1. About the 25G Ethernet Intel FPGA IP Core

The Intel® Arria® 10 25G Ethernet Intel FPGA IP core implements the 25G & 50G Ethernet Specification, Draft 1.6 from the 25 Gigabit Ethernet Consortium and the IEEE 802.3by 25Gb Ethernet specification. The IP core includes an option to support unidirectional transport as defined in Clause 66 of the IEEE 802.3-2012 Ethernet Standard. The MAC client side interface for the 25G Ethernet Intel FPGA IP core is a 64-bit Avalon® Streaming (Avalon-ST) interface. It maps to one 25.78125 Gbps transceiver. The IP core optionally includes the IEEE 802.3-2018 Clause 108 Reed-Solomon forward error correction (RS-FEC) for support of IEEE802.3-2018 Clause 107 25GBASE-R PCS. IEEE 802.3 Clause 73 Auto-Negotiation and IEEE 802.3 Clause 74 CR/KR-FEC are not supported. Transceiver interface to 25GBASE-SR optical Physical Medium Dependent (PMD) transceiver is supported.

The IP core provides standard media access control (MAC) and physical coding sublayer (PCS), Reed-Solomon Forward Error Correction (RS-FEC), and PMA functions shown in the following block diagram. The PHY comprises the PCS, optional Reed-Solomon FEC, and PMA.

Figure 1. 25G Ethernet Intel FPGA IP MAC and PHY IP Clock Diagram

The following block diagram shows an example of a network application with 25G Ethernet Intel FPGA IP MAC and PHY.
1.1. 25G Ethernet Intel FPGA IP Core Supported Features

The 25G Ethernet Intel FPGA IP core is designed to the 25G & 50G Ethernet Specification, Draft 1.6 from the 25 Gigabit Ethernet Consortium and designed to the IEEE 802.3by 25Gb Ethernet specification, as well as the IEEE 802.3ba-2012 High...
Speed Ethernet Standard available on the IEEE website (www.ieee.org). The MAC provides RX cut-through frame processing to optimize latency. The IP core supports the following features:

- **PHY features:**
  - Soft PCS logic that interfaces seamlessly to Intel Arria 10 FPGA 25.78125 gigabits per second (Gbps) serial transceivers.
  - Optional Reed-Solomon forward error correction (FEC).

- **Frame structure control features:**
  - Support for jumbo packets, defined as packets greater than 1500 bytes.
  - Receive (RX) CRC removal and pass-through control.
  - Transmit (TX) CRC generation and insertion.
  - RX and TX preamble pass-through option for applications that require proprietary user management information transfer.
  - TX automatic frame padding to meet the 64-byte minimum Ethernet frame length.

- **Frame monitoring and statistics:**
  - RX CRC checking and error reporting.
  - RX malformed packet checking per IEEE specification.
  - Optional statistics counters.
  - Optional fault signaling detects and reports local fault and generates remote fault, with IEEE 802.3ba-2012 Ethernet Standard Clause 66 support.
  - Unidirectional transport as defined in Clause 66 of the IEEE 802.3-2012 Ethernet Standard.

- **Flow control:**
  - Standard IEEE 802.3 Clause 31 and Priority-Based IEEE 802.1Qbb flow control.
• Precision Time Protocol support:
  — Optional support for the IEEE Standard 1588-2008 Precision Clock Synchronization Protocol (1588 PTP). This feature supports PHY operating speed with a constant timestamp accuracy of ± 3 ns and a dynamic timestamp accuracy of ± 1 ns.

• Debug and testability features:
  — Programmable serial PMA local loopback (TX to RX) at the serial transceiver for self-diagnostic testing.
  — TX error insertion capability.
  — Optional access to Native PHY Debug Master Endpoint (NPDME) for serial link debugging or monitoring PHY signal integrity.

• User system interfaces:
  — Avalon Memory-Mapped (Avalon-MM) management interface to access the IP core control and status registers.
  — Avalon Streaming (Avalon-ST) data path interface connects to client logic.
  — Configurable ready latency of 0 or 3 clock cycles for Avalon-ST TX interface.
  — Hardware and software reset control.

For a detailed specification of the Ethernet protocol refer to the IEEE 802.3 Ethernet Standard.

1.3. IP Core Verification

To ensure functional correctness of the 25G Ethernet Intel FPGA IP core, Intel performs extensive validation through both simulation and hardware testing. Before releasing a version of the 25G Ethernet Intel FPGA IP core, Intel runs comprehensive regression tests in the current version of the Intel Quartus Prime software.

Intel verifies that the current version of the Intel Quartus Prime software compiles the previous version of each IP core. Any exceptions to this verification are reported in the Intel FPGA IP Release Notes. Intel does not verify compilation with IP core versions older than the previous release.

Related Information

- Knowledge Base Issues for IP core
  Exceptions to functional correctness are documented in the 25G Ethernet Intel FPGA IP core errata.

- 25G Ethernet Intel FPGA IP Release Notes

- Intel Quartus Prime Design Suite Update Release Notes
  Includes changes in minor releases (updates).

1.3.1. Simulation Environment

Intel performs the following tests on the 25G Ethernet Intel FPGA IP core in the simulation environment using internal and third-party standard bus functional models (BFM):

- Constrained random tests that cover randomized frame size and contents.
- Assertion based tests to confirm proper behavior of the IP core with respect to the specification.
- Extensive coverage of our runtime configuration space and proper behavior in all possible modes of operation.
1.3.2. Compilation Checking

Intel performs compilation testing on an extensive set of 25G Ethernet Intel FPGA IP core variations and designs to ensure the Intel Quartus Prime software places and routes the IP core ports correctly.

1.3.3. Hardware Testing

Intel performs hardware testing of the key functions of the 25G Ethernet Intel FPGA IP core using internal loopback and standard 25 Gbps Ethernet network test equipment. The hardware tests also ensure reliable solution coverage for hardware related areas such as performance, link synchronization, and reset recovery.

1.4. Performance and Resource Utilization

The following table shows the typical device resource utilization for selected configurations using the current version of the Intel Quartus Prime software. With the exception of M20K memory blocks, the numbers of ALMs and logic registers are rounded up to the nearest 100. The timing margin for this IP core is a minimum of 15%.

Table 4. IP Core Variation Encoding for Resource Utilization Table

"On" indicates the parameter is turned on. The symbol "—" indicates the parameter is turned off or not available.

1.5. Release Information

IP versions are the same as the Intel Quartus Prime Design Suite software versions up to v19.1. From Intel Quartus Prime Design Suite software version 19.2 or later, IP cores have a new IP versioning scheme.

The IP versioning scheme (X.Y.Z) number changes from one software version to another. A change in:

- X indicates a major revision of the IP. If you update your Intel Quartus Prime software, you must regenerate the IP.
- Y indicates the IP includes new features. Regenerate your IP to include these new features.
- Z indicates the IP includes minor changes. Regenerate your IP to include these changes.

- Project Management Best Practices
  Guidelines for efficient management and portability of your project and IP files.

2.1. Installing and Licensing Intel FPGA IP Cores

The Intel Quartus Prime software installation includes the Intel FPGA IP library. This library provides many useful IP cores for your production use without the need for an additional license. Some Intel FPGA IP cores require purchase of a separate license for production use. The Intel FPGA IP Evaluation Mode allows you to evaluate these licensed Intel FPGA IP cores in simulation and hardware, before deciding to purchase a full production IP core license. You only need to purchase a full production license for licensed Intel IP cores after you complete hardware testing and are ready to use the IP in production.

The Intel Quartus Prime software installs IP cores in the following locations by default:

**Figure 3. IP Core Installation Path**
```
intelFPGA(_pro)  
  quartus - Contains the Intel Quartus Prime software  
  ip - Contains the Intel FPGA IP library and third-party IP cores  
  altera - Contains the Intel FPGA IP library source code  
  <IP name> - Contains the Intel FPGA IP source files
```

**Table 7. IP Core Installation Locations**

</tbody>
</table>
Note: The Intel Quartus Prime software does not support spaces in the installation path.

2.1.1. Intel FPGA IP Evaluation Mode

The free Intel FPGA IP Evaluation Mode allows you to evaluate licensed Intel FPGA IP cores in simulation and hardware before purchase. Intel FPGA IP Evaluation Mode supports the following evaluations without additional license:

- Simulate the behavior of a licensed Intel FPGA IP core in your system.
- Verify the functionality, size, and speed of the IP core quickly and easily.
- Generate time-limited device programming files for designs that include IP cores.
- Program a device with your IP core and verify your design in hardware.

Intel FPGA IP Evaluation Mode supports the following operation modes:

- **Tethered**—Allows running the design containing the licensed Intel FPGA IP indefinitely with a connection between your board and the host computer. Tethered mode requires a serial joint test action group (JTAG) cable connected between the JTAG port on your board and the host computer, which is running the Intel Quartus Prime Programmer for the duration of the hardware evaluation period. The Programmer only requires a minimum installation of the Intel Quartus Prime software, and requires no Intel Quartus Prime license. The host computer controls the evaluation time by sending a periodic signal to the device via the JTAG port. If all licensed IP cores in the design support tethered mode, the evaluation time runs until any IP core evaluation expires. If all of the IP cores support unlimited evaluation time, the device does not time-out.

- **Untethered**—Allows running the design containing the licensed IP for a limited time. The IP core reverts to untethered mode if the device disconnects from the host computer running the Intel Quartus Prime software. The IP core also reverts to untethered mode if any other licensed IP core in the design does not support tethered mode.

When the evaluation time expires for any licensed Intel FPGA IP in the design, the design stops functioning. All IP cores that use the Intel FPGA IP Evaluation Mode time out simultaneously when any IP core in the design times out. When the evaluation time expires, you must reprogram the FPGA device before continuing hardware verification. To extend use of the IP core for production, purchase a full production license for the IP core.

You must purchase the license and generate a full production license key before you can generate an unrestricted device programming file. During Intel FPGA IP Evaluation Mode, the Compiler only generates a time-limited device programming file (<project name>_time_limited.sof) that expires at the time limit.
Figure 4. Intel FPGA IP Evaluation Mode Flow

1. **Install the Intel Quartus Prime Software with Intel FPGA IP Library**
2. **Parameterize and Instantiate a Licensed Intel FPGA IP Core**
3. **Verify the IP in a Supported Simulator**
4. **Compile the Design in the Intel Quartus Prime Software**
5. **Generate a Time-Limited Device Programming File**
6. **Program the Intel FPGA Device and Verify Operation on the Board**

**IP Ready for Production Use?**

- **Yes**
  - **Purchase a Full Production IP License**
  - **Include Licensed IP in Commercial Products**

- **No**

**Note:** Refer to each IP core's user guide for parameterization steps and implementation details.

Intel licenses IP cores on a per-seat, perpetual basis. The license fee includes first-year maintenance and support. You must renew the maintenance contract to receive updates, bug fixes, and technical support beyond the first year. You must purchase a full production license for Intel FPGA IP cores that require a production license, before generating programming files that you may use for an unlimited time. During Intel FPGA IP Evaluation Mode, the Compiler only generates a time-limited device programming file (\(<project name>\_time\_limited.sof\)) that expires at the time limit. To obtain your production license keys, visit the Self-Service Licensing Center.

The Intel FPGA Software License Agreements govern the installation and use of licensed IP cores, the Intel Quartus Prime design software, and all unlicensed IP cores.
2.2. Specifying the 25G Ethernet Intel FPGA IP Core Parameters and Options

The 25G Ethernet Intel FPGA IP parameter editor allows you to quickly configure your custom IP variation. Use the following steps to specify IP core options and parameters in the Intel Quartus Prime software.

1. Depending on whether you are using the Intel Quartus Prime Pro Edition software or the Intel Quartus Prime Standard Edition software, perform one of the following actions:
   - In the Intel Quartus Prime Pro Edition, click File ➤ New Project Wizard to create a new Quartus Prime project, or File ➤ Open Project to open an existing Quartus Prime project. The wizard prompts you to specify a device.
   - In the Intel Quartus Prime Standard Edition software, in the IP Catalog (Tools ➤ IP Catalog), select the Arria 10 target device family.

2. In the IP Catalog (Tools ➤ IP Catalog), locate and double-click the name of the IP core to customize. The New IP Variation window appears.

3. In the New IP Variation dialog box, specify a top-level name for your custom IP variation. The parameter editor saves the IP variation settings in a file named <your_ip>.qsys (in Intel Quartus Prime Standard Edition) or <your_ip>.ip (in Intel Quartus Prime Pro Edition).

4. In the Intel Quartus Prime Standard Edition software, you must select a specific Intel Arria 10 device in the Device field, or keep the default device the Quartus Prime software proposes.

5. Click OK. The parameter editor appears.

6. On the IP tab, specify the parameters for your IP core variation. Refer to 25G Ethernet Intel FPGA IP Core Parameters on page 24 for information about specific IP core parameters.

7. Optionally, to generate a simulation testbench or compilation and hardware design example, follow the instructions in the Intel Arria 10 25G Ethernet Design Example User Guide.

8. Click Generate HDL. The Generation dialog box appears.

9. Specify output file generation options, and then click Generate. The IP variation files generate according to your specifications.

   Note: A functional VHDL IP core is not available. Specify Verilog HDL only, for your IP core variation.

10. Click Finish. The parameter editor adds the top-level .qsys or .ip file to the current project automatically. If you are prompted to manually add the .qsys or .ip file to the project, click Project ➤ Add/Remove Files in Project to add the file.

11. After generating and instantiating your IP variation, make appropriate pin assignments to connect ports.
2.3. Simulating the IP Core

You can simulate your 25G Ethernet Intel FPGA IP core variation with the functional simulation model and the testbench generated with the IP core. The functional simulation model is a cycle-accurate model that allows for fast functional simulation of your IP core instance using industry-standard Verilog HDL simulators. You can simulate the Intel-provided testbench or create your own testbench to exercise the IP core functional simulation model.

The functional simulation model and testbench files are generated in project subdirectories. These directories also include scripts to compile and run the design example.

**Note:** Use the simulation models only for simulation and not for synthesis or any other purposes. Using these models for synthesis creates a nonfunctional design.

In the top-level wrapper file for your simulation project, you can set the following RTL parameters to enable simulation optimization. These optimizations significantly decrease the time to reach link initialization.

- **SIM_SHORT_RST:** Shortens the reset times to speed up simulation.
- **SIM_SHORT_AM:** Shortens the interval between alignment markers to accelerate alignment marker lock. Alignment markers are used when Reed-Solomon FEC is enabled.
- **SIM_SIMPLE_RATE:** Sets the PLL reference clock (clk_ref) to 625 MHz instead of 644.53125 MHz to optimize PLL simulation model behavior.

In general, parameters are set through the IP core parameter editor and you should not change them manually. The only exceptions are these simulation optimization parameters.

To set these parameters on the PHY blocks, add the following lines to the top-level wrapper file:

```vhdl
defparam <dut instance>.SIM_SHORT_RST = 1'b1;
defparam <dut instance>.SIM_SHORT_AM = 1'b1;
defparam <dut instance>.SIM_SIMPLE_RATE = 1'b1;
```

**Note:** You can use the example testbench as a guide for setting the simulation parameters in your own simulation environment. These lines are already present in the Intel-provided testbench for the IP core.

**Related Information**
2.4. Generated File Structure

The Intel Quartus Prime software generates the following IP core output file structure.

For information about the file structure of the design example, refer to the Arria 10 25G Ethernet Intel FPGA IP Design Example User Guide.

Figure 5. IP Core Generated Files

Example location for your IP core design example files. The default location is alt_e25_0_example_design, but you are prompted to specify a different path.

### 2.5. Integrating Your IP Core in Your Design

#### 2.5.1. Pin Assignments

When you integrate your 25G Ethernet Intel FPGA IP core instance in your design, you must make appropriate pin assignments. While compiling the IP core alone, you can create virtual pins to avoid making specific pin assignments for top-level signals. When you are ready to map the design to hardware, you can change to the correct pin assignments.

**Related Information**

**Intel Quartus Prime Help**

For information about the Intel Quartus Prime software, including virtual pins.
2.5.2. Adding the Transceiver PLL

The 25G Ethernet Intel FPGA IP core targets Arria 10 GT devices. Intel Arria 10 GT devices require an external PLL to drive the TX transceiver serial clock, in order to compile and to function correctly in hardware. In many cases, the same PLL can be shared with an additional transceiver in your design.

**Figure 6. PLL Configuration Example**

The TX transceiver PLL is instantiated with an ATX PLL IP core. The TX transceiver PLL must always be instantiated outside the 25G Ethernet Intel FPGA IP core.

You can use the IP Catalog to create a transceiver PLL.

- Select **Intel Arria 10 Transceiver ATX PLL**.
- In the parameter editor, set the following parameter values:
  - **PLL output frequency** to **12890.625 MHz**. The transceiver performs dual edge clocking, using both the rising and falling edges of the input clock from the PLL. Therefore, this PLL output frequency setting supports a 25.78125 Gbps data rate through the transceiver.
  - **PLL reference clock frequency** to **644.53125 MHz**.

You must connect the ATX PLL to the 25G Ethernet Intel FPGA IP core as follows:

- Connect the clock output port of the ATX PLL to the `tx_serial_clk` input port of the 25G Ethernet Intel FPGA IP core.
- Connect the `pll_locked` output port of the ATX PLL to the `tx_pll_locked` input port of the 25G Ethernet Intel FPGA IP core.
- Drive the ATX PLL reference clock port and the 25G Ethernet Intel FPGA IP core `clk_ref` input port with the same clock. The clock frequency must be the frequency you specify for the ATX PLL IP core **PLL reference clock frequency** parameter.

**Related Information**

- **Transceivers** on page 56
The RX path in the 25G Ethernet Intel FPGA IP core includes cascaded PLLs. Therefore, the IP core clocks might experience additional jitter in Intel Arria 10 devices.

Refer to the KDB Answer How do I compensate for the jitter of PLL cascading or non-dedicated clock path for Arria 10 PLL reference clock? for a workaround you should apply to the IP core, in your design.

Related Information
KDB Answer: How do I compensate for the jitter of PLL cascading or non-dedicated clock path for Arria 10 PLL reference clock?

2.5.4. Adding the External Time-of-Day Module for Variations with 1588 PTP Feature

25G Ethernet Intel FPGA IP cores that include the 1588 PTP module require an external time-of-day (TOD) module to provide a continuous flow of current time-of-day information. The TOD module must update the time-of-day output value on every clock cycle, and must provide the TOD value in the V2 format (96 bits) or the 64-bit TOD format, or both.

Intel provides the following components that you can combine to create the TOD module the 25G Ethernet Intel FPGA IP core requires:

- A simple TOD clock module, available from the IP Catalog (Interface Protocols > Ethernet > Reference Design Components > Ethernet IEEE 1588 Time of Day Clock Intel FPGA IP). You can instantiate two of these clock modules and connect one to the TX MAC and the other to the RX MAC.
- A single-format TOD synchronizer, available from the IP Catalog (Interface Protocols > Ethernet > Reference Design Components > Ethernet IEEE 1588 TOD Synchronizer Intel FPGA IP). This component can handle only a single TOD format. Therefore, if you set the Time of day format parameter to the value of Enable both formats, you must instantiate and connect two TOD synchronizer modules. If your IP core supports only a single TOD format, your design requires only a single TOD synchronizer module.

Each TOD synchronizer connects a master TOD clock and a slave TOD clock.

- If you create your TOD module with a single TOD synchronizer, the master TOD clock connects to the TX MAC of the 25G Ethernet Intel FPGA IP core and the slave TOD clock connects to the RX MAC of the 25G Ethernet Intel FPGA IP core.
- Alternatively, you can drive both the TX and RX TOD clocks from a single master TOD clock. In that case, your design must include two TOD synchronizers, one to connect the master TOD clock and the slave TX TOD clock and one to connect the master TOD clock and the slave RX TOD clock.
If your IP core supports both TOD formats, double the number of TOD synchronizers in your TOD module. The configuration you implement depends on your system design requirements for 1588 PTP functionality.

**Figure 7. TOD Synchronizer and TOD Clocks in 96-Bit TOD Format Design**

Shows the required connections between two TOD clock components and a TOD synchronizer component in a single TOD format design. In a simple TOD module, the master TOD clock connects to the TX MAC of the IP core, and the slave TOD clock connects to the RX MAC of the IP core. If your 25G Ethernet Intel FPGA IP core supports both TOD formats, a second TOD synchronizer connects to the corresponding 64-bit time-of-day signals of the same master and slave TOD clocks.

For information about the Ethernet IEEE 1588 Time of Day Clock and Ethernet IEEE 1588 TOD Synchronizer components, and the requirements for the PLL that connects to the TOD synchronizer, refer to the Ethernet Design Example Components User Guide.

**Table 9. TOD Module Required Connections to 25G Ethernet Intel FPGA IP Core**

Lists the required connections between the TOD module and the 25G Ethernet Intel FPGA IP core, using signal names for TOD modules that provide both a 96-bit TOD and a 64-bit TOD. If you create your own TOD module it must have the output signals required by the 25G Ethernet Intel FPGA IP core. However, its signal names could be different than the TOD module signal names in the table. The signals that the IP core includes depend on the value you set for **Time of day format** in the parameter editor. For example, an RX TOD module might require only a 96-bit TOD out signal. This table does not list required connections between the TOD module and additional parts of your design.

#### 2.5.5. Placement Settings for the 25G Ethernet Intel FPGA IP Core

The Quartus Prime software provides the options to specify design partitions and Logic Lock (Standard) or Logic Lock regions for incremental compilation, to control placement on the device. To achieve timing closure for your design, you might need to provide floorplan guidelines using one or both of these features.

The appropriate floorplan is always design-specific, and depends on your design.

#### Related Information

  Describes incremental compilation, design partitions, and Logic Lock (Standard) regions.

**IEEE 1588 Options**

| Enable IEEE 1588 | Enabled, Disabled | Disabled | If enabled, the IP core supports the IEEE Standard 1588-2008 Precision Clock Synchronization Protocol, by providing the hooks to implement the Precise Timing Protocol (PTP). This parameter is not available if you turn on Enable TX CRC passthrough. This parameter is not available if you turn on Enable RS-FEC. |

| Time of day format | Enable 96-bit timestamp format, Enable 64-bit timestamp format, Enable both formats | Enable both formats | Specifies the interface to the Time of Day module. If you select Enable both formats, the IP core includes both the 64-bit interface and the 96-bit interface. This parameter is available only in variations with Enable IEEE 1588 turned on. The IP core provides the Time of Day interface; the IP core does not include Time of Day and synchronizer modules to connect to this interface. |

| Fingerprint width | 1–32 | 4 | Specifies the number of bits in the fingerprint that the IP core handles. This parameter is available only in variations with Enable IEEE 1588 turned on. |

**Configuration, Debug and Extension Options**

| Enable Native PHY Debug Master Endpoint (NPDME) | Enabled, Disabled | Disabled | If enabled, the IP core turns on the following features in the Intel Arria 10 PHY IP core that is included in the 25G Ethernet Intel FPGA IP core:  
• Enable Native PHY Debug Master Endpoint (NPDME)  
• Enable capability registers  
If turned off, the IP core is configured without these features. For information about these Intel Arria 10 features, refer to the Intel Arria 10 Transceiver PHY User Guide. |

4. Functional Description

4.1. 25G Ethernet Intel FPGA IP Core Functional Description

The 25G Ethernet Intel FPGA IP core implements an Ethernet MAC in accordance with the 25G & 50G Ethernet Specification. The IP core implements an Ethernet PCS and PMA (PHY) that handles the frame encapsulation and flow of data between a client logic and Ethernet network.

Figure 8. 25G Ethernet Intel FPGA IP Core MAC and PHY Clock Diagram

In the TX direction, the MAC assembles packets and sends them to the PHY. It completes the following tasks:

- Accepts client frames.
- Inserts the inter-packet gap (IPG), preamble, start of frame delimiter (SFD), and padding. The source of the preamble and SFD depends on whether the IP core is in preamble-pass-through mode.
- Adds the CRC bits if enabled.
- Updates statistics counters if enabled.

The PHY encodes MAC frames for reliable transmission over the media to the remote end.
In the RX direction, the PMA passes frames to the PCS that sends them to the MAC. The MAC completes the following tasks:

- Performs CRC and malformed packet checks.
- Updates statistics counters if enabled.
- Strips out the CRC, preamble, and SFD.
- Passes the remainder of the frame to the client.

In preamble pass-through mode, the MAC passes on the preamble and SFD to the client instead of stripping them out. In RX CRC pass-through mode, the MAC passes on the CRC bytes to the client and asserts the end-of-packet signal in the same clock cycle as the final CRC byte.

4.1.1. 25G Ethernet Intel FPGA IP Core TX MAC Datapath

The TX MAC module receives the client payload data with the destination and source addresses. It then adds, appends, or updates various header fields in accordance with the configuration specified. The MAC does not modify the destination address, the source address, or the payload received from the client. However, the TX MAC module adds a preamble, if the IP core is not configured to receive the preamble from user logic. It pads the payload of frames greater than eight bytes to satisfy the minimum Ethernet frame payload of 46 bytes. By default, the MAC inserts the CRC bytes. The TX MAC module inserts IDLE bytes to maintain an average IPG of 12.

Figure 9. Typical Client Frame at the Transmit Interface

Illustrates the changes that the TX MAC makes to the client frame. This figure uses the following notational conventions:

- \(<p>\) = payload size, which is arbitrarily large
- \(<s>\) = number of padding bytes (0–46)
- \(<g>\) = number of IPG bytes

Figure 10. TX MAC Functions

![TX MAC Functions Diagram]
4. Functional Description

4.1.1.1. Frame Padding

When the length of the client frame is less than 64 bytes, the TX MAC module inserts pad bytes (0x00) after the payload to create a frame length equal to the minimum size of 64 bytes (including CRC).

The IP core filters out all client frames with lengths less than 9 bytes. The IP core drops these frames silently.

4.1.1.2. Preamble Insertion

In the TX datapath the MAC prepends an eight-byte preamble to the client frame. If you turn on **Enable link fault generation**, this MAC module also incorporates the functions of the reconciliation sublayer (RS).

The source of the 7-byte preamble (including a Start byte) and 1-byte SFD depends on whether you turn on **Enable preamble passthrough** in the parameter editor.

If the preamble pass-through feature is enabled, the client provides the eight-byte preamble (including the 0xFB Start byte and final 1-byte SFD) on l1_tx_data. The client is responsible for providing the correct Start byte (0xFB) and an appropriate SFD byte. If the preamble pass-through feature is disabled, the MAC inserts the standard Ethernet preamble in the transmitted Ethernet frame.

Note that a single parameter in the 25G Ethernet Intel FPGA IP parameter editor turns on both RX and TX preamble passthrough.

4.1.1.3. Inter-Packet Gap Generation and Insertion

The TX MAC maintains the minimum inter-packet gap (IPG) between transmitted frames required by the IEEE 802.3 Ethernet standard. The deficit idle counter (DIC) maintains the average IPG of 12 bytes.

4.1.1.4. Frame Check Sequence (CRC32) Insertion

The component GUI includes the **Enable TX CRC passthrough** parameter to control CRC generation. When enabled, TX MAC does not insert the CRC32 checksum in the out-going frame. In pass-through mode, the client must provide frames with at least 64 bytes, so that the IP core does not pad them. When disabled, the TX MAC computes and inserts a 32-bit Frame Check Sequence (FCS) in the TX MAC frame. The MAC computes the CRC32 over the frame bytes that include the source address, destination address, length, data, and pad (if applicable). The CRC checksum computation excludes the preamble, SFD, and FCS.

In pass-through mode, the l1_tx_endofpacket, l1_rx_endofpacket, l1_tx_empty[2:0], and l1_rx_empty are asserted in the same clock cycle with the final FCS byte. When pass-through mode is disabled, the l1_tx_endofpacket, l1_rx_endofpacket, l1_tx_empty[2:0], and l1_rx_empty are asserted in the same clock cycle with the byte before the first FCS bytes.

The encoding is defined by the following generating polynomial:

\[
FCS(X) = X^{32} + X^{26} + X^{23} + X^{17} + X^{16} + X^{12} + X^{11} + X^{10} + X^9 + X^7 + X^5 + X^4 + X^2 + X + 1
\]

CRC bits are transmitted with MSB first.
Note that you control whether the IP core implements TX CRC insertion or passthrough with a parameter in the 25G Ethernet Intel FPGA IP parameter editor. You control RX CRC forwarding dynamically with the MAC_CRC_CONFIG register.

**Related Information**
Order of Transmission on page 49

### 4.1.2. 25 GbE TX PCS

The soft TX PCS implements MII encoding and scrambling. The 66-bit output stream is input to the hard PCS and PMA block.

**Figure 11. High Level Block Diagram of the Soft TX PCS**

![High Level Block Diagram of the Soft TX PCS](image)

The Hard PCS and PMA blocks are configured in 66:64 bit basic generic 10G PCS mode whose status can be read through Control and Status registers. These blocks use FIFOs in elastic-buffer mode. The PMA operates at 25.78125 Gbps.

**Related Information**
Ethernet section of the Intel Arria 10 Transceiver PHY User Guide
Provides more information about the PMA and PCS for Ethernet protocols.

### 4.1.2.1. TX RSFEC

If you turn on *Enable RS-FEC* in the 25G Ethernet Intel FPGA IP parameter editor, the IP core includes Reed-Solomon forward error correction (FEC) in both the receive and transmit datapaths.

The IP core implements Reed-Solomon FEC per Clause 108 of the IEEE Standard 802.3by. The Reed-Solomon FEC algorithm includes the following modules:
- 64B/66B to 256B/257B Transcoding
- 257:80 gearbox
- High-Speed Reed-Solomon Encoder
- 80:66 gearbox

You cannot turn on both *Enable RS-FEC* and *Enable IEEE 1588* in the 25G Ethernet Intel FPGA IP parameter editor.
4.1.3. 25G Ethernet Intel FPGA IP Core RX MAC Datapath

The RX MAC receives Ethernet frames and forwards the payload with relevant header bytes to the client after performing some MAC functions on header bytes. The RX MAC processes all incoming valid frames.

**Figure 12. Flow of Client Frame With Preamble Pass-Through Turned On**

This figure uses the following notational conventions:

- `<p>` = payload size, which is arbitrarily large.
- `<s>` = number of padding bytes (0–46).

**Figure 13. Flow of Client Frame With Preamble Pass-Through Turned Off**

This figure uses the following notational conventions:

- `<p>` = payload size, which is arbitrarily large.
- `<s>` = number of padding bytes (0–46).
4.1.3.1. IP Core Preamble Processing

If you turn on **Enable preamble passthrough** in the parameter editor, the RX MAC forwards preamble bytes. The TX MAC requires the preamble bytes to be included in the frames at the Avalon Streaming interface.

If you turn off **Enable preamble passthrough**, the IP core removes the preamble bytes. `l1_rx_startofpacket` is aligned to the MSB of the destination address.

Note that a single parameter in the 25G Ethernet Intel FPGA IP parameter editor turns on both RX and TX preamble passthrough.

4.1.3.2. IP Core Malformed Packet Handling

While receiving an incoming packet from the Ethernet link, the 25G Ethernet Intel FPGA IP core expects to detect a terminate character at the end of the packet. When it detects an expected terminate character, the IP core generates an EOP on the client interface. However, sometimes the IP core detects an unexpected control character when it expects a terminate character.

If the 25G Ethernet Intel FPGA IP core detects an Error character, a Start character, an IDLE character, or any other non-terminate control character, when it expects a terminate character, it performs the following actions:

- Generates an EOP.
- Asserts a malformed packet error (`l1_rx_error[0]`).

If the IP core subsequently detects a terminate character, it does not generate another EOP indication.
When the IP core receives a packet that contains an error deliberately introduced on the Ethernet link using the 25G Ethernet Intel FPGA IP TX error insertion feature, the IP core identifies it as a malformed packet.

At this time, the 25G Ethernet Intel FPGA IP core does not recognize non-zero 4-bit ordered set types as an error.

### 4.1.3.3. Length/Type Field Processing

This two-byte header represents either the length of the payload or the type of MAC frame.

- **Length/type < 0x600**—The field represents the payload length of a basic Ethernet frame. The MAC RX continues to check the frame and payload lengths.
- **Length/type >= 0x600**—The field represents the frame type. The following frame types are possible:
  - **Length/type = 0x8100**—VLAN or stacked VLAN tagged frames. The MAC RX continues to check the frame and payload lengths.
  - **Length/type = 0x8808**—Control frames. The next two bytes are the Opcode field that indicates the type of control frame. For pause frames (Opcode = 0x0001) and PFC frames (Opcode = 0x0101), the MAC RX proceeds with pause frame processing. In addition to processing any pause request, the IP core passes these frames to the RX client interface and updates the appropriate ll_rxstatus_data bits.
  - For other field values, the MAC RX forwards the receive frame to the client.

#### 4.1.3.3.1. Length Checking

The MAC function checks the frame and payload lengths of basic, VLAN tagged, and stacked VLAN tagged frames.

The IP core checks that the frame length is valid—is neither undersized nor oversized. A valid frame length is at least 64 (0x40) bytes and does not exceed the following maximum value for the different frame types:

- **Basic frames**—The number of bytes specified in the MAX_RX_SIZE_CONFIG register.
- **VLAN tagged frames**—The value specified in the MAX_RX_SIZE_CONFIG register plus four bytes.
- **Stacked VLAN tagged frames**—The value specified in the MAX_RX_SIZE_CONFIG register plus eight bytes.
If the length/type field in a basic MAC frame or the client length/type field in a VLAN tagged frame has a value less than 0x600, the IP core also checks the payload length. The IP core keeps track of the payload length as it receives a frame, and checks the length against the relevant frame field. The payload length is valid if it satisfies the following conditions:

- The actual payload length matches the value in the length/type or client length/type field.
- Basic frames—the payload length is between 46 (0x2E) and 1536 (0x0600) bytes, excluding 1536.
- VLAN tagged frames—the payload length is between 42 (0x2A) and 1536 (0x0600), excluding 1536.
- Stacked VLAN tagged frames—the payload length is between 38 (0x26) and 1536 (0x0600), excluding 1536.

The RX MAC does not drop frames with invalid length or invalid payload length. If the frame or payload length is not valid, the MAC function asserts output error bits.

If the length field value is greater than the actual payload length, the IP core asserts `l1_rx_error[4]`. If the length field value is less than the actual payload length, the MAC RX considers the frame to have excessive padding and does not assert `l1_rx_error[4]`.

### 4.1.3.4. RX CRC Checking and Dynamic Forwarding

The RX MAC checks the incoming CRC32 for errors. It asserts `l1_rx_error[1]` in the same cycle as `l1_rx_endofpacket` when it detects an error. CRC checking takes several cycles. The packet frame is delayed to align the CRC output with the end of the frame.

By default, the RX MAC strips off the CRC bytes before forwarding the packet to the MAC client. You can configure the core to retain the RX CRC and forward it to the client by updating the `MAC_CRC_CONFIG` register.

### 4.1.4. Link Fault Signaling Interface

Link fault signaling reflects the health of the link. It operates between the remote Ethernet device Reconciliation Sublayer (RS) and the local Ethernet device RS. The link fault modules communicate status during the interframe period.

You enable link fault signaling by turning on **Enable link fault generation** in the parameter editor. For bidirectional fault signaling, the IP core implements the functionality defined in the **IEEE 802.3ba 10G Ethernet Standard** and **Clause 46** based on the `LINK_FAULT` configuration register settings.

For unidirectional fault signaling, the core implements **Clause 66 of the IEEE 802.3-2012 Ethernet Standard**.
Local Fault (LF)

If an Ethernet PHY sublayer detects a fault that makes the link unreliable, it notifies the RS of the local fault condition. If unidirectional is not enabled, the core follows Clause 46. The RS stops sending MAC data, and continuously generates a remote fault status on the TX datapath. After a local fault is detected, the RX PCS modifies the MII data and control to send local fault sequence ordered sets. Refer to Link Fault Signaling Based On Configuration and Status below.

The RX PCS cannot recognize the link fault under the following conditions:
- The RX PCS is not fully aligned.
- The bit error rate (BER) is high.

Remote Fault (RF)

If unidirectional is not enabled, the core follows Clause 46. If the RS receives a remote fault status, the TX datapath stops sending MAC data and continuously generates idle control characters. If the RS stops receiving fault status messages, it returns to normal operation, sending MAC client data. Refer to Link Fault Signaling Based On Configuration and Status below.

Link Status Signals

The MAC RX generates two link fault signals: local_fault_status and remote_fault_status.

Note: These signals are real time status signals that reflect the status of the link regardless of the settings in the link fault configuration register.

This register is generated only if you turn on Enable link fault generation. The MAC TX interface uses the link fault status signals for additional link fault signaling.

Table 11. Link Fault Signaling Based On Configuration and Status

For more information about the LINK_FAULT register, refer to TX MAC Registers.

### 4.1.5. 25 GbE RX PCS

The soft RX PCS interfaces to the hard PCS and PMA blocks configured in 66:64 10G PCS Basic Generic Mode with bitslip enabled. The hard PCS drives a 66-bit output stream to the soft RX PCS. The soft RX PCS implements word lock, descrambling, and MII decoding. It drives output data to the MAC. You can read the status of FIFOs at the interface of Hard RX PCS using the Control and Status registers.
4.1.5.1. RX RSFEC

If you turn on **Enable RS-FEC** in the 25G Ethernet Intel FPGA IP parameter editor, the IP core includes Reed-Solomon forward error correction (FEC) in both the receive and transmit datapaths.

The IP core implements Reed-Solomon FEC per Clause 108 of the IEEE Standard 802.3by. The Reed-Solomon FEC algorithm includes the following modules:

- Alignment marker lock
- 66:80 gearbox
- High-speed Reed-Solomon decoder
- 80:257 gearbox
- 256B/257B to 64B/66B Transcoding

You cannot turn on both **Enable RS-FEC** and **Enable IEEE 1588** in the 25G Ethernet Intel FPGA IP parameter editor.

4.1.6. Flow Control

Flow control reduces congestion at the local or remote link partner. When either link partner experiences congestion, the respective transmit control sends pause frames. XOFF Pause frames stop the remote transmitter. XON Pause frames let the remote transmitter resume data transmission. The 25G Ethernet Intel FPGA IP core supports both standard and Priority-based Flow Control (PFC) control frames.
Figure 17. **Flow Control Module Conceptual Overview**

The flow control module acts as a buffer between client logic and the TX and RX MAC.

Standard Flow Control (Pause Frame Flow Control):
- Inhibits the next client frame transmission on the reception of a valid Pause frame.

Priority-based Flow Control (PFC):
- PFC frame transmission follows a priority-based arbitration scheme, where the Frame Type indication is provided for the usage of external downstream logic.
- Inhibits the per-queue client frame transmission on the reception of a valid PFC frame from the client. Includes per-queue PFC Pause quanta duration indicator

Flow Control includes the following features:

</table>
Caution: The 25G Ethernet Intel FPGA IP core supports the flow control feature for either value of the Ready Latency parameter. However, in standard flow control you might experience data delay if you select the value of 3 for this parameter. The IP core might still hold user data packet in its internal buffer if transmission of the IP core stops due to flow control. This issue does not occur in priority-based flow control.

Related Information
Pause/PFC Flow Control Registers on page 70
Describes the registers that the IP core uses to implement the flow control functionality.

4.1.6.1. TX Pause/PFC Flow Control Frame Transmission Request

An XON/XOFF request triggers the IP core to transmit a Pause or PFC flow control frame on the Ethernet link. You can control XON/XOFF requests using the TX flow control registers or the pause_insert_tx0 and pause_insert_tx1 input signals.

You can specify whether the IP core accepts XON/XOFF requests in 1-bit or 2-bit format by updating the TX Flow Control Request Mode register field. By default the IP core assumes 1-bit requests.
4.1.6.2. XON/XOFF Pause Frames

Priority-based Flow Control

You can trigger the 25G Ethernet Intel FPGA IP core to transmit PFC XOFF frame with a pause duration that is specified in TX Flow Control Quanta register by updating the `pause_insert_tx0` and `pause_insert_tx1` input signals or TX flow control registers. If an enabled priority queue is in the XOFF condition, a new PFC frame is transmitted after the minimum time gap. You specify the minimum time gap in the per priority queue TX Flow Control Signal XOFF Request Hold Quanta register. The minimum time gap between two consecutive PFC frames is 1 pause quanta or 512-bit times. PFC frame transmission ends when none of the PFC interfaces of all enabled priority queues is requesting PFC frames.

A transition from XOFF to XON in any enabled priority queue triggers the IP core to transmit a PFC frame with pause quanta of 0 for the associated priority queue. The IP core sends a single XON flow control frame. In the rare case that the XON frame is lost or corrupted, the remote partner should still be able to resume transmission. The remote partner resumes transmission after the duration or the pause quanta value specified in the previous XOFF flow control frame expires.

Standard Flow Control

In the case of standard flow control, the IP core transmits Pause frames instead of PFC frames. The transmission behavior is identical.

When the IP core is in standard flow control mode and receives a Pause frame, the IP core stops processing TX client data, either immediately or at the next frame boundary. Client data transmission resumes when all of the following conditions are true:

- The time specified by the pause quanta has elapsed and there is no new quanta value.
- A valid pause frame with 0 pause duration has been received.

A Pause frame has no effect if the associated TX Flow Control Enable register bit is set to disable XON and XOFF flow control.

4.1.7. 1588 Precision Time Protocol Interfaces

If you turn on Enable IEEE 1588, the 25G Ethernet Intel FPGA IP core processes and provides 1588 Precision Time Protocol (PTP) timestamp information as defined in the IEEE 1588-2008 Precision Clock Synchronization Protocol for Networked Measurement and Control Systems Standard. This feature supports PHY operating speed with a constant timestamp accuracy of ± 3 ns and a dynamic timestamp accuracy of ± 1 ns.

1588 PTP packets carry timestamp information. The 25G Ethernet Intel FPGA IP core updates the incoming timestamp information in a 1588 PTP packet to transmit a correct updated timestamp with the data it transmits on the Ethernet link, using a one-step or two-step clock.

A fingerprint can accompany a 1588 PTP packet. You can use this information for client identification and other client uses. If provided fingerprint information, the IP core passes it through unchanged.
The IP core connects to a time-of-day (TOD) module that continuously provides the current time of day based on the input clock frequency. Because the module is outside the 25G Ethernet Intel FPGA IP core, you can use the same module to provide the current time of day for multiple modules in your system.

### 4.1.7.1. Implementing a 1588 System That Includes a 25G Ethernet Intel FPGA IP Core

The 1588 specification in *IEEE 1588-2008 Precision Clock Synchronization Protocol for Networked Measurement and Control Systems Standard* describes various systems you can implement in hardware and software to synchronize clocks in a distributed system by communicating offset and frequency correction information between master and slave clocks in arbitrarily complex systems. A 1588 system that includes the 25G Ethernet Intel FPGA IP core with 1588 PTP functionality uses the incoming and outgoing timestamp information from the IP core and the other modules in the system to synchronize clocks across the system.

The 25G Ethernet Intel FPGA IP core with 1588 PTP functionality provides the timestamp manipulation and basic update capabilities required to integrate your IP core in a 1588 system. You can specify that packets are PTP packets, and how the IP core should update incoming timestamps from the client interface before transmitting them on the Ethernet link. The IP core does not implement the event messaging layers of the protocol, but rather provides the basic hardware capabilities that support a system in implementing the full 1588 protocol.
You can implement both master and slave clocks using the 25G Ethernet Intel FPGA IP core with 1588 PTP functionality. Refer to Adding the External Time-of-Day Module for Variations with 1588 PTP Feature for implementation of the TOD module.

Refer to Adding the External Time-of-Day Module for Variations with 1588 PTP Feature for implementation of the TOD module.

The IEEE 1588-2008 Precision Clock Synchronization Protocol for Networked Measurement and Control Systems Standard is available on the IEEE website.
4.1.7.2. PTP Receive Functionality

If you turn on Enable IEEE 1588 in the 25G Ethernet Intel FPGA IP parameter editor, the IP core provides a 96-bit (V2 format) or 64-bit timestamp with every packet on the RX client interface, whether it is a 1588 PTP packet or not. The value on the timestamp bus \( \text{rx}_\text{ingress}_\text{timestamp}_\text{96b}_\text{data}[95:0] \) or \( \text{rx}_\text{ingress}_\text{timestamp}_\text{64b}_\text{data}[63:0] \) or both, if present) is valid in the same clock cycle as the RX SOP signal. The value on the timestamp bus is not the current timestamp; instead, it is the timestamp from the time when the IP core received the packet on the Ethernet link. The IP core captures the time-of-day from the TOD module on \( \text{rx}_\text{time}_\text{of}_\text{day}_96b_\text{data} \) or \( \text{rx}_\text{time}_\text{of}_\text{day}_64b_\text{data} \) at the time it receives the packet on the Ethernet link, and sends that timestamp to the client on the RX SOP cycle on the timestamp bus \( \text{rx}_\text{ingress}_\text{timestamp}_\text{96b}_\text{data}[95:0] \) or \( \text{rx}_\text{ingress}_\text{timestamp}_\text{64b}_\text{data}[63:0] \) or both, if present. User logic can use this timestamp or ignore it.

IEEE website

The IEEE 1588-2008 Precision Clock Synchronization Protocol for Networked Measurement and Control Systems Standard is available on the IEEE website.
4.1.7.3. PTP Transmit Functionality

When you send a 1588 PTP packet to a 25G Ethernet Intel FPGA IP core with Enable IEEE 1588 turned on in the parameter editor, you should assert the following respective input signals with the TX SOP signal to tell the IP core the PTP operations or processes that the IP core should perform to the packet:

- `tx_egress_timestamp_request_valid`: assert this signal to tell the IP core to process the current packet in two-step processing mode.
- `tx_etstamp_ins_ctrl_timestamp_insert`: assert this signal to tell the IP core to process the current packet in one-step processing mode and to insert the exit timestamp for the packet in the packet (insertion mode).
- `tx_etstamp_ins_ctrl_residence_time_update`: assert this signal to tell the IP core to process the current packet in one-step processing mode and to update the timestamp in the packet by adding the latency through the IP core (the residence time in the IP core) to the cumulative delay field maintained in the packet (correction mode). This mode supports transparent clock systems.

**Note:** If `tx_etstamp_ins_ctrl_residence_time_update` is asserted, you should not assert `tx_egress_timestamp_request_valid` or `tx_etstamp_ins_ctrl_timestamp_insert` as the result will be undefined.

The IP core transmits the 1588 PTP packet in an Ethernet frame after PTP processing.

**Figure 23.** PTP Transmit Block Diagram

In one-step mode, the IP core either overwrites the timestamp information provided at the user-specified offset with the packet exit timestamp (insertion mode), or adds the residence time in this system to the value at the specified offset (correction mode). You tell the IP core how to process the timestamp by asserting the appropriate signal with the TX SOP signal. You must specify the offset of the timestamp in the packet (`tx_etstamp_ins_ctrl_offset_timestamp`) in insertion mode, or the offset of the correction field in the packet.
(tx_etstamp_ins_ctrl_offset_correction_field) in correction mode. In addition, the IP core zeroes out or updates the UDP checksum, or leaves the UDP checksum as is, depending on the mutually exclusive tx_etstamp_ins_ctrl_checksum_zero and tx_etstamp_ins_ctrl_checksum_correct signals. Checksum calculation is mandatory for the UDP/IPv6 protocol. You must extend 2 bytes at the end of the UDP payload of the PTP packet. The MAC function modifies the extended bytes to ensure that the UDP checksum remains uncompromised.

Two-step PTP processing ignores the values on the one-step processing signals. In two-step processing mode, the IP core does not modify the current timestamp in the packet. Instead, the IP core transmits a two-step derived timestamp on the separate tx_egress_timestamp_96b_data[95:0] or tx_egress_timestamp_64b_data[63:0] bus, when it begins transmitting the Ethernet frame. The value on the tx_egress_timestamp_(96b,64b)_data bus is the packet exit timestamp. The tx_egress_timestamp_(96b,64b)_data bus holds a valid value when the corresponding tx_egress_timestamp_(96b,64b)_valid signal is asserted.

In addition, to help the client to identify the packet, you can specify a fingerprint to be passed by the IP core in the same clock cycle with the timestamp. To specify the number of distinct fingerprint values the IP core can handle, set the Fingerprint width parameter to the desired number of bits W. You provide the fingerprint value to the IP core in the tx_egress_timestamp_request_fingerprint[(W–1):0] signal. The IP core then drives the fingerprint on the appropriate tx_egress_timestamp_(96b,64b)_fingerprint[(W–1):0] port with the corresponding output timestamp, when it asserts the tx_egress_timestamp_(96b,64b)_valid signal.

The IP core calculates the packet exit timestamp.

exit TOD = entry TOD + IP core maintained expected latency + user-configured PMA latency

- entry TOD is the value in tx_time_of_day_96b_data or tx_time_of_day_64b_data when the packet enters the IP core.
- The expected latency through the IP core is a static value. The IP core maintains this value internally.
- The IP core reads the user-configured PMA latency from the TX_PTP_PMA_LATENCY register. This option is provided for user flexibility.

The IP core provides the exit TOD differently in different processing modes.

- In two-step mode, the IP core drives the exit TOD on tx_egress_timestamp_96b_data and on tx_egress_timestamp_64b_data, as available.
- In one-step processing insertion mode, the IP core inserts the exit TOD in the timestamp field of the packet at the offset you specify in tx_etstamp_ins_ctrl_offset_timestamp.
- In one-step processing correction mode, the IP core calculates the exit TOD and uses it only to calculate the residence time.
In one-step processing correction mode, the IP core calculates the updated correction field value:

\[
\text{exit correction field value} = \text{entry correction field value} + \text{residence time} + \text{asymmetry extra latency}
\]

- residence time = exit TOD – entry (ingress) timestamp.
- entry (ingress) timestamp is the value on \(tx\_etstamp\_ins\_ctrl\_ingress\_timestamp\_{95,64}b\) in the SOP cycle when the IP core received the packet on the TX client interface. The application is responsible to drive this signal with the correct value for the cumulative calculation. The correct value depends on system configuration.

- The IP core reads the asymmetry extra latency from the \(TX\_PTP\_ASYM\_DELAY\) register if the \(tx\_egress\_asymmetry\_update\) signal is asserted. This option is provided for additional user-defined precision. You can set the value of this register and set the \(tx\_egress\_asymmetry\_update\) signal to indicate the register value should be included in the latency calculation.

  The IEEE 1588-2008 Precision Clock Synchronization Protocol for Networked Measurement and Control Systems Standard is available on the IEEE website.

4.1.7.4. External Time-of-Day Module for 1588 PTP Variations

25G Ethernet Intel FPGA IP cores that include the 1588 PTP module require an external time-of-day (TOD) module to provide the current time-of-day in each clock cycle, based on the incoming clock. The TOD module must update the time-of-day output value on every clock cycle, and must provide the TOD value in the V2 format (96 bits) or the 64-bit TOD format, or both.

Related Information
- Adding the External Time-of-Day Module for Variations with 1588 PTP Feature on page 21

4.1.7.5. PTP Timestamp and TOD Formats

The 25G Ethernet Intel FPGA IP core supports a 96-bit timestamp (V2 format) or a 64-bit timestamp (correction-field format) in PTP packets. The 64-bit timestamp and TOD signals of the IP core are in an Intel-defined 64-bit format that is distinct from the V1 format, for improved efficiency in one-step processing correction mode. Therefore, if your system need not handle any packets in one-step processing correction mode, you should set the Time of day format parameter to the value of Enable 96-bit timestamp format.

You control the format or formats the IP core supports with the Time of day format parameter. If you set the value of this parameter to Enable 96-bit timestamp format or Enable both formats, your IP core can support two-step processing mode, one-step processing insertion mode, and one-step processing correction mode, and can support both V1 and V2 formats. You can set the parameter value to Enable 64-bit timestamp format to support one-step processing correction mode more efficiently. However, if you do so, your IP core variation cannot support two-step processing mode and cannot support one-step processing insertion mode. If you turn
on both of these parameters, the value you drive on the 
tx_estamp_ins_ctrl_timestamp_format or 
tx_etstamp_ins_ctrl_residence_time_calc_format signal determines the 
format the IP core supports for the current packet.

The IP core completes all internal processing in the V2 format. However, if you specify 
V1 format for a particular PTP packet in one-step insertion mode, the IP core inserts 
the appropriate V1-format timestamp in the outgoing packet on the Ethernet link.

**V2 Format**

The IP core maintains the time-of-day (TOD) in V2 format according to the IEEE 
specification:

- Bits [95:48]: Seconds (48 bits).
- Bits [47:16]: Nanoseconds (32 bits). This field overflows at 1 billion.
- Bits [15:0]: Fractions of nanosecond (16 bits). This field is a true fraction; it 
  overflows at 0xFFFF.

The IP core can receive time-of-day information from the TOD module in V2 format or 
in 64-bit TOD format, or both, depending on your setting for the Time of day format 
parameter.

**V1 Format**

V1 timestamp format is specified in the IEEE specification:

- Bits [63:32]: Seconds (32 bits).
- Bits [31:0]: Nanoseconds (32 bits). This field overflows at 1 billion.

**Intel 64-Bit TOD Format**

The Intel 64-bit TOD format is distinct from the V1 format and supports a longer time 
delay. It is intended for use in transparent clock systems, in which each node adds its 
own residence time to a running total latency through the system. This format 
matches the format of the correction field in the packet, as used in transparent clock 
mode.

- Bits [63:16]: Nanoseconds (48 bits). This field can specify a value greater than 4 
  seconds.
- Bits [15:0]: Fractions of nanosecond (16 bits). This field is a true fraction; it 
  overflows at 0xFFFF.

The TOD module provides 64-bit TOD information to the IP core in this 64-bit TOD 
format. The expected format of all 64-bit input timestamp and TOD signals to the IP 
core is the Intel 64-bit TOD format. The format of all 64-bit output timestamp and 
TOD signals from the IP core is the Intel 64-bit TOD format. If you build your own TOD 
module that provides 64-bit TOD information to the IP core, you must ensure it 
provides TOD information in the Intel 64-bit TOD format.

**Related Information**

IEEE website

The IEEE 1588-2008 Precision Clock Synchronization Protocol for Networked 
Measurement and Control Systems Standard is available on the IEEE website.
4.2. User Interface to Ethernet Transmission

The IP core reverses the bit stream for transmission per Ethernet requirements. The transmitter handles the insertion of the inter-packet gap, frame delimiters, and padding with zeros as necessary. The transmitter also handles FCS computation and insertion.

The IP core transmits complete packets. After transmission begins, it must complete with no IDLE insertions. Between the end of one packet and the beginning of the next packet, the data input is not considered and the transmitter sends IDLE characters. An unbounded number of IDLE characters can be sent between packets.

4.2.1. Order of Transmission

The IP core transmits bytes on the Ethernet link starting with the preamble and ending with the FCS in accordance with the IEEE 802.3 standard. On the transmit client interface, the IP core expects the client to send the most significant bytes of the frame first, and to send each byte in big-endian format. Similarly, on the receive client interface, the IP core sends the client the most significant bytes of the frame first, and orders each byte in big-endian format.

Figure 24. Byte Order on the Client Interface Lanes

Describes the byte order on the Avalon Streaming interface. Destination Address[40] is the broadcast/multicast bit (a type bit), and Destination Address[41] is a locally administered address bit.

<table>
<thead>
<tr>
<th>Octet</th>
<th>Destination Address (DA)</th>
<th>Source Address (SA)</th>
<th>Type/Length (TL)</th>
<th>Data (D)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5 4 3 2 1 0</td>
<td>5 4 3 2 1 0</td>
<td>1 0 0 0</td>
<td>... NN</td>
</tr>
<tr>
<td>Bit</td>
<td>[47:40]</td>
<td>[39:32]</td>
<td>[31:24]</td>
<td>[23:16]</td>
</tr>
</tbody>
</table>

For example, the destination MAC address includes the following six octets AC-DE-48-00-00-80. The first octet transmitted (octet 0 of the MAC address described in the 802.3 standard) is AC and the last octet transmitted (octet 5 of the MAC address) is 80. The first bit transmitted is the low-order bit of AC, a zero. The last bit transmitted is the high order bit of 80, a one.

The preceding table and the following figure show that in this example, 0xAC is driven on DA5 (DA[47:40]) and 0x80 is driven on DA0 (DA[7:0]).
4.2.2. Bit Order For TX and RX Datapaths

The TX bit order matches the placement shown in the PCS lanes as illustrated in *IEEE Standard for Ethernet, Section 4, Figure 49-5*. The RX bit order matches the placement shown in *IEEE Standard for Ethernet, Section 4, Figure 49-6*.

Related Information

IEEE website

The *IEEE Standard for Ethernet, Section 4* is available on the IEEE website.
5. Reset

Control and Status registers control three parallel soft resets. These soft resets are not self-clearing. Software clears them by writing to the appropriate register. Asserting the external hard reset csr_rst_n returns Control and Status registers to their original values.

Figure 26. Conceptual Overview of Reset Logic

The three hard resets are top-level ports. The soft resets are internal signals which are outputs of the PHY_CONFIG register. Software writes the appropriate bit of the PHY_CONFIG to assert a soft reset.

The internal soft reset signals reset the following functions:

- **soft_txp_rst**: Resets the IP core in TX direction. Resets the TX PCS, MAC, and adapter. This soft reset leads to deassertion of tx_lanes_stable output signal.
- **soft_rxp_rst**: Resets the IP core in RX direction. Resets the RX PCS, MAC, and adapter. This soft reset leads to the deassertion of rx_pcs_ready output signal.
- **eio_sys_rst**: Resets the IP core. Resets the TX and RX MACs, PCS, adapters, and transceivers. Does not reset the Control and Status registers. This soft reset leads to the deassertion of tx_lanes_stable and rx_pcs_ready output signal.

6. Interfaces and Signal Descriptions

Figure 27. 25G Ethernet Intel FPGA IP Signals and Interfaces

6.1. TX MAC Interface to User Logic

The TX MAC provides an Avalon Streaming interface to the FPGA fabric. The minimum packet size is nine bytes.
Table 12.   Avalon-ST TX Datapath

All interface signals are clocked by the clk_txmac clock. The value you specify for Ready Latency in the 25G Ethernet Intel FPGA IP parameter editor is the Avalon Streaming readyLatency value on this interface.

<table>
<thead>
<tr>
<th>Signal</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>clk_txmac</td>
<td>Output</td>
<td>Clock for the TX logic. Derived from pll_refclk, and is an output from the 25G Ethernet Intel FPGA IP core. clk_txmac is guaranteed to be stable when tx_lanes_stable is asserted. The frequency of this clock is 390.625 MHz. All TX MAC interface signals are synchronous to clk_txmac.</td>
</tr>
<tr>
<td>l1_tx_data[63:0]</td>
<td>Input</td>
<td>Data input to MAC. Bit 63 is the MSB and bit 0 is the LSB. Bytes are read in the usual left to right order. The 25G Ethernet Intel FPGA IP core does not process incoming frames of less than nine bytes correctly. You must ensure such frames do not reach the TX client interface. You must send each TX data packet without intermediate idle cycles. Therefore, you must ensure your application can provide the data for a single packet in consecutive clock cycles. If data might not be available otherwise, you must buffer the data in your design and wait to assert l1_tx_startofpacket when you are assured the packet data to send on l1_tx_data[63:0] is available or will be available on time.</td>
</tr>
<tr>
<td>l1_tx_valid</td>
<td>Input</td>
<td>When asserted, indicates valid data is available on l1_tx_data[63:0]. You must assert this signal continuously between the assertions of l1_tx_startofpacket and l1_tx_endofpacket for the same packet.</td>
</tr>
<tr>
<td>l1_tx_startofpacket</td>
<td>Input</td>
<td>When asserted, indicates the first byte of a frame. When l1_tx_startofpacket is asserted, the MSB of l1_tx_data drives the start of packet. Packets that drive l1_tx_startofpacket and l1_tx_endofpacket in the same cycle are ignored.</td>
</tr>
<tr>
<td>l1_tx_endofpacket</td>
<td>Input</td>
<td>When asserted, indicates the end of a packet. Packets that drive l1_tx_startofpacket and l1_tx_endofpacket in the same cycle are ignored.</td>
</tr>
<tr>
<td>l1_tx_empty[2:0]</td>
<td>Input</td>
<td>Specifies the number of empty bytes on l1_tx_data when l1_tx_endofpacket is asserted.</td>
</tr>
<tr>
<td>l1_tx_error</td>
<td>Input</td>
<td>When asserted in the same cycle as l1_tx_endofpacket, indicates the current packet should be treated as an error packet. Assertion at any other position in the packet is ignored. The TX statistics counters do not reflect errors the IP core creates in response to this signal.</td>
</tr>
<tr>
<td>l1_tx_ready</td>
<td>Output</td>
<td>When asserted, indicates that the MAC can accept the data. The IP core asserts the l1_tx_ready signal on clock cycle (&lt;n + \text{readyLatency}&gt;) to indicate that clock cycle (&lt;n + \text{readyLatency}&gt;) is a ready cycle. The client may only assert l1_tx_valid and transfer data during ready cycles.</td>
</tr>
<tr>
<td>l1_txstatus_valid</td>
<td>Output</td>
<td>When asserted, indicates that l1_txstatus_data[39:0] is driving valid data.</td>
</tr>
</tbody>

### 6.3. Transceivers

The transceivers require a separately instantiated advanced transmit (ATX) PLL to generate the high speed serial clock. In many cases, the same ATX PLL can serve as input to an additional transceiver that has similar input clocking requirements. In comparison to the fractional PLL (fPLL) and clock multiplier unit PLL, the ATX PLL has the best jitter performance and supports the highest frequency operation.

**Table 14. Transceiver Signals**

6.4. Transceiver Reconfiguration Signals

You access the transceiver control and status registers using the transceiver reconfiguration interface. This is an Avalon Memory-Mapped interface.

The Avalon Memory-Mapped interface implements a standard memory-mapped protocol. You can connect an Avalon master to this bus to access the registers of the embedded Transceiver PHY IP core.

Table 15. Reconfiguration Interface Ports with Shared Native PHY Reconfiguration Interface

All interface signals are clocked by the reconfig_clk clock.

<table>
<thead>
<tr>
<th>Port Name</th>
<th>Direction</th>
<th>Description</th>
</tr>

6.5. Avalon Memory-Mapped Management Interface

You access control and status registers using an Avalon Memory-Mapped management interface. The interface responds regardless of the link status. It also responds when the IP core is in a reset state driven by any reset signal or soft reset other than the csr_rst_n signal. Asserting the csr_rst_n signal resets all control, status, and statistics registers; while this reset is in process, the Avalon Memory-Mapped management interface does not respond.

Table 16. Avalon Memory-Mapped Management Interface

### Signal Name | Direction | Description
--- | --- | ---

**tx_time_of_day_64b_data[63:0]** | Input | Current 64-bit TOD in clk_txmac clock domain. Connect this signal to the external TOD module. This signal is available only if you set the Time of day format parameter to the value of Enable 64-bit timestamp format or Enable both formats.

**rx_time_of_day_96b_data[95:0]** | Input | Current V2-format (96-bit) TOD in clk_rxmac clock domain. Connect this signal to the external TOD module. This signal is available only if you set the Time of day format parameter to the value of Enable 96-bit timestamp format or Enable both formats.

**rx_time_of_day_64b_data[63:0]** | Input | Current 64-bit TOD in clk_rxmac clock domain. Connect this signal to the external TOD module. This signal is available only if you set the Time of day format parameter to the value of Enable 64-bit timestamp format or Enable both formats.

**PTP Interface to Client**

**TX Signals Related to One Step Processing**

- **tx_etstamp_ins_ctrl_timestamp_insert**
  - Input
  - Indicates the current packet on the TX client interface is a 1588 PTP packet, and directs the IP core to process the packet in one-step processing insertion mode. In this mode, the IP core overwrites the timestamp of the packet with the timestamp field when the packet appears on the TX Ethernet link.
  - The TX client must assert and deassert this signal synchronously with the TX SOP signal for the 1588 PTP packet.
  - If the TX client asserts this signal simultaneously with tx_etstamp_ins_ctrl_residence_time_update, the results are undefined.

- **tx_etstamp_ins_ctrl_residence_time_update**
  - Input
  - Indicates the current packet on the TX client interface is a 1588 PTP packet, and directs the IP core to process the packet in one-step processing correction mode. In this mode, the IP core adds the latency through the IP core (residence time) to the current contents of the timestamp field.
  - The TX client must assert and deassert this signal synchronously with the TX SOP signal for the 1588 PTP packet.
  - If the TX client asserts this signal simultaneously with either of tx_etstamp_ins_ctrl_timestamp_insert or tx_egress_timestamp_request_valid, the results are undefined.

- **tx_etstamp_ins_ctrl_ingress_timestamp_96b[95:0]**
  - Input
  - Indicates the V2-format TOD when the packet entered the system.
  - The TX client must ensure this signal is valid in each TX SOP cycle when it asserts tx_etstamp_ins_ctrl_residence_time_update. The TX client must maintain the desired value on this signal while the TX SOP signal is asserted. This signal is useful only in transparent clock mode when the TX client asserts tx_etstamp_ins_ctrl_residence_time_update.
  - This signal is available only if you set the Time of day format parameter to the value of Enable 96-bit timestamp format or Enable both formats.

- **tx_etstamp_ins_ctrl_ingress_timestamp_64b[63:0]**
  - Input
  - Indicates the TOD (in Intel 64-bit format) when the packet entered the system.
  - The TX client must ensure this signal is valid in each TX SOP cycle when it asserts tx_etstamp_ins_ctrl_residence_time_update. The TX client must maintain the desired value on this signal while the TX SOP
<table>
<thead>
<tr>
<th>Signal Name</th>
<th>Direction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>signal is asserted. This signal is useful only in transparent clock mode when the TX client asserts tx_etstamp_ins_ctrl_residence_time_update. This signal is available only if you set the Time of day format parameter to the value of Enable 64-bit timestamp format or Enable both formats.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| tx_etstamp_ins_ctrl_timestamp_format | Input     | Specifies the timestamp format (V1 or V2 format) for the current packet if the TX client simultaneously asserts tx_etstamp_ins_ctrl_timestamp_insert. Values are:  
  - 1'b0: 96-bit timestamp format (V2)  
  - 1'b1: 64-bit timestamp format (V1)  
  The TX client must maintain the desired value on this signal while the TX SOP signal is asserted.  
  If the client specifies the V1 format, you read and write the V1 format TOD (32 bits of seconds and 32 bits of nanoseconds) in bits [79:16] of the 96-bit timestamp and TOD signals.  
  Note: If you set the Time of day format parameter to the value of Enable 64-bit timestamp format, the results of asserting tx_etstamp_ins_ctrl_timestamp_insert are undefined. Therefore, the timestamp in any case maps to the 96-bit signals. |
| tx_etstamp_ins_ctrl_residence_time_calc_format | Input     | Specifies the TOD format (Intel 64-bit TOD format or the V2 96-bit format) for the current packet if the TX client simultaneously asserts tx_etstamp_ins_ctrl_residence_time_update. Values are:  
  - 1'b0: 96-bit TOD format (V2)  
  - 1'b1: 64-bit TOD format  
  The TX client must maintain the desired value on this signal while the TX SOP signal is asserted.  
  If you set the Time of day format parameter to the value of Enable 96-bit timestamp format or Enable both formats, and the client specifies the 64-bit format, the IP core maps the 64-bit TOD format time-of-day (32 bits of seconds and 32 bits of nanoseconds) as is in bits [79:16] of the 96-bit timestamp and TOD signals.  
  If you set the Time of day format parameter to the value of Enable 64-bit timestamp format and the client specifies the 96-bit format (V2), the results are undefined. |
| tx_etstamp_ins_ctrl_offset_timestamp[15:0] | Input     | Specifies the byte offset of the timestamp information in the current packet if the TX client simultaneously asserts tx_etstamp_ins_ctrl_timestamp_insert. The IP core overwrites the value at this offset. The TX client must maintain the desired value on this signal while the TX SOP signal is asserted.  
  If the packet supports V2 format, the timestamp has 96 bits. In this case, the IP core inserts ten bytes (bits [95:16]) of the timestamp at this offset and the remaining two bytes (bits [15:0]) of the timestamp at the offset specified in tx_etstamp_ins_ctrl_offset_correction_field.  
  The TX client must ensure that:  
  - The offset includes the entire timestamp in a single packet.  
  - If the packet is more than 256 bytes, the offset supports inclusion of the entire timestamp in the first 256 bytes of the packet.  
  - The timestamp bytes do not overlap with the bytes in any other field, including the UDP checksum field. (If these particular two fields overlap, the result is undefined). |
| tx_etstamp_ins_ctrl_offset_correction_field[15:0] | Input     | If the TX client simultaneously asserts tx_etstamp_ins_ctrl_residence_time_update, this signal specifies the byte offset of the correction field in the current packet. |

Note: If you set the Time of day format parameter to the value of Enable 64-bit timestamp format, the results of asserting tx_etstamp_ins_ctrl_timestamp_insert are undefined. Therefore, the timestamp in any case maps to the 96-bit signals.
### Signal Name | Direction | Description
---|---|---
If the TX client simultaneously asserts `tx_etstamp_ins_ctrl_timestamp_insert` and deasserts (sets to the value of 0) the `tx_etstamp_ins_ctrl_timestamp_format` signal, this signal specifies the byte offset of bits [15:0] of the timestamp.

The TX client must maintain the desired value on this signal while the TX SOP signal is asserted.

In addition, the TX client must ensure that:
- The offset includes the entire correction field or timestamp in a single packet.
- If the packet is more than 256 bytes, the offset supports inclusion of the entire timestamp or correction field in the first 256 bytes of the packet.
- The correction field or timestamp bytes do not overlap with the bytes in any other field, including the UDP checksum field. (If these particular two fields overlap, the result is undefined).

| `tx_etstamp_ins_ctrl_checksum_zero` | Input | The TX client asserts this signal during a TX SOP cycle to tell the IP core to zero the UDP checksum in the current packet.
If the TX client asserts the `tx_etstamp_ins_ctrl_checksum_correct` signal, it cannot assert this signal. This signal is meaningful only in one-step clock mode.
A zeroed UDP checksum indicates the checksum value is not necessarily correct. This information is useful to tell the application to skip checksum checking of UDP IPv4 packets. This function is illegal for UDP IPv6 packets.

| `tx_etstamp_ins_ctrl_offset_checksum_field[15:0]` | Input | Indicates the byte offset of the UDP checksum in the current packet. The TX client must ensure this signal has a valid value during each TX SOP cycle when it also asserts the `tx_etstamp_ins_ctrl_checksum_zero` signal. Holds the byte offset of the two bytes in the packet that the IP core should reset. This signal is meaningful only in one-step clock mode.
The TX client must ensure that:
- The offset includes the entire checksum in a single packet.
- The checksum bytes do not overlap with the bytes in any other field, including the timestamp bytes. (If these particular two fields overlap, the result is undefined).

| `tx_etstamp_ins_ctrl_checksum_correct` | Input | The TX client asserts this signal during a TX SOP cycle to tell the IP core to update (correct) the UDP checksum in the current packet.
If the TX client asserts the `tx_etstamp_ins_ctrl_checksum_zero` signal, it cannot assert this signal. This signal is meaningful only in one-step clock mode.
The application must assert this signal for correct processing of UDP IPv6 packets.

| `tx_etstamp_ins_ctrl_offset_checksum_correction[15:0]` | Input | Indicates the byte offset of the UDP checksum correction field in the current packet represented by the extended bytes before CRC. The TX client must ensure this signal has a valid value during each TX SOP cycle when it also asserts the `tx_etstamp_ins_ctrl_checksum_correct` signal. Holds the byte offset of the two bytes in the packet that the IP core should correct. This signal is meaningful only in one-step clock mode.
The TX client must ensure that:
- The offset and length of the checksum correction field includes the entire two bytes of the checksum correction field in a single packet.
- The checksum bytes do not overlap with the bytes in any other field, including the timestamp bytes. (If these particular two fields overlap, the result is undefined).
- The end of the UDP payload of the PTP packet is extended by 2 bytes. The MAC function modifies the extended bytes to ensure that the UDP checksum remains uncompromised.

**continued...**
### Signal Name | Direction | Description
--- | --- | ---
**tx_egress_asymmetry_update** | Input | Indicates the IP core should include the value in the TX_PTPASYM_DELAY register in its correction calculations. The TX client must maintain the desired value on this signal while the TX SOP signal is asserted. This option is useful in one-step correction mode.

### TX Signals Related to Two Step Processing

**tx_egress_timestamp_request_valid** | Input | Indicates the current packet on the TX client interface is a 1588 PTP packet, and directs the IP core to process the packet in two-step processing mode. In this mode, the IP core outputs the timestamp of the packet when it exits the IP core, and does not modify the packet timestamp information. The TX client must assert and deassert this signal synchronously with the TX SOP signal for the 1588 PTP packet. If the TX client asserts this signal simultaneously with tx_etstamp_ins_ctrl_residence_time_update, the results are undefined.

**tx_egress_timestamp_96b_data[95:0]** | Output | Provides the V2-format timestamp when a 1588 PTP frame begins transmission on the Ethernet link. Value is valid when the tx_egress_timestamp_96b_valid signal is asserted. This signal is meaningful only in two-step clock mode. This signal is available only if you set the Time of day format parameter to the value of Enable 96-bit timestamp format or Enable both formats.

**tx_egress_timestamp_96b_valid** | Output | Indicates that the tx_egress_timestamp_96b_data and tx_egress_timestamp_96b_fingerprint signals are valid in the current clk_txmac clock cycle. This signal is meaningful only in two-step clock mode. This signal is available only if you set the Time of day format parameter to the value of Enable 96-bit timestamp format or Enable both formats.

**tx_egress_timestamp_64b_data[63:0]** | Output | Provides the timestamp when a V1-format 1588 PTP frame begins transmission on the Ethernet link. Value is valid when the tx_egress_timestamp_64b_valid signal is asserted. This signal is meaningful only in two-step clock mode. This signal is available only if you set the Time of day format parameter to the value of Enable 64-bit timestamp format or Enable both formats.

**tx_egress_timestamp_64b_valid** | Output | Indicates that the tx_egress_timestamp_64b_data and tx_egress_timestamp_64b_fingerprint signals are valid in the current clk_txmac clock cycle. This signal is meaningful only in two-step clock mode. This signal is available only if you set the Time of day format parameter to the value of Enable 64-bit timestamp format or Enable both formats.

**tx_egress_timestamp_request_fingerprint[(W–1):0]** | Input | Fingerprint of the current packet. The TX client must assert and deassert this signal synchronously with the TX SOP signal for the 1588 PTP packet.

**tx_egress_timestamp_96b_fingerprint[(W–1):0]** | Output | Provides the fingerprint of the V2-format 1588 PTP frame currently beginning transmission on the Ethernet link. Value is valid when the tx_egress_timestamp_96b_valid signal is asserted. This signal is available only if you set the Time of day format parameter to the value of Enable 96-bit timestamp format or Enable both formats.

<td>Active low hard global reset. Resets the full IP core. Resets the TX MAC, RX MAC, TX PCS, RX PCS, adapters, transceivers, and control, status, and statistic registers. This reset leads to the deassertion of the tx_lanes_stable and rx_pcs_ready output signals.</td>
</tr>
</tbody>
</table>
7. Control, Status, and Statistics Register Descriptions

This section provides information about the memory-mapped registers. You access these registers using the IP core Avalon Memory-Mapped control and status interface. The registers use 32-bit addresses; they are not byte addressable.

Write operations to a read-only register field have no effect. Read operations that address a Reserved register return an unspecified result. Write operations to Reserved registers have no effect. Accesses to registers that do not exist in your IP core variation, or to register bits that are not defined in your IP core variation, have an unspecified result. You should consider these registers and register bits Reserved. Although you can only access registers in 32-bit read and write operations, you should not attempt to write or ascribe meaning to values in undefined register bits.

<td>XON/XOFF flow control frame request bit 0. Interpretation depends on whether the IP core is in 1-bit FC request mode or in 2-bit FC request mode. This register affects a flow control queue only if the corresponding bit of the TX Flow Control Enable register has the value of 1. In 2-bit mode, in addition, this register is active for a specific flow control queue only if the corresponding bit in the TX 2-bit Flow Control Request Mode register field ([FCQN-1]:0) of the register at offset 0x641) specifies that the flow control logic accepts input from this register. The following encodings are defined for 1-bit mode. The IP core reads the 1-bit mode value in TX Flow Control CSR XON/XOFF Request 0. 0 = No request 0 to 1 = Generate XOFF request 1 = Continue to generate XOFF request 1 to 0 = Generate XON request The following encodings are defined for 2-bit mode. The IP core reads the 2-bit mode value in {TX Flow Control CSR XON/XOFF Request 1, TX Flow Control CSR XON/XOFF Request 1}. 00 = No request 01 = XON request 10 = XOFF request 11 = Invalid You can modify the value of this field dynamically.</td>

### Related Information
- **Flow Control** on page 37
  Describes how the IP core uses the information in these registers to provide flow control functionality.

### 7.5. Statistics Registers

The 25G Ethernet Intel FPGA IP statistics registers count Ethernet traffic and errors. The 64-bit statistics registers are designed to roll over, to ensure timing closure on the FPGA. However, these registers should never roll over if the link is functioning properly. The statistics registers check the size of frames, which includes the following fields:

- Size of the destination address
- Size of the source address
- Size of the data
- Four bytes of CRC

The statistics counters module is a synthesis option. The statistics registers are counters that are implemented inside the CSR. When you turn on the **Enable MAC statistics counters** parameter in the 25G Ethernet Intel FPGA IP parameter editor, the counters are implemented in the CSR. When you turn off the **Enable MAC statistics counters** parameter in the 25G Ethernet Intel FPGA IP parameter editor, the counters are not implemented in the CSR, and read access to the counters returns undefined results.

After system power-up, the statistics counters have random values. You must clear these registers and confirm the system is stable before using their values. To clear the registers, use any of the following methods:

1. Assert `csr_rst_n` to clear both the TX and RX statistic counters.
2. Assert `tx_rst_n` to clear the TX statistic counters.
3. Assert `rx_rst_n` to clear the RX statistic counters.
4. Write `1'b1` to bit[0], `eio_sys_rst` of the PHY_CONFIG (0x310) register to clear both the TX and RX statistic counters.
5. Write 1'b1 to bit[1], soft_txp_rst of the PHY_CONFIG (0x310) register to clear the TX statistic counters.

6. Write 1'b1 to bit[2], soft_rxp_rst of the PHY_CONFIG (0x310) register to clear the RX statistic counters.

7. Write 1'b1 to bit[0] of the CNTR_TX_CONFIG (0x845) to clear the TX statistic counters.

8. Write 1'b1 to bit[0] of the CNTR_RX_CONFIG (0x945) to clear the RX statistic counters.

The configuration register at offset 0x845 allows you to clear all of the TX statistics counters. The configuration register at offset 0x945 allows you to clear all of the RX statistics counters. If you exclude these registers, you can monitor the statistics counter increment vectors that the IP core provides at the client side interface and maintain your own counters.

Reading the value of a statistics register does not affect its value.

To ensure that the counters you read are consistent, you should issue a shadow request to create a snapshot of all of the TX or RX statistics registers, by setting bit [2] of the configuration register at offset 0x845 or 0x945, respectively. Until you reset this bit, the counters continue to increment but the readable values remain constant. You can read bit [1] of the status register at offset 0x846 or 0x946, respectively, to confirm your shadow request has been granted or released.

### 7.5.1. TX Statistics Registers

**Table 26. Transmit Side Statistics Registers**

The TX statistics counters do not reflect TX CRC errors the user forces by asserting the l1_tx_error signal.

7.6. 1588 PTP Registers

The 1588 PTP registers together with the 1588 PTP signals process and provide Precision Time Protocol (PTP) timestamp information as defined in the IEEE 1588-2008 Precision Clock Synchronization Protocol for Networked Measurement and Control Systems Standard. The 1588 PTP module provides you the support to implement the 1588 Precision Time Protocol in your design.

8. Debugging the Link

Begin debugging your link at the most basic level, with word lock. Then, consider higher level issues.

The following steps should help you identify and resolve common problems that occur when bringing up a 25G Ethernet Intel FPGA IP core link:

1. Establish word lock—The RX lanes should be able to achieve word lock even in the presence of extreme bit error rates. If the IP core is unable to achieve word lock, check the transceiver clocking and data rate configuration. Check for cabling errors such as the reversal of the TX and RX lanes. Check the clock frequency monitors (KHZ_REF, KHZ_TX, KHZ_RX PHY registers) in the Control and Status registers.

To check for word lock: Clear the FRM_ERR register by writing the value of 1 followed by another write of 0 to the SCLR_FRM_ERR register at offset 0x324. Then read the FRM_ERR register at offset 0x323. If the value is zero, the core has word lock. If non-zero the status is indeterminate.

2. When having problems with word lock, check the EIO_FREQ_LOCK register at address 0x321. The values in this register define the status of the recovered clock. In normal operation, all the bits should be asserted. A non-asserted (value-0) or toggling logic value on the bit that corresponds to any lane, indicates a clock recovery problem. Clock recovery difficulties are typically caused by the following problems:
   - Bit errors
   - Failure to establish the link
   - Incorrect clock inputs to the IP core

3. Check the PMA FIFO levels by selecting appropriate bits in the EIO_FLAG_SEL register and reading the values in the EIO_FLAGS register. During normal operation, the TX and RX FIFOs should be nominally filled. Observing a the TX FIFO is either empty or full typically indicates a problem with clock frequencies. The RX FIFO should never be full, although an empty RX FIFO can be tolerated.

4. Establish lane integrity—When operating properly, the lanes should not experience bit errors at a rate greater than roughly one per hour per day. Bit errors within data packets are identified as FCS errors. Bit errors in control information, including IDLE frames, generally cause errors in XL/CGMII decoding.

5. Verify packet traffic—The Ethernet protocol includes automatic lane reordering so the higher levels should follow the PCS. If the PCS is locked, but higher level traffic is corrupted, there may be a problem with the remote transmitter virtual lane tags.

6. Tuning—You can adjust transceiver analog parameters to improve the bit error rate. If you turn on ADME in the IP core parameter editor, you can use the Transceiver Toolkit for this purpose.
In addition, your IP core can experience loss of signal on the Ethernet link after it is established. In this case, the TX functionality is unaffected, but the RX functionality is disrupted. The following symptoms indicate a loss of signal on the Ethernet link:

- The IP core deasserts the `rx_pcs_ready` signal, indicating the IP core has lost alignment marker lock.
- The IP core deasserts the RX PCS fully aligned status bit (bit [0]) of the `RX_PCS_FULLY_ALIGNED_S` register at offset 0x326. This change is linked to the change in value of the `rx_pcs_ready` signal.
- If `Enable link fault generation` is turned on, the IP core sets `local_fault_status` to the value of 1.
- The IP core asserts the Local Fault Status bit (bit [0]) of the `Link_Fault` register at offset 0x308. This change is linked to the change in value of the `local_fault_status` signal.
- The IP core triggers the RX digital reset process by asserting `soft_rxp_rst`.

### 8.1. Error Insertion Test and Debugging

Error insertion allows you to test 25G Ethernet Intel FPGA IP core test error handling.

To use this feature, the Avalon Streaming TX client asserts `l1_tx_error` in the same cycle as `l1_tx_endofpacket`. The error appears as a 66-bit error block that consists of eight `/E/` characters (EBLOCK_T) in the Ethernet frame. The 25G Ethernet Intel FPGA IP core overwrites Ethernet frame data with an EBLOCK_T error block when it transmits the Ethernet frame that corresponds to the packet EOP. The RX interface detects the frame corruption resulting in a CRC error output.
9. 25G Ethernet Intel Arria 10 FPGA IP User Guide Archive

IP versions are the same as the Intel Quartus Prime Design Suite software versions up to v19.1. From Intel Quartus Prime Design Suite software version 19.2 or later, IP cores have a new IP versioning scheme.

If an IP core version is not listed, the user guide for the previous IP core version applies.

| 2019.12.16       | 19.4                       | 19.4.0     | • Updated the description in the About the 25G Ethernet Intel FPGA IP Core section.  
• Updated Table: IP Core FPGA Resource Utilization for 25G Ethernet Intel FPGA IP Core for Intel Arria 10 Devices.  
• Updated the description in the PTP Transmit Functionality section.  
• Updated the descriptions for the following signals in Table: Signals of the 1588 Precision Time Protocol Interface:  
  – tx_etstamp_ins_ctrl_offset_timestamp[15:0]  
  – tx_etstamp_ins_ctrl_offset_correction_field[15:0]  
  – tx_etstamp_ins_ctrl_offset_checksum_field[15:0]  
  – tx_etstamp_ins_ctrl_offset_checksum_correction[15:0]  
• Added rx_am_lock to Table: Miscellaneous Status and Debug Signals.  
• Updated the description and reset value for RXMAC_CONTROL in Table: RX MAC Registers.  
• Updated the description of the Avalon Memory-Mapped Management Interface section.  
• Updated the Statistics Registers section.  
• Renamed Altera Debug Master Endpoint (ADME) to Native PHY Debug Master Endpoint (NPDME).  
• Updated for latest Intel branding standards. |
| 2018.10.23       | 17.0                       | 17.0       | • Updated Table: PHY Registers:  
  – Added bit[1] description for RX_PCS_FULLYAligned_.S.  
  – Updated the descriptions for KHZ_REF, KHZ_RX, and KHZ_TX.  
• Made minor editorial updates to the document. |
| 2018.07.17       | 17.0                       | 17.0       | • Renamed the document as 25G Ethernet Intel Arria 10 FPGA IP User Guide.  
• Renamed "25G Ethernet" IP core to "25G Ethernet Intel FPGA IP" as per Intel rebranding.  
• Updated Table: TX 1588 PTP Registers to correct the HW reset value of the TX_PTP_CLK_Period register to 0x28F5C.  
• Updated Table: RX 1588 PTP Registers to correct the HW reset value of the RX_PTP_CLK_Period register to 0x28F5C.  
• Updated for latest Intel branding standards. |
## Document Revision History for the 25G Ethernet Intel Arria 10 FPGA IP User Guide

<table>
<thead>
<tr>
<th>Date</th>
<th>Quartus Prime Version</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>2017.11.07</td>
<td>17.0</td>
<td>Added link to KDB Answer that provides workaround for potential jitter on Intel Arria 10 devices due to cascading ATX PLLs in the IP core. Refer to Handling Potential Jitter in Intel Arria 10 Devices on page 21.</td>
</tr>
</tbody>
</table>
| 2017.08.28 | 17.0                  | - Updated for new Quartus Prime software v17.0 release  
  - Updated instructions to generate the IP core. Refer to Specifying the 25G Ethernet Intel FPGA IP Core Parameters and Options on page 15  
  - Updated IP Cores Generated Files figure. Refer to Generated File Structure on page 17.  
- Updated information about specification compliance. The IP core now complies with Draft 1.6 of the 25G & 50G Ethernet Specification from the 25 Gigabit Ethernet Consortium, and the IEEE 802.3by 25Gb Ethernet specification is no longer a draft. Refer to About the 25G Ethernet Intel FPGA IP Core on page 4 and 25G Ethernet Intel FPGA IP Core Supported Features on page 5.  
- Added shadow feature for reading statistics registers. Replaced the CLEAR_TX_STATS and CLEAR_RX_STATS registers with new CNTR_TX_CONFIG and CNTR_RX_CONFIG registers at offsets 0x845 and 0x945. Added new CNTR_TX_STATUS and CNTR_RX_STATUS registers at offsets 0x846 and 0x946, respectively. Refer to Statistics Registers on page 74.  
- Removed statements that parameter editor fails to enforce certain incompatible parameter constraints. The IP core parameter editor no longer allows you to select unsupported parameter value combinations. Refer to 25G Ethernet Intel FPGA IP Core Parameters on page 24.  
- Removed Vendor ID from Release Information on page 11.  
- Clarified that the IP core clk_ref input signal and the ATX PLL reference clock input signal must be driven by the same clock. Refer to Adding the Transceiver PLL on page 20.  
- Clarified that the design example includes SDC files that you can modify for your own design. Refer to Compiling the Full Design and Programming the FPGA on page 23.  
- Clarified that the IP core does not support VHDL models. Refer to Specifying the 25G Ethernet Intel FPGA IP Core Parameters and Options on page 15 and Generated File Structure on page 17.  
- Clarified that the TX statistics counters do not count the errors you generate by asserting the l1_tx_error signal. Refer to TX MAC Interface to User Logic on page 52 and TX Statistics Registers on page 75.  
- Clarified that both read and write accesses to undefined registers or register fields, including accesses to registers and register fields not defined in the current IP core variation, return unspecified results. Refer to Control, Status, and Statistics Register Descriptions on page 65.  
- Removed the section "Creating a Signal Tap II Debug File to Match Your Design Hierarchy" from the Debugging chapter. The files cited (build_stp.tcl) do not exist in the file hierarchy generated by the Intel Quartus Prime Standard Edition v17.0 software.  
- Reworded the definitions of the TX flow control/PFC registers at offsets 0x606 and 0x641 for clarity. The register functionality has not changed. Refer to Pause/PFC Flow Control Registers on page 70.  
- Updated flow control register descriptions to use the variable FCQN as it is defined in TX MAC Interface to User Logic on page 52: the number of flow control queues in the IP core. Refer to Pause/PFC Flow Control Registers on page 70.  
- Updated REV_ID register values in Pause/PFC Flow Control Registers on page 70, 1588 PTP Registers on page 82, TX Reed-Solomon FEC Registers on page 83 and RX Reed-Solomon FEC Registers on page 84.

| 2016.10.31 | 16.1                  | * Added clarification that non-character bytes in NAME registers are not printable, in register sections that previously indicated only the value zero for these bytes. Refer to PHY Registers on page 66 and Pause/PFC Flow Control Registers on page 70.  
* Mentioned that the IP core does not correctly flag received non-zero 4-bit ordered set types as erroneous. Refer to IP Core Malformed Packet Handling on page 32 and Link Fault Signaling Interface on page 34.  
* Added reference to Intel FPGA Answer that explains the requirement for certain additions to .sdc file. Refer to Compiling the Full Design and Programming the FPGA on page 23.  
* Reorganized Features list for reading clarity. Refer to 25G Ethernet Intel FPGA IP Core Supported Features on page 5.  
* Fixed assorted typos and minor errors. |

Initial release.
