Transmit Example on page 4-15

100G Interlaken IP Core Interleaved Mode (Segmented Mode) Example

In Interleaved Mode, you are responsible for scheduling the burst. You need to drive an extra pair of signals, Start of Burst (SOB) and End of Burst (EOB), to indicate the burst boundary. You can send the traffic in packet order or interleaved order, as long as you set the SOB and EOB flags correctly to establish the data boundaries.
This example illustrates the expected behavior of the 100G Interlaken IP core application interface transmit signals during data transfers from the application to the IP core on the TX user data transfer interface in interleaved, single segment mode.

The figure shows the timing diagram for an interleaved data transfer in Interleaved mode. In cycle 1, the application asserts `itx_sop[1]` and `itx_sob[1]`, indicating that this cycle is both the start of the burst and the start of the packet. The value the application drives on `itx_chan` indicates the data originates from channel 2.

In cycle 2, the application asserts `itx_eob`, indicating the data the application transfers to the IP core in this clock cycle is the end of the burst. (`itx_chan` only needs to be valid when `itx_sob[1]` or `itx_sop[1]` is asserted). `itx_num_valid[7:4]` indicates all eight words are valid. However, the data in this cycle is not end of packet data. The application is expected to transfer at least one additional data burst in this packet, possibly interleaved with one or more bursts in packets from different data channels.

Cycle 3 is a short burst with both `itx_sob[1]` and `itx_eob` asserted. The application drives the value of three on `itx_num_valid[7:4]` to indicate that three words of the eight-word `itx_din_words` data bus are valid. The data is packed in the most significant words of `itx_din_words`. The application drives the value of `4'b1011` on `itx_eopbits` to indicate that the data the application transfers to the IP core in this cycle are the final words of the packet, and that in the final word of the packet, only three bytes are valid data. The value the application drives on `itx_chan` indicates this burst originates from channel 4.

In cycle 4, the `itx_num_valid[7:4]` signal has the value of zero, which means this cycle is an idle cycle.

In cycle 5, the application sends another single-cycle data burst from channel 2, by asserting `itx_sob[1]` and `itx_eob` to indicate this data is both the start and end of the burst. The application does not assert `itx_sop[1]`, because this burst is not start of packet data. `itx_eopbits` has the value of `4'b0000`, indicating this burst is also not end of packet data. This data follows the data burst transferred in cycles 1 and 2, within the same packet from channel 2.

In cycle 6, the application sends a start of packet, single-cycle data burst from channel 3.

In cycles 7 and 8, the application sends a two-cycle data packet in one two-cycle burst. In cycle 8, the second data cycle, the application drives the value of two on `itx_num_valid[7:4]` and the value of...
4'b1011 on itx_eopbits, to tell the IP core that in this clock cycle, the two most significant words of the data symbol contain valid data and the remaining words do not contain valid data, and that in the second of these two words, only the three most significant bytes contain valid data.

In Interleaved Mode, you can transfer a packet without interleaving as long as the channel number does not toggle during the same packet transfer. However, you must still assert the itx_sob and itx_eob signals correctly to maintain the proper burst boundaries.

If you do not drive the itx_sob and itx_eob signals, the 100G Interlaken IP Core does not operate properly and the transmit FIFO may overflow, since in this mode the internal logic is looking for itx_sob and itx_eob assertion for insertion of proper burst control words.

**100G Interlaken IP Core Packet Mode Operation Example**

**Figure 4-6: Packet Transfer on Transmit Interface in Packet Mode**

This example illustrates the expected behavior of the 100G Interlaken IP core application interface transmit signals during a packet transfer in single segment packet mode.

The figure illustrates a packet mode data transfer of 179 bytes on the transmit interface into the IP core. In this mode, the 100G Interlaken IP core ignores the itx_sob and itx_eob input signals.

To start a transfer, you assert itx_sop[1] when you have data ready on itx_din_words. At the following rising edge of the clock, the IP core detects that itx_sop[1] is asserted, indicating that the value on itx_din_words in the current cycle is the start of an incoming data packet. When you assert itx_sop[1], you must also assert the correct value on itx_chan to tell the IP core the data channel source of the data. In this example, the value 2 on itx_chan tells the IP core that the data originates from channel number 2.
During the SOP cycle (labeled with data value d1) and the cycle that follows the SOP cycle (labeled with data value d2), you must hold the value of \texttt{itx\_num\_valid[7:4]} at 4'b1000. In the following clock cycle, labeled with data value d3, you must hold the following values on critical input signals to the IP core:

- \texttt{itx\_num\_valid[7:4]} at the value of 4'b0111 to indicate the current data symbol contains seven 64-bit words of valid data.
- \texttt{itx\_eopbits[3]} high to indicate the current cycle is an EOP cycle.
- \texttt{itx\_eopbits[2:0]} at the value of 3'b011 to indicate that only three bytes of the final valid data word are valid data bytes.

This signal behavior correctly transfers a data packet with the total packet length of 179 bytes to the IP core, as follows:

- In the SOP cycle, the IP core receives 64 bytes of valid data (d1).
- In the following clock cycle, the IP core receives another 64 bytes of valid data (d2).
- In the third clock cycle, the EOP cycle, the IP core receives six full words (6 x 8 = 48 bytes) and three bytes of valid data, for a total of 51 valid bytes.

The total packet length is 64 + 64 + 51 = 179 bytes.

\textbf{100G Interlaken IP Core Back-Pressured Packet Transfer Example}

\textit{Figure 4-7: Packet Transfer on Transmit Interface with Back Pressure}

This example illustrates the expected behavior of the 100G Interlaken application interface transmit signals during a packet transfer with back pressure.

In this example, the 100G Interlaken IP Core accepts the first four data symbols (256 bytes) of a data packet. The clock cycles in which the application transfers the data values d2 and d3 to the 100G Interlaken IP Core are grace-period cycles following the 100G Interlaken IP Core's de-assertion of \texttt{itx\_ready}.

The 100G Interlaken IP Core supports up to 4 cycles of grace period, enabling you to register the input data and control signals, as well as the \texttt{itx\_ready} signal, without changing functionality. The grace period
supports your design in achieving timing closure more easily. In any case you must ensure that you hold
\texttt{itx\_num\_valid} at the value of 0 when you are not driving data.

You can think of this interface as a FIFO write interface. When \texttt{itx\_num\_valid[7:4]} is nonzero, both
data and control information (including \texttt{itx\_num\_valid[7:4]} itself) are written to the transmit side data
interface. The \texttt{itx\_ready} signal is the inverse of a hypothetical FIFO-almost-full flag. When \texttt{itx\_ready}
is high, the 100G Interlaken IP Core is ready to accept data. When \texttt{itx\_ready} is low, you can continue to
send data for another 6 to 8 clock cycles of \texttt{tx\_usr\_clk}.

Related Information

100G Interlaken IP Core In-Band Calendar Bits on Transmit Side on page 4-17
Description of in-band calendar bits on the TX user data transfer interface.
This example illustrates the expected behavior of the 100G Interlaken IP core application interface transmit signals during dual segment transfers of three data bursts in interleaved mode.

The figure shows three data bursts in dual segment mode on the TX user data transfer interface. In cycle 1, the application asserts `itx_sop[1]` and `itx_sob[1]`, indicating that this cycle is both the start of the burst and the start of the packet, and that data starts from the most significant byte of the data symbol. The application drives the value of 2 on `itx_chan` to indicate the data originates from channel 2.
In cycle 2, the following two events occur:

- The first data burst completes. The application asserts `itx_eob`, indicating the data the application transfers to the IP core in this clock cycle is the end of the burst. The value the application drives on `itx_num_valid[7:4]` indicates that one word in this data symbol is valid data associated with this burst. In addition, the application drives `itx_eopbits` to the value of `4'b0000` to indicate that the data the application transfers to the IP core in this clock cycle is not the end of the packet. Therefore, all bytes in this data word are valid.

- A second data burst starts at Word 3. This transfer is a dual segment transfer, as is allowed whether or not the IP core is configured in dual segment mode on the RX side. The application asserts `itx_sop[0]` and `itx_sob[0]`, indicating that this cycle is both the start of the burst and the start of the packet, and that data in this burst and packet starts from Byte 31 of the data symbol. The application drives the value of 3 on `itx_chan` to indicate the data originates from channel 3. The value of `itx_num_valid[7:4]` is `4'b0100`, indicating this data transfer is a dual segment data transfer—that it begins at Word 3. The value of `itx_num_valid[7:4]` has no relevance for the data words in this burst that appear in this data symbol, except to indicate the previous burst includes no data in these words of the data symbol (Words 3 through 0), and therefore, that they are available for the second data burst. As is required, the dual segment data transfer places valid data in all four words in the least significant half of the data symbol.

In cycles 3 and 4, the second data burst continues with no EOB or EOP indication. The IP core does not sample the value of `itx_chan` in these clock cycles, and its value is therefore a Don’t Care. The value on `itx_num_valid[7:4]` indicates that all eight words in each of these data symbols are valid data associated with this burst.

In cycle 5, the following two events occur:

- The second data burst completes. The application asserts `itx_eob`, indicating the data transferred in this clock cycle is the end of the burst. The value the application drives on `itx_num_valid[7:4]` indicates that four words in this data symbol are valid data associated with this burst. In addition, the value the application drives on `itx_eopbits` indicates the data is the end of the packet, and that all eight bytes of the final data word are valid data bytes.

- A third data burst starts at Word 3. This transfer is a dual segment transfer, as is allowed whether or not the IP core is configured in dual segment mode on the RX side. The application asserts `itx_sob[0]`, indicating that this cycle is the start of the burst and that data in this burst starts from Byte 31 of the data symbol. However, the application does not assert `itx_sop[0]`, indicating this burst is not the first burst in the packet. The value the application drives on `itx_chan` indicates the data originates from channel 2. Therefore, we can conclude this data burst is the second burst in a packet from channel 2. The value the application drives on `itx_num_valid[3:0]` is `4'b0100`, indicating this data transfer is a dual segment data transfer—that it begins at Word 3. The value of `itx_num_valid[7:4]` has no relevance for the data words in this burst that appear in this data symbol, except to indicate the previous burst includes no data in these words of the data symbol (Words 3 through 0), and therefore, that they are available for the second data burst. As is required, the dual segment data transfer places valid data in all four words in the least significant half of the data symbol.

In cycle 6, the third data burst completes. The application asserts `itx_eob`, indicating the data transferred in this clock cycle is the end of the burst. The value on `itx_num_valid[7:4]` indicates that five words in this data symbol are valid data associated with this burst. In addition, the value the application drives on `itx_eopbits` indicates the data is the end of the packet, and that all eight bytes of the final data word are valid data bytes. Because the data from this burst occupies words 7 through 3 of the data symbol, another burst cannot start in the current data symbol.
In dual segment mode as in single segment mode, if the IP core is in Interleaved mode, you can transfer a packet without interleaving—if you do not toggle the channel number during the packet transfer, the packet is not interleaved with another packet. However, you must still assert the itx_sob and itx_eob signals correctly to maintain the proper burst boundaries.

If you do not drive the itx_sob and itx_eob signals, the 100G Interlaken IP Core does not operate properly and the transmit FIFO may overflow, since in this mode the internal logic is looking for itx_sob and itx_eob assertion for insertion of proper burst control words.

**Related Information**

*Dual Segment Mode* on page 4-8

**100G Interlaken IP Core In-Band Calendar Bits on Transmit Side**

If you turn on *Include in-band flow control functionality*, the itx_calendar input signal supports in-band flow control. It is synchronous with tx_usr_clk, but does not align with the packets on the user data interface. The 100G Interlaken IP Core reads the itx_calendar bits and encodes them in control words (Burst control words and Idle control words) opportunistically.

If you hold all the calendar bits at one, you indicate an XON setting for each channel. You should set the calendar bits to 1 to indicate that the Interlaken link partner does not need to throttle the data it transfers to this 100G Interlaken IP Core. Set this value by default if you choose not to use the in-band flow control feature of the 100G Interlaken IP Core. If you decide to turn off any channel, you must drive the corresponding bits of itx_calendar with zero (the XOFF setting) for that channel.

If you turn on *Include in-band flow control functionality*, the 100G Interlaken IP Core transmits each page of the itx_calendar bits on the Interlaken link in a separate control word, starting with the most significant page and working through the pages, in order, to the least significant page. If you turn off *Include in-band flow control functionality*, the IP core fills each flow control bit in each control word with the value of 1.

Consider an example where the number of calendar pages is four and itx_calendar bits are set to the value 64’h1111_2222_3333_4444. In this example, the Number of calendar pages parameter is set to four, and therefore the width of the itx_calendar signal is 4 x 16 = 64 bits. Each of these bits is a calendar bit. The transmission begins with the page with the value of 16’h1111 and works through the pages in order until the least significant page with the value of 16’h4444.

In this example, four control words are required to send the full set of 64 calendar bits from the itx_calendar signal. The 100G Interlaken IP Core automatically sets the Reset Calendar bit[56] of the next available control word to the value of one, to indicate the start of transmission of a new set of calendar pages, and copies the most significant page (16’h1111 in this example) to the In-Band Flow Control bits[55:40] of the control word. It maps the most significant bit of the page to the control word bit[55] and the least significant bit of the page to the control word bit[40].
The table shows the value of the Reset Calendar bit and the In-Band Flow Control bits in the four Interlaken link control words that transmit the 64'h1111_2222_3333_4444 value of itx_calendar:

<table>

</tbody>
</table>

For details of the control word format, refer to the Interlaken Protocol Specification, Revision 1.2.

The 100G Interlaken IP Core supports itx_calendar widths of 1, 2, 4, 8, and 16 16-bit calendar pages. You configure the width in the 100G Interlaken IP Core parameter editor.

By convention, in a standard case, each calendar bit corresponds to a single data channel. However, the 100G Interlaken IP Core assumes no default usage. You must map the calendar bits to channels or link status according to your specific application needs. For example, if your design has 64 physical channels, but only 16 priority groups, you can use a single calendar page and map each calendar bit to four physical channels. As another example, for a different application, you can use additional calendar bits to pass quality-of-service related information to the Interlaken link partner.

If your application flow-controls a channel, you are responsible for dropping the relevant packet. Altera supports the transfer of the itx_calendar values you provide without examining the data that is affected by in-band flow control of the Interlaken link.

Related Information

- **100G Interlaken IP Core Back-Pressured Packet Transfer Example** on page 4-13
  Example of in-band calendar bits usage on the TX user data transfer interface.
- **Interlaken Protocol Specification, Revision 1.2**
The 100G Interlaken IP core transmit data path has the following four main functional blocks:

100G Interlaken IP Core TX Transmit Buffer on page 4-19
100G Interlaken IP Core TX MAC on page 4-19
100G Interlaken IP Core TX PCS on page 4-19
100G Interlaken IP Core TX PMA on page 4-20

100G Interlaken IP Core TX Transmit Buffer

The 100G Interlaken MegaCore function TX transmit buffer performs the following functions:

- Aligns the incoming user application data, itx_data, in the IP core internal format.
- Implements domain crossing from the tx_usr_clk clock domain to the tx_mac_clk clock domain.

100G Interlaken IP Core TX MAC

The 100G Interlaken MegaCore function TX MAC performs the following functions:

- Inserts burst and idle control words in the incoming data stream. Burst delineation allows packet segmentation in the Interlaken protocol.
- Performs flow adaption of the data stream, repacking the data to ensure the maximum number of words is available on each valid clock cycle.
- Calculates and inserts CRC24 bits in all burst and idle words.
- Inserts calendar data in all burst and idle words, if you configure in-band flow control.
- Stripes the data across the PCS lanes. Configurable order, default is MSB of the data goes to lane 0.
- Buffers data between the application and the TX PCS block in the TX FIFO buffer. The TX PCS block uses the FIFO buffer to recover bandwidth when the number of words delivered to the transmitter is less than the full width.

100G Interlaken IP Core TX PCS

TX PCS logic is an embedded hard macro and does not consume FPGA soft logic elements.
The 100G Interlaken MegaCore function TX PCS block performs the following functions for each lane:

- Inserts the meta frame words in the incoming data stream.
- Calculates and inserts the CRC32 bits in the meta frame diagnostic words.
- Scrambles the data according to the scrambler seed and the protocol-specified polynomial.
- Performs 64B/67B encoding.

100G Interlaken IP Core TX PMA

The 100G Interlaken MegaCore function TX PMA serializes the data and sends it out on the Interlaken link.

100G Interlaken IP Core Receive Path

The 100G Interlaken MegaCore function receives data on the Interlaken link, monitors and removes Interlaken overhead, and provides user data and calendar information to the application.

Calendar information is available only if you turn on Include in-band flow control block in the 100G Interlaken parameter editor.

100G Interlaken IP Core Receive User Data Interface Examples

The following examples illustrate how to use the Altera 100G Interlaken IP core RX user data interface:

100G Interlaken IP Core Receiver Side Example on page 4-20
100G Interlaken IP Core Dual Segment Interleaved Data Transfer Receive Example on page 4-22

100G Interlaken IP Core Receiver Side Example

The 100G Interlaken IP Core can generate interleaved data transfers on the RX user data transfer interface. The IP core always toggles the irx_sob and irx_eob signals to indicate the beginning of the burst and end of the burst. In single segment mode, only irx_sob[1] toggles. In dual segment mode, irx_sob[0] toggles if the current burst starts at word 4 of the data symbol.
Figure 4-10: 100G Interlaken IP Core Receiver Side Single Segment Example

This example illustrates the expected behavior of the 100G Interlaken IP core application interface receive signals during data transfers from the IP core to the application on the RX user data transfer interface in interleaved, single segment mode.

The figure shows the timing diagram for an interleaved data transfer in Interleaved mode. In cycle 1, the IP core asserts irx_sop[1] and irx_sob[1], indicating that this cycle is both the start of the burst and the start of the packet. The first word is MSB aligned at the top. The value the IP core drives on irx_chan indicates the data targets channel 2. You must sample irx_chan during cycles in which irx_sob[1] is asserted. The irx_chan output signal is not guaranteed to remain valid for the duration of the burst.

In cycle 2, the IP core asserts irx_eob, indicating the data the IP core transfers to the application in this clock cycle is the end of the burst. irx_num_valid[7:4] indicates all eight words are valid. However, the data in this cycle is not end of packet data. The IP core will transfer at least one additional data burst in this packet, possibly interleaved with one or more bursts in packets that target different data channels.

Cycle 3 is a short burst with both irx_sob[1] and irx_eob asserted. The IP core drives the value of three on irx_num_valid[7:4] to indicate that three words of the eight-word irx_dout_words data bus are valid. The data is packed in the most significant words of irx_dout_words. The IP core drives the value of 4'b1011 on irx_eopbits to indicate that the data the IP core transfers to the application in this cycle are the final words of the packet, and that in the final word of the packet, only three bytes are valid data. The value the IP core drives on irx_chan indicates this burst targets channel 4.

In cycle 4, the irx_num_valid[7:4] signal has the value of zero, which means this cycle is an idle cycle.

In cycle 5, the IP core sends another single-cycle data burst to channel 2, by asserting irx_sob[1] and irx_eob to indicate this data is both the start and end of the burst. The IP core does not assert irx_sop[1], because this burst is not start of packet data. irx_eopbits has the value of 4'b0000, indicating this burst is also not end of packet data. This data follows the data burst transferred in cycles 1 and 2, within the same packet the IP core is sending to channel 2.

In cycle 6, the IP core sends a start of packet, single-cycle data burst to channel 3.
In cycles 7 and 8, the IP core sends a two-cycle data packet in one two-cycle burst. In cycle 8, the second data cycle, the IP core drives the value of two on `irx_num_valid[7:4]` and the value of `4'b1011` on `irx_eopbits`, to tell the application that in this clock cycle, the two most significant words of the data symbol contain valid data and the remaining words do not contain valid data, and that in the second of these two words, only the three most significant bytes contain valid data.

### 100G Interlaken IP Core Dual Segment Interleaved Data Transfer Receive Example

**Figure 4-11: Dual Segment Data Transfer on Receive Interface in Interleaved Mode**

This example illustrates the expected behavior of the 100G Interlaken IP core application interface receive signals during dual segment transfers of three data bursts in interleaved mode. The 100G Interlaken IP core can generate dual segment data transfers only if you configure the IP core in dual segment mode.

The figure shows three data bursts in dual segment mode on the RX user data transfer interface. In cycle 1, the IP core asserts `irx_sop[1]` and `irx_sob[1]`, indicating that this cycle is both the start of the burst and
the start of the packet, and that data starts from the most significant byte of the data symbol. The IP core drives the value of 2 on irx_chan to indicate the data targets channel 2.

In cycle 2, the following two events occur:

- The first data burst completes. The IP core asserts irx_eob, indicating the data the IP core transfers to the application in this clock cycle is the end of the burst. The value the IP core drives on irx_num_valid[7:4] indicates that one word in this data symbol is valid data associated with this burst. In addition, the IP core drives irx_eopbits to the value of 4'b0000 to indicate that the data the IP core transfers to the application in this clock cycle is not the end of the packet.

- A second data burst starts at Word 3, as is allowed in dual segment mode. The IP core asserts irx_sop[0] and irx_sob[0], indicating that this cycle is both the start of the burst and the start of the packet, and that data in this burst and packet starts from Byte 31 of the data symbol. The IP core drives the value of 3 on irx_chan to indicate the data targets channel 3. The value of irx_num_valid[3:0] is 4'b0100, indicating this data transfer is a dual segment data transfer—that it begins at Word 3. The value of irx_num_valid[7:4] has no relevance for the data words in this burst that appear in this data symbol, except to indicate the previous burst includes no data in these words of the data symbol (Words 3 through 0), and therefore, that they are available for the second data burst. As is required, the dual segment data transfer places valid data in all four words in the least significant half of the data symbol.

In cycles 3 and 4, the second data burst continues with no EOB or EOP indication. The application should not sample the value of irx_chan in these clock cycles. The value on irx_num_valid[7:4] indicates that all eight words in each of these data symbols are valid data associated with this burst.

In cycle 5, the following two events occur:

- The second data burst completes. The IP core asserts irx_eob, indicating the data transferred in this clock cycle is the end of the burst. The value the IP core drives on irx_num_valid[7:4] indicates that four words in this data symbol are valid data associated with this burst. In addition, the value the IP core drives on irx_eopbits indicates the data is the end of the packet, and that all eight bytes of the final data word are valid data bytes.

- A third data burst starts at Word 3, as is allowed in dual segment mode. The IP core asserts irx_sob[0], indicating that this cycle is the start of the burst and that data in this burst starts from Byte 31 of the data symbol. However, the IP core does not assert irx_sop[0], indicating this burst is not the first burst in the packet. The value the IP core drives on irx_chan indicates the data targets channel 2. Therefore, we can conclude this data burst is the second burst in a packet that targets channel 2. The value the IP core drives on irx_num_valid[3:0] is 4'b0100, indicating this data transfer is a dual segment data transfer—that it begins at Word 3. The value of irx_num_valid[7:4] has no relevance for the data words in this burst that appear in this data symbol, except to indicate the previous burst includes no data in these words of the data symbol (Words 3 through 0), and therefore, that they are available for the second data burst. As is required, the dual segment data transfer places valid data in all four words in the least significant half of the data symbol.

In cycle 6, the third data burst completes. The IP core asserts irx_eob, indicating the data transferred in this clock cycle is the end of the burst. The value on irx_num_valid[7:4] indicates that five words in this data symbol are valid data associated with this burst. In addition, the value the IP core drives on irx_eopbits indicates the data is the end of the packet, and that all eight bytes of the final data word are valid data bytes. Because the data from this burst occupies words 7 through 3 of the data symbol, another burst cannot start in the current data symbol.
By default, the RX user data transfer interface can generate interleaved data. However, the IP core can also transfer a packet without interleaving—if the IP core does not toggle the channel number during the packet transfer, the packet is not interleaved with another packet. In this case, the IP core still asserts the irx_sob and irx_eob signals correctly to maintain the proper burst boundaries.

Related Information
Dual Segment Mode on page 4-8

100G Interlaken IP Core RX Errored Packet Handling

The 100G Interlaken IP Core provides information about errored packets on the RX user data transfer interface through the following output signals:

- **irx_eopbits[3:0]**—If this signal has the value of 4'b0001, an error indication arrived with the packet on the incoming Interlaken link: the EOP_Format field of the control word following the final burst of the packet on the Interlaken link has this value, which indicates an error and EOP.

- **irx_err**—If you turn on Include advanced error reporting and handling, the 100G Interlaken IP Core checks the integrity of incoming packets on the Interlaken link, and reports some packet corruption errors it detects on the RX user data transfer interface in the irx_err output signal. The IP core asserts the irx_err output signal synchronously with the irx_eob signal. The IP core asserts this signal only if it can determine the burst in which the error occurred. If the IP core cannot determine the burst in which the error occurred, it does not assert the irx_err in response.

In both cases, the application is responsible for discarding the relevant packet.

If you turn on Include advanced error reporting and handling, the irx_err signal reflects CRC24 errors that are associated with a data or control burst. Some CRC24 errors might be an indication of one of the following conditions:

- Loss of lane alignment
- Illegal control word
- Illegal framing pattern
- Missing SOP or EOP indicator

If you turn on Include advanced error reporting and handling, the irx_err output signal is aligned with irx_eob. If you do not turn on this parameter, the value on the irx_err output signal is invalid and should be ignored.

The irx_err signal indicates where an error occurs. The IP core asserts this signal only if an error occurs in an identifiable burst. Corruption can occur at the SOP of the current packet, in some later cycle in the payload of the current packet, in a packet that is interleaved with the current packet, or in the current EOP cycle. However, the IP core asserts the irx_err signal only in a subset of these cases. If the current EOP cycle data is corrupted so badly that the EOP indication is missing, or if an error occurs during an IDLE cycle, the IP core does not assert the irx_err signal.
For CRC24 errors, you should use the `crc24_err` status signal, rather than relying on the `irx_err` signal, in the following situations:

- If you monitor the link when only Idle control words are being received (no data is flowing), you should monitor the real time status signal `crc24_err`.
- If you maintain a count of CRC24 errors, you should monitor the number of times that the real time status signal `crc24_err` is asserted.
- If you turn off Include advanced error reporting and handling, `crc24_err` is your only indicator of CRC24 errors.

Related Information
Include Advanced Error Reporting and Handling on page 3-3

100G Interlaken IP Core Receiver Side Example With Errors and In-Band Calendar Bits
Figure 4-12: 100G Interlaken IP Core Receiver Side Single Segment Example With irx_err Errors

This example illustrates the expected behavior of the 100G Interlaken IP core application interface receive signals during a packet transfer in single segment mode with CRC or other errors. In the example, the errored packet transfer is followed by two idle cycles and a non-errored packet transfer.

This figure illustrates the attempted transfer of a 179-byte packet on the RX user data transfer interface to channel 2, after the 100G Interlaken IP Core receives the packet on the Interlaken link and detects corruption. Following the errored packet, the IP core transfers an uncorrupted packet to channel 3.

In cycle 1, the 100G Interlaken IP Core asserts `irx_sop[1]` when data is ready on `irx_dout_words`. When the 100G Interlaken IP Core asserts `irx_sop[1]`, it also asserts the correct value on `irx_chan` to tell the application the data channel destination of the data. In this example, the value 2 on `irx_chan` tells the application that the data should be sent to channel number 2.

During the SOP cycle (labeled with data value d1) and the cycle that follows the SOP cycle (labeled with data value d2), the 100G Interlaken IP Core holds the value of `irx_num_valid[7:4]` at 4'b1000. In the...
following clock cycle, labeled with data value d3, the 100G Interlaken IP Core holds the following values on critical output signals:

- \text{irx\_num\_valid}[7:4] \text{ at the value of } 4'b0111 \text{ to indicate the current data symbol contains seven 64-bit words of valid data.}
- \text{irx\_eopbits}[3] \text{ high to indicate the current cycle is an EOP cycle.}
- \text{irx\_eopbits}[2:0] \text{ at the value of } 3'b011 \text{ to indicate that only three bytes of the final valid data word are valid data bytes.}

This signal behavior, in the absence of the \text{irx\_err} flag, would correctly transfer a data packet with the total packet length of 179 bytes from the 100G Interlaken IP Core.

However, the 100G Interlaken IP Core marks the burst as errored by asserting the \text{irx\_err} signal, even though the \text{irx\_eopbits} signal would appear to indicate the packet is valid.

The application is responsible for discarding the errored packet when it detects that the IP core has asserted the \text{irx\_err} signal.

Following the corrupted packet, the IP core waits two idle cycles and then transfers a valid 139-byte packet.

- \textbf{100G Interlaken IP Core Packet Mode Operation Example} on page 4-12
  The first data transfer in the current example is the receiver interface equivalent of the transmitter interface transfer example described at this link.
- \textbf{In-Band Calendar Bits on the 100G Interlaken IP Core Receiver User Data Interface} on page 4-26
  Description of in-band calendar bits on the RX user data transfer interface.

\section*{In-Band Calendar Bits on the 100G Interlaken IP Core Receiver User Data Interface}

The 100G Interlaken IP core receiver logic decodes incoming control words (both Burst control words and Idle control words) on the incoming Interlaken link. If you turn on \textbf{Include in-band flow control functionality}, the receiver logic extracts the calendar pages from the In-Band Flow Control bits and assembles them into the \text{irx\_calendar} output signal. If you turn off \textbf{Include in-band flow control functionality}, the IP core sets all the bits of \text{irx\_calendar} to the value of 1, indicating that the IP core is not flow controlling the incoming data on the Interlaken link.

The 100G Interlaken IP core receives the most significant calendar page in a control word with the Reset Calendar bit set, indicating the beginning of the calendar page sequence. The mapping of bits from the control words to the \text{irx\_calendar} output signal is consistent with the mapping of bits from the \text{itx\_calendar} input signal to the control words.

On the RX side, your application is responsible for mapping the calendar pages to the corresponding channels, according to any interpretation agreed upon with the Interlaken link partner application in sideband communication. On the TX side, your application is responsible for throttling the data it transfers to the TX user data transfer interface, in response to the agreed upon interpretation of the \text{irx\_calendar} bits.

Related Information

- \textbf{100G Interlaken IP Core In-Band Calendar Bits on Transmit Side} on page 4-17
- \textbf{100G Interlaken IP Core Receiver Side Example With Errors and In-Band Calendar Bits} on page 4-25
  Example of in-band calendar bits usage on the RX user data transfer interface.
The 100G Interlaken IP core receive data path has the following four main functional blocks:

100G Interlaken IP Core RX PMA on page 4-27
100G Interlaken IP Core RX PCS on page 4-27
100G Interlaken IP Core RX MAC on page 4-28
100G Interlaken IP Core RX Regroup Block on page 4-28

100G Interlaken IP Core RX PMA

The 100G Interlaken MegaCore function RX PMA deserializes data that the IP core receives on the serial lines of the Interlaken link.

100G Interlaken IP Core RX PCS

RX PCS logic is an embedded hard macro and does not consume FPGA soft logic elements.

The 100G Interlaken MegaCore function RX PCS block performs the following functions to retrieve the data:

- Detects word lock and word synchronization.
- Checks running disparity.
- Reverses gearboxing and 64/67B encoding.
- Descrambles the data.
- Delineates meta frame boundaries.
- Performs CRC32 checking.
- Sends lane status information to the calendar and status blocks, if Include in-band flow control functionality is turned on.
100G Interlaken IP Core RX MAC

To recover a packet or burst, the RX MAC takes data from each of the PCS lanes and reassembles the packet or burst.

The 100G Interlaken MegaCore function RX MAC performs the following functions:

- Data de-striping, including lane alignment and burst assembly from the PCS lanes.
- CRC24 validation
- Calendar recovery, if Include in-band flow control functionality is turned on

100G Interlaken IP Core RX Regroup Block

The 100G Interlaken MegaCore function RX regroup block performs the following functions:

- Translates the IP core internal data format to the outgoing user application data irx_data format.
- Implements domain crossing from the rx_mac_clk clock domain to the rx_usr_clk clock domain.

**Note:** Regroup block requires the upstream logic to send packets with the minimum BURSTMIN and BURSTSHORT parameter setting as 64 bytes.
The 100G Interlaken MegaCore function communicates with the surrounding design through multiple external signals.

<td>Output</td>
<td>1</td>
<td>Synchronous reset signal that the IP core asserts high while the transmitter is initializing. This signal is synchronous with clk_tx_common. This signal goes low to indicate that the transceiver PLL has locked to the reference clock. The TX PCS and the TX MAC are held in reset while the srst_tx_common reset signal is asserted. You can use this signal for diagnostic purposes.</td>
</tr>
<tr>
<td>srst_rx_common</td>
<td>Output</td>
<td>1</td>
<td>Synchronous reset that is active at startup. This signal is synchronous with clk_rx_common. This signal goes low to indicate that the transceiver PLL has achieved lock and the recovered clock has locked to data in normal operation, this signal is deasserted after the transceiver completes its reset sequence. The RX PCS and the RX MAC are held in reset while the srst_rx_common reset signal is asserted. This signal is also active in the event of a serious clock data recovery failure on any of the RX lanes.</td>
</tr>
<tr>
<td>tx_usr_srst</td>
<td>Output</td>
<td>1</td>
<td>Transmit side reset output signal. Indicates the transmit side user data interface is resetting. This signal is synchronous with tx_usr_clk. Your application can use this signal to reset any status counters you may maintain in the tx_usr_clk domain.</td>
</tr>
<tr>
<td>rx_usr_srst</td>
<td>Output</td>
<td>1</td>
<td>Receive side reset output signal. Indicates the receive side user data interface is resetting. This signal is synchronous with rx_usr_clk. Your application can use this signal to reset any status counters you may maintain in the rx_usr_clk domain.</td>
</tr>
</tbody>
</table>
100G Interlaken IP Core User Data Transfer Interface Signals

Table 5-4: 100G Interlaken IP Core User Data Transfer Interface

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Width (Bits)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>itx_chan</td>
<td>Input</td>
<td>8</td>
<td>Transmit logic channel number. The IP core supports up to 256 channels. The 100G Interlaken IP core samples this value only when a bit of itx_sop or itx_sob is high and itx_num_valid has a non-zero value.</td>
</tr>
<tr>
<td>itx_num_valid</td>
<td>Input</td>
<td>8</td>
<td>itx_num_valid[7:4] specifies the number of valid 64-bit words in the current packet in the current data symbol. The maximum value of itx_num_valid[7:4] is eight, because a data symbol on the 512 bit wide data path has eight words (8 x 64 bits = 512 bits). In non-valid cycles, you must set the value of itx_num_valid[7:4] to zero. In valid cycles, you must set the value of itx_num_valid[7:4] as follows: • 4'b1000: if all eight words contain valid data from the current packet. • 4'b0xxx: where xxx indicates the number of valid words that are part of the current packet, if the number is less than eight. Data is always MSB aligned (left aligned). For example, the value of 4'b0111 indicates that word 0 (bit [63:0]) is not valid. In dual segment mode, if the value of itx_num_valid[7:4] is four or less (but not zero), the application can hold itx_num_valid[2] high to indicate the current data symbol also includes the first four 64-bit words of a new packet. The only valid values for itx_num_valid[3:0] are 4'b0100 and 4'b0000. When itx_num_valid[3:0] has the value of 4'b0100, you must also hold itx_sop[0] high. You must set the value of itx_num_valid to zero in all non-valid cycles, even when itx_ready is not asserted.</td>
</tr>
<tr>
<td>itx_sop</td>
<td>Input</td>
<td>2</td>
<td>Indicates the current data symbol on itx_din_words contains the start of a packet (SOP). This signal has the following valid values: • 2'b00—The current data symbol does not contain the start of a packet. • 2'b10—If itx_sop[1] has the value of 1, the start-of-packet aligns with the most significant byte (byte 63) of the data. • 2'b01—If itx_sop[0] has the value of 1, the start-of-packet aligns with byte 31 of the data.</td>
</tr>
<tr>
<td>Signal Name</td>
<td>Direction</td>
<td>Width (Bits)</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>--------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| itx_eopbits         | Input     | 4            | Indicates whether the current data symbol contains the end of a packet (EOP) with or without an error, and specifies the number of valid bytes in the current end-of-packet, non-error 8-byte data word, if relevant. You must set the value of `itx_eopbits` as follows:
  - 4'b0000: no end of packet, no error.
  - 4'b0001: Error and end of packet.
  - 4'b1xxx: End of packet. xxx indicates the number of valid bytes in the final valid 8-byte word of the packet, as follows:
    - 3'b000: all 8 bytes are valid.
    - 3'b001: 1 byte is valid.
    - ...
    - 3'b111: 7 bytes are valid.
  All other values (4'b01xx, 4'b001x) are undefined.
  The valid bytes always start in bit positions [63:56] of the final valid data word of the packet. |
| itx_sob             | Input     | 2            | Indicates the current data symbol contains the start of a burst (SOB). If the 100G Interlaken IP core is in Interleaved mode, you are responsible for providing this start of the burst signal. If the 100G Interlaken IP core is in Packet mode, the IP core ignores this signal. The 100G Interlaken IP core samples the `itx_chan` signal during this cycle.
  This signal has the following valid values:
  - 2'b00—The current data symbol does not contain the start of a burst.
  - 2'b10—If `itx_sob[1]` has the value of 1, the start-of-burst aligns with the most significant byte (byte 63) of the data.
  - 2'b01—If `itx_sob[0]` has the value of 1, the start-of-burst aligns with byte 31 of the data.
  Typically, you use this mode for sending interleaved packets. However, you can still send non-interleaved packets as long as you provide the `itx_sob` and `itx_eob` signal values. You are responsible to comply with the BurstMax and BurstMin parameters. If the burst you send is too large, it can overflow the 100G Interlaken transmit buffer. |
| itx_eob             | Input     | 1            | End of the burst. If the 100G Interlaken IP core is in Interleaved mode, you are responsible for providing this end of the burst signal. If the 100G Interlaken IP core is in Packet mode, the IP core ignores this signal. You are responsible to comply with the BurstMax and BurstMin parameters. |
| itx_din_words       | Input     | 512          | The eight 64-bit words of input data (one data symbol). When `itx_num_valid` has the value of zero, the IP core ignores `itx_din_words`. |
### 100G Interlaken IP Core User Data Transfer Interface Signals

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Width (Bits)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>itx_calendar</td>
<td>Input</td>
<td>16 N</td>
<td>Multiple pages (16 bits per page) of calendar input bits. The 100G Interlaken IP Core copies these bits to the in-band flow control bits in N control words that it sends on the Interlaken link. N is the value of the <strong>Number of calendar pages</strong> parameter, which can be any of 1, 2, 4, 8, or 16. This signal is synchronous with tx_usr_clk, although it is not part of the user data transfer protocol.</td>
</tr>
<tr>
<td>itx_ready</td>
<td>Output</td>
<td>1</td>
<td>Flow control signal to back pressure transmit traffic. When this signal is high, you can send traffic to the IP core. When this signal is low, you should stop sending traffic to the IP core within one to four cycles. You can consider the inverse of itx_ready to be a FIFO-almost-full indicator. In full duplex mode, itx_ready is low when rx_lanes_aligned is low.</td>
</tr>
</tbody>
</table>
| itx_ifc_err   | Output    | 1            | Indicates the transmit side user data transfer interface received traffic that the 100G Interlaken IP Core does not support. The IP core asserts the itx_ifc_err signal in the following cases:  
- In Interleaved mode, the IP core receives a burst that exceeds the size of MaxBurst.  
- itx_sop or itx_sob has the invalid value of 2'b11 in a valid data cycle.  
- Two instances of non-zero itx_sop (a start of packet), or two instances of non-zero itx_sob (a start of burst), are separated by fewer than 64 bytes.  
The IP core asserts the itx_ifc_err signal for a single clock cycle. The signal pulses within the current burst, with a delay of one or two cycles after the error on the transmit side user data transfer interface. |
<p>| irx_chan      | Output    | 8            | Receive logic channel number. The IP core supports up to 256 channels. You should sample this value when a bit of irx_sop or irx_sob is high and irx_num_valid has a non-zero value. |</p>
<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Width (Bits)</th>
<th>Description</th>
</tr>
</thead>
</table>
| irx_num_valid | Output    | 8            | irx_num_valid[7:4] specifies the number of valid 64-bit words in the current packet in the current data symbol. The maximum value of irx_num_valid[7:4] is eight, because a data symbol on the 512 bit wide data path has eight words (8 x 64 bits = 512 bits). In valid cycles, the IP core sets the value of irx_num_valid[7:4] as follows:  
  • 4'b1000: if all eight words contain valid data from the current packet.  
  • 4'b0xxx: where xxx indicates the number of valid words that are part of the current packet, if the number is less than eight. Data is always MSB aligned (left aligned). For example, the value of 4'b0111 indicates that word 0 (bit [63:0]) is not valid.  
In dual segment mode, if the value of irx_num_valid[7:4] is four or less (but not zero), the IP core can hold irx_num_valid[2] high to indicate the current data symbol also includes the first four 64-bit words of a new packet. The only valid values for irx_num_valid[3:0] are 4'b0100 and 4'b0000.  
When irx_num_valid[3:0] has the value of 4'b0100, the IP core also holds irx_sop[0] high.  
The IP core sets the value of irx_num_valid to zero in all non-valid cycles. |
| irx_sop       | Output    | 2            | Indicates the current data symbol on irx_dout_words contains the start of a packet (SOP). This signal has the following valid values:  
  • 2'b00—The current data symbol does not contain the start of a packet.  
  • 2'b10—If irx_sop[1] has the value of 1, the start-of-packet aligns with the most significant byte (byte 63) of the data.  
  • 2'b01—If irx_sop[0] has the value of 1, the start-of-packet aligns with byte 31 of the data. This value is valid only in variations configured in dual segment mode. |
<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Width (Bits)</th>
<th>Description</th>
</tr>
</thead>
</table>
| irx_eopbits      | Output    | 4            | Indicates whether the current data symbol contains the end of a packet (EOP) with or without an error, and specifies the number of valid bytes in the current end-of-packet, non-error 8-byte data word, if relevant. The IP core sets the value of `irx_eopbits` as follows:  
- 4b'0000: no end of packet, no error.  
- 4b'0001: Error and end of packet.  
- 4b'1xxx: End of packet. xxx indicates the number of valid bytes in the final valid 8-byte word of the packet, as follows:  
  - 3b'000: all 8 bytes are valid.  
  - 3b'001: 1 byte is valid.  
  - ...  
  - 3b'111: 7 bytes are valid. All other values (4'b01xx, 4'b001x) are undefined and are not generated by the IP core. The valid bytes always start in bit positions [63:56] of the final valid data word of the packet. |
| irx_sob          | Output    | 2            | Start of the burst. The 100G Interlaken IP core indicates the start of the burst. The signal `irx_channel` is only valid when `irx_sob` is high. This signal toggles in Packet Mode and in Interleaved Mode. This signal has the following valid values:  
- 2'b00—The current data symbol does not contain the start of a burst.  
- 2'b10—If `irx_sob[1]` has the value of 1, the start-of-burst aligns with the most significant byte (byte 63) of the data.  
- 2'b01—If `irx_sob[0]` has the value of 1, the start-of-burst aligns with byte 31 of the data. |
<p>| irx_eob          | Output    | 1            | End of the burst. The 100G Interlaken IP core indicates the end of the burst. This signal toggles in Packet Mode and in Interleaved Mode.                                                                                                                                                                                                  |
| irx_dout_words   | Output    | 512          | The eight 64-bit words of output data (one data symbol). When <code>irx_num_valid</code> has the value of zero, you should ignore <code>irx_dout_words</code>.                                                                                                                                                                                                  |
| irx_calendar     | Output    | 16 × N       | Multiple pages (16 bits per page) of calendar output bits. The value is the in-band flow control bits from N control words on the incoming Interlaken link. N is the value of the Number of calendar pages parameter, which can be any of 1, 2, 4, 8, or 16. This signal is synchronous with <code>rx_usr_clk</code>, although it is not part of the user data transfer protocol. |</p>

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Width (Bits)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>burst_max_in</td>
<td>Input</td>
<td>4</td>
<td>Encodes the BurstMax parameter for the IP core. The actual value of the BurstMax parameter must be a multiple of 64 bytes. While traffic is present, this input signal should remain static. However, when no traffic is present, you can modify the value of the burst_max_in signal to modify the BurstMax value of the IP core. The 100G InterlakenIP core supports the following valid values for this signal: 2: 128 bytes 4: 256 bytes 8: 512 bytes</td>
</tr>
<tr>
<td>burst_short_in</td>
<td>Input</td>
<td>4</td>
<td>Encodes the BurstShort parameter for the IP core. The 100G Interlaken IP core supports the following valid value for this parameter: 2: 64 bytes In general, the presence of the BurstMin parameter makes the BurstShort parameter obsolete.</td>
</tr>
<tr>
<td>burst_min_in</td>
<td>Input</td>
<td>4</td>
<td>Encodes the BurstMin parameter for the IP core. The IP core supports the following valid values for this signal: 0: Disable optional enhanced scheduling. Altera recommends you do not drive this value in variations in dual segment mode. If you disable enhanced scheduling, performance is non-optimal. 2: 64 bytes 4: 128 bytes The BurstMin parameter should have a value that is less than or equal to half of the value of the BurstMax parameter. Altera recommends that you modify the value of this input signal only when no traffic is present on the TX user data interface. You do not need to reset the IP core.</td>

### 100G Interlaken IP Core Management Interface

The 100G Interlaken IP core management interface allows you to communicate with IP core internal status and control registers. This interface manages the PMA (resets and serial loopback controls) and PCS control and status registers. This interface does not provide access to the hard PCS registers on the device.

The management interface is a typical 32-bit memory-mapped register port. It complies with the Avalon Memory-Mapped (Avalon-MM) specification defined in the *Avalon Interface Specifications*.

#### Table 5-6: 100G Interlaken IP Core Management Interface Signals

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Width (Bits)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mm_clk</td>
<td>Input</td>
<td>1</td>
<td>Management clock. Clocks the register accesses. It is also used for clock rate monitoring and some analog calibration procedures. You must run this clock at a frequency in the range of 100 MHz–125 MHz.</td>
</tr>
<tr>
<td>mm_read</td>
<td>Input</td>
<td>1</td>
<td>Read access to the register ports.</td>
</tr>
<tr>
<td>mm_write</td>
<td>Input</td>
<td>1</td>
<td>Write access to the register ports.</td>
</tr>
<tr>
<td>mm_addr</td>
<td>Input</td>
<td>16</td>
<td>Address to access the register ports.</td>
</tr>
<tr>
<td>mm_rdata</td>
<td>Output</td>
<td>32</td>
<td>When mm_rdata_valid is high, mm_rdata holds valid read data.</td>
</tr>
<tr>
<td>mm_rdata_valid</td>
<td>Output</td>
<td>1</td>
<td>Valid signal for mm_rdata.</td>
</tr>
<tr>
<td>mm_wdata</td>
<td>Input</td>
<td>32</td>
<td>When mm_write is high, mm_wdata holds valid write data.</td>
</tr>
</tbody>
</table>

If you do not use the management interface, drive the management inputs as follows:

- **mm_clk** must connect to a stable clock. However, the clock signal need not be of unusually high quality.
- **mm_read** and **mm_write** must be tied to zero.
If you use the management interface, drive the control lines as shown in the examples and observing the following constraints:

- During a write operation, you must maintain the mm_write signal asserted for at least two clock cycles. Back-to-back writes must be separated by at least one clock cycle.
- During a read operation, you must maintain the mm_read signal asserted for at least two clock cycles. Back-to-back reads must be separated by at least one clock cycle.

**Figure 5-1: 100G Interlaken IP Core Management Interface Write Operation**

Shows the timing requirements for a write operation on the 100G Interlaken IP core management interface.

**Figure 5-2: 100G Interlaken IP Core Management Interface Read Operation**

Shows the timing requirements for a read operation on the 100G Interlaken IP core management interface. The IP core asserts the mm_rdata_valid signal two cycles after the mm_read signal is asserted.

**Related Information**

- **Avalon Interface Specifications**

**Device Dependent Signals**

Some of the 100G Interlaken MegaCore function signals depend on the device that your variation targets. Variations that target an Arria V device or a Stratix V device have an interface to connect to an Altera Transceiver Reconfiguration Controller that you must instantiate outside the 100G Interlaken IP core for successful functioning in hardware. Variations that target an Arria 10 device have Arria 10-specific
requirements to support the Arria 10 transceivers. The following 100G Interlaken IP core interfaces are device specific:

**Transceiver Reconfiguration Controller Interface Signals** on page 5-15

**Arria 10 External PLL Interface Signals** on page 5-15

**Arria 10 Transceiver Reconfiguration Interface Signals** on page 5-16

**Transceiver Reconfiguration Controller Interface Signals**

100G Interlaken IP core variations that target an Arria V or a Stratix V device require an external reconfiguration controller to function correctly in hardware. 100G Interlaken IP core variations that target an Arria 10 device include a reconfiguration controller block and do not require an external reconfiguration controller.

<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Width (Bits)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reconfig_to_xcvr</td>
<td>Input</td>
<td>70 bits per reconfiguration interface.</td>
<td>Bus from the external transceiver reconfiguration controller to the 100G Interlaken IP core. The bus includes signals from multiple transceiver reconfiguration interfaces. **Arria 10 External PLL Interface Signals**

100G Interlaken IP core variations that target an Arria 10 device require an external transceiver PLL to function correctly in hardware. 100G Interlaken IP core variations that target an Arria V or Stratix V device include the transceiver PLLs and do not require that you configure any additional PLLs.

### Arria 10 Transceiver Reconfiguration Interface Signals

The 100G Interlaken IP core Arria 10 transceiver reconfiguration interface allows you to communicate with Arria 10 hard PCS registers. This interface is available only in variations that target an Arria 10 device. You use this interface to reconfigure the transceiver and to take advantage of built-in transceiver features that the 100G Interlaken IP Core supports for IP core testing. The interface allows you to address a single register in a single transceiver channel at one time.

The Arria 10 transceiver reconfiguration interface is a typical 32-bit memory-mapped register port. It complies with the Avalon Memory-Mapped (Avalon-MM) specification defined in the *Avalon Interface Specifications*.

**Related Information**

Avalon Interface Specifications
Depending on the features you turn on in the 100G Interlaken parameter editor, your 100G Interlaken IP core supports the following test features:

**Internal Serial Loopback Mode** [page 7-1]

The 100G Interlaken IP core supports an internal TX to RX serial loopback mode.

**External Loopback Mode** [page 7-2]

The 100G Interlaken IP core operates correctly in an external loopback configuration.

**PRBS Generation and Validation** [page 7-2]

**CRC32 Error Injection** [page 7-7]

**CRC24 Error Injection** [page 7-8]

### Internal Serial Loopback Mode

The 100G Interlaken IP core supports an internal TX to RX serial loopback mode.

To turn on internal serial loopback:

- Reset the IP core by asserting and then deasserting the active low `reset_n` signal.
- After reset completes, set the value of bits `[NUM_LANES-1:0]` of the `LOOPBACK` register at offset `0x12` to all ones.

**Note:** Refer to "IP Core Reset" for information about the required wait period for register access.

- Monitor the RX lanes aligned bit (bit 0) of the `ALIGN` register at offset `0x20` or the `rx_lanes_aligned` output signal. After the RX lanes are aligned, the IP core is in internal serial loopback mode.

Resetting the IP core turns off internal serial loopback. To turn off internal serial loopback:

- Reset the IP core by asserting and then deasserting the active low `reset_n` signal. Resetting the IP core sets the value of bits `[NUM_LANES-1:0]` of the `LOOPBACK` register at offset `0x12` to all zeroes.
- Monitor the RX lanes aligned bit (bit 0) of the `ALIGN` register at offset `0x20` or the `rx_lanes_aligned` output signal. After the RX lanes are aligned, the IP core is in normal operational mode.

### Related Information

**IP Core Reset** [page 4-5]

Describes the required delay from reset to successful register access attempts.
External Loopback Mode

The 100G Interlaken IP core operates correctly in an external loopback configuration.

To put the IP core in external loopback mode, connect the TX lanes to the RX lanes of the IP core. This mode does not require any special programming of the IP core.

PRBS Generation and Validation

The 100G Interlaken IP core supports generation and validation of several predetermined pseudo-random binary sequences (PRBS) for Interlaken link testing.

This feature is available if you turn on Include diagnostic features in the 100G Interlaken parameter editor.

Table 7-1: PRBS Polynomials Available in the 100G Interlaken IP Core

</table>

For instructions to activate and use the PRBS test feature in your 100G Interlaken IP core IP core, refer to one of the following two topics:

Setting up PRBS Mode in Arria V and Stratix V Devices on page 7-2

Setting up PRBS Mode in Arria 10 Devices on page 7-4

Setting up PRBS Mode in Arria V and Stratix V Devices

To enable the IP core to generate PRBS output, you must program the relevant hard PCS registers to enable the PRBS generator clock, to set the test_enable bit, and to select the PRBS polynomial. To enable the IP core to receive PRBS input, you must program the relevant hard PCS registers to enable the PRBS receiver clock, to set the test_enable bit, and to select the expected PRBS polynomial. If you perform your PRBS testing in loopback mode, you must enable the IP core to both generate and receive PRBS sequences.

The PRBS feature is available only if you turn on Include diagnostic features in the 100G Interlaken parameter editor.

This section describes the register values you must program. For instructions to program the registers that activate the PRBS test feature in your Arria V or Stratix V 100G Interlaken IP core, refer to the hard PCS register programming instructions in the Native PHY IP Core chapter for your target device family and in the Transceiver Reconfiguration Controller chapter of the *Altera Transceiver PHY IP Core User Guide.*
To turn on the PRBS feature in the hard PCS, you must program the following hard PCS registers in the order shown, for each of the TX and RX sides. These registers are not accessible using the 100G Interlaken IP core Management interface. You must access these registers through the Transceiver Reconfiguration Controller that connects to the IP core.

Ensure you set these register bits using a read-modify-write register access sequence (per register), to avoid modifying the other register fields.

After you activate an IP core that targets an Arria V or Stratix V device to generate PRBS output, it immediately begins transmitting PRBS output on the Interlaken link. After you enable the IP core to
receive PRBS input, you can check the receive PRBS status in the 100G Interlaken IP core PRBS status registers (RX_PRBS_DONE, RX_PRBS_ERR, and RX_PRBS_COUNT).

After your testing is complete, you must reset these register bits to their default values to enable normal operation.

### Setting up PRBS Mode in Arria 10 Devices

To enable the IP core to generate PRBS output, for each Interlaken lane, you must program the relevant hard PCS registers to enable the PRBS generator clock, to set the test_enable bit, and to select the PRBS polynomial. To enable the IP core to receive PRBS input, for each Interlaken lane, you must program the relevant hard PCS registers to enable the PRBS receiver clock and to select the expected PRBS polynomial, in addition to some bookkeeping tasks. If you perform your PRBS testing in loopback mode, you must enable the IP core to both generate and receive PRBS sequences. After you set the hard PCS registers for PRBS mode, you must perform a soft reset of the transceiver.

The PRBS feature is available only if you turn on Include diagnostic features in the 100G Interlaken parameter editor.

This section describes the register values you must program. For instructions to program the registers that activate the PRBS test feature in your Arria 10 100G Interlaken IP core, refer to the hard PCS register information in the *Arria 10 Transceiver PHY User Guide*. You program the hard PCS registers using the 100G Interlaken IP core Arria 10 transceiver reconfiguration interface.

### Table 7-3: Programming the Hard PCS Registers in Arria 10 Devices

To turn on the PRBS feature in the hard PCS for IP core variations that target an Arria 10 device, you must program the following hard PCS registers in the order shown, for each of the TX and RX sides. These registers are not accessible using the 100G Interlaken IP core management interface. You must access these registers through the Arria 10 transceiver reconfiguration interface of the 100G Interlaken IP core.

Ensure you set these register bits using a read-modify-write register access sequence (per register), to avoid modifying the other register fields.

After you enable the IP core to generate or receive PRBS output, by setting the relevant register field values for each Interlaken lane, you must perform a soft reset of the transceiver transmitters and receivers. To perform a soft reset of the transceiver transmitters and receivers, on the 100G Interlaken IP core management interface, program bit [2] of the 100G Interlaken IP core `RESET` register at offset 0x13 with the value of 1. On the following `mm_clk` cycle, or later, program the bit 0x13[2] with the value of 0 to clear the reset. After you reset the transceivers and subsequently clear the reset bit, the IP core immediately begins transmitting PRBS output on the Interlaken link. You can check the receive PRBS status in the 100G Interlaken IP core PRBS status registers (`RX_PRBS_DONE`, `RX_PRBS_ERR`, and `RX_PRBS_COUNT`).

After your testing is complete, you must reset these register bits to their default values and perform the soft reset to enable normal operation.

CRC32 Error Injection

The 100G Interlaken IP core supports the injection of CRC32 errors on the Interlaken link for validation of the Interlaken link partner's error handling, and for validation of this IP core's error handling in a loopback configuration. Variations that target an Arria V or Stratix V device require that you first enable the feature in the hard PCS; variations that target an Arria 10 device do not require this step.

This feature is available if you turn on Include diagnostic features in the 100G Interlaken parameter editor.

To enable the CRC32 error injection feature in your 100G Interlaken IP core that targets an Arria V or Stratix V device, set the value of bit [15] of the hard PCS register at offset 0x138 (offset 0xC from the hard PCS base address of 0x12C) to the value of 1. Ensure you set the register bit using a read-modify-write register access sequence, to avoid modifying the other register fields. This step is not necessary in 100G Interlaken IP core devices that target an Arria 10 device, because CRC32 error injection is enabled by default in these variations.

For instructions to program the hard PCS registers in Arria V and Stratix V devices, refer to the Native PHY IP Core chapter for your target device family and to the Transceiver Reconfiguration Controller chapter of the Altera Transceiver PHY IP Core User Guide.

After you enable the IP core to inject CRC32 errors in the output to the Interlaken link, you can turn on the feature using the 100G Interlaken IP core CRC32_ERR_INJECT register. You must maintain each register bit at the value of 1 for the duration of a Meta Frame, at least, to ensure that the IP core transmits at least one CRC32 error on the corresponding lane.

After your testing is complete, in Arria V and Stratix V devices, you must reset the hard PCS register bit to its default value of zero to enable normal operation.

The 100G Interlaken IP core CRC32 error injection feature does not keep a count of the errors injected.

CRC24 Error Injection

The 100G Interlaken IP core supports the injection of CRC24 errors on the Interlaken link for validation of the Interlaken link partner's error handling, and for validation of this IP core's error handling in a loopback configuration.

This feature is available if you turn on Include diagnostic features in the 100G Interlaken parameter editor.

To force the IP core to inject a bit error in the output to the Interlaken link, you write the value of 1 to bit [0] of the 100G Interlaken IP core ERR_INJECT register at offset 0x102. This change to the register field value forces the IP core to inject a single bit error, which will cause one or possibly more CRC24 errors.

Before you can inject a second bit error, you must write the value of 0 to the register. Altera recommends that you write the value of 1 and then the value of 0 to inject a single bit error, rather than waiting until you want to inject a second error before writing the value of 0 to clear the register.
Advanced users can further customize the 100G Interlaken IP core by modifying hidden parameters that are not displayed in the 100G Interlaken parameter editor. These parameters can only be modified in the Verilog RTL instantiation in the generated ilk_core.sv file and the instantiation of the 100G Interlaken IP core in the top level design file.

The following topics describe the hidden parameters and tell you how to modify their values.

Hidden Parameters on page 8-1
Modifying Hidden Parameter Values on page 8-3

Hidden Parameters

The advanced parameters affect the behavior of the 100G Interlaken MegaCore function.

Note: Altera recommends that you do not modify any RTL parameters that are not listed here. Some undocumented modifications might overwrite settings you specify in the parameter editor.

To customize your 100G Interlaken MegaCore function, you can modify parameters to specify the following properties:

Include Temp Sense on page 8-1
RXFIFO Address Width on page 8-2
SWAP_TX_LANES and SWAP_RX_LANES (Data Word Lane Swapping) on page 8-2

Include Temp Sense

The Include Temp Sense parameter specifies whether the IP core includes logic to sense the device's case temperature. If the value is set to 1, the IP core is configured with internal temperature sensing. If the value is set to 0, this logic is synthesized away.

This parameter is not available in IP core variations that target an Arria 10 device.

The default value of this parameter is 1.

Related Information
Modifying Hidden Parameter Values on page 8-3
RXFIFO Address Width

The **RXFIFO Address Width** parameter specifies the number of bits in the address (offset) of an entry in the RX Reassembly FIFO. The number of bits is \( \log_2 \) of the depth of this FIFO. Each RX Reassembly FIFO entry is a 64-bit word.

The default value for the **RXFIFO Address Width** parameter is 12, specifying this FIFO can hold \( 2^{12} \) (==4K) 64-bit words. Adjusting this parameter may affect your ability to close timing for your design. However, you can adjust this parameter subject to the successful closure of the timing.

**Related Information**

*Modifying Hidden Parameter Values* on page 8-3

SWAP_TX_LANES and SWAP_RX_LANES (Data Word Lane Swapping)

The 100G Interlaken IP core supports a lane reversal feature (lane swapping). Lane swapping parameters determine the order in which blocks are distributed and gathered from the lanes. The 100G Interlaken IP core provides the following two options for the lane order:

- **Straight Lane order.** The transmitter sends Interlaken blocks sequentially across the lanes starting with the top lane, ending with Lane 0. The receiver takes in Interlaken blocks starting with the top lane, ending with Lane 0.

  ![Figure 8-1: Straight Lane Order](image)

  - Lane N
  - Lane (N-1)
  - Lane (N-2)
  - Lane (N-3)
  - Lane 2
  - Lane 1
  - Lane 0

- **Swapped Lane order.** The transmitter sends Interlaken blocks sequentially across the lanes starting with Lane 0, ending with Lane N. The receiver takes in Interlaken blocks starting with Lane 0, ending with Lane N.
Two parameters determine lane order:

SWAP_TX_LANES

SWAP_RX_LANES

When a parameter is set to 0, the 100G Interlaken IP core implements the Straight Lane order. When a parameter is set to 1, the 100G Interlaken IP core implements the Swapped Lane order. The TX and RX parameters are independent and can be set separately.

To conform with the Interlaken specification, the default value of SWAP_TX_LANES and SWAP_RX_LANES is 1.

**Note:** Running traffic with incompatible lane swapping configuration results in CRC24 errors and incorrect data at the receiver.

**Related Information**

*Modifying Hidden Parameter Values* on page 8-3

---

**Modifying Hidden Parameter Values**

To modify the value of a hidden parameter, you must edit one or more generated files. Every time you regenerate the 100G Interlaken IP core, the files are overwritten and you must edit them again.

**Table 8-1: Files to Edit to Modify the Value of a Hidden Parameter**

In each entry, the first file controls the RTL parameter value for synthesis, and the second file controls the RTL parameter value for simulation.

The 100G Interlaken MegaCore function includes logic to provide the out-of-band flow control functionality described in the Interlaken Protocol Specification, Revision 1.2, Section 5.3.4.2. This optional feature is intended for applications that require transmission rate control.

Figure 9-1: Out-of-Band Flow Control Block Interface

This figure lists the signals on the four interfaces of the out-of-band flow control block.

The out-of-band flow control block is provided as two separate modules that can be stitched to the 100G Interlaken IP core and user logic. You can optionally instantiate these blocks in your own custom logic. To enable the use of these out-of-band modules, the signals on the far left side of the figure must be connected to user logic, and the signals on the far right side of the figure should be connected to the complementary flow control blocks of the Interlaken link partner.

You must connect the out-of-band flow control receive and transmit interface signals to device pins.

**Related Information**

*Interlaken Protocol Specification, Revision 1.2*
To achieve 100G Ethernet line rates through the application interface of your 100G Interlaken IP core, you must run the transmit side and receiver side user interface clocks \( tx_{\text{usr clk}} \) and \( rx_{\text{usr clk}} \) at the following minimum required operating frequency:

- 300 MHz in single segment mode and in 24 lane variations\(^{(2)}\)
- 225 MHz in 12 lane variations in dual segment mode

The following discussion describes the packet rate calculation that supports this requirement.

**Figure A-1: Interlaken Ethernet Packet**

To transmit a minimum size (64-byte) Ethernet packet, the Interlaken link transmitter must send 672 bits of data.

<table>
<thead>
<tr>
<th>Preamble</th>
<th>Minimum Packet</th>
<th>Interpacket Gap</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 Bytes</td>
<td>64 Bytes</td>
<td>12 Bytes</td>
</tr>
</tbody>
</table>

672 Bits

To support an Ethernet line rate of 100Gb/s, the Interlaken link must process 1000 bits in 10ns. The following calculation derives the required clock frequency.

\[
100 \times 1,000,000,000 \text{ bits/sec} \div 672 = 148.8 \text{ million packets/sec} \\
\approx 150 \text{ million packets/sec}
\]

This packet rate requires that the user interface handle one packet per cycle if the operating clock runs at 150 MHz, or one packet per two cycles if the operating clock runs at 300 MHz.

In dual segment mode, because the final cycle of one packet can overlap with the initial cycle of another packet, the operating clock frequency requirements are derived from the average number of cycles

\(^{(2)}\) The restriction to a minimum of 300 MHz in dual segment mode in 24 lane variations is an artifact of the clocking scheme in this IP core.
required for a single packet in back-to-back traffic. The calculations that follow show that the minimum operating clock frequency in dual segment mode is 225 MHz.

The following figures explain the derivation of the minimum frequency requirements.

**Figure A-2: Packet Processing Requirements in Single Segment Mode**

A 65-byte packet comprises \((65 + 20) \times 8 = 680\) bits. Therefore, for traffic that consists mainly of 65-byte packets, the most inefficient traffic possible, the user interface must handle:

\[
100 \times 1,000,000,000 \text{ bits/sec} \div 680 = 147 \text{ Million packets/sec}, \text{ or one packet every 6.8 ns.}
\]

Case 2 in the single segment mode figure shows that the user interface requires two cycles to process each 65-byte packet. At 300 MHz, two cycles take 6.66 ns, which is a sufficiently small amount of time.

A 129-byte packet comprises \((129 + 20) \times 8 = 1192\) bits. Therefore, for traffic that consists mainly of 129-byte packets, the user interface must handle:

\[
100 \times 1,000,000,000 \text{ bits/sec} \div 1192 = 83.9 \text{ Million packets/sec}, \text{ or one packet every 11.9 ns.}
\]

Case 3 in the single segment mode figure shows that the user interface requires three cycles to process each 129-byte packet. At 300 MHz, three cycles take 10 ns, which is a sufficiently small amount of time.

The same calculations applied to lower frequencies yield an average time per packet that is not sufficiently short. Therefore, 300 MHz is the recommended frequency for the two user data transfer interface clocks in your single segment mode 100G Interlaken IP core. For logistical clocking reasons, this frequency is also recommended for your 24-lane variation in dual segment mode.

**Figure A-3: Packet Processing Requirements in Dual Segment Mode**

In dual segment mode, a 65-byte packet or a 129-byte packet can be followed in the same cycle by the first 32 bytes of the following packet. The table summarizes the numbers illustrated in the figure.
Table A-1: Packet Processing Time in Dual Segment Mode at 225 MHz

The time to process two consecutive packets at 225 MHz is simply the time taken by the relevant number of cycles at 225 MHz. The required maximum time per packet is derived in the discussion of the requirements for single segment mode.

<table>
<thead>
<tr>
<th>Packet Size (Bytes)</th>
<th>Processing Time</th>
<th>Required Maximum Time per Packet (ns) (derived earlier)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Number of Cycles for Two Consecutive Packets</td>
<td>At 225 MHz:</td>

<tr>
<td>65</td>
<td>3</td>
<td>13.33</td>
</tr>
<tr>
<td>129</td>
<td>5</td>
<td>22.23</td>
</tr>
</tbody>
</table>

Both of the average times per packet are sufficiently short, based on the packets per second requirements for the different sized packets (6.66 < 6.8 and 11.12 < 11.9). The same calculations applied to lower frequencies yield an average time per packet that is not sufficiently short. Therefore, 225 MHz is the recommended frequency for the two user data transfer interface clocks in your 12-lane, dual segment mode 100G Interlaken IP core.
This section provides additional information about the document and Altera.

### 100G Interlaken MegaCore Function User Guide Archives

If an IP core version is not listed, the user guide for the previous IP core version applies.

</thead>
<tbody>
<tr>
<td>2015.11.02</td>
<td>15.1</td>
<td>• Updated for new Quartus Prime software v15.1 release.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Added new <strong>Enable Native XCVR PHY ADME</strong> parameter for Arria 10 variations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Updated behavior of <code>irx_err</code> signal. In previous releases, this signal was asserted synchronously with <code>irx_eop</code>. Now it is asserted synchronously with <code>irx_eob</code>, and is only asserted if the IP core can identify the burst with which the error is associated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Updated with change in process to generate legacy testbench.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Added new Arria 10 hardware example design.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Updated generated directory structure for non-Arria 10 variations and location of testbench files for all variations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Corrected descriptions of TX out-of-band flow control interface signals <code>fc_clk</code>, <code>fc_data</code>, and <code>fc_sync</code> to indicate they are intended to connect to an upstream RX out-of-band block rather than a downstream block.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Corrected 100G Interlaken IP Core Transceiver Initialization Sequence figure. Corrected descriptions of use of <code>reset_n</code> signal to indicate user must assert (low) and deassert (raise) the signal to initiate the reset sequence.</td>
</tr>
<tr>
<td>2015.05.04</td>
<td>15.0</td>
<td>• Added new <strong>TX scrambler seed</strong> parameter in new section. Previously this parameter was hidden (<code>SCRAM_CONST</code>) and unavailable for Arria 10 devices. In the IP core version 15.0 and later, you must modify the scrambler seed from the parameter editor.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Improved description of <code>itx_ifc_err</code> output signal.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Improved description of <code>itx_hungry</code> output signal.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Updated filenames for hidden parameter editing to include the filenames for Arria 10 variations.</td>
</tr>
<tr>
<td>2014.12.15</td>
<td>14.1</td>
<td>• Updated release-specific information for the software release v14.1, including new resource utilization numbers and new Arria 10 speed grade notation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Updated for new Quartus II IP Catalog, which replaces the MegaWizard Plug-In Manager starting in the Quartus II software v14.0. Changes are located primarily in Getting Started With the 100G Interlaken IP Core chapter. Reordered the chapter to accommodate the new descriptions.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Fixed speed grade information for Arria 10 devices in Device Speed Grade Support section.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Removed <code>mm_clk_locked</code> signal. Signal is removed in the IP core v14.0 and later.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Corrected management interface read operation waveform and requirements. In the IP core v13.1 and later, the read data is valid two cycles after <code>mm_read</code> is asserted, not one cycle as was previously shown.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Corrected instructions to connect the external TX PLL to include the <code>tx_cal_busy</code> signal, and added example figure to illustrate the required connections between the IP core and an ATX PLL. Changes are located in Adding the External PLL section.</td>

</table>
| December 2013   | 13.1 Arria 10 Edition (2013.12.02)| - In relevant parameter description sections, removed note to ignore the compilation warnings if you turn off any of the following parameters. The issue is fixed in the SDC file in the IP core version 14.0 and later.  
  - **Include advanced error reporting and handling**  
  - **Enable M20K ECC support**  
  - **Include diagnostic features**  
  - **Include in-band flow control functionality**  
  - Removed **CNTR_BITS RTL** parameter. Parameter is removed in the IP core v14.0 and later.  
  - Added information to IP Core Reset section about the current required wait from reset to successful register access in IP Core Reset section.  
  - Corrected width of **reconfig_waitrequest** signal to one bit. This signal has been a single bit in all versions that support Arria 10 devices, starting with the IP core version 13.1 Arria 10 Edition.  
  - Corrected the text that describes the trade-offs between enabling and disabling the **Enable M20K ECC support** parameter.  
  - Added information about turning on and off loopback mode in two new sections, External Loopback Mode and Internal Serial Loopback Mode, in IP Core Test Features chapter.  
  - Clarified that the testbench and example design are generated only if you specify the IP core synthesis and simulation models are in Verilog HDL. The IP core does not support VHDL models, despite the fact that in the IP core v14.0 and later, the parameter editor appears to offer that option.  
  - Fixed assorted typos and formatting issues.  
  - Added preliminary support for Arria 10 devices.  
  - Documented features of new Arria 10 variations:  
    - User logic must configure external PLLs.  
    - IP core includes reconfiguration controller.  
    - IP core includes new Avalon-MM interface to program Arria 10 Native PHY IP core registers.  
    - IP core does not support all of the hidden parameters.  
    - IP core does not support temperature register and other registers related to unsupported parameters.  
    - IP core provides a different process to enable the PRBS and CRC32 error injection testing features in Arria 10 variations.  
  - Corrected recommended simulation value for **Meta frame length in words** parameter, from 64 (an unsupported value) to 128 (the minimum supported value). |
<table>

</tr>
</thead>
</table>
| November 2013 | 13.1 (2013.11.04) | • Documented change from **Received data format** to **Data format** parameter. If you select Single segment mode, the IP core can no longer handle incoming dual segment traffic on the TX client data interface.  
• Added information about the four new parameters:  
  - **Include advanced error reporting and handling**  
  - **Enable M20K ECC support**  
  - **Include diagnostic features**  
  - **Include in-band flow control functionality**  
• Documented new ECC feature for Arria 10 and Stratix V device M20K memory blocks, including four new registers:  
  - CNT_ERR_TX  
  - CNT_UNCOR_TX  
  - CNT_ERR_RX  
  - CNT_UNCOR_RX  
• Documented new diagnostic feature: CRC24 error injection, including the **new ERR_INJECT** register.  
• Added resource utilization information.  
• Updated IP core generation instructions to indicate the MegaWizard Plug-In Manager no longer prompts the user to generate or not generate the example design. Instead, the example design is generated in all cases.  
• Provided additional information about **TEMP_SENSE** register.  
• Corrected typo in width of **itx_hungry** signal.  
• Added OpenCore Plus feature support in Installation and Licensing section. |
| May 2013    | 13.0 (2013.05.06) | • Documented the new dual segment mode, including:  
  - New **Received data format** parameter in the 100G Interlaken parameter editor.  
  - Changed user data transfer signal widths.  
  - Added new **itx_ifc_err** signal.  
  - Expanded Fmax requirements discussion to include the dual segment mode case.  
• Documented the new **Transfer mode selection** parameter in the 100G Interlaken parameter editor. Previously this parameter was hidden (TX_PKTMOD_ONLY).  
• Documented new error handling features, including changes to and renaming of **irx_crc_24_err** signal to **irx_err**.  
• Added PRBS support. Changes include addition of new hard PCS registers.  
• Added support for CRC-32 error injection.  
• Updated device speed grade information.  
• Modified document format. |

| February 2013 | 12.1 SP1     | • Reformatted figures.  
• Modified Figure 4–1 on page 4–2, Figure 4–2 on page 4–4, Figure 5–1 on page 5–10, and Figure 5–2 on page 5–10 for readability.  
• Removed mention of OpenCore evaluation feature from “100G Interlaken IP Core Evaluation Features” on page 1–5 because the feature name caused confusion with the OpenCore Plus evaluation feature. The current and past descriptions of the evaluation features are correct.  
• Added default parameter values in Chapter 3, Parameter Settings and in Chapter 7, Advanced Parameter Settings.  
• Renamed Appendix A, Performance and Fmax Requirements for 100G Ethernet Traffic.  
• Consolidated information about 100G Interlaken MegaCore function license. All variations of this IP core are available if you have a single Altera license for this IP core.  
• Enhanced description of RX and TX data paths in new sections “Transmit Path Blocks” on page 4–9 and “Receive Path Blocks” on page 4–13.  
• Corrected location of “Receiver Side Timing Diagrams” on page 4–10 to “Receive Path” on page 4–10. |
| November 2012 | 12.1         | Initial release.                                                                                                                                |
