Intel® Quartus® Prime Pro Edition User Guides - Combined

This auto-generated document contains the following user guides. To download individual standalone documents, click on the respective PDF/HTML links.

Quartus® Prime Pro Edition User Guide

Getting Started

Updated for Quartus® Prime Design Suite: **24.1**

This document is part of a collection - Quartus® Prime Pro Edition User Guides - Combined PDF link

Answers to Top FAQs:

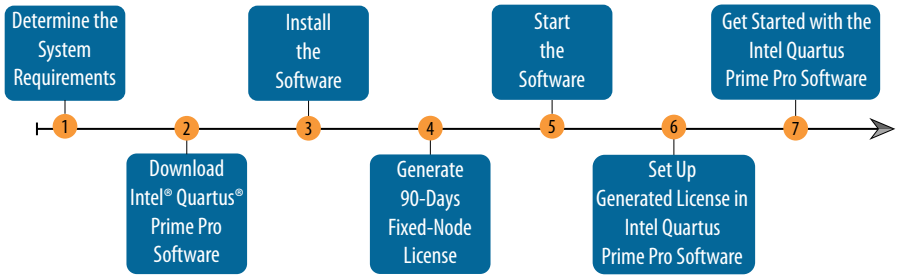
Contents

1. Introduction to Quartus® Prime Pro Edition

This user guide describes basic concepts, files, and design flow of the Quartus® Prime Pro Edition software, including initial design planning considerations, selecting a starting point to set up your Quartus Prime Pro Edition project and managing those projects and working with intellectual property (IP).

The Quartus Prime design suite is a comprehensive development platform to design with Intel FPGAs(1), from design entry and synthesis to optimization, verification, simulation, and binary generation. The Quartus Prime software supports fast design processing, straightforward device programming, and integration with other industry-standard EDA tools. The user interface makes it easy for you to focus on your design—not on the design tool. The modular compiler streamlines the FPGA development process and ensures the highest performance for the least effort.

Quartus Prime Pro Edition Software Quick Start Steps



(1) A field-programmable gate array (FPGA) is a specialized integrated circuit that you can customize and reconfigure multiple times. To learn about and select a target Intel FPGA device family, refer to https://www.intel.com/content/www/us/en/products/details/fpga.html.

Use the following links to get started with the Quartus Prime Pro Edition software:

Table 1. Quartus Prime Pro Edition Software Quick Start Steps

Step		Useful Links
Determine the System Requirements	Verify hardware and software requirements and review Quartus Prime Pro Edition software release notes.	• Reviewing the Quartus Prime Installer Software Release Notes • Determining Hardware Requirements • Determining Software Requirements
Download the software	Download the latest Quartus Prime Pro Edition software.	• Quartus Prime Design Software Download Page • FPGA Software Download Center • Downloading Software Using the Quartus Prime Installer or Quartus Prime Installer (GUI mode) • Downloading Software Packages Manually
Install the software	Install the latest Quartus Prime Pro Edition software.	• Quartus Prime Installer (GUI mode) or Installing Intel® FPGA Software Through Quartus Prime Installer • Installing the Intel FPGA Software Manually • Setting Quartus Prime Environment Variables
Generate 90-days Fixed-node License	Generate 90- days free license in Intel FPGA Self-Service Licensing Center (SSLC).	• Intel FPGA Self-Service Licensing Center • Intel FPGA SSLC No-cost/Evaluation License Setup • Setting up Intel FPGA SSLC No-cost/ Evaluation License
Start the software	**On Windows:** Use one of the following options: • On the desktop, double-click the Intel FPGA software icon.  • Click **Start ➤ All Programs ➤ Intel FPGA *<Version>* Pro Edition ➤ Quartus (Quartus Prime Pro *<Version>*** • At the command prompt, type: `<installation-directory>\bin64\quartus` **On Linux:** • At the command prompt, type: `<installation-directory>/quartus/bin/quartus`	Starting the Quartus Prime Software
Set up the generated license in the Quartus Prime Pro Edition software	In the Quartus Prime Pro Edition software, click **Tools ➤ License Setup**, browse and select the license file, and click **OK**.	• Intel FPGA Self-Service Licensing Center (SSLC) • Setting up Intel FPGA SSLC No-cost/ Evaluation License • Summary of Intel FPGA Software Licenses Required • Licensing Intel FPGA Software Walkthrough

Plan FPGA Design for RTL Flow	Planning for RTL flow is an essential step for advanced FPGA design. Determining your design priorities early on helps you to choose the best device, tools, features, and methodologies for your design.	Plan FPGA Design for RTL Flow
Create your FPGA project	The Quartus Prime software makes it easy for you to quickly setup a new FPGA design project.	Creating a New FPGA Design Project on page 22

Quartus Prime Software Editions

The Quartus Prime Software is available in three editions based on your design requirements:

Table 2. Quartus Prime Software Editions

	Pro Edition	Standard Edition	Lite Edition
	Optimized to support the advanced features in Intel FPGAs and SoCs with the following device families: • Agilex™ 5 • Agilex 7 • Stratix® 10 • Arria® 10 • Cyclone® 10 GX	Includes extensive support for earlier device families in addition to the following device families: • Cyclone 10 LP • MAX® 10	An ideal entry point to Intel's high-volume device families and is available as a free download with no license file required.

Supported Features

The following is the Quartus Prime feature support matrix:

Figure 2. Quartus Prime Feature Support Matrix

Software Features	Intel Quartus® Prime Pro Edition	Intel Quartus® Prime Standard Edition
Intel Agilex® 5 Device Support	✔	
Intel Agilex® 7 Device Support	✔	
Intel Stratix® 10 Device Support	✔	
New Hybrid Placer & Global Router	✔	✔
New Timing Analyzer	✔	✔
New Physical Synthesis	✔	✔
Platform Designer (formerly Qsys)	✔	✔
Partial Reconfiguration	✔	
Block-Based (Hierarchical) Design Flows	✔	
Interface Planner (formerly BluePrint)	✔	
Incremental Fitter Optimization	✔	

The following features are only available in the Quartus Prime Pro Edition software:

Table 3. Supported Features of the Quartus Prime Pro Edition Software

Feature	Description
Hyper-Aware Design Flow	Use Hyper-Retiming to reach the highest performance in Agilex 5, Agilex 7, and Stratix 10 devices.
Advanced synthesis	Integrates new, stricter language parser supporting all major IEEE RTL languages, with enhanced algorithms, and parallel synthesis capabilities, and support for SystemVerilog 2009.
Hierarchical project structure	Preserves individual post-synthesis, post-placement, and post-place and route results for design instances. Optimizes without impacting other partition placement or routing.
Incremental Fitter Optimizations	Run and optimize Fitter stages incrementally. Each Fitter stage generates detailed reports.
Faster, more accurate I/O placement	Plan interface I/O in Interface Planner.
Platform Designer (Pro)	Builds on the system design and custom IP integration capabilities of Platform Designer (Standard). Platform Designer (Pro) introduces hierarchical isolation between system interconnect and IP components.
Block-Based Design Flows	Preserve and reuse design blocks at various stages of compilation.

Quartus Prime Pro Edition software does not support the following Quartus Prime Standard Edition features:

- I/O Timing Analysis
- NativeLink third party tool integration (other third-party tool integration available)
- Video and Image Processing Suite IP Cores
- Talkback features
- Various register merging and duplication settings
- Saving a node-level netlist as `.vqm` or RTL to schematic conversion

Supported Intel FPGA Developmental Tools

The Quartus Prime software suite supports the following Intel FPGA development tools:

Table 4. Intel FPGA Developmental Tools Supported by the Quartus Prime Software Suite

Tools	Description
Questa*-Intel FPGA Edition	Simulates FPGA designs using Intel-specific simulation libraries. It includes all features of Siemens EDA Questa* Core, including behavioral simulation, HDL test benches, and Tcl scripting.
Intel Advanced Link Analyzer	Analyzes jitter/noise and evaluates high-speed serial link performance. It is an ideal predesign tool supporting Intel FPGA IBIS-AMI standards and enhanced models to help you understand how Intel FPGA solutions can fit your system requirements.
Intel SoC FPGA Embedded Development Suite	A comprehensive tool suite for embedded software development on Intel SoC FPGAs.
Ashling* RiscFree* IDE for Intel FPGAs	Integrated development environment for creating embedded applications on the RISC-V-based Nios® V soft processors and the Arm*-based hard processor system.
Intel HLS Compiler	A high-level synthesis (HLS) tool that accepts untimed C++ code as an input and generates production-quality register transfer level (RTL) code optimized for Intel FPGAs. This tool accelerates verification time over RTL by raising the abstraction level for FPGA hardware design. Models developed in C++ have typically verified orders of magnitude faster than RTL.
DSP Builder for Intel FPGAs	Supports a model-based design flow from algorithms to hardware in a common environment.
Intel oneAPI Base Toolkit	Enables you to target FPGAs for heterogeneous acceleration and simulate entire system flows by abstracting some parts of the hardware.
Intel Simics® simulator for Intel FPGAs	A full-system simulator that supports defining, developing, and deploying virtual platforms.
FPGA AI Suite	Provides several components to help in enabling Artificial Intelligence (AI) and creating optimized Intel FPGA AI platforms efficiently.
Intel FPGA Power and Thermal Calculator	Estimates your design's power consumption and provides thermal design parameters for Intel FPGA devices, such as Agilex 5, Agilex 7, and Stratix 10.

1.1. Before You Begin

Before you get started with setting up your Quartus Prime Pro Edition project, review the following topics:

1.1.1. Prerequisite Knowledge and Training

Using the Quartus Prime software to create a basic FPGA design requires the following basic knowledge. There are several training modules available if you need help.

Prerequisite Knowledge

- Basic knowledge of digital logic design.
- Basic knowledge of how to describe a hardware design using VHDL, Verilog HDL, SystemVerilog, or EDA schematic tools.

Note: You can accelerate design creation and success by starting your design project from a pre-verified design example that targets an Intel FPGA development board, as Creating a New Project from a Design Example on page 24 describes.

Prerequisite Training

If you are new to FPGA or the Quartus Prime software, you can review the following training modules:

- Read Me First!
- How to Begin a Simple FPGA Design
- University Self-Guided Lab: Become an FPGA Designer in 4 Hours
- Beginner Workshop for Intel FPGAs
- University Self-Guided Lab: Introduction to FPGAs and the Quartus Prime Software
- Basics of Programmable Logic: History of Digital Logic Design
- Basics of Programmable Logic: FPGA Architecture
- The Quartus Prime Software: Foundation (Pro Edition) (Online Training)
- Instructor-Led Training: Using Quartus Prime Software
- Using the Quartus Prime Standard Edition Software: An Introduction
- Verilog HDL Basics
- Verilog HDL Advanced
- VHDL Basics
- SystemVerilog with the Quartus Prime Software
- Introduction to Tcl Scripting

Related Information

- FPGAs for Dummies eBook

1.1.2. Navigate Content Through Tasks

Use the following navigation diagram to navigate this guide through user-tasks:

Table 6. Navigate Content Through Tasks

A	B	C	D
Plan FPGA Design for RTL Flow or Work With Intel FPGA IP Cores	Create a New Project or Migrate Your Existing Project to Quartus Prime Pro Edition Software	Manage Your Quartus Prime Pro Edition Projects	Review Next Steps

1.1.3. Acronyms

This document uses the following acronyms throughout:

Acronym	Meaning
ALR	Additional Logic Resources
DSE	Design Space Explorer
DSP	Digital Signal Processing
EDA	Electronic Design Automation
EDS	Embedded Design Suite
EPE	Early Power Estimator
FIFO	First In, First Out
FPGA	Field Programmable Gate Arrays
GUI	Graphical User Interface
HDL	Hardware Description Language
HTML	HyperText Markup Language
HPS	Hard Processor System
IEEE	Institute of Electrical and Electronics Engineers
IP	Intellectual Property
JTAG	Joint Test Action Group
LAB	Logic Array Block
LAI	Logic Analyzer Interface
MTBF	Mean Time Between Failures
PCB	Printed Circuit Board
PLD	Programmable Logic Devices
PLLs	Phase-Locked Loops
PTC	Power and Thermal Calculator
PVT	Process, Voltage, and Temperature
QSF	Quartus Settings File

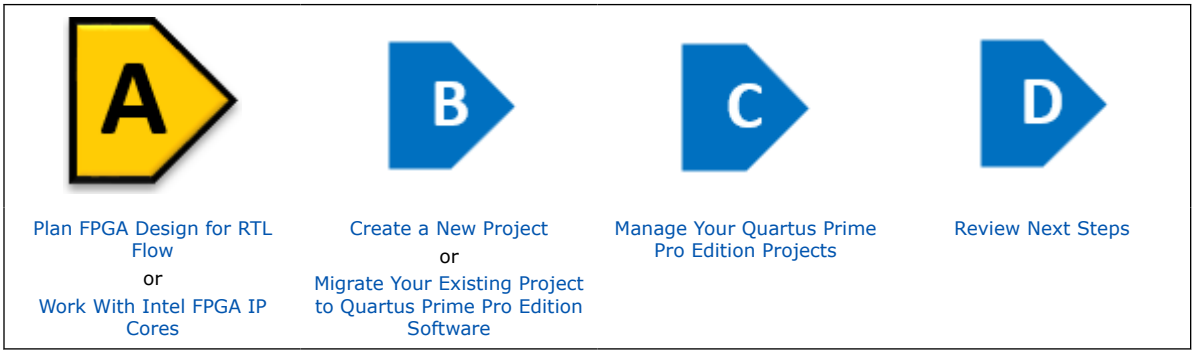
continued...

Acronym	Meaning
RAM	Random-Access Memory
RTL	Register-Transfer Level or Register-Transfer Logic
SDC	Synopsys* Design Constraints
Tcl	Tool Command Language
UART	Universal Asynchronous Receiver-Transmitter
VCS	Verilog Compiler and Simulator
VHDL	Very High Speed Integrated Circuit Hardware Description Language
VPN	Virtual Private Network
VREF	Voltage Reference

2. Planning FPGA Design for RTL Flow

Navigating Content Through Tasks

Use the following navigation diagram to navigate this guide through user-tasks:



Planning for RTL flow is an essential step for advanced FPGA design. This chapter provides some useful tips and programming methods to consider in your planning process to help you detect and solve potential problems early in the design cycle. Determining your design priorities early on helps you to choose the best device, tools, features, and methodologies for your design.

Review the following topics to help you get started with the planning process:

2.1. Design Planning

Design planning is an essential step in advanced FPGA design. System architects must consider the target device characteristics in order to plan for interface I/O, integration of IP, on-chip debugging tools, and use of other EDA tools. Designers must consider device power consumption and programming methods when planning the layout. You can solve potential problems early in the design cycle by following the design planning considerations in this chapter.

By default, the Quartus Prime software optimizes designs for the best overall results. However, you can adjust settings to better optimize one aspect of your design, such as performance, routability, area, or power utilization. Consider your own design priorities and trade-offs when reviewing the techniques in this chapter. For example, certain device features, density, and performance requirements can increase system cost. Signal integrity and board issues can impact I/O pin locations. Power, timing performance, and area utilization all affect one another. Compilation time is affected when optimizing these priorities.

Determining your design priorities early on helps you to choose the best device, tools, features, and methodologies for your design.

Table 7. Checklist for Design Planning

Item	Considerations	Links
Create a design specification and test plan	• Create detailed design specifications that define the system. • Specify the I/O interfaces for the FPGA. • Identify the different clock domains. • Include a block diagram of basic design functions. • Create a test plan for verification and ease of manufacture. • Consider a common design directory structure or source control system to make design integration easy. • Consider whether you want to standardize on an interface protocol for each design block.	
Planning for Target Device or Board	• Refer to the Product Selector tool to compare the specifications and features of Intel FPGA devices and development kits. • Refer to the device family documentation for detailed device characteristics. View a summary of each device's resources by selecting a device in the Device dialog box (**Assignments ➤ Device**). • Consider whether the device family meets your design requirements for high-speed transceivers, global or regional clock networks, and the number of phase-locked loops (PLLs). • Consider the density requirements of your design. — Devices with more logic resources and higher I/O counts can implement larger and more complex designs, but at a higher cost. — Smaller devices use lower static power. — Select a device larger than what your design requires if you may want to add more logic later in the design cycle, or to reserve logic and memory for on-chip debugging. • Consider requirements for types of dedicated logic blocks, such as memory blocks of different sizes, or digital signal processing (DSP) blocks to implement certain arithmetic functions. • Alternatively, create a system that targets a specific development board to accelerate the process of appropriately configuring, connecting, and validating IP for the target board.	• Product Selector Guide Tool • Using the Board-Aware Flow
Planning for Device Migration	• Determine whether you want to migrate your design to another device density to allow flexibility when your design nears completion. • Target a small (less expensive) device and move to a larger device if necessary to meet your design requirements. • Develop a prototype of your design in a larger device to reduce optimization time and achieve timing closure more quickly, and then migrate to a smaller device after prototyping. *Note:* Selecting a migration device impacts pin placement because some pins may serve different functions in different device densities or package sizes.	
Planning for Intellectual Property (IP) Cores	Plan which I/O interfaces or blocks in the system you want to implement using IP cores. Integrate functions into your design using Intel FPGA IP cores, many of which are available for production use in the Quartus Prime software without additional license.	• Working With Intel FPGA IP Cores on page 50 • Intel FPGA IP Portfolio Web Page

continued...

Item	Considerations	Links
	For IP cores that require additional licenses for production, use the Intel FPGA IP Evaluation Mode, which allows you to program the FPGA to verify the IP in the hardware before you purchase the IP license.	
Planning for Standard Interfaces	• Use standard interfaces in system design to ensure compatibility between design blocks from different design teams or vendors. • Use the Quartus Prime Interface Planner to accurately plan constraints for design implementation, prototype interface implementations, and rapidly define a legal device floorplan. • Use the Quartus PrimePlatform Designer system integration tool to use standard interfaces and speed-up system-level integration.	Quartus Prime Pro Edition User Guide: Platform Designer
Planning for Device Power Consumption	Estimating power consumption early in the design cycle allows you to plan power budgets and avoid unexpected results when designing the PCB. • Use the Early Power Estimator (EPE) spreadsheet for older devices, such as the Arria 10 and Cyclone 10 families or to estimate power consumption before compiling or creating any source code. • Use the Quartus Prime Power Analyzer to ensure that your design satisfies thermal and power supply requirements. • Use the Intel FPGA Power and Thermal Calculator (PTC) to estimate power utilization for your design for Stratix 10, Agilex 7, and Agilex 5 device families. PTC does not support older devices.	• Quartus Prime Pro Edition User Guide: Power Analysis and Optimization • Intel FPGA Power and Thermal Calculator User Guide
Planning for I/O Interfaces	• Create a preliminary pin-out for an Intel FPGA with the Quartus Prime Pin Planner before you develop the source code, based on standard I/O interfaces (such as memory and bus interfaces) and any other I/O requirements for your system. • Configure how to connect the functions and cores to each other by specifying matching node names for selected ports. • Create other I/O-related assignments for these interfaces or other design I/O pins in the Pin Planner. • Compile your design to automatically run I/O Assignment Analysis in Fitter to validate I/O-related assignments that you created or modified throughout the design process.	• Quartus Prime Pro Edition User Guide: Design Optimization • I/O Planning Overview
Planning for Other EDA Tools	• Use supported standard third-party EDA synthesis tools to synthesize your Verilog HDL or VHDL design, and compile the resulting output netlist file in the Quartus Prime software. • Use the simulator version that your Quartus Prime software version supports for best results. You must also use the model libraries provided with your Quartus Prime software version. Libraries can change between versions, which might cause a mismatch with your simulation netlist.	• Quartus Prime Pro Edition User Guide: Third-party Synthesis • Quartus Prime Pro Edition User Guide: Third-party Synthesis

continued...

Item	Considerations	Links
Planning for On-Chip Debugging Tools	• Consider whether to include on-chip debugging tools early in the design process. Adding the debugging tools late in the design process can be more time-consuming and error-prone. • Consider the following debugging requirements when planning your design to support debugging tools: — **JTAG connections**—required to perform in-system debugging with JTAG tools. Plan your system and board with JTAG ports that are available for debugging. — **Additional logic resources (ALR)**—required to implement JTAG hub logic. If you set up the appropriate tool early in your design cycle, you can include these device resources in your early resource estimations to ensure that you do not overload the device with logic. — **Reserve device memory**—required if your tool uses device memory to capture data during system operation. To ensure that you have enough memory resources to take advantage of this debugging technique, consider reserving device memory to use during debugging. — **Reserve I/O pins**—required if you use the Logic Analyzer Interface (LAI), which requires I/O pins for debugging. If you reserve I/O pins for debugging, you do not have to later change your design or board. The LAI can multiplex signals with design I/O pins if required. Ensure that your board supports a debugging mode, in which debugging signals do not affect system operation. — **Instantiate an IP core in your HDL code**—required if your debugging tool uses an Intel FPGA IP core. — **Instantiate the Signal Tap Logic Analyzer IP core**—required if you want to manually connect the Signal Tap Logic Analyzer to nodes in your design and ensure that the tapped node names do not change during synthesis.	• Factors to Consider When Using Debugging Tools During Design Planning Stages • Quartus Prime Pro Edition User Guide: Debug Tools
Planning HDL Coding Styles	• Use synchronous design practices to consistently meet your design goals. In a synchronous design, a clock signal triggers all events. When you meet all register timing requirements, a synchronous design behaves in a predictable and reliable manner for all process, voltage, and temperature (PVT) conditions. You can easily target synchronous designs to different device families or speed grades. *Note:* Problems with asynchronous design techniques include reliance on propagation delays in a device, incomplete timing analysis, and possible glitches. • Use dedicated clock pins and clock routing for best results, and if you have PLLs in your target device, use the PLLs for clock inversion, multiplication, and division. • For clock multiplexing and gating, use the dedicated clock control block or PLL clock switchover feature instead of combinational logic, if these features are available in your device. If you must use internally generated clock signals, register the output of any combinational logic used as a clock signal to reduce glitches.	• Quartus Prime Pro Edition User Guide: Design Recommendations • Quartus Prime Pro Edition User Guide: Timing Analyzer

continued...

Item	Considerations	Links
	• Consider the architecture of the device you choose so that you can use specific features in your design. For example, the control signals should use the dedicated control signals in the device architecture. Sometimes, you might need to limit the number of different control signals used in your design to achieve the best results. • HDL coding styles can have a significant effect on the quality of results for programmable logic designs. Follow the coding guidelines for inferring Intel FPGA IP and targeting dedicated device hardware, such as memory and DSP blocks. • Ensure that your design accounts for synchronization between any asynchronous clock domains. Consider using a synchronizer chain of more than two registers for high-frequency clocks and frequently-toggling data signals to reduce the chance of a metastability failure. • Use the Quartus Prime software to analyze the average mean time between failures (MTBF) due to metastability when a design synchronizes asynchronous signals, and optimize your design to improve the metastability MTBF.	
Planning your Project Path Length	Design files with lengthy file paths might cause an internal error in the Windows* version of the Quartus Prime Pro Edition software. Windows has a 260-character maximum path length limitation on the combined length of a file name and its file path. To reduce the length of a file path to a design file, Intel strongly recommends creating, storing, or moving your Quartus Prime project to a shorter path. For example: `C:\quartus_pro\<version>\project` *Tip:* There are several third-party software freely available to help you fix the long path issue for Windows.	Maximum Path Length Limitation

Table 8. Factors to Consider When Using Debugging Tools During Design Planning Stages

Design Planning Factor	Signal Tap Logic Analyzer	System Console	In-System Memory Content Editor	Logic Analyzer Interface (LAI)	Signal Probe	In-System Sources and Probes	Virtual JTAG IP Core
JTAG connections	Yes	Yes	Yes	Yes	—	Yes	Yes
Additional logic resources	—	Yes	—	—	—	—	Yes
Reserve device memory	Yes	Yes	—	—	—	—	—
Reserve I/O pins	—	—	—	Yes	Yes	—	—
Instantiate IP core in your HDL code	—	—	—	—	—	Yes	Yes

2.2. Selecting the Design Methodology

When creating an FPGA design, you must consider various design methodologies the Quartus Prime software offers, such as the incremental block-based design, flat design, and partial reconfiguration design. You can use these design flows with or without EDA design entry and synthesis tools. Refer to the following topics for more information about each of these methodologies.

2.2.1. Flat Design Vs. Incremental Block-based Design

With the Quartus Prime Pro Edition software, you can either develop a flat design or a block-based design:

- **Flat Designs**: In a flat compilation flow, the design hierarchy is flattened without design partitions and the Quartus Prime software compiles the entire design in a "flat" netlist. Although the source code may be hierarchical, the compiler flattens and synthesizes all the design logic. Whenever you recompile the project, the compiler re-performs all available logic and placement optimizations on the entire design.

  The flat compilation flow does not require any planning for design partitions. However, because the Quartus Prime software recompiles the entire design whenever you change your design, flat design practices may require more overall compilation time for large designs. Additionally, you may find that the results for one part of the design change when you change a different part of your design.

  If you plan to develop a small design with no plans to reuse or preserve blocks, use a flat design. However, flat designs are generally more difficult to optimize and debug because you cannot always isolate the timing issue.

- **Block-based designs**: In block-based (hierarchical) flows, you can divide your design by creating design partitions. Block-based design flow is also known as modular or hierarchical design flow. You can designate a design block as a design partition to preserve or reuse the block. A design partition is a logical, named, hierarchical boundary assignment that you can apply to a design instance. Hierarchical flows allow you to isolate, optimize, and preserve compilation results for specific design blocks but require more design planning to ensure effective results.

  Using a hierarchical design methodology offers several advantages, such as:

  — Reuse design blocks with the same periphery configuration, share a synthesized design block with another designer, or replicate placed and routed IP in another project.

  — Design, implement, and verify core or periphery blocks once, and then reuse those blocks multiple times across different projects that use the same device.

  — Perform easier debugging and optimization of individual design blocks.

  — Assign the design hierarchy elements into logical partitions that are functionally independent.

  — Perform stand-alone block verification.

  — Use design blocks for reuse and preserve synthesis and timing results for blocks that are fully coded and meeting timing.

  — Preserve earlier results for a block you do not want to change when you change RTL code or compiler settings for another block in the design. The compiler produces different compilation results compared to previous settings and can cause timing violations in blocks that do not reflect the same corresponding code or setting changes. Block-based incremental compilation flow allows for preserving the block.

  — Partition a design, compile the design partitions separately, and reuse the results for unchanged partitions. You can preserve the performance of unchanged blocks and reduce the number of design iterations. The performance preservation of incremental block-based compilation allows you to focus timing closure on unpreserved partitions or on blocks that have difficulty meeting timing requirements

For more information about the block-based designing, refer to the *Quartus Prime Pro Edition User Guide: Block-Based Design*.

Related Information

Quartus Prime Pro Edition: Block-Based Design

2.2.2. Partial Reconfiguration Design

Partial reconfiguration (PR) allows you to reconfigure a portion of the FPGA dynamically while the remaining FPGA design continues to function. You can define multiple personas for a particular region in your design without impacting operation in areas outside this region. This methodology is effective in systems with various functions that time-share the same FPGA device resources. PR enables the implementation of more complex FPGA systems.

The Quartus Prime Pro Edition software supports the PR feature for the Agilex 5, Agilex 7, Stratix 10, Arria 10, and Cyclone 10 GX device families.

PR provides the following advantages over a flat design:

- Allows run-time design reconfiguration.
- Increases scalability of the design through time-multiplexing.
- Lowers cost and power consumption through efficient use of board space.
- Supports dynamic time-multiplexing functions in the design.
- Improves initial programming time through smaller bitstreams.
- Reduces system downtime through line upgrades.
- Enables easy system updates by allowing remote hardware change.
- Supports a simplified compilation flow for partial reconfiguration.

For more information about the PR design, refer to the *Quartus Prime Pro Edition User Guide: Partial Reconfiguration*.

3. Selecting a Starting Point for Your Quartus Prime Pro Edition Project

Navigating Content Through Tasks

Use the following navigation diagram to navigate this guide through user-tasks:

There are multiple ways you can set up your project depending on your design needs Either you can create a new project with project files and libraries or with a design example, or you can import an existing project into the Quartus Prime Pro Edition software.

Select one of the following methods to set up your Quartus Prime Pro Edition project:

3.1. Creating a New FPGA Design Project

The Quartus Prime software makes it easy for you to quickly setup a new FPGA design project.

Use the quick access icons on the home page to set up your FPGA design project:

- **New Project Wizard**: Use this option to create a project either by specifying project files, libraries, target device family, and EDA tool settings, or using an existing design example.
- **Open Example Project**: Use this option if you want to base your current project on a pre-installed and verified design example.
- **Open Project**: Use this option to browse and open your existing projects.

The wizard guides you through specifying various options for new project setup and includes access to helpful project templates and design examples that allow you to preconfigure project settings for specific applications, FPGA devices, and target boards.

3.1.1. Using the Board-Aware Flow

The Quartus Prime Pro Edition software allows you to create a system that targets a specific development board, rather than only targeting a specific FPGA device. When you target a specific development board, the Quartus Prime software is *aware* of the target board (board-aware) which accelerates the process of appropriately configuring, connecting, and validating IP for the target board.

What is the Quartus Prime Software Board-Aware Flow?

In the board-aware flow, you can optionally start your project from a pre-verified design example (rather than an empty project) and target a specific Intel FPGA development board. You can also create appropriate IP presets to target the specific board. The Quartus Prime Platform Designer system integration tool is also board-aware, allowing you to automatically set pin assignments and export appropriate system interfaces for the target board.

The board-aware flow simplifies the application of appropriate parameters and pin assignments for the instantiated IP in your project, thereby reducing the chance of configuration errors. You can also save and reuse your preferred and verified board and IP configurations for use in other projects that target the same IP or board.

The board-aware flow helps to ensure the proper hand-off, consistency, and reuse of configuration options across multiple projects, developers, and boards.

Note: To define new boards and IP preset files in Platform Designer, refer to *Intel Quartus Prime Pro Edition User Guide: Platform Designer* and *AN 988: Using the Board-Aware Flow in the Intel Quartus Prime Pro Edition Software*.

Related Information

- Creating a New Project from a Design Example on page 24
- Specifying a Target Board for the Project on page 32
- Applying Preset Parameters for Specific Applications on page 61
- Intel Quartus Prime Pro Edition User Guide: Platform Designer
- AN 988: Using the Board-Aware Flow in the Intel Quartus Prime Pro Edition Software

3.1.1.1. Creating a New Project from a Design Example

The Quartus Prime software provides access to installed and online platform- and board-specific design examples that you can use as a starting point for your own design. You can accelerate your design progress by starting from a pre-validated design example that installs with the Quartus Prime software or is available online.

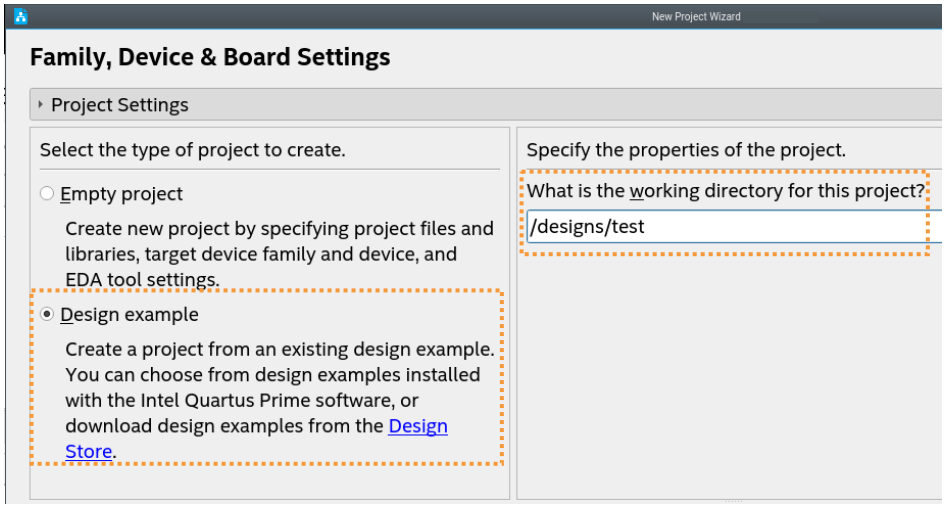
This technique can be especially helpful if you are new to FPGA design or EDA design tools. The design example can help you to quickly analyze a validated design on a board and appropriately configure it in various ways to match your users' needs. Alternatively, you can start with an **Empty Project** for which you specify all settings and design files.

- **Pre-installed design examples**—you can immediately access the design examples that install along with the Quartus Prime software installation at: `<quartus>\acds\quartus\common\board_designs`.
- **Online design examples**—you can access design examples hosted online, which includes designs from the Intel FPGA Design Store or directly from Quartus Prime software by clicking **Open Example Project** from the home page. For more information, refer to Design Example Discovery.
- **Downloaded design examples**—you can access your previously downloaded design examples, or any design example that you store in a local drive, under downloaded reference designs.

To create a new Quartus Prime project that is based on a design example, follow these steps:

1. the Quartus Prime software, click **File ➤ New Project Wizard**. Click **Next** to view the **Family, Device & Board Settings** wizard page.
2. Under the **Select the type of project to create**, select **Design Example** and click **Next**. The **Family, Device & Board Settings** page appears, allowing you to find and select the design example from which to base your project.

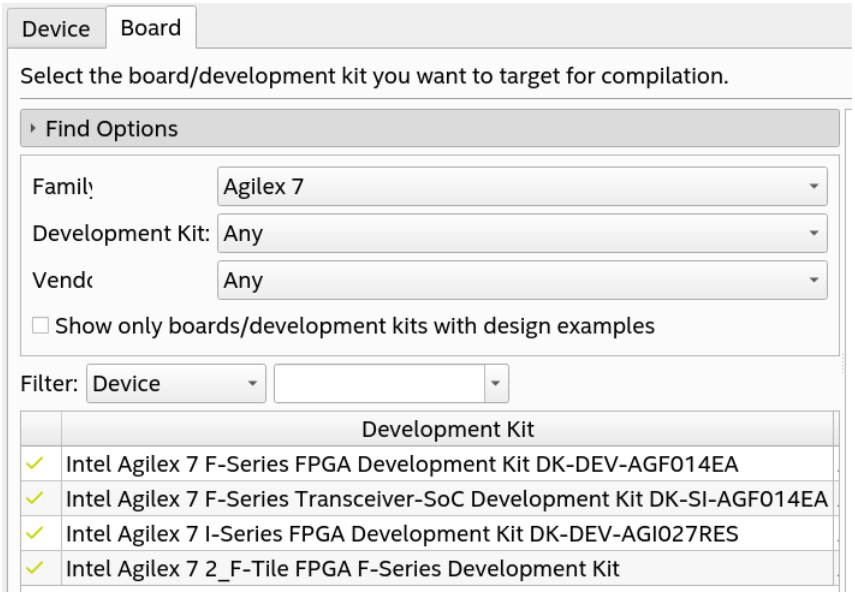
Figure 4. Family, Device & Board Settings Page of New Project Wizard



3. Under **What is the working directory for this project?**, specify the directory to store your project files and click **Next**.

4. Under **Find Options**, select the **Family**, **Development Kit**, and **Vendor** design example you want to use. Refer to Family, Device & Board Settings on page 25.

Figure 5. Board Tab in New Project Wizard



The search results display the design examples that meet your search criteria.

5. Select the design example that you want in the search results and click **Next**. If the design example is licensed by Intel FPGA, a **Software License Agreement** page appears that prompts you to accept the license agreement before you can proceed.
6. Click **Next** to proceed to the **Summary** page.
7. Click **Finish** to deploy the selected design example in the Quartus Prime software. When a design example downloads, the design's `.par` downloads to the download path that you define in **More Settings**, but the design itself extracts to the project working directory that you specify.

Also refer to Accessing Online Design Examples on page 27 and Accessing Downloaded Design Examples on page 31.

Intel FPGA Design Examples

3.1.1.1.1. Family, Device & Board Settings

The following options are available in the **Family, Device & Board Settings** page of the **New Project Wizard**. Specify these options to locate and deploy a validated design example targeting a specific board as a starting point for your FPGA design project. Some options are only available from **File ➤ Open Example Project**

Table 9. Family, Device & Board Settings Page Options

Option	Description
Select the type of project to create	• **Empty**—create a new empty FPGA design project to which you add all design files, settings, and constraints. • **Design example**—create a new project from an existing design example. You can access installed or online available design examples.
What is the working directory for this project?	Specifies the directory where you want to extract and deploy the design example.
Find Options	Allows you to filter design example search results by one of the following facets: • **Load from** >**Pre-installed design examples**—specifies that search includes examples installed with the Quartus Prime software. • **Load from** > **User downloaded design examples**—search includes design examples that you download or your own design examples that you store in a local repository. • **Load from** > **Online design examples**—search includes design examples hosted online, including examples from the Intel FPGA Design Store. • **Family**—search only includes design examples for the device families that you specify. You can specify multiple values. • **Quartus Prime version**—search only includes design examples that support the Quartus Prime software version that you specify. You can specify multiple pipe separated values. • **Development kit**—search only includes design examples that support the Intel FPGA development kit that you specify. You can specify multiple pipe separated values.
More settings button	Opens the **Options** panel that allows you to configure the **Internet Connectivity** and **Design Examples** connection and download settings, as Design Examples Options on page 30 describes.
Reset button	Resets the **Find Options** to default settings.
Legend panel	Displays the meaning of design example status icons in the search results. Design example status is validated (checkmark icon), unvalidated (question mark icon), or unsupported for the current Intel Quartus Prime software version (x icon).
Filter text box	Specifies a text string to further filter design example search results according to any text string you specify.
Search results list	Displays the design examples, status, and location that match your search filters.
Details panel	Displays a detailed description and diagram of the selected design example.
Design Store button	Opens the Design Store website in your default web browser from which you can download available Intel FPGA validated design examples.

3.1.1.1.2. Accessing Pre-Installed Design Examples

The Quartus Prime software installation includes design examples for your immediate use.

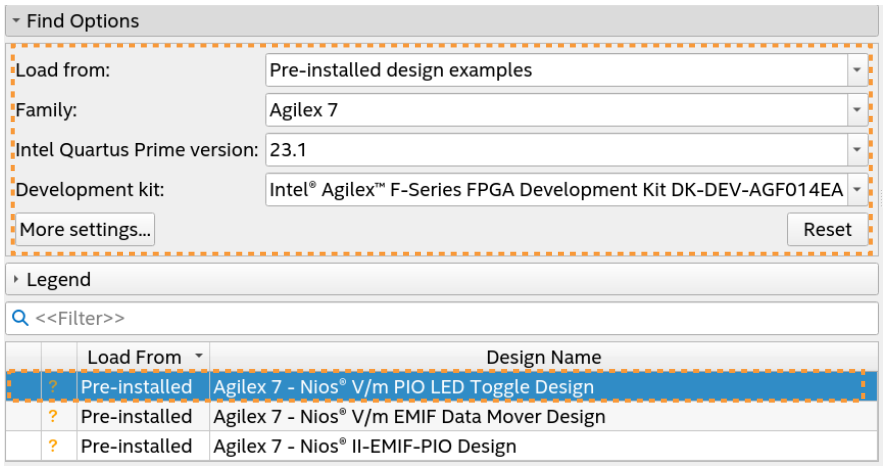
You can access the pre-installed design examples while using the Quartus Prime software using the following methods:

- Click **File ➤ New Project Wizard ➤ Family, Device & Board Settings** page.
- Click **Open Example Project** on the **Home** tab (**Help ➤ Home**).
- Click **File ➤ Open Example Project**.

To create a new project based on pre-installed design examples, follow these steps Quartus Prime Pro Edition software:

1. Click **File ➤ Open Example Project**. The **Design Example** page of the **New Project Wizard** opens.
2. For **What is the working directory for this project?**, specify the directory location to store your project files.

Figure 6. Find Options Locate Pre-Installed Design Example



3. Under **Find Options**, specify the following settings to filter the list of design examples for the target device and board. Also refer to Family, Device & Board Settings on page 25.
   a. In **Load from**, select the **Pre-Installed design examples**, repository.
   b. In **Family**, select your target FPGA device family.
   c. In **Intel Quartus Prime version**, select the software version.
   d. In **Development kit**, select the target kit or board.
4. Under **Design name**, select the design example to base your project on.
5. Click **Next**, and then click **Finish**. The design extracts to the working directory and opens in the Quartus Prime software.

Design Example Discovery

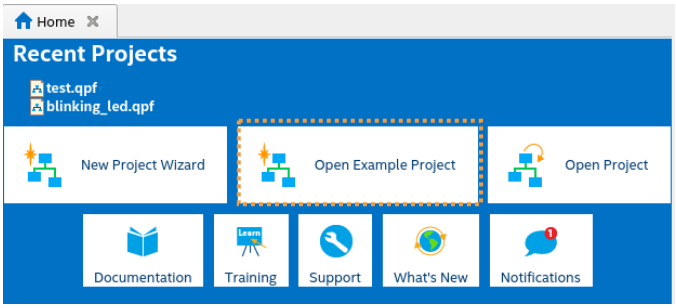
3.1.1.1.3. Accessing Online Design Examples

You can create a new project based on a design example that you access from an online repository. To use this method, you may need to specify a proxy server for access and the download path.

To create a new project in the Intel Quartus Prime software based on online design examples, follow these steps:

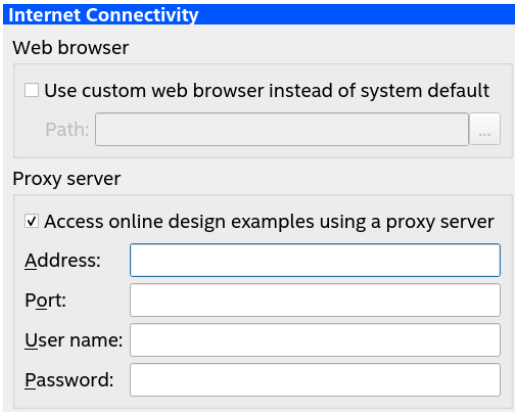
1. Click **File ➤ Open Example Project**. The **Design Example** page of the **New Project Wizard** opens.

Figure 7. Open Example Project Icon on Home Page



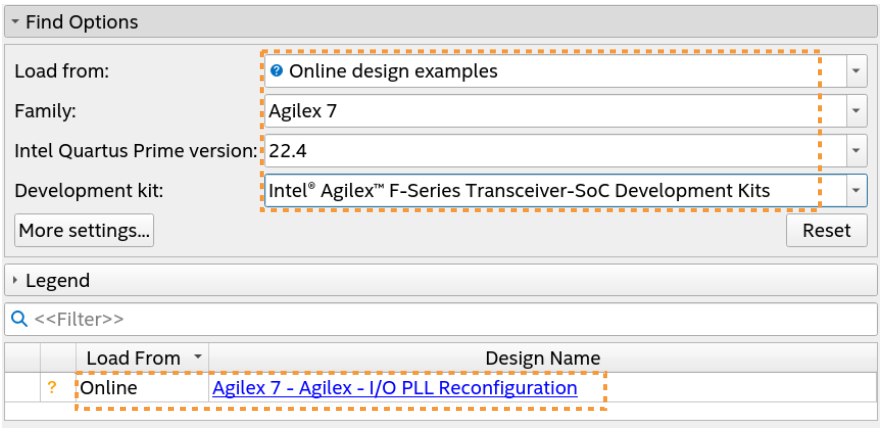
2. For **What is the working directory for this project?**, specify the directory location to store your project files.
3. Click the **More Settings** button. The **Options** dialog box opens with the **Internet Connectivity** tab open by default.

Figure 8. Intel Quartus Prime Software Internet Connectivity Settings



4. If your internet connection requires a proxy server (using VPN), turn on the **Access online design examples using a proxy server** option, and then specify your proxy **Address**, **Port**, **User name**, and **Password**. If your internet connection does not require a proxy server, skip this step.
5. On the **Design Example Search Locations** tab, specify the **Download path** for download of the design example `.par` file.
6. Click **OK**.
7. Under **Find Options**, specify the following settings. Also refer to Family, Device & Board Settings on page 25.
   a. In **Load from**, select **Downloaded design examples**.
   b. In **Family**, **Intel Quartus Prime version**, and **Development kit** fields select the values to match your target design and board.
8. In the design example list, select the design that you want to deploy.

Figure 9. Online Agilex 7 - I/O PLL Reconfiguration Design



9. Click **Next**, and then click **Finish**. The design extracts to the working directory and opens in the Quartus Prime software.

Internet Connectivity Options

You can specify the following internet connectivity options that determine how the Quartus Prime software connects to the internet for various functions, such as accessing Help and design examples, with either of the following:

- Click **Tools ➤ Options ➤ Internet Connectivity**

  Or

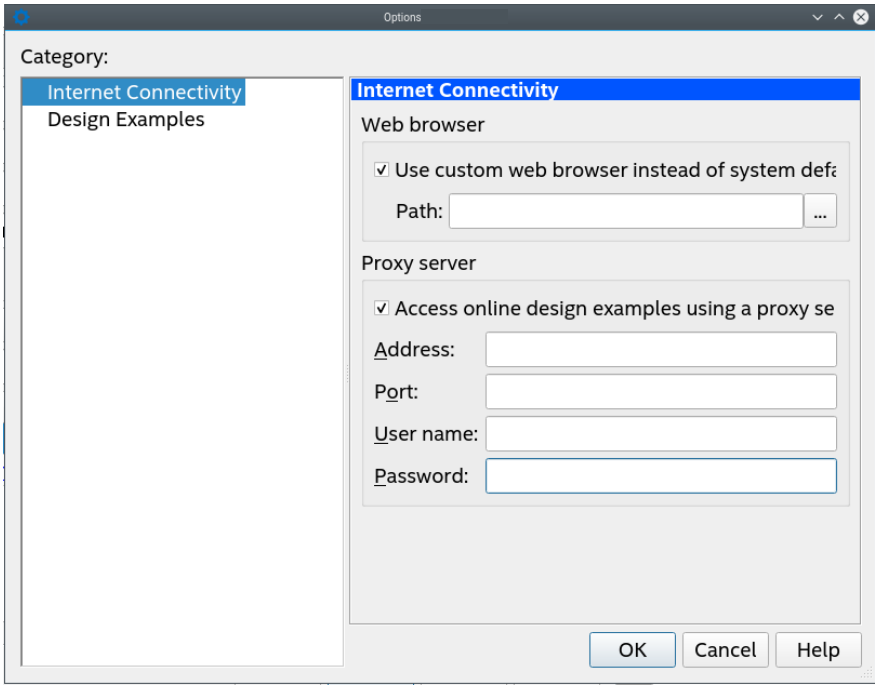
- Click **More Settings** on the **Design Example** page of the **New Project Wizard** (**File ➤ New Project Wizard**).

The following options are available on the **Internet Connectivity** options page.

Table 10. Internet Connectivity Options

Option	Description
Web browser	Specifies the web browser that deploys when the Quartus Prime software accesses the internet, including the Intel FPGA Design Store web page. Enable **Use custom web browser** to specify the path to your preferred supported web browser.
Proxy server	Specify options if connecting to the internet through a proxy server. To access online design examples specify the appropriate option: • **Access online design examples using a proxy server**—turn on this option if you are connected to the internet through a VPN. Turn off this option if you are not connected to the internet through a VPN (such as connection through a private network).

Figure 10. Internet Connectivity Page



Related Information

Design Example Options Page on page 30

Design Examples Options

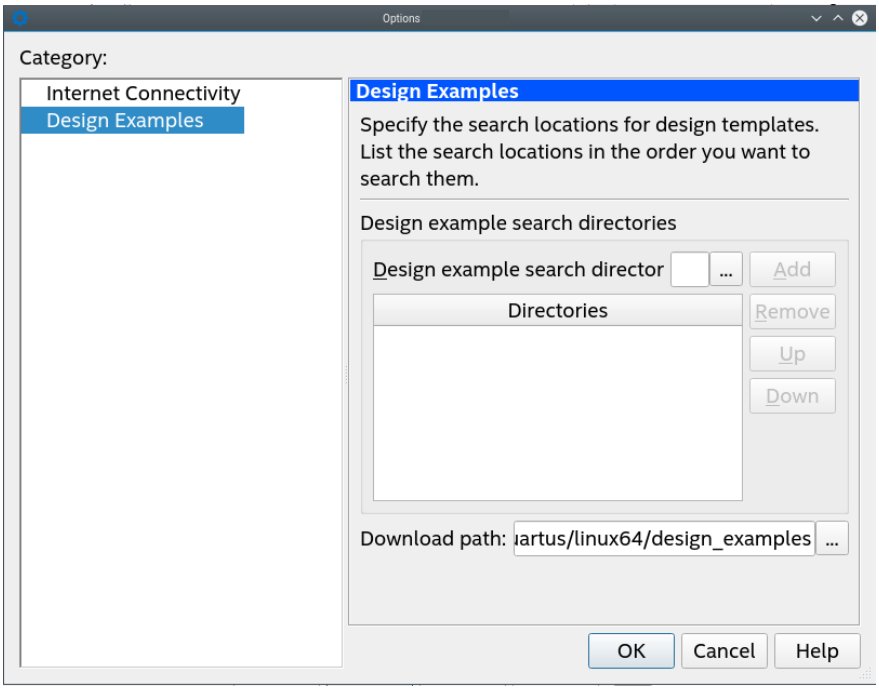
You can click the following to specify options that determine how the Quartus Prime software accesses available design examples.

- Click **File ➤ New Project Wizard** and then click the **More Settings** button on the **Design Example** page of the **New Project Wizard**.

Table 11. Design Examples Options

Option	Description
Design Example search directory	Specifies the local directories that the Quartus Prime software searches for design examples. This setting determines which directories you include in search when using the **New Project Wizard** to start a project from an existing design example. Click **Add**, **Remove**, **Up**, or **Down** to change the search order and contents in the **Directories** list.
Directories	Lists the various directories that you include in the design example search path for the **New Project Wizard**.
Download path	Specifies the path for download of online design examples.

Figure 11. Design Examples Page



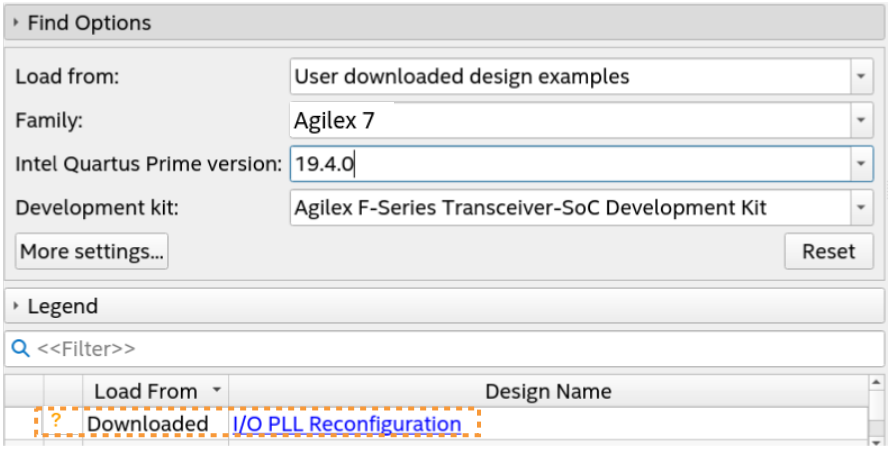
3.1.1.1.4. Accessing Downloaded Design Examples

You can create a new project from a design example that you have previously downloaded. Download a design example `.par` file from an online repository (such as the Intel FPGA Design Store) into your working directory. Designs that you create yourself and store in a local drive also appear as downloaded examples.

To create a new project based on downloaded design examples, follow these steps:

1. Download a design example, as Accessing Online Design Examples on page 27 describes.
2. Click the **Open Example Project** icon on the Quartus Prime Pro Edition **Home** page. The **Design Example** page of the **New Project Wizard** opens.
3. For **What is the working directory for this project?**, specify the directory location to store your project files.
4. Under **Find Options**, specify the following settings. Refer to Family, Device & Board Settings on page 25.
   a. In **Load from**, select **Downloaded design examples**.
   b. In **Family**, **Intel Quartus Prime version**, and **Development kit** fields select the values to match your target design and board.
5. In the design example list, select the design that you want to deploy.

Figure 12. Downloaded Agilex 7 I/O PLL Reconfiguration Design



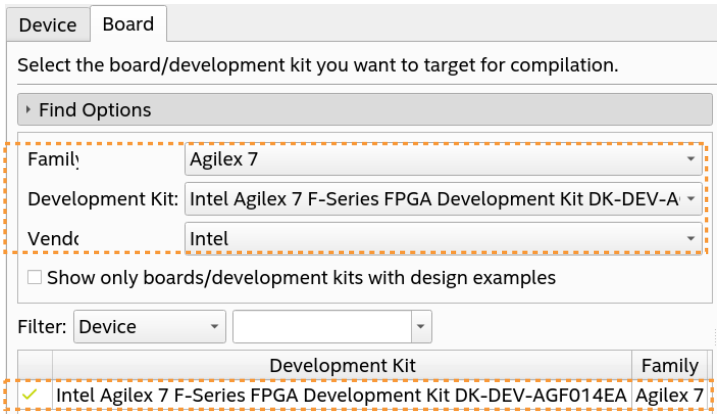
6. Click **Next**, and then click **Finish**. The design extracts to the working directory and opens in the Quartus Prime software.

3.1.1.2. Specifying a Target Board for the Project

You can specify the target for a new project in the New Project Wizard, or you can specify a target board for an existing project by clicking **Assignments ➤ Device**. To specify a target board for an existing project, follow these steps:

1. Click **Assignments ➤ Device**. The **Device** dialog box appears.
2. Click the **Board** tab. The **Board** tab allows you to target a specific FPGA device board, rather than just a specific FPGA device.

Figure 13. Board Tab Settings



3. In the **Family**, **Intel Quartus Prime version**, and **Development kit** fields, select the values to match your target design and board.
4. Click the desired board in the list. The board details appear in the right pane.
5. Click **OK**. Your project now targets the specified board and device.

3.2. Migrating Projects from Other Quartus Prime Editions to Quartus Prime Pro Edition

The Quartus Prime Pro Edition software supports migration of Quartus Prime Standard Edition, Quartus Prime Lite Edition, and Quartus II software projects.

Note: The migration steps for Quartus Prime Lite Edition, Quartus Prime Standard Edition, and the Quartus II software are identical. For brevity, this section refers to these design tools collectively as "other Quartus software products."

Migrating to Quartus Prime Pro Edition requires the following changes to other Quartus software product projects:

1. Upgrade project assignments and constraints with equivalent Quartus Prime Pro Edition assignments.
2. Upgrade all Intel FPGA IP core variations and Platform Designer systems in your project.
3. Upgrade design RTL to standards-compliant VHDL, Verilog HDL, or SystemVerilog.

This document describes each migration step in detail.

Related Information

Migrating to the Quartus Prime Pro Edition Software

3.2.1. Keeping Pro Edition Project Files Separate

The Quartus Prime Pro Edition software does not support project or constraint files from other Quartus software products. Do not place project files from other Quartus software products in the same directory as Quartus Prime Pro Edition project files. In general, use Quartus Prime Pro Edition project files and directories only for Quartus Prime Pro Edition projects, and use other Quartus software product files only with those software tools.

Quartus Prime Pro Edition projects do not support compilation in other Quartus software products, and vice versa. The Quartus Prime Pro Edition software generates an error if the Compiler detects other Quartus software product's features in project files.

Before migrating other Quartus software product projects, click **Project ➤ Archive Project** to save a copy of your original project before making modifications for migration.

3.2.2. Upgrading Project Assignments and Constraints

Quartus Prime Pro Edition software introduces changes to handling of project assignments and constraints that the Quartus Settings File (`.qsf`) stores. Upgrade other Quartus software product project assignments and constraints for migration to the Quartus Prime Pro Edition software. Upgrade other Quartus software product assignments with **Assignments ➤ Assignment Editor**, by editing the `.qsf` file directly, or by using a Tcl script.

Note: If you open a Quartus Prime Standard Edition software project in the Quartus Prime Pro Edition software, and that project contains unsupported junction temperature setting values, you can modify these settings by clicking **Assignments ➤ Settings ➤ Operating Settings and Conditions ➤ Temperature**. Click **OK**, and then click **Yes** when prompted to update the values.

The following sections detail the various types of project assignment upgrade that migration requires.

Related Information

- Modifying Entity Name Assignments on page 34
- Resolving Timing Constraint Entity Names on page 34
- Verifying Generated Node Name Assignments on page 35
- Replace Logic Lock (Standard) Regions on page 35
- Modifying Signal Tap Logic Analyzer Files on page 37
- Removing Unsupported Feature Assignments on page 38

3.2.2.1. Modifying Entity Name Assignments

Quartus Prime Pro Edition software supports assignments that include instance names *without* a corresponding entity name.

- "`a_entity:a|b_entity:b|c_entity:c`" (includes deprecated entity names)
- "`a|b|c`" (omits deprecated entity names)

While the current version of the Quartus Prime Pro Edition software still *accepts* entity names in the `.qsf`, the Compiler *ignores* the entity name. The Compiler generates a warning message upon detection of an entity names in the `.qsf`. Whenever possible, you should remove entity names from assignments, and discontinue reliance on entity-based assignments. Future versions of the Quartus Prime Pro Edition software may eliminate all support for entity-based assignments.

3.2.2.2. Resolving Timing Constraint Entity Names

The Quartus Prime Pro Edition Timing Analyzer honors entity names in Synopsys Design Constraints (`.sdc`) files.

Use `.sdc` files from other Quartus software products without modification. However, any scripts that include custom processing of names that the `.sdc` command returns, such as `get_registers` may require modification. Your scripts must reflect that returned strings do not include entity names.

The `.sdc` commands respect wildcard patterns containing entity names. Review the Timing Analyzer reports to verify application of all constraints. The following example illustrates differences between functioning and non-functioning `.sdc` scripts:

```
# Apply a constraint to all registers named "acc" in the entity "counter".
# This constraint functions in both SE and PE, because the SDC
# command always understands wildcard patterns with entity names in them
set_false_path –to [get_registers  “counter:*|*acc”]

# This does the same thing, but first it converts all register names to
# strings, which includes entity names by default in the SE
# but excludes them by default in the PE. The regexp will therefore
# fail in PE by default.
```

```
#
# This script would also fail in the SE, and earlier
# versions of Quartus II, if entity name display had been disabled
# in the QSF.
set all_reg_strs [query_collection –list –all [get_registers *]]
foreach keeper $all_reg_strs {
   if {[regexp {counter:*|:*acc} $keeper]} {
      set_false_path –to $keeper
   }
}
```

Removal of the entity name processing from `.sdc` files may not be possible due to complex processing involving node names. Use standard `.sdc` whenever possible to replace such processing. Alternatively, add the following code to the top and bottom of your script to temporarily re-enable entity name display in the `.sdc` file:

```
# This script requires that entity names be included
# due to custom name processing
set old_mode [set_project_mode -get_mode_value always_show_entity_name]
set_project_mode -always_show_entity_name on

<... the rest of your script goes here ...>

# Restore the project mode
set_project_mode -always_show_entity_name $old_mode
```

3.2.2.3. Verifying Generated Node Name Assignments

Quartus Prime synthesis generates and automatically names internal design nodes during processing. The Quartus Prime Pro Edition uses different conventions than other Quartus software products to generate node names during synthesis. When you synthesize your other Quartus software product project in Quartus Prime Pro Edition, the synthesis-generated node names may change. If any scripts or constraints depend on the synthesis-generated node names, update the scripts or constraints to match the Quartus Prime Pro Edition synthesis node names.

Avoid dependence on synthesis-generated names due to frequent changes in name generation. In addition, verify the names of duplicated registers and PLL clock outputs to ensure compatibility with any script or constraint.

3.2.2.4. Replace Logic Lock (Standard) Regions

Quartus Prime Pro Edition software introduces more simplified and flexible Logic Lock constraints, compared with previous Logic Lock regions. You must replace all Logic Lock (Standard) assignments with compatible Logic Lock assignments for migration.

To convert Logic Lock (Standard) regions to Logic Lock regions:

1. Edit the `.qsf` to delete or comment out all of the following Logic Lock assignments:

```
set_global_assignment -name LL_ENABLED*
set_global_assignment -name LL_AUTO_SIZE*
set_global_assignment -name LL_STATE FLOATING*
set_global_assignment -name LL_RESERVED*
set_global_assignment -name LL_CORE_ONLY*
set_global_assignment -name LL_SECURITY_ROUTING_INTERFACE*
set_global_assignment -name LL_IGNORE_IO_BANK_SECURITY_CONSTRAINT*
set_global_assignment -name LL_PR_REGION*
set_global_assignment -name LL_ROUTING_REGION_EXPANSION_SIZE*
set_global_assignment -name LL_WIDTH*
```

```
set_global_assignment -name LL_HEIGHT
set_global_assignment -name LL_ORIGIN
set_instance_assignment -name LL_MEMBER_OF
```

2. Edit the `.qsf` or click **Tools ➤ Chip Planner** to define new Logic Lock regions. Logic Lock constraint syntax is simplified, for example:

```
set_instance_assignment -name PLACE_REGION "1 1 20 20" -to fifo1
set_instance_assignment -name RESERVE_PLACE_REGION OFF -to fifo1
set_instance_assignment -name CORE_ONLY_PLACE_REGION OFF -to fifo1
```

Compilation fails if synthesis finds other Quartus software product's Logic Lock assignments in an Quartus Prime Pro Edition project. The following table compares other Quartus software product region constraint support with the Quartus Prime Pro Edition software.

Table 12. Region Constraints Per Edition

Constraint Type	Logic Lock (Standard) Region Support Other Quartus Software Products	Logic Lock Region Support Quartus Prime Pro Edition
Fixed rectangular, nonrectangular or non-contiguous regions	Full support.	Full support.
Chip Planner entry	Full support.	Full support.
Periphery element assignments	Supported in some instances.	Full support. Use “core-only” regions to exclude the periphery.
Nested (“hierarchical”) regions	Supported but separate hierarchy from the user instance tree.	Supported in same hierarchy as user instance tree.
Reserved regions	Limited support for nested or nonrectangular reserved regions. Reserved regions typically cannot cross I/O columns; use non-contiguous regions instead.	Full support for nested and nonrectangular regions. Reserved regions can cross I/O columns without affecting periphery logic if the regions are "core-only".
Routing regions	Limited support via “routing expansion.” No support with hierarchical regions.	Full support (including future support for hierarchical regions).
Floating or autosized regions	Full support.	No support.
Region names	Regions have names.	Regions are identified by the instance name of the constrained logic.
Multiple instances in the same region	Full support.	Support for non-reserved regions. Create one region per instance, and then specify the same definition for multiple instances to assign to the same area. Not supported for reserved regions.
Member exclusion	Full support.	No support for arbitrary logic. Use a core-only region to exclude periphery elements. Use non-rectangular regions to include more RAM or DSP columns as needed.

3.2.2.4.1. Logic Lock Region Assignment Examples

The following examples show the syntax of Logic Lock region assignments in the `.qsf` file. Optionally, you can enter these assignments in the Assignment Editor, the Logic Lock Regions Window, or the Chip Planner.

Example 1. Assign Rectangular Logic Lock Region

Assigns a rectangular Logic Lock region to a lower left corner location of (10,10), and an upper right corner of (20,20) inclusive.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
```

Example 2. Assign Non-Rectangular Logic Lock Region

Assigns instance with full hierarchical path "x|y|z" to non-rectangular L-shaped Logic Lock region. The software treats each set of four numbers as a new box.

```
set_instance_assignment –name PLACE_REGION –to x|y|z "X10 Y10 X20 Y50; X20 Y10
X50 Y20"
```

Example 3. Assign Subordinate Logic Lock Instances

By default, the Quartus Prime software constrains every child instance to the Logic Lock region of its parent. Any constraint to a child instance intersects with the constraint of its ancestors. For example, in the following example, all logic beneath "a|b|c|d" constrains to box (10,10), (15,15), and not (0,0), (15,15). This result occurs because the child constraint intersects with the parent constraint.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
set_instance_assignment –name PLACE_REGION –to a|b|c|d "X0 Y0 X15 Y15"
```

Example 4. Assign Multiple Logic Lock Instances

By default, a Logic Lock region constraint allows logic from other instances to share the same region. These assignments place instance c and instance g in the same location. This strategy is useful if instance c and instance g are heavily interacting.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
set_instance_assignment –name PLACE_REGION –to e|f|g "X10 Y10 X20 Y20"
```

Example 5. Assigned Reserved Logic Lock Regions

Optionally reserve an entire Logic Lock region for one instance and any of its subordinate instances.

```
set_instance_assignment –name PLACE_REGION –to a|b|c "X10 Y10 X20 Y20"
set_instance_assignment –name RESERVE_PLACE_REGION –to a|b|c ON

# The following assignment causes an error. The logic in e|f|g is not
# legally placeable anywhere:
# set_instance_assignment –name PLACE_REGION –to e|f|g "X10 Y10 X20 Y20"

# The following assignment does *not* cause an error, but is effectively
# constrained to the box (20,10), (30,20), since the (10,10),(20,20) box is
reserved
# for a|b|c
set_instance_assignment –name PLACE_REGION –to e|f|g "X10 Y10 X30 Y20"
```

3.2.2.5. Modifying Signal Tap Logic Analyzer Files

Quartus Prime Pro Edition introduces new methodology for entity names, settings, and assignments. These changes impact the processing of Signal Tap Logic Analyzer Files (.stp).

If you migrate a project that includes `.stp` files generated by other Quartus software products, you must make the following changes to migrate to the Quartus Prime Pro Edition:

1. Remove entity names from `.stp` files. The Signal Tap Logic Analyzer allows without error, but ignores, entity names in `.stp` files. Remove entity names from `.stp` files for migration to Quartus Prime Pro Edition:
   a. Click **View ➤ Node Finder** to locate and remove appropriate nodes. Use Node Finder options to filter on nodes.
   b. Click **Processing ➤ Start ➤ Start Analysis & Elaboration** to repopulate the database and add valid node names.
2. Remove post-fit nodes. Quartus Prime Pro Edition uses a different post-fit node naming scheme than other Quartus software products.
   a. Remove post-fit tap node names originating from other Quartus software products.
   b. Click **View ➤ Node Finder** to locate and remove post-fit nodes. Use Node Finder options to filter on nodes.
   c. Click **Processing ➤ Start Compilation** to repopulate the database and add valid post-fit nodes.
3. Run an initial compilation in Quartus Prime Pro Edition from the GUI. The Compiler automatically removes Signal Tap assignments originating other Quartus software products. Alternatively, from the command-line, run `quartus_stp` once on the project to remove outmoded assignments.

   Note: `quartus_stp` introduces no migration impact in the Quartus Prime Pro Edition. Your scripts require no changes to `quartus_stp` for migration.
4. Modify `.sdc` constraints for JTAG. Quartus Prime Pro Edition does not support embedded `.sdc` constraints for JTAG signals. Modify the timing template to suit the design's JTAG driver and board.

3.2.2.6. Removing References to .qip Files

In Quartus Prime Standard Edition projects, Platform Designer (Standard) generates `.qip` files. These files describe the parameterized IP cores to the Compiler, and appear as assignments in the project's `.qsf` file. However, in Quartus Prime Pro Edition projects, the parameterized IP core description occurs in `.ip` files. Moreover, references to `.qip` files in a project's `.qsf` file cause synthesis errors during compilation.

- When migrating a project to Quartus Prime Pro Edition, remove all references to `.qip` files from the `.qsf` file.

3.2.2.7. Removing Unsupported Feature Assignments

The Quartus Prime Pro Edition software does not support some feature assignments that other Quartus software products support. Remove the following unsupported feature assignments from other Quartus software product `.qsf` files for migration to the Quartus Prime Pro Edition software.

- Incremental Compilation (partitions)—The current version of the Quartus Prime Pro Edition software does not support Quartus Prime Standard Edition incremental compilation. Remove all incremental compilation feature assignments from other Quartus software product `.qsf` files before migration.
- Quartus Prime Standard Edition Physical synthesis assignments. Quartus Prime Pro Edition software does not support Quartus Prime Standard Edition Physical synthesis assignments. Remove any of the following assignments from the `.qsf` file or design RTL (instance assignments) before migration.

```
PHYSICAL_SYNTHESIS_COMBO_LOGIC_FOR_AREA
    PHYSICAL_SYNTHESIS_COMBO_LOGIC
    PHYSICAL_SYNTHESIS_REGISTER_DUPLICATION
    PHYSICAL_SYNTHESIS_REGISTER_RETIMING
    PHYSICAL_SYNTHESIS_ASYNCHRONOUS_SIGNAL_PIPELINING
    PHYSICAL_SYNTHESIS_MAP_LOGIC_TO_MEMORY_FOR_AREA
```

Note: If you open a Quartus Prime Standard Edition software project in the Quartus Prime Pro Edition software, and that project contains unsupported junction temperature setting values, you can modify these settings by clicking **Assignments ➤ Settings ➤ Operating Settings and Conditions ➤ Temperature**. Click **OK**, and then click **Yes** when prompted to update the values.

3.2.3. Upgrading IP Cores and Platform Designer Systems

Upgrade all IP cores and Platform Designer systems in your project for migration to the Quartus Prime Pro Edition software. The Quartus Prime Pro Edition software uses standards-compliant methodology for instantiation and generation of IP cores and Platform Designer systems. Most Intel FPGA IP cores and Platform Designer systems upgrade automatically in the **Upgrade IP Components** dialog box.

Other Quartus software products use a proprietary Verilog configuration scheme within the top level of IP cores and Platform Designer systems for synthesis files. The Quartus Prime Pro Edition does not support this scheme. To upgrade all IP cores and Platform Designer systems in your project, click **Project ➤ Upgrade IP Components**.[(2)]

Table 13. IP Core and Platform Designer System Differences

Other Quartus Software Products	Quartus Prime Pro Edition
IP and Platform Designer system generation use a proprietary Verilog HDL configuration scheme within the top level of IP cores and Platform Designer systems for synthesis files. This proprietary Verilog HDL configuration scheme prevents RTL entities from ambiguous instantiation errors during synthesis. However, these errors may manifest in simulation. Resolving this issue requires writing a Verilog HDL configuration to disambiguate the instantiation, delete the duplicate entity from the project, or rename one of the conflicting entities. Quartus Prime Pro Edition IP strategy resolves these issues.	IP and Platform Designer system generation does not use proprietary Verilog HDL configurations. The compilation library scheme changes in the following ways: • Compiles all variants of an IP core into the same compilation library across the entire project. Quartus Prime Pro Edition identically names IP cores with identical functionality and parameterization to avoid ambiguous entity instantiation errors. For example, the files for every Arria 10 PCI Express* IP core variant compile into the `altera_pcie_a10_hip_151` compilation library. • Simulation and synthesis file sets for IP cores and systems instantiate entities in the same manner. • The generated RTL directory structure now matches the compilation library structure.

(2) For brevity, this section refers to Quartus Prime Standard Edition, Intel Quartus Prime Lite Edition, and the Quartus II software collectively as "other Quartus software products."

Note: For complete information on upgrading IP cores, refer to *Managing Quartus Prime Projects*.

Related Information

- Working With Intel FPGA IP Cores on page 50
- Managing Quartus Prime Projects on page 85

3.2.4. Upgrading Non-Compliant Design RTL

The Quartus Prime Pro Edition software introduces a new synthesis engine (`quartus_syn` executable).

The `quartus_syn` synthesis enforces stricter industry-standard HDL structures and supports the following enhancements in this release:

- Support for modules with SystemVerilog Interfaces
- Improved support for VHDL2008
- New RAM inference engine infers RAMs from GENERATE statements or array of integers
- Stricter syntax/semantics check for improved compatibility with other EDA tools

Account for these synthesis differences in existing RTL code by ensuring that your design uses standards-compliant VHDL, Verilog HDL, or SystemVerilog. The Compiler generates errors when processing non-compliant RTL. Use the guidelines in this section to modify existing RTL for compatibility with the Quartus Prime Pro Edition synthesis.

3.2.4.1. Verifying Verilog Compilation Unit

Quartus Prime Pro Edition synthesis uses a different method to define the compilation unit. The Verilog LRM defines the concept of compilation unit as “a collection of one or more Verilog source files compiled together” forming the compilation-unit scope. Items visible only in the compilation-unit scope include macros, global declarations,

and default net types. The contents of included files become part of the compilation unit of the parent file. Modules, primitives, programs, interfaces, and packages are visible in all compilation units. Ensure that your RTL accommodates these changes.

Table 14. Verilog Compilation Unit Differences

Other Quartus Software Products	Quartus Prime Pro Edition
Synthesis in other Quartus software products follows the Multi-file compilation unit (MFCU) method to select compilation unit files. In MFCU, all files compile in the same compilation unit. Global definitions and directives are visible in all files. However, the default net type is reset at the start of each file.	Quartus Prime Pro Edition synthesis follows the Single-file compilation unit (SFCU) method to select compilation unit files. In SFCU, each file is a compilation unit, file order is irrelevant, and the macro is only defined until the end of the file.

Note: You can optionally change the MFCU mode using the following assignment:
`set_global_assignment -name VERILOG_CU_MODE MFCU`

3.2.4.1.1. Verilog HDL Configuration Instantiation

Quartus Prime Pro Edition synthesis requires instantiation of the Verilog HDL configuration, and not the module. In other Quartus software products, synthesis automatically finds any Verilog HDL configuration relating to a module that you instantiate. The Verilog HDL configuration then instantiates the design.

If your top-level entity is a Verilog HDL configuration, set the Verilog HDL configuration, rather than the module, as the top-level entity.

Table 15. Verilog HDL Configuration Instantiation

Other Quartus Software Products	Quartus Prime Pro Edition
From the Example RTL, synthesis automatically finds the `mid_config` Verilog HDL configuration relating to the instantiated module.	From the Example RTL, synthesis does not find the `mid_config` Verilog HDL configuration. You must instantiate the Verilog HDL configuration directly.
Example RTL: `config mid_config;` `design good_lib.mid;` `instance mid.sub_inst use good_lib.sub;` `endconfig` `module test (input a1, output b);` `mid_config mid_inst ( .a1(a1), .b(b));` **`// in other Quartus products preceding line would have been:`** **`//mid mid_inst ( .a1(a1), .b(b));`** `endmodule` `module mid (input a1, output b);` `sub sub_inst (.a1(a1), .b(b));` `endmodule`	

3.2.4.2. Updating Entity Auto-Discovery

All editions of the Quartus Prime and Quartus II software search your project directory for undefined entities. For example, if you instantiate entity "sub" in your design without specifying "sub" as a design file in the Quartus Settings File (`.qsf`), synthesis searches for `sub.v`, `sub.vhd`, and so on. However, Quartus Prime Pro Edition performs auto-discovery at a different stage in the flow. Ensure that your RTL code accommodates these auto-discovery changes.

Table 16. Entity Auto-Discovery Differences

Other Quartus Software Products	Quartus Prime Pro Edition
Always automatically searches your project directory and search path for undefined entities.	Always automatically searches your project directory and search path for undefined entities. Quartus Prime Pro Edition synthesis performs auto-discovery earlier in the flow than other Quartus software products. This results in discovery of more syntax errors. Optionally disable auto-discovery with the following `.qsf` assignment: `set_global_assignment -name AUTO_DISCOVER_AND_SORT OFF`

3.2.4.3. Ensuring Distinct VHDL Namespace for Each Library

Quartus Prime Pro Edition synthesis requires that VHDL namespaces are distinct for each library. The stricter library binding requirement complies with VHDL language specifications and results in deterministic behavior. This benefits team-based projects by avoiding unintentional name collisions. Confirm that your RTL respects this change.

Table 17. VHDL Namespace Differences

Other Quartus Software Products	Quartus Prime Pro Edition
For the Example RTL, the analyzer searches all libraries in an unspecified order until the analyzer finds package `utilities_pack` and uses items from that package. If another library, for example `projectLib` also contains `utilities_pack`, the analyzer may use this library instead of `myLib.utilites_pack` if found before the analyzer searches `myLib`.	For the Example RTL, the analyzer uses the specific `utilities_pack` in `myLib`. If `utilities_pack` does not exist in library `myLib`, the analyzer generates an error.
Example RTL: `library myLib; use myLib.utilities_pack.all;`	

3.2.4.4. Removing Unsupported Parameter Passing

Quartus Prime Pro Edition synthesis does not support parameter passing using `set_parameter` in the `.qsf`. Synthesis in other Quartus software products supports passing parameters with this method. Except for the top-level of the design where permitted, ensure that your RTL does not depend on this type of parameter passing.

Table 18. SystemVerilog Feature Differences

Other Quartus Software Products	Quartus Prime Pro Edition
From the Example RTL, synthesis overwrites the value of parameter SIZE in the instance of `my_ram` instantiated from entity `mid-level`.	From the Example RTL, synthesis generates a syntax error for detection of parameter passing assignments in the `.qsf`. Specify parameters in the RTL. The following example shows the supported top-level parameter passing format. This example applies only to the top-level and sets a value of 4 to parameter `N`: `set_parameter -name N 4`
Example RTL: `set_parameter –entity mid_level –to my_ram –name SIZE 16`	

3.2.4.5. Removing Unsized Constant from WYSIWYG Instantiation

Quartus Prime Pro Edition synthesis does not allow use of an unsized constant for WYSIWYG instantiation. Synthesis in other Quartus software products allows use of SystemVerilog (`.sv`) unsized constants when instantiating a WYSIWYG in a `.v` file.

Quartus Prime Pro Edition synthesis allows use of unsized constants in `.sv` files for uses other than WYSIWYG instantiation. Ensure that your RTL code does not use unsized constants for WYSIWYG instantiation. For example, specify a sized literal, such as 2'b11, rather than '1.

3.2.4.6. Removing Non-Standard Pragmas

Quartus Prime Pro Edition synthesis does not support the `vhdl(verilog)_input_version` pragma or the `library` pragma. Synthesis in other Quartus software products supports these pragmas. Remove any use of the pragmas from RTL for Quartus Prime Pro Edition migration. Use the following guidelines to implement the pragma functionality in Quartus Prime Pro Edition:

- `vhdl(verilog)_input_version` Pragma—allows change to the input version in the middle of an input file. For example, to change VHDL 1993 to VHDL 2008. For Quartus Prime Pro Edition migration, specify the input version for each file in the `.qsf`.
- `library` Pragma—allows changes to the VHDL library into which files compile. For Quartus Prime Pro Edition migration, specify the compilation library in the `.qsf`.

3.2.4.7. Declaring Objects Before Initial Values

Quartus Prime Pro Edition synthesis requires declaration of objects before initial value. Ensure that your RTL declares objects before initial value. Other Quartus software products allow declaration of initial value prior to declaration of the object.

Table 19. Object Declaration Differences

Other Quartus Software Products	Quartus Prime Pro Edition
From the Example RTL, synthesis initializes the output `p_prog_io1` with the value of `p_progio1_reg`, even though the register declaration occurs in Line 2.	From the Example RTL, synthesis generates a syntax error when you specify initial values before declaring the register.
Example RTL: `1 output p_prog_io1 = p_prog_io1_reg;` `2 reg p_prog_io1_reg;`	

3.2.4.8. Confining SystemVerilog Features to SystemVerilog Files

Quartus Prime Pro Edition synthesis does not allow SystemVerilog features in Verilog HDL files. Other Quartus software products allow use of a subset of SystemVerilog (`.sv`) features in Verilog HDL (`.v`) design files. To avoid syntax errors in Quartus Prime Pro Edition, allow only SystemVerilog features in Verilog HDL files.

To use SystemVerilog features in your existing Verilog HDL files, rename your Verilog HDL (`.v`) files as SystemVerilog (`.sv`) files. Alternatively, you can set the file type in the .qsf, as shown in the following example:

```
set_global_assignment -name SYSTEMVERILOG_FILE <file>.v
```

Table 20. SystemVerilog Feature Differences

Other Quartus Software Products	Quartus Prime Pro Edition
From the Example RTL, synthesis interprets `$clog2` in a `.v` file, even though the Verilog LRM does not define the `$clog2` feature. Other Quartus software products allow other SystemVerilog features in `.v` files.	From the Example RTL, synthesis generates a syntax error for detection of any non-Verilog HDL construct in `.v` files. Quartus Prime Pro Edition synthesis honors SystemVerilog features only in `.sv` files.
Example RTL: `localparam num_mem_locations = 1050;` `wire mem_addr [$clog2(num_mem_locations)-1 : 0];`	

3.2.4.9. Avoiding Assignment Mixing in Always Blocks

Quartus Prime Pro Edition synthesis does not allow mixed use of blocking and non-blocking assignments within ALWAYS blocks. Other Quartus software products allow mixed use of blocking and non-blocking assignments within ALWAYS blocks. To avoid syntax errors, ensure that ALWAYS block assignments are of the same type for Quartus Prime Pro Edition migration.

Table 21. ALWAYS Block Assignment Differences

Other Quartus Software Products	Quartus Prime Pro Edition
Synthesis honors the mixed blocking and non-blocking assignments, although the Verilog Language Specification no longer supports this construct.	Synthesis generates a syntax error for detection of mixed blocking and non-blocking assignments within an ALWAYS block.

3.2.4.10. Avoiding Unconnected, Non-Existent Ports

Quartus Prime Pro Edition synthesis requires that a port exists in the module prior to instantiation and naming. Other Quartus software products allow you to instantiate and name an unconnected port that does not exist in the module. Modify your RTL to match this requirement.

To avoid syntax errors, remove all unconnected and non-existent ports for Quartus Prime Pro Edition migration.

Table 22. Unconnected, Non-Existent Port Differences

Other Quartus Software Products	Quartus Prime Pro Edition
Synthesis allows you to instantiate and name unconnected or non-existent ports that do not exist on the module.	Synthesis generates a syntax error for detection of mixed blocking and non-blocking assignments within an ALWAYS block.

3.2.4.11. Avoiding Invalid Parameter Ranges

Quartus Prime Pro Edition synthesis generates an error for detection of constant numeric (integer or floating point) parameter values that exceed the language specification. Other Quartus software products allow constant numeric (integer or floating point) values for parameters that exceed the language specifications. To avoid syntax errors, ensure that constant numeric (integer or floating point) values for parameters conform to the language specifications.

3.2.4.12. Updating Verilog HDL and VHDL Type Mapping

Quartus Prime Pro Edition synthesis requires that you use `0` for "`false`" and `1` for "`true`" in Verilog HDL files (`.v`). Other Quartus software products map "true" and "false" strings in Verilog HDL to TRUE and FALSE Boolean values in VHDL. Quartus Prime Pro Edition synthesis generates an error for detection of non-Verilog HDL constructs in `.v` files. To avoid syntax errors, ensure that your RTL accommodates these standards.

3.2.4.13. Converting Symbolic BDF Files to Acceptable File Formats

Starting from the Quartus Prime Pro Edition software version 23.3, the compiler cannot synthesize schematic Block Design File (`.bdf`). You must convert it to an acceptable format, such as Verilog HDL or VHDL using the Intel Quartus Prime Standard Edition command `quartus_map` as shown in the following:

- To convert your `.bdf` file to Verilog Design File (`.v`):

```
quartus_map <project_name> --convert_bdf_to_verilog=<bdf_file_name>
```

- To convert your `.bdf` file to VHDL Design File (`.vhd`):

```
quartus_map <project_name> --convert_bdf_to_vhdl=<bdf_file_name>
```

3.3. Migrating Your AMD* Vivado* Project to Quartus Prime Pro Edition

Designing for Intel FPGA devices is similar in concept and practice to designing for AMD* Xilinx* FPGA devices. In most cases, you can import your RTL into the Quartus Prime Pro Edition software and compile your design to the target device.

Refer to the AN 307: Intel FPGA Design Flow for AMD* Xilinx* Users, which covers the following information:

- A comparison of the current AMD* Xilinx* and Intel FPGA technologies, features, and devices available for different process technologies.
- A comparison between the design flows in the AMD* Vivado* software and Quartus Prime Pro Edition software.
- Guidelines to convert AMD* Vivado* designs to the Quartus Prime Pro Edition software, including AMD* Xilinx* IP catalog modules and instantiated primitives.
- Guidelines to translate device and design constraints.

3.4. Migrating Projects Across Operating Systems

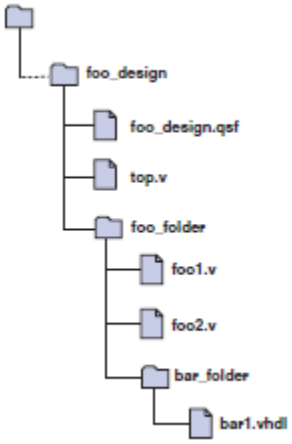
Consider the following cross-platform issues when moving your project from one operating system to another (for example, from Windows* to Linux*).

3.4.1. Migrating Design Files and Libraries

Consider file naming differences when migrating projects across operating systems.

- Use appropriate case for your platform in file path references.
- Use a character set common to both platforms.
- Do not change the forward-slash (`/`) and back-slash (`\`) path separators in the `.qsf`. The Quartus Prime software automatically changes all back-slash (`\`) path separators to forward-slashes (`/ `)in the `.qsf`.
- Observe the target platform's file name length limit.
- Use underscore instead of spaces in file and directory names.
- Change library absolute path references to relative paths in the `.qsf`.
- Ensure that any external project library exists in the new platform's file system.
- Specify file and directory paths as relative to the project directory. For example, for a project titled `foo_design`, specify the source files as: `top.v`, `foo_folder /foo1.v`, `foo_folder /foo2.v`, and `foo_folder/bar_folder/bar1.vhdl`.
- Ensure that all the subdirectories are in the same hierarchical structure and relative path as in the original platform.

Figure 14. All Inclusive Project Directory Structure

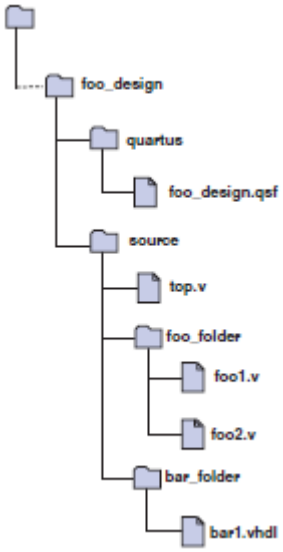


3.4.1.1. Use Relative Paths

Express file paths using relative path notation (`../`).

For example, in the directory structure shown you can specify `top.v` as `../source/top.v` and `foo1.v` as `../source/foo_folder/foo1.v`.

Figure 15. Quartus Prime Project Directory Separate from Design Files



3.4.2. Design Library Migration Guidelines

The following guidelines apply to library migration across computing platforms:

1. The project directory takes precedence over the project libraries.
2. For Linux, the Quartus Prime software creates the file in the `altera.quartus` directory under the <*home*> directory.
3. All library files are relative to the libraries. For example, if you specify the `user_lib1` directory as a project library and you want to add the `/user_lib1/foo1.v` file to the library, you can specify the `foo1.v` file in the `.qsf` as `foo1.v`. The Quartus Prime software includes files in specified libraries.
4. If the directory is outside of the project directory, an absolute path is created by default. Change the absolute path to a relative path before migration.
5. When copying projects that include libraries, you must either copy your project library files along with the project directory or ensure that your project library files exist in the target platform.
   - On Windows*, the Quartus Prime software searches for the `quartus2.ini` file in the following directories and order:
   - `USERPROFILE`, for example, `C:\Documents and Settings\<user name>`
   - Directory specified by the TMP environmental variable
   - Directory specified by the TEMP environmental variable
   - Root directory, for example, `C:\`

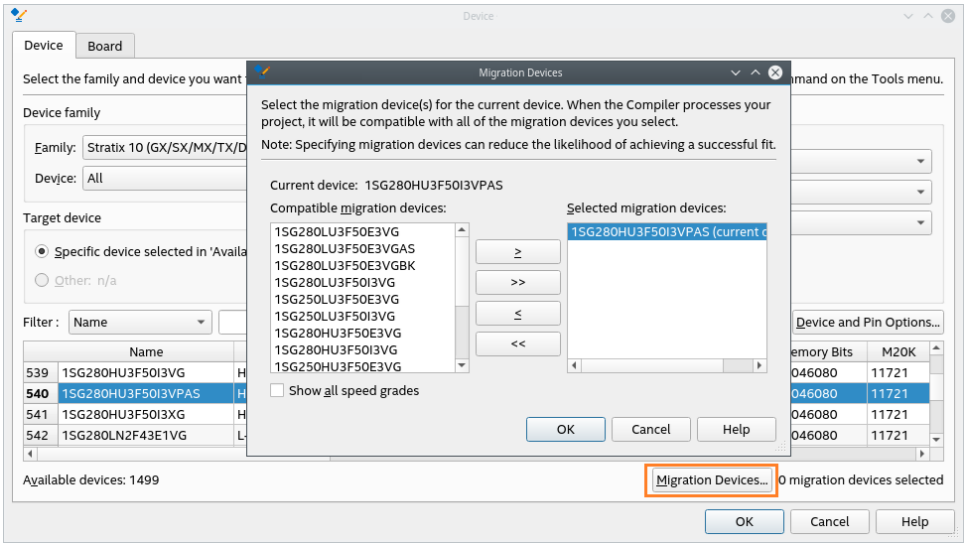
3.5. Migrating Project From One Device to Another

The Quartus Prime Pro Edition software supports migrating project from one device to another by providing a list of compatible migration devices available for the device your design targets.

To migrate your device, launch **Migration Devices** using one of the following options in the Quartus Prime Pro Edition software GUI:

- Right-click on your device in the **Project Navigator** and select **Device ➤ Migration Devices**.
- **Assignments ➤ Device ➤ Migration Devices**

Figure 16. Device Migration



In the **Migration Devices** dialog box, click **>**, **>>**, **<**, and **<<** to move migration devices between the **Compatible migration devices** list and the **Selected migration devices** list.

A device name in the **Selected migration devices** list with the text `(current device)` indicates that the device is currently specified in the **Available devices** list in the **Device** dialog box.

A device name in the **Compatible migration devices** list with the text `(not installed)` indicates that the device is supported in the Quartus Prime Pro Edition software, but support for the device is not installed in your copy of the software. To move this device to the **Selected migration devices** list, you must first install support for the device by running a custom installation procedure of the Quartus Prime software. For more information, refer to the Downloading Device Support in the *Intel FPGA Software Installation and Licensing* or contact Intel Support.

If you want the Quartus Prime software to display all compatible migration devices in the **Compatible migration devices** list regardless of a migration device's speed grade, turn on the **Show All Speed Grades** checkbox. If you want the Quartus Prime software to display in the **Compatible migration devices** list only the compatible migration devices that have the same speed grade as the target device, turn off **Show all speed grades**.

4. Working With Intel FPGA IP Cores

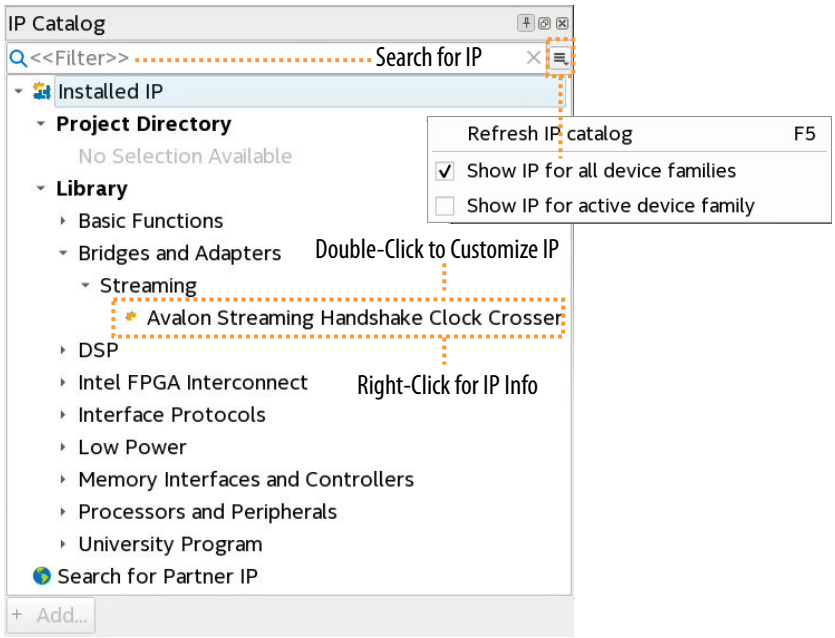
Intel and strategic IP partners offer a broad portfolio of configurable IP cores optimized for Intel FPGA devices.

The Quartus Prime software installation includes the Intel FPGA IP library. Integrate optimized and verified Intel FPGA IP cores into your design to shorten design cycles and maximize performance. The Quartus Prime software also supports integration of IP cores from other sources. Use the IP Catalog (**Tools ➤ IP Catalog**) to efficiently parameterize and generate synthesis and simulation files for your custom IP variation. The Intel FPGA IP library includes the following types of IP cores:

Basic functions	Interface protocols
Bridges and adapters	Low power functions
DSP functions	Memory interfaces and controllers
Intel FPGA interconnect	Processors and peripherals

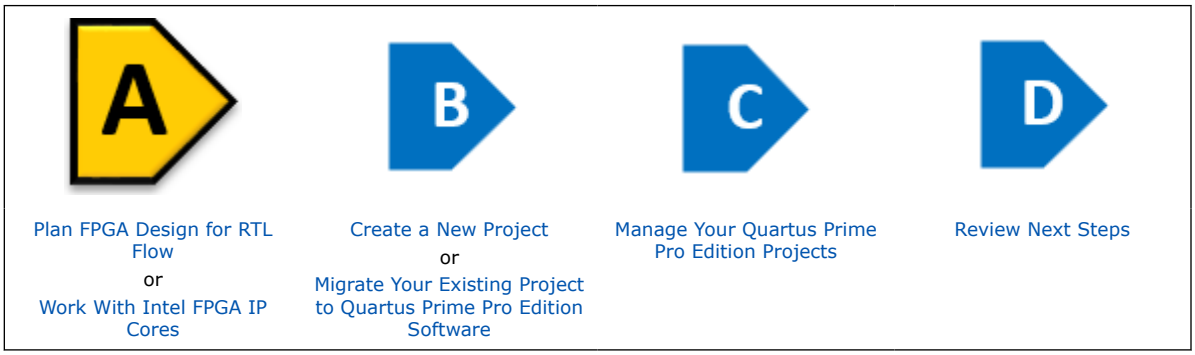
This document provides basic information about parameterizing, generating, upgrading, and simulating stand-alone IP cores in the Quartus Prime software.

Figure 17. Intel FPGA IP Catalog



Navigating Content Through Tasks

Use the following navigation diagram to navigate this guide through user-tasks:



4.1. IP Catalog and Parameter Editor

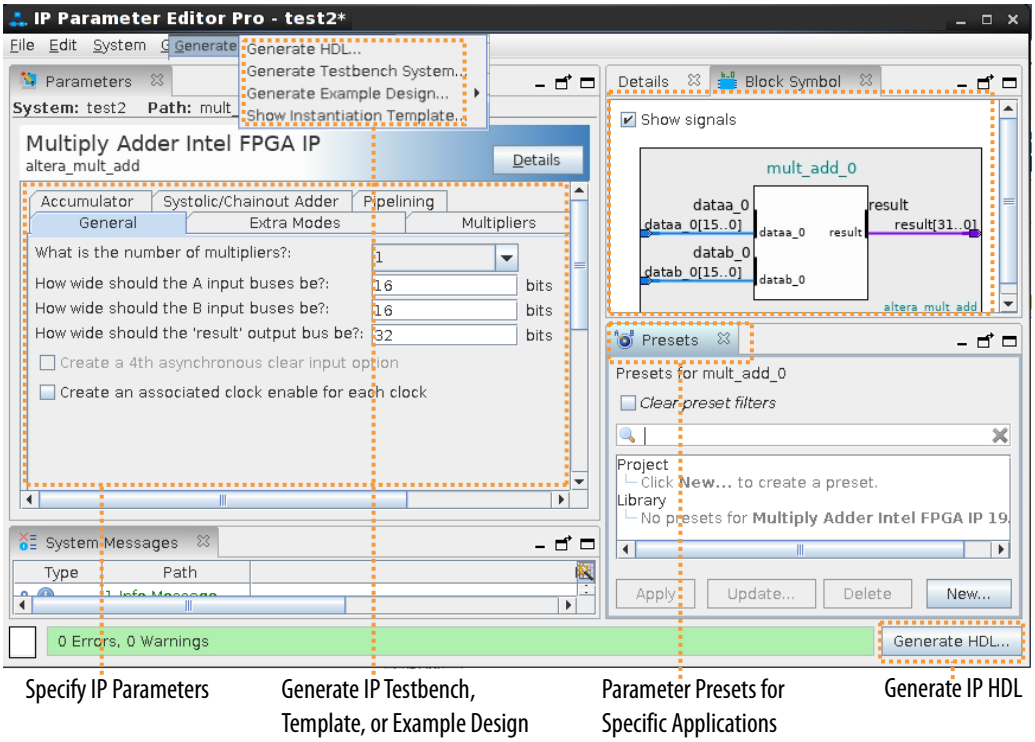
The IP Catalog displays the IP cores available for your project, including Intel FPGA IP and other IP that you add to the IP Catalog search path. Use the following features of the IP Catalog to locate and customize an IP core:

- Filter IP Catalog to **Show IP for active device family** or **Show IP for all device families**. If you have no project open, select the **Device Family** in IP Catalog.
- Type in the Search field to locate any full or partial IP core name in IP Catalog.
- Right-click an IP core name in IP Catalog to display details about supported devices, to open the IP core's installation folder, and for links to IP documentation.
- Click **Search for Partner IP** to access partner IP information on the web.

The parameter editor prompts you to specify an IP variation name, optional ports, and output file generation options. The parameter editor generates a top-level Quartus Prime IP file (`.ip`) for an IP variation in Quartus Prime Pro Edition projects. This file represents the IP variation in the project, and stores parameterization information.(3)

(3) The parameter editor generates a top-level Quartus IP file (`.qip`) for an IP variation in Quartus Prime Standard Edition projects.

Figure 18. Example IP Parameter Editor



4.1.1. The Parameter Editor

The parameter editor helps you to configure IP core ports, parameters, and output file generation options. The basic parameter editor controls include the following:

- Use the **Presets** window to apply preset parameter values for specific applications (for select cores).
- Use the **Details** window to view port and parameter descriptions, and click links to documentation.
- Click **Generate ➤ Generate Testbench System** to generate a testbench system (for select cores).
- Click **Generate ➤ Generate Example Design** to generate an example design (for select cores).
- Click **Validate System Integrity** to validate a system's generic components against companion files. (Platform Designer systems only)
- Click **Sync All System Info** to validate a system's generic components against companion files. (Platform Designer systems only)

The IP Catalog is also available in Platform Designer (**View ➤ IP Catalog**). The Platform Designer IP Catalog includes exclusive system interconnect, video and image processing, and other system-level IP that are not available in the Quartus Prime IP Catalog. Refer to *Creating a System with Platform Designer* or *Creating a System with Platform Designer* for information on use of IP in Platform Designer and Platform Designer, respectively.

Related Information

Creating a System with Platform Designer

4.2. Installing and Licensing Intel FPGA IP Cores

The Quartus Prime software installation includes the Intel FPGA IP library. This library provides many useful IP cores for your production use without the need for an additional license. Some Intel FPGA IP cores require purchase of a separate license for production use. The Intel FPGA IP Evaluation Mode allows you to evaluate these licensed Intel FPGA IP cores in simulation and hardware, before deciding to purchase a full production IP core license. You only need to purchase a full production license for licensed Intel IP cores after you complete hardware testing and are ready to use the IP in production.

The Quartus Prime software installs IP cores in the following locations by default:

Figure 19. IP Core Installation Path

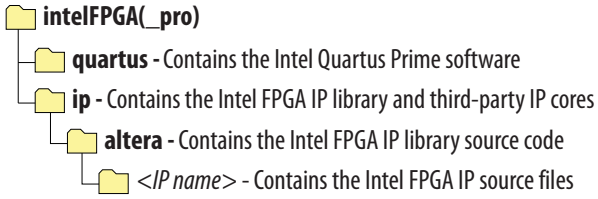


Table 23. IP Core Installation Locations

Location	Software	Platform
`<drive>:\intelFPGA_pro\quartus\ip\altera`	Quartus Prime Pro Edition	Windows
`<drive>:\intelFPGA\quartus\ip\altera`	Quartus Prime Standard Edition	Windows
`<home directory>:/intelFPGA_pro/quartus/ip/altera`	Quartus Prime Pro Edition	Linux*
`<home directory>:/intelFPGA/quartus/ip/altera`	Quartus Prime Standard Edition	Linux

Note: The Quartus Prime software does not support spaces in the installation path.

4.2.1. Intel FPGA IP Evaluation Mode

The free Intel FPGA IP Evaluation Mode allows you to evaluate licensed Intel FPGA IP cores in simulation and hardware before purchase. Intel FPGA IP Evaluation Mode supports the following evaluations without additional license:

- Simulate the behavior of a licensed Intel FPGA IP core in your system.
- Verify the functionality, size, and speed of the IP core quickly and easily.
- Generate time-limited device programming files for designs that include IP cores.
- Program a device with your IP core and verify your design in hardware.

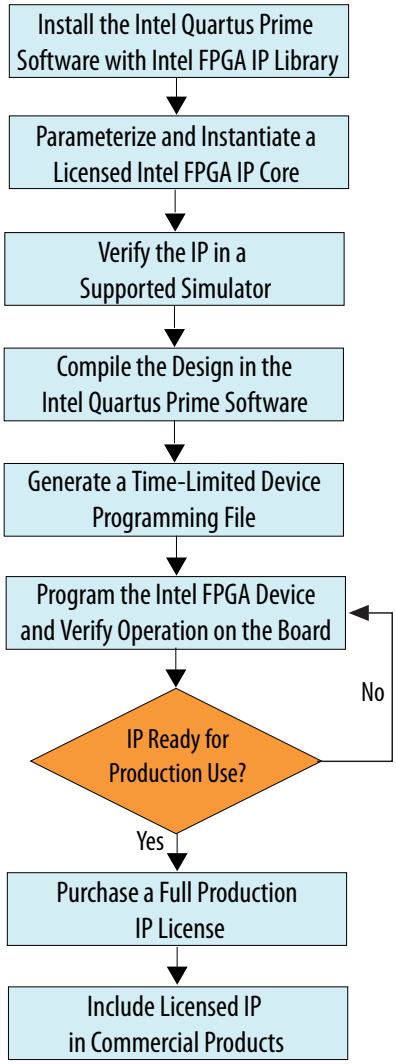
Intel FPGA IP Evaluation Mode supports the following operation modes:

- **Tethered**—Allows running the design containing the licensed Intel FPGA IP indefinitely with a connection between your board and the host computer. Tethered mode requires a serial joint test action group (JTAG) cable connected between the JTAG port on your board and the host computer, which is running the Quartus Prime Programmer for the duration of the hardware evaluation period. The Programmer only requires a minimum installation of the Quartus Prime software, and requires no Quartus Prime license. The host computer controls the evaluation time by sending a periodic signal to the device via the JTAG port. If all licensed IP cores in the design support tethered mode, the evaluation time runs until any IP core evaluation expires. If all of the IP cores support unlimited evaluation time, the device does not time-out.
- **Untethered**—Allows running the design containing the licensed IP for a limited time. The IP core reverts to untethered mode if the device disconnects from the host computer running the Quartus Prime software. The IP core also reverts to untethered mode if any other licensed IP core in the design does not support tethered mode.

When the evaluation time expires for any licensed Intel FPGA IP in the design, the design stops functioning. All IP cores that use the Intel FPGA IP Evaluation Mode time out simultaneously when any IP core in the design times out. When the evaluation time expires, you must reprogram the FPGA device before continuing hardware verification. To extend use of the IP core for production, purchase a full production license for the IP core.

You must purchase the license and generate a full production license key before you can generate an unrestricted device programming file. During Intel FPGA IP Evaluation Mode, the Compiler only generates a time-limited device programming file (<*project name*>`_time_limited.sof`) that expires at the time limit.

Figure 20. Intel FPGA IP Evaluation Mode Flow



Note: Refer to each IP core's user guide for parameterization steps and implementation details.

Intel licenses IP cores on a per-seat, perpetual basis. The license fee includes first-year maintenance and support. You must renew the maintenance contract to receive updates, bug fixes, and technical support beyond the first year. You must purchase a full production license for Intel FPGA IP cores that require a production license, before generating programming files that you may use for an unlimited time. During Intel FPGA IP Evaluation Mode, the Compiler only generates a time-limited device programming file (`<project name>_time_limited.sof`) that expires at the time limit. To obtain your production license keys, visit the Intel FPGA Self-Service Licensing Center.

The Intel FPGA Software License Agreements govern the installation and use of licensed IP cores, the Quartus Prime design software, and all unlicensed IP cores.

Related Information

- Intel FPGA Licensing Support Center
- Introduction to Intel FPGA Software Installation and Licensing

4.2.1.1. Intel FPGA IP Versioning

Intel FPGA IP versions match the Quartus Prime Design Suite software versions until v19.1. Starting in Quartus Prime Design Suite software version 19.2, Intel FPGA IP has a new versioning scheme.

The Intel FPGA IP version (X.Y.Z) number can change with each Quartus Prime software version. A change in:

- X indicates a major revision of the IP. If you update the Quartus Prime software, you must regenerate the IP.
- Y indicates the IP includes new features. Regenerate your IP to include these new features.
- Z indicates the IP includes minor changes. Regenerate your IP to include these changes.

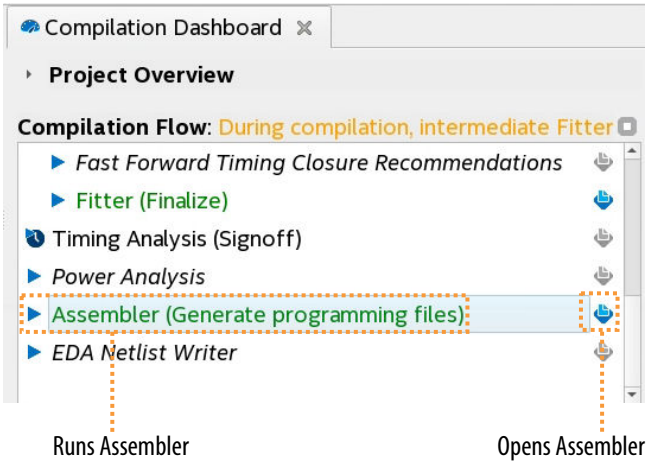
4.2.1.2. Checking the IP License Status

You can check the license status of all IP in an Quartus Prime project by viewing the Assembler report.

To generate and view the Assembler report in the GUI:

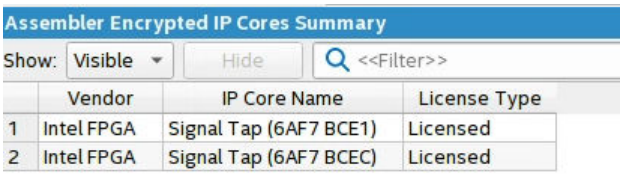
1. Click **Assembler** on the Compilation Dashboard.
2. When the Assembler (and any prerequisite stages of compilation) complete, click the **Report** icon for the Assembler in the Compilation Dashboard.

Figure 21. Assembler Report Icon in Compilation Dashboard



3. Click the **Encrypted IP Cores Summary** report.

Figure 22. Encrypted IP Cores Summary Report



To generate and view the Assembler report at the command line:

1. Type the following command:

```
quartus_asm <project name> -c  <project revision>
```

2. View the output report in `/output_files/<project_name>.asm.rpt`.

```
+-----------------------------------------------------------------------+
; Assembler Encrypted IP Cores Summary                                  ;
+--------+--------------------------------------------+--------------+
; Vendor ; IP Core Name                               ; License Type ;
+--------+--------------------------------------------+--------------+
; Intel  ; PCIe SRIOV with 4-PFs and 2K-VFs (6AF7 00FB) ; Unlicensed   ;
; Intel  ; Signal Tap (6AF7 BCE1)                     ; Licensed     ;
; Intel  ; Signal Tap (6AF7 BCEC)                     ; Licensed     ;
+--------+--------------------------------------------+--------------+
```

4.3. IP General Settings

The following settings control how the Quartus Prime software manages IP cores in a project:

Table 24. Location of IP Core General Settings in the Quartus Prime Software

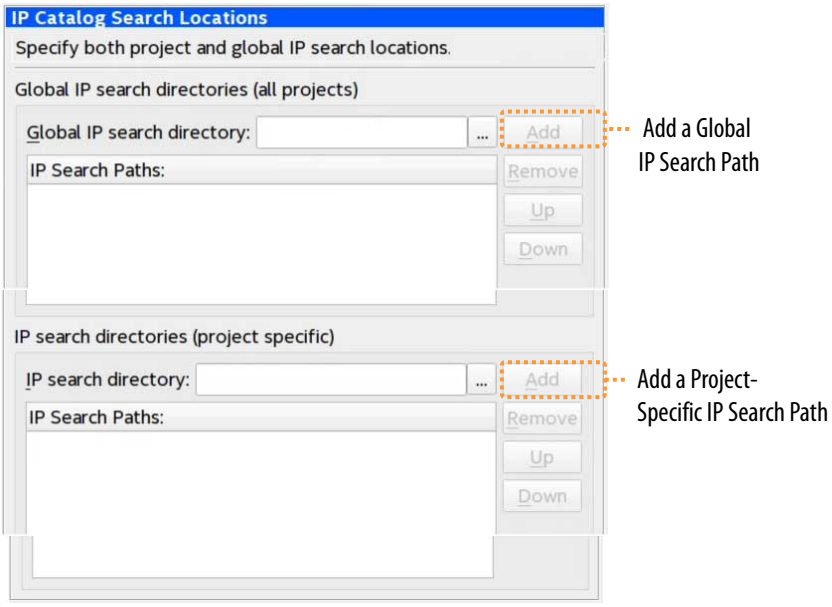
Setting	Description	Location
Maximum Platform Designer memory usage size	Increase if you experience slow processing for large systems, or for out of memory errors.	**Tools ➤ Options ➤ IP Settings** Or **Tasks pane ➤ Settings ➤ IP Settings**
IP generation HDL preference	The parameter editor generates the HDL you specify for IP variations.	
IP Regeneration Policy	Controls when synthesis files regenerate for each IP variation. Typically, you **Always regenerate synthesis files for IP cores** after making changes to an IP variation.	
Generate IP simulation model when generating IP	Enables automatic generation of simulation models every time you generate the IP.	
Use available processors for parallel generation of Quartus project IPs	Directs Platform Designer to generate IPs in parallel, using the number of processors that you specify in the **Compilation Process Settings** pane of the Quartus Prime project settings.	
Additional project and global IP search locations.	The Quartus Prime software searches for IP cores in the project directory, in the Quartus Prime installation directory, and in the IP search path.	**Tools ➤ Options ➤ IP Catalog Search Locations** Or **Tasks pane ➤ Settings ➤ IP Catalog Search Locations**

4.4. Adding IP to IP Catalog

The IP Catalog automatically displays Intel FPGA IP and other IP components that have a corresponding `_hw.tcl` or `.ipx` file located in the project directory, in the default Quartus Prime installation directory, or in the IP search path. You can optionally add your own custom or third-party IP component to IP Catalog by adding the component's `_hw.tcl` or `.ipx` file to the IP search path.

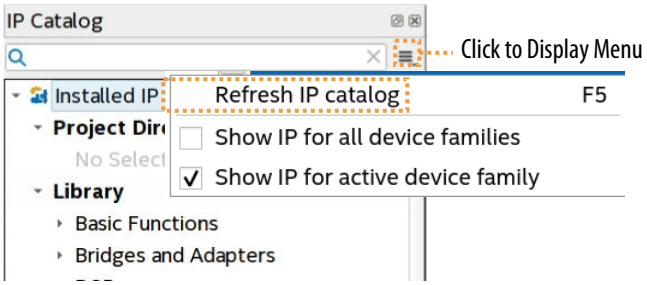
Follow these steps to add custom or third-party IP to the IP Catalog:

Figure 23. Specifying IP Search Locations



1. In the Quartus Prime software, click **Tools ➤ Options ➤ IP Search Path**) to open the **IP Search Path Options** dialog box.
2. Click **Add** or **Remove** to add/remove a location that contains IP.
3. To refresh the IP Catalog, click **Refresh IP Catalog** in the Quartus Prime Platform Designer, or click **File ➤ Refresh System** in Platform Designer.

Figure 24. Refreshing IP Catalog



4.5. Best Practices for Intel FPGA IP

Use the following best practices when working with Intel FPGA IP:

- Do not manually edit or write your own `.qsys`, `.ip`, or `.qip` file. Use the Quartus Prime software tools to create and edit these files.

  Note: When generating IP cores, do not generate files into a directory that has a space in the directory name or path. Spaces are not legal characters for IP core paths or names.
- When you generate an IP core using the IP Catalog, the Quartus Prime software generates a `.qsys` (for Platform Designer-generated IP cores) or a `.ip` file (for Quartus Prime Pro Edition) or a `.qip` file. The Quartus Prime Pro Edition software automatically adds the generated `.ip` to your project. In the Quartus Prime Standard Edition software, add the `.qip` to your project. Do not add the parameter editor generated file (`.v` or `.vhd`) to your design without the `.qsys` or `.qip` file. Otherwise, you cannot use the IP upgrade or IP parameter editor feature.
- Plan your directory structure ahead of time. Do not change the relative path between a `.qsys` file and it's generation output directory. If you must move the `.qsys` file, ensure that the generation output directory remains with the `.qsys` file.
- Do not add IP core files directly from the `/quartus/libraries/megafunctions` directory in your project. Otherwise, you must update the files for each subsequent software release. Instead, use the IP Catalog and then add the `.qip` to your project.
- Do not use IP files that the Quartus Prime software generates for RAM or FIFO blocks targeting older device families (even though the Quartus Prime software does not issue an error). The RAM blocks that Quartus Prime generates for older device families are not optimized for the latest device families.
- When generating a ROM function, save the resulting `.mif` or `.hex` file in the same folder as the corresponding IP core's `.qsys` or `.qip` file. For example, moving all of your project's `.mif` or `.hex` files to the same directory causes relative path problems after archiving the design.
- Always use the Quartus Prime `ip-setup-simulation` and `ip-make-simscript` utilities to generate simulation scripts for each IP core or Platform Designer system in your design. These utilities produce a single simulation script that does not require manual update for upgrades to Quartus Prime software or IP versions, as Simulating Intel FPGA IP Cores on page 75 describes.

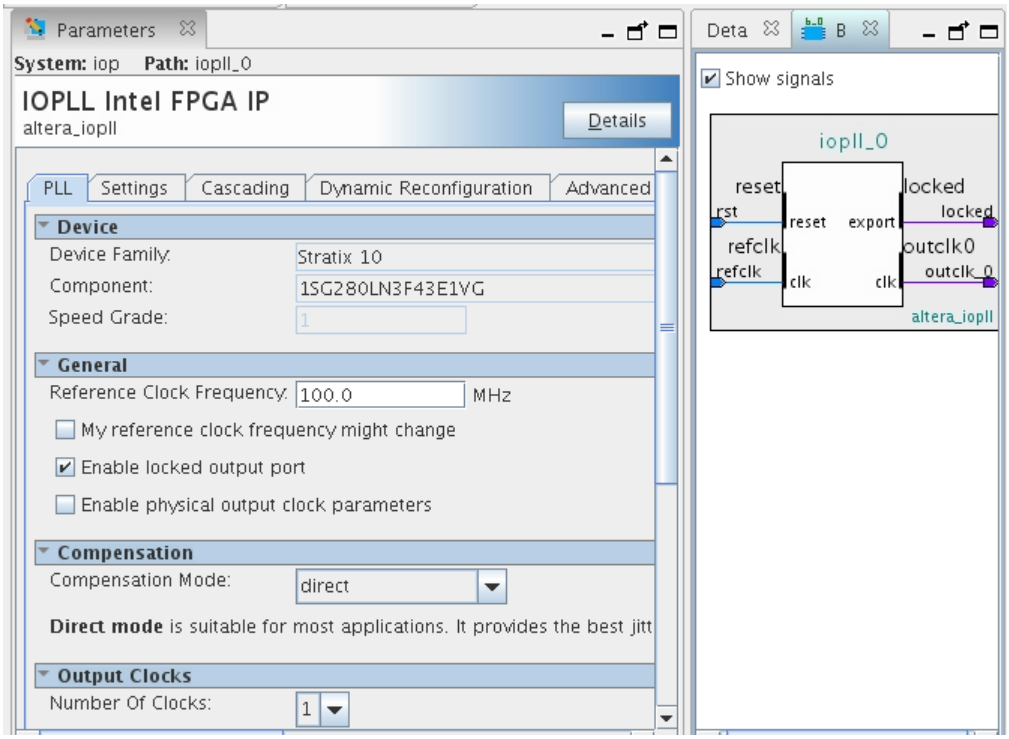
4.6. Specifying the IP Core Parameters and Options (Quartus Prime Pro Edition)

Quickly configure Intel FPGA IP cores in the Quartus Prime parameter editor. Double-click any component in the IP Catalog to launch the parameter editor. The parameter editor allows you to define a custom variation of the IP core. The parameter editor generates the IP variation synthesis and optional simulation files, and adds the `.ip` file representing the variation to your project automatically.

Follow these steps to locate, instantiate, and customize an IP core in the parameter editor:

1. Create or open an Quartus Prime project (`.qpf`) to contain the instantiated IP variation.
2. In the IP Catalog (**Tools ➤ IP Catalog**), locate and double-click the name of the IP core to customize. To locate a specific component, type some or all of the component's name in the IP Catalog search box. The New IP Variation window appears.
3. Specify a top-level name for your custom IP variation. Do not include spaces in IP variation names or paths. The parameter editor saves the IP variation settings in a file named `<your_ip>.ip`. Click **OK**. The parameter editor appears.

Figure 25. IP Parameter Editor (Quartus Prime Pro Edition)



4. Set the parameter values in the parameter editor and view the block diagram for the component. The **Parameterization Messages** tab at the bottom displays any errors in IP parameters:
   - Optionally, select preset parameter values if provided for your IP core. Presets specify initial parameter values for specific applications.
   - Specify parameters defining the IP core functionality, port configurations, and device-specific features.
   - Specify options for processing the IP core files in other EDA tools.

   Note: Refer to your IP core user guide for information about specific IP core parameters.
5. Click **Generate HDL**. The **Generation** dialog box appears.

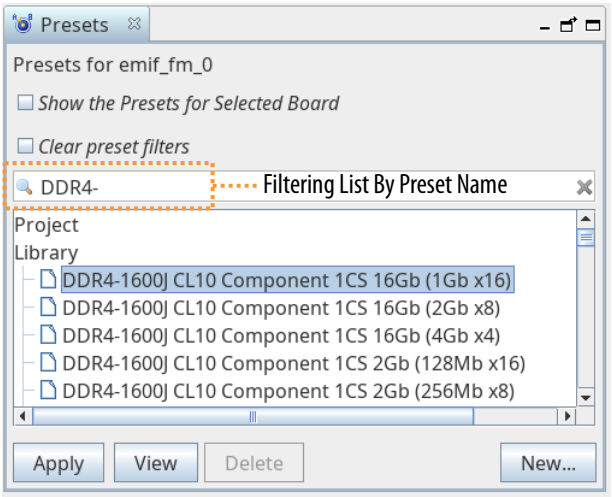
6. Specify output file generation options, and then click **Generate**. The synthesis and simulation files generate according to your specifications.
7. To generate a simulation testbench, click **Generate ➤ Generate Testbench System**. Specify testbench generation options, and then click **Generate**.
8. To generate an HDL instantiation template that you can copy and paste into your text editor, click **Generate ➤ Show Instantiation Template**.
9. Click **Finish**. Click **Yes** if prompted to add files representing the IP variation to your project.
10. After generating and instantiating your IP variation, make appropriate pin assignments to connect ports.

    Note: Some IP cores generate different HDL implementations according to the IP core parameters. The underlying RTL of these IP cores contains a unique hash code that prevents module name collisions between different variations of the IP core. This unique code remains consistent, given the same IP settings and software version during IP generation. This unique code can change if you edit the IP core's parameters or upgrade the IP core version. To avoid dependency on these unique codes in your simulation environment, refer to *Generating a Combined Simulator Setup Script*.

4.6.1. Applying Preset Parameters for Specific Applications

The **Preset** tab displays the names of available preset settings for an IP component. A preset is a specific collection of parameter settings that are appropriate for a specific protocol, application, or board. Double-click the preset name (or click **Apply**) to instantly apply the parameter values defined in the preset to the current IP instance.

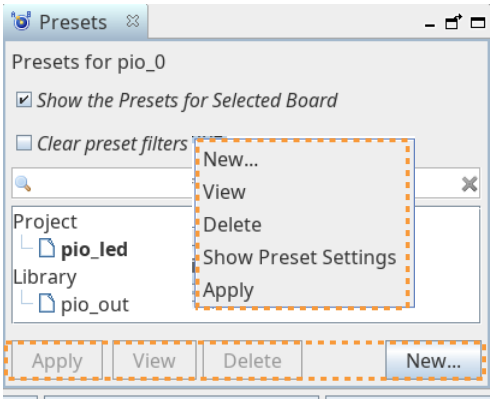
Figure 26. Selecting Preset Parameters



4.6.1.1. Viewing, Applying, and Deleting IP Presets

You can view the properties of a preset, apply a preset, or delete any existing preset in the **Presets** tab.

Figure 27. View, Apply, and Delete Presets in Presets Tab

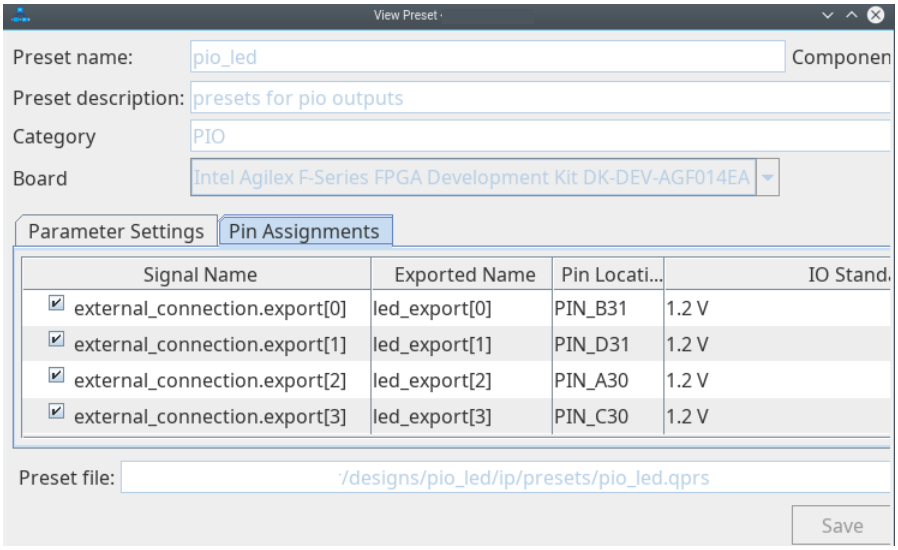


Note: Right-click a preset to access the same **View**, **Apply**, and **Delete** preset functions in the context menu.

Viewing Presets

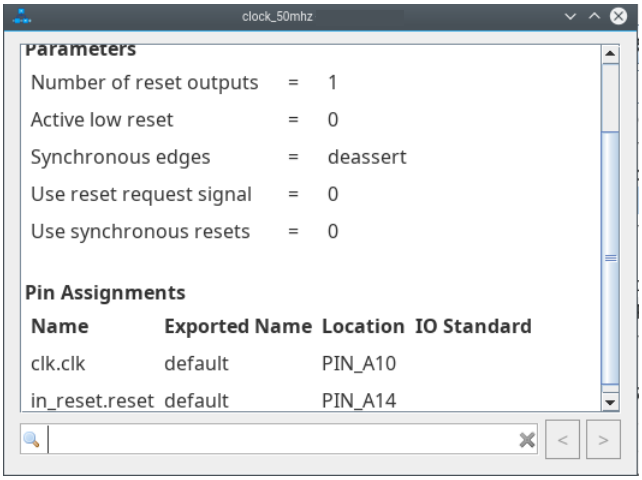
Click the **View** button to show the preset properties in the read-only **Update Preset** dialog box.

Figure 28. View Button Opens View Preset Dialog Box



Right-click a preset and click **Show Preset Settings** to view a searchable report of the preset settings.

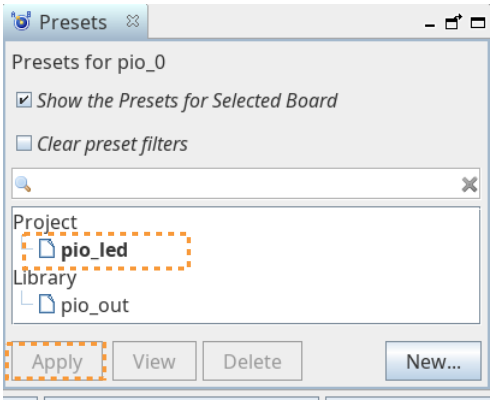
Figure 29. Show Preset Settings Searchable Report



Applying Presets to IP Instances

Click the **Apply** button (or double-click) to apply the IP preset to the currently selected IP. Applied presets appear in bold text.

Figure 30. Applied Presets Appear in Bold Text



Deleting Presets from the System

Click the **Delete** button to delete the current preset from the Platform Designer system.

4.6.2. Customizing IP Presets

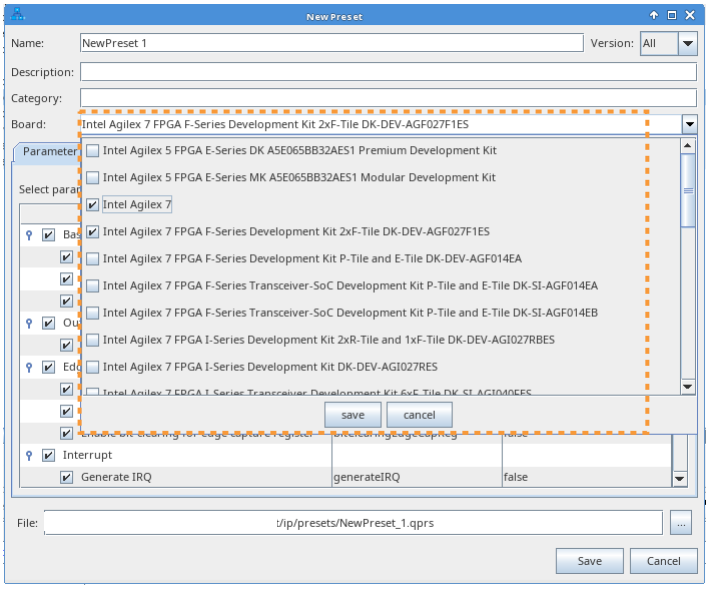
You can optionally define and save a custom set of parameter settings as an IP preset, and then apply the preset whenever you add an instance of the IP component to any system.

Follow these steps to save a custom IP preset:

1. In IP Catalog, double-click any component to launch the parameter editor.
2. To search for a specific preset to base initial settings, type a partial preset name in the search box.
3. In the **Presets** tab, click **New** to specify the **Preset name** and **Preset description**.
4. In the **Board** dropdown, specify the target board. The **Default** setting specifies the current board as the target board for this preset.

   Note: You can specify multiple boards for a preset, provided that the preset parameters and assignments are applicable to all boards in the preset.
5. Under **Select parameters to include in the preset**, enable or disable the parameters you want to include in the preset.
6. Specify the path for the **Preset file** that preserves the collection of parameter settings. The location of the new `.qprs` preset file is added to the IP search path automatically.

Figure 31. Create New Preset



7. Click **Save**.
8. To apply the preset to an IP component, click **Apply**. Preset parameter values that match the current parameter settings appear in bold.

4.6.2.1. Defining Preset Pin Assignments

You can define pin assignments that are included as part of an IP preset. When you apply the IP preset to an IP instance, the pin assignments export during the IP or system's HDL generation.

You define preset pin assignments in the **Pin Assignments** tab of the **New Preset** dialog box, or in a Pin Assignments File (`.tcl`) that you create.

4.6.2.1.1. Defining Preset Pin Assignments in Pin Assignments Tab

The **Pin Assignments** tab allows you to specify the **Exported Name** of the signals, to select the appropriate **Pin Location,** and to select the appropriate **IO Standard** for the target board.

By default, the **Exported Name** name takes the form of:

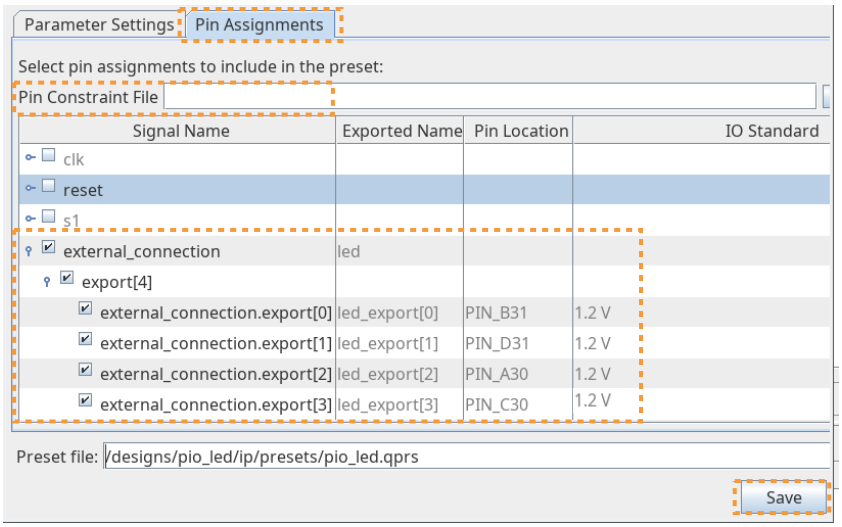
```
module_name + interface_name + pin_role
```

For example:

```
pio0_external_connection_export[0]
```

You can change the **Exported Name** by double-clicking on the **Exported Name** for the interface and typing a new name. All of the signals of the interface then update automatically to reflect the name you specify.

Figure 32. Pin Assignments Tab

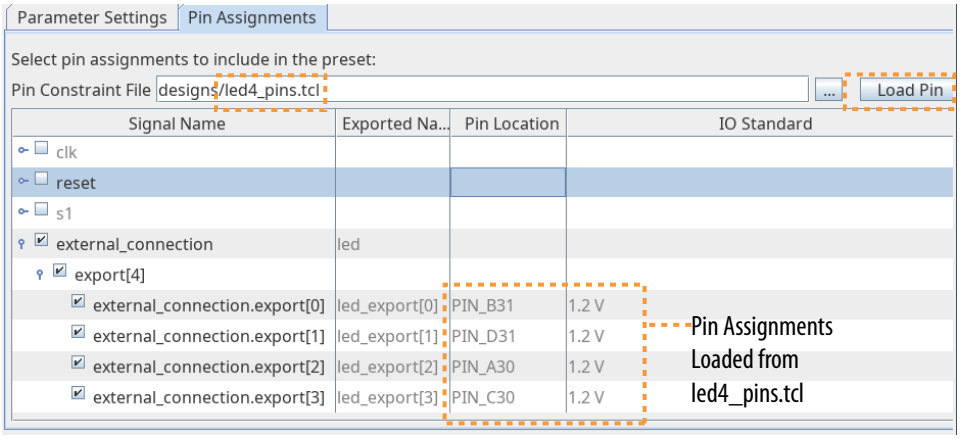


For example, typing `led` for the **external_connection** interface updates the signals of the interface to `led_export[n]`. The **external_connection** is the interface name, and **external_connection_export(0)** is the signal name.

4.6.2.1.2. Defining Preset Pin Assignments in a Pin File

Alternatively, you can specify the pin assignments in a Pin Constraints File (`.tcl`), which can be more efficient for projects with many ports. You specify this `.tcl` file as the **Pin Constraint File** on the **Pin Assignments** tab, and then click **Load Pin**. The **Pin Location** and **IO Standard** update per the loaded pin assignments.

Figure 33. Loading Pin Assignments from Tcl File



The following shows the contents of an example Pin Constraints File (`.tcl`):

```
set_instance_assignment -to "led_export[0]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[0]" "PIN_B31"
set_instance_assignment -to "led_export[1]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[1]" "PIN_D31"
set_instance_assignment -to "led_export[2]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[2]" "PIN_A30"
set_instance_assignment -to "led_export[3]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[3]" "PIN_C30"
```

4.7. IP Core Generation Output (Quartus Prime Pro Edition)

The Quartus Prime software generates the following output file structure for individual IP cores that are not part of a Platform Designer system.

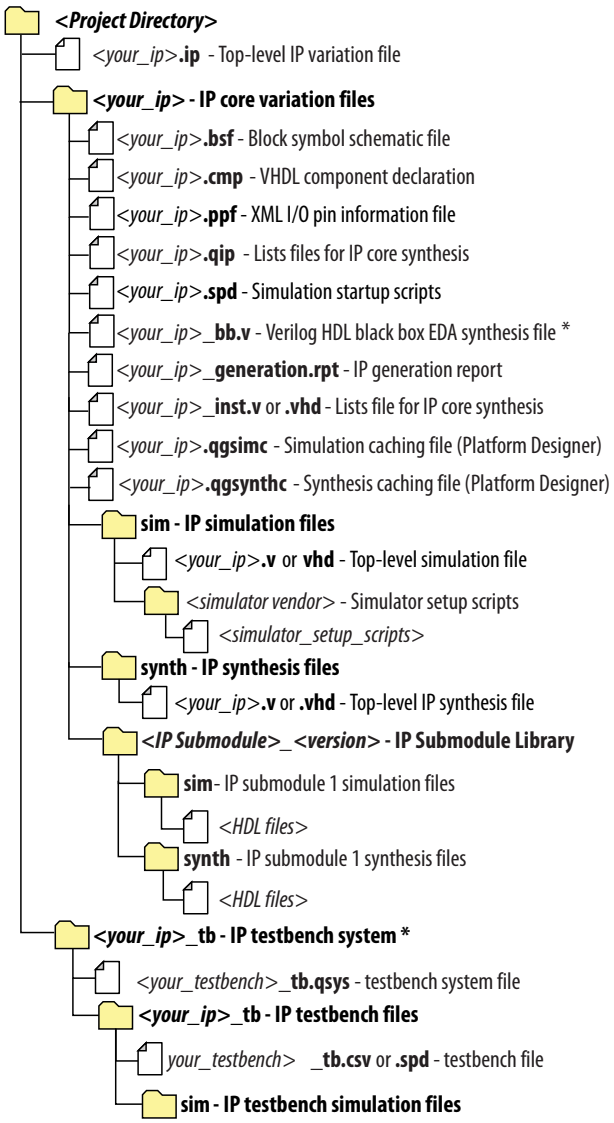
Table 25. Output Files of Intel FPGA IP Generation

File Name	Description
<*your_ip*>.ip	Top-level IP variation file that contains the parameterization of an IP core in your project. If the IP variation is part of a Platform Designer system, the parameter editor also generates a `.qsys` file.
<*your_ip*>.cmp	The VHDL Component Declaration (`.cmp`) file is a text file that contains local generic and port definitions that you use in VHDL design files.
<*your_ip*>_generation.rpt	IP or Platform Designer generation log file. Displays a summary of the messages during IP generation.
<*your_ip*>.qgsimc (Platform Designer systems only)	Simulation caching file that compares the `.qsys` and `.ip` files with the current parameterization of the Platform Designer system and IP core. This comparison determines if Platform Designer can skip regeneration of the HDL.
<*your_ip*>.qgsynth (Platform Designer systems only)	Synthesis caching file that compares the `.qsys` and `.ip` files with the current parameterization of the Platform Designer system and IP core. This comparison determines if Platform Designer can skip regeneration of the HDL.
<*your_ip*>.csv	Contains information about the upgrade status of the IP component.
<*your_ip*>.bsf	A symbol representation of the IP variation for use in Block Diagram Files (`.bdf`).

continued...

File Name	Description
<*your_ip*>.spd	Input file that `ip-make-simscript` requires to generate simulation scripts. The `.spd` file contains a list of files you generate for simulation, along with information about memories that you initialize.
<*your_ip*>.ppf	The Pin Planner File (`.ppf`) stores the port and node assignments for IP components you create for use with the Pin Planner.
<*your_ip*>_bb.v	Use the Verilog blackbox (`_bb.v`) file as an empty module declaration for use as a blackbox.
<*your_ip*>_inst.v or _inst.vhd	HDL example instantiation template. Copy and paste the contents of this file into your HDL file to instantiate the IP variation.
<*your_ip*>.regmap	If the IP contains register information, the Quartus Prime software generates the `.regmap` file. The `.regmap` file describes the register map information of host and agent interfaces. This file complements the `.sopcinfo` file by providing more detailed register information about the system. This file enables register display views and user customizable statistics in System Console.
<*your_ip*>.svd	Allows HPS System Debug tools to view the register maps of peripherals that connect to HPS within a Platform Designer system. During synthesis, the Quartus Prime software stores the `.svd` files for agent interface visible to the System Console hosts in the `.sof` file in the debug session. System Console reads this section, which Platform Designer queries for register map information. For system agents, Platform Designer accesses the registers by name.
<*your_ip*>.v <*your_ip*>.vhd	HDL files that instantiate each submodule or child IP core for synthesis or simulation.
mentor/	Contains a `msim_setup.tcl` script to set up and run a simulation with a supported Siemens EDA simulator, such as the QuestaSim simulator.
aldec/	Contains a Riviera-PRO* script `rivierapro_setup.tcl` to setup and run a simulation.
/synopsys/vcs /synopsys/vcsmx	Contains a shell script `vcs_setup.sh` to set up and run a VCS* simulation. Contains a shell script `vcsmx_setup.sh` and `synopsys_sim.setup` file to set up and run a VCS MX simulation.
/xcelium	Contains an Xcelium* Parallel simulator shell script `xcelium_setup.sh` and other setup files to set up and run a simulation.
/submodules	Contains HDL files for the IP core submodule.
<*IP submodule*>/	Platform Designer generates `/synth` and `/sim` sub-directories for each IP submodule directory that Platform Designer generates.

Figure 34. Individual IP Core Generation Output (Quartus Prime Pro Edition)



* If supported and enabled for your IP core variation.

4.8. Scripting IP Core Generation

Use the `qsys-script` and `qsys-generate` utilities to define and generate an IP core variation outside of the Quartus Prime GUI.

To parameterize and generate an IP core at command-line, follow these steps:

1. Run `qsys-script` to start a Tcl script that instantiates the IP and sets parameters:

```
qsys-script --script=<script_file>.tcl
```

2. Run `qsys-generate` to generate the IP core variation:

```
qsys-generate <IP variation file>.qsys
```

4.9. Modifying an IP Variation

After generating an IP core variation, use any of the following methods to modify the IP variation in the parameter editor.

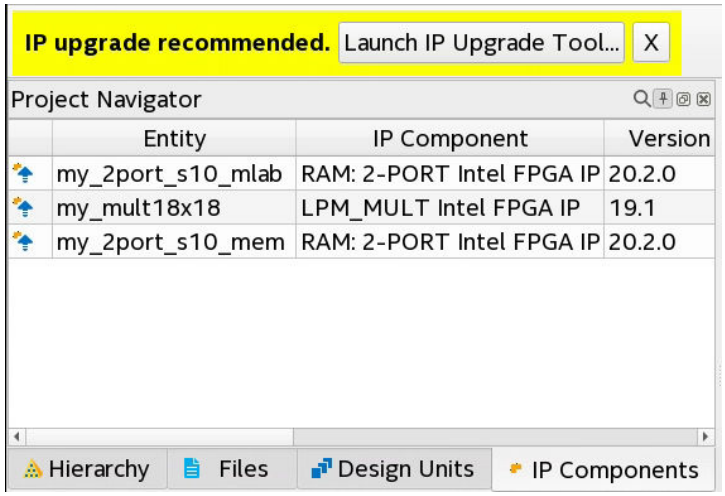
Table 26. Modifying an IP Variation

Menu Command	Action
File ➤ Open	Select the top-level HDL (`.v`, or `.vhd`) IP variation file to launch the parameter editor and modify the IP variation. Regenerate the IP variation to implement your changes.
View ➤ Project Navigator ➤ IP Components	Double-click the IP variation to launch the parameter editor and modify the IP variation. Regenerate the IP variation to implement your changes.
Project ➤ Upgrade IP Components	Select the IP variation and click **Upgrade in Editor** to launch the parameter editor and modify the IP variation. Regenerate the IP variation to implement your changes.

4.10. Upgrading IP Cores

Any Intel FPGA IP variations that you generate from a previous version or different edition of the Quartus Prime software, may require upgrade before compilation in the current software edition or version. The Project Navigator displays a banner indicating the IP upgrade status. Click **Launch IP Upgrade Tool** or **Project ➤ Upgrade IP Components** to upgrade outdated IP cores.

Figure 35. IP Upgrade Alert in Project Navigator



Icons in the **Upgrade IP Components** dialog box indicate when IP upgrade is required, optional, or unsupported for an IP variation in the project. Upgrade IP variations that require upgrade before compilation in the current version of the Quartus Prime software.

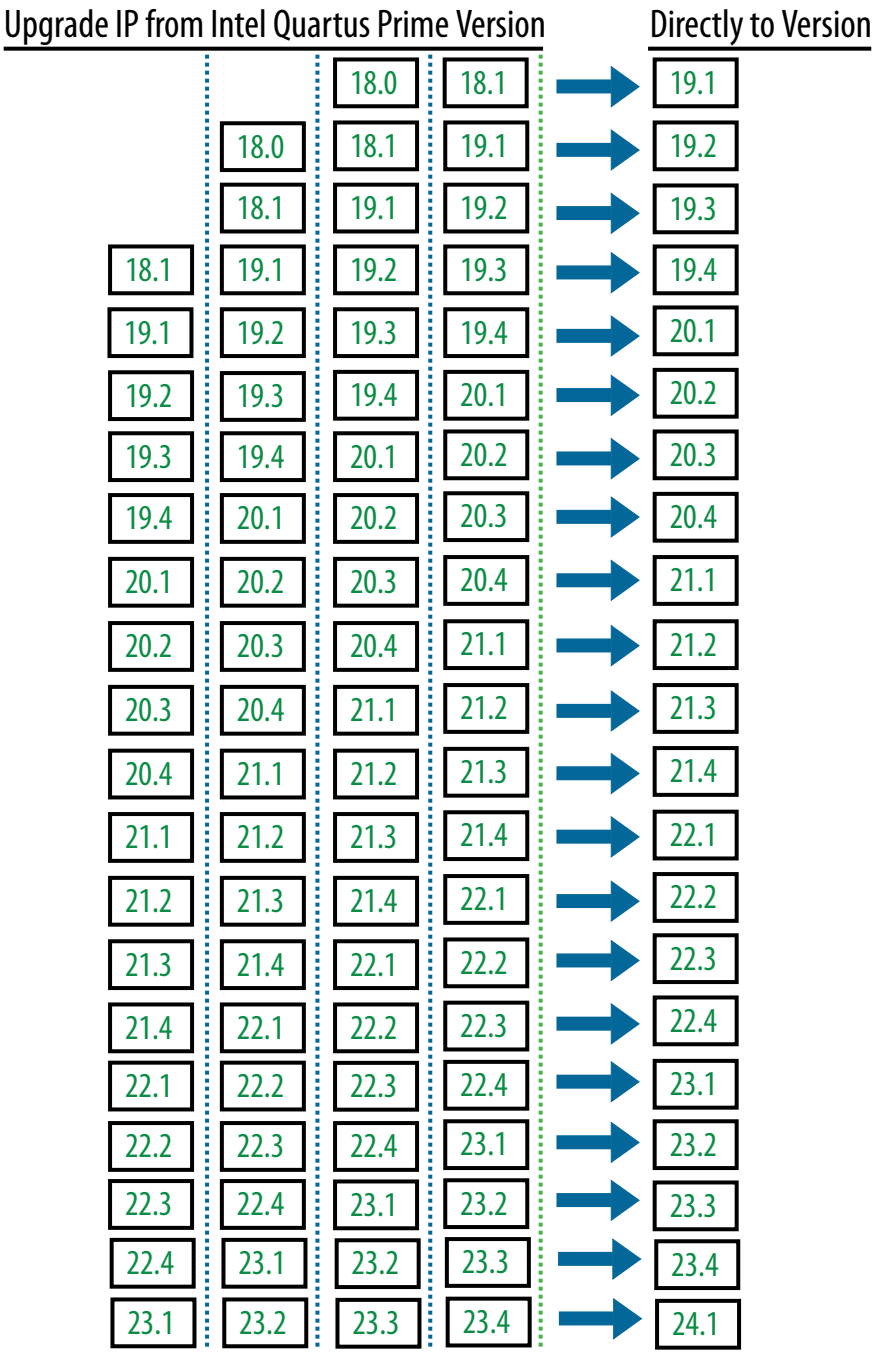
Note: Upgrading IP cores may append a unique identifier to the original IP core entity names, without similarly modifying the IP instance name. There is no requirement to update these entity references in any supporting Quartus Prime file, such as the Quartus Prime Settings File (`.qsf`), Synopsys* Design Constraints File (`.sdc`), or Signal Tap File (`.stp`), if these files contain instance names. The Quartus Prime software reads only the instance name and ignores the entity name in paths that specify both names. Use only instance names in assignments.

Table 27. IP Core Upgrade Status

IP Core Status	Description
IP Upgraded 	Indicates that your IP variation uses the latest version of the Intel FPGA IP core.
IP Component Outdated 	Indicates that your IP variation uses an outdated version of the IP core.
IP End of Life 	Indicates that Intel designates the IP core as end-of-life status. You may or may not be able to edit the IP core in the parameter editor. Support for this IP core discontinues in future releases of the Quartus Prime software.
IP Upgrade Mismatch Warning 	Provides warning of non-critical IP core differences in migrating IP to another device family.
IP has incompatible subcores 	Indicates that the current version of the Quartus Prime software does not support compilation of your IP variation, because the IP has incompatible subcores.
Compilation of IP Not Supported 	Indicates that the current version of the Quartus Prime software does not support compilation of your IP variation. This can occur if another edition of the Quartus Prime software, such as the Quartus Prime Standard Edition, generated this IP. Replace this IP component with a compatible component in the current edition.

Note: Beginning with the Quartus Prime Pro Edition software version 19.1, IP upgrade supports migration of IP released within one year of the Quartus Prime Pro Edition software version, as the following chart defines:

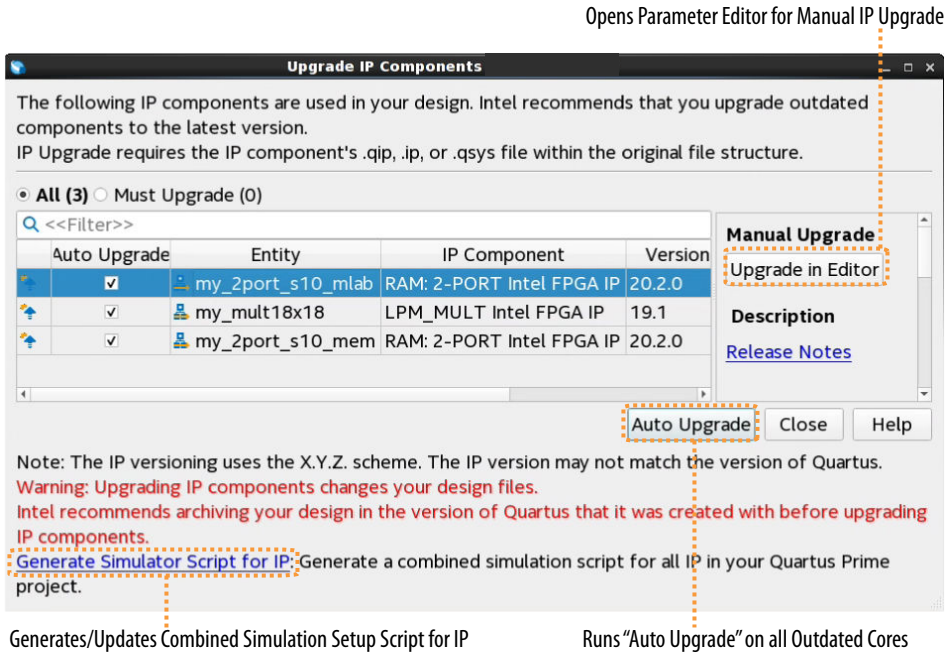
Figure 36. Quartus Prime Pro Edition IP Version Upgrade Paths



Follow these steps to upgrade IP cores:

1. In the latest version of the Quartus Prime software, open the Quartus Prime project containing an outdated IP core variation. The **Upgrade IP Components** dialog box automatically displays the status of IP cores in your project, along with instructions for upgrading each core. To access this dialog box manually, click **Project ➤ Upgrade IP Components**.
2. To upgrade one or more IP cores that support automatic upgrade, ensure that you turn on the **Auto Upgrade** option for the IP cores, and click **Auto Upgrade**. The **Status** and **Version** columns update when upgrade is complete. Example designs that any Intel FPGA IP core provides regenerate automatically whenever you upgrade an IP core.
3. To manually upgrade an individual IP core, select the IP core and click **Upgrade in Editor** (or simply double-click the IP core name). The parameter editor opens, allowing you to adjust parameters and regenerate the latest version of the IP core.

Figure 37. Upgrading IP Cores (Quartus Prime Pro Edition Example)



Note: Intel FPGA IP cores older than Quartus Prime software version 12.0 do not support upgrade. Intel verifies that the current version of the Quartus Prime software compiles the previous two versions of each IP core. The *Intel FPGA IP Core Release Notes* reports any verification exceptions for Intel FPGA IP cores. Intel does not verify compilation for IP cores older than the previous two releases.

Related Information

Intel FPGA IP Release Notes

4.10.1. Upgrading IP Cores at Command-Line

Optionally, upgrade an Intel FPGA IP core at the command-line, rather than using the GUI. IP cores that do not support automatic upgrade do not support command-line upgrade.

- To upgrade a single IP core at the command-line, type the following command:

```
quartus_sh –ip_upgrade –variation_files <my_ip>.<qsys,.v, .vhd> \
     <quartus_project>

Example:
quartus_sh -ip_upgrade -variation_files mega/pll25.qsys hps_testx
```

- To simultaneously upgrade multiple IP cores at the command-line, type the following command:

```
quartus_sh –ip_upgrade –variation_files “<my_ip1>.<qsys,.v, .vhd>> \
     ;  <my_ip_filepath/my_ip2>.<hdl>”  <quartus_project>

Example:
quartus_sh -ip_upgrade -variation_files "mega/pll_tx2.qsys;mega/
pll3.qsys" hps_testx
```

4.10.2. Migrating IP Cores to a Different Device

Migrate an Intel FPGA IP variation when you want to target a different (often newer) device. Most Intel FPGA IP cores support automatic migration. Some IP cores require manual IP regeneration for migration. A few IP cores do not support device migration, requiring you to replace them in the project. The **Upgrade IP Components** dialog box identifies the migration support level for each IP core in the design.

1. To display the IP cores that require migration, click **Project ➤ Upgrade IP Components**. The **Description** field provides migration instructions and version differences.
2. To migrate one or more IP cores that support automatic upgrade, ensure that the **Auto Upgrade** option is turned on for the IP cores, and click **Perform Automatic Upgrade**. The **Status** and **Version** columns update when upgrade is complete.
3. To migrate an IP core that does not support automatic upgrade, double-click the IP core name, and click **OK**. The parameter editor appears. If the parameter editor specifies a **Currently selected device family**, turn off **Match project/default**, and then select the new target device family.
4. Click **Generate HDL**, and confirm the **Synthesis** and **Simulation** file options. Verilog HDL is the default output file format. If you specify VHDL as the output format, select **VHDL** to retain the original output format.
5. Click **Finish** to complete migration of the IP core. Click **OK** if the software prompts you to overwrite IP core files. The **Device Family** column displays the new target device name when migration is complete.
6. To ensure correctness, review the latest parameters in the parameter editor or generated HDL.

Note: IP migration may change ports, parameters, or functionality of the IP variation. These changes may require you to modify your design or to re-parameterize your IP variant. During migration, the IP variation's HDL generates into a library that is different from the original output location of the IP core. Update any assignments that reference outdated locations. If a symbol in a supporting Block Design File schematic represents your upgraded IP core, replace the symbol with the newly generated `<my_ip>.bsf`. Migration of some IP cores requires installed support for the original and migration device families.

Related Information

Intel FPGA IP Release Notes

4.10.3. Troubleshooting IP or Platform Designer System Upgrade

The **Upgrade IP Components** dialog box reports the version and status of each Intel FPGA IP core and Platform Designer system following upgrade or migration.

If any upgrade or migration fails, the **Upgrade IP Components** dialog box provides information to help you resolve any errors.

Note: Do not use spaces in IP variation names or paths.

During automatic or manual upgrade, the Messages window dynamically displays upgrade information for each IP core or Platform Designer system. Use the following information to resolve upgrade errors:

Table 28. IP Upgrade Error Information

Upgrade IP Components Field	Description
Status	Displays the "Success" or "Failed" status of each upgrade or migration. Click the status of any upgrade that fails to open the **IP Upgrade Report**.
Version	Dynamically updates the version number when upgrade is successful. The text is red when the IP requires upgrade.
Device Family	Dynamically updates to the new device family when migration is successful. The text is red when the IP core requires upgrade.
Auto Upgrade	Runs automatic upgrade on all IP cores that support auto upgrade. Also, automatically generates a `<Project Directory>/ip_upgrade_port_diff_reports` report for IP cores or Platform Designer systems that fail upgrade. Review these reports to determine any port differences between the current and previous IP core version.

Use the following techniques to resolve errors if your IP core or Platform Designer system "Failed" to upgrade versions or migrate to another device. Review and implement the instructions in the **Description** field, including one or more of the following:

- If the current version of the software does not support the IP variant, right-click the component and click **Remove IP Component from Project**. Replace this IP core or Platform Designer system with the one supported in the current version of the software.
- If the current target device does not support the IP variant, select a supported device family for the project, or replace the IP variant with a suitable replacement that supports your target device.
- If an upgrade or migration fails, click **Failed** in the **Status** field to display and review details of the **IP Upgrade Report**. Click the **Release Notes** link for the latest known issues about the IP core. Use this information to determine the nature of the upgrade or migration failure and make corrections before upgrade.
- Run **Auto Upgrade** to automatically generate an **IP Ports Diff** report for each IP core or Platform Designer system that you upgrade. Review the reports to determine any port differences between the current and previous IP core version. Click **Upgrade in Editor** to make specific port changes and regenerate your IP core or Platform Designer system.
- If your IP core or Platform Designer system does not support **Auto Upgrade**, click **Upgrade in Editor** to resolve errors and regenerate the component in the parameter editor.

4.11. Simulating Intel FPGA IP Cores

The Quartus Prime software supports IP core RTL simulation in specific EDA simulators. IP generation optionally creates simulation files, including the functional simulation model, any testbench (or example design), and vendor-specific simulator

setup scripts for each IP core. You can use the functional simulation model and any testbench or example design for simulation. IP generation output may also include scripts to compile and run any testbench. The scripts list all models or libraries you require to simulate your IP core.

The Quartus Prime software provides integration with many simulators and supports multiple simulation flows, including your own scripted and custom simulation flows. Whichever flow you choose, IP core simulation involves the following steps:

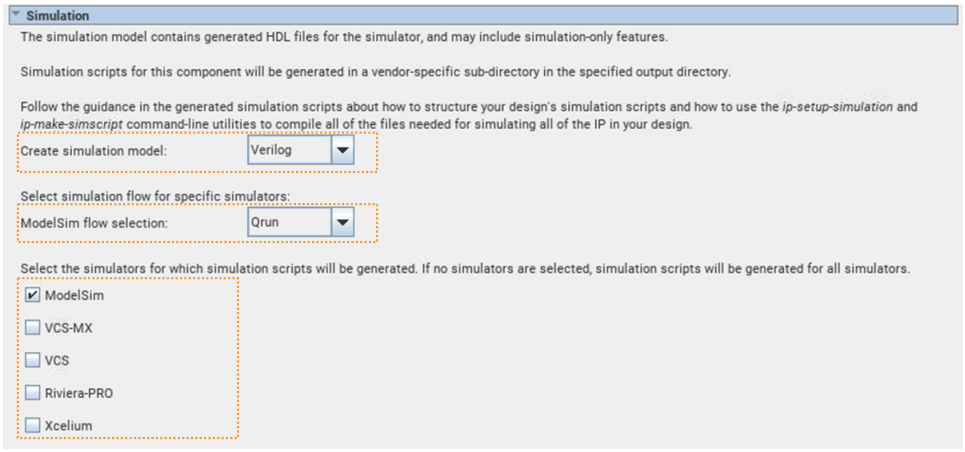
1. Generate IP HDL, testbench (or example design), and simulator setup script files.
2. Set up your simulator environment and any simulation scripts.
3. Compile simulation model libraries.
4. Run your simulator.

4.11.1. Generating IP Simulation Files

The Quartus Prime software optionally generates the functional simulation model, any testbench (or example design), and vendor-specific simulator setup scripts when you generate an IP core. To specify options for the generation of IP simulation files, follow these steps:

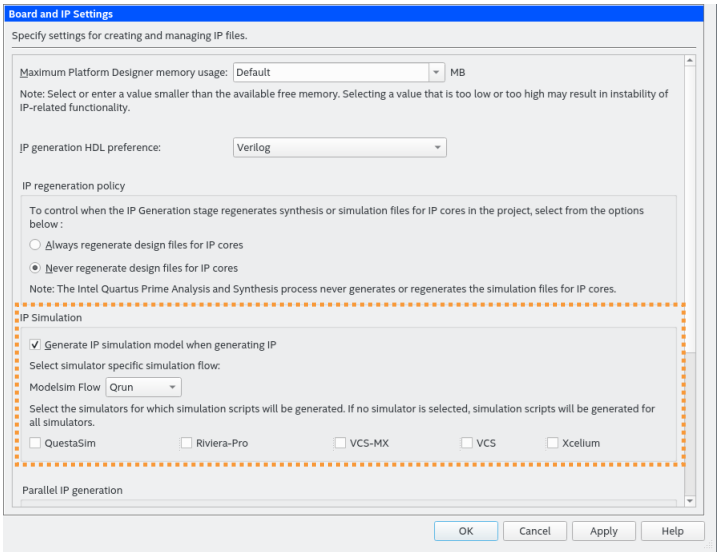
- To specify your supported simulator and options for design simulation file generation, click **Assignment ➤ Settings ➤ EDA Tool Settings ➤ Simulation**.

Figure 39. Simulation Options in Generation Dialog Box



- To specify your supported simulator and options for IP simulation file generation, click **Assignments ➤ Settings ➤ Board and IP Settings ➤ IP Simulation** and specify the following:
  - To enable automatic generation of simulation models for all IP in the project when you generate IP during compilation, turn on the **Generate IP simulation model when generating IP** option.
  - To specify one or more supported simulators for which to generate setup scripts, turn on one or more simulator option, or disable all simulator options to generate scripts for all simulators automatically.

Figure 40. Project-Wide IP Generation Settings



- To generate the simulation files, click **Processing ➤ Start Compilation** to compile the design. The simulation models and setup scripts for the Intel FPGA IP generate in the *<your_project>*/*<ip name>*/sim/*<vendor>* directory.

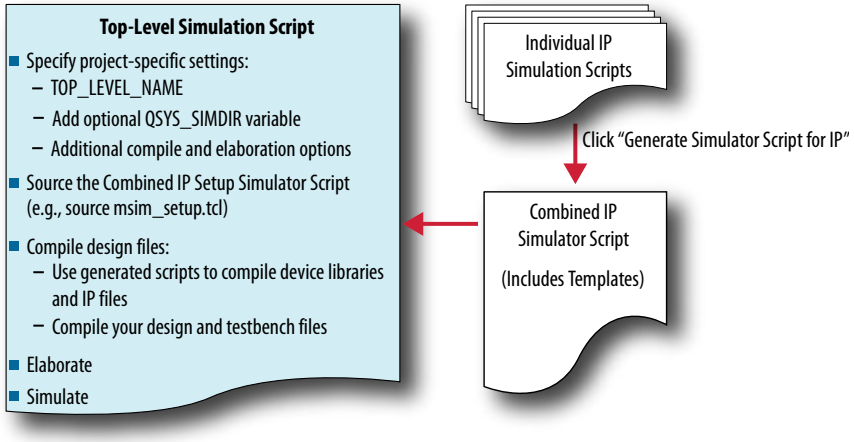
You can optionally override these project-level **IP Settings** when you generate HDL for individual IP cores with the IP Parameter Editor. Prior to generation, you can specify a supported simulator, or specify no simulator to generate the setup scripts for all simulators in the parameter editor.

4.11.2. Scripting IP Simulation

The Quartus Prime software supports the use of scripts to automate simulation processing in your preferred simulation environment. Use the scripting methodology that you prefer to control simulation.

Use a version-independent, top-level simulation script to control design, testbench, and IP core simulation. Because Quartus Prime-generated simulation file names may change after IP upgrade or regeneration, your top-level simulation script must "source" the generated setup scripts, rather than using the generated setup scripts directly. Follow these steps to generate or regenerate combined simulator setup scripts:

Figure 41. Incorporating Generated Simulator Setup Scripts into a Top-Level Simulation Script



1. Click **Tools ➤ Generate Simulator Script for IP** (or run the `ip-setup-simulation` utility) to generate or regenerate a combined simulator setup script for all IP for each simulator.
2. Use the templates in the generated script to source the combined script in your top-level simulation script. Each simulator's combined script file contains a rudimentary template that you adapt for integration of the setup script into a top-level simulation script.

   This technique eliminates manual update of simulation scripts if you modify or upgrade the IP variation.

4.11.2.1. Generating a Combined Simulator Setup Script

You can run the **Generate Simulator Setup Script for IP** command to generate a combined simulator setup script.

You can then source this combined script from a top-level simulation script. Click **Tools ➤ Generate Simulator Setup Script for IP** (or use of the `ip-setup-simulation` utility at the command-line) to generate or update the combined scripts, after any of the following occur:

- IP core initial generation or regeneration with new parameters
- Quartus Prime software version upgrade
- IP core version upgrade

Table 29. ip-setup-simulation Utility

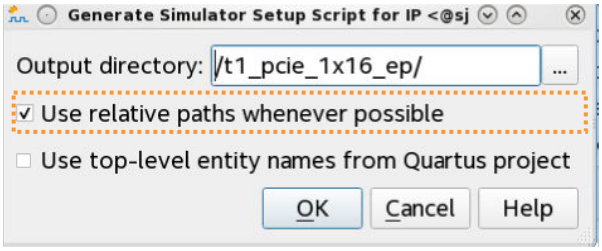
Utility	Syntax
`ip-setup-simulation` generates a combined, version-independent simulation script for all Intel FPGA IP cores in your project. The command also automates regeneration of the script after upgrading software or IP versions. Use the `compile-to-work` option to compile all simulation files into a single work library if your simulation environment requires. Use the `--use-relative-paths` option to use relative paths whenever possible.	`ip-setup-simulation` `--quartus-project=<my proj>` `--output-directory=<my_dir>` `--use-relative-paths` `--compile-to-work` `--use-relative-paths` and `--compile-to-work` are optional. For command-line help listing all options for these executables, type: `<utility name> --help`.

To generate a combined simulator setup script for all project IP cores for each simulator:[4]

1. Click **Tools ➤ Generate Simulator Setup Script for IP** (or run the `ip-setup-simulation` utility). Specify the **Output Directory** and library compilation options. Click **OK** to generate the file. By default, the files generate into the */<project directory>/<simulator>/* directory using relative paths.

   Note: For designs with F-tile IP, do not turn on the **Use top-level entity names from Quartus project** option.

Figure 42. Generate Simulator Setup Script for IP Dialog Box



2. To incorporate the generated simulator setup script into your top-level simulation script, refer to the template section in the generated simulator setup script as a guide to creating a top-level script:
   a. Copy the specified template sections from the simulator-specific generated scripts and paste them into a new top-level file.
   b. Remove the comments at the beginning of each line from the copied template sections.
   c. Specify the customizations you require to match your design simulation requirements, for example:
      - Specify the TOP_LEVEL_NAME variable to the design's simulation top-level file. The top-level entity of your simulation is often a testbench that instantiates your design. Then, your design instantiates IP cores or Platform Designer systems. Set the value of TOP_LEVEL_NAME to the top-level entity.
      - If necessary, set the QSYS_SIMDIR variable to point to the location of the generated IP simulation files.
      - Specify any other changes, such as using the `grep` command-line utility to search a transcript file for error signatures, or e-mail a report.
3. Re-run **Tools ➤ Generate Simulator Setup Script for IP** (or `ip-setup-simulation`) after regeneration of an IP variation.

Related Information

Quartus Prime Pro Edition User Guide: Third-party Simulation

[4] If your design contains one or more F-tile IPs, you must first perform **Start Analysis & Elaboration** and then **Support-Logic Generation** before performing these steps.

4.12. Generating Simulation Files for Platform Designer Systems and IP Variants

If your design contains Intel FPGA IP or a Platform Designer system, you must first generate files for RTL simulation of the IP or system with the Quartus Prime Platform Designer before running simulation.

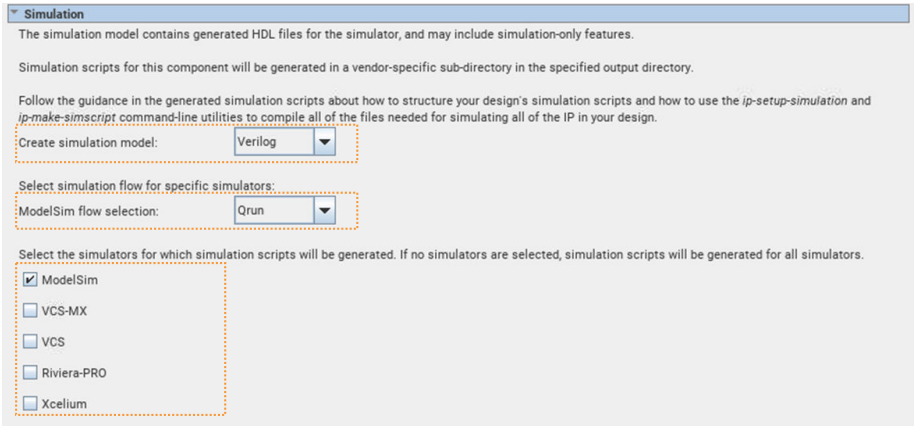
When you generate the system (or IP variant), Platform Designer optionally creates simulation files, including the functional simulation model, any testbench (or example design), and vendor-specific simulator setup scripts for each IP core.

You can use the functional simulation model and any testbench or example design for simulation of the IP or system. The IP generation output may also include scripts to compile and run any testbench. The scripts list all models or libraries you require to simulate your IP core.

To generate the simulation model and simulator setup scripts for your Platform Designer system or component, follow these steps:

1. Click **Tools ➤ Platform Designer**. Platform Designer and open or create a Platform Designer system or IP variant.
2. In Platform Designer, after specifying parameters, click **Generate ➤ Generate HDL**. The **Generation** dialog box appears.
3. Under **Simulation**, specify **Verilog** or **VHDL** for the **Create simulation model** option.

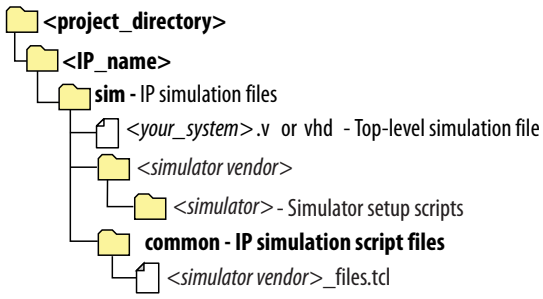
Figure 43. Simulation Options in Generation Dialog Box



4. If you want to specifically use ModelSim*, specify **Traditional** or **Qrun** for the ModelSim flow option. Otherwise, **Qrun** flow is the default selection.
5. Turn on or off the **ModelSim**, **VCS-MX**, **VCS**, **Riviera-Pro**, or **Xcelium** option to generate simulator setup scripts for the simulation tool. If you turn on no simulator options, the scripts generate for all simulators.
6. Click the **Generate** button. Platform Designer generates the simulation models and setup scripts for your system or IP component in the following directory:

```
<top-level system name>/<system name>/<sim>/<simulator>
```

Figure 44. Generated Simulation Files Location



By default, Platform Designer generates the simulation scripts for the currently loaded system and all subsystems. Alternatively, you can open a subsystem to generate a simulation script only for that subsystem.

You can use scripts to compile the required device libraries and system design files in the correct order and elaborate or load the top-level system for simulation.

Table 30. Simulation Script Variables

The simulation scripts provide variables that allow flexibility in your simulation environment.

Variable	Description
TOP_LEVEL_NAME	If the testbench Platform Designer system is not the top-level instance in your simulation environment because you instantiate the Platform Designer testbench within your own top-level simulation file, set the TOP_LEVEL_NAME variable to the top-level hierarchy name.
QSYS_SIMDIR	If the simulation files generated by Platform Designer are not in the simulation working directory, use the QSYS_SIMDIR variable to specify the directory location of the Platform Designer simulation files.
QUARTUS_INSTALL_DIR	Points to the Quartus installation directory that contains the device family library.

Example 6. Top-Level Simulation HDL File for a Testbench System

The example below shows the `pattern_generator_tb` generated for a Platform Designer system called `pattern_generator`. The `top.sv` file defines the top-level module that instantiates the `pattern_generator_tb` simulation model, as well as a custom SystemVerilog test program with BFM transactions, called `test_program`.

```
module top();
 pattern_generator_tb tb();
 test_program pgm();
endmodule
```

4.13. Synthesizing IP Cores in Other EDA Tools

Optionally, use another supported EDA tool to synthesize a design that includes Intel FPGA IP cores. When you generate the IP core synthesis files for use with third-party EDA synthesis tools, you can create an area and timing estimation netlist. To enable generation, turn on **Create timing and resource estimates for third-party EDA synthesis tools** when customizing your IP variation.

The area and timing estimation netlist describes the IP core connectivity and architecture, but does not include details about the true functionality. This information enables certain third-party synthesis tools to better report area and timing estimates. In addition, synthesis tools can use the timing information to achieve timing-driven optimizations and improve the quality of results.

The Quartus Prime software generates the <*variant name*>_syn.v netlist file in Verilog HDL format, regardless of the output file format you specify. If you use this netlist for synthesis, you must include the IP core wrapper file <*variant name*>.v or <*variant name*> .vhd in your Quartus Prime project.

4.14. Instantiating IP Cores in HDL

Instantiate an IP core directly in your HDL code by calling the IP core name and declaring the IP core's parameters. This approach is similar to instantiating any other module, component, or subdesign. When instantiating an IP core in VHDL, you must include the associated libraries.

4.14.1. Example Top-Level Verilog HDL Module

Verilog HDL ALTFP_MULT in Top-Level Module with One Input Connected to Multiplexer.

```
module MF_top (a, b, sel, datab, clock, result);
       input [31:0] a, b, datab;
       input clock, sel;
       output [31:0] result;
       wire [31:0] wire_dataa;

       assign wire_dataa = (sel)? a : b;
       altfp_mult inst1
(.dataa(wire_dataa), .datab(datab), .clock(clock), .result(result));

       defparam
               inst1.pipeline = 11,
               inst1.width_exp = 8,
               inst1.width_man = 23,
               inst1.exception_handling = "no";
endmodule
```

4.14.2. Example Top-Level VHDL Module

VHDL ALTFP_MULT in Top-Level Module with One Input Connected to Multiplexer.

```
library ieee;
use ieee.std_logic_1164.all;
library altera_mf;
use altera_mf.altera_mf_components.all;

entity MF_top is
        port (clock, sel  : in  std_logic;
              a, b, datab : in  std_logic_vector(31 downto 0);
              result      : out std_logic_vector(31 downto 0));
end entity;

architecture arch_MF_top of MF_top is
signal wire_dataa : std_logic_vector(31 downto 0);
begin

wire_dataa <= a when (sel = '1') else b;

inst1 : altfp_mult
```

```
        generic map    (
                  pipeline => 11,
                  width_exp => 8,
                  width_man => 23,
                  exception_handling => "no")
        port map (
                  dataa => wire_dataa,
                  datab => datab,
                  clock => clock,
                  result => result);
end arch_MF_top;
```

4.15. Support for the IEEE 1735 Encryption Standard

The Quartus Prime Pro Edition software supports the IEEE 1735 v1 encryption standard for IP core file decryption. You can encrypt the Verilog HDL or VHDL IP files with the `encrypt_1735` utility, or with a third-party encryption tool that supports the IEEE 1735 standard. You can then use the encrypted files in the Quartus Prime Pro Edition software and simulation tools that support the IEEE 1735 encryption standard.

The encryption key is the same for Verilog HDL and VHDL. You can pass parameters to the instantiation of an encrypted module using the same method as a non-encrypted module.

Type `encrypt_1735 --help` at the Quartus Prime command line to view syntax and all supported options for the `encrypt_1735` utility.

```
encrypt_1735 [-h | --help[=<option|topic>] | -v]
encrypt_1735 <other options>

Options:
--------
    -?
    -f <argument file>
    -h
    --256_bit[=<value>]
    --help[=<option|topic>]
    --language=<verilog | systemverilog| vhdl>
    --lower_priority
    --of=<some_file>
    --quartus
    --simulation[=<aldec | cadence | mentor | synopsys (comma delimited)>]
    --tcl_jou_file=<[tcl_jou_filename=]on|off>
    --tcl_log_file=<[tcl_log_filename=]on|off>
```

Adding the following Verilog or VHDL pragma to your RTL, along with the public key, enables the Quartus Prime software to use the key to decrypt IP core files.

Verilog/SystemVerilog Encryption Pragma (Third-Party Tools):

```
`pragma protect key_keyowner="Intel Corporation"
`pragma protect data_method="aes128-cbc"
`pragma protect key_method="rsa"
`pragma protect key_keyname="Intel-FPGA-Quartus-RSA-1"
`pragma protect key_public_key
<encrypted session key>

`pragma protect begin
`pragma protect end
```

VHDL Encryption Pragma (Third-Party Tools):

```
`protect key_keyowner = “Intel Corporation”
`protect data_method="aes128-cbc"
`protect key_method = “rsa”
`protect key_keyname = “Intel-FPGA-Quartus-RSA-1”
`protect key_block
<Encrypted session key>
```

Only file encryption with a third-party tool requires the public encryption key. File encryption with the Quartus Prime Pro Edition software does not require the public encryption key.

Use one of the following methods to obtain the public encryption key:

- If you are using the Quartus Prime Pro Edition software version 19.3 or later, the public encryption key is in *<install directory>*\quartus\common\misc\public_key.
- If you are using a version of the Quartus Prime Pro Edition software earlier than version 19.3, to obtain the encryption key, login or register for a My-Intel account, and then submit an Intel Premier Support case requesting the encryption key.
- If you are ineligible for Intel Premier Support, you can submit a question regarding the "IEEE 1735 Encryption Public Key" to the Intel Community Forum for assistance.

Note: The Quartus Prime Standard Edition software does not support IEEE 1735 encryption.

Related Information

- My-Intel.com
- Intel Community Forum

4.16. Related Trainings and Resources

You can take up the following training to help you understand how you can work with Intel FPGA IP cores:

- Creating Reusable Design Blocks: Introduction to IP Reuse with the Quartus Prime Software
- Creating Reusable Design Blocks: IP Integration with the Quartus Prime Software
- Creating Reusable Design Blocks: IP Design & Implementation with the Quartus Prime Software

For other IP-related trainings, review the Intel FPGA Training Catalog and YouTube*'s Intel FPGA channel.

Also, refer to the Embedded Peripherals IP User Guide for detailed description of the IP cores that the Quartus Prime design software provides.

5. Managing Quartus Prime Projects

The Quartus Prime software organizes and manages the elements of your design within a *project*. The project encapsulates information about your design files, hierarchy, libraries, constraints, and project settings. This chapter describes the basics of working with Quartus Prime software projects, including viewing project information, adding design files and constraints, and viewing and exporting the design compilation results.

After you create or open a project, the GUI displays integrated information and controls for the open project.

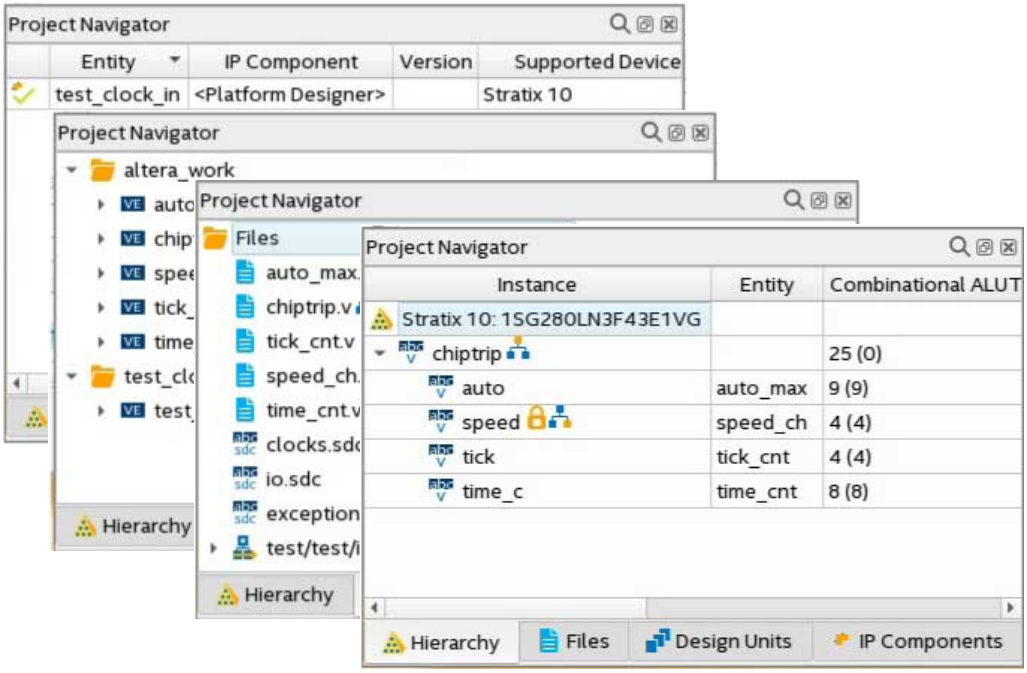
Navigating Content Through Tasks

Use the following navigation diagram to navigate this guide through user-tasks:

5.1. Viewing Basic Project Information

View basic information about your project in the Project Navigator, the **Tasks** pane, Compilation Dashboard, Report panel, and **Messages** window.

Figure 45. Project Navigator Hierarchy, Files, Design Units, and IP Components Tabs



The Project Navigator

The **Project Navigator** (**View ➤ Project Navigator**) displays the elements of your project, such as the design files, IP components, and your project hierarchy (after elaboration). Right-click in the **Project Navigator** to locate the elements of your project. Project information appears on the **Files**, **Hierarchy**, **Design Units**, and **IP Components** tabs.

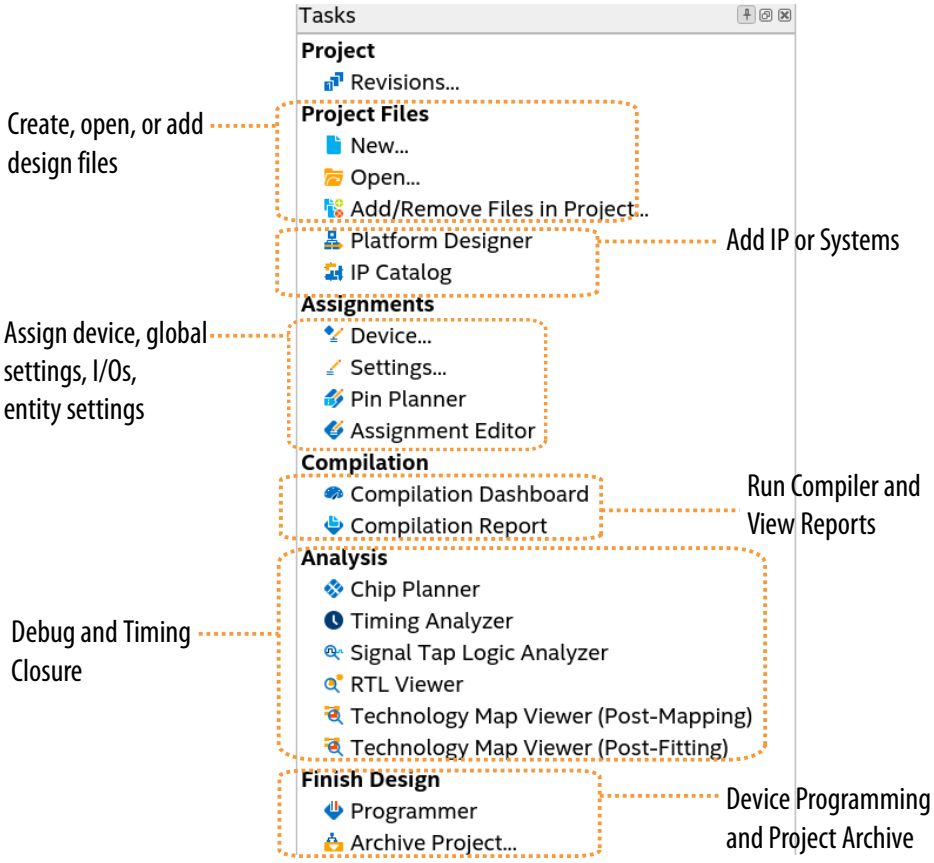
Table 31. Project Navigator Tabs

Project Navigator Tab	Description
Files	Lists all design files in the current project. Right-click design files in this tab to run these commands: • **Open** the file • **Remove** the file from project • View file **Properties**
Hierarchy	Provides a visual representation of the project hierarchy, specific resource usage information, and device and device family information. Right-click items in the hierarchy to **Locate**, **Set as Top-Level Entity**, or define Logic Lock regions or design partitions.
Design Units	Displays the design units in the project. Right-click a design unit to **Locate in Design File**.
IP Components	Displays the design files that make up the IP instantiated in the project, including Intel FPGA IP, Platform Designer components, and third-party IP. Click **Launch IP Upgrade Tool** from this tab to upgrade outdated IP components.

Project Tasks Pane

The **Tasks** pane (**View ➤ Tasks**) launches common project tasks, such as creating design files, adding IP, running compilation, and device programming.

Figure 46. Tasks Pane

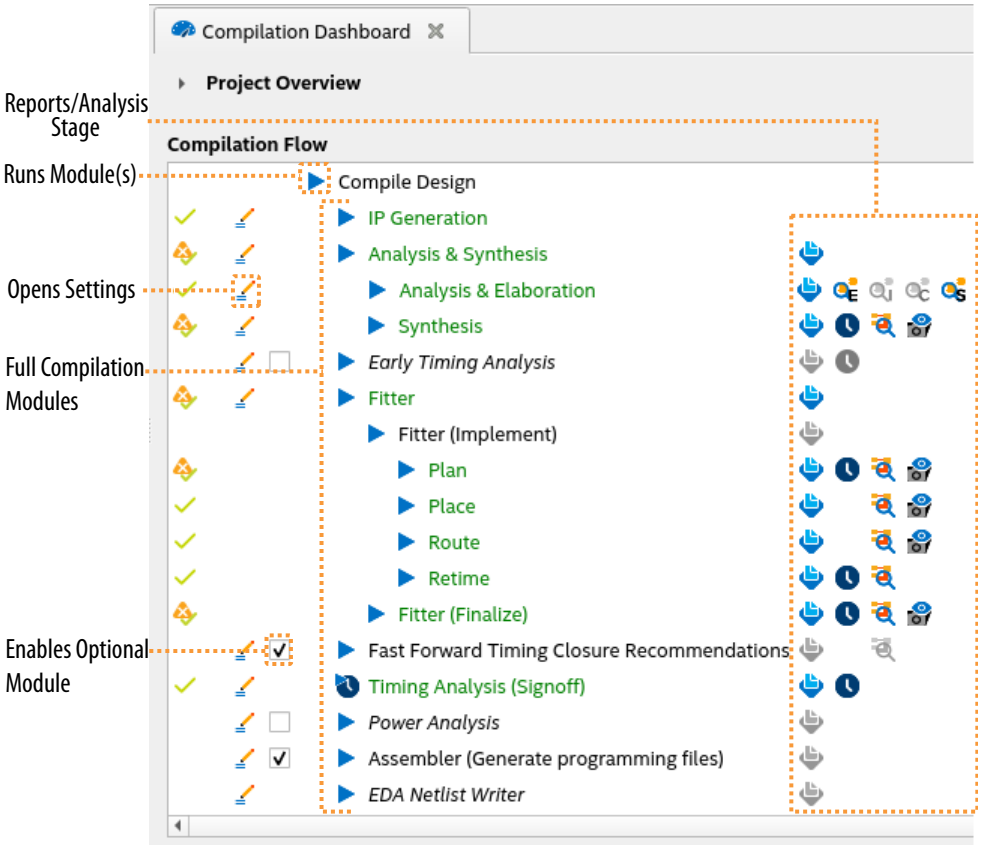


5.1.1. Using the Compilation Dashboard

The Compilation Dashboard provides immediate access to settings, controls, and reporting for each stage of the compilation flow.

The Compilation Dashboard appears by default when you open a project, or you can click **Compilation Dashboard** in the Tasks window to re-open it.

Figure 47. Compilation Dashboard



- Click the **Pencil** icon to edit settings for that stage of the compilation flow.
- Click any Compiler stage to run one or more Compiler stage.

  You can click a Compiler stage to resume an interrupted compilation flow provided no compilation settings have changed from the initial start of the compilation flow.
- Click the **Report**, **RTL Viewer**, **Technology Map Viewer**, **Timing Analyzer**, or **Snapshot Viewer** icons for analysis of stage results.

As the Compiler progresses through the flow, the dashboard updates the status of each module, and enables icons that you can click for reports and analysis. The dashboard is also updated if you run your compilation flow from a command line with the `quartus_sh --flow` command.

5.1.2. Exploring Quartus Prime Project Contents

The Quartus Prime software organizes your design work within a project. You can create and compare multiple revisions of your project, to experiment with settings that achieve your design goals. When you create a new project in the GUI, the Quartus Prime software automatically creates an Quartus Prime Project File (`.qpf`) for that project. The `.qpf` references the Quartus Prime Settings File (`.qsf`). The `.qsf` lists the project's design, constraint, and IP files, and stores project-wide and entity-

specific settings that you specify in the GUI. You do not need to edit the text-based `.qpf` or `.qsf` files directly. The Quartus Prime software creates and updates these files automatically as you make changes in the GUI.

Table 32. Quartus Prime Project Files

File Type	Contains	To Edit	Format
Project file	Project and revision name	**File ➤ New Project Wizard**	Quartus Prime Project File (`.qpf`)
Settings file	Lists design files, entity settings, target device, synthesis directives, placement constraints	**Assignments ➤ Settings**	Quartus Prime Settings File (`.qsf`)
Quartus database	Project compilation results	**Project ➤ Export Design**	Quartus Database File (`.qdb`)
Partition database	Partition compilation results	**Project ➤ Export Design Partition**	Partition Database File (`.qdb`)
Timing constraints	Clock properties, exceptions, setup/hold	**Tools ➤ Timing Analyzer**	Synopsys Design Constraints File (`.sdc`)
Logic design files	RTL and other design source files	**File ➤ New**	All supported HDL files
Programming files	Device programming image and information	**Tools ➤ Programmer**	SRAM Object File (`.sof`) Programmer Object File (`.pof`)
IP core files	IP core variation parameterization	**Tools ➤ IP Catalog**	Quartus Prime IP File (`.ip`)
Platform Designer system files	System definition	**Tools ➤ Platform Designer**	Platform Designer System File (`.qsys`)
EDA tool files	Scripts for third-party EDA tools	**Assignments ➤ Settings ➤ EDA Tool Settings**	Verilog Output File (`.vo`) VHDL Output File (`.vho`) Verilog Quartus Mapping File (`.vqm`)
Archive files	Complete project as single compressed file	**Project ➤ Archive Project**	Quartus Prime Archive File (`.qar`)

5.1.2.1. Project File Best Practices

The Quartus Prime software provides various options for specifying project settings and constraints. The following best practices help ensure automated management and portability of your project files.

- Avoid manually editing Quartus Prime data files, such as the Quartus Prime Project File (`.qpf`), Quartus Prime Settings File (`.qsf`), Quartus IP File (`.ip`), or Platform Designer System File (`.qsys`). Syntax errors in these files cause errors during compilation. For example, the software may ignore improperly formatted settings and assignments.
- Do not compile multiple projects into the same directory. Instead, use a separate directory for each project.
- By default, the Quartus Prime software saves all project output files, such as Text-Format Report Files (`.rpt`), in the project directory. If you want to change the location of output files, instead of manually moving project output files, click **Assignments ➤ Settings ➤ Compilation Process Settings**, and specify the **Save project output files in specified directory** option.

5.1.3. Viewing Design Hierarchy and Adding Missing Source Files

With the introduction of the fast hierarchy display feature, you can now view the design hierarchy quickly and add the missing source files without having to wait until the completion of the Analysis & Elaboration compilation process.

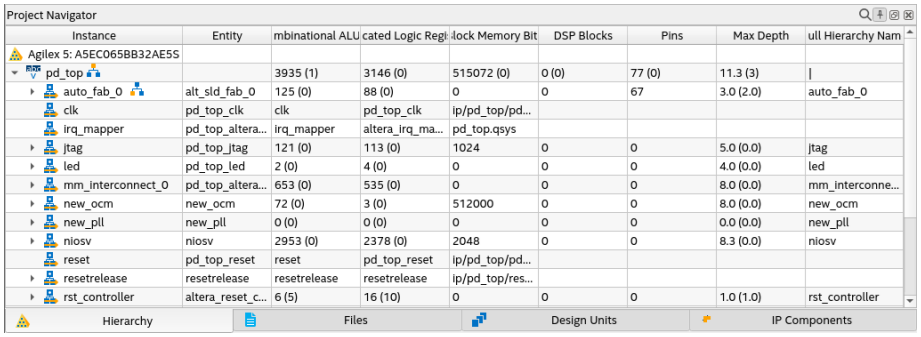
Perform these steps to view the design hierarchy and add the missing source files:

Prerequisite: After launching the Quartus Prime Pro Edition software GUI and creating your project, ensure you have added all RTL source files to the project and top-level entity name of the design, without which, you cannot proceed with Analysis & Elaboration.

1. Run either **Analysis & Synthesis** or **Analysis & Elaboration** on the compilation dashboard.
2. Navigate to the left-hand **Project Navigator ➤ Hierarchy** tab.

   The **Hierarchy** viewer allows you to quickly view your design hierarchy, and any errors or warnings before the design is fully elaborated. You can also cross-probe between the source files and information, warnings or error messages. All entities with missing source files are highlighted enabling you to make quick design fixes.

Figure 48. Fast Display of Design Hierarchy

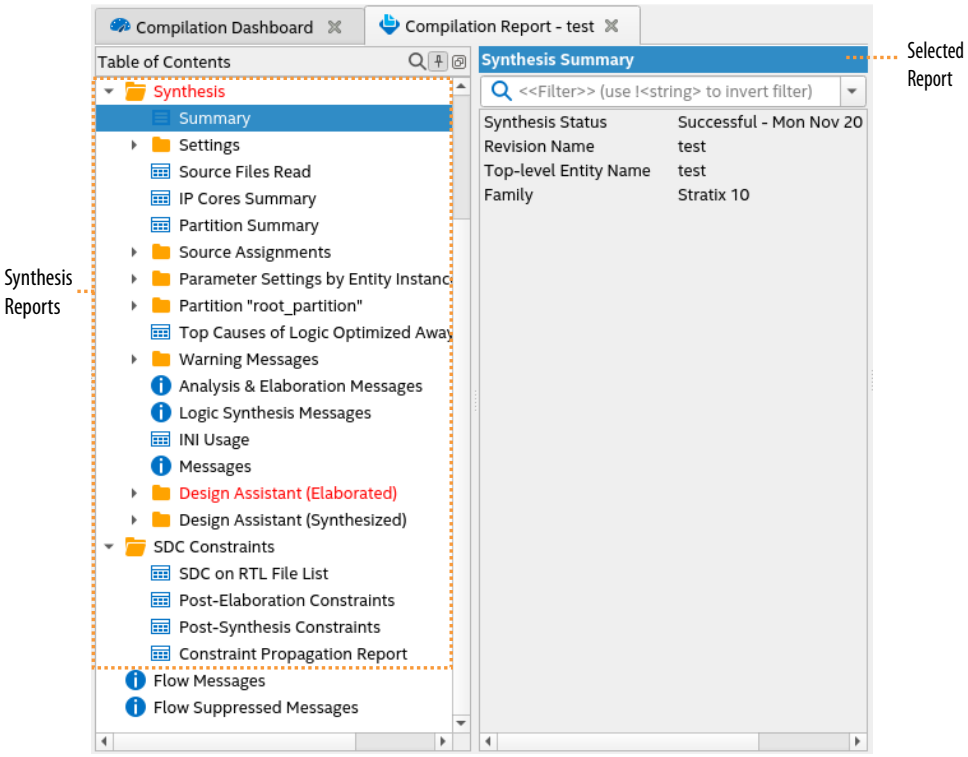


5.1.4. Viewing Project Reports

The Compilation Report panel updates dynamically to display detailed reports during project processing. To access Compilation Reports, click (**Processing ➤ Compilation Report**).

Review the detailed information in these the compilation reports to determine correct implementation. Right-click report data to locate and edit the source in project files.

Figure 49. Compilation Report

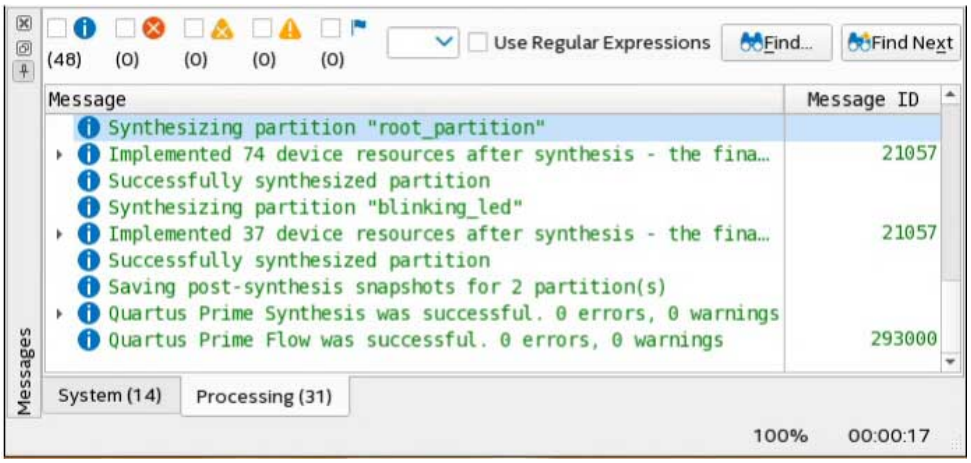


5.1.5. Viewing Project Messages

The Messages window (**View ➤ Messages**) displays information, warning, and error messages about Quartus Prime processes. Right-click messages to locate the source or get message help.

- **Processing** tab—displays messages from the most recent process
- **System** tab—displays messages unrelated to design processing
- **Find**—locates specific messages

Figure 50. Messages Window



5.1.5.1. Viewing Synthesis Warning Messages

Warning messages may contain hierarchies. In **Compilation Report ➤ Synthesis ➤ Messages** window, you can view hierarchical warning messages up to any level including the parent and child messages. For each message, you can view its source, file location, line number, and message ID by selecting appropriate column under **Message Column** (right-click on a message in the **Message** panel as shown in the following image and click **Message Column**).

Figure 51. Synthesis Warning Messages (Two levels)

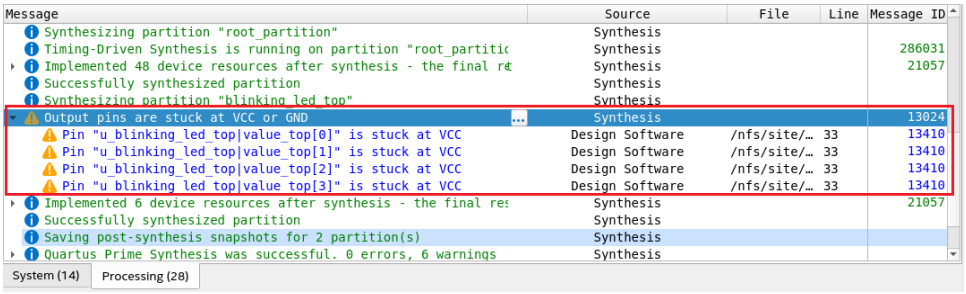


Figure 52. Example of Synthesis Warning Messages With Three Levels

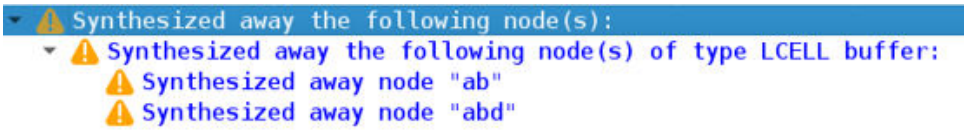


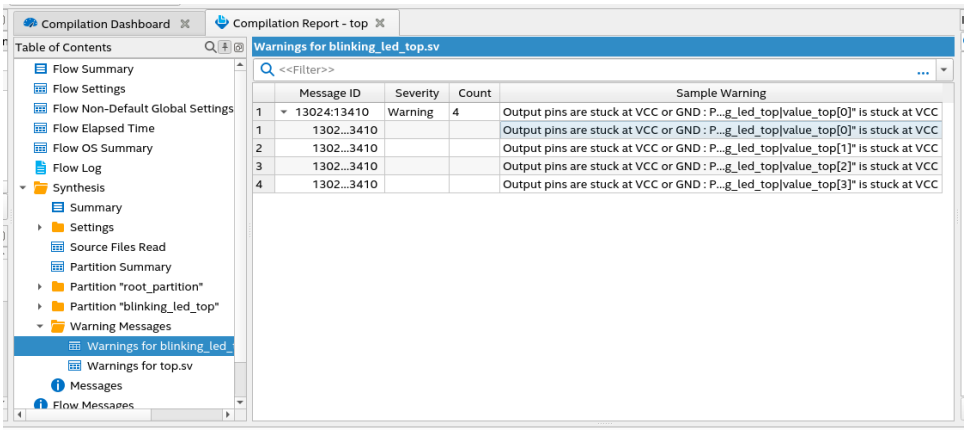
In **Compilation Report ➤ Synthesis ➤ Warning Messages**, you can view a comprehensive list of synthesis warning messages for each source file included in your design. You can view all child warning messages hidden within a parent warning message by expanding the collapsible rows. To view the location of each warning, perform these steps:

1. Right-click on the message.
2. Select the **Locate Node** option.
3. Select the desired tool to view the node.

Note: In the source file-specific warning messages window, messages are hierarchical in nature and display up to three levels. If the warning messages go deeper than three levels, use the **Message** (**View ➤ Messages**) window to view them.

In the source file-specific warning messages window, hierarchical messages are displayed with message IDs and sample warning messages that are a combination of the parent and child messages.

Figure 53. Synthesis Warning Messages for Each Source File



5.1.5.2. Suppressing Message Display

You can suppress display of unimportant messages from the Messages window, so that you can focus on the messages that are important to you. To suppress one or more messages from displaying in the Messages window, right-click the message, and then click any of the following commands:

- **Suppress Message**—suppresses all messages that match the exact text you specify.
- **Suppress Messages with Matching ID**—suppresses all messages that match the message ID number you specify, ignoring variables.
- **Suppress Messages with Matching Keyword**—suppresses all messages that match the keyword or hierarchy you specify.
- **Message Suppression Manager**—allows you to create and edit message suppression rules. You can define message suppression rules by message text, message ID number, or keyword.

Note:

- You cannot suppress error or Intel legal agreement messages.
- Suppressing a message also suppresses any submessages.
- A root message does not display if you suppress all of the root message's submessages.
- Message suppression is project revision-specific. Derivative project revisions inherit any suppression.
- You cannot edit messages or suppression rules during compilation.
- Messages are written to `stdout` when you use command-line executables.

Figure 54. Message Suppression Manager

Suppressing Messages by Design Entity

You can optionally suppress messages by design entity without modifying HDL. Entity-based message suppression can be helpful to eliminate insignificant warnings for specific IP components or design entities that may be obscuring other more important warnings.

To suppress messages by design entity, add the following line to the project `.qsf`, or to the `.qip` file for stand-alone IP components:

```
set_global_assignment -name MESSAGE_DISABLE -entity <name>
```

5.1.5.3. Promoting Critical Warnings to Errors

You can promote critical warnings to errors so that the compilation flow halts on receiving the critical warnings as it does with an errors. All critical warnings are supported.

You can only promote the message IDs on open projects.

1. In the **Message** dialog box, right-click on the critical warning you want to promote to an error.
2. Click **Message Promotion ➤ Promote Critical Message ID to Error**
   The software now treats the critical warning as an error.
3. To clear all promotions, click **Message Promotion ➤ Clear All Message Promotions**
4. Alternatively, manually promote or demote a critical warning in the `.qsf`. For example:

   ```
   set_global_assignment -name PROMOTE_WARNING_TO_ERROR 12677
   ```

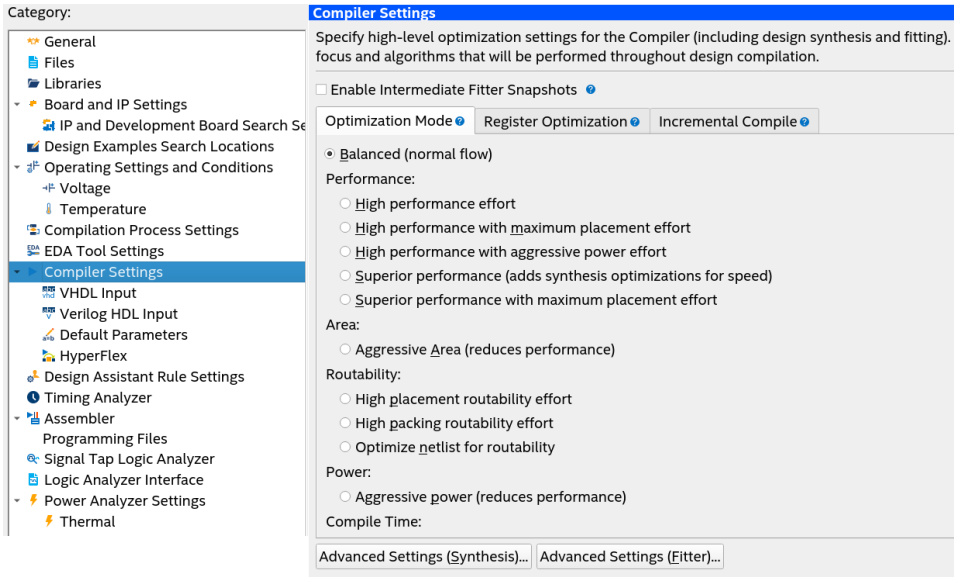
5.2. Managing Project Settings

The New Project Wizard guides you to make initial project settings when you setup a new project. You can modify these and other global project settings in the **Settings** and **Device** dialog boxes, respectively. The `.qsf` stores the settings for each project revision. The optimization of these project settings helps the Compiler to generate programming files that meet or exceed your specifications.

Global Project Settings

To access global project settings, click **Assignments ➤ Settings**, or click **Settings** on the **Tasks** pane.

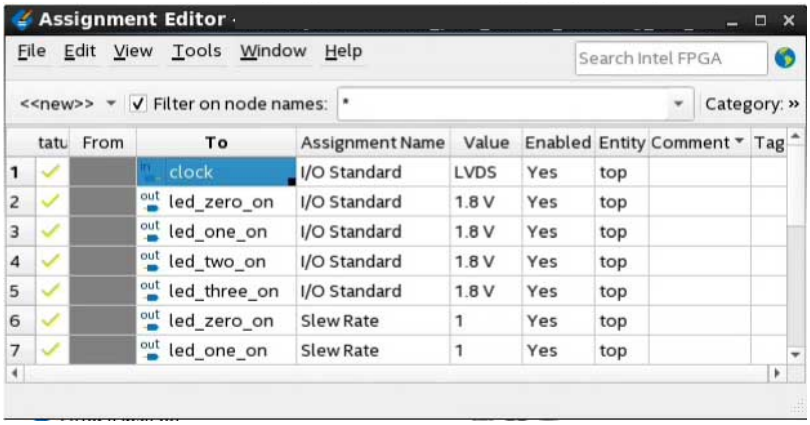
Figure 55. Settings Dialog Box for Global Project Settings



The **Settings** dialog box provides access to settings that control project design files, synthesis, Fitter, and timing constraints, operating conditions, EDA tool file generation, programming file generation, and other project-level settings.

Additionally, the Assignment Editor (**Assignments ➤ Assignment Editor**) provides a spreadsheet-like interface for specifying instance-specific settings and constraints.

Figure 56. Assignment Editor

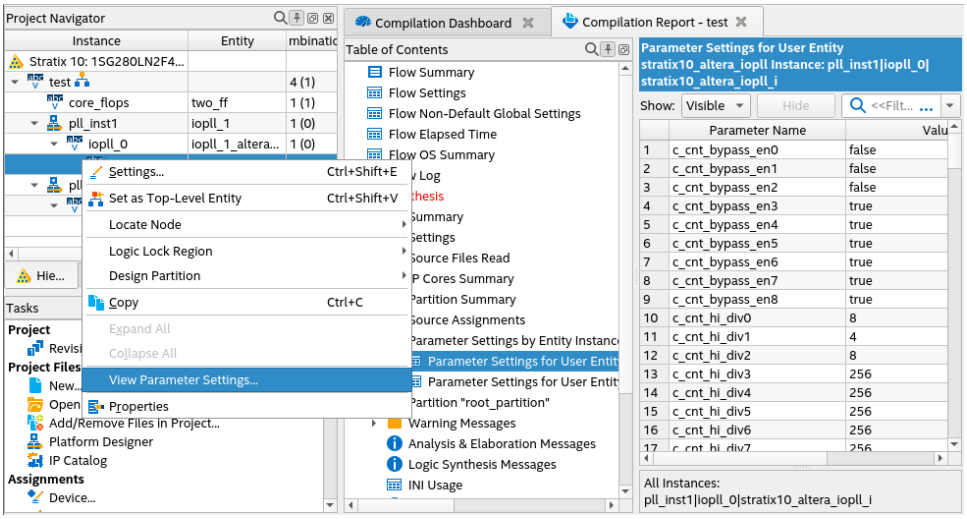


5.3. Viewing Parameter Settings From the Project Navigator

Starting from the Quartus Prime Pro Edition software version 23.3, you can view the parameter settings for a module directly from the **Project Navigator**.

To access the settings, locate the module, right-click and select **View Parameter Settings** in the context-sensitive menu. Compilation Report appears displaying the parameter settings for the entity, as shown in the following image:

Figure 57. Viewing Parameter Settings



5.4. Managing Logic Design Files

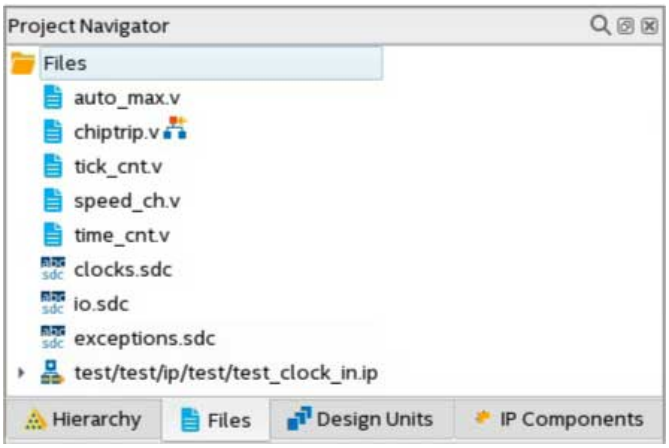
The Quartus Prime software helps you create and manage the logic design files in your project. Logic design files contain the logic that implements your design. When you add a logic design file to the project, the Compiler automatically includes that file in the next compilation. The Compiler synthesizes your logic design files to generate programming files for your target device.

The Quartus Prime software includes full-featured schematic and text editors, as well as HDL templates to accelerate your design work. The Quartus Prime software supports VHDL Design Files (`.vhd`), Verilog HDL Design Files (`.v`), and SystemVerilog (`.sv`). In addition, you can combine your logic design files with Intel and third-party IP core design files, including combining components into a Platform Designer system (`.qsys`).

Caution: Starting from the Quartus Prime Pro Edition software version 23.3, the compiler cannot synthesize schematic Block Design File (`.bdf`). For more information, refer to Converting Symbolic BDF Files to Acceptable File Formats on page 45.

The New Project Wizard prompts you to identify logic design files. Add or remove project files by clicking **Project > Add/Remove Files in Project.** View the project's logic design files in the Project Navigator.

Figure 58. Design and IP Files in Project Navigator



Right-click files in the Project Navigator to:

- **Open** and edit the file
- **Remove File from Project**
- **Set as Top-Level Entity** for the project revision
- **Create a Symbol File for Current File** for display in schematic editors
- Edit file **Properties**

5.4.1. Including Design Libraries

Include design files libraries in your project. Specify libraries for a single project, or for all Quartus Prime projects. The `.qsf` stores project library information.

The `quartus2.ini` file stores global library information.

1. Click **Assignment > Settings**.
2. Click **Libraries** and specify the **Project Library name** or **Global Library name**. Alternatively, you can specify project libraries with SEARCH_PATH in the `.qsf`, and global libraries in the `quartus2.ini` file.

Related Information

Design Library Migration Guidelines on page 47

5.4.2. Creating a Project Copy

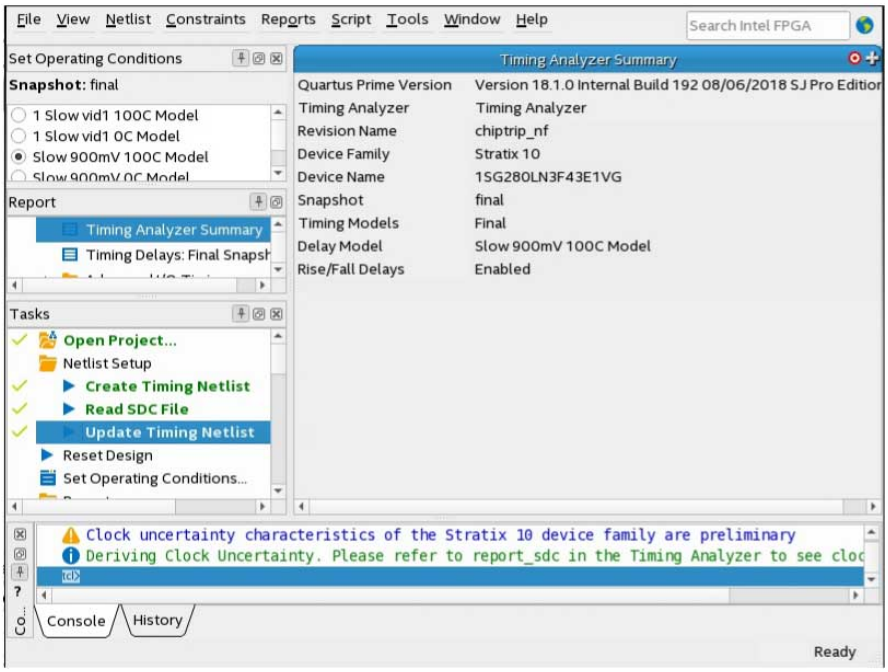
Click **Project > Copy Project** to create a separate copy of your project, rather than just a revision within the same project.

The project copy includes separate copies of all design files, any `.qsf` files, and project revisions. You can use this technique to optimize project copies for different applications that require design file differences. For example, you can optimize one project to interface with a 32-bit data bus, and optimize a project copy to interface with a 64-bit data bus.

5.5. Managing Timing Constraints

Apply appropriate timing constraints to correctly optimize fitting and analyze timing for your design. The Fitter optimizes the placement of logic in the device to meet your specified timing and routing constraints.

Figure 59. Timing Analyzer



Specify timing constraints in the Timing Analyzer (**Tools > Timing Analyzer**), or in an `.sdc` file. Specify constraints for clock characteristics, timing exceptions, and external signal setup and hold times before running analysis. The Timing Analyzer reports detailed information about the performance of your design compared with constraints in the Compilation Report panel.

Save the constraints you specify in the GUI in an industry-standard Synopsys Design Constraints File (`.sdc`). You can subsequently edit the text-based `.sdc` file directly. If you refer to multiple `.sdc` files in a parent `.sdc` file, the Timing Analyzer reads the `.sdc` files in the order you list.

5.6. Integrating Other EDA Tools

You can optionally integrate supported EDA synthesis, netlist partitioning, simulation, and signal integrity verification tools into the Quartus Prime design flow.

The Quartus Prime software supports input netlist files from supported EDA synthesis tools. The Compiler's EDA Netlist Writer module (`quartus_eda`) can automatically generate output files for processing in other EDA tools. The EDA Netlist Writer runs optionally as part of a full compilation, or you can run EDA Netlist Writer separately from the GUI or at the command line. The following functions are available to simplify EDA tool integration:

Table 33. EDA Tool Integration Functions

EDA Integration Task	EDA Integration Function
Specify settings for generation of output files for processing in other EDA tools.	Click **Assignments ➤ Settings ➤ EDA Tool Settings** to specify options for supported tools.
Generate output files for processing in other EDA tools.	Click **Processing ➤ Start ➤ Start EDA Netlist Writer** (or run `quartus_eda`) to generate files.
Compile RTL and gate-level simulation model libraries for your device, supported EDA simulators, and design language.	Click **Tools ➤ Launch Simulation Library Compiler** to compile simulation libraries easily.
Generate EDA tool-specific setup scripts to compile, elaborate, and simulate Intel FPGA IP models and simulation model library files.	Specify options for **Simulation** file output when generating Intel FPGA IP with IP parameter editor.
Generate files that allow supported EDA tools to perform netlist modifications, such as adding new modules, partitioning the netlist, and changing module connectivity.	Use the `quartus_eda –resynthesis` command to generate a Verilog Quartus Mapping File (`.vqm`) that contains a node-level (or atom) representation of the netlist in standard structural Verilog RTL.
Include files generated by other EDA design entry or synthesis tools in your project as synthesized design files.	Click **Project ➤ Add/Remove Files In Project** to add supported **Design File** files from other EDA tools.

5.7. Exporting Compilation Results

The Quartus Prime Compiler writes the results to a set of database files. You can run a command to export the compilation results database as a single Quartus Database File (`.qdb`).

After running design compilation, the exported `.qdb` file contains the data to reproduce similar compilation results in another project, or in a later software version. You can export your project's compilation results database for import to another project or migration to a later Quartus Prime software version.

You can export the `.qdb` for your entire project or for a design partition that you define in your project. When migrating the database for an entire project, you can export the compilation database in a *version-compatible* format to ensure

compatibility for import to a later software version. Although you cannot directly read the contents of the .qdb file after export, you can view attributes of the database file in the Quartus Database File Viewer.

Table 34. Exporting Compilation Results

To Export Compilation Results For	Method	Description
Complete Design	Click **Project ➤ Export Design**	Saves compilation results for the current project revision in a version-compatible Quartus database file (.qdb) that you can import to another project or migrate to a later version of the Quartus Prime software. You can export the results for the synthesized or final compilation snapshot. *Note:* Not supported for Agilex 7 devices.
Design Partition	Click **Project ➤ Export Design Partition**	Saves compilation results for a design partition as a Partition Database File (.qdb) that you can import to another project using the same version of the Quartus Prime software. You can export the results for the synthesized or final compilation snapshot.

5.7.1. Exporting a Version-Compatible Compilation Database

You can export a project compilation database to a format that ensures version-compatibility with a later version of the Quartus Prime software. The Quartus Prime Pro Edition software version supports export of version-compatible databases for the following software versions and devices:

Table 35. Version-Compatible Compilation Database Support

The first table column indicates the first version to support version-compatible compilation database export for the specified devices.

Note:

- Database import supports two major versions back. For example, a database that you export from version 19.3, you can then import using version 19.3, 20.1, and 20.3. However, you cannot import version 19.3 to 21.1.
- You can export from any version that follows a supported version, if the version still supports the devices.

First Version with 'Export Design' Support	Stratix 10 and Devices	Arria 10 and Cyclone 10 GX Devices
18.0	No Support.	Supports all devices.
18.1	• 1SG250L • 1SG280H_S2 • 1SG280L • 1SG280L_S3 • 1SX250L • 1SX280L • 1SX280L_S3	Supports all devices.
19.1	• 1SM16BH • 1SM21BH • 1SM16CH	Supports all devices.

continued...

First Version with 'Export Design' Support	Stratix 10 and Devices	Arria 10 and Cyclone 10 GX Devices
	• 1SM21CH • 1SM21KH • 1SM16KH • 1SM21LH • 1SM16LH	
19.3	• 1SG10MH_U1 • 1SG10MH_U2 • 1ST250E • 1ST280E • 1SM16E • 1SM21E • 1ST165E • 1ST210E • 1SG166H • 1SG211H	Supports all devices.
20.1	• 1SD280P • 1ST040E • 1ST085E • 1ST110E	Supports all devices.
20.3	• 1SD21BP • 1SG040H • 1SX040H	Supports all devices.
20.4	• 1SN21BH • 1SN21CE	Supports all devices.

1. In the Quartus Prime software, open the project that you want to export.
2. Generate synthesis or final compilation results by running one of the following commands:
   - Click **Processing ➤ Start ➤ Start Analysis & Synthesis** to generate synthesized compilation results.
   - Click **Processing ➤ Start Compilation** to generate final compilation results.
3. Click **Project ➤ Export Design**. Select the **synthesized** or **final Snapshot**.

Figure 60. Export Design Dialog Box

4. Specify a name for the **Quartus Database File** to contain the exported results, and click **OK**.
5. To include the exported design's settings and constraint files, copy the `.qsf` and `.sdc` files to the import project directory.

5.7.2. Importing a Version-Compatible Compilation Database

Follow these steps to import a project compilation database into a newer version of the Quartus Prime software:

Note: Designs exported from the Quartus Prime Pro Edition software versions 23.2 or earlier cannot be imported into version 23.3 due to the new DNI database.

1. Export a version-compatible compilation database for a complete design, as Exporting a Version-Compatible Compilation Database on page 100 describes.
2. In a newer version of the Quartus Prime software, open the original project. Click **Yes** if prompted to open a project created with a different software version.
3. Click **Project ➤ Import Design** and specify the **Quartus Database File**. To remove previous results, turn on **Overwrite existing project's databases**

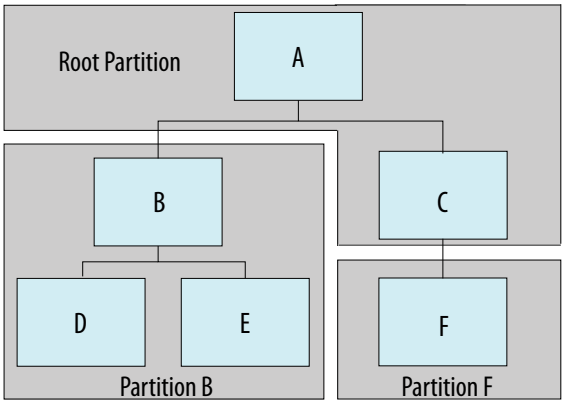
Figure 61. Import Design Dialog Box

4. Click **OK**. When you compile the imported design, run only Compiler stages that occur after the stage the `.qdb` preserves, rather than running a full compilation. For example, if you import a version-compatible database that contains the synthesized snapshot, start compilation with the Fitter (**Processing ➤ Start ➤ Start Fitter**). If you import a version-compatible database that contains the final snapshot, start compilation with Timing Analysis (Signoff) (**Processing ➤ Start ➤ Start Timing Analysis (Signoff)**).

5.7.3. Creating a Design Partition

A design partition is a logical, named, hierarchical boundary that you can assign to an instance in your design. Defining a design partition allows you to optimize and lock down the compilation results for individual blocks. You can then optionally export the compilation results of a design partition for reuse in another context, such as reuse in another project.

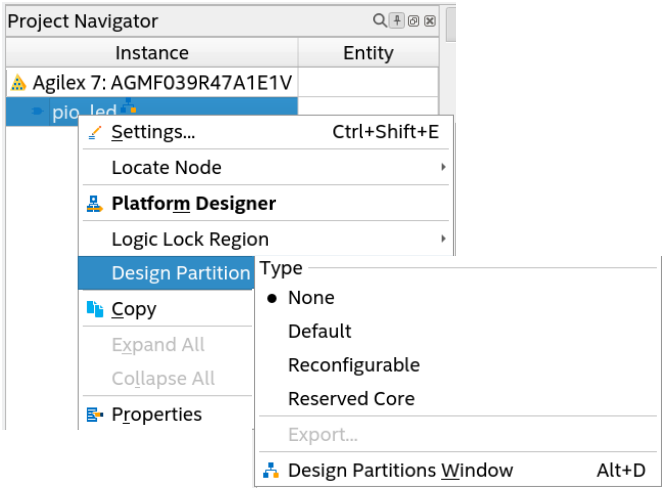
Figure 62. Design Partitions in Design Hierarchy



Follow these steps to create and modify design partitions:

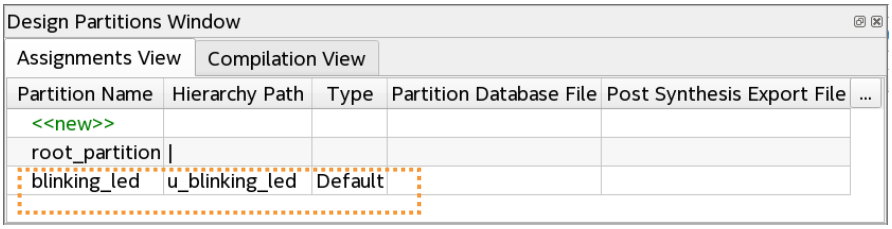
1. In the Quartus Prime software, open the project that you want to partition.
2. Generate synthesis or final compilation results by running one of the following commands:
   - Click **Processing ➤ Start ➤ Start Analysis & Synthesis** to generate synthesized compilation results.
   - Click **Processing ➤ Start Compilation** to generate final compilation results.
3. In the Project Navigator, right-click an instance in the **Hierarchy** tab, click **Design Partition ➤ Set as Design Partition**.

Figure 63. Creating a Design Partition from the Project Hierarchy



4. To view and edit all design partitions in the project, click **Assignments ➤ Design Partitions Window**.

Figure 64. Design Partitions Window



5. Specify the properties of the design partition in the Design Partitions Window. The following settings are available:

Table 36. Design Partition Settings

Option	Description
Partition Name	Specifies the partition name. Each partition name must be unique and consist of only alphanumeric characters. The Quartus Prime software automatically creates a top-level (|) "root_partition" for each project revision.
Hierarchy Path	Specifies the hierarchy path of the entity instance that you assign to the partition. You specify this value in the **Create New Partition** dialog box. The root partition hierarchy path is |.
Type	Double-click to specify one of the following partition types that control how the Compiler processes and implements the partition: • **Default**—Identifies a standard partition. The Compiler processes the partition using the associated design source files. • **Reconfigurable**—Identifies a reconfigurable partition in a partial reconfiguration flow. Specify the **Reconfigurable** type to preserve synthesis results, while allowing refit of the partition in the PR flow. • **Reserved Core**—Identifies a partition in a block-based design flow that is reserved for core development by a Consumer reusing the device periphery.
Empty	Specifies an empty partition that the Compiler skips. This setting is incompatible with the **Reserved Core** and **Partition Database File** settings for the same partition.
Partition Database File	Specifies a Partition Database File (.qdb) that the Compiler uses during compilation of the partition. You export the .qdb for the stage of compilation that you want to reuse (synthesized or final). Assign the .qdb to a partition to reuse those results in another context.
Entity Re-binding	• PR Flow—specifies the entity that replaces the default persona in each implementation revision. • Root Partition Reuse Flow —specifies the entity that replaces the reserved core logic in the consumer project.
Color	Specifies the color-coding of the partition in the Chip Planner and Design Partition Planner displays.
Post Synthesis Export File	Automatically exports post-synthesis compilation results for the partition to the specified .qdb file each time Analysis & Synthesis runs. You can automatically export any design partition that does not have a preserved parent partition, including the root_partition.
Post Final Export File	Automatically exports post-final compilation results for the partition to the specified .qdb file each time the final stage of the Fitter runs. You can automatically export any design partition that does not have a preserved parent partition, including the root_partition.

5.7.4. Exporting a Design Partition

The following steps describe export of design partitions that you create in your project.

Note: Design partitions exported from the Quartus Prime Pro Edition software versions 23.2 or earlier cannot be imported into version 23.3 or later due to the new DNI database.

When you compile a design containing design partitions, the Compiler can preserve a synthesis or final snapshot of results for each partition. You can export the synthesized or final compilation results for individual design partitions with the **Export Design Partition** dialog box.

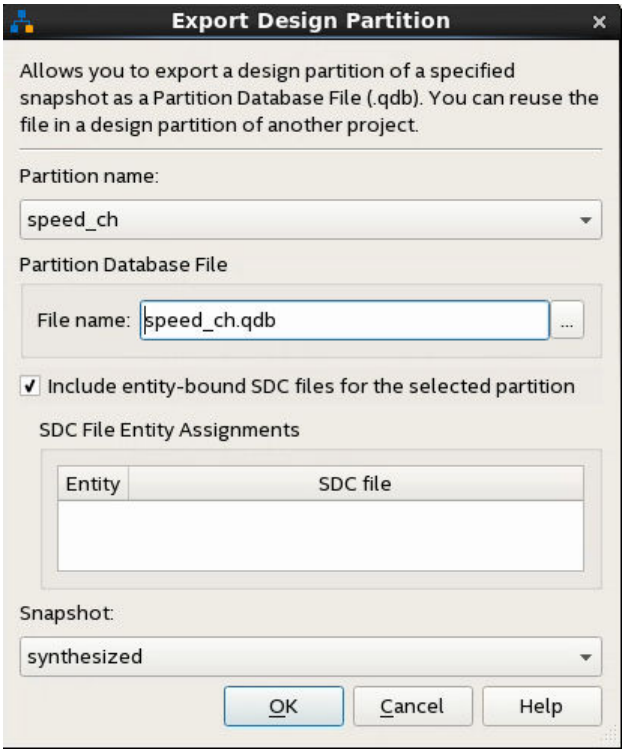
If the partition includes any entity-bound `.sdc` files, you can include those constraints in the `.qdb`. In addition, you can automate export of one or more partitions in the Design Partitions Window.

Manual Design Partition Export

Follow these steps to manually export a design partition with the **Export Design Partition** dialog box:

1. Open a project and create one or more design partitions. Creating a Design Partition on page 102 describes this process.
2. Run synthesis (**Processing ➤ Start ➤ Start Analysis & Synthesis**) or full compilation (**Processing ➤ Start Compilation**), depending on which compilation results that you want to export.
3. Click **Project ➤ Export Design Partition**, and specify one or more options in the **Export Design Partition** dialog box:

Figure 65. Export Design Partition Dialog Box



- Select the **Partition name** and the compilation **Snapshot** for export.
- To include any entity-bound `.sdc` files in the exported `.qdb`, turn on **Include entity-bound SDC files for the selected partition**.

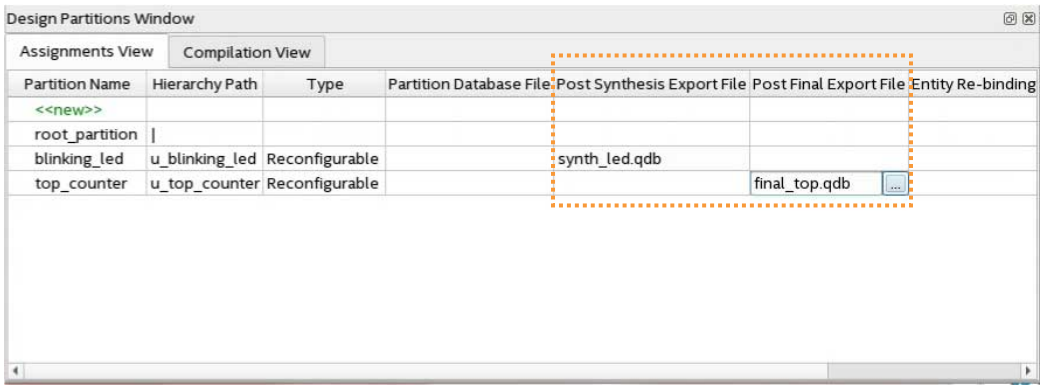
4. Click **OK**. The compilation results for the design partition exports to the file that you specify.

Automated Design Partition Export

Follow these steps to automatically export one or more design partitions following each compilation:

1. Open a project containing one or more design partitions. Creating a Design Partition on page 102 describes this process.
2. To open the Design Partitions Window, click **Assignments ➤ Design Partitions Window**.
3. To automatically export a partition with synthesis results after each time you run synthesis, specify the a `.qdb` export path and file name for the **Post Synthesis Export File** option for that partition. If you specify only a file name without a path, the file exports to the `output_files` directory after compilation.
4. To automatically export a partition with final snapshot results each time you run the Fitter, specify a `.qdb` file name for the **Post Final Export File** option for that partition. If you specify only a file name without a path, the file exports to the `output_files` directory after compilation.

Figure 66. Specifying Export File in Design Partitions Window



`.qsf` Equivalent Assignment:

```
set_instance_assignment -name EXPORT_PARTITION_SNAPSHOT_<FINAL|SYNTHESIZED> \
     <hpath> -to <file_name>.qdb
```

Related Information

- Intel Quartus Prime Pro Edition User Guide: Block Based Design
- Intel Quartus Prime Pro Edition User Guide: Partial Reconfiguration

5.7.5. Reusing a Design Partition

You can reuse the compilation results of a design partition exported from another Quartus Prime project. Reuse of a design partition allows you to share a synthesized or final design block with another designer. Refer to *Intel Quartus Prime Pro Edition User Guide: Block-Based Design* for more information about reuse of design partitions.

To reuse an exported design partition in another project, you assign the exported partition `.qdb` to an appropriately configured design partition in the target project via the Design Partition Window:

1. Export a design partition with the appropriate snapshot, as Exporting a Design Partition on page 104 describes.
2. Open the target Quartus Prime project that you want to reuse the exported partition.
3. Click **Processing ➤ Start ➤ Start Analysis & Elaboration**.
4. Click **Assignments ➤ Design Partitions Window**, and then create a design partition to contain the logic and compilation results of the exported `.qdb`.
5. Click the **Partition Database File** option for the new partition and select the exported `.qdb` file.

Figure 67. Partition Database File Setting in Design Partitions Window

6. Specify any other properties of the design partition in the Design Partitions Window. The Compiler uses the partition's assigned `.qdb` as the source.

5.7.6. Viewing Quartus Database File Information

Although you cannot directly read a `.qdb` file, you can view helpful attributes about the file to quickly identify its contents and suitability for use.

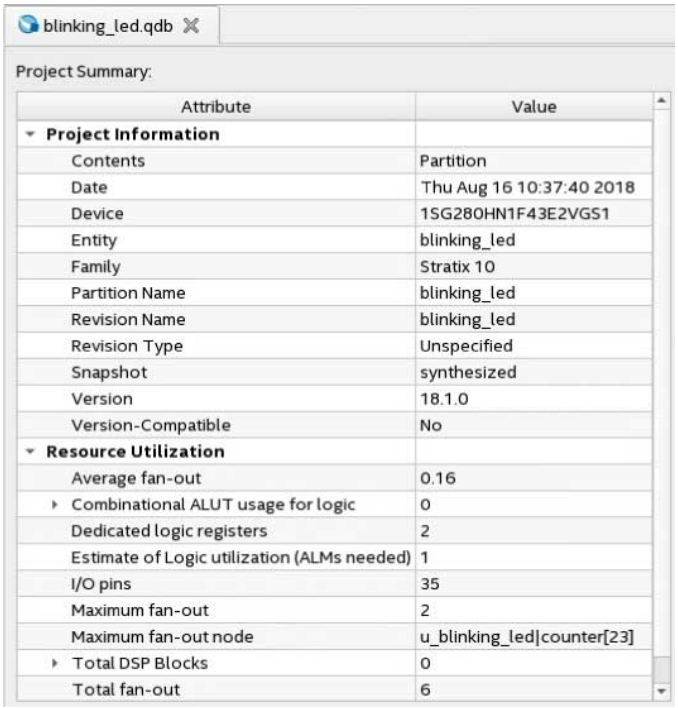
The Quartus Prime software automatically stores metadata about the project of origin when you export a Quartus Database File (`.qdb`). You can then use the Quartus Database File Viewer to display the attributes of any of these `.qdb` files.
Follow these steps to view the attributes of a `.qdb` file:

1. In the Quartus Prime software, click **File ➤ Open**, select **Design Files** for **Files of Type**, and select a `.qdb` file.
2. Click **Open**. The Quartus Database File Viewer displays project and resource utilization attributes of the `.qdb`.

   Alternatively, run the following command-line equivalent:

```
quartus_cdb --extract_metadata --file <archive_name.qdb> \
     --type quartus --dir <extraction_directory> \
     [--overwrite]
```

Figure 68. Quartus Database File Viewer



5.7.6.1. QDB File Attribute Types

The Quartus Database Viewer can display the following attributes of a `.qdb` file:

Table 37. QDB File Attributes

QDB Attribute Types	Attribute	Example
Project Information	Contents	`Partition`
	Date	`Thu Jan 23 10:56:23 2018`
	Device	`10AX016C3U19E2LG`
	Entity (if Partition)	`Counter`
	Family	`Arria 10`
	Partition Name	`root_partition`
	Revision Name	`Top`
	Revision Type	`PR_BASE`
	Snapshot	`synthesized`
	Version	`18.1.0 Pro Edition`
	Version-Compatible	`Yes`
Resource Utilization (exported for partition QDB only)	For synthesized snapshot partition lists data from the **Synthesis Resource Usage Summary** report.	`Average fan-out.16` `Dedicated logic registers:14` `Estimate of Logic utilization:1`

continued...

		I/O pins:35 Maximum fan-out:2 Maximum fan-out node:counter[23] Total DSP Blocks:0 Total fan-out:6 ...
	For the final snapshot partition, lists data from the **Fitter Partition Statistics** report.	Average fan-out:.16 Combinational ALUTs: 16 I/O Registers M20Ks ...

5.7.7. Clearing Compilation Results

You can clean the project database if you want to remove prior compilation results for all project revisions or for specific revisions. For example, you must clear previous compilation results before importing a version-compatible database to an existing project.

1. Click **Project > Clean Project**.
2. Select **All revisions** to clear the databases for all revisions of the current project, or specify a **Revision name** to clear only the revision's database you specify.
3. Click **OK**. A message indicates when the database is clean.

Figure 69. Clean Project Dialog Box Cleans the Project Database

5.8. Archiving Projects

You can optionally save the elements of a project in a single, compressed Quartus Prime Archive File (`.qar`) by clicking **Project > Archive Project**. The `.qar` preserves RTL design, project, and settings files required to restore the project.

Use this technique to share projects between designers, or to transfer your project to a new version of the Quartus Prime software, or to Intel support. Optionally add compilation results, Platform Designer system files, and third-party EDA tool files to the archive.

Related Information

Project Archive Commands on page 114

5.8.1. Manually Adding Files To Archives

Follow these steps to add files to a project archive manually:

Note: If preserving a custom component as part of an Quartus Prime Archive (`.qar`), you must first explicitly add the component `_hw.tcl` file to the project to ensure that the `.qar` includes the component. Click **Project ➤ Add/Remove Files in Project** to add files to your project.

1. Click **Project ➤ Archive Project** and specify the archive file name.
2. Click **Advanced**.
3. Select the **File set** for archive or select **Custom**. Turn on **File subsets** for the archive.
4. Click **Add** and select Platform Designer system or EDA tool files. Click **OK**.
5. Click **Archive**.

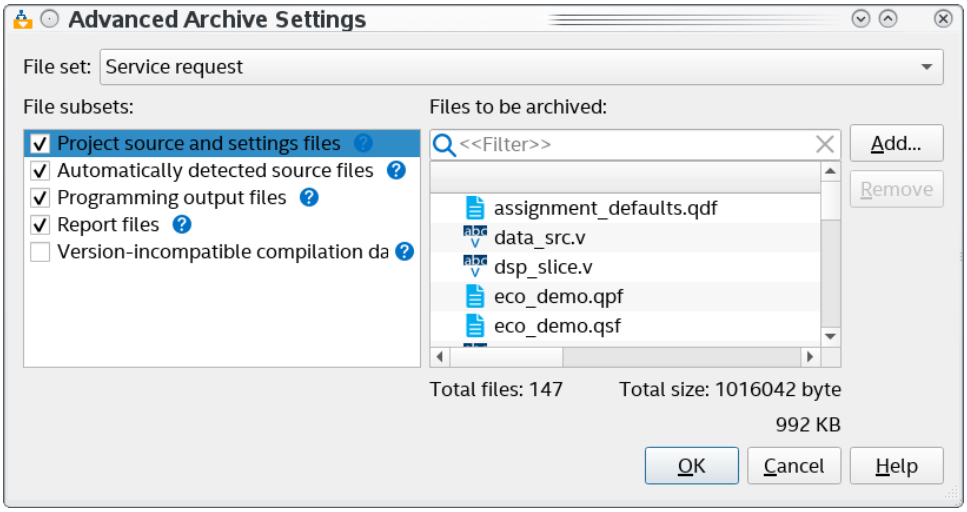
5.8.2. Archiving Projects for Service Requests

When archiving projects for a service request, include all needed file types for proper debugging by customer support.

To identify and include appropriate archive files for an Intel service request:

1. Click **Project > Archive Project** and specify the archive file name.
2. Click **Advanced**.
3. In **File set**, select **Service request** to include files for Intel Support.
   - Project source and setting files (`.v`, `.vhd`, `.vqm`, `.qsf`, `.sdc`, `.qip`, `.qpf`, `.cmp`)
   - Automatically detected source files (various)
   - Programming output files (`.jdi`, `.sof`, `.pof`)
   - Report files (`.rpt`, `.pin`, `.summary`, `.smsg`)
4. Click **OK**, and then click **Archive**.

Figure 70. Archiving Project for Service Request



5.8.3. Archiving Projects for External Revision Control

Your project may involve different team members with distributed responsibilities, such as sub-module design, device and system integration, simulation, and timing closure. In such cases, it may be useful to track and protect file revisions in an external revision control system.

While Quartus Prime project revisions preserve various project setting and constraint combinations, external revision control systems can also track and merge RTL source code, simulation testbenches, and build scripts. External revision control supports design file version experimentation through branching and merging different versions of source code from multiple designers. Refer to your external revision control documentation for setup information.

5.8.3.1. Project Files to Include In External Revision Control

When archiving Quartus Prime projects for external source control, The **Source control** setting in **Advanced Archive Settings** dialog box is preset to include all appropriate file types for source control automatically.

Figure 71. Advanced Archive Settings Dialog Box

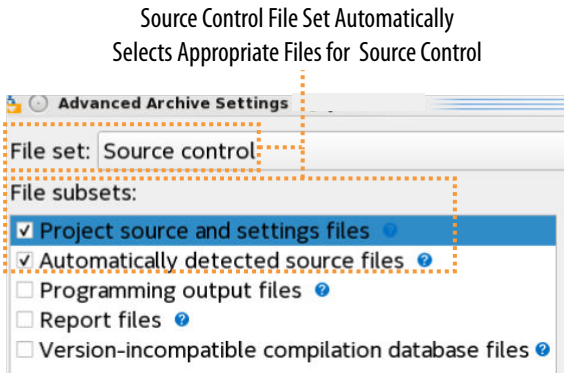


Table 38. Project Files to Include In External Revision Control

File Type	Description
Quartus Prime project setting and assignment files	• Quartus Prime Project Files (`.qpf`) • Quartus Prime Settings Files (`.qsf`) • Quartus Prime Pin Planner File (`.ppf`)
Timing constraint files	Synopsys Design Constraint Files (`.sdc`)
Design files	• Verilog HDL Design Files (`.v`) • SystemVerilog Design Files (`.sv`) • VHDL Design Files (`.vhd`) • Block Symbol Files (`.bsf`) • Verilog Quartus Mapping Files (`.vqm`) • Platform Designer System Files (`.qsys`) • State Machine Editor Files (`.smf`) • Tcl Script Design Files (`.tcl`)
System and IP files	• IP variation file (`.ip`) • Verilog IP design files (`.v`) • SystemVerilog IP design files (`.sv`) • VHDL IP design files (`.sv`) • VHDL Component Declaration Files (`.cmp`) • Quartus Prime IP file (`.qip`) • Quartus Prime Simulation IP File (`.sip`) • Platform Designer System Files (`.qsys`) • Platform Designer connection and parameterization files (`.sopcinfo`) • IP upgrade status files (`.csv`) • IP synthesis parameters files (`.qgsynthc`) • IP simulation parameters files (`.qgsimc`) • Platform Designer system exported as (`.tcl`).
EDA tool integration files	• Verilog HDL Output Files (`.vo`) • VHDL Output Files (`.vho`) • VHDL simulation model files (`.vhd`) • Verilog HDL simulation model files (`.v`) • Simulation library files (`cds.lib`, `hdl.var`) • Simulation setup scripts (`_setup.sh`, `.tcl`, `.spd`, `.txt`)

5.8.4. Creating Database-Only Archives

If your project contains sensitive RTL that you do not want to share with Intel support, you can create a *database-only* archive. A database-only archive contains only the minimum files required to run timing analysis, fitter, assembler, and GUI design-inspection tools like Chip Planner.

A database-only archive includes only the project Quartus databases and any additional files required for compilation. It does not include RTL files.

You can review the complete list of files included in the archive in a report generated when you create a database-only archive.

Security Note:

A database-only archive does not guarantee protection for sharing your design without sharing your RTL. The RTL Netlist Viewer, Technology Map Viewer, and other views, along with the EDA Netlist Writer, are still available for projects exported using this feature.

With some effort, the original content can be reverse engineered.

To disable these features, encrypt your design. For details, see Support for the IEEE 1735 Encryption Standard on page 83.

Before creating a database-only archive, your project must have completed one of the following compilation stages:

- Synthesis

  Archives that are created after running Synthesis can be used to run the fitter and then complete timing analysis, run the assembler, and use GUI-based design-inspection tools.

- Finalized

  Archives that are created after completing a full compilation flow for your project can be used to complete timing analysis, run the assembler, and use GUI design-inspection tools.

To create a database-only archive, run the following command:

```
quartus_sh --archive_database -project <project_file> [-use_final_db]
```

Specify the `-use_final_db` option to create a database-only archive based on the finalized snapshot of your project. Otherwise, a database-only archive based on the synthesized snapshot is created.

The command generates two files: a `.qar` file that contains the database-only archive, and a `.contents.txt` file that lists files that are included in the `.qar` file.

You can get command syntax details by running the following command:

```
quartus_sh --help=archive_database
```

Related Information

Support for the IEEE 1735 Encryption Standard on page 83

5.9. Command-Line Interface

You can optionally use command-line executables or scripts to run project commands, rather than using the GUI. This technique can be helpful if you have many settings and wish to track them in a single file or spreadsheet for iterative comparison. The `.qsf` supports only a limited subset of Tcl commands. Therefore, pass settings and constraints using a Tcl script:

1. Create a text file with the extension `.tcl` that contains your assignments in Tcl format.
2. Source the Tcl script file by adding the following line to the .qsf: `set_global_assignment -name SOURCE_TCL_SCR IPT_FILE <file name>`.

5.9.1. Project Revision Commands

create_revision Command

`create_revision` defines the properties of a new project revision.

```
create_revision <name> -based_on <revision_name> -set_current -new_rev_type \
     <rev_type> -root_partition_qdb_file <root qdb>
```

Table 39. create_revision Command Options

Option	Description
`based_on` (optional)	Specifies the revision name on which the new revision bases its settings.
`set_current` (optional)	Sets the new revision as the current revision.
`-new_rev_type`	Specifies a `base` or `impl` (implementation) type for a new revision.
`root_partition_qdb_file`	Specifies the name of a static region .qdb if already known when creating a revision.

get_project_revisions Command

`get_project_revisions` returns a list of all revisions in the project.

```
get_project_revisions <project_name>
```

delete_revision Command

`delete_revision` deletes the revision you specify from your project.

```
delete_revision <revision name>
```

set_current_revision Command

`set_current_revision` sets the revision you specify as the current revision.

```
set_current_revision -force <revision name>
```

5.9.2. Project Archive Commands

project_archive Command

`project_archive` archives your project into a single, compressed `.qar` file.

```
project_archive <name>.qar
```

Table 40. project_archive Command Options

Options	Description
`-all_revisions`	Includes all revisions of the current project in the archive.
`-common_directory /<name>`	Preserves original project directory structure in specified subdirectory.
`-include_libraries`	Includes libraries in archive.
`-include_outputs`	Includes output files in archive.
`-use_file_set <file_set>`	Includes specified fileset in archive.
`-version_compatible_database`	Includes version-compatible database files in archive.

restore_archive Command

Restores an archived project to a destination directory with optional overwriting of current contents.

```
project_restore <name>.qar -destination <directory name> -overwrite
```

Related Information

Archiving Projects on page 109

5.9.3. Project Database Commands

export_database Command

`export_design` exports the specified project database to the `.qdb` file you specify.

These commands require the `quartus_cdb` executable.

```
quartus_cdb <revision name> --export_design --file <file name>.qdb \
     --snapshot <synthesized/final>
```

import_database Command

`import_design` imports the specified project database to the `.qdb` file you specify.

```
quartus_cdb <revision name> --import_design --file <file name>.qdb
```

export_block Command

`export_block` exports the specified partition database to the `.qdb` file you specify.

```
quartus_cdb -r  <project name> -c <revision name> --export_block \
     <partition name> --snapshot <name> --file <file name>.qdb
```

5.9.3.1. quartus_cdb Executables to Manage Version-Compatible Databases

The command-line arguments to the `quartus_cdb` executable in the Quartus Prime Pro software are `export_design` and `import_design`. The exported version-compatible design files are archived in a file (with a `.qdb` extension). This differs from the Quartus Prime Standard Edition software, which writes all files to a directory.

In the Quartus Prime Standard Edition software, the flow exports both post-map and post-fit databases. In the Quartus Prime Pro Edition software, the export command requires the `snapshot` argument to indicate the target snapshot to export. If the specified snapshot has not been compiled, the flow exits with an error. In ACDS 16.0, export is limited to "synthesized" and "final" snapshots.

```
quartus_cdb <project_name> [-c <revision_name>] --export_design
--snapshot <snapshot_name> --file <filename>.qdb
```

The import command takes the exported `*.qdb` file and the project to which you want to import the design.

```
quartus_cdb <project_name> [-c <revision_name>] --import_design
--file <archive>.qdb [--overwrite] [--timing_analysis_mode]
```

The `--timing_analysis_mode` option is only available for Arria 10 designs. The option disables legality checks for certain configuration rules that may have changed from prior versions of the Quartus Prime software. Use this option only if you cannot successfully import your design without it. After you have imported a design in timing analysis mode, you cannot use it to generate programming files.

B. Using the Design Space Explorer II

The Design Space Explorer II tool (**Tools ➤ Launch Design Space Explorer II**) allows you to find optimal project settings for resource, performance, or power optimization goals.

Refer to the following links for information on how to use the tool and what each option means in the GUI:

- Design Space Explorer II Tool
  - Setup Page
  - Project Page
  - Exploration Page
  - Status Page
  - Report Page
- Using Design Space Explorer

B.1. Optimizing Project Settings

Optimize project settings to meet your design goals.

The Quartus Prime Design Space Explorer II iteratively compiles your project with various setting combinations to find the optimal settings for your goals. Alternatively, you can create a project revision or project copy to manually compare various project settings and design combinations.

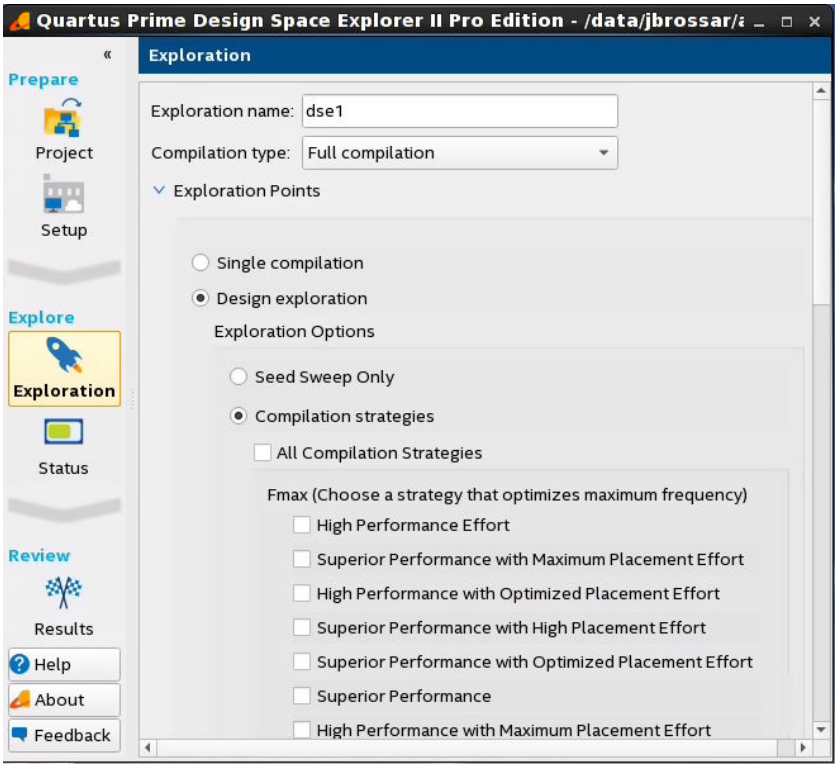
B.1.1. Optimizing Settings with Design Space Explorer II

Design Space Explorer II (DSE II) processes a design using combinations of settings and constraints, and reports the best combination of settings and constraints for the design. You can also take advantage of the DSE II parallelization abilities to compile on multiple computers.

In DSE II, an *exploration point* is a collection of Analysis & Synthesis, Fitter, and placement settings, and a group of exploration points is a *design exploration*. A design exploration can also include different fitter seeds.

DSE II compiles the design using the settings corresponding to each exploration point. When the compilation finishes, DSE II evaluates the performance data against an optimization goal that you specify. You can direct the DSE II to optimize for timing, area, or power. DSE II attempts multiple seeds to identify one meeting your requirements. DSE II can run different compilations on multiple computers in parallel to streamline timing closure.

Figure 72. Design Space Explorer II



You can run DSE II at any step in the design process. However, because large changes in a design can neutralize gains achieved from optimizing settings, Intel recommends that you run DSE II late in the design cycle.

Note: When comparing the results of different seed sweeps with DSE II, changing any of the following variables can cause differences in the compilation results between seed sweeps, resulting in a somewhat different fit in each case:

- The number or type of CPUs that DSE II uses to perform the seed sweeps
- Any change to the operating system
- Any change to source file content or location
- Any change to the Compiler settings or Timing Analyzer settings

For more information, refer to Fitter Seed.

B.1.1.1. DSE II Computing Resources

You can configure DSE II to take advantage of your computing resources to run the design explorations. In the DSE II GUI, the **Setup** page contains the job launch options, and the **Status** page allows you to monitor and control jobs.

DSE II supports running compilations on your local computer or a remote host through LSF, SSH or Torque. For SSH, you can also define a comma-separated list of remote hosts.

If you have a laptop or standard computer, you can use the single compilation feature to compile your design on a workstation with higher computing performance and memory capacity.

When running on a compute farm, you can direct the DSE II to safely exit after submitting all the jobs while the compilations continue to run until completion. Optionally, you can receive an e-mail when the compilations are complete.

If you launch jobs using SSH, the remote host must enable public and private key authentication. For private keys encrypted with a pass phrase, the remote host must run the ssh key agent to decrypt the private key, so the `quartus_dse` executable can access the key.

Note: Windows remote hosts require Cygwin's sshd server and PuTTY.

B.1.1.2. DSE II Optimization Parameters

DSE II provides a collection of predefined exploration spaces that focus on what you want to optimize. Additionally, you can define a set of compilation seeds. The number of explorations points is the number of seeds multiplied by the number of exploration modes.

Note: The availability of predefined spaces depends on the device family that the design targets.

In the DSE GUI, you specify these settings in the **Exploration** page.

B.1.1.3. DSE II Result Management

DSE II compares the compilation results to determine the best Quartus Prime software settings for the design. The **Report** page displays a summary of results.

In an exploration, DSE II selects the best worst-case slack value from among all timing corners across all exploration points. If you want to optimize for worst-case setup slack or hold slack, specify timing constraints in the Quartus Prime software.

Disk Space

By default, DSE II saves all the compilation data. You can save disk space by limiting the type of files that you want to save after a compilation finishes. These settings are in the **Exploration** page, **Results** section.

Reports

DSE II has reporting tools that help you quickly determine important design metrics, such as worse-case slack, across all exploration points.

DSE II provides a performance data report for all points it explores and saves the information in a `project-name.dse.rpt` file in the project directory. DSE II archives the settings of the exploration points in Quartus Prime Archive Files (`.qar`).

B.1.2. Optimizing Settings with Project Revisions

You can save multiple, named project revisions within your Quartus Prime project (**Project > Revisions**). Each project revision captures a unique set of project settings and constraints, while using the same set of logic design files.

Use revisions to experiment with different settings while preserving the original. Optimize different revisions for separate applications:

- Create a unique revision to optimize a design for different criteria, such as by area in one revision and by f_{MAX} in another revision.
- When you create a new revision the default Quartus Prime settings initially apply.
- Create a revision of a revision to experiment with settings and constraints. The child revision includes all the assignments and settings of the parent revision.

You create, delete, and edit revisions in the **Revisions** dialog box. Each time you create a new project revision, the Quartus Prime software creates a new `.qsf` using the revision name.

To compare each revision's synthesis, fitting, and timing analysis results side-by-side, click **Project > Revisions** and then click **Compare**. In addition to viewing the compilation **Results** of each revision, you can also compare the **Assignments** for each revision. This comparison reveals how different optimization options affect your design.

Figure 73. Comparing Project Revisions

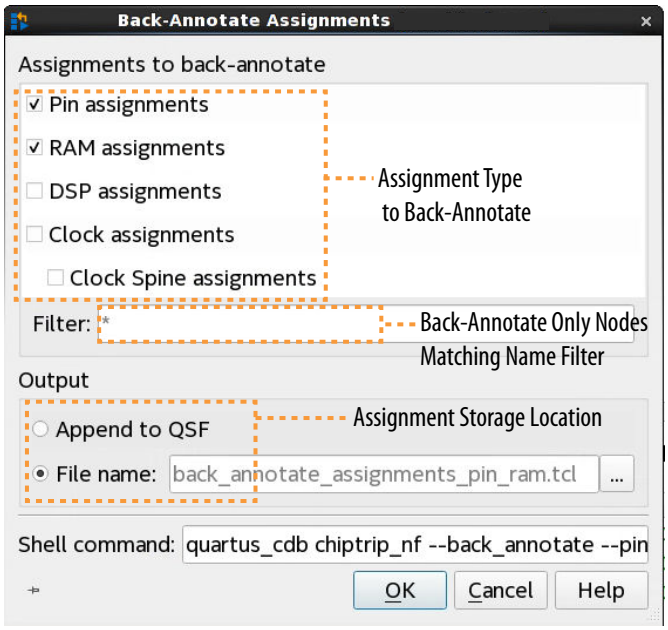
- Using Design Space Explorer II (DSE II) Video

B.1.3. Back-Annotating Optimized Assignments

The Compiler maps the elements of your design to specific device resources during fitting. After compilation, you can back-annotate (copy) the Compiler's resource assignments to preserve that same implementation in subsequent compilations. Back-annotation can simplify timing closure by allowing you to lock down placement of your optimized results.

Locking down placement of large blocks related to Clocks, RAMs, and DSPs can produce higher f_{MAX} with less noise. Large blocks like RAMs and DSPs have heavier connectivity than regular LABs, complicating movement during placement. When a seed produces good results from suitable RAM and DSP placement, you can capture that placement with back-annotation. Subsequent compiles can then benefit from the high quality RAM and DSP placement from the good seed.

Figure 74. Back-Annotate Assignments Dialog Box



To back-annotate (copy) the device resource assignments from the last compilation to the project `.qsf` (or to a Tcl file) for use in the next compilation:

1. Run a full compilation, or run the Fitter through at least the **Place** stage.
2. Click **Assignments ➤ Back-Annotate Assignments**.
3. Under **Assignments to back-annotate**, specify whether you want to preserve **Pin assignments**, **RAM assignments**, **DSP assignments**, **Clock assignments**, and **Clock Spine assignments** in the back-annotation.
4. In **Filter**, specify a text string (including wildcards) if you want to filter back-annotated assignments by entity name.
5. Under **Output**, specify whether to save the back-annotated assignments to the `.qsf` or to a Tcl file. A default Tcl file name displays.

Alternatively, you can run back-annotation with the following `quartus_cdb` executable. The **Shell command** field displays the shell command constructed by the options that you specify in the GUI.

```
quartus_cdb chiptrip_nf --back_annotate --pin --ram --dsp --clocks \
    --spines --file "<file>.tcl"
```

Note: Check available arguments by running `quartus_cdb <project> --back_annotate --help`.

Related Information

Back Annotation in Quartus Prime Software

B.2. Running DSE II

Note: Before running DSE II, specify the timing constraints for the design.

This description covers the type of settings that you need to define when you want to run a design exploration. For details about all the options available in the GUI, refer to the Quartus Prime Help.

To perform a design exploration with the DSE II tool:

1. Start the DSE II tool.

   If you have an open project in the Quartus Prime software and launch DSE II, a dialog box appears asking if you want to close the Quartus Prime software. Click **Yes**.
2. In the **Project** page, specify the project and revision that you want to explore.
3. In the **Setup** page, specify whether you want to perform a local or a remote exploration, and set up the job launch.
4. In the **Exploration** page, specify optimization settings and goals.
5. When the configuration is complete, click **Start**.

B.3. Setting Up Remote Farm Using Design Space Explorer II

To launch Design Space Explorer II, in the Quartus Prime Pro Edition GUI, click **Tools ➤ Launch Design Space Explorer II**. Click **Yes** to the message that appears. This closes the Quartus Prime software and launches the Design Space Explorer II.

Under the **Project** tab, click **Open Project** to add your project to the Design Space Explorer II. Refer to Project Page (Design Space Explorer II) for information about all options on this tab.

Use one of the following methods to set up your remote farm:

LSF Remote Farm

Follow these steps to set up your remote machine using the Design Space Explorer II and LSF remote compilation type:

1. Ensure you have set up your LSF environment. If not, request your IT administrator to set up the LSF environment.
2. Once the LSF environment is ready, launch the command line interface and execute the `bsub sleep 60` command.
3. Under the **Setup** tab, select **Remote** compilation type and choose the LSF option from the drop-down list. Populate all mandatory settings under **Specify custom settings for LSF** with the LSF environment-specific information.

   Refer to Setup Page (Design Space Explorer II) for information about all options on this tab.
4. Customize the settings as necessary.
5. Under the **Exploration** tab, expand the **Exploration Points** section.
6. Select **Design exploration**.
7. Under **Exploration Options**, select **Seed Sweep Only**.
8. Under **Seeds**, select **Create**. By default, it must be set to 2 seeds.
9. Click **Start**. Wait until the design exploration is complete.
10. Click the **Results** tab to review the status of the design exploration.

SSH Remote Farm

Follow these steps to set up your remote machine using the Design Space Explorer II and SSH remote compilation type:

1. Install the open-source PuTTY Key Generator tool and launch it.
2. Click **Generate** to generate the public/private key pair.
3. Enter the key passphrase.
4. Click **Save private key** to save the private key with a `.ppk` extension.
5. Click **Save public key** to save the public key as `putty_gen_public_key.pub`.
6. On your machine, change to the SSH directory and copy the contents of the `putty_gen_public_key.pub` file.
7. In the Design Space, under the **Setup** tab, select **SSH** compilation type and specify the following:
   - For **Hostname**, enter the server name.
   - For **private_key**, enter the path to your private key (`.ppk` file).
   - For **SSH Client**, enter the path to the `plink.exe` file. You can find this in the same directory where you installed the PuTTy tool.
   - For **Farm Operating System**, enter your system type (`linux` or `windows`).

   The remaining settings are similar to LSF settings. Refer to Setup Page (Design Space Explorer II) for information about all options on this tab.
8. Under the **Exploration** tab, expand the **Exploration Points** section.
9. Select **Design exploration**.

10. Under **Exploration Options**, select **Seed Sweep Only**.
11. Under **Seeds**, select **Create**. By default, it must be set to 2 seeds.
12. Click **Start**. Wait until the design exploration is complete.
13. Click the **Results** tab to review the status of the design exploration.

C. Document Revision History for Quartus Prime Pro Edition User Guide Getting Started

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Made the following updates in *Introduction to Quartus Prime Pro Edition*: — Included additional steps to the quick start table. — Updated the Quartus Prime software main page image in the table. — Updated the support matrix image to include Agilex 5 device support. — Updated supported features table to include Agilex 5 device support for hyper-aware design flow. — Updated the Intel FPGA developmental tools table to include Agilex 5 device support for PTC. • Revised prerequisite training list in *Prerequisite Knowledge and Training*. • Consolidated the information of design planning into a table in *Planning FPGA Design for RTL Flow*. • Added *Viewing Design Hierarchy and Adding Missing Source Files*. • Removed the Quartus Prime software main page image in *Creating a New FPGA Design Project*. • Revised the IP version upgrade path image in *Upgrading IP Cores*. • Revised *Generating IP Simulation Files* topic entirely. • Revised the note about `.bdf` files in *Managing Logic Design Files*.
2023.12.04	23.4	• Made major reorganization of chapters and topics. • Added additional information to *Introduction to Quartus Prime Pro Edition*. • Renamed *FPGA Basic Design Prerequisites* as *Prerequisite Knowledge and Training* and included a list of trainings. • Revised the information for accessing online design examples in *Creating a New Project from a Design Example*. • Renamed the chapter title "Design Planning" to "Planning FPGA Design for RTL Flow." • Renamed the topic "Plan for Hierarchical and Team-Based Designs" to "Selecting the Design Methodology."

continued...

Document Version	Quartus Prime Version	Changes
		• Added the following: — *Before You Begin* — *Acronyms* — *Navigate Content Through Tasks* — *Selecting the Design Methodology* — *Flat Design Vs. Incremental Block-based Design* — *Partial Reconfiguration Design* — *Related Trainings* — *Migrating Your AMD* Vivado* Project to Quartus Prime Pro Edition* — *Migrating Project From One Device to Another* — *Converting Symbolic BDF Files to Acceptable File Formats* — *Project Path Length Considerations* • Renamed the chapter name from *Migrating to Quartus Prime Pro Edition* to *Selecting a Starting Point for Your Quartus Prime Pro Edition Project*. • Moved *Creating a New FPGA Design Project*, *Migrating Projects Across Operating Systems* and their subtopics from *Managing Quartus Prime Projects* chapter to this chapter. • Chapter renamed as "Working With Intel FPGA IP Cores." • Removed the following topics and added a reference to *Quartus Prime Pro Edition User Guide: Third-party Simulation* where these topics are explained in detail. — *Sourcing Aldec ActiveHDL* or Riviera Pro* Simulator Setup Scripts* — *Sourcing Cadence Incisive* Simulator Setup Scripts* — *Sourcing Cadence Xcelium Simulator Setup Scripts* — *Sourcing QuestaSim* Simulator Setup Scripts* — *Sourcing Synopsys VCS Simulator Setup Scripts* — *Sourcing Synopsys VCS MX Simulator Setup Scripts* • Moved *Creating a New FPGA Design Project*, *Migrating Projects Across Operating Systems* and their subtopics to *Selecting a Starting Point for Your Quartus Prime Pro Edition Project* chapter. • In *Managing Logic Design Files*, added information about converting `.bdf` to `.v` or `.vhd` file. • Removed "Block Diagram/Schematic Design Files (`.bdf`)" in *Project Files to Include In External Revision Control*. • Added *Viewing Parameter Settings From the Project Navigator*. • Added an appendix about *Using Design Space Explorer II* and included related topics. • Revised the Power and Thermal Calculator (PTC) image in *Planning for Device Power Consumption*.
2023.10.02	23.3	• Updated the compilation dashboard image in *Introduction to Quartus Prime Pro Edition* and *Using the Compilation Dashboard*. • Removed OpenCL support from the "Intel Quartus Prime Feature Support Matrix" image in *Selecting an Quartus Prime Software Edition*. • Made a minor correction in *Logic Lock Region Assignment Examples*. • Revised the "Quartus Prime Pro Edition IP Version Upgrade Paths" image in *Upgrading IP Cores*. • Updated the dashboard image in *Using the Compilation Dashboard*.
2023.06.26	23.2	• Updated *Power Analyzer Settings* screenshot for new settings name.

continued...

Document Version	Quartus Prime Version	Changes
2023.04.03	23.1	• Updated product family name to "Intel Agilex 7." • Added note to *Upgrade Project Assignments and Constraints* about new prompt to update operating temperatures in a migrated project. • Updated *Support for the IEEE 1735 Encryption Standard* topic for new installed location of public encryption key. • Updated *Intel Quartus Prime Pro Edition IP Version Upgrade Paths* support chart.
2022.12.12	22.4	• Updated *Plan for the Target Device or Board* topic for board-aware features. • Revised *Applying Preset Parameters for Specific Applications* topic for board-aware features. • Added new *Viewing, Applying, and Deleting IP Presets* topic. • Added new *Example IP Preset File (.qprs)* topic. • Revised *Customizing IP Presets* topic for board-aware features. • Added new *Defining Preset Pin Assignments* section. • Revised *Creating a New FPGA Design Project* for board-aware features. • Added *Using the Board-Aware Flow* topic. • Added *Creating a New Project from a Design Example* topic. • Added *Family, Device & Board Settings* topic. • Added *Accessing Pre-Installed Design Examples* topic. • Added *Accessing Online Design Examples* topic. • Added *Accessing Downloaded Design Examples* topic. • Added *Internet Connectivity Options* topic. • Added *Design Examples Options* topic. • Added *Specifying a Target Board for the Project* topic.
2022.06.20	22.2	• Added new *Top FAQs* navigation to document cover. • Revised *Introduction* to add FPGA definition and device selection footnote. • Added new *FPGA Basic Design Prerequisites* topic. • Added new *Experiment with a Design Example* topic. • Removed obsolete *Simultaneous Switching Noise Analysis* topic from this basic discussion.
2022.03.28	22.1	• Added information about Power and Thermal Calculator in *Plan for Device Power Consumption*. • Removed references to obsolete Advisors from *Optimizing Project Settings* topic. • Added *Viewing Synthesis Warning Messages* topic. • Removed the topic *Automated Problem Reports*.
2021.10.04	21.3	• Added support for Questa*-Intel FPGA Edition simulator. • Removed support for ModelSim - Intel FPGA Edition simulator. • Updated *Quartus Prime Pro Edition IP Version Upgrade Paths* figure for latest versions.
2021.06.21	21.2	• Added *Version-Compatible Compilation Database Support* table. • Added "Promoting Critical Warnings to Errors" topic.
2021.03.29	21.1	• Enhanced *Simulating Intel FPGA Designs* topic with screenshot, links, and additional contextual details. • Updated supported simulator versions and removed support for Cadence Incisive Enterprise* in *Simulator Support* topic. • Revised *Generating IP Simulation Files* topic for new simulation file output options.

continued...

Document Version	Quartus Prime Version	Changes
		• Revised *Using the EDA Netlist Writer* wording for clarity. • Added "Creating Database-Only Archives" topic. • Added "Promoting Critical Warnings to Errors" topic
2020.11.09	20.3	• Revised "Introduction to Intel FPGA IP Cores" topic to include Bridges and Adapters and Intel FPGA Interconnect categories in IP Catalog. Updated IP Catalog image. • Revised wording of "Intel FPGA IP Versioning" topic for clarity. • Added screenshot to "Checking the IP License Status" topic. • Added "IP Version Upgrade Paths" diagram to "Upgrading IP Cores" topic. • Updated IP Port Differences Report image in "Troubleshooting IP or System Upgrade" topic.
2020.09.28	20.3	• Updated GUI screenshot in Introduction. • Updated "Back-Annotate Optimized Assignments" for support of pins, clocks, RAMs, and DSPs.
2020.05.01	20.1	• Added note about `.qar` file requirements to "Design Guidelines for Component Instances" topic.
2019.09.30	19.3	• Added compilation support for Agilex 7 devices. • Added "Checking the IP License Status" topic. • Added details to "Support for the IEEE 1735 Encryption Standard." • Added Intel FPGA IP Versioning" topic. • Added "Disabling Automated Problem Reports" topic. • Added "Suppressing Messages" topic.
2019.05.13	18.1	• Added archives topic. • Updated the keyname and added --help information to "Support for the IEEE 1735 Encryption Standard."
2018.10.24	18.1	• Updated information about obtaining IEEE 1735 Encryption key.
2018.09.24	18.1	• Added screenshot of Quartus Prime Pro Edition GUI. • Moved information about specifying the target board to "Specifying the Target Device or Board" in *Managing Projects* chapter. • Retitled "Creating Design Specifications" to "Create a Design Specification and Test Plan." • Retitled "Selecting Intellectual Property Cores" to "Plan for Intellectual Property Cores." • Retitled "Using Standard Interfaces" to "Plan for Standard Interfaces." Corrected references to Platform Designer. • Retitled "Device Selection" to "Plan for the Target Device." Updated this content to correct Platform Designer names. • Moved "Setting Pin Assignments" to *Managing Projects* chapter as "Generating Pin Assignments for a Target Board." • Retitled "Estimating Power" to "Plan for Device Power Consumption." Reorganized this topic into sections for EPE and Power Analyzer. • Added link to "Simulator Support, *Third-Party Simulation User Guide* • Retitled "Planning for Device Programming or Configuration" to "Plan for Device Programming" • Retitled "Selecting Third-Party EDA Tools" to "Plan for other EDA Tools." • Retitled "Planning for On-Chip Debugging Tools" to "Plan for On-Chip Debugging Tools."

continued...

Document Version	Quartus Prime Version	Changes
		• Retitled *Design Planning with the Intel Quartus Prime Software* to *Design Planning* • Added information about removing assignments from the qsf file that point to legacy output files. • Added statement that the Quartus Prime software installer does not support spaces in the installation path. • Added "Intel FPGA IP Best Practices" topic. • Divided "Introduction to Intel FPGA IP Cores" into separate chapter of *Getting Started User Guide*. • Subdivided "Exporting, Archiving, and Migrating Projects" into separate sections. • Described migration of full chip database in "Exporting a Version-Compatible Compilation Database" topic. • Described automated `.qdb` partition export in "Exporting a Design Partition" topic. • Added "Viewing Quartus Database File Information" topic. • Added "Specifying the Target Device or Board" topic. • Divided "Introduction to Intel FPGA IP Cores" into separate chapter. • Moved "IP Core Best Practices" topic to *Introduction to Intel FPGA IP Cores* chapter. • Moved "Factors Affecting Compilation Results" topic to *Design Compilation: Intel Quartus Prime Pro Edition User Guide*.
2018.05.07	18.0	• Initial release as separate chapter of *Getting Started User Guide.* Separated *Migrating to Quartus Prime Pro Edition* as independent chapter in user guide. • Initial release as separate chapter of *Getting Started User Guide.* Separated *Design Planning* as independent chapter in user guide. • Initial release as separate chapter of *Getting Started User Guide.* Separated *Introduction to Intel FPGA IP Cores* as independent chapter in user guide. • Updated screenshots of IP Catalog and Parameter Editor for latest IP names. • Added note about Generate Combined Simulator Setup Scripts command limitations. • Added information about generation of simulation files for Xcelium* • Initial release as chapter of *Getting Started User Guide.* • Revised "Exporting a Design Partition" topic to add Include entity-bound SDC files for the selected partition option, to add prerequisite steps, and to remove import step covered in separate topic. • Changed title of "Managing Team-Based Designs" to "Exporting, Archiving, and Migrating Projects" and updated content. • Changed title of "Migrating Compilation Results Across Software Versions" to "Exporting the Compilation Database" and updated content. • Changed title of "Exporting the Results Database" to "Exporting a Version-Compatible Design Compilation Database" and updated content. • Changed title of "Importing the Results Database" to "Importing a Version-Compatible Design Compilation Database" and updated content. • Changed title of "Cleaning the Project Database" to "Cleaning the Project Compilation Database." • Updated screenshots of IP Catalog and Parameter Editor for latest IP names.

continued...

Document Version	Quartus Prime Version	Changes
2017.11.06	17.1	• Described Quartus Prime tool name updates for Platform Designer (Qsys), Interface Planner (BluePrint), Timing Analyzer (TimeQuest), Eye Viewer (EyeQ), and Intel Advanced Link Analyzer (Advanced Link Analyzer). • Added Verilog HDL Macro example. • Updated for latest Intel branding conventions. • Added Verilog HDL Macro example. • Updated for latest Intel branding conventions. • Revised product branding for Intel standards. • Revised topics on Intel FPGA IP Evaluation Mode (formerly OpenCore).
2017.05.08	17.0	• Removed statement about limitations for safe state machines. The Compiler supports safe state machines. State machine inference is enabled by default. • Added reference to Block-Based Design Flows. • Removed procedure on manual dynamic synthesis report generation. The Compiler automatically generates dynamic synthesis reports when enabled. • Removed statement about limitations for safe state machines. The Compiler supports safe state machines. State machine inference is enabled by default. • Added note that IP core encryption is supported only in Quartus Prime Pro Edition. • Revised product branding for Intel standards.
2016.10.31	16.1	• Implemented Intel rebranding. • Added reference to Partial Reconfiguration support. • Added to list of Quartus Prime Standard Edition features unsupported by Quartus Prime Pro Edition. • Added topic on Safe State Machine encoding. • Described unsupported Quartus Prime Standard Edition physical synthesis options. • Removed deprecated **Per-Stage Compilation (Beta)** Compilation Flow. • Changed title from "Remove Filling Vectors" to "Remove Unsized Constant". • Implemented Intel rebranding. • Described unsupported Quartus Prime Standard Edition physical synthesis options. • Changed title from "Remove Filling Vectors" to "Remove Unsized Constant". • Removed references to `.qsys` file creation during Quartus Prime Pro Edition stand-alone IP generation. • Added references to `.ip` file creation during Quartus Prime Pro Edition stand-alone IP generation. • Updated IP Core Generation Output files list and diagram. • Indicated distinctions between Quartus Prime Pro Edition and Quartus Prime Standard Edition features. • Added Support for IP Core Encryption topic.
2016.05.03	16.0	• Removed software beta status and revised feature set. • Added topic on Safe State Machine encoding. • Added Generating Dynamic Synthesis Reports. • Corrected statement about Verilog Compilation Unit. • Corrected typo in Modify Entity Name Assignments. • Added description of Fitter Plan, Place and Route stages, reporting, and optimization. • Added **Per-Stage Compilation (Beta)** Compilation Flow.

continued...

Document Version	Quartus Prime Version	Changes
		• Added Platform Designer information. • Added OpenCL and Signal Tap with routing preservation as unique Pro Edition features. • Clarified limitations for multiple Logic Lock instances in the same region. • Added topic on Safe State Machine encoding. • Corrected statement about Verilog Compilation Unit. • Corrected typo in Modify Entity Name Assignments. • Clarified limitations for multiple Logic Lock instances in the same region.
2015.11.02	15.1	• First version of document.

D. Quartus Prime Pro Edition User Guides

Refer to the following user guides for comprehensive information on all phases of the Quartus Prime Pro Edition FPGA design flow.

Related Information

- Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Quartus Prime Pro Edition software, including managing Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

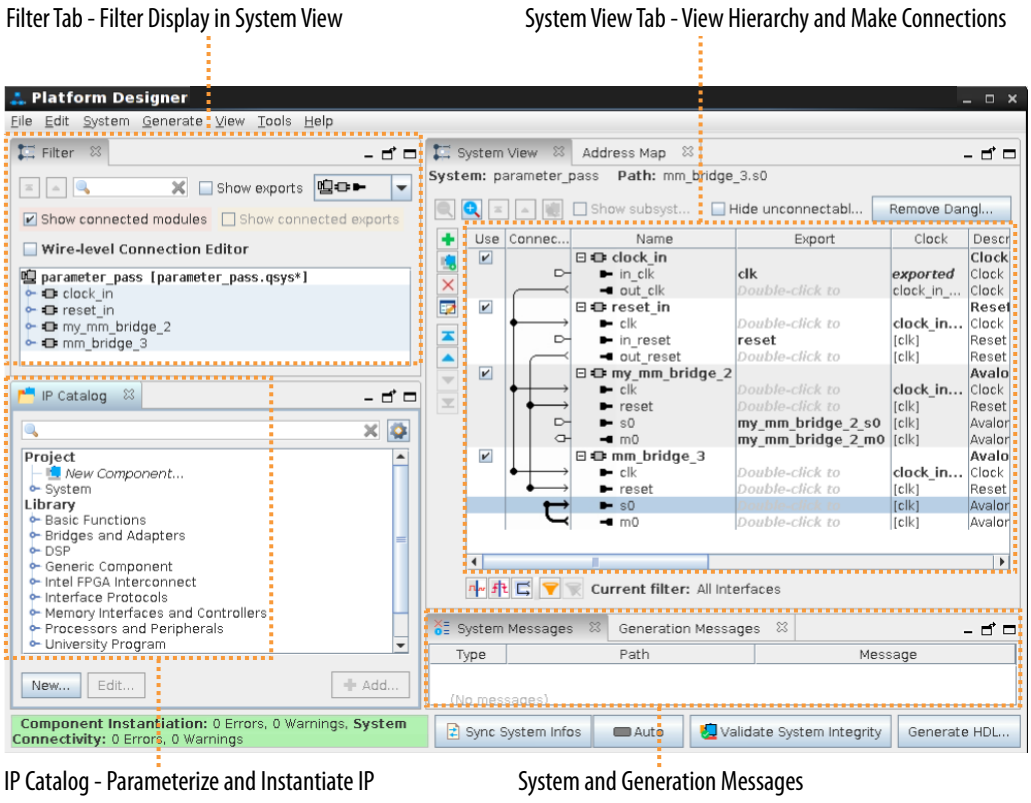
Contents

1. Creating a System with Platform Designer

The Quartus® Prime software includes the Platform Designer system integration tool. Platform Designer simplifies the task of defining and integrating custom IP components (IP cores) into your FPGA design.

Platform Designer automatically creates interconnect logic from high-level connectivity that you specify. The interconnect automation eliminates the time-consuming task of specifying system-level HDL connections.

Figure 1. Platform Designer GUI



Platform Designer allows you to specify interface requirements and integrate IP components within a graphical representation of the system. The Quartus Prime software installation includes the Intel FPGA IP library available from the IP Catalog in Platform Designer.

You can integrate optimized and verified Intel FPGA IP cores into a design to shorten design cycles and maximize performance. Platform Designer also supports integration of IP cores from third-parties, or custom components that you define.

Platform Designer supports a hierarchical framework that offers fast response times for interconnecting large systems and blackbox entities. Platform Designer supports a variety of design entry methods, such as register transfer level (RTL) and schematic entry. Platform Designer supports the creation of your own custom components, as well as generic components that define only the interface and signal connections to the rest of the system.

Platform Designer provides support for the following:

- Create and reuse components—define and reuse custom parameterizable components in a Hardware Component Definition File (`_hw.tcl`) that describes and packages IP components.
- Define generic IP components—instantiate generic IP components without an HDL implementation.
- Incremental generation—optimize and generate IP components incrementally.
- Avalon® to AXI interconnect—Platform Designer generates appropriate types of interconnect logic to handle protocol differences.
- Hierarchical system support—generates a separate `.ip` file that isolates the system from the IP component parameterization. Change parameters of a single IP component without regeneration of other IP components.
- Command-line support—optionally use command-line utilities and scripts to perform functions available in the Platform Designer GUI.
- Up to 64-bit addressing.
- Optimization of interconnect and pipelining within the system and auto-adaptation of data widths and burst characteristics.
- Inter-operation between standard protocols.

1.1. Platform Designer Interface Support

Platform Designer is most effective when you use standard interfaces available in the IP Catalog to design custom IP. Standard interfaces operate efficiently with Intel FPGA IP components, and you can take advantage of the bus functional models (BFMs), monitors, and other verification IP that the IP Catalog provides.

Platform Designer also supports connections between Avalon and AXI interfaces by generating the interconnect logic. This logic enables you to handle the protocol difference. Platform Designer creates the interconnect logic by converting all the protocols to a proprietary packet format. Then, the tool routes the packet through network switches to the appropriate agents. Here, the packet converts to the agent's protocol.(1)

Platform Designer supports the following interface specifications:

- Intel FPGA Avalon Memory-Mapped and Streaming
- Arm* AMBA* 3 AXI (version 1.0)
- Arm AMBA 4 AXI (version 2.0)

(1) This document now refers to the Avalon "host" and "agent," and the AXI "manager" and "subordinate," to replace formerly used terms. Refer to the current *AMBA AXI and ACE Protocol Specification* for the latest AMBA AXI and ACE protocol terminology.

- Arm AMBA 4 AXI-Lite (version 2.0)
- Arm AMBA 4 AXI-Stream (version 1.0)
- Arm AMBA 3 APB (version 1.0)

IP components (IP Cores) can have any number of interfaces in any combination. Each interface represents a set of signals that you can connect within a Platform Designer system, or export outside of a Platform Designer system.

Platform Designer IP components can include the following interface types:

Table 1. IP Component Interface Types

Interface Type	Description
Memory-Mapped	Connects memory-referencing host devices with agent memory devices. Host devices can be processors and DMAs, while agent memory devices can be RAMs, ROMs, and control registers. Data transfers between Avalon Memory Mapped host and agent may be uni-directional (read only or write only), or bi-directional (read and write).
Streaming	Connects Avalon Streaming sources and sinks that stream unidirectional data, as well as high-bandwidth, low-latency IP components. Streaming creates datapaths for unidirectional traffic, including multichannel streams, packets, and DSP data. The Avalon interconnect is flexible and can implement on-chip interfaces for industry standard telecommunications and data communications cores, such as Ethernet, Interlaken, and video. You can define bus widths, packets, and error conditions.
Interrupts	Connects interrupt senders to interrupt receivers. Platform Designer supports individual, single-bit interrupt requests (IRQs). In the event that multiple senders assert their IRQs simultaneously, the receiver logic (typically under software control) determines which IRQ has highest priority, then responds appropriately.
Clocks	Connects clock output interfaces with clock input interfaces. Clock outputs can fan-out without the use of a bridge. A bridge is required only when a clock from an external (exported) source connects internally to more than one source.
Resets	Connects reset sources with reset input interfaces. If your system requires a particular positive-edge or negative-edge synchronized reset, Platform Designer inserts a reset controller to create the appropriate reset signal. If you design a system with multiple reset inputs, the reset controller ORs all reset inputs and generates a single reset output.
Conduits	Connects point-to-point conduit interfaces, or represent signals that you export from the Platform Designer system. Platform Designer uses conduits for component I/O signals that are not part of any supported standard interface. You can connect two conduits directly within a Platform Designer system as a point-to-point connection. Alternatively, you can export conduit interfaces and bring the interfaces to the top-level of the system as top-level system I/O. You can use conduits to connect to external devices, for example external DDR SDRAM memory, and to FPGA logic defined outside of the Platform Designer system.

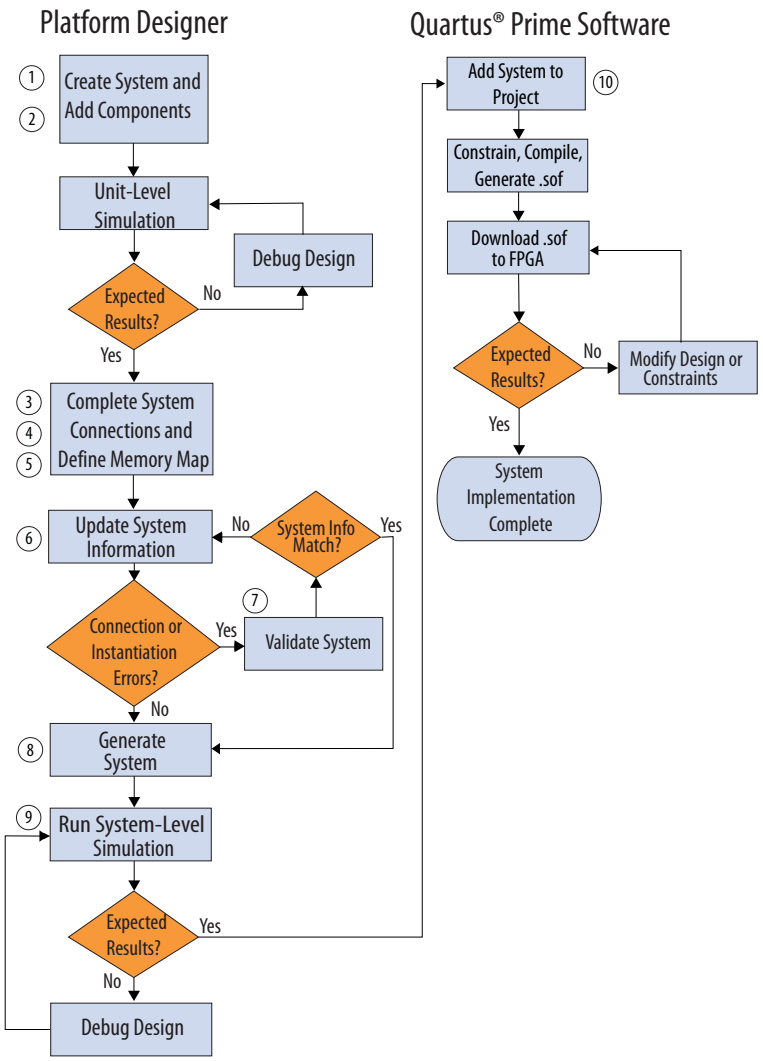
Exporting HDL Parameters to a System on page 189

1.2. Platform Designer System Design Flow

You can use the Platform Designer GUI to quickly create and customize a Platform Designer system for integration with an Quartus Prime project. Alternatively, you can perform many of the functions available in the Platform Designer GUI at the command-line, as Platform Designer Command-Line Utilities on page 441 describes.

When you create a system in the GUI, Platform Designer creates a `.qsys` file that represents the system in your Quartus Prime software project.

Figure 2. Platform Designer System Design Flow



1.3. Creating or Opening a Platform Designer System

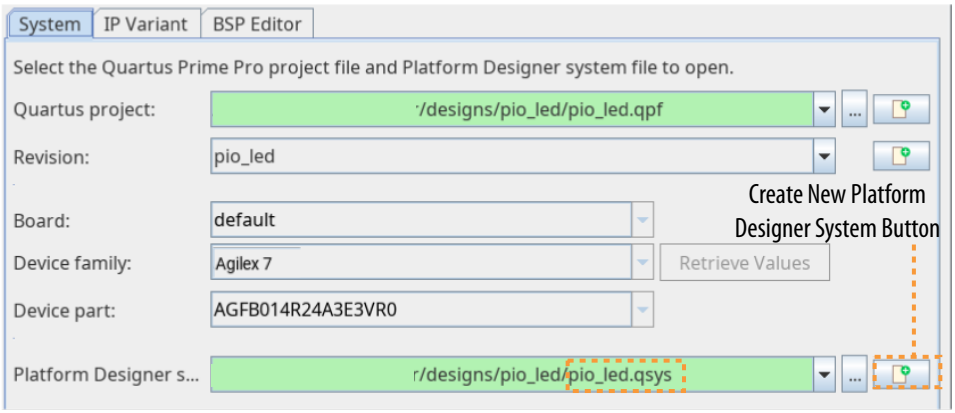
You can launch Platform Designer from the Quartus Prime software to create or open a Platform Designer system.

When you create or open a system, Platform Designer requires that you specify the Quartus Prime project to contain this system. If this project does not yet exist, you can define a new project from within Platform Designer. Alternatively, you can specify an existing project. When you launch Platform Designer with an Quartus Prime project open, Platform Designer automatically specifies that project by default. The target device or board for the system reflects the project settings by default. Refer to Using the Board-Aware Flow in Platform Designer on page 18.

Follow these steps to create or open a Platform Designer system:

1. In the Quartus Prime software, click **File ➤ Open Project** to open the Quartus Prime project that you want to include the Platform Designer system. You can optionally skip this step and launch Platform Designer in view-only mode without opening a project.
2. Click **Tools ➤ Platform Designer**. Platform Designer launches and displays the **Open Project** dialog box automatically.
3. Specify the **Quartus project**. If you have a project open, this project name appears automatically. Otherwise, browse for an existing project, or click the **Create New Quartus Project** button and specify a new project name. Selecting **None** for **Quartus project** opens Platform Designer in view-only mode.

Figure 3. System Tab of Open System Dialog Box



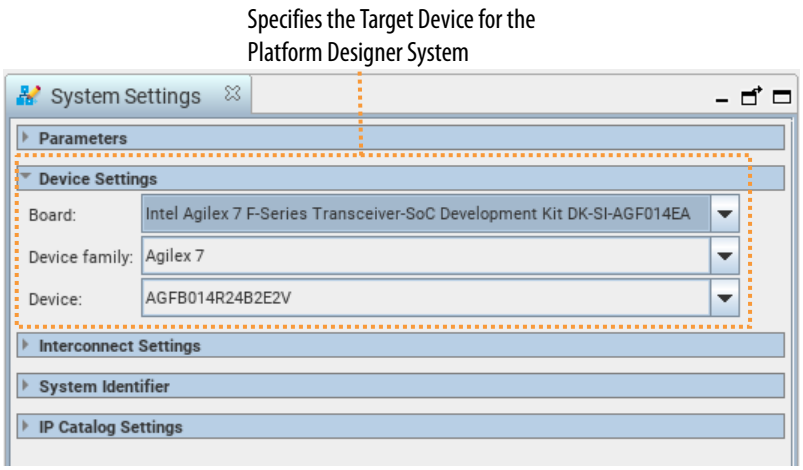
4. Select the **Platform Designer system**, or click the **Create New Platform Designer System** button and specify the name of a new system. Optionally select a specific revision of your project, or click the **Create New Revision** button and define a new project revision.
5. Change the project associated with a Platform Designer system at any time by clicking **File ➤ Select Quartus Project** in Platform Designer.

1.3.1. Specifying the Target FPGA Device or Board for a System

When you create a new Platform Designer system, the system settings automatically reflect the target device or board that the current Quartus Prime project targets. The Platform Designer system generation output is specific to the target Intel® FPGA **Device family** or **Board** specified for the project and system. The available IP components, parameters, and output options for your system vary according to the target **Device family** or **Board**.

Note: The **System Settings** tab now replaces the **Device Family** tab in Platform Designer.

Figure 4. System Settings Tab in Platform Designer



After creating a system, you can modify the target **Device family** or **Board** setting for your system on the Platform Designer **System Settings** tab. If you specify a target **Device family** or **Board** that is different from the current project settings, Platform Designer updates the target device family or board for the project to match the **Device family** or **Board** specification. Platform Designer prompts you to upgrade any IP components that are incompatible with the **Device family** or **Board** that you specify.

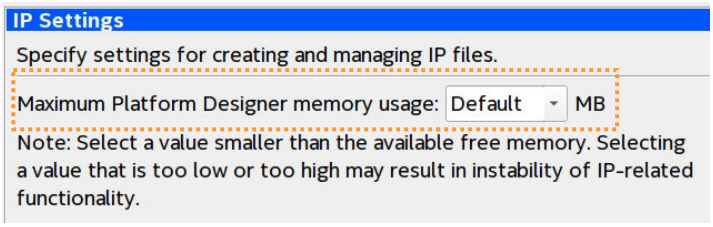
Note: To get started quickly with the board-aware flow, refer to Using the Board-Aware Flow in Platform Designer on page 18.

1.3.2. Specifying Additional Application Memory

If Platform Designer requires more than the default memory to run efficiently, you can increase the amount of application memory.

- From within the Quartus Prime software, increase memory for your Platform Designer system, by clicking **Tools ➤ Options ➤ IP Settings**, and then specifying the amount of memory with the **Maximum Platform Designer memory usage** option.
- From the command-line, you can add an option to increase the memory. For example, the following `qsys-edit` command allows you to open Platform Designer with 2 gigabytes of memory.

Figure 5. Specifying Additional Application Memory for Platform Designer



```
qsys-edit --jvm-max-heap-size=2g
```

1.3.3. Synchronizing IP File References

When you open a system containing IP components, Platform Designer confirms that the list of IP files in your Platform Designer system matches the list of IP files included in the corresponding Quartus Prime project.

The **IP Synchronization Result** dialog box automatically displays any discrepancies between these IP file references in the system.

To manually start a check for IP reference mismatches between the system and corresponding Quartus Prime project:

1. In Platform Designer, click **File ➤ Synchronize IP File References**.
2. View the results of the synchronization. Platform Designer identifies the following types of mismatches with the IP synchronization:

Table 2. IP Synchronization Results

Mismatch Type	Description
Duplicate IP files	The IP files references in the Platform Designer system and the associated Quartus Prime project match. These IP files contain the same name, but are present in different locations. In such cases, the IP files referenced in the Quartus Prime project takes precedence. Platform Designer replaces the IP file reference in the system with the one in the Quartus Prime project during compilation. *Note:* If the Quartus Prime project contains more than one IP of the same file name, Platform Designer retains the first instance and removes all other occurrences of the IP file with the specific name.
Missing IP files	Lists the IP file references missing from Platform Designer system and the corresponding Quartus Prime project. In such cases, Platform Designer allows you to specify the active IP file.
Missing Platform Designer IP files	Lists the IP file references missing from your Platform Designer system that the Quartus Prime project references. If Platform Designer locates a valid reference in the Quartus Prime project, it replaces the missing reference in the Platform Designer system with IP file reference from the Quartus Prime project.
Missing Quartus IP files	Lists the IP file references missing from your Quartus Prime project that the Platform Designer system references. Platform Designer adds the missing IP file reference to the Quartus Prime project. If the project's `.qsf` file already contains reference to the missing IP file, but the file cannot be located in the specified path, Platform Designer removes the reference in the `.qsf` file, and adds the reference to the IP file in the Platform Designer system.

1.3.4. Converting Incompatible Components

If you open a Platform Designer system with incompatible components, Platform Designer prompts you to convert these components to the current Platform Designer format. On conversion, the **Platform Designer Conversion Results** dialog box appears, listing all the converted system and IP source files.

Platform Designer stores the converted `.ip` files inside an `ip` folder, relative to the Platform Designer system file (`.qsys`) location. Platform Designer prefixes the system name to the `.ip` file name. Platform Designer automatically adds these converted files to the associated Quartus Prime project. Ensure that you maintain these `.ip` files, along with your system files.

1.4. Using the Board-Aware Flow in Platform Designer

Platform Designer allows you to create a system that targets a specific development board, rather than only targeting a specific FPGA device. When you target a specific development board, Platform Designer is *aware* of the target board (board-aware) which simplifies the IP parameterization, pin assignments, and exporting interfaces for the system.

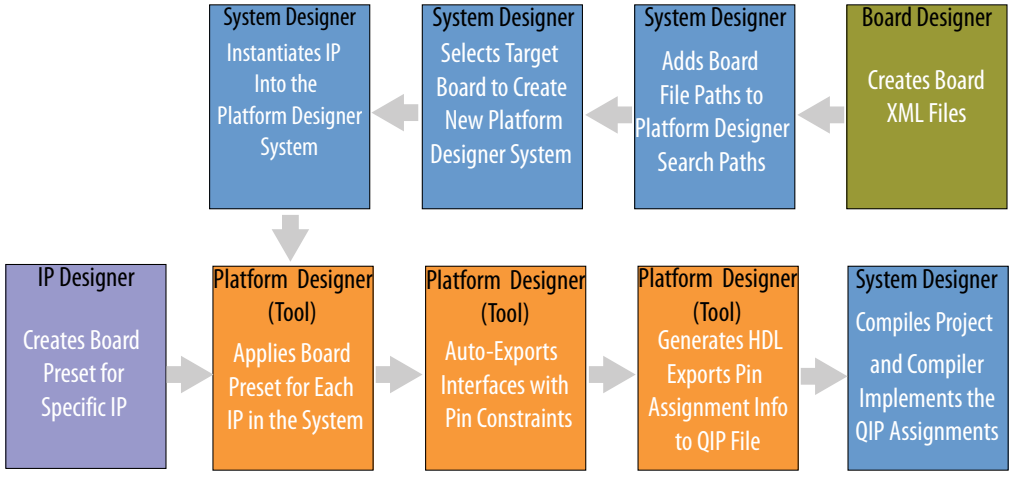
The board-aware flow accelerates the process of appropriately configuring, connecting, and validating IP for the target board by using IP presets together with a board definition file that specifies the details of a target board. You can use (and reuse) the board definition file and IP presets to automatically include the appropriate IP pin assignments, parameters, and exported interfaces for the target development board during system generation.

To use the board definition file and IP presets together, you first specify the board information in a board file (`_board.xml`), and then apply IP presets that are appropriate for the specific development board. IP preset files specify the list of valid parameters and pin assignments that are appropriate for your target board of choice. You can also define your own custom IP presets and board files. When you generate the IP or system using this board-aware flow, Platform Designer performs the following. Refer to Creating IP Presets Targeting Specific Boards on page 45 for details.

- Presets appropriate IP parameters for the target board.
- Exports pin assignment to a `.qip` file read during design compilation.
- Exports the appropriate interfaces for the board.

In the FPGA system design flow, different engineers often handle specific steps of development. For example, a board engineer often creates the board definition file. An IP designer may create the board presets for specific IP. A system designer can use the board file and IP presets to perform design entry. At each stage, you can share the board file and IP presets to reduce any chance of configuration errors from hand-off between developers or projects.

Figure 6. Board-Aware Flow Typical Tasks and Roles



The board-aware flow helps to ensure the proper hand-off, consistency, and reuse of configuration options across multiple projects, developers, and boards.

Related Information

- AN 988: Using the Board-Aware Flow in the Intel Quartus Prime Pro Edition Software
- Board-Aware Flow Scripting Support on page 447

1.4.1. Accessing FPGA Design Examples

You can optionally base your design project on a pre-verified FPGA design example that targets a specific FPGA board or development kit, or you can start with an empty project. Access available design examples using any of the following methods:

- **Pre-installed design examples**—you can immediately access the design examples that install along with the Quartus Prime software installation at: `<quartus>\acds\quartus\common\board_designs`.
- **Online design examples**—you can access design examples hosted online, which include designs from the Intel FPGA Design Store.
- **Downloaded design examples**—you can access previously downloaded design examples, or any design example that you store in a local drive, under downloaded design examples.

1.4.2. Specifying the Target Board for a Platform Designer System

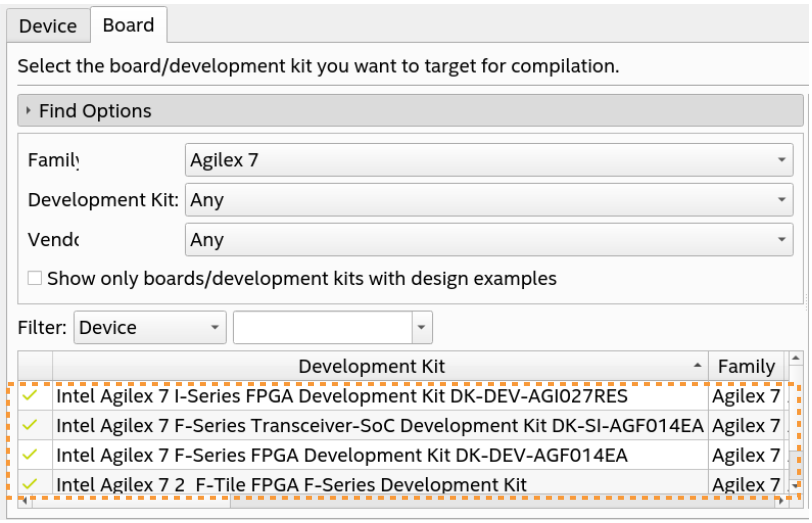
You can specify a target board when you setup any Quartus Prime project. By default, Platform Designer automatically inherits the target board information from the currently open Quartus Prime project.

Specifying the target board for the system, rather than just specifying a target FPGA device, helps to ensure the appropriate IP parameterization, pin assignments, and export of interfaces for the system.

Use any of these methods to specify a target board for the project:

- New Project Wizard (**File ➤ New Project Wizard**).
- Quartus Prime **Home** page, click **Open Example Project** icon.
- Click **File ➤ Open Example Project**.
- **Board** tab of the **Device** dialog Box (**Assignments ➤ Device ➤ Board**).

Figure 7. Board Tab of Device Dialog Box



1.4.2.1. Changing the Target Board for a Platform Designer System

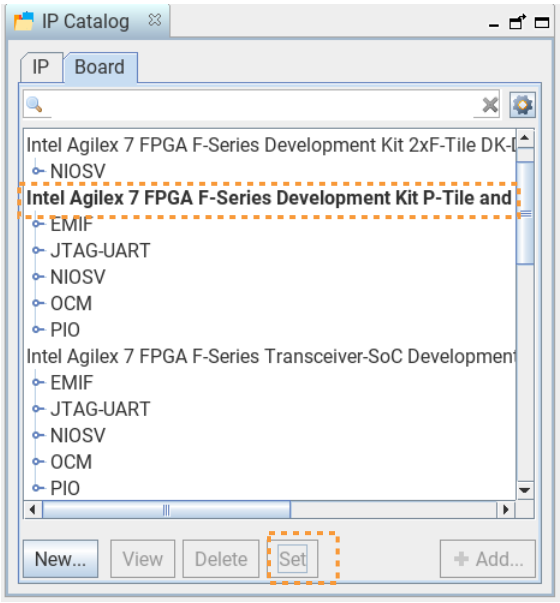
After creating or opening a system, you can use any of the following methods to change the target board for your system:

Figure 8. Change the Target Board in Platform Designer System Settings

Click **System ➤ System Settings** in Platform Designer to change the target board at any time.

Or
In Platform Designer's IP Catalog, click the **Board** tab, then select the target board in the list and click **Set**. The board name appears in bold when set as the target board.

Figure 9. Changing the Target Board in IP Catalog



Alternatively, you can specify the target board by adding board arguments to `qsys-edit` and `qsys-generate` at the command line. The board argument is optional:

```
$qsys-edit --board=[board name]
$qsys-edit --board=[board name] -family=[device family] --part=[device part]
```

`qsys-edit` opens the **Open System** dialog box and automatically sets the board that the argument specifies.

Note: The `--board` option takes precedence over the device `family` and device `part` options. If you specify a `board`, the device `family` and device `part` associated with board automatically update to the board's default device family and part. If you specify the `board`, device `family`, and device `part` , the `board` option with mapped device family and part is selected.

1.4.2.2. Using Board Files

You can define a custom board file (`_board.xml`) that specifies target board information for your system. You can then specify this board as the target for any system. The board file specifies the following information about the target board:

- Board name, such as `Agilex 7 F-Series FPGA Development Kit DK-DEV-AGF014EA`
- Device part, such as AGFB014R24B2E2V
- Device family, such as `Agilex 7`
- Board vendor, such as `Intel`
- Board file version, such as `1.0`

1.4.2.2.1. Creating a New Board File

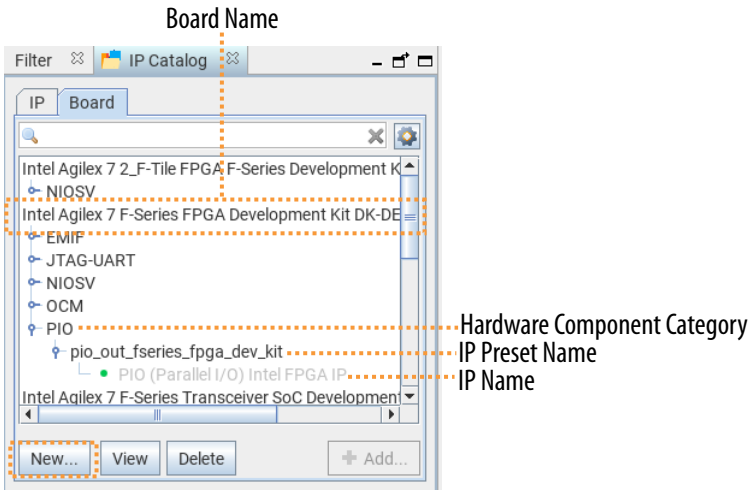
Platform Designer displays all existing board files that have the `_board.xml` extension in the Board Catalog. The Board Catalog is a tab of Platform Designer IP Catalog.

By default, the Board Catalog shows the IPs that you associate with the current selected board file. Under each board file name appears a list of any hardware components associated with the board, such as a button, LED, or JTAG UART. Under each component name appears the IP preset name that applies. Under each preset name appears the IP name to which the preset applies.

To define a new board file in Platform Designer, follow these steps:

1. Click **Tools ➤ Platform Designer**. Platform Designer launches and displays the **Open Project** dialog box automatically.
2. Specify the **Quartus project**. If you have a project open, the project name appears automatically. Otherwise, browse for an existing project, or click the **Create New Quartus Project** button and specify a new project name. If **Device family** or **Device part** are unsynchronized, click **Retrieve Values**.
3. Select the **Platform Designer system**, or click the **Create New Platform Designer System** button and specify the name of a new system.
4. In the Platform Designer IP Catalog, click the **Board** tab. The **Board** tab displays any existing board files (`_board.xml`) in `<quartus>\ip\altera\board_preset_files\`.
5. On the **Board** tab, click the **New** button. The **Create New Board** dialog box appears with options that Create New Board Dialog Box Options on page 23 describes.

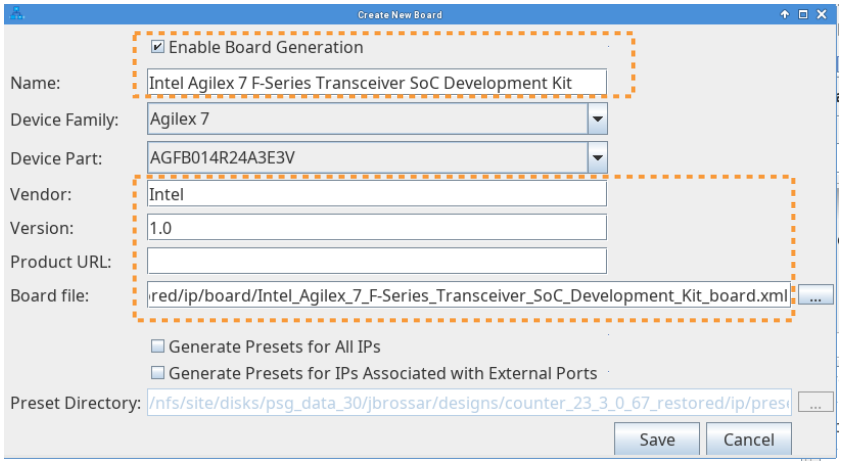
Figure 10. Board Catalog Displays Existing Boards Defined



6. To create a new board file, make sure that **Enable Board Generation** is on.
7. Specify the board **Name**, target **Device family**, **Device part**, board **Vendor**, and board file **Version**. By default, **Device part** and **Device family** reflects the current project settings.
8. For **Product URL**, optionally specify URL of a board product description online.

9. Next to **Board file**, click the browse (**...**) button to specify a **File name**. Platform Designer automatically adds the `_board.xml` extension. Click **OK**.

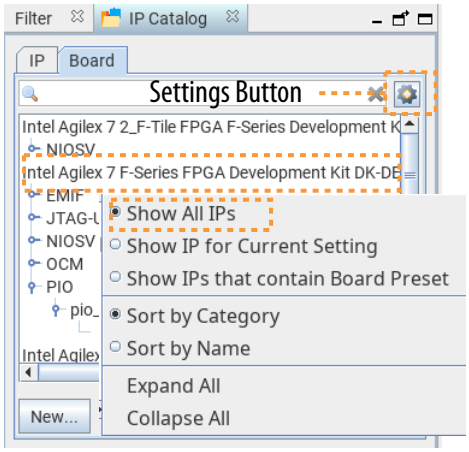
Figure 11. Create New Board Dialog Box



Note: Specifying an existing board file name for **Board file** overwrites the selected board file with the new definition.

10. In the **Create New Board** dialog box, click the **Save** button. If the directory that you specify is new, Platform Designer confirms adding this directory to the search path.
11. To view the new board in the Board Catalog, click the Settings button on the right side of the search field, and select **Show All IPs**.

Figure 12. Agilex™ 7 FPGA DevKit Board Visible in Board Catalog



1.4.2.2.2. Create New Board Dialog Box Options

The **Create New Board** dialog box allows you to specify the details about your target development board in Platform Designer. Platform Designer saves the board data in a board file (`_board.xml`). You define the details of the board and then reuse that board file for other projects that target the same board.

Note: Turning on **Enable Board Generation** in combination with either the **Generate Presets for All IPs** or **Generate Presets for IPs Associated with External Ports** causes the system presets to target the new board that you are creating. Turning on only **Generate Presets for All IPs** or **Generate Presets for IPs Associated with External Ports** with **Enable Board Generation** turned off causes the system presets to target the current board in Platform Designer.

Table 3. Create New Board Dialog Box Settings

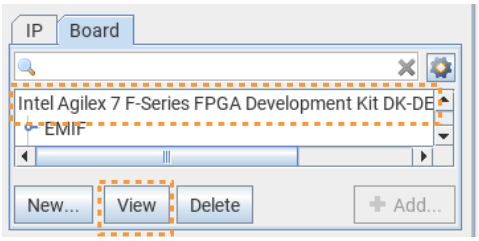
Setting Name	Description
Enable Board Generation	Turn on this option to generate a new board file (`_board.xml`) when you click the **Save** button. Leave this option off to generate only a system presets file (`.qprs`) based on the current system and target board. This option is on by default.
Name	Specifies the name for the board file that appears in the Platform Designer Board Catalog.
Device family	Select the target design family for the Platform Designer system. This setting reflects the current project settings by default.
Device part	Select the target FPGA device part for the Platform Designer system. This setting reflects the current project settings by default.
Vendor	Specifies the vendor of the target board, such as Intel. This setting is optional.
Version	Specifies the version number of the board file, such as 2.0. This setting is optional.
Board file	Specifies the name of the new board file that you are creating.
Preset Directory	Specifies the file name and path of the new system preset file (`.qprs`) that generates when you click the **Save** button. If you instead select an existing preset file for this setting, that file is overwritten with the new preset parameter values.
Generate Presets for All IPs	Turn on this option to enable presets generation for all IPs in a pre-existing Platform Designer system.
Generate Presets for IPs Associated with External Ports	Turn on this option to enable presets generation for IPs with external ports only.
Save	Creates (or overwrites) the board and preset files, according to your specifications in this dialog box.

1.4.2.2.3. Viewing or Deleting Board Files

You can view or delete board files (`_board.xml`) in the Board Catalog. To view the details of an existing board file in the Platform Designer Board Catalog, follow these steps:

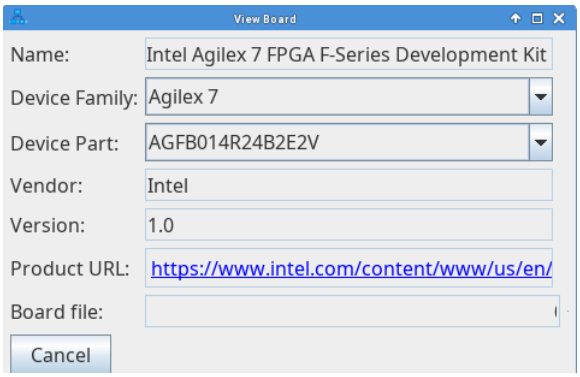
1. In Platform Designer, click the **Board** tab in IP Catalog. (**View ➤ IP Catalog**). The Board Catalog displays any board files (`_board.xml`) in the Platform Designer search path.
2. On the **Board** tab, select the board that you want to view.

Figure 13. Board File in Board Catalog



3. Click the **View** button. The **View Board** dialog box displays the board properties, as Create New Board Dialog Box Options on page 23 describes.

Figure 14. View Board Dialog Box



Deleting a Board File

To delete a board file from the Board Catalog, follow these steps:

1. On the **Board** tab, select the board file that you want to delete.
2. Click the **Delete** button. Click **Yes** to confirm the deletion of the board file.

1.4.3. Generating Board and Preset Files for Existing Systems

You can generate and apply board and preset files to an existing system design that did not originally include board or preset files. This technique allows you to quickly specify appropriate configuration options when you are targeting the same board and IP as the board and preset files. You can apply the board and preset files to the existing system using either the command-line or in Platform Designer.

1.4.3.1. Generating Board and Preset Files for Existing Systems Using Platform Designer

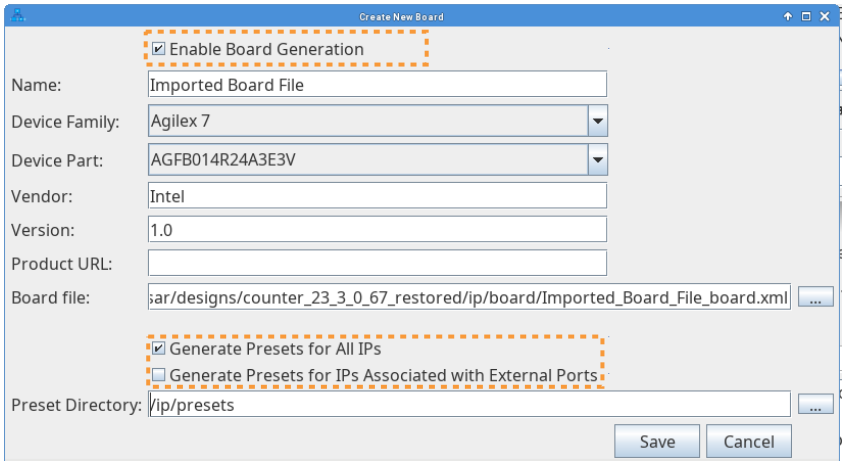
To apply board and preset files to an existing Platform Designer system using the Platform Designer GUI, you first load the pin assignments from the Quartus Prime Settings File (`.qsf`). You then define a new board file that overwrites any existing board file and IP presets. You must ensure that either the **Generate Presets for All IPs** or **Generate Presets for IPs Associated with External Ports** option is on when defining the new board. For details on creating IP presets, refer to Creating IP Presets Targeting Specific Boards.

Note: Before using this flow, you must regenerate the Platform Designer system and run Quartus Prime Analysis and Synthesis.

To apply board and preset files to an existing system using Platform Designer, follow these steps:

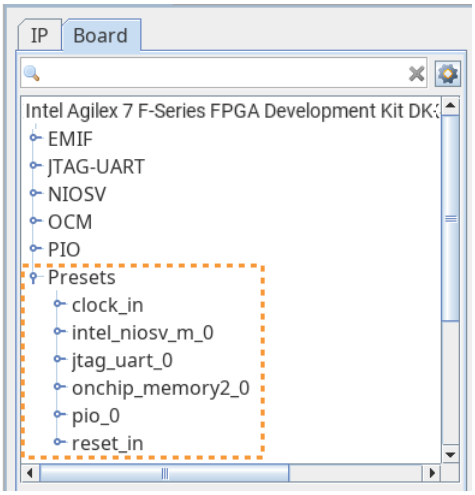
1. In the Quartus Prime software, open and compile the project that contains the target Platform Designer system for board and preset files. The Fitter selects the pin assignments or uses the constraints that you specify in the Pin Planner.
2. In Platform Designer, open the target system for application of board and preset files.
3. Click **File ➤ Load Pin from Quartus Project**. The pin assignments from the current Quartus Prime project load into the Platform Designer system.
4. Confirm the loaded pin assignments in the **Exported Interface** tab, as Editing Pin Assignments for Presets on page 53 describes.
5. Define a new board and presets by clicking **New** in the Platform Designer Board Catalog. The **Create New Board** dialog box opens.

Figure 15. Create New Board Dialog Box



6. Specify options for the new board file, as Creating a New Board File on page 22 describes. When specifying options, turn on the **Enable Board Generation** and either **Generate Presets for All IPs** or **Generate Presets for IPs Associated with External Ports** to overwrite any existing board or preset files for the system.
7. Click **Save** to generate the new board and preset files.
8. View the new system presets in the **Board** tab.

Figure 16. System Presets in Board Tab



1.4.3.2. Generating Presets for Existing Systems with Multiple Instances

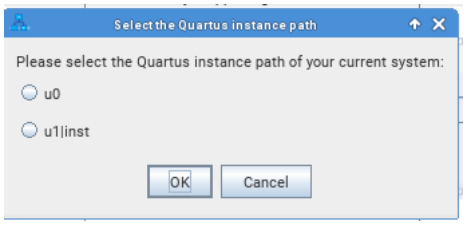
Note: Before using this flow, you must regenerate the Platform Designer system and run Quartus Prime Analysis and Synthesis.

When generating presets for existing Platform Designer systems with two or more separate instances, Platform Designer displays a prompt allowing you to select the relevant instance for the presets.

To generate presets for existing systems with multiple instances, follow these steps:

1. In Platform Designer, open the target system for application of system preset files.
2. Click **File ➤ Load Pin from Quartus Project**.
3. If the system contains more than one instance, select the appropriate instance path and click **OK** to confirm the correct instance path in the dialog box that appears.

Figure 17. Select the Instance Path



The pin assignments from the current Quartus Prime project load into the Platform Designer system.

4. Confirm the loaded pin assignments in the **Exported Interface** tab, as Editing Pin Assignments for Presets on page 53 describes.
5. Define a new board and presets by clicking **New** in the Platform Designer Board Catalog. The **Create New Board** dialog box opens.

6. Specify options for the new board file, as Creating a New Board File on page 22 describes. When specifying options, turn on the **Enable Board Generation** and **Enable System Preset Generation** to overwrite any existing board or preset files for the system.
7. Click **Save** to generate the new board and preset files.
8. View the new system presets in the **Board** tab.

1.4.3.3. Generating Board and Presets for Existing Systems Using Command Line

The command line method of applying board and presets to existing systems implements the same steps in a script that you can perform in the Platform Designer GUI. To apply board and preset files to an existing Platform Designer system using the command line, you must first create a Tcl script that performs the following:

1. Loads the correct Platform Designer package version number with `package require`.
2. Imports the pin assignments from the corresponding Quartus Prime Setting file (`.qsf`) with `load_pin_from_quartus_project`.
3. Saves the system to apply the pin assignment to the system with `save_system`.
4. Exports the system or IP presets and board file with `export_system_preset`.

The following shows an example script that implements these steps:

```
package require -exact qsys <version number>
load_pin_from_quartus_project
save_system
export_system_preset test_preset.qprs
export_board_file "<board name>" <filename_board.xml>
```

Note: The *<version number>* must be 22.4 or later.

The following command runs the example script:

```
$ qsys-script --script=export.tcl --quartus-project=[test_project] \
     --system-file=[test_system.qsys]
```

The following example shows the content of `export.tcl` if there is one instance in a Platform Designer system in the project:

```
package require -exact qsys 22.4
load_pin_from_quartus_project
export_system_preset ip/presets
export_board_file "My Board" test_board.xml
```

The following example shows the content of `export.tcl` if there is more than one instance in a Platform Designer system in the project:

```
package require -exact qsys 22.4
set instance_paths [get_quartus_instance_path_for_entity]

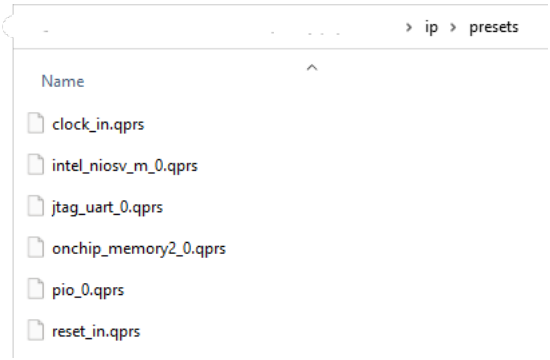
# select the correct Quartus instance path for your \
    Platform Designer system (e.g using the 1st path)

set my_instance_path [lindex $instance_paths 0]
load_pin_from_quartus_project $my_instance_path
export_system_preset ip/presets
export_board_file "My Board" test_board.xml
```

1.4.3.4. Preset Files Saved

After you create system presets using System Preset Generation, each of the presets for each of the IP in the Platform Designer system save into different `.qprs` files to ensure easier modification (if needed) for preset `.qprs` files. For better organization, you can create a specific folder for presets only, as the following example shows.

Figure 18. Example of Preset Files Saved



1.5. Viewing a Platform Designer System

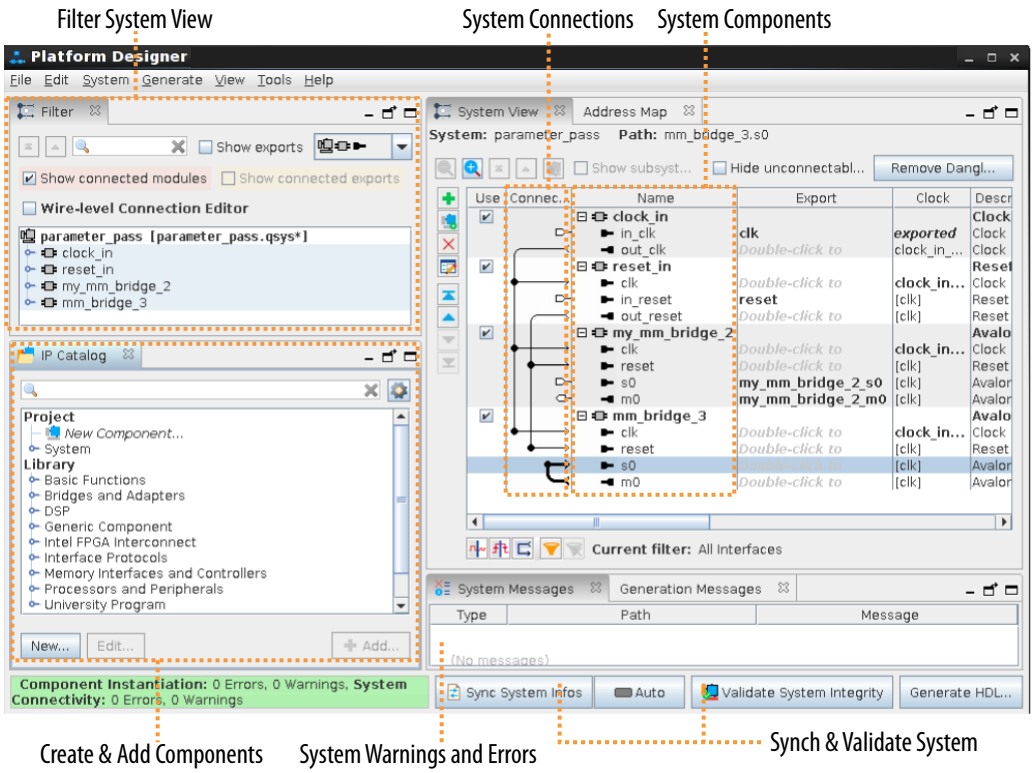
Platform Designer allows you to visualize all aspects of your system. By default, Platform Designer displays the contents of your system in the **System View** tab whenever you open a system. You can also access other tabs that allow you to view and modify various elements of the system.

When you select or edit an item in one Platform Designer tab, all other tabs update to reflect your selection or edit. For example, if you select the `cpu_0` in the **Hierarchy** tab, the **Parameters** tab immediately updates to display `cpu_0` parameters.

Click the View menu to interact with the elements of your system in various tabs.

- The **System View**, **Address Map**, **Exported Interfaces**, and **Details** tabs display in the central pane.
- By default, the **IP Catalog** and **Filter** tabs appear to the left of the **System View** tab.
- **Parameters**, **System Info**, and **Component Instantiation** tabs appear to the right of the **System View** tab when you open them.
- The **System Messages** and **Generation Messages** tabs display in the lower portion of Platform Designer.

Figure 19. Platform Designer GUI



The Platform Designer GUI is fully customizable. You can arrange and display Platform Designer GUI elements that you most commonly use, and then save and reuse useful GUI layouts.

1.5.1. Viewing the System Hierarchy

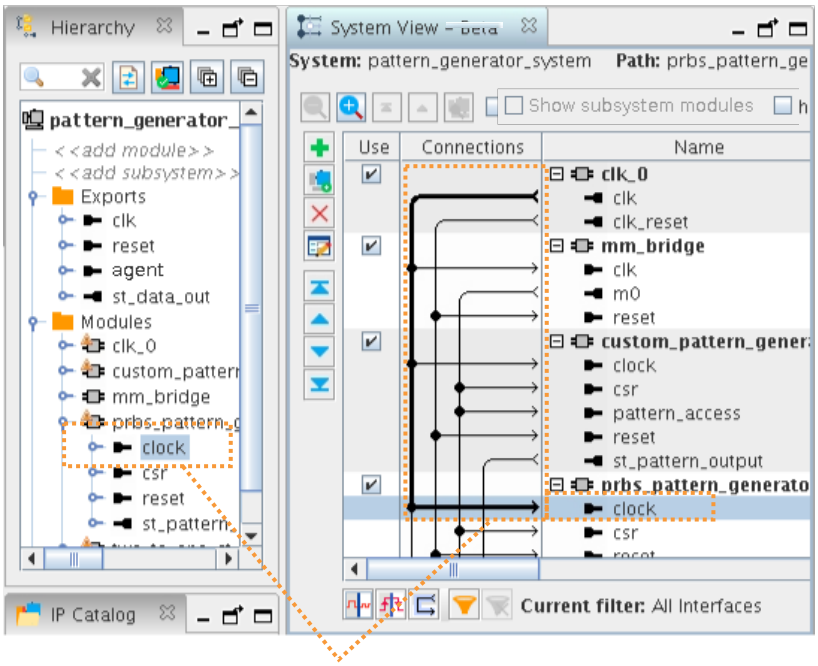
The **Hierarchy** tab hierarchically displays the modules, connections, and exported signals in the current system. You can expand and traverse though the system hierarchy, zoom in for detail, and locate to elements in other Platform Designer panes.

The **Hierarchy** tab provides the following information and functionality:

- Lists connections between components.
- Lists names of signals in exported interfaces.
- Right-click to connect, edit, add, remove, or duplicate elements in the hierarchy.
- Displays internal connections of Platform Designer subsystems that you include as IP components. By contrast, the **System View** tab displays only the exported interfaces of Platform Designer subsystems.

Click the **+** icon to expand any interface in the **Hierarchy** tab to view sub-components, associated elements, and signals for the interface. The **Hierarchy** tab displays a unique icon for each element type in the system. In the example below, the `clock` signal for the `prbs_pattern_generator` is selected in both the **System View** and **Hierarchy** tabs.

Figure 20. Expanding System View in the Hierarchy Tab



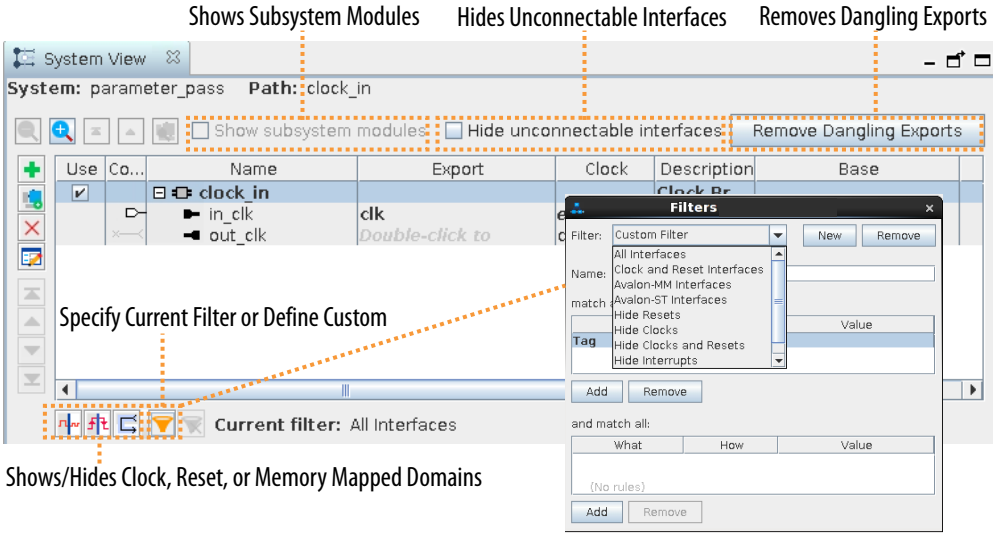
1.5.2. Filtering the System View

You can use the filtering controls in **System View** and the **Filter** tab to change the level of detail in the **System View**. You can filter for various component characteristics, such as component, interface type, or instance name. Filtering the System View allows you to simplify the display and focus only on the items you want.

Table 4. System View Tab Filtering Controls

Filter Control	Description
Filter Button	Defines the type of interfaces that the System View displays. The options are **Clock and Reset**, **Avalon Memory Mapped Interfaces**, **Avalon Streaming Interfaces**, **Hide Resets**, **Hide Clocks**, **Hide Clocks and Resets**, **Hide Interrupts**, or a **Custom Filter** that you define.
Show Memory Mapped domains in the system table button	Shows or hides all Avalon memory mapped domains present in the system in the **System View**.
Show reset domains in the system table	Shows or hides all reset domains in the system in the **System View**.
Show clock domains in the system table	Shows or hides all clock domains in the system in the **System View**.
Show connected modules	Shows or hides the modules that have connections in the **System View**.
Hide unconnectable interfaces	Shows or hides the modules not available for connection in the **System View**.
Remove Dangling Exports	Removes unconnected exported connections from the **System View**.

Figure 21. Filter Controls in System View Tab



The **Filter** tab offers other filtering controls that change the display of components in the **System View**. Select one or more components on the **Filter** tab (**View ➤ Filter**) to display only the selected component in the **System View** tab.

Figure 22. Filter Tab

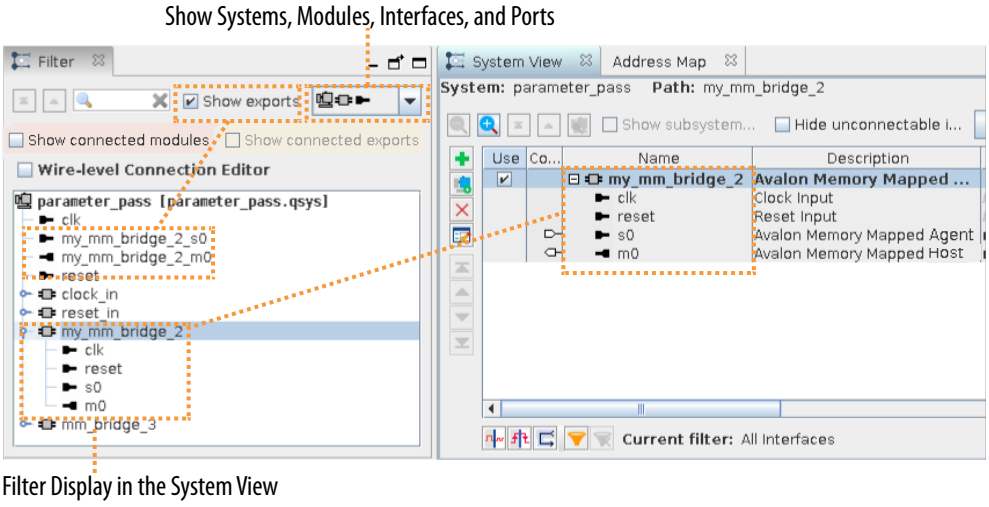


Table 5. Filter Tab Filtering Controls

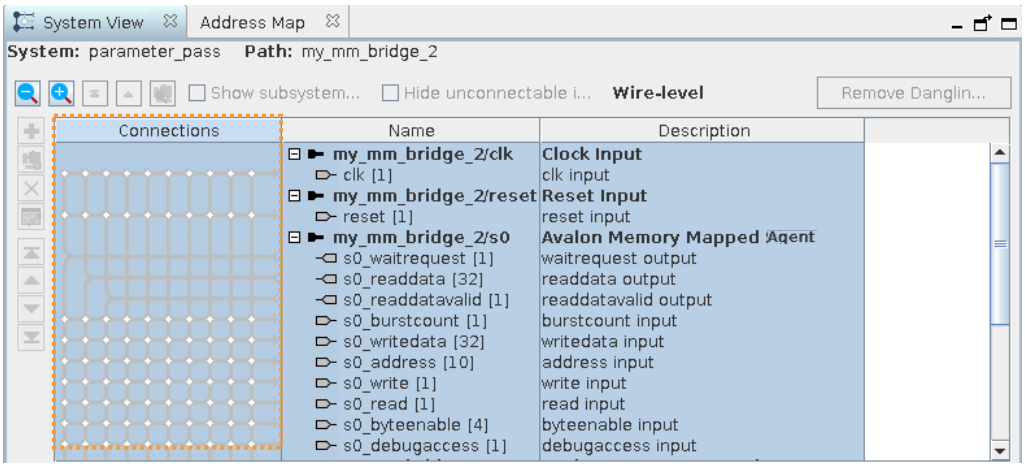
Filter Control	Description
Search text field	In the **Filter** tab, displays the system, module, interface, and port names that match the text string you enter.
Show exports option	In the **Filter** tab, shows or hides the interfaces that you export.
Tree display list	In the **Filter** tab, specifies the level of detail to display. Show or hide all systems, modules, interfaces, and ports.

continued...

Filter Control	Description
Show connected modules option	In the **System View**, shows or hides the modules that have connections to the items that you select in the **Filter** tab tree.
Show connected exports	In the **System View**, shows or hides the exports that have connections to the items that you select in the **Filter** tab tree.
Wire-level Connection Editor	In the **System View**, shows or hides all wire-level connections in the Connections column.

Figure 23. Wire-level Connection Editor



1.5.3. Viewing Clock and Reset Domains

The Platform Designer **Clock Domains** and **Reset Domains** tabs list the clock and reset domains in the Platform Designer system, respectively.

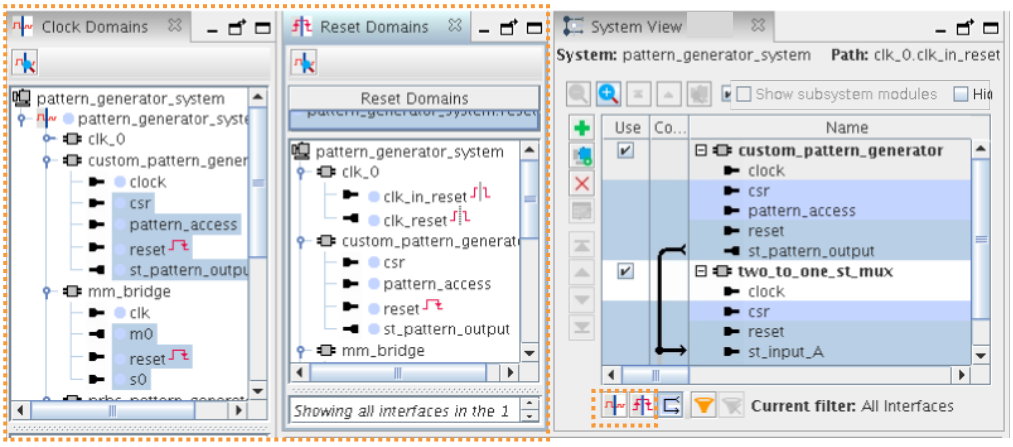
Click **View ➤ Clock Domains** or click **View ➤ Reset Domains** to display these tabs.

Platform Designer determines clock and reset domains by the associated clocks and resets. This information displays when you hover over interfaces in your system.

The **Clock Domains** and **Reset Domains** tabs also allow you to locate system performance bottlenecks. The tabs indicate connection points where Platform Designer automatically inserts clock-crossing adapters and reset synchronizers during system generation. View the following information on these tabs to create optimal connections between interfaces:

- The number of clock and reset domains in the system
- The interfaces and modules that each clock or reset domain contains
- The locations of clock or reset crossings
- The connection point of automatically inserted clock or reset adapters
- The proper location for manual insertion of a clock or reset adapter

Figure 24. Clock Domains, Reset Domains, and System View Tabs



1.5.3.1. Viewing Clock Domains in a System

You can filter the **System View** tab to display a single clock domain, or multiple clock domains. When you select an element in the **Clock Domains** tab, the corresponding selection appears highlighted in the **System View** tab.

Follow these steps to filter and highlight clock domains in the **System View**:

1. Click **View ➤ Clock Domains**.
2. Select any clock or reset domain in the list to view associated interfaces. The corresponding selection appears in the **System View** tab.
3. To highlight clock domains in the **System View** tab, click **Show clock domains in the system table** or at the bottom of the **System View** tab.

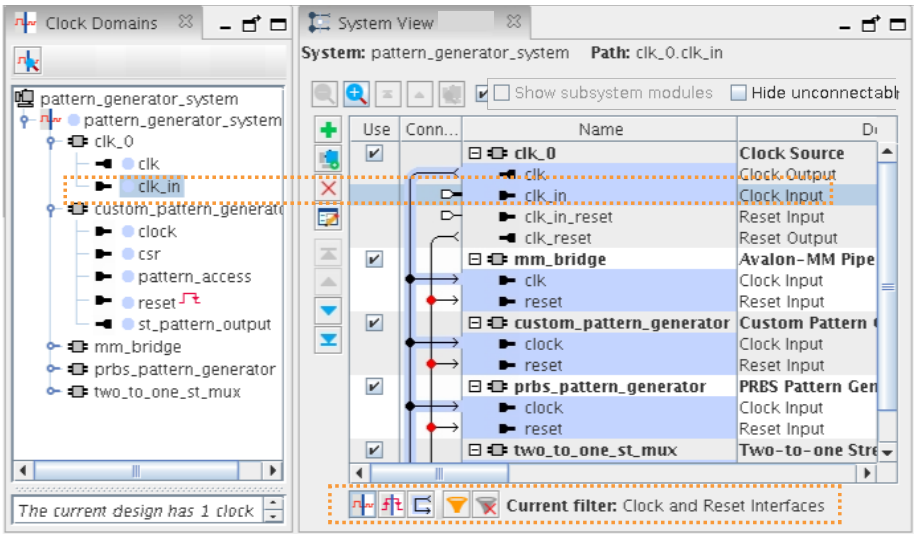
Figure 25. Shows Clock Domains in the System Table

4. To view a single clock domain, or multiple clock domains and their modules and connections, select the clock name or names in the **Clock Domains** tab. The modules for the selected clock domain or domains and connections highlight in the **System View** tab. Detailed information for the current selection appears in the clock domain details pane.

   Note: If a connection crosses a clock domain, the connection circle appears as a red dot in the **System View** tab

5. To view interfaces that cross clock domains, expand the **Clock Domain Crossings** icon in the **Clock Domains** tab, and select each element to view its details in the **System View** tab.

Figure 26. Selected Clock in Clock Domains and System View Tabs



Platform Designer lists the interfaces that cross clock domains under **Clock Domain Crossings**. As you click through the elements, detailed information appears in the clock domain details pane. Platform Designer also highlights the selection in the **System View** tab.

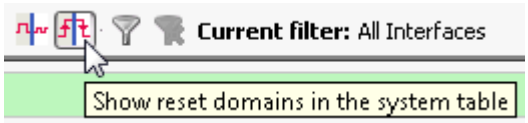
1.5.3.2. Viewing Reset Domains in a System

On the **Reset Domains** tab, you can filter the **System View** tab to display a single reset domain, or multiple reset domains. When you select an element in the **Reset Domains** tab, the corresponding selection appears in the **System View** tab.

Follow these steps to filter and highlight reset domains in the **System View**:

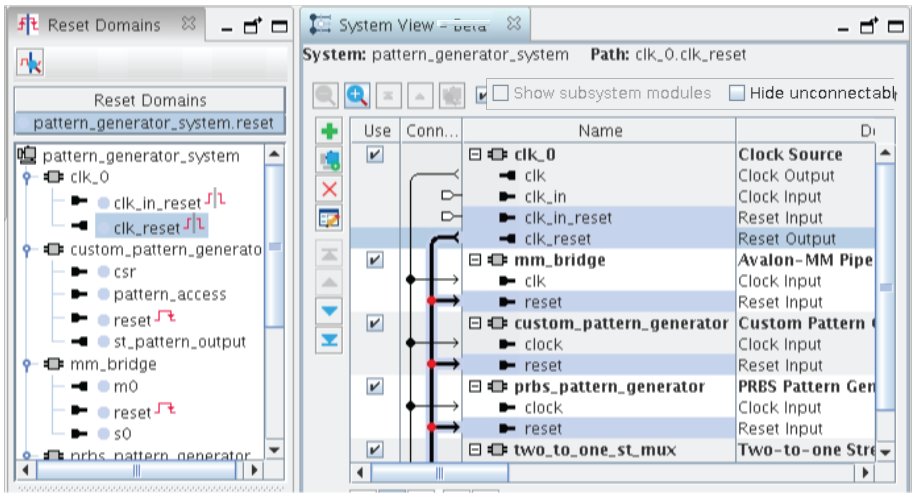
1. To open the **Reset Domains** tab, click **View ➤ Reset Domains**.
2. To show reset domains in the **System View** tab, click the **Show reset domains in the system table** icon in the **System View** tab.

Figure 27. Show Reset Domains in the System Table



3. To view a single reset domain, or multiple reset domains and their modules and connections, click the reset names in the **Reset Domain** tab.

Figure 28. Selected Reset Signal in Reset Domains and System View Tabs



Platform Designer displays your selection according to the following rules:

- When you select multiple reset domains, the **System View** tab shows interfaces and modules in both reset domains.
- When you select a single reset domain, the other reset domains are grayed out, unless the two domains have interfaces in common.
- Reset interfaces appear black when connected to multiple reset domains.
- Reset interfaces appear gray when they are not connected to all of the selected reset domains.
- If an interface is contained in multiple reset domains, the interface is grayed out.

Detailed information for your selection appears in the reset domain details pane. Red dots in the **Connections** column between reset sinks and sources indicate auto insertions by Platform Designer during system generation, for example, a reset synchronizer. Platform Designer decides when to display a red dot with the following protocol, and ends the decision process at first match.

- Multiple resets fan into a common sink.
- Reset inputs are associated with different clock domains.
- Reset inputs have different synchronicity.

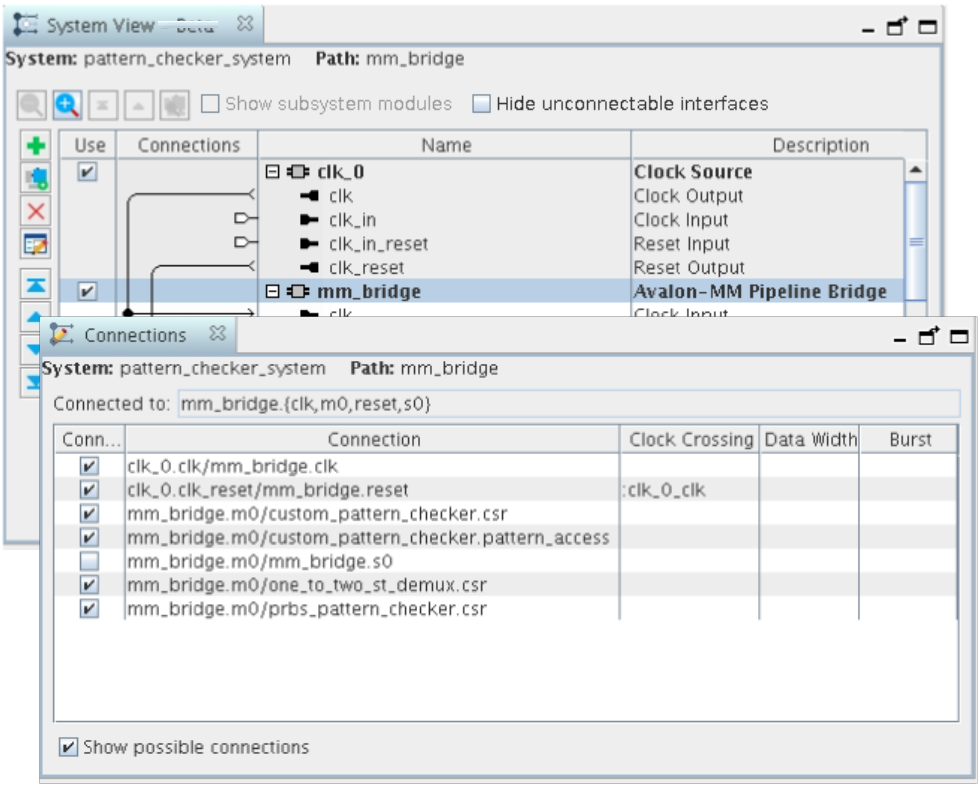
1.5.4. Viewing System Connections

The **Connections** tab allows you to connect or un-connect every connection in the Platform Designer system.

Click **View ➤ Connections** to display this tab.

If you connect or unconnect modules on the **Connections** tab, the connection immediately updates in the **System View** tab. You can also make connections in the **System View** tab directly.

Figure 29. Connections tabs in Platform Designer



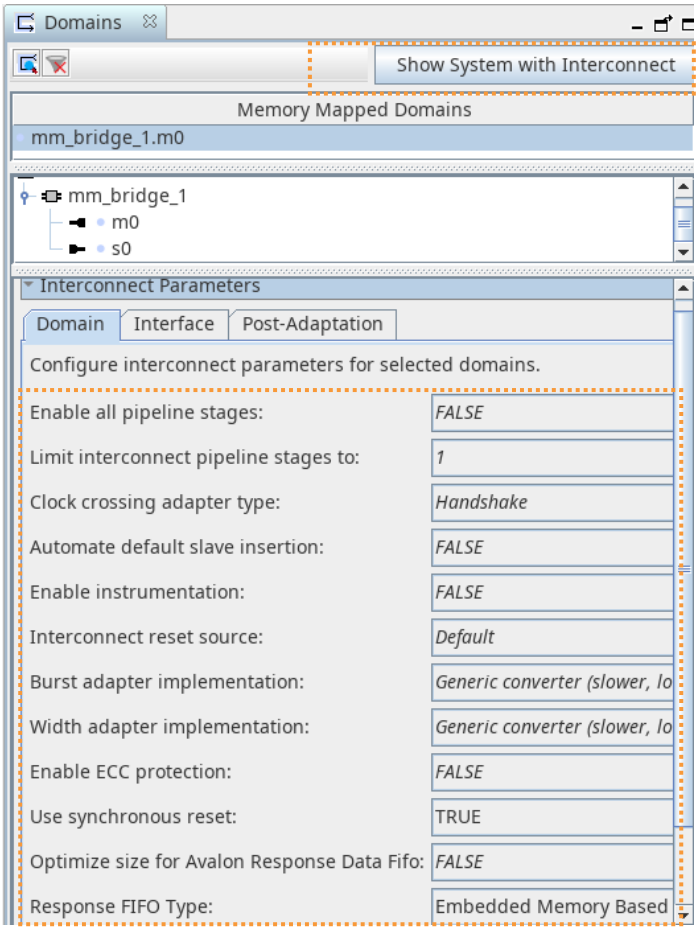
1.5.5. Viewing Avalon Memory-Mapped Domains in a System

The **Domains** tab displays a list of all the Avalon memory mapped domains in the system, allowing you to specify interconnect parameters. When you select a domain in the **Domains** tab, the corresponding selection highlights in the **System View** tab.

Click **View ➤ Domains** to display this tab.

- Filter the **System View** tab to display a single Avalon domain, or multiple domains. Further filter your view with selections in the **Filters** dialog box.
- To rename an Avalon memory-mapped domain, double-click the domain name. Detailed information for the current selection appears in the Avalon domain details pane.
- On the **Domain** tab, specify interconnect parameters, as Specifying Interconnect Parameters on page 71 describes.
- To enable and disable the highlighting of the Avalon domains in the **System View** tab, click the domain control tool at the bottom of the **System View** tab.

Figure 30. Domains Tab



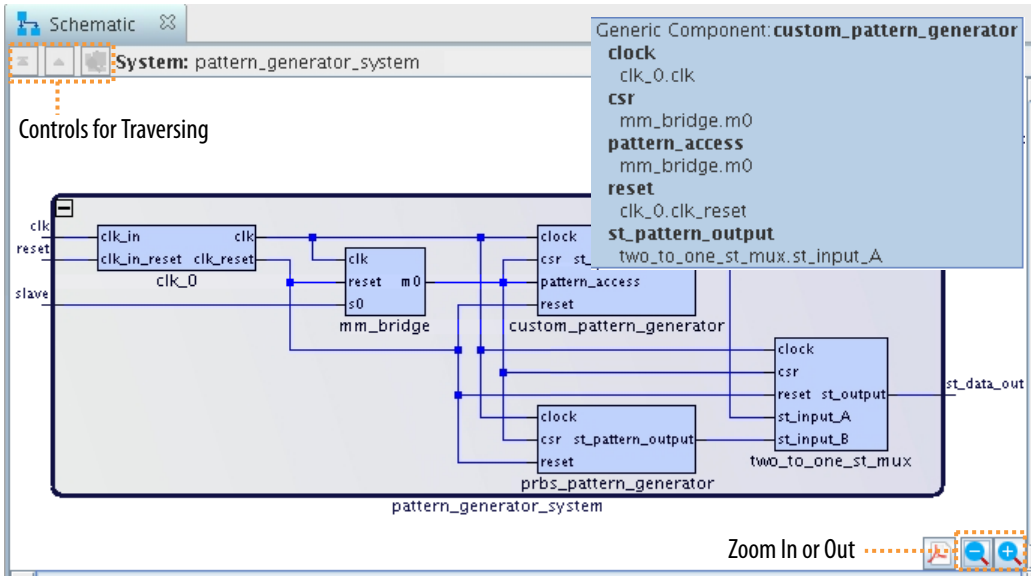
1.5.6. Viewing the System Schematic

The **Schematic** tab displays a schematic representation of the current Platform Designer system. You can zoom into a component or connection to view more details. You can use the image handles in the right panel to resize the schematic image.

Click **View ➤ Schematic** to display this tab.

If your selection is a subsystem, You can use the **Move to the top of the hierarchy** **Move up one level of hierarchy**, and **Drill into a subsystem to explore its contents** buttons to traverse the schematic of a hierarchical system.

Figure 31. Schematic Tab



Related Information

Editing a Subsystem on page 110

1.5.7. Customizing the Platform Designer Layout

You can arrange your workspace by dragging and dropping, and then grouping tabs in an order appropriate to your design development, or close or dock tabs that you are not using.

Dock tabs in the main frame as a group, or individually by clicking the tab control in the upper-right corner of the main frame. Tool tips on the upper-right corner of the tab describe possible workspace arrangements, for example, restoring or disconnecting a tab to or from your workspace.

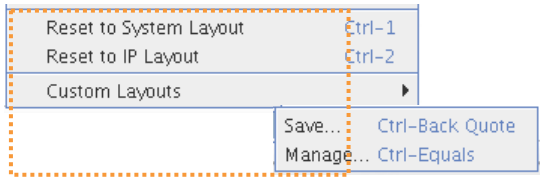
When you save your system, Platform Designer also saves the current workspace configuration. When you re-open a saved system, Platform Designer restores the last saved workspace.

The **Reset to System Layout** command on the View menu restores the workspace to its default configuration for Platform Designer system design. The **Reset to IP Layout** command restores the workspace to its default configuration for defining and generating single IP cores.

Follow these steps to customize and save the Platform Designer layout:

1. Click items on the View menu to display and then optionally dock the tabs. Rearrange the tabs to suit your preferences.
2. To save the current Platform Designer window configuration as a custom layout, click **View ➤ Custom Layouts ➤ Save**. Platform Designer saves your custom layout in your project directory, and adds the layout to the custom layouts list, and the `layouts.ini` file. The `layouts.ini` file determines the order of layouts in the list.

Figure 32. Platform Designer View Menu and Layouts



3. Use any of the following methods to revert to another layout:
   - To revert the layout to the default system design layout, click **View ➤ Reset to System Layout**. This layout displays the **System View**, **Address Map**, **Interconnect Requirements**, and **Messages** tabs in the main pane, and the **IP Catalog** and **Hierarchy** tabs along the left pane.
   - To revert the layout to the default system design layout, click **View ➤ Reset to IP Layout**. This layout displays the **Parameters** and **Messages** tabs in the main pane, and the **Details**, **Block Symbol**, and **Presets** tabs along the right pane.
   - To reset your Platform Designer window configuration to a previously saved layout, click **View ➤ Custom Layouts**, and then select the custom layout.
   - Press Ctrl+3 to quickly change the Platform Designer layout.
4. To manage your saved custom layouts, click **View ➤ Custom Layouts**. The **Manage Custom Layouts** dialog box opens and allows you to apply a variety of functions that facilitate custom layout management. For example, you can import or export a layout from or to a different directory.

1.5.8. Changing the Platform Designer Font

Click **Tools ➤ Options ➤ Fonts** to change the font name, style, and size in Platform Designer to suit your viewing preferences. A **Sample** pane displays a font example. Click **Finish** to apply the setting.

Note: Some GUI elements may require refresh (reopening) before font changes are visible. Platform Designer prompts you to restart Platform Designer after changing font settings so that font changes appear throughout.

You can click the **Reset Font** button to reset the Platform Designer font to the default value.

1.6. Adding IP Components to a System

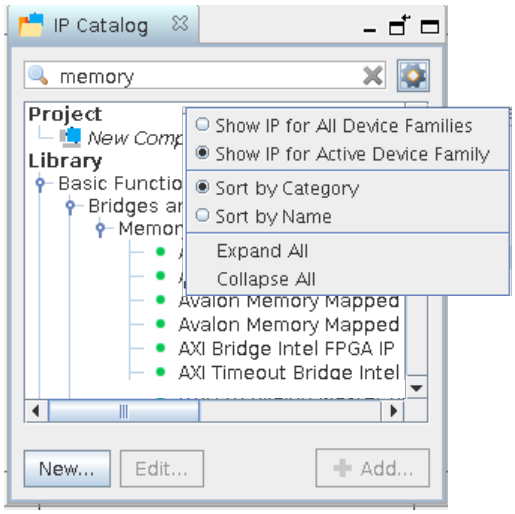
You can add Intel FPGA IP components to a system from the IP Catalog in Platform Designer. The IP Catalog launches a parameter editor for specifying options and generating the component's HDL. Your Platform Designer system can contain a single instance of an IP component, or multiple, individually parameterized variations of multiple or the same IP components.

When you first add Intel FPGA IP components to a system, Platform Designer automatically adds the IP as a generic component (except for HPS IP components). Generic components allow you to define only the interface and signal connections to the rest of the system, without immediately defining the HDL implementation.

To parameterize, and instantiate an IP component in a Platform Designer system:

1. Type some of the component's name in the IP Catalog search box to find the IP by name or category.

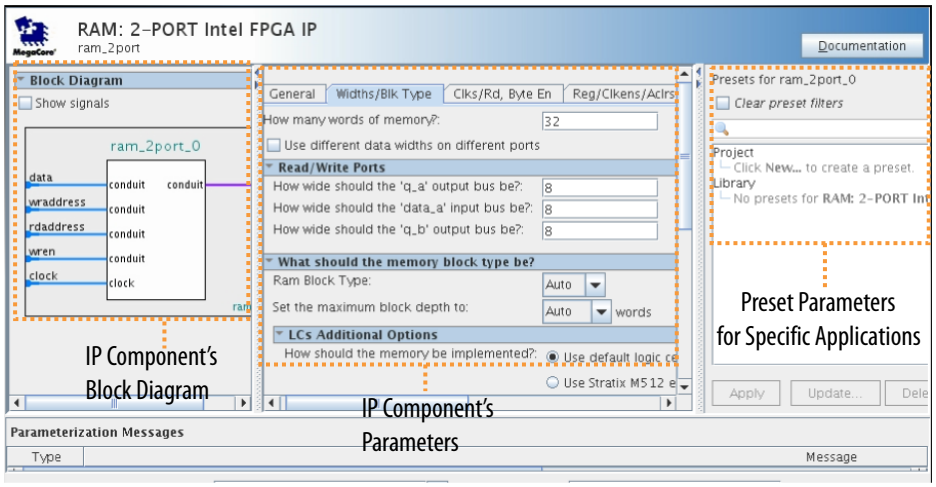
Figure 33. Platform Designer IP Catalog



2. Double-click any component to launch the parameter editor. The **Parameterization Messages** tab displays any parameterization errors.
3. After specifying parameters, click **Finish** to instantiate the component in the system. The IP component appears in the **System View** and **Component Instantiation** tabs. Platform Designer creates a corresponding `.ip` file for the IP component on instantiation, and stores the file in the <ip> folder in the project directory.

   Platform Designer instantiates a generic component in place of the actual IP core with a reference to the HDL entity name, module and interface assignments, compilation library, HDL ports, interfaces, and system-info parameters.

Figure 34. Parameter Editor



1.6.1. Modifying IP Parameters

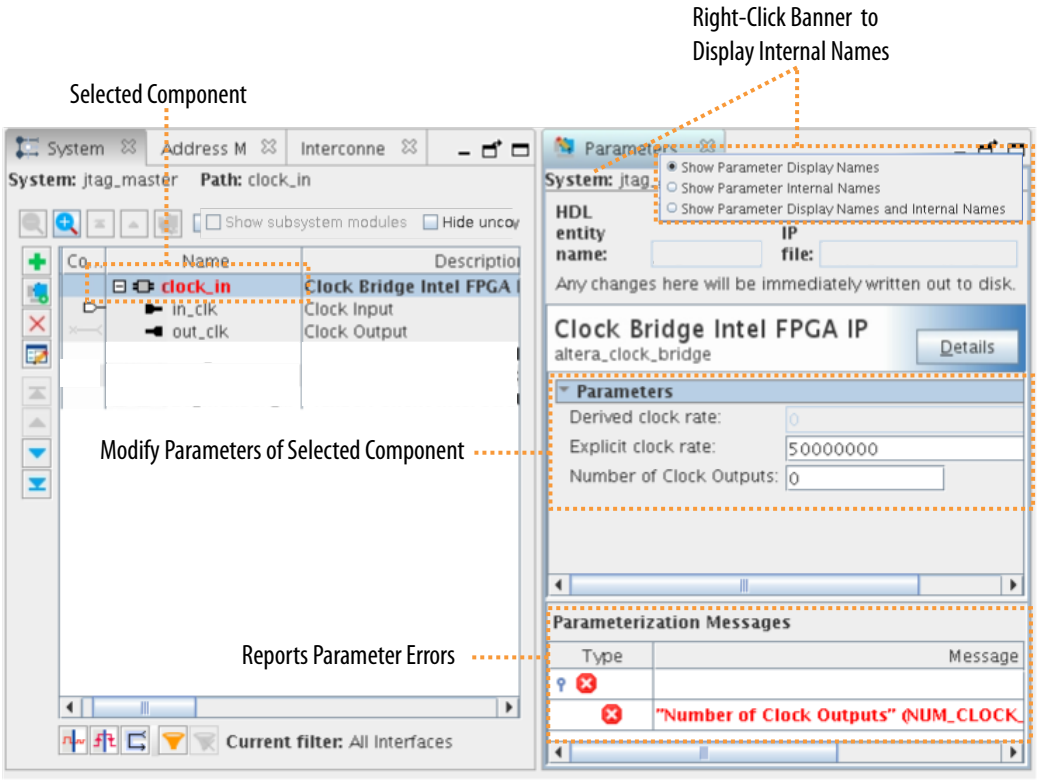
The **Parameters** tab allows you to view and edit the current parameter settings for IP components in your system.

To display a components parameters on the **Parameters** tab:

1. click **View ➤ Parameters**.
2. Select the component in the **System View** or **Hierarchy** tabs.

- **Parameters** field—adjust the parameters to align with your design requirements, including changing the name of the top-level instance.
- Component Banner—displays the hierarchical path for the component and internal names. Displays the HDL entity name and the IP file path for the selected IP component. Right-click in the banner to display internal parameter names for use with scripted flows.
- **Details**—displays links to detailed information about the component.
- **Parameterization Messages**—displays parameter warning and error messages about the IP component.

Figure 35. Platform Designer Parameters Tab



Changes that you make in the **Parameters** tab affect your entire system, and dynamically update other open tabs in Platform Designer. Any change that you make on the **Parameters** tab, automatically updates the corresponding `.ip` file that stores the component's parameterization.

If you create your own custom IP components, you can use the Hardware Component Description File (`_hw.tcl`) to specify configurable parameters.

Note: If you use the `ip-deploy` or `qsys-script` commands rather than the Platform Designer GUI, you must use internal parameter names with these parameters.

1.6.1.1. Viewing Component or Parameter Details

The **Details** tab provides information for a component or parameter that you select. Platform Designer updates the information in the **Details** tab as you select different components.

To view a component's details:

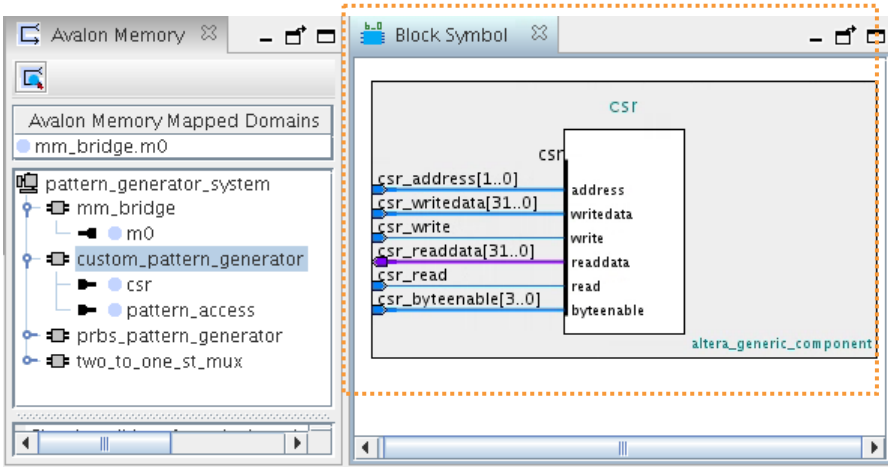
1. Click the parameters for a component in the parameter editor, Platform Designer displays the description of the parameter in the **Details** tab.
2. To return to the complete description for the component, click the header in the **Parameters** tab.

1.6.1.2. Viewing a Component's Block Symbol

The **Block Symbol** tab displays a symbolic representation of any component you select in the **Hierarchy** or **System View** tabs. The block symbol shows the component's port interfaces and signals. The **Show signals** option allows you to turn on or off signal graphics.

The **Block Symbol** tab appears by default in the parameter editor when you add a component to your system. When the **Block Symbol** tab is open in your workspace, it reflects changes that you make in other tabs.

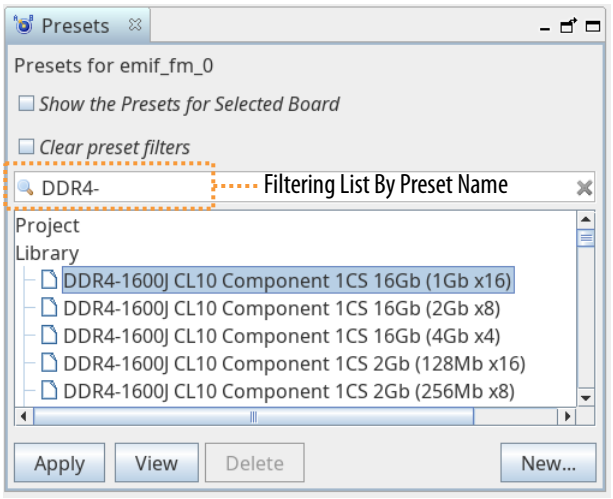
Figure 36. Block Symbol Tab



1.6.2. Applying Preset Parameters for Specific Applications

The **Preset** tab displays the names of available preset settings for an IP component. A preset is a specific collection of parameter settings that are appropriate for a specific protocol, application, or board. Double-click the preset name (or click **Apply**) to instantly apply the parameter values defined in the preset to the current IP instance.

Figure 37. Selecting Preset Parameters



1.6.2.1. Customizing IP Presets

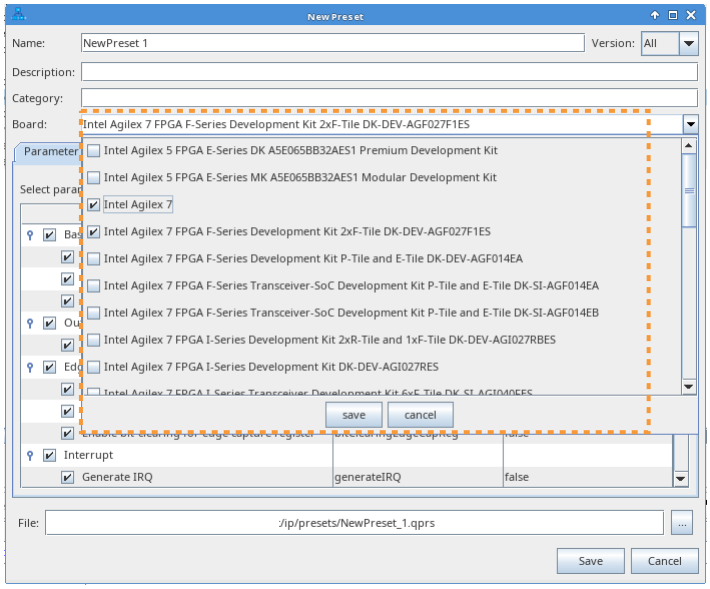
You can optionally define and save a custom set of parameter settings as an IP preset, and then apply the preset whenever you add an instance of the IP component to any system.

Follow these steps to save a custom IP preset:

1. In IP Catalog, double-click any component to launch the parameter editor.
2. To search for a specific preset to base initial settings, type a partial preset name in the search box.
3. In the **Presets** tab, click **New** to specify the **Preset name** and **Preset description**.
4. In the **Board** dropdown, specify the target board. The **Default** setting specifies the current board as the target board for this preset.

   Note: You can specify multiple boards for a preset, provided that the preset parameters and assignments are applicable to all boards in the preset.
5. Under **Select parameters to include in the preset**, enable or disable the parameters you want to include in the preset.
6. Specify the path for the **Preset file** that preserves the collection of parameter settings. The location of the new `.qprs` preset file is added to the IP search path automatically.

Figure 38. Create New Preset

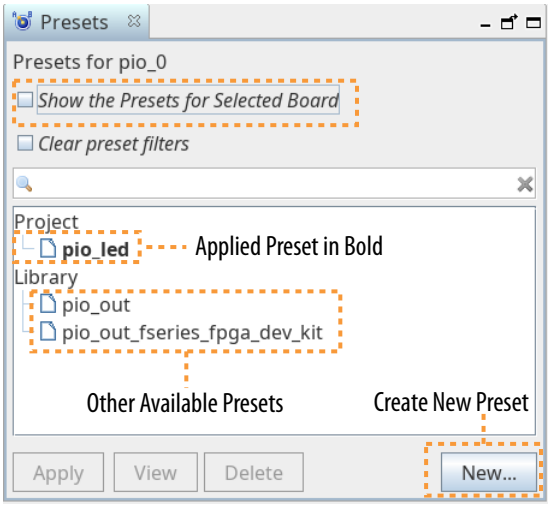


7. Click **Save**.
8. To apply the preset to an IP component, click **Apply**. Preset parameter values that match the current parameter settings appear in bold.

1.6.3. Creating IP Presets Targeting Specific Boards

Use the **Presets** tab in Platform Designer to define a custom group of preset parameter settings and pin assignments appropriate for the target board.

Figure 39. Presets Tab Displays Available IP Presets



You can apply the presets to IP, view and delete presets, and filter presets by board name in the **Presets** tab. If you click on any IP in the **System View**, the **Presets** tab displays the associated presets for each board. Turn off **Show the Presets for**

Selected Board to display all available presets for the IP. Turn off this option to view and apply preset files that do not contain board and pin information located under the **Library**.

Note: You cannot edit a preset in the **Preset** tab. Rather than editing an existing preset, create a new preset.

When you define an IP preset in the **Presets** tab, an underlying `.qprs` file stores the following information about the preset:

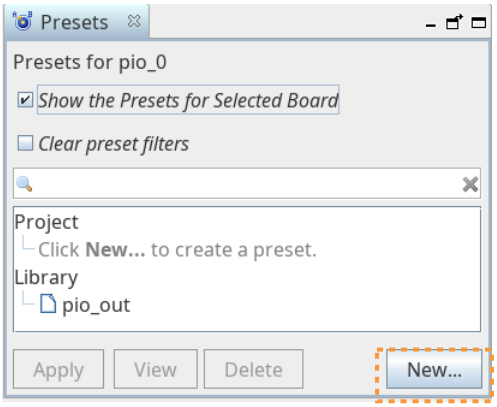
- Preset name
- Preset description
- Preset category
- Supported board
- Parameter settings
- Pin assignments

1.6.3.1. Creating IP Presets

To create an IP preset with appropriate parameters and pin assignments for the target board, follow these steps:

1. In the Platform Designer **System View**, select the IP that you want to create presets for and view the **Presets** tab (**View > Presets**).
2. In the **Presets** tab click the **New** button to define a new IP preset file for the IP. The **New Preset** dialog box appears.

Figure 40. Presets Tab



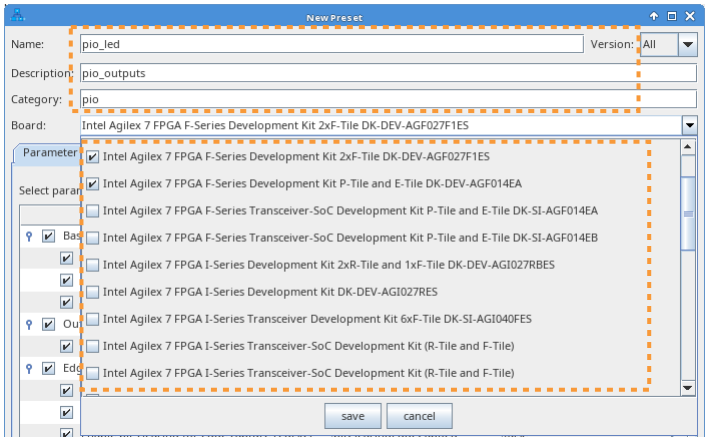
3. Enter a **Preset name**, **Preset description**, and **Category**.

Figure 41. New Preset Dialog Box

4. In the **Board** list, specify the target board. The **Default** setting specifies the current board as the target board for this preset.

   Note: You can specify multiple boards for a preset, provided that the preset parameters and assignments are applicable to all boards in the preset.

Figure 42. Create New Preset



5. On the **Parameter Settings** tab, enable or disable the appropriate parameters for your target board.
6. To specify pin location and I/O standard assignments for the preset, click the **Pin Assignments** tab.
7. For the exported interfaces, turn on the **external_connection** checkbox and enter the exported signal name in the **Exported Name** cell.

   Note: You can change the interface and signal names by double-clicking cells under **Exported Name**. Alternatively, you can type the pin locations and I/O standard details in the cell without using the **Board** dropdown.
8. Select the appropriate **Pin Location** and **IO Standard** for each exported signal. Refer to Defining Preset Pin Assignments.
9. By default, the **Preset file** setting suggests a `.qprs` file name based on the **Preset name**.
10. Click **Save**. The new IP preset appears in the **Presets** tab. Manage presets in the **Presets** tab, as Viewing, Applying, and Deleting IP Presets on page 50 describes.

Figure 43. Pin Assignments in New Preset Dialog Box

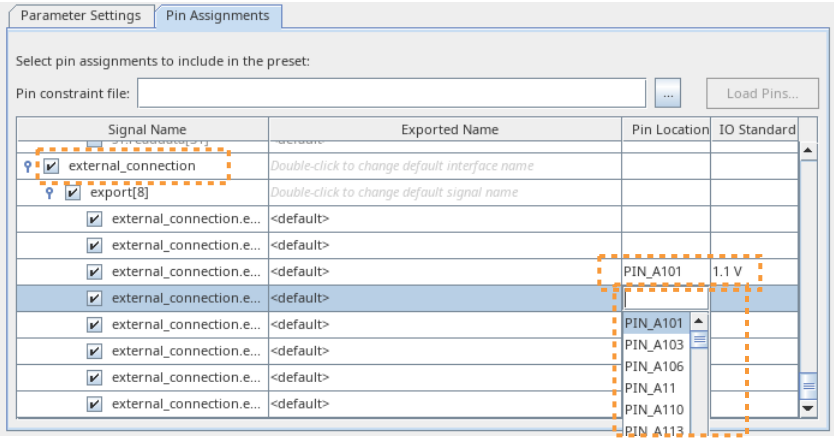


Figure 44. New pio_led Preset Appears in Presets Tab

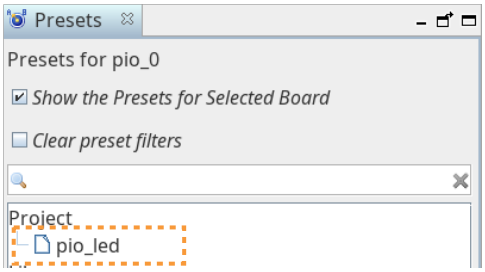


1.6.3.2. Defining Preset Pin Assignments

You can define pin assignments that are included as part of an IP preset. When you apply the IP preset to an IP instance, the pin assignments export during the IP or system's HDL generation.

You define preset pin assignments in the **Pin Assignments** tab of the **New Preset** dialog box, or in a Pin Assignments File (`.tcl`) that you create.

1.6.3.2.1. Defining Preset Pin Assignments in Pin Assignments Tab

The **Pin Assignments** tab allows you to specify the **Exported Name** of the signals, to select the appropriate **Pin Location,** and to select the appropriate **IO Standard** for the target board.

By default, the **Exported Name** name takes the form of:

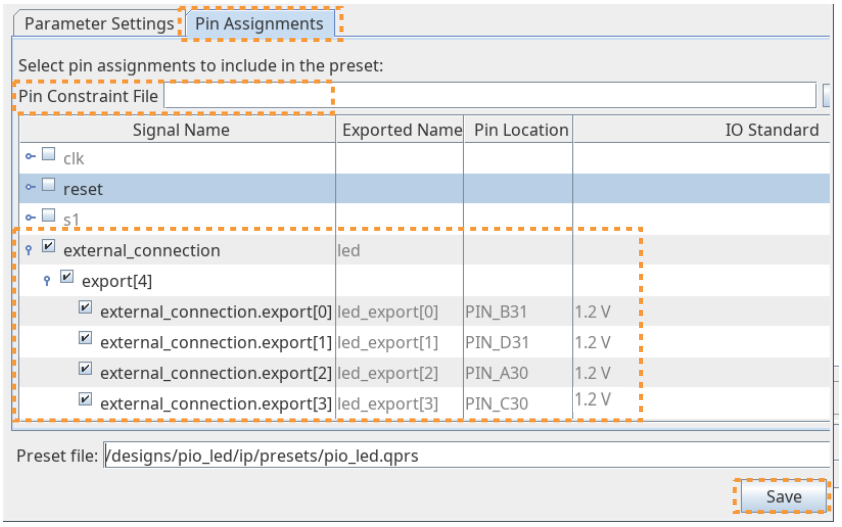
```
module_name + interface_name + pin_role
```

For example:

```
pio0_external_connection_export[0]
```

You can change the **Exported Name** by double-clicking on the **Exported Name** for the interface and typing a new name. All of the signals of the interface then update automatically to reflect the name you specify.

Figure 45. Pin Assignments Tab

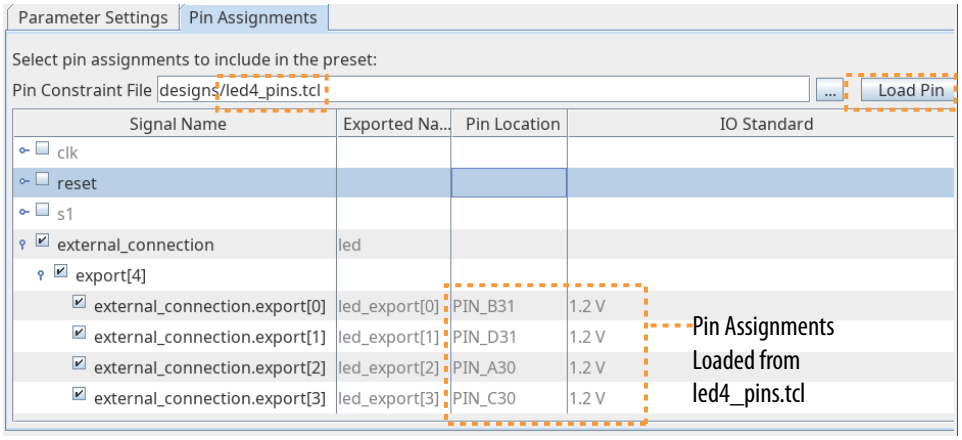


For example, typing `led` for the **external_connection** interface updates the signals of the interface to `led_export[n]`. The **external_connection** is the interface name, and **external_connection_export(0)** is the signal name.

1.6.3.2.2. Defining Preset Pin Assignments in a Pin File

Alternatively, you can specify the pin assignments in a Pin Constraints File (`.tcl`), which can be more efficient for projects with many ports. You specify this `.tcl` file as the **Pin Constraint File** on the **Pin Assignments** tab, and then click **Load Pin**. The **Pin Location** and **IO Standard** update per the loaded pin assignments.

Figure 46. Loading Pin Assignments from Tcl File



The following shows the contents of an example Pin Constraints File (`.tcl`):

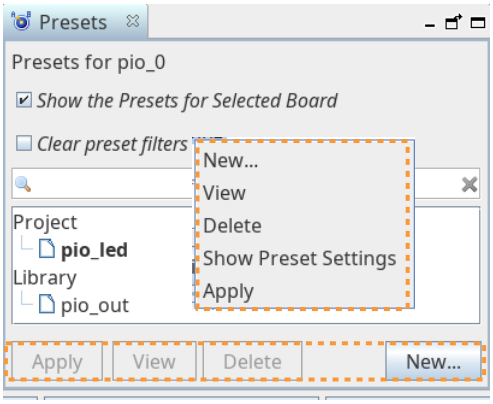
```
set_instance_assignment -to "led_export[0]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[0]" "PIN_B31"
set_instance_assignment -to "led_export[1]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[1]" "PIN_D31"
set_instance_assignment -to "led_export[2]" -name IO_STANDARD "1.2 V"
```

```
set_location_assignment -to "led_export[2]" "PIN_A30"
set_instance_assignment -to "led_export[3]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[3]" "PIN_C30"
```

1.6.3.3. Viewing, Applying, and Deleting IP Presets

You can view the properties of a preset, apply a preset, or delete any existing preset in the **Presets** tab.

Figure 47. View, Apply, and Delete Presets in Presets Tab

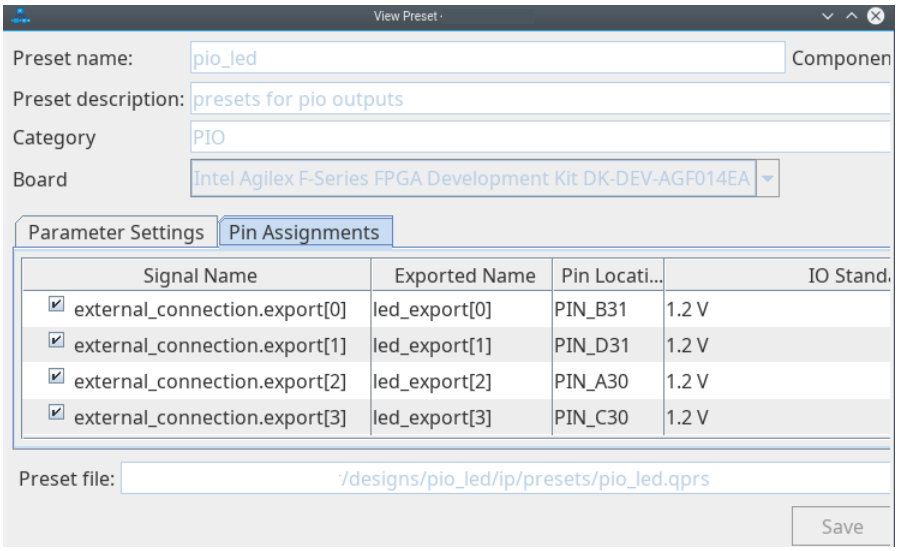


Note: Right-click a preset to access the same **View**, **Apply**, and **Delete** preset functions in the context menu.

Viewing Presets

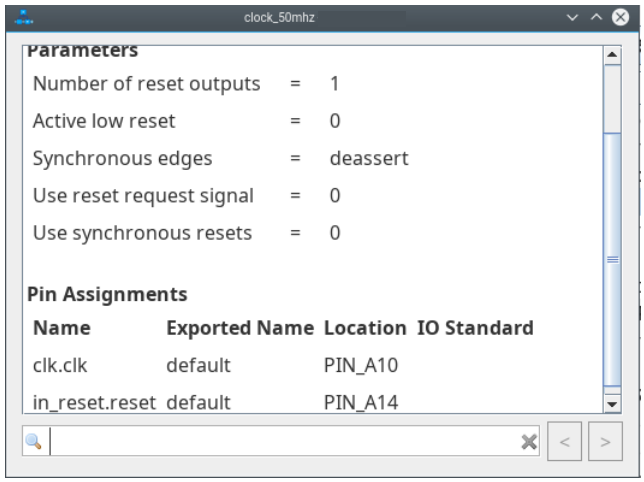
Click the **View** button to show the preset properties in the read-only **Update Preset** dialog box.

Figure 48. View Button Opens View Preset Dialog Box



Right-click a preset and click **Show Preset Settings** to view a searchable report of the preset settings.

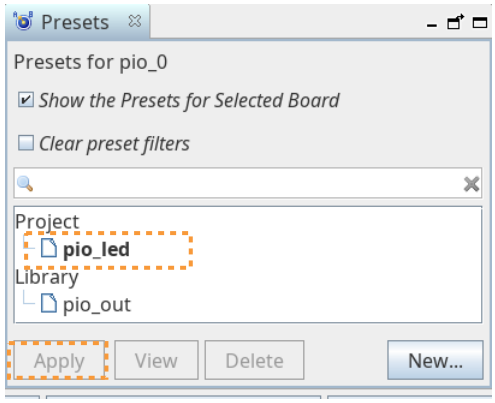
Figure 49. Show Preset Settings Searchable Report



Applying Presets to IP Instances

Click the **Apply** button (or double-click) to apply the IP preset to the currently selected IP. Applied presets appear in bold text.

Figure 50. Applied Presets Appear in Bold Text



Deleting Presets from the System

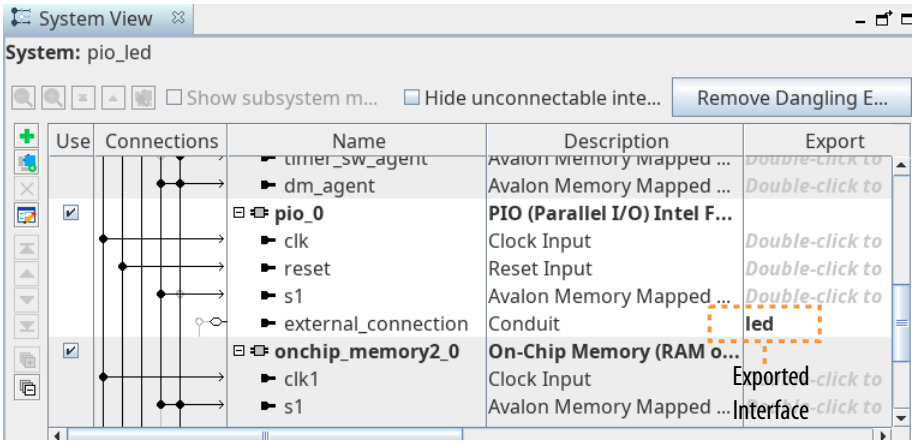
Click the **Delete** button to delete the current preset from the Platform Designer system.

1.6.3.4. Auto-Exporting IP Preset Interfaces and Pins

Once you apply a preset with pin assignments to an IP instance, Platform Designer automatically exports the preset interfaces that have pin constraints to external systems.

Note: If an IP with presets is not within the top-level Platform Designer system, you must export those interfaces as well.

Figure 51. Auto-Exported LED Interface IP Preset



After you click **Generate HDL** for the IP or system with pin assignment presets, Platform Designer automatically exports the pin assignments to the system `.qip` file for subsequent design compilation in the Quartus Prime software.

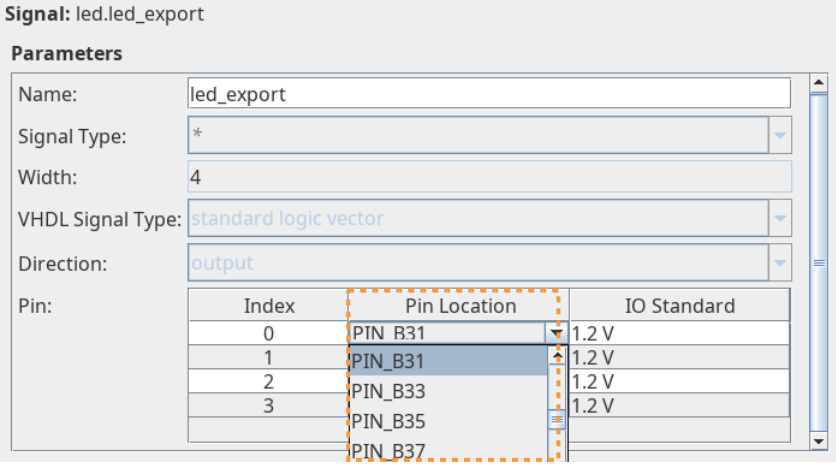
The following shows an example of the pin assignment Tcl commands exported to the system `.qip` file:

```
set_instance_assignment -to "led_export[0]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[0]" "PIN_B31"
set_instance_assignment -to "led_export[1]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[1]" "PIN_D31"
set_instance_assignment -to "led_export[2]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[2]" "PIN_A30"
set_instance_assignment -to "led_export[3]" -name IO_STANDARD "1.2 V"
set_location_assignment -to "led_export[3]" "PIN_C30"
```

1.6.3.5. Editing Pin Assignments for Presets

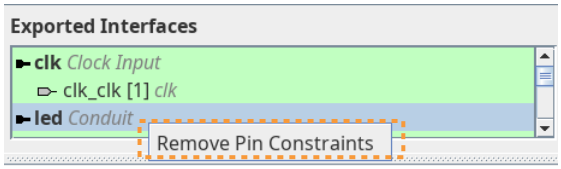
After you apply presets to IP, you can later view, edit, and remove those pin assignments for selected signals in the **Exported Interfaces** tab in Platform Designer. This action does not change the preset, but only changes the pin assignments of the exported system signals. To edit pin assignments for an existing IP preset, follow these steps:

Figure 52. Changing Preset Pin Location Assignments



1. In Platform Designer, click **View ➤ Exported Interfaces**. The **Exported Interfaces** tab displays the exported interfaces in the system.
2. Under **Exported Interfaces**, select a specific exported signal. The **Parameters** field displays the signal and editable **Pin** assignment information. The interface **Name** and signal name match the `exported_interface_name` and `exported_signal_name` values in the preset `.qprs` file.
3. To change the pin location or I/O standard for the signal, select a different **Pin Location** or **IO Standard** in the **Pin** field.
4. To remove any pin constraint, right-click the signal interface name under **Exported Interfaces**, and then click **Remove Current Pin Constraints**.

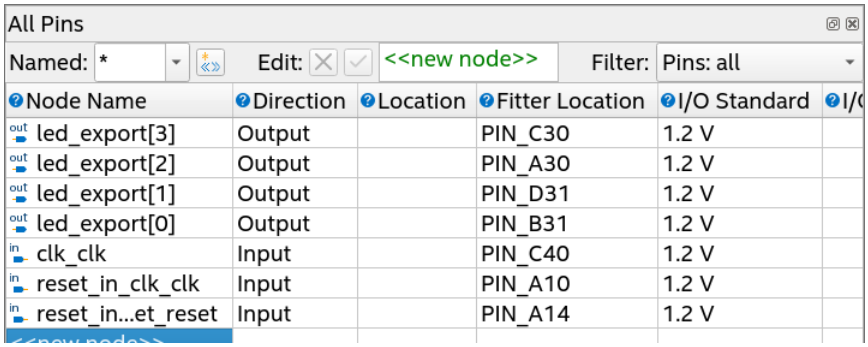
Figure 53. Remove Current Pin Constraints



To change only the exported port name, you can do so in the **System View** tab. You must still make detail changes in the **Exported Interfaces** tab.

5. After design compilation, review the exported preset pin assignments in the Quartus Prime software Pin Planner.

Figure 54. Exported Interface Pins in Pin Planner After Design Compilation

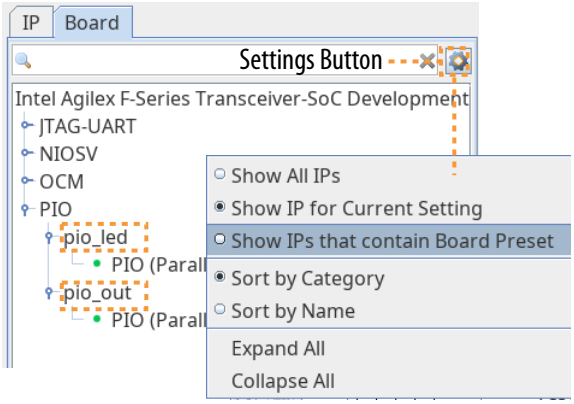


1.6.3.6. Viewing IP Presets In Board Catalog

You can easily view all presets defined for a target board in the Board Catalog in Platform Designer. The Board Catalog lists the name of each board defined, followed by a hierarchical list of the associated components, presets, and IP of the board.

You can use the search field and the adjacent Settings button to filter the list of list of IP to match your needs:

Figure 55. Viewing pio_led and pio_out Presets in Board Catalog



- Click the Settings button, and then select **Show IPs that contain Board Preset**. The Board Catalog displays only the IPs that have presets for the target board. Under the IP name, the available presets for that IP appear.

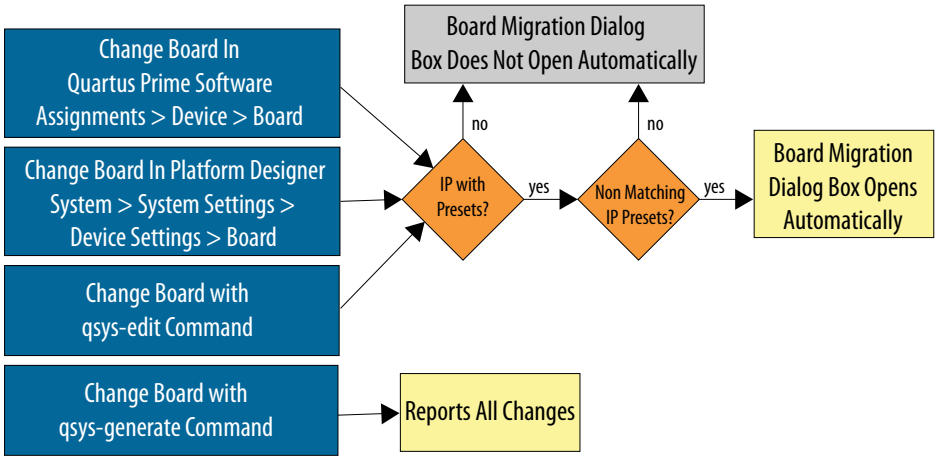
1.6.4. Applying Presets After Migrating a Board

You can save time by applying available presets when you migrate your design to a different board. The **Board Migration** dialog box helps you to quickly apply appropriate presets to each IP in the Platform Designer system to ensure consistency and accuracy of the system on the migrated board, even for hierarchical systems.

The **Board Migration** dialog box allows you to readily view a comparison of the parameters and pin assignments in the current system, versus the selected presets.

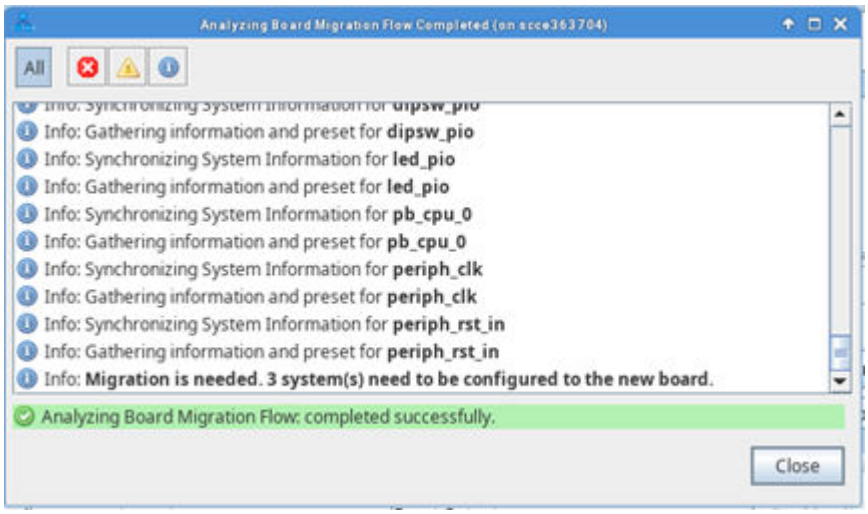
You can access the **Board Migration** dialog box using any of the following methods:

Figure 56. Opening the Board Migration Dialog Box



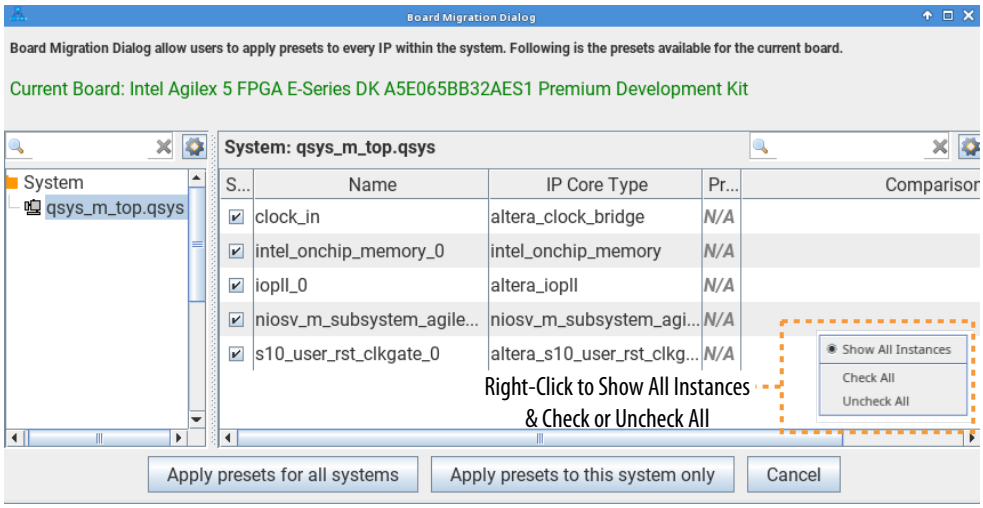
1. The **Board Migration** dialog box opens automatically using any of the following methods:
   - Click **Assignments ➤ Device ➤ Board** tab in the Quartus Prime Pro Edition software.
   - Click **System ➤ System Settings ➤ Device Settings ➤ Board** in Platform Designer.
   - Use the `--board` option with the qsys-edit command.
2. Upon completing step 1, the **Analyzing Board Migration** window appears showing the progress of system analysis and synchronization for the new target board. Analysis messages eventually indicate either that **Migration is needed** or **No migration is needed** to align with the target board. Click the **Close** button when system migration analysis is compete.

Figure 57. Analyzing Board Migration Window



If migration is needed, the **Board Migration** dialog box opens automatically displaying the systems and subsystems in the design you are migrating.

Figure 58. Board Migration Dialog Box



3. By default, the **Board Migration** dialog box displays only IP that do not have presets matching with the current configuration. To view all IP or systems, right-click in the dialog box and then click **Show All Instances**.

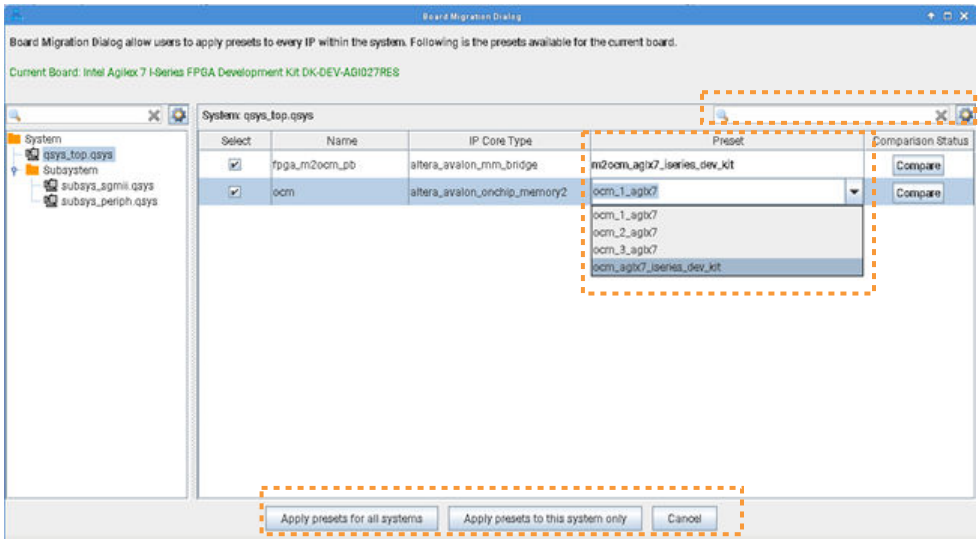
Note: Using the `--board` option with `qsys-generate` command does not launch the Board Migration dialog box. Rather, an information message appears suggesting that you to launch Platform Designer and use the **Board Migration** dialog box to determine the presets that apply to the new targeted board. The Board Migration dialog box does not open for migration of designs containing IP subsystems.

1.6.4.1. Comparing and Applying IP Presets

Follow these steps to compare the parameter and pin assignment differences of your current board configuration with your chosen board IP preset in the **Board Migration** dialog box and apply the desired presets:

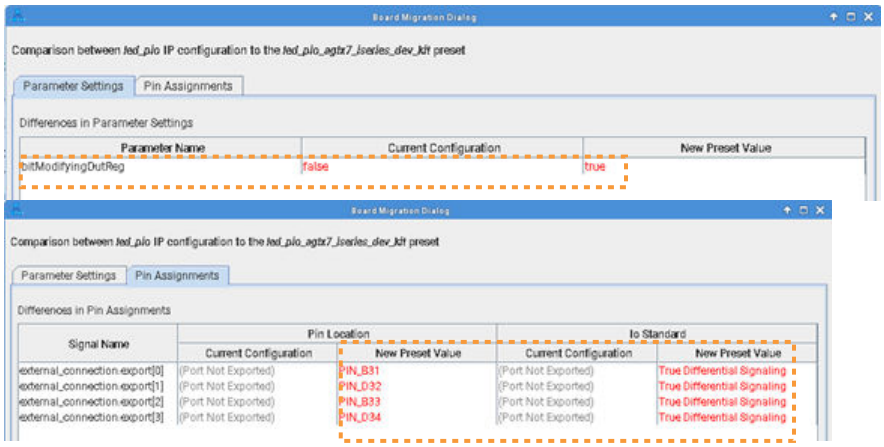
1. In the **Preset** column, type or select the preset name for the IP that you want to compare against the current configuration. If you have multiple IP or systems, type the IP or system name in the search bar to narrow the non-case-sensitive search.
2. To begin comparison, click the **Compare** button. Following comparison, the **Parameter Settings** and **Pin Assignments** tabs show the comparison results (differences) for parameter settings and pin assignments, respectively.

Figure 59. Setup Comparisons



IP with matching configurations and presets display **Matched** in green under **Comparison Status**. IP with no presets available display **N/A** in the **Preset** column.

Figure 60. Pin Assignment and Parameter Setting Comparison Results



3. When the presets match the board configuration as desired, click either the **Apply Presets to This System Only** button or the **Apply Presents for All Systems** button. The presets apply to your system according to your specifications.

Figure 61. IP with No Presets Available Display N/A

1.6.5. Adding Third-Party IP Components

You can add third-party IP components created by Intel partners to your Platform Designer system. Third-party partner IP components have interfaces that Platform Designer supports, such as Avalon memory mapped or AMBA AXI. Third-party partner IP components can also include timing and placement constraints, software drivers, simulation models, and reference designs.

To locate supported third-party IP components on the Intel web page, follow these steps:

1. From the Intel website, navigate to the *Find IP* page, and then click Find IP on the tool.
2. Use the **Search** box and the **End Market**, **Technology**, **Devices** or **Provider** filters to locate the IP that you want to use.
3. Click **Enter**.
4. Sort the table of results for the **Platform Designer Compliant** column. You cannot use non-compliant components in Platform Designer.
5. Click the IP name to view information, request evaluation, or request download.
6. After you download the IP files, add the IP location to the IP search path to add the IP to IP Catalog, as IP Search Path Recursive Search on page 58 describes.

Related Information

Find Intel FPGA and Partner IP

1.6.5.1. IP Search Path Recursive Search

The Quartus Prime software automatically searches and identifies IP components in the IP search path. The search is recursive for some directories, and only to a specific depth for others. During a recursive descent search, whenever search finds a `_hw.tcl` or `.ipx` file, search does not descend further.

In the following list of search locations, ** indicates a recursive descent.

Table 6. IP Search Locations

Location	Description
`PROJECT_DIR/*`	Finds IP components and index files in the Quartus Prime project directory.
`PROJECT_DIR/ip/**/*`	Finds IP components and index files in any subdirectory of the `/ip` subdirectory of the Quartus Prime project directory.

1.6.5.1.1. IP Search Path Precedence

If the Quartus Prime software recognizes two IP cores with the same name, the following search path precedence rules determine the resolution of files:

1. Project directory.
2. Project database directory.
3. Project IP search path specified in **IP Search Locations**, or with the SEARCH_PATH assignment for the current project revision.
4. Global IP search path specified in **IP Search Locations**, or with the SEARCH_PATH assignment in the `quartus2.ini` file.
5. Quartus software libraries directory, such as <*Quartus Installation*>`\libraries`.

1.6.5.1.2. IP Component Description Files

The Quartus Prime software identifies parameterizable IP components in the IP search path for the following files:

- Component Description File (`_hw.tcl`)—defines a single IP core.
- IP Index File (`.ipx`)—each `.ipx` file indexes a collection of available IP cores. This file specifies the relative path of directories to search for IP cores. In general, `.ipx` files facilitate faster searches.

1.6.5.2. Defining the IP Search Path with Index Files

You can create an IP Index File (`.ipx`) to specify a path that Platform Designer searches for IP components.

You can optionally specify the search path in a `user_components.ipx` file, in addition to **Tools ➤ Options ➤ IP Catalog Search Locations**. The `user_components.ipx` file allows you to add locations independent of the default search path.

A <*path*> element in a `.ipx` file specifies a directory where Platform Designer can search for IP components. A <*component*> entry specifies the path to a single component. <*path*> elements allow wildcards in definitions. An asterisk matches any file name. If you use an asterisk as a directory name, it matches any number of subdirectories.

Example 1. Path Element in an .ipx File

```
<library>
        <path path="…<user directory>" />
        <path path="…<user directory>" />
        …
        <component … file="…<user directory>" />
        …
</library>
```

A <*component*> element in an `.ipx` file contains several attributes to define a component. If you provide the required details for each component in an `.ipx` file, the startup time for Platform Designer is less than if Platform Designer must discover the files in a directory.

Example 2. Component Element in an .ipx File

The example shows two *<component>* elements. Note that the paths for file names are specified relative to the `.ipx` file.

```
<library>
  <component
    name="A Platform Designer Component"
    displayName="Platform Designer FIR Filter Component"
    version="2.1"
    file="./components/qsys_filters/fir_hw.tcl"
   />
  <component
    name="rgb2cmyk_component"
    displayName="RGB2CMYK Converter(Color Conversion Category!)"
    version="0.9"
    file="./components/qsys_converters/color/rgb2cmyk_hw.tcl"
   />
</library>
```

Note: You can verify that IP components are available with the `ip-catalog` command.

Related Information

Create an .ipx File with ip-make-ipx on page 449

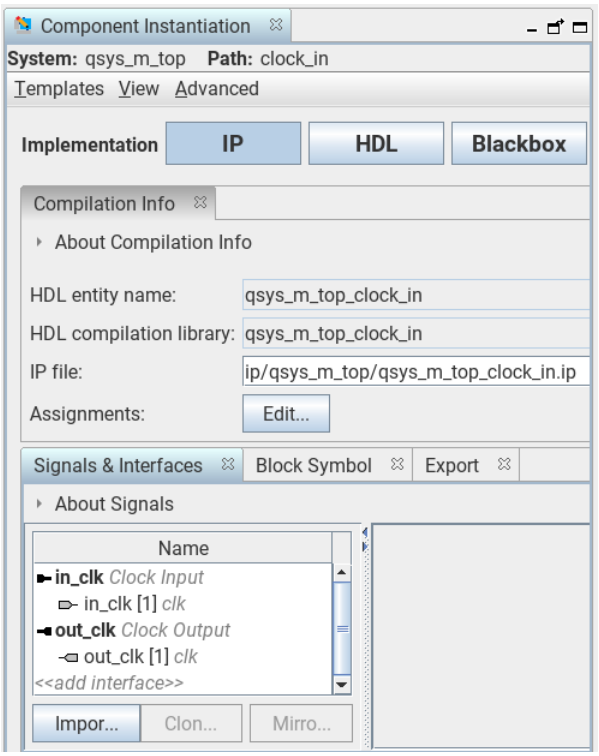
1.6.6. Specifying IP Component Instantiation Options

When you instantiate an Intel FPGA IP component in a system, Platform Designer instantiates the IP as a generic component that contains references to the HDL entity name, module and interface assignments, compilation library, HDL ports, interfaces, and system-info parameters. You can specify options that control the appearance of a component in the system.

To specify options that control the appearance of IP details and symbol in the system, follow these steps:

1. To open the **Component Instantiation** tab, click **View ➤ Component Instantiation**.
2. For **Implementation Type**, select the **IP** (Default), **HDL**, or **Blackbox** type. Component Implementation Type Options on page 61 defines these types.
3. Under **Compilation Info**, specify the **HDL Entity name** and **HDL compilation library** name for the implementation. These values are fixed for the **IP Implementation Type**.
4. In the **Signals & Interfaces** tab, define the port boundary of the component. Click ***<<add interface>>*** or ***<<add signal>>*** to add the interfaces and signals.
5. Optionally, click the **Block symbol** tab to visualize the signals and interfaces added in the **Signals & Interfaces** tab.
6. Optionally, in the **Export** tab you can export the signals and interfaces of an IP component as an IP-XACT file or a `_hw.tcl` file.

Figure 62. Component Instantiation Tab



Note: Platform Designer supports importing and exporting files in IP-XACT 2009 format and exporting IP-XACT files in 2014 format.

1.6.6.1. Component Implementation Type Options

Table 7. Component Implementation Type Options

Implementation Type	Description
IP	The default implementation type for any new component. Platform Designer reads the **IP Implementation Type** to perform the following functions: • Runs background checks against the port widths between the IP component and the `.ip` file to ensure continuity. • Scans the `.ip` file for the error flag to determine if any component has parameterization errors. • Checks for system-info mismatches between the IP file and the IP component in the system, and prompts resolution with IP instantiation warnings in the **Instantiation Messages** tab.
HDL	Allows you to define a component in your system from existing RTL. You can populate the signals and interfaces parameters of the generic component from an RTL file.
Blackbox	Defines a component that represents only the signal and interface boundary of an entity, without providing the component's implementation. You then provide the implementation of the component for processing with the Quartus Prime software or an RTL simulator.

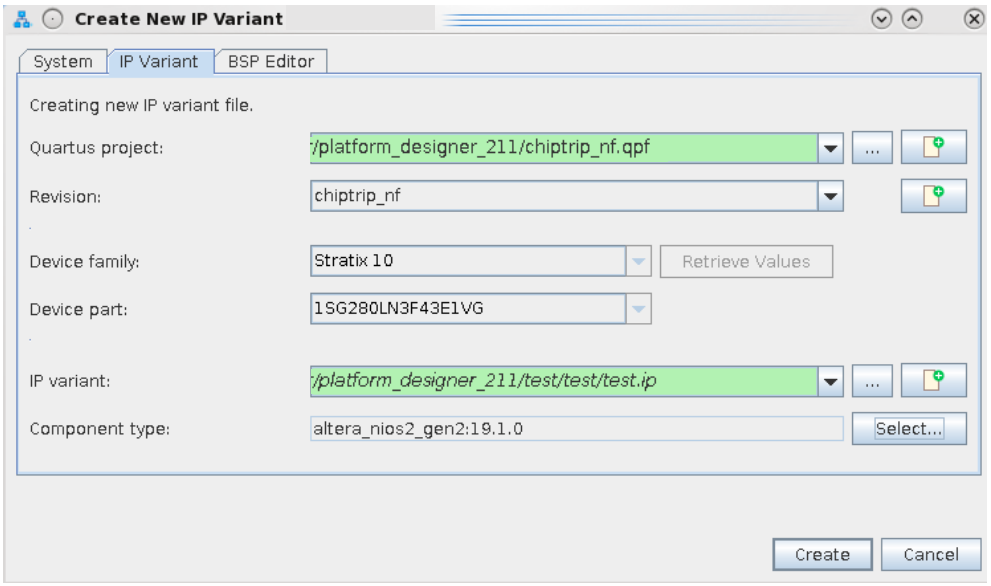
1.6.7. Creating or Opening an IP Core Variant

In addition to creating a system, Platform Designer allows you to define a stand-alone IP core variant that you can add to your Quartus Prime project or to a Platform Designer system.

Follow these steps to define an IP core variant in Platform Designer:

1. In Platform Designer, click **File ➤ New IP Variant**.
2. On the **IP Variant** tab, specify the **Quartus project** to contain the IP variant.
3. Specify any of the following options:
   - **Revision**—optionally select a specific revision of a project.
   - **Device family**—when defining a new project or **None**, allows you to specify the target FPGA device family. Otherwise this field is non-editable and displays the **Quartus project** target device family. Click **Retrieve Values** to populate the fields.
   - **Device part**—when defining a new project or **None**, allows you to specify the target FPGA device part number. Otherwise this field is non-editable and displays the **Quartus project** target device part number.
4. Specify the **IP variant** name, or browse for an existing IP variant.
5. For **Component type**, click **Select** and select the IP component from the IP Catalog.
6. Click **Create**. The IP parameter editor appears. Specify the parameter values that you want for the IP variant.
7. To generate the IP variant synthesis and optional simulation files, click **Generate HDL**, specify **Generation Options**, and click **Generate**. Refer to Generation Dialog Box Options on page 90 for generation options.

Figure 63. Platform Designer IP Variant Tab

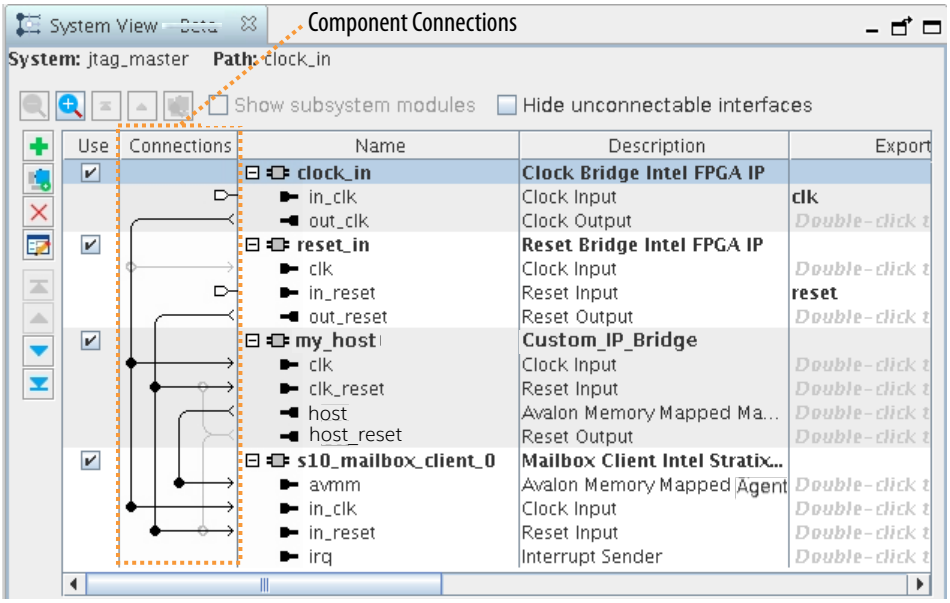


1.7. Connecting System Components

You must appropriately connect the components in your Platform Designer system. The **System View** and **Connections** tabs allow you to connect and configure IP components quickly. Platform Designer supports connections between interfaces of compatible types and opposite directions.

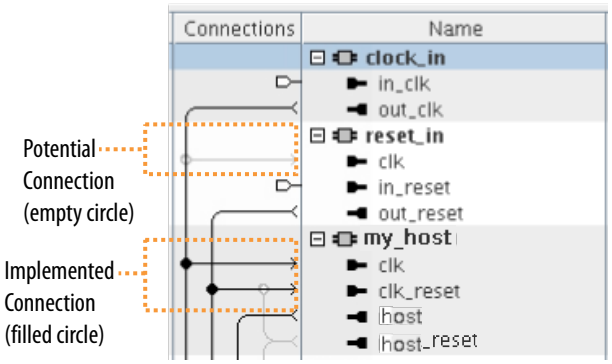
For example, you can connect a memory-mapped host interface to an agent interface, and an interrupt sender interface to an interrupt receiver interface. You can connect any interfaces exported from a Platform Designer system within a parent system.

Figure 64. Connections Column in the System Contents Tab



Platform Designer uses the high-level connectivity you specify to instantiate a suitable HDL fabric to perform the needed adaptation and arbitration between components. Platform Designer generates and includes this interconnect fabric in the RTL system output. Potential connections between interfaces appear as gray interconnect lines with an open circle icon at the intersection of the potential connection.

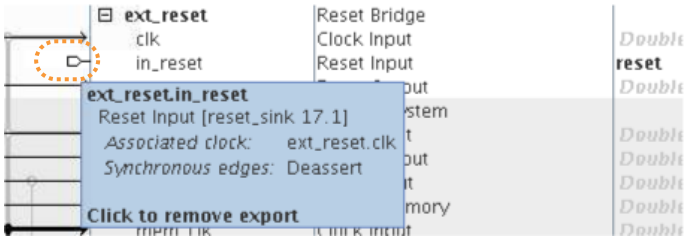
Figure 65. Potential and Implemented Connections in System View



To implement a connection, follow these steps:

1. Click inside an open connection circle to implement the connection between the interfaces. When you make a connection, Platform Designer changes the connection line to black, and fills the connection circle. Clicking a filled-in circle removes the connection.
2. To display the list of current and possible connections for interfaces in the **Hierarchy** or **System View** tabs, click **View ➤ Connections**.

Figure 66. Connection Display for Exported Interfaces



3. Perform any of the following to modify connections:
   - On the **Connections** tab, enable or disable the **Connected** column to enable or disable any connection. The **Clock Crossing**, **Data Width**, and **Burst** columns provide interconnect information about added adapters that can result in slower f_{MAX} or increased area utilization.
   - On the **System View** tab, right-click in the **Connection** column and disable or enable **Allow Connection Editing**.
   - On the **Connections** tab view and make connections for exported interfaces. Double-click an interface in the **Export** column to view all possible connections in the **Connections** column as pins. To restore the representation of the connections, and remove the interface from the **Export** column, click the pin.

1.7.1. Platform Designer 64-Bit Addressing Support

Platform Designer interconnect supports up to 64-bit addressing for all Platform Designer interfaces and IP components, with a range of: `0x0000 0000 0000 0000` to `0xFFFF FFFF FFFF FFFF`, inclusive.

The address parameters appear in the **Base** and **End** columns in the **System View** tab, on the **Address Map** tab, in the parameter editor, and in validation messages. Platform Designer displays as many digits as needed in order to display the top-most set bit, for example, 12 hex digits for a 48-bit address.

A Platform Designer system can have multiple 64-bit hosts, with each host having its own address space. You can share agents between hosts, and hosts can map agents to different addresses. For example, one host can interact with agent `0` at base address `0000_0000_0000`, and another host can see the same agent at base address `c000_000_000`.

Quartus Prime debugging tools provide access to the state of an addressable system via the Avalon memory mapped interconnect. These tools are also 64-bit compatible, and process within a 64-bit address space, including a JTAG to Avalon host bridge.

Platform Designer supports auto base address assignment for Avalon memory mapped components. In the **Address Map** tab, click **Auto Assign Base Address**.

1.7.1.1. Support for Avalon Memory Mapped Non-Power of Two Data Widths

Platform Designer requires that you connect all multi point Avalon memory mapped connections to interfaces with data widths that are equal to powers of two.

Platform Designer issues a validation error if an Avalon memory mapped host or agent interface on a multi-point connection is parameterized with a non-power of two data width.

Note: Avalon memory mapped point-to-point connections between an Avalon memory mapped host and an Avalon memory mapped agent are an exception, you can set their data widths to a non-power of two.

1.7.2. Connecting Hosts and Agents

Specify connections between host and agent components in the **Address Map** tab. You specify the address range that each memory-mapped host uses to connect to an agent in the Platform Designer system.

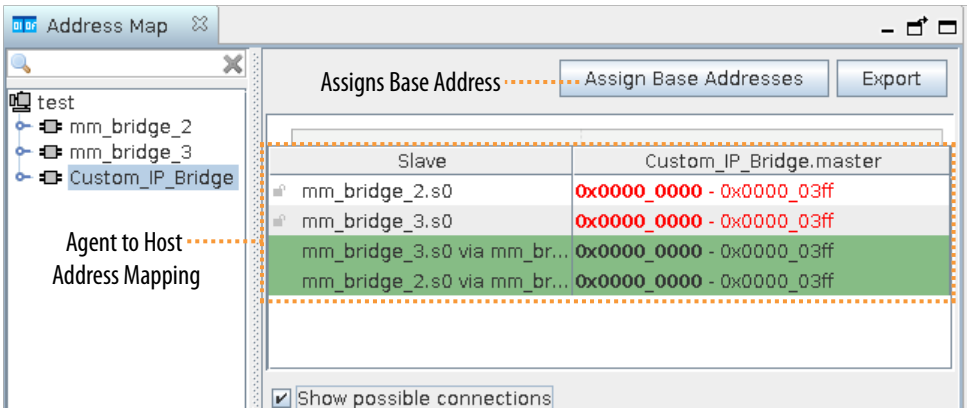
The **Address Map** tab shows the agents on the left, the hosts across the top, and the address span of the connection in each cell. If there is no connection between a host and an agent, the table cell is empty. In this case, use the **Address Map** tab to view the individual memory addresses for each connected host.

Platform Designer enables you to design a system where two hosts access the same agent at different addresses. If you use this feature, Platform Designer labels the **Base** and **End** address columns in the **System View** tab as "mixed" rather than providing the address range.

To create or edit a connection between host and agent IP components:

1. In Platform Designer, click the **Address Map** tab.
2. Locate the table cell that represents the connection between the host and agent.
3. Type in a base address, or update the current base address in the cell. The base address of an agent component must be a multiple of the address span of the component.

Figure 67. Address Map Tab for Connection Hosts and Agents



1.7.3. Connecting NoC IP in Platform Designer

Agilex™ 7 M-Series FPGAs support an integrated Network-on-Chip (NoC) to facilitate high-bandwidth data movement between the FPGA core logic and memory resources, such as HBM2e and DDR5 memories.

In the regular NoC compilation flow, you specify connections between NoC IP in the NoC Assignment Editor after running Analysis & Elaboration. You also specify address mapping and performance requirements for these connections in the NoC Assignment Editor. These assignments are required to perform RTL simulation of your design.

An optional early RTL simulation flow is available where you can specify NoC IP connection and addressing in Platform Designer. In this early simulation flow, you can perform RTL simulation after generating HDL for your Platform Designer system, but before running Analysis & Elaboration and making assignments in NoC Assignment Editor.

Note: If you use this early RTL simulation flow, you must still run Analysis & Elaboration and make connection and addressing assignments in NoC Assignment Editor before performing compilation.

If you want to enable early RTL simulation for your design, follow the steps below to specify NoC IP connectivity and addressing in Platform Designer. If you run Analysis & Elaboration and use the NoC Assignment Editor to make these assignments before running simulation, these steps are unnecessary.

1. Connect the AXI4 NoC manager ports to appropriate AXI4 NoC subordinate ports in the Platform Designer **System View** tab. The AXI4 NoC manager ports are on the NoC Initiator Intel FPGA IP. The AXI4 NoC subordinate ports are on the High Bandwidth Memory (HBM2E) Interface Agilex 7 FPGA IP and on the External Memory Interfaces Agilex 7 Intel FPGA IP.
2. Click the **Address Map** tab in Platform Designer to assign starting addresses for each NoC initiator to target connection. If an initiator connects to multiple targets, ensure that each target has a unique starting address. The end address is auto calculated based on the memory span.
3. Save you system and click **Generate HDL**. Platform Designer stores the NoC connectivity and addressing as assignments in the project `.qsf`.

   Note: This connectivity and addressing is not present in the HDL netlist that Platform Designer generates.

When using the Platform Designer flow for specifying NoC connectivity and addressing, the design is ready for RTL simulation after generating HDL for the Platform Designer system. For details on simulation, refer to *Agilex 7 M-Series FPGA Network-on-Chip (NoC) User Guide*.

Related Information

Agilex 7 M-Series FPGA Network-on-Chip (NoC) User Guide

1.7.4. Wire-Level Connectivity

Wire-level connectivity enables you to manipulate wire-level connections in the system level view of Platform Designer. For example, you can enter a Verilog style syntax expression to drive an input port of an IP component. You can implement wire-level connectivity with the Platform Designer GUI or with the `qsys-script` utility.

After applying the expression, the port you specify moves from the current interface into a **Wire-Level Endpoint** interface. The new interface name appends `_wirelevel` to the existing interface name. If you remove the wire-level expression, the port restores to the original interface. However, not all interfaces are restorable to legal interfaces after certain ports change. Moving a port from its original interface might result in validation errors on the original interface.

After you move a port to a **Wire-Level Endpoint** interface, wire-level expressions must drive all bits in the vector. You cannot connect ports contained within this new interface type to any other interfaces.

The following general rules apply to wire-level expressions:

- Wire-level connectivity is only available on optional input ports.
- Wire-level expressions can consist of input, output, and bi-directional ports, constant values, and logic terms using standard Verilog syntax.
- Wire-level expressions can only consist of ports within the same level of hierarchy. If you require elements from a higher or lower hierarchy, you must export the appropriate elements to the same hierarchical context.
- You can apply multiple expressions to a single input port unless they collide or cause bus contention.
- You must resolve validation errors occurring on the original interface for the interface to function correctly.

Platform Designer validates the wire-level expressions and provides messages for syntax, port existence, and other systematic errors. This validation includes the following:

- Validation of Verilog syntax.
- Warning if any sub-operator elements don’t match bit size.
- Warning if resulting combined bit size does not match the driven input port.
- Validation that all module and port names exist.
- Validation that all ports in a wire-level interface are input ports.
- Validation that all wire-level expressions drive each input port within a wire-level interface.
- Validation of no bus-contention, meaning that no one wire is driven by more than one expression.
- In a composed `_hw.tcl` module, validation that all ports driven by wire-level expressions are not in any connection.
- In a composed `_hw.tcl` module, validation that all ports driven by wire-level expressions are not exported.

After you define wire-level expressions, generate the system to create the Verilog files. When the Platform Designer GUI or `qsys-script` utility applies the expression, the expression inserts into the Verilog wrapper file that generates for your system. When you apply the wire-level connections with composed `_hw.tcl` commands, the wire-level expression inserts in the IP component's Verilog wrapper file.

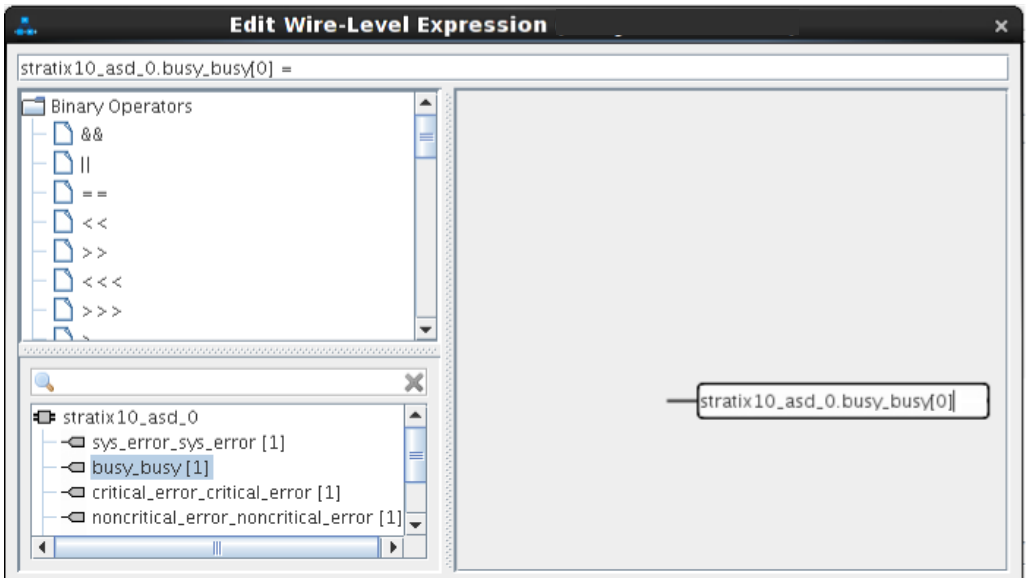
1.7.4.1. Editing Wire-Level Expressions

After you add a wire-level expression to an optional input port, you can add, edit, or remove wire-level expressions and connections in the Platform Designer GUI.

Follow these steps to edit wire-level expressions in the Platform Designer GUI:

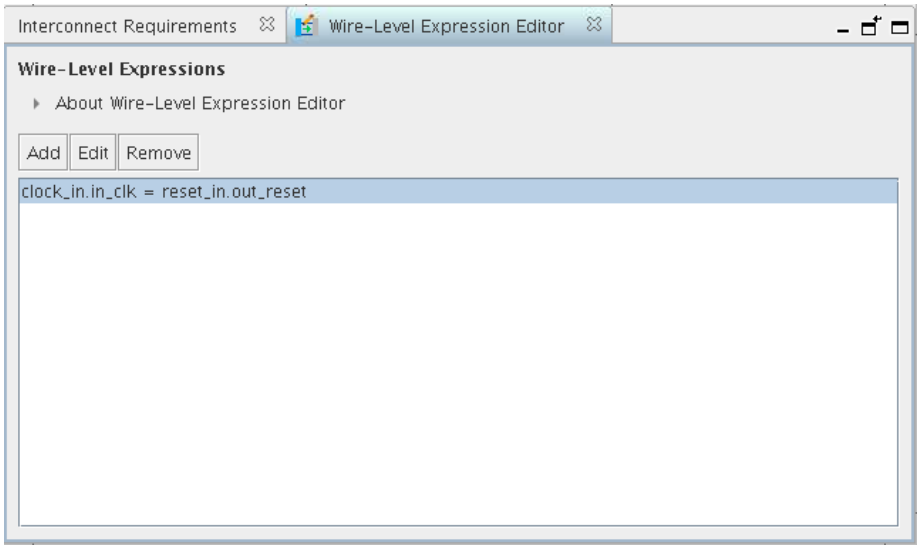
1. To specify a new wire-level expression, right-click an input port in the **Hierarchy** tab and click **Add Wire-Level Expression**. The **Edit Wire-Level Expression** dialog box appears.
2. To construct the expression, drag operators or ports from the list of operators or ports, and drop them into the expression field. Refer to Wire-Level Expression Syntax on page 69 for a list of legal operators.
3. Click the text field at the top of the **Edit Wire-Level Expression** dialog box and press the Down Arrow key to enable the expression assistant. The assistant provides a context sensitive list of available operators at the cursor position.

Figure 68. Edit Wire-Level Expression Dialog Box



4. Modify the elements of the expression in the workspace:
   - To add a value to an expression, right-click a node and select **Insert Value**.
   - Double-click on a value to enter a numeric value or port name.
   - Click an operator node to change the operator type.
   - Reorder nodes or move nodes between operators by dragging them.
5. To manage all wire-level expressions, click **View ➤ Wire-Level Expression Editor**. The **Wire-Level Expression Editor** allows you to add new wire-level expressions, edit, or remove existing wire-level expressions.

Figure 69. Wire-Level Expression Editor



1.7.4.2. Wire-Level Expression Syntax

The wire-level expression derives from Verilog syntax. The following is an example and list of legal operators and elements that you can use for wire-level expressions.

Example Expressions:

```
foo1.port1[5:0] = foo2.port1[5:0]
foo3.port1[8:4] = foo5.port1[4:0] & 5'b10101
foo6.port1[0] = 'b1
foo7.port1 = foo8.port1
foo9.port1[0] = ~foo10.port1[0]
foo10.port1[3:0] = foo11.port2[1:0] + 4'b1100
foo12:port1[3:0] = {4{0}}
foo13.port1[7:0] = {foo14.port1[3:0], 4'b0011}
```

Table 8. Ports

Port	Description
<instance_name>.<port_name>	Whole port
<instance_name>.<port_name>[*x*]	Wire *x* of port
<instance_name>.<port_name>[*y*:*x*]	Wires *x* to *y* of port. Port ranges must be in decreasing order, for example `a[1:0]`.
<constant base x values>	For example: 1, 'b1, 4'hf, 4'o7, 32'd9

Table 9. Operators (Bitwise)

Operator	Description
~	Negation
&	AND
|	OR
~&	NAND

continued...

Operator	Description
~|	NOR
^	XOR
~^	XNOR

Table 10. Operators (Logical)

Operator	Description
?	Conditional
!	Negation
&&	AND
||	OR

Table 11. Operators (Relational, Equality, and Shift)

Operator	Description
>	Greater Than
<	Less Than
>=	Greater Than or Equal To
<=	Less Than or Equal To
==	Equal To
!=	Not Equal To
<<	Shift Left
>>	Shift Right

Table 12. Operators (Mathematical)

Operator	Description
+	Addition
-	Subtraction
*	Multiplication
/	Division
%	Modulus

Table 13. Operators (Other)

Operator	Description
{integer {*x*}}	Replication of *x*
{*x*, *y*, ...}	Concatenation

1.7.4.3. Adding or Removing Ports from Wire-Level Endpoint Interfaces

You can quickly add or remove ports from wire-level interfaces.

Follow these steps to add or remove ports from wire-level endpoint interfaces:

1. To move the port to a wire-level endpoint interface, in the **Hierarchy** tab, right-click a port and then click **Move Port to Wire-Level Interface**. After you move a port to a wire-level endpoint interface, you can view and edit it in the **Component Instantiation** tab.
2. To remove the port from a wire-level endpoint interface, in the **Hierarchy** tab, right-click a port and then click **Remove Port from Wire-Level Interface**.

1.7.4.4. Scripting Wire-Level Expressions

Platform Designer supports system scripting commands to apply wire-level expressions to input ports in IP components.

The following commands function with the `qsys-script` utility or in a `_hw.tcl` file to set, retrieve, or remove an expression on a port:

```
set_wirelevel_expression <instance_or_port_bit> <expression>
get_wirelevel_expressions <instance_or_port_bit>
remove_wirelevel_expressions <instance_or_port_bit
```

These commands require a string that you compose from the left-handed and right-handed components of the expression. Platform Designer reports errors in syntax, existence, or system hierarchy.

Related Information

- Wire-Level Connection Commands on page 633
- set_wirelevel_expression on page 633
- get_wirelevel_expressions on page 634
- remove_wirelevel_expressions on page 635

1.8. Specifying Interconnect Parameters

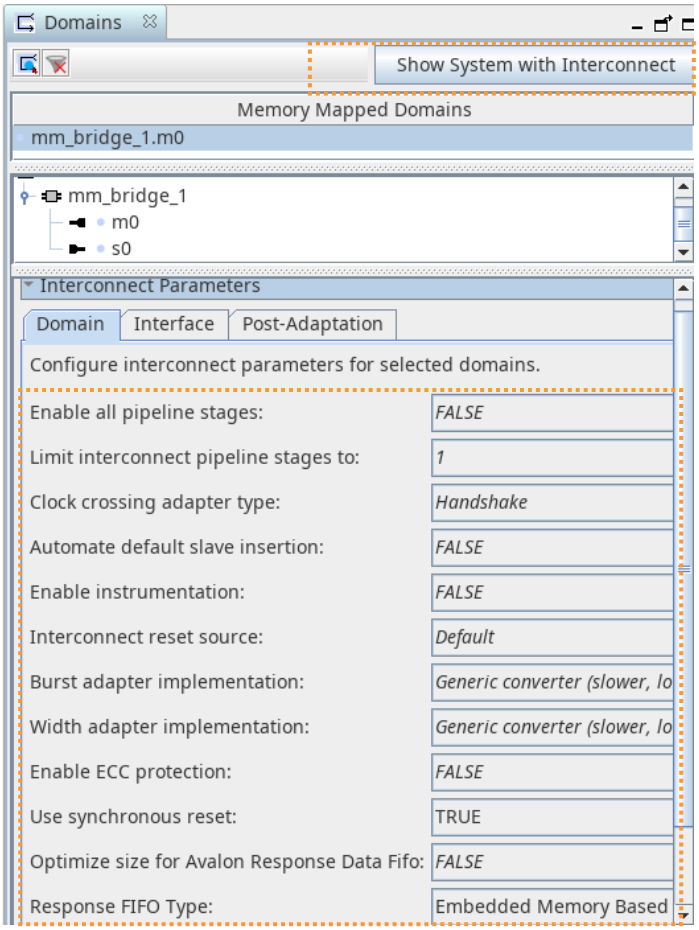
Specify system-wide or domain-specific interconnect parameters on the **Domains** tab. Interconnect parameters allow you to customize the implementation of the system interconnection.

The **Domains** tab displays the memory mapped interfaces in your system, and allows you to specify legal values for available system-level or interface parameters. While specifying parameters, you can click **Show System with Interconnect** to view a schematic preview of the Platform Designer complete system interconnect.

Follow these steps to specify interconnect parameters:

1. Open or create a Platform Designer system.
2. Click **View ➤ Domains**.
3. Under **Memory Mapped Domains**, select one or more domains.

Figure 70. Domains Tab



4. On the **Domain** tab, specify values for interconnect parameter settings, as Interconnect Parameters on page 73 describes.
5. To view a preview of the Platform Designer complete system interconnect, click **Show System with Interconnect**. Refer to Previewing the System Interconnect on page 74 for detailed description of this preview.
6. To manually add pipeline stages to the interconnect schematic, refer to Add Pipeline Stages to the Interconnect Schematic on page 330.

Related Information

- Burst Adapter on page 273
- Width Adaptation on page 271
- Platform Designer Interconnect on page 251
- Reset Interfaces on page 316
- Domains and Interfaces on page 483

1.8.1. Interconnect Parameters

The following parameters are available on the **Domains** tab:

Table 14. Interconnect Parameters

Option	Description
Enable all pipeline stages	• **FALSE**—default setting. The **Limit interconnect pipeline stages to** value and post-adaptation assignments control pipeline insertion. • **TRUE**—enables all pipeline stages within this domain. Ignores the **Limit interconnect pipeline stages to** and any post-adaptation assignment. Also disables manual editing of pipelines in the schematic. Although this setting ignores post-adaptation assignments, the assignments still remain in the design.
Limit interconnect pipeline stages to	Specifies the maximum number of pipeline stages that Platform Designer can insert in each command and response path to increase the f_{MAX} at the expense of additional latency. You can specify between 0 and 4 as the maximum number of pipeline stages to insert. The default value is 1. A value of 0 indicates no pipelines and a combinational datapath. When you specify 1 or greater, Platform Designer inserts *up to* the number you specify, depending on availability of pipeline locations. *Note:* If certain adapters or IP components are not present in the interconnect, or if there are not enough pipelineable locations in the interconnect, Platform Designer does not add all of the pipeline stages specified. Click **Show System with Interconnect** to view the number of stages added for a particular domain.
Clock crossing adapter type	Specifies the default implementation for automatically inserted clock crossing adapters: • **Handshake**—this adapter uses a simple handshaking protocol to propagate transfer control signals and responses across the clock boundary. This methodology uses fewer hardware resources because each transfer is safely propagated to the target domain before the next transfer can begin. The **Handshake** adapter is appropriate for systems with low throughput requirements. • **FIFO**—this adapter uses dual-clock FIFOs for synchronization. The latency of the FIFO-based adapter is a couple of clock cycles more than the handshaking clock crossing component. However, the FIFO-based adapter can sustain higher throughput because it supports multiple transactions at any given time. FIFO-based clock crossing adapters require more resources. The **FIFO** adapter is appropriate for memory-mapped transfers requiring high throughput across clock domains. • **Auto**—if you select **Auto**, Platform Designer specifies the **FIFO** adapter for bursting links, and the **Handshake** adapter for all other links.
Automate default slave insertion	Directs Platform Designer to automatically insert a default Avalon agent or AXI subordinate for undefined memory region accesses during system generation.(2)
Enable instrumentation	When you set this option to TRUE, Platform Designer enables debug instrumentation in the Platform Designer interconnect, which then monitors interconnect performance in the system console.
Interconnect reset source	Select **Default** or a specific reset signal in your design.
Burst adapter implementation	Allows you to choose the converter type that Platform Designer applies to each burst. • **Generic converter (slower, lower area)**—default setting. Controls all burst conversions with a single converter that is able to adapt incoming burst types. This results in an adapter that has lower f_{MAX}, but smaller area. • **Per-burst-type converter (faster, higher area)**—controls incoming bursts with a particular converter, depending on the burst type. This results in an adapter that has higher f_{MAX}, but higher area. This setting is useful when you have AXI managers or subordinates and you want a higher f_{MAX}.

continued...

(2) This document now refers to the Avalon "host" and "agent," and the AXI "manager" and "subordinate," to replace former terms. Refer to the current *AMBA AXI and ACE Protocol Specification* for the latest AMBA AXI and ACE protocol terminology.

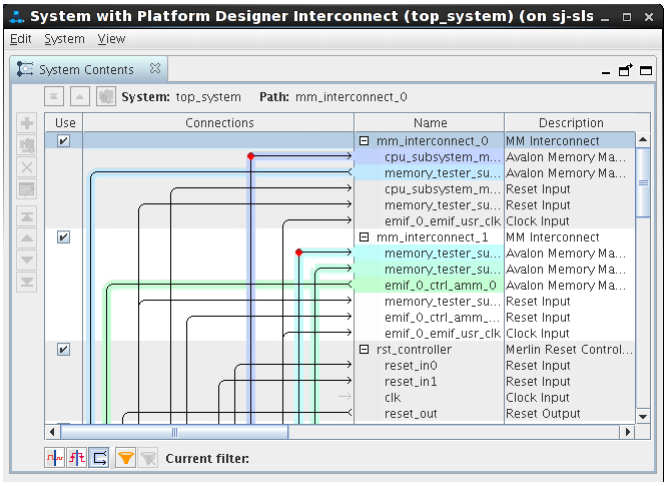
Option	Description
Width adapter implementation	• **Generic converter (slower, lower area)**—default. Controls all width adaptations with a single converter that is able to adapt incoming widths. This results in an adapter that has lower f_{MAX}, but smaller area. • **Optimized converter (faster, higher area)**—controls width adaptations with a particular converter, depending on the width. This results in an adapter that has higher f_{MAX}, but higher area. This setting is useful when you have AXI managers or subordinates and you want a higher f_{MAX}.
Enable ECC protection	Specifies the default implementation for ECC protection for memory elements. • **FALSE**—default. Disables ECC protection for memory elements in the Platform Designer interconnect. • **TRUE**—enables ECC protection for memory elements. Platform Designer interconnect sends uncorrectable errors arising from memory as DECODEERROR (DECERR) on the Avalon response bus. For more information about Error Correction Coding (ECC), refer to Error Correction Coding (ECC) in Platform Designer Interconnect on page 331.
Use synchronous reset	When set to **TRUE**, all registers in the interconnect use synchronous reset. Assert the reset for at least 16 cycles and start transactions 16 cycles after deassertion of the reset. This period allows all the IP components to reset and come out of the reset state. To avoid deadlocks in the interconnect, reset hosts and agents simultaneously. If hosts and agents have different resets, agents must reset only after responding to all necessary transactions. The **Use synchronous reset** option is enabled by default for Hyperflex® architecture devices, but is disabled by default for all other devices. Enabling synchronous reset for the interconnect does not enable synchronous reset for IP components in the system. You must separately enable the synchronous reset parameter for any component.
Optimize size for Avalon Response Data Fifo	When enabled, Platform Designer does not increase the size of the Avalon interface agent read FIFO to the next power of 2. You can enable this setting to decrease the size of the FIFO if needed.
Response FIFO Type	Specifies the implementation method for the Platform Designer response FIFO that stores information for processing of response in the interconnect, such as width adaptation and routing to the Avalon host or AXI manager. The following options are available: • **Register Based**—default option that implements the response FIFO using registers. When **Register Based** is selected, FIFO uses the LUT's to hold responses. This consumes more LUT's, but the minimum response latency is 1. • **Embedded Memory Based**—implements the response FIFO using M20K memory blocks, rather than LUTs. When you specify **Embedded Memory Based**, the minimum response latency is 3, and FIFO consumes far fewer LUT resources, but consumes M20K memory resources.

1.8.2. Previewing the System Interconnect

You can review a graphical representation of the Platform Designer interconnect before you generate the system. The System with Platform Designer Interconnect window Platform Designer's conversion of connections between interfaces to interconnect logic during system generation.

To open the System with Platform Designer Interconnect window, click **System ➤ Show System With Platform Designer Interconnect**, or click the **Show System With Interconnect** button in the **Domains** tab.

Figure 71. System with Platform Designer Interconnect window



The System with Platform Designer Interconnect window has the following tabs:

- **System Contents**—displays the original instances in your system, as well as the inserted interconnect instances. Connections between interfaces are replaced by connections to interconnect where applicable.
- **Schematic**—displays a schematic representation that shows the multiple interconnects together as a complete system.
- **Hierarchy**—displays a system hierarchical navigator, expanding the system contents to show modules, interfaces, signals, contents of subsystems, and connections.
- **Parameters**—displays the parameters for the selected element in the **Hierarchy** tab.
- **Memory-Mapped Interconnect**—allows you to select a memory-mapped interconnect module and view its internal command and response networks. You can also insert pipeline stages to achieve timing closure.

The **System Contents**, **Hierarchy**, and **Parameters** tabs are read-only. Edits that you apply on the **Memory-Mapped Interconnect** tab are automatically reflected on the **Interconnect Requirements** tab.

The **Memory-Mapped Interconnect** tab in the System with Platform Designer Interconnect window displays a graphical representation of command and response datapaths in your system. Datapaths allow you precise control over pipelining in the interconnect, as Add Pipeline Stages to the Interconnect Schematic on page 330 describes. Platform Designer displays separate figures for the command and response datapaths. You can access the datapaths by clicking their respective tabs in the **Memory-Mapped Interconnect** tab.

Each node element in a figure represents either a host or agent that communicates over the interconnect, or an interconnect sub-module. Each edge is an abstraction of connectivity between elements, and its direction represents the flow of the commands or responses.

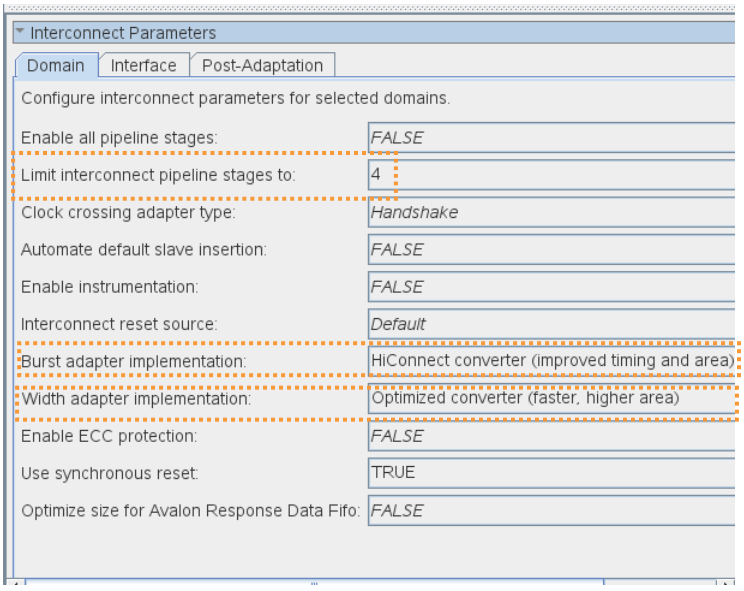
Click **Highlight Mode** (**Path**, **Successors**, **Predecessors**) to identify edges and datapaths between modules. Turn on **Show Pipelinable Locations** to add greyed-out registers on edges where pipelining is allowed in the interconnect.

1.9. Correcting Platform Designer System Timing Issues

You can help alleviate Platform Designer system timing issues by adjusting the following interconnect parameters on the **Domains** tab:

- **Limit interconnect pipeline stages to**—increase the use of interconnect pipeline stages in each command and response path by increasing the value of this option up to **4**. Platform Designer can insert up to four pipeline stages, depending on availability of pipeline locations, at the possible expense of additional latency and area. The default value is **1** pipeline stage.
- **Burst adapter implementation**—enable the **HiConnect converter (Improved timing and area)** or **Per-burst-type HiConnect converter (faster, higher area)** implementation to control incoming bursts with optimized burst adapters. These settings produce an adapter that has improved timing, but may require more device resources for implementation.
- **Width adapter implementation**—enable the **Optimized converter (faster, higher area)** implementation to control width adaptation with a particular converter. This setting produces an adapter that has higher f_{MAX}, but requires more device resources for implementation.

Figure 72. Correcting Platform Designer System Timing Issues with Domains Tab Settings



Note: To manually add pipeline stages to the interconnect schematic, refer to Add Pipeline Stages to the Interconnect Schematic on page 330.

Related Information

- Specifying Interconnect Parameters on page 71
- Interconnect Pipelining on page 328
- Burst Adapter on page 273
- Width Adaptation on page 271

1.10. Specifying Signal and Interface Boundary Requirements

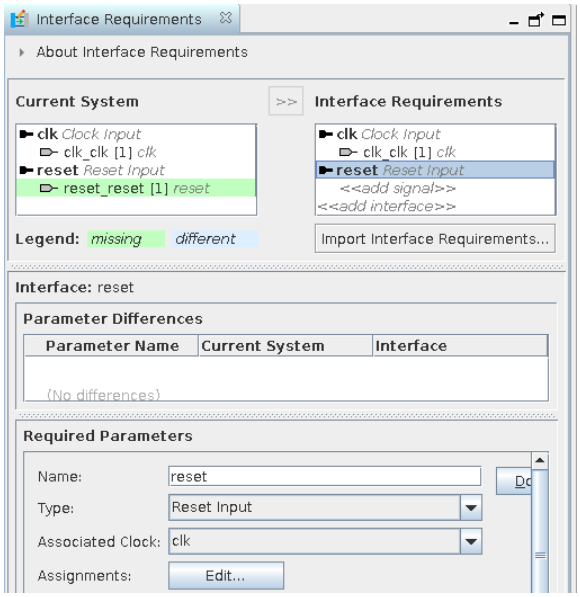
If you export an interface that does not match the interface requirements of the system, Platform Designer generates component instantiation errors. You must match all the exported interfaces with the interface requirements of the system.

The **Interface Requirements** tab allows you to assign a component's top-level HDL module signals to an interface, specify the expected signal and interface boundary requirements for the interface, and to resolve any interface requirement mismatches. You can also modify the signal names in an exported interface.

1. Click **View ➤ Interface Requirements**.
2. To load the interface requirements from a Platform Designer system, click **Import Interface Requirements** in the **Interface Requirements** table. Select the `.ipxact` representation of the Platform Designer system.
3. To manually add new interface or signal requirements, click *<<add interface>>* or *<<add signal>>* in the **Interface Requirements** table.
4. To correct the mismatches, select the missing or mismatched interface or signal in the **Current System** table and click **>>**.

   Note: Platform Designer highlights the mismatches between the system and interface requirements in blue, and highlights the missing interfaces and signals in green.
5. To rename an exported signal or interface, use any of the following methods:
   - Double-click the signal or interface in **Current System** table.
   - Select the signal or interface in the **Current System** table and press F2.
   - Select the signal or interface in the **Current System** table and rename from the **Current Parameters** pane at the bottom of the tab. The **Current Parameters** pane displays all the parameters of the selected interface or signal.

Figure 73. Interface Requirements Tab



Related Information

Editing Exported Interface Signal Names on page 78

1.10.1. Interface Requirements Tab Fields

The Platform Designer **Interface Requirements** tab contains the following fields.

Table 15. Interface Requirements Tab Fields

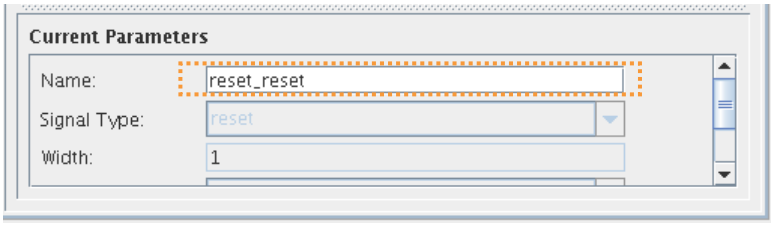
Name	Description
Current System	Displays all the exported interfaces in the current Platform Designer system. Add or remove the interfaces in the **Current System** by adding or removing components from the **System View** tab.
Interface Requirements	This table shows all the interface requirements set for the current Platform Designer system.
Parameter Differences	This table lists the **Parameter Name**, **Current System Value**, and **Interface Requirement Value** for the selected mismatched interface. *Note:* The **Interface Requirements** tab highlights in blue the signals and interfaces that are the same, but have different parameter values. Selecting a blue item populates the **Parameter Differences** table.
Import Interface Requirements	This button allows you to populate the **Interface Requirements** table from an IP-XACT(3) file representing a generic component or an entire Platform Designer system.
Parameters	This table lists the signal and interface parameters for the selected interface. You can view the table as **Current Parameters** when you select an interface or signal from the **Current System** table, and as **Required Parameters** when you select the signal or interface from **Interface Requirements** table. You can modify the name of the exported signal or interface from this table. For more information about how to edit the name of an exported signal or interface, refer to *Edit the Name of Exported Interfaces and Signals*.

1.10.2. Editing Exported Interface Signal Names

To rename an exported signal or interface:

- Double-click the signal or interface in **Current System** table.
- Select the signal or interface in the **Current System** table. Edit the interface or signal's parameters in the **Current Parameters** pane.

Figure 74. Editing the Name of Exported Interfaces and Signals



Note: All other parameters in the **Current Parameters** except **Name** are read-only for the current system.

(3) Platform Designer supports importing and exporting files in IP-XACT 2009 format and exporting IP-XACT files in 2014 format.

1.11. Configuring Platform Designer System Security

Specify system or interconnect **Security** requirements on the **Domains** tab.

Platform Designer interconnect supports the Arm TrustZone® security extension. The Platform Designer Arm TrustZone security extension includes secure and non-secure transaction designations, and a protocol for processing between the designations.(4)

The AXI AxPR0T protection signal specifies a secure or non-secure transaction. When an AXI manager sends a command, the AxPR0T signal specifies whether the command is secure or non-secure. When an AXI subordinate receives a command, the AxPR0T signal determines whether the command is secure or non-secure. Determining the security of a transaction while sending or receiving a transaction is a run-time protocol.

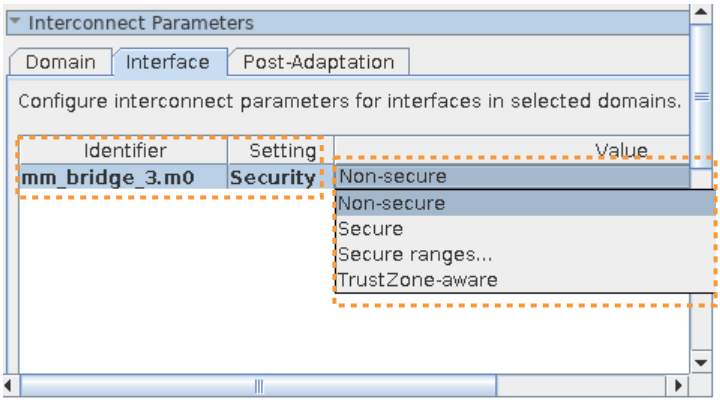
AXI managers and subordinates can be TrustZone-aware. All other host and agent interfaces, such as Avalon memory mapped interfaces, are non-TrustZone-aware.

The Avalon specification does not include a protection signal. Consequently, when an Avalon host sends a command, there is no embedded security and Platform Designer recognizes the command as non-secure. Similarly, when an Avalon agent receives a command, the agent always accepts the command and responds.

To set compile-time security support for non-TrustZone-aware components:

1. To begin creating a secure system, add Avalon hosts and agents and AXI managers and subordinates to your system, as Adding IP Components to a System describes.
2. Make connections between the hosts and agents and between the managers and subordinates in your system, as Connecting Hosts and Agents describes.
3. Click **View ➤ Domains**.

Figure 75. Security Settings in Domains Tab



4. To specify security requirements for an interconnect, click the **Interface** tab under **Interconnect Parameters**,

(4) This document now refers to the Avalon "host" and "agent," and the AXI "manager" and "subordinate," to replace formerly used terms with inclusive language. Refer to the current *AMBA AXI and ACE Protocol Specification* for the latest AMBA AXI and ACE protocol terminology.

5. Click the **Add** button.
6. In the **Identifier** column, select the interconnect in the **new_target** cell.
7. In the **Setting** column, select **Security**.
8. In the **Value** column, select the appropriate **Secure**, **Non-Secure**, **Secure Ranges**, or **TrustZone-aware** security for the interface. Refer to System Security Options for details of each option.
9. After setting compile-time security options for non-TrustZone-aware manager and subordinate interfaces, you must identify those managers that require a default subordinate before generation, as Specifying a Default Avalon Agent or AXI Subordinate describes.

Related Information

- Platform Designer Interconnect on page 251
- Platform Designer System Design Components on page 367

1.11.1. System Security Options

Table 16. Security Options

Option	Description
Secure	The Avalon host or AXI manager sends only secure transactions, and the Avalon agent or AXI subordinate receives only secure transactions. Platform Designer treats transactions from a secure manager as secure. Platform Designer blocks non-secure transactions to a secure agent or subordinate and routes to the default agent or subordinate.
Non-Secure	The host or manager sends only non-secure transactions, and the agent or subordinate receives any transaction, secure or non-secure. Platform Designer treats transactions from a non-secure host or manager as non-secure. Platform Designer allows all transactions, regardless of security status, to reach a non-secure agent or subordinate.
Secure Ranges	Applies to only the agent or subordinate interface. Allows you to specify secure memory regions for an agent or subordinate. Platform Designer blocks non-secure transactions to secure regions and routes to the default agent or subordinate. The specified address ranges within the agent or subordinate's address span are secure, all other address ranges are not. The format is a comma-separated list of inclusive-low and inclusive-high addresses, for example, `0x0:0xfff,0x2000:0x20ff`
TrustZone-aware	TrustZone-aware managers have signals that control the security status of their transactions. TrustZone-aware subordinates can accept these signals and handle security independently. The following applies to secure systems that mix secure and non-TrustZone-aware components: • All AXI, AMBA 3 AXI, and AMBA 3 AXI-Lite managers are TrustZone-aware. • You can set AXI, AMBA 3 AXI, and AMBA 3 AXI-Lite subordinates as TrustZone-aware, secure, non-secure, or secure range ranges. • You can set non-AXI host interfaces as secure or non-secure. • You can set non-AXI agent interfaces as secure, non-secure, or secure address ranges.

1.11.2. Specifying a Default Avalon Agent or AXI Subordinate

If an AXI manager issues "per-access" or "not allowed" transactions, your design must contain a default subordinate. Per-access refers to the ability of a TrustZone-aware AXI manager to allow or disallow access or transactions.

You can achieve an optimized secure system by partitioning your design and carefully designating secure or non-secure address maps to maintain reliable data. Avoid a design that includes a non-secure AXI manager or Avalon host that initiates transactions to a secure subordinate or agent resulting in unsuccessful transfers, within the same hierarchy.

A transaction that violates security is rerouted to the default subordinate or agent and subsequently responds to the AXI manager or Avalon host with an error. The following rules apply to specifying a default subordinate or agent:

- You can designate any AXI subordinate or Avalon agent as the default subordinate or agent.
- You can share a default subordinate or agent between multiple AXI managers or Avalon hosts, respectively.
- You should have one default subordinate or agent for each interconnect domain.
- An interconnect domain is a group of connected memory-mapped managers and subordinates or hosts and agents that share the same interconnect. The `altera_error_response_slave` component includes the required TrustZone features.
- *Note:* If you do not specify a value for the **Default Slave** option, and the **Automate default slave insertion** option is off, Platform Designer automatically assigns the AXI subordinate or Avalon agent in the system. Platform Designer automatically assigns the AXI subordinate or Avalon agent that has largest address span within the memory map for the issuing AXI manager or Avalon host. In the case of multiple, large AXI subordinates or Avalon agents that have the same address span, Platform Designer selects the AXI subordinate or Avalon agent at the lowest base offset.

To designate a subordinate or agent interface as the default subordinate or agent for non-TrustZone-aware interfaces, follow these steps:

1. Specify interconnect security settings, as Configuring Platform Designer System Security on page 79 describes.
2. In the **System View**, right-click any column and turn on the **Security** and **Default Slave** columns.
3. In the **System View** tab, turn on the **Default Slave** option for the subordinate or agent interface. A manager or host can have only one default subordinate or agent.

Figure 76. Security and Other Columns

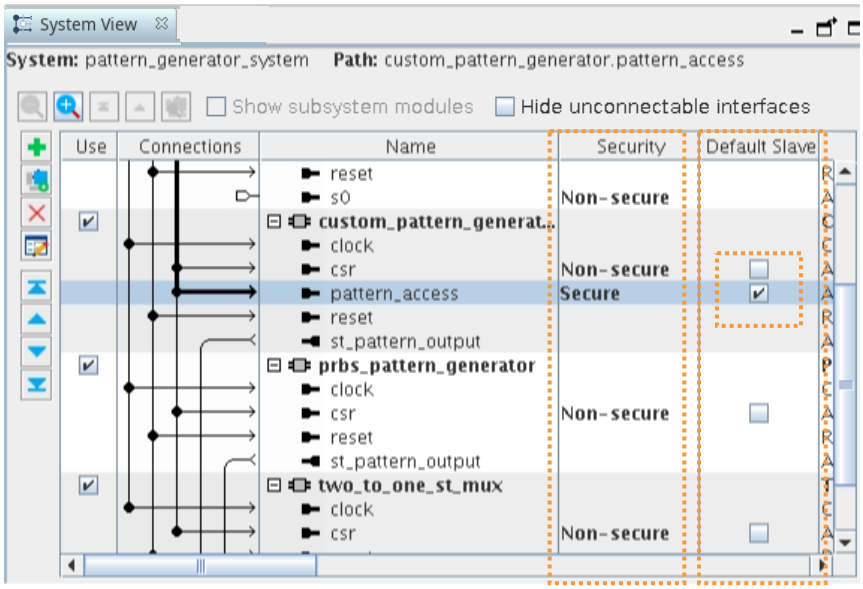


Table 17. Secure and Non-Secure Access Between Manager or Host, Subordinate or Agent, and Memory Components

Transaction Type	TrustZone-aware manager	Non-TrustZone-aware manager/host Secure	Non-TrustZone-aware manager/host Non-Secure
TrustZone-aware subordinate memory	OK	OK	OK
Non-TrustZone-aware subordinate/ agent (secure)	Per-access	OK	Not allowed
Non-TrustZone-aware subordinate/ agent (non-secure)	OK	OK	OK
Non-TrustZone-aware memory (secure region)	Per-access	OK	Not allowed
Non-TrustZone-aware memory (non-secure region)	OK	OK	OK

Related Information

- Error Response Slave Intel FPGA IP on page 390
- Designating a Default Agent on page 396

1.11.3. Accessing Undefined Memory Regions

Access to an undefined memory region occurs when a transaction from an AXI manager or Avalon host targets a memory region unspecified in the AXI subordinate or Avalon agent memory map. To ensure predictable response behavior when this condition occurs, you must specify a default subordinate or agent, as Specifying a Default Avalon Agent or AXI Subordinate on page 80 describes.

You can designate any memory-mapped subordinate or agent as a default subordinate or agent. You may have only one default subordinate or agent for each interconnect domain in your system. Platform Designer then routes undefined memory region accesses to the default subordinate or agent, which terminates the transaction with an error response.

Note: If you do not specify a value for the **Default Slave** option, and the **Automate default slave insertion** option is off, Platform Designer automatically assigns the AXI subordinate or Avalon agent in the system. Platform Designer automatically assigns the AXI subordinate or Avalon agent that has largest address span within the memory map for the issuing AXI manager or Avalon host. In the case of multiple, large AXI subordinates or Avalon agents that have the same address span, Platform Designer selects the AXI subordinate or Avalon agent at the lowest base offset.

Accessing undefined memory regions can occur in the following cases:

- When there are gaps within the accessible memory map region that are within the addressable range of subordinate or hosts, but are not mapped.
- Accesses by a manager or host to a region mapped to that manager or host that does not belong to any subordinates or agents.
- When a non-secured transaction is accessing a secured subordinate. This applies to only subordinates that are secured at compilation time.
- When a read-only subordinate or agent is accessed with a write command, or a write-only subordinate or agent is accessed with a read command.

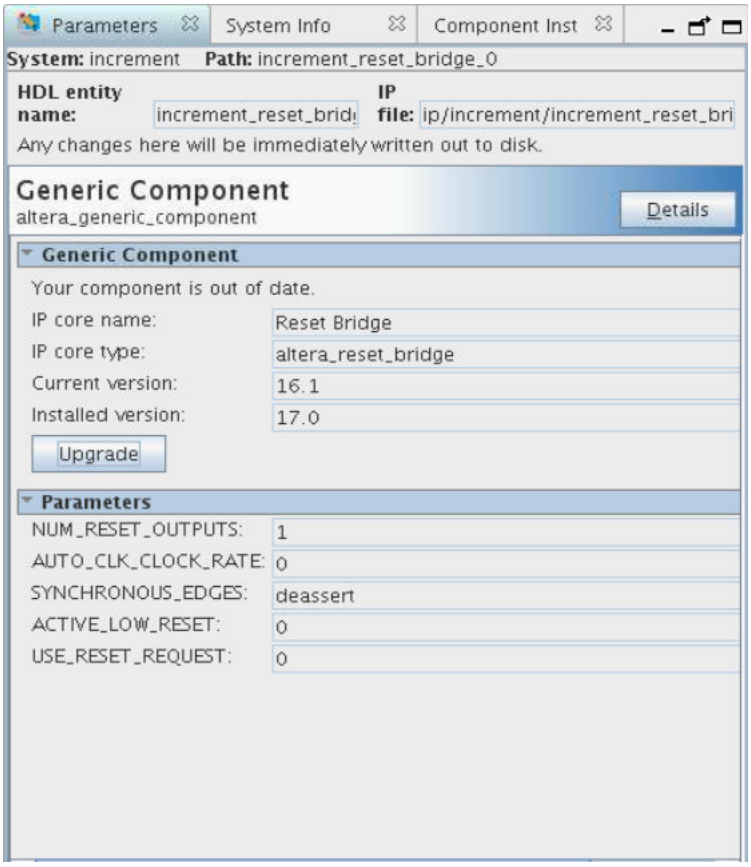
1.12. Upgrading Outdated IP Components in Platform Designer

When you open a Platform Designer system containing outdated IP components, you can retain and use the RTL of previously generated IP components within the Platform Designer system. If Platform Designer is unable to locate the IP core's original version, you cannot re-parametrize the IP core without upgrading the IP core to the latest version. However, Platform Designer allows you to view the parametrization of the original IP component without upgrading.

To upgrade individual IP components in your Platform Designer system:

1. Click **View ➤ Parameters**.
2. Select the outdated IP component in the **Hierarchy** or the **System View** tab.
3. Click the **Parameters** tab. This tab displays information on the current version, as well as the installed version of the selected IP component.
4. Click **Upgrade**. Platform Designer upgrades the IP component to the installed version, and deletes all the RTL files associated with the IP component.

Figure 77. Upgrade IP Component in your Platform Designer System



To upgrade an IP component from the command-line, type the following:

```
qsys-generate --upgrade-ip-cores <ip_file>
```

To upgrade all the IP components in your Platform Designer system, open the associated project in the Quartus Prime software, and click **Project ➤ Upgrade IP Components**.

1.13. Synchronizing System Component Information

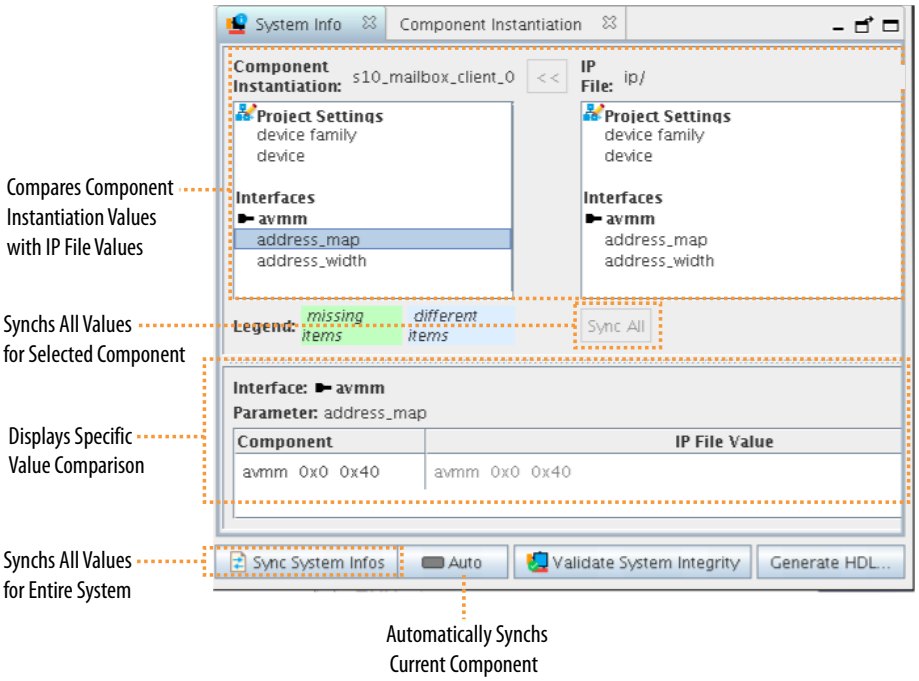
When a component instantiation values do not match the component's corresponding `.ip` file, Platform Designer reports these mismatches as Component Instantiation Warnings in the **System Messages** tab.

You must synchronize any mismatches between the component instantiation, and the component's corresponding `.ip` prior to system generation.

Follow these steps to synchronize one or more components in your system:

1. Select the mismatched signal or interface in the **System View** tab, and then click **View ➤ System Info**. Alternatively, you can double-click the corresponding Component Instantiation Warning in the **System Messages** tab.

Figure 78. System Info Tab



2. View any component mismatches in the **System Info** tab. Select individual interfaces, signals, or parameters to view the specific value differences in the **Component** and **IP file** columns. Value mismatches between the **Component Instantiation** and the **IP file** appear in blue. Missing elements appear in green.
3. To synchronize the **Component Instantiation** and **IP file** `.ip` values in the system, perform one or more of the following:
   - Select a specific mismatched parameter, interface, or signal and click **>>** to synchronize the items.
   - Click **Sync All** to synchronize all values for the current component.
   - Click **Sync System Infos** to synchronize all IP components (except "Missing Items") in the current system at once.

   Note: The following guidelines apply to synchronizing system elements that Platform Designer identifies as "Different Items" and "Missing Items":
   - You can synchronize "Different Items" but not "Missing Items."
   - For "Missing Items," you must replace the IP component in the Platform Designer system to ensure that the number and names of the parameters match.

1.13.1. System Info Tab Fields

Table 18. System Info Tab Fields

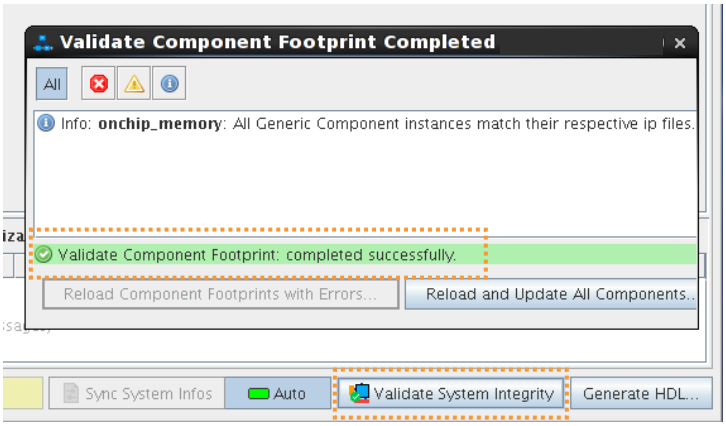
Name	Description
Component Instantiation	Lists the signals and interfaces for the selected component with respect to the component instantiation. Value mismatches between the **Component Instantiation** and the **IP file** appear in blue. Missing elements appear in green.
IP file	Lists the signal and interface information with respect to the `.ip` file. Value mismatches appear in blue. Missing elements appear in green.
Component Column	Displays the selected interface parameter value with respect to the **Component Instantiation**.
IP File Value	Displays the selected interface parameter value with respect to the **IP file**.
>>	Manually synchronizes the selected mismatch between signals and interfaces in the **Component Instantiation** and the **IP file**.
Sync All	Synchronizes **Component Instantiation** and **IP file** mismatches in the current system.

1.14. Validating System Integrity

You can use any of the following methods to validate Platform Designer system integrity.

- To perform system integrity check for the entire system, click the **Validate System Integrity** button at the bottom of main Platform Designer window. If validation finds errors, click **Reload and Update All Components** to reload signal and interface values from the corresponding IP component file.

Figure 79. Validating System Integrity



- View any errors and warnings on the **System Messages** tab. Double-click the warning or error messages to locate the issue in the **System View** or **Parameters** tab to correct the issue. Platform Designer generates the following types of system validation errors and warnings:

Table 19. System Messages Types in Platform Designer

System Messages Types	Description
Component Instantiation Warning	Indicates the mismatches between system information parameters or IP core parameterization errors. A system information parameters mismatch refers to the mismatch between an IP component's system parameter expectations and the component's saved system information parameters in the corresponding `.ip` file. For example: • Interface types do not match • Interface is missing • Port has been moved to another interface • Port role has changed • Interface assignment is mismatched • Interface assignment is missing
Component Instantiation Error	Indicates the mismatches between HDL entity name, compilation library, or ports which results in downstream compilation errors. The component instantiation errors always indicate the fundamental mismatches between generated system and interconnect fabric RTL. For example: • Port is missing from the ip file • Port is missing from instantiation • Port direction has changed • Port HDL type has changed • Port width has changed • Interface Parameter is mismatched • Interface Parameter is missing
System Connectivity Warning	Platform Designer system connectivity warnings.
System Connectivity Error	Platform Designer system connectivity errors.

1.14.1. Validating the System Integrity of Individual Components

To validate the system integrity for your IP components:

1. Select the IP component in the **System View** tab.
2. Right-click and select **Validate Component Footprint** to check for any mismatches between the IP component and its `.ip` file representation.
3. If there are any errors, click **Reload Component Footprint** to reload the signals and interfaces for the component from the `.ip` file.

1.15. Preserving System Elements for Debug

The Compiler optimizes the module, interface, and port names in your Platform Designer system during synthesis and place-and-route. Unless preserved, the module, interface, and port names in your system may not exist in the post-fit netlist after optimizations. For example, synthesis can merge duplicate registers, or add tildes (~) to net names that fan-out from a node.

You can use any of the following methods to prevent synthesis from performing optimizations on specific modules, interfaces, or port names, allowing the names to persist into the post-fit netlist for Signal Tap and other debug monitoring.

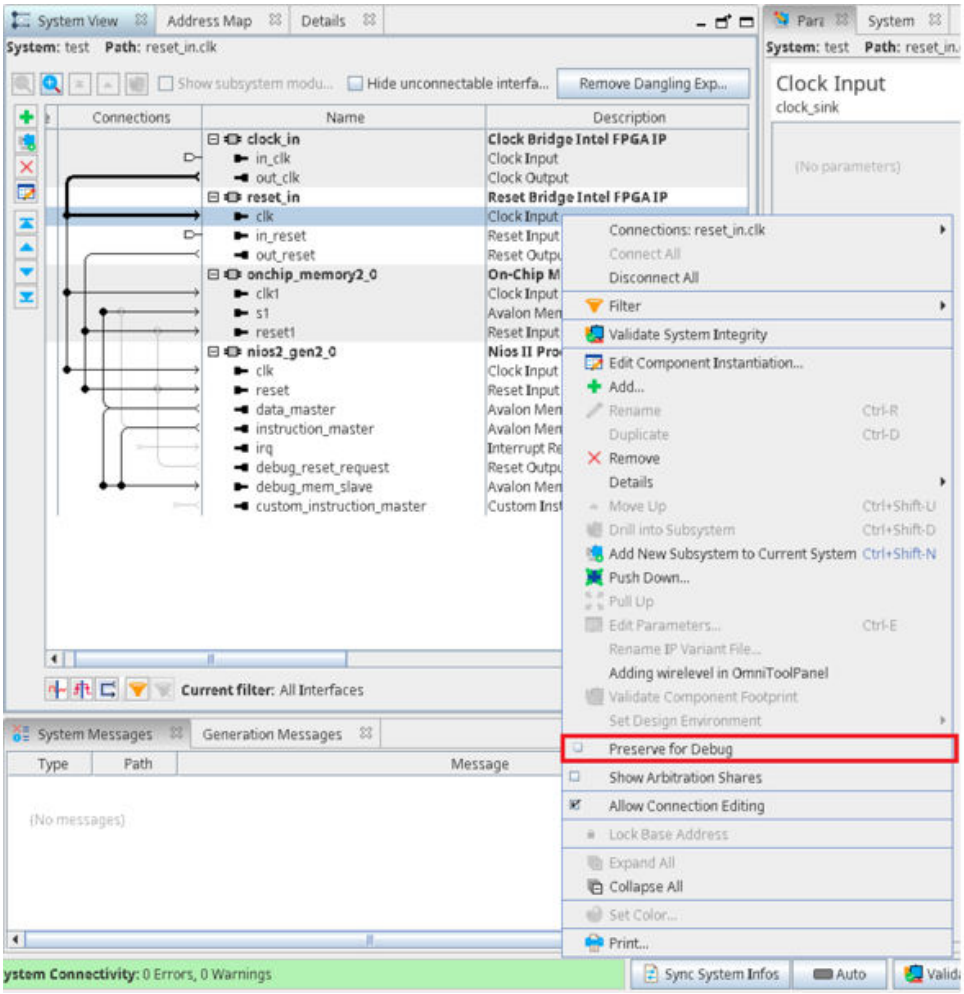
1. Enable preserve for debug using any of the following methods:

- On the **System View** tab, right-click any module, interface or port, and click **Preserve for Debug** in the context menu.
- On the **Filter** tab, right-click any module, interface, or port, and click **Preserve for Debug** in the context menu. A green icon color in the **Filter** tab indicates that preservation is applied.

Applying **Preserve for Debug** adds corresponding assignments to the `.qip`. Once applied, you can verify the assignments are correct in the `.qip`.

2. Recompile the design to apply the **Preserve for Debug** and view the preserved nodes following compilation.

Figure 80. Preserve for Debug from System View



Note: For more information about preserving signals, refer to *Preserving Registers During Synthesis*, in *Hyperflex Architecture High-Performance Design Handbook*. Specifying preservation synthesis attributes may increase device resource utilization or decrease timing performance when the attribute is active.

1.16. Generating a Platform Designer System

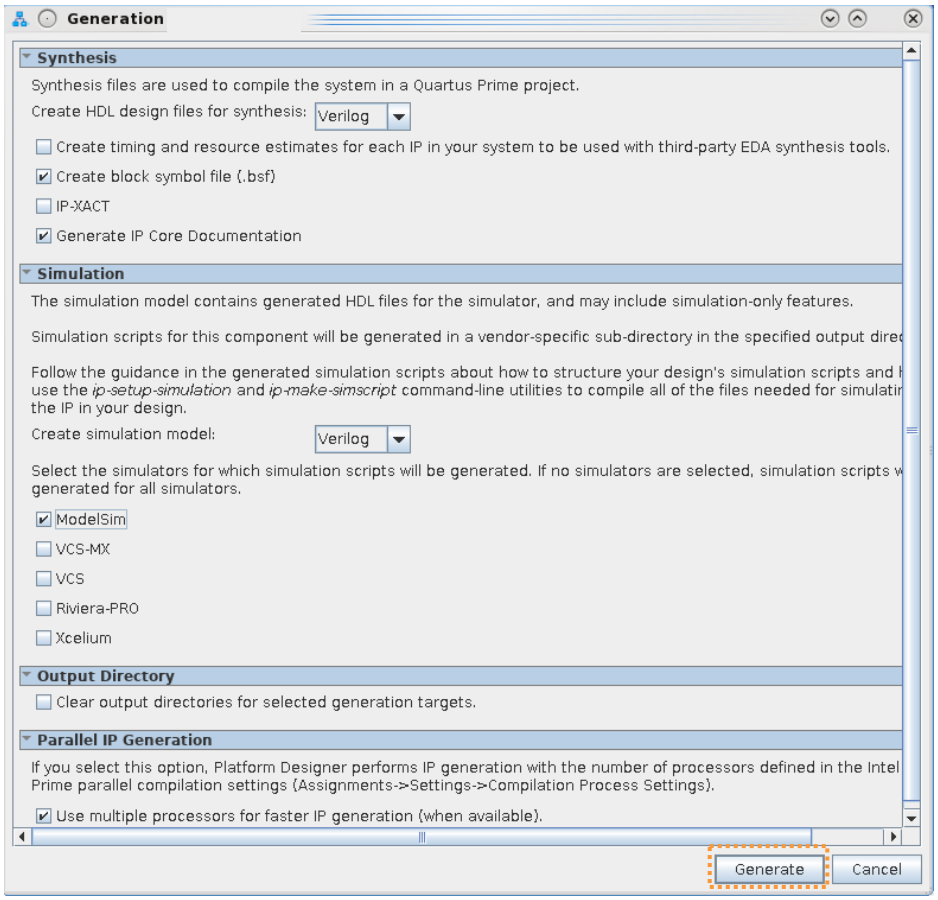
Platform Designer system generation creates the interconnect between IP components, and generates files for Quartus Prime synthesis and simulation in supported third-party tools.

If you make changes to your system, Platform Designer prompts you to generate your system before closing. Generate your system to ensure that the Compiler includes any changes you make to your system.

Follow these steps to generate a Platform Designer system:

1. Open a system in Platform Designer.
2. Consider whether to specify a unique generation ID, as Specifying the Generation ID on page 91 describes.

Figure 81. Platform Designer Generation Dialog Box



3. Click the **Generate HDL** button. The **Generation** dialog box appears.

4. Specify options for generation of **Synthesis**, **Simulation**, and testbench files, as Generation Dialog Box Options on page 90 describes.
5. Consider whether to specify options for **Parallel IP Generation**, as Disabling or Enabling Parallel IP Generation on page 92 describes.
6. To start system generation, click **Generate**.

   Note: Platform Designer may add unique suffixes (hashes) to ip component files during generation to ensure uniqueness of the file. The uniqueness of the files is necessary because the IP component is dynamic. The RTL generates during runtime, according to the input parameters. This methodology ensures no collisions between the multiple variants of the same IP. The hash derives from the parameter values that you specify. A given set of parameter values produces the same hash for each generation.

1.16.1. Generation Dialog Box Options

Platform Designer system generation creates files for Quartus Prime synthesis and supported third-party simulators. The **Generation** dialog box appears when you click **Generate HDL**, or when you attempt to close a system prior to generation.

By default, the synthesis and simulation files generate into the Platform Designer project directory.

You can specify the following system generation options in the **Generation** dialog box:

Table 20. Generation Dialog Box Options

Option	Description
Create HDL design files for synthesis	Allows you to specify **Verilog** or **VHDL** file type generation for the system's top-level definition and child instances. Select **None** to skip generation of synthesis files.
Create timing and resource estimates for each IP in your system to be used with third-party synthesis tools	Generates a non-functional Verilog Design File (`.v`) for use by supported third-party EDA synthesis tools. Estimates timing and resource usage for the IP component. The generated netlist file name is `<ip_component_name>_syn.v`.
Create Block Symbol File (.bsf)	Generates a Block Symbol File (`.bsf`) for use in a larger system schematic Block Diagram File (`.bdf`).
IP-XACT	Generates an IP-XACT file for the system, and adds the file to the IP Catalog. *Note:* Platform Designer supports importing and exporting files in IP-XACT 2009 format and exporting IP-XACT files in 2014 format.
Generate IP Core Documentation	Generates the IP user guide documentation for the components in your system (when available).
Create simulation model	Generates Verilog HDL or VHDL simulation models and simulator setup scripts. Enable the checkbox for one or more simulators to generate setup scripts for those tools in the following location: `<top-level system name>/<system name>/<sim>/<simulator>` If you do not specify a simulator, the setup scripts generate for all supported tools.
Clear output directories for selected generation targets	Clears previous synthesis and simulation file generation data for the current system.
Use multiple processors for faster IP generation (when available)	Disables or enables parallel IP generation for faster IP generation using multiple processors when available in your system.

Note: The Questa* Intel FPGA Edition simulator supports native, mixed-language (VHDL, Verilog HDL, SystemVerilog) simulation. Therefore, Intel simulation libraries may not be compatible with single language simulators. If you have a VHDL-only license, some versions of ModelSim* simulators may not support simulation for IPs written in Verilog. As a workaround, you can use the Questa Intel FPGA Edition simulator, or purchase a mixed-language simulation license from Siemens EDA.

Related Information

List of Supported Simulators

1.16.2. Specifying the Generation ID

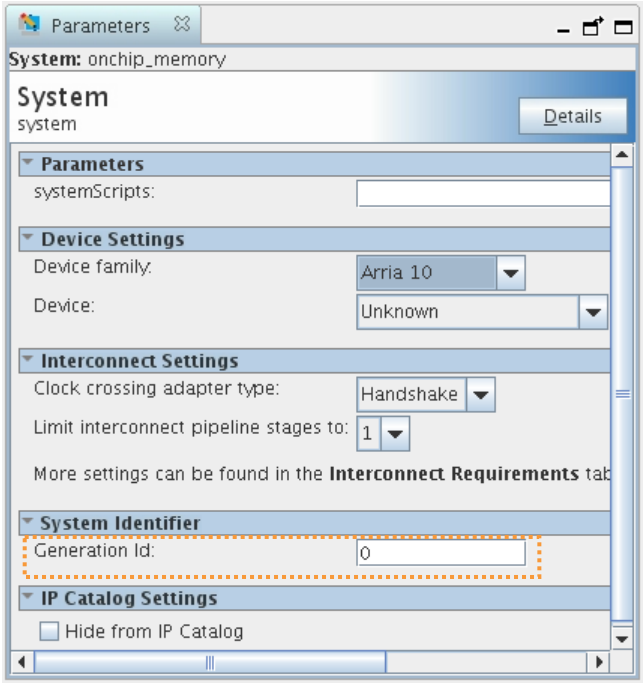
You can specify the **Generation ID** to uniquely identify that specific system generation number. This parameter allows system tools, such as Nios II processor, Nios V processor, or HPS (Hard Processor System) tools, to verify software-build compatibility with a specific Platform Designer system.

The **Generation ID** parameter is a unique integer value that derives from the timestamp during Platform Designer system generation. You can optionally modify this value to a value of your choosing to identify the system.

To specify the **Generation ID** parameter:

1. In the **Hierarchy** tab, select the top-level system.
2. Click **View ➤ Parameters**.
3. Under **System Identifier**, view or edit the value of **Generation ID**.

Figure 82. Generation ID in Parameters Tab



1.16.3. Disabling or Enabling Parallel IP Generation

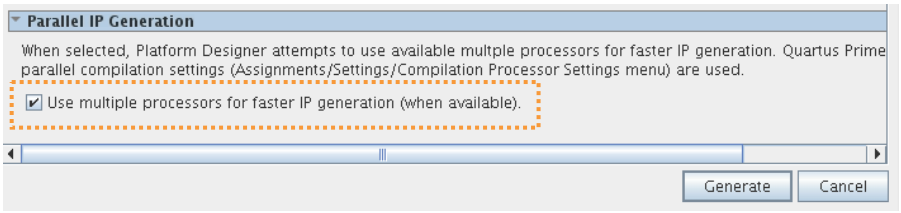
By default, the Quartus Prime software and Platform Designer use multiple processors if available in your PC or workstation for faster IP generation. IP generation for large systems can be time consuming. The use of parallel IP generation can potentially reduce the total IP generation time for designs with large numbers of IP.

The `qsys-generate` command line utility similarly uses parallel IP generation by default when multiple processors are available. You can disable or enable the use of parallel IP generation for the current IP generation, for the current project, or for all projects. You can also specify the maximum number of processors to use for parallel IP generation.

Disabling or Enabling Parallel IP Generation for the Current IP Generation

1. Open a system or IP component in Platform Designer, and click **Generate HDL**.
2. In the **Generation** dialog box, turn on or off **Use multiple processors for faster IP generation (when available)**. Platform Designer retains this setting for subsequent generations.

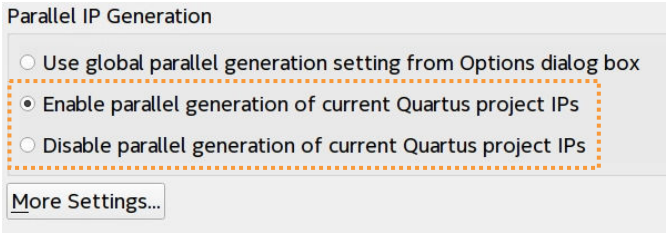
Figure 83. Disables or Enables Parallel IP Generation for the Current IP Generation



Disabling or Enabling Parallel IP Generation for a Single Project

1. In the Quartus Prime software, click **Assignments ➤ Settings ➤ Compilation Process Settings**.
2. Under **Parallel IP Generation**, select **Disable parallel generation of current Quartus project IPs** to disable parallel IP generation for the current project. Select **Enable parallel generation of current Quartus project IPs** to enable parallel IP generation for the current project.

Figure 84. Enables or Disables Parallel IP Generation for a Single Project



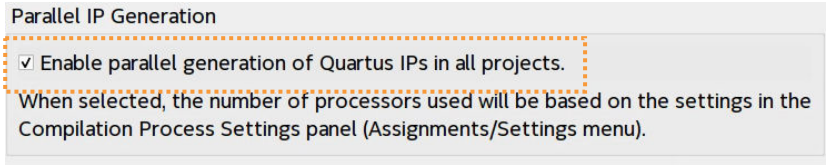
Alternatively, you can disable or enable parallel IP generation for a project with the following line in the project `.qsf` file:

```
set_global_assignment -name PROJECT_IP_GEN_PARALLEL_ENABLED <off|on>
```

Disabling or Enabling Parallel IP Generation for all Projects

1. In the Quartus Prime software, click **Tools ➤ Options ➤ IP Settings**.
2. Under **Parallel IP Generation**, enable or disable the **Enable parallel generation of Quartus IPs in all projects option**. When enabled, the Quartus Prime software uses multiple processors (if available in your system) for faster IP generation.

Figure 85. Enables or Disables Parallel IP Generation for all Projects



Alternatively, you can disable or enable parallel IP generation for all projects by adding the following line to the `quartus2.ini` file:

```
ENABLE_PARALLEL_IP_GEN=<off|on>
```

Specifying the Maximum Number of Processors

Parallel IP generation derives the maximum number of processors to use from the **Maximum processors allowed** Compiler setting. If you specify no value for this setting, the Quartus Prime software selects an appropriate number based on the available processors, and the number of tasks the processors can execute in parallel.

1. In the Quartus Prime software, click **Assignments ➤ Settings ➤ Compilation Process Settings**.
2. Under **Parallel compilation**, specify the **Maximum processors allowed** for processing designs.

Alternatively, you can set the number of processors with the following line in the project `.qsf` file:

```
set_global_assignment -name NUM_PARALLEL_PROCESSORS <number>
```

For the `qsys-generate` command line utility, you can use the `--parallel[=<number>]` argument, where <*number*> indicates the target number of processors.

Related Information

qsys-generate Command-Line Options on page 444

1.16.4. Files Generated for Platform Designer Systems

The Quartus Prime Pro Edition software generates the following output file structure for Platform Designer systems. Platform Designer automatically adds the generated `.qsys` system file to the open Quartus Prime project following generation.

Figure 86. Files generated for Platform Designer Systems

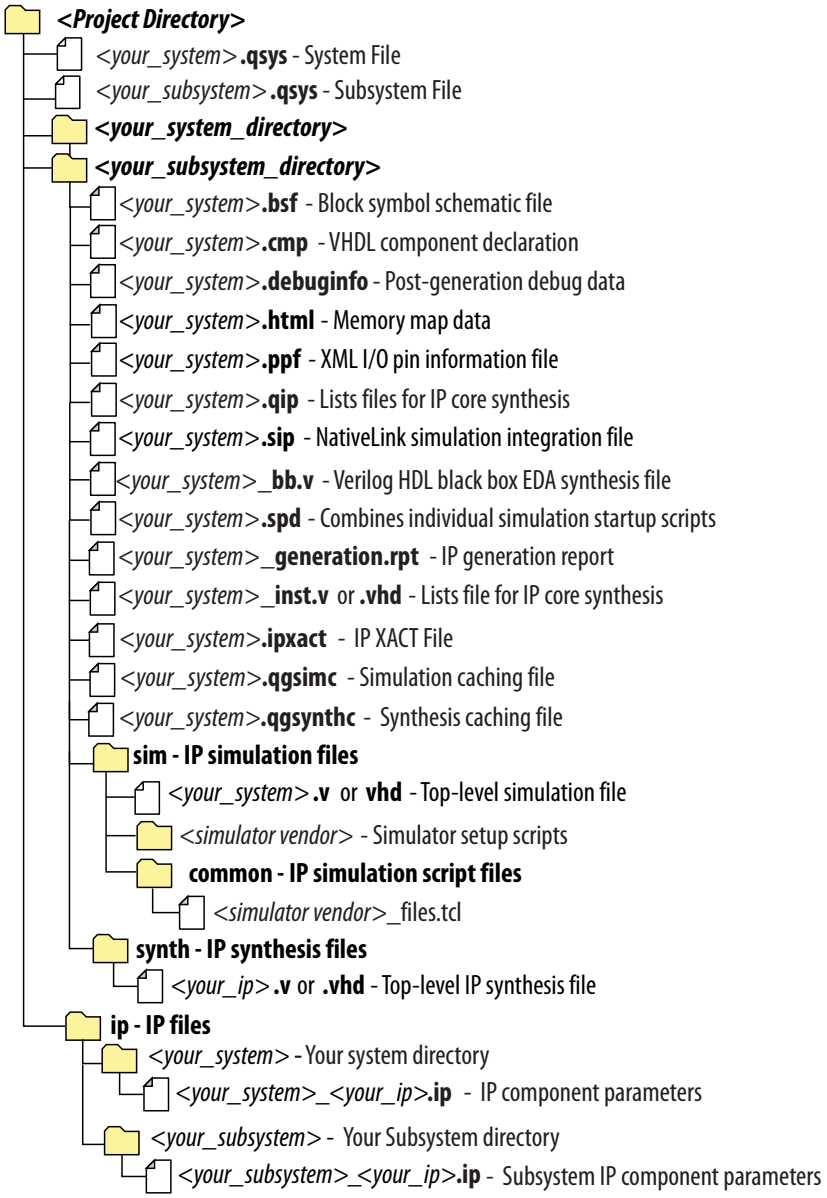


Table 21. Files Generated for Platform Designer Systems

File Name	Description
<your_system>.qsys	The Platform Designer system.
<your_subsystem>.qsys	The Platform Designer subsystem.
ip/	Contains the parameter files for the IP components in the system and subsystems.
<your_ip>.cmp	The VHDL Component Declaration (.cmp) file is a text file that contains local generic and port definitions that you can use in VHDL design files.

continued...

File Name	Description
<*your_system*>_generation.rpt	IP or Platform Designer generation log file. A summary of the messages during IP generation.
<*your_system*>.qgsimc	Simulation caching file that compares the .qsys and .ip files with the current parameterization of the Platform Designer system and IP core. This comparison determines if Platform Designer can skip regeneration of the HDL.
<*your_system*>.qgsynth	Synthesis caching file that compares the .qsys and .ip files with the current parameterization of the Platform Designer system and IP core. This comparison determines if Platform Designer can skip regeneration of the HDL.
<*your_system*>.qip	Contains all the required information about the IP component to integrate and compile the IP component in the Quartus Prime software.
<*your_system*>.csv	Contains information about the upgrade status of the IP component.
your_system.bsf	A Block Symbol File (.bsf) representation of the IP variation for use in Block Diagram Files (.bdf).
<*your_system*<>.spd	Required input file for ip-make-simscript to generate simulation scripts for supported simulators. The .spd file contains a list of files generated for simulation, along with information about memories that you can initialize.
<*your_system*>.ppf	The Pin Planner File (.ppf) stores the port and node assignments for IP components created for use with the Pin Planner.
<*your_system*>_bb.v	Use the Verilog black box (_bb.v) file as an empty module declaration for use as a black box.
<*your_system*>.sip	Contains information required for NativeLink simulation of IP components. Add the .sip file to your Quartus Prime Standard Edition project to enable NativeLink for supported devices. The Quartus Prime Pro Edition software does not support NativeLink simulation.
<*your_system*>_inst.v or _inst.vhd	HDL example instantiation template. Copy and paste the contents of this file into your HDL file to instantiate the IP variation.
<*your_system*>.regmap	If the IP contains register information, the Quartus Prime software generates the .regmap file. The .regmap file describes the register map information of host and agent interfaces. This file complements the .sopcinfo file by providing more detailed register information about the system. This file enables register display views and user customizable statistics in System Console.
<*your_system*>.svd	Allows HPS System Debug tools to view the register maps of peripherals connected to HPS within a Platform Designer system. During synthesis, the Quartus Prime software stores the .svd files for agent interface visible to the System Console hosts in the .sof file in the debug session. System Console reads this section, which Platform Designer can query for register map information. For system agents, Platform Designer can access the registers by name.
<*your_system*>.v <*your_ip*>.vhd	HDL files that instantiate each submodule or child IP core for synthesis or simulation.
mentor/	Contains a ModelSim script msim_setup.tcl to set up and run a simulation.
aldec/	Contains a Riviera-PRO* script rivierapro_setup.tcl to setup and run a simulation.
/synopsys/vcs /synopsys/vcsmx	Contains a shell script vcs_setup.sh to set up and run a VCS* simulation. Contains a shell script vcsmx_setup.sh and synopsys_ sim.setup file to set up and run a VCS MX simulation.
/cadence	Contains a shell script ncsim_setup.sh and other setup files to set up and run an NCSIM simulation.

continued...

File Name	Description
/xcelium	Contains a shell script xcelium_setup.sh and other setup files to set up and run a Xcelium* simulation.
/common	Contains a set of Tcl files, <simulator>_files.tcl, which provide all design related simulation information required by a corresponding simulation script. The Tcl file contains designs from current system-level hierarchy, and references to sub-systems and IP components.
/submodules	Contains HDL files for the IP core submodule.
<IP submodule>/	For each generated IP submodule directory, Platform Designer generates /synth and /sim sub-directories.

For generated IP components, Platform Designer appends unique suffixes (hashes) to the IP component's RTL file name to ensure uniqueness of the RTL file and IP component file. The uniqueness of the files is necessary because a system can have multiple instances of the same IP, each with different parameterizations, resulting in multiple variances of the IP component. The hash derives from the parameterization that you specify for the IP component. This methodology ensures no collisions between the multiple variants of the same IP.

1.16.5. Generating System Testbench Files

Platform Designer can generate testbench files that instantiate the current Platform Designer system and add Bus Functional Models (BFMs) to drive the top-level interfaces. BFMs interact with the system in the simulator.

You can generate a standard or simple testbench system with BFM or Mentor Verification IP (for AMBA 3 AXI or AMBA 4 AXI) components that drive the external interfaces of the system. Platform Designer generates a Verilog HDL or VHDL simulation model for the testbench system to use in the simulation tool.

First generate a testbench system, and then modify the testbench system in Platform Designer before generating the simulation model. Typically, you select only one of the simulation model options.

Follow these steps to generate system testbench files:

1. Open and configure a system in Platform Designer.
2. Click **Generate ➤ Generate Testbench System**. The **Generation** dialog box appears.
3. Specify options for the test bench system, as Testbench Generation Options describes.
4. Click **Generate**. The testbench files generate according to your specifications.
5. Open the testbench system in Platform Designer. Make changes to the BFMs, as needed, such as changing the instance names and **VHDL ID** value. For example, you can modify the **VHDL ID** value in the **Avalon Interrupt Source Intel FPGA IP** component.
6. If you modify a BFM, regenerate the simulation model for the testbench system.
7. Compile the system and load the Platform Designer system and testbench into your simulator, and then run the simulation.

Figure 87. Platform Designer Simulation Testbench Directory Structure

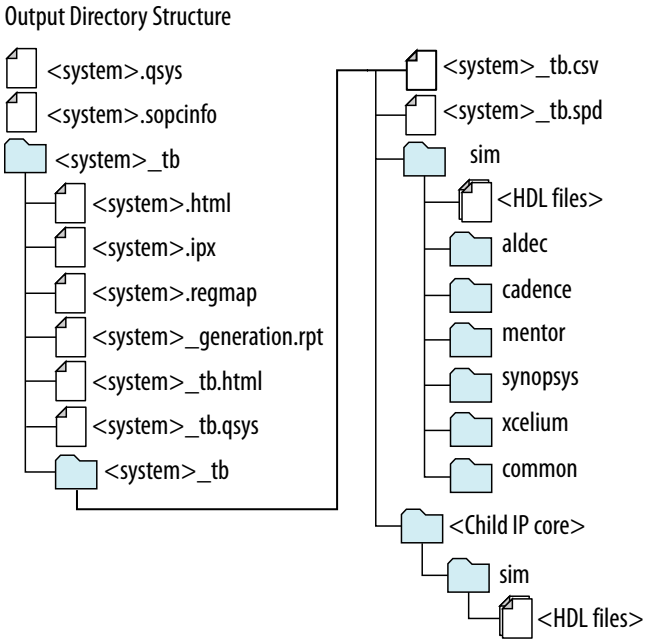

Table 22. Testbench Generation Options

Option	Description
Create testbench Platform Designer system	Specifies a simple or standard testbench system: • **Standard, BFMs for standard Platform Designer Interconnect**—Creates a testbench Platform Designer system with BFM IP components attached to exported Avalon and AMBA 3 AXI or AMBA 3 AXI interfaces. Includes any simulation partner modules specified by IP components in the system. The testbench generator supports AXI interfaces and can connect AMBA 3 AXI or AMBA 3 AXI interfaces to Mentor Graphics AMBA 3 AXI or AMBA 3 AXI manager and subordinate BFMs. However, BFMs support address widths only up to 32-bits. • **Simple, BFMs for clocks and resets**—Creates a testbench Platform Designer system with BFM IP components driving only clock and reset interfaces. Includes any simulation partner modules specified by IP components in the system.
Create testbench simulation model	Specifies Verilog HDL or VHDL simulation model files and simulation scripts for the testbench. Use this option if you do not need to modify the Platform Designer-generated testbench before running the simulation.
Output directory	Specifies the path for output of generated testbench files. Turn on **Clear output** to remove any previously generated content from the location.
Parallel IP Generation	Turn on **Use multiple processors for faster IP generation (when available)** to generate IP using multiple CPUs when available in your system.

1.16.5.1. Platform Designer Testbench Files

Platform Designer generates the following testbench files.

Table 23. Platform Designer Testbench Files

File Name or Directory Name	Description
<*system*>_tb.qsys	The Platform Designer testbench system.
<*system*>_tb.v or <*system*>_tb.vhd	The top-level testbench file that connects BFMs to the top-level interfaces of <*system*>_*tb*.qsys.
<*system*>_tb.spd	Required input file for `ip-make-simscript` to generate simulation scripts for supported simulators. The `.spd` file contains a list of files generated for simulation and information about memory that you can initialize.
<*system*>.html and <*system*>_tb.html	A system report that contains connection information, a memory map showing the address of each agent with respect to each host to which it is connected, and parameter assignments.
<*system*>_generation.rpt	Platform Designer generation log file. A summary of the messages that Platform Designer issues during testbench system generation.
<*system*>.ipx	The IP Index File (`.ipx`) lists the available IP components, or a reference to other directories to search for IP components.
<*system*>.svd	Allows HPS System Debug tools to view the register maps of peripherals connected to HPS within a Platform Designer system. Similarly, during synthesis the `.svd` files for agent interfaces visible to System Console hosts are stored in the `.sof` file in the debug section. System Console reads this section, which Platform Designer can query for register map information. For system agents, Platform Designer can access the registers by name.
mentor/	Contains a ModelSim script `msim_setup.tcl` to set up and run a simulation
aldec/	Contains a Riviera-PRO script `rivierapro_setup.tcl` to setup and run a simulation.
/synopsys/vcs /synopsys/vcsmx	Contains a shell script `vcs_setup.sh` to set up and run a VCS simulation. Contains a shell script `vcsmx_setup.sh` and `synopsys_ sim.setup` file to set up and run a VCS MX simulation.
/cadence	Contains a shell script `ncsim_setup.sh` and other setup files to set up and run an NCSIM simulation.
/xcelium	Contains a shell script `xcelium_setup.sh` and other setup files to set up and run an Xcelium simulation.
/common	Contains a set of Tcl files, `<simulator>_files.tcl`, which provide all design related simulation information required by a corresponding simulation script. The Tcl file contains designs from current system-level hierarchy, and references to sub-systems and IP components.
/submodules	Contains HDL files for the submodule of the Platform Designer testbench system.
<*child IP cores*>/	For each generated child IP core directory, Platform Designer testbench generates `/synth` and `/sim` subdirectories.

1.16.6. Generating Example Designs for IP Components

Some Platform Designer IP components include example designs that you can use or modify to replicate similar functionality in your own system. You must generate the examples to view or use them.

Use any of the following methods to generate example designs for IP components:

- Double-click the IP component in the Platform Designer IP Catalog or **System View** tab. The parameter editor for the component appears. If available, click the **Example Design** button in the parameter editor to generate the example design. The **Example Design** button only appears in the parameter editor if an example is available.
- For some IP components, click **Generate ➤ Generate Example Design** to access an example design. This command only enables when a design example is available.

The following Platform Designer system example designs demonstrate various design features and flows that you can replicate in your Platform Designer system.

Related Information

Intel FPGA Design Example Web Page

1.16.7. Incremental System Generation Example

You can modify the parameters of an IP component and regenerate the RTL for just that particular IP component.

The following example demonstrates incremental generation of a Platform Designer System:

1. Create a new Platform Designer system, as Creating or Opening a Platform Designer System on page 14 describes.
2. Use the IP Catalog to locate and add the **On-Chip Memory (RAM or ROM)** **Reset Bridge**, and **Clock Bridge** components to the system, as Adding IP Components to a System on page 40 describes.
3. Make the necessary system connections between the IP components added to the system, as Connecting System Components on page 63 describes.
4. To save and close the system without generating, click **File ➤ Save** and close Platform Designer.
5. In the Quartus Prime software, click **File ➤ Open Project**.
6. Select the Quartus Prime project associated with your saved Platform Designer system. The Quartus Prime software opens the project and the associated Platform Designer system.
7. To start the compilation of the Quartus Prime project, click **Processing ➤ Start Compilation**.
8. After compilation completes, in Platform Designer, click **File ➤ Open**.
9. Select the `.ip` file for any one of the IP components in your saved system.
10. Modify some parameter in this `.ip` file.

Note: Make sure your modifications do not affect the parent system, requiring a system update by running **Validate System Integrity** from within the Platform Designer system after loading the parent system, or by running `qsys-validate` from the command-line.

11. To save the IP file, click **File ➤ Save**.
12. To restart the compilation of the same Quartus Prime project with modified Platform Designer system, click **Processing ➤ Start Compilation** in the Quartus Prime software. Platform Designer generates the RTL only for the modified IP component, skipping the generation of the other components in the system.

1.16.8. Generating the HPS IP Component System View Description File

Platform Designer systems that contain an HPS IP component generate a System View Description (`.svd`) file that lists peripherals connected to the ARM® processor.

The `.svd` (or CMSIS-SVD) file format is an XML schema specified as part of the Cortex Microcontroller Software Interface Standard (CMSIS) that ARM provides. The `.svd` file allows HPS system debug tools (such as the DS-5 Debugger) to view the register maps of peripherals connected to HPS in a Platform Designer system.

Related Information

- Component Interface Tcl Reference on page 666
- CMSIS - Cortex Microcontroller Software

1.16.9. Generating Header Files for Host Components

You can use the `sopc-create-header-files` command from the Nios II command shell to create header files for any host component in your Platform Designer system. The Nios II tool chain uses this command to create the processor's `system.h` file. You can also use this command to generate system level information for a hard processing system (HPS) in Intel's SoC devices or other external processors. The header file includes address map information for each agent, relative to each host that accesses the agent. Different hosts may have different address maps to access a particular agent component. By default, the header files are in C format and have a `.h` suffix. You can select other formats with appropriate command-line options.

Table 24. sopc-create-header-files Command-Line Options

Option	Description
`<sopc>`	Path to Platform Designer `.sopcinfo` file, or the file directory. If you omit this option, the path defaults to the current directory. If you specify a directory path, you must make sure that there is a `.sopcinfo` file in the directory.
`--separate-hosts`	Does not combine a module's hosts that are in the same address space.
`--output-dir[=<dirname>]`	Allows you to specify multiple header files in *dirname*. The default output directory is '.'
`--single[=<filename>]`	Allows you to create a single header file, *filename*.
`--single-prefix[=<prefix>]`	Prefixes macros from a selected single host.
`--module[=<moduleName>]`	Specifies the module name when creating a single header file.

continued...

Option	Description
`--host[=<hostName>]`	Specifies the host name when creating a single header file.
`--format[=<type>]`	Specifies the header file format. Default file format is `.h`.
`--silent`	Does not display normal messages.
`--help`	Displays help for `sopc-create-header-files`.

By default, the `sopc-create-header-files` command creates multiple header files. There is one header file for the entire system, and one header file for each host group in each module. A host group is a set of hosts in a module in the same address space. In general, a module may have multiple host groups. Addresses and available devices are a function of the host group.

Alternatively, you can use the `--single` option to create one header file for one host group. If there is one CPU module in the Platform Designer system with one host group, the command generates a header file for that CPU's host group. If there are no CPU modules, but there is one module with one host group, the command generates the header file for that module's host group.

You can use the `--module` and `--host` options to override these defaults. If your module has multiple host groups, use the `--host` option to specify the name of a host in the desired host group.

Table 25. Supported Header File Formats

Type	Suffix	Uses	Example
h	`.h`	C/C++ header files	`#define FOO 12`
m4	`.m4`	Macro files for m4	`m4_define("FOO", 12)`
sh	`.sh`	Shell scripts	`FOO=12`
mk	`.mk`	Makefiles	`FOO := 12`
pm	`.pm`	Perl scripts	`$macros{FOO} = 12;`

Note: You can use the `sopc-create-header-files` command when you want to generate C macro files for DMAs that have access to memory that the Nios II processor cannot access.

1.17. Generating Simulation Files for Platform Designer Systems and IP Variants

If your design contains Intel FPGA IP or a Platform Designer system, you must first generate files for RTL simulation of the IP or system with the Quartus Prime Platform Designer before running simulation.

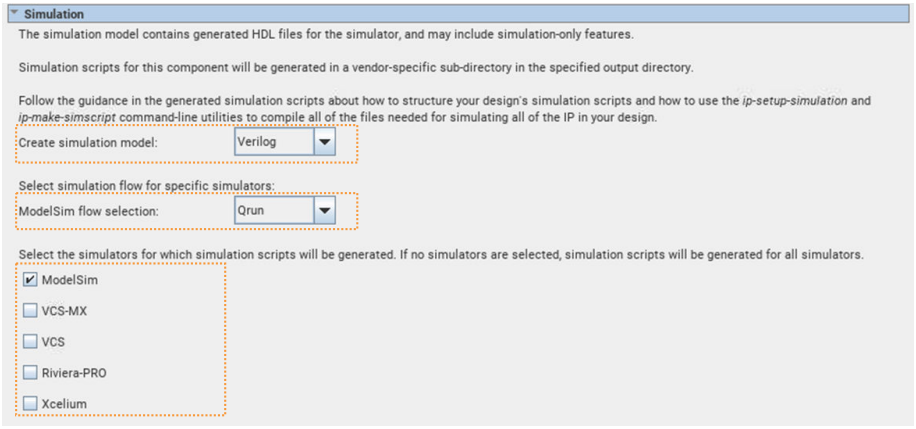
When you generate the system (or IP variant), Platform Designer optionally creates simulation files, including the functional simulation model, any testbench (or example design), and vendor-specific simulator setup scripts for each IP core.

You can use the functional simulation model and any testbench or example design for simulation of the IP or system. The IP generation output may also include scripts to compile and run any testbench. The scripts list all models or libraries you require to simulate your IP core.

To generate the simulation model and simulator setup scripts for your Platform Designer system or component, follow these steps:

1. Click **Tools ➤ Platform Designer**. Platform Designer and open or create a Platform Designer system or IP variant.
2. In Platform Designer, after specifying parameters, click **Generate ➤ Generate HDL**. The **Generation** dialog box appears.
3. Under **Simulation**, specify **Verilog** or **VHDL** for the **Create simulation model** option.

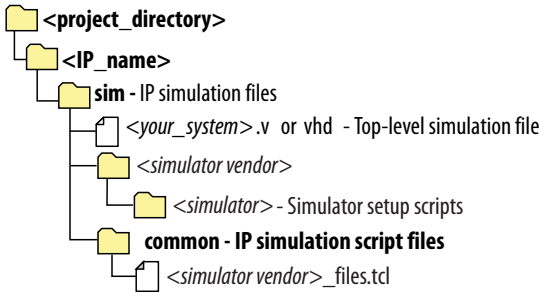
Figure 88. Simulation Options in Generation Dialog Box



4. If you want to specifically use ModelSim, specify **Traditional** or **Qrun** for the ModelSim flow option. Otherwise, **Qrun** flow is the default selection.
5. Turn on or off the **ModelSim**, **VCS-MX**, **VCS**, **Riviera-Pro**, or **Xcelium** option to generate simulator setup scripts for the simulation tool. If you turn on no simulator options, the scripts generate for all simulators.
6. Click the **Generate** button. Platform Designer generates the simulation models and setup scripts for your system or IP component in the following directory:

```
<top-level system name>/<system name>/<sim>/<simulator>
```

Figure 89. Generated Simulation Files Location



By default, Platform Designer generates the simulation scripts for the currently loaded system and all subsystems. Alternatively, you can open a subsystem to generate a simulation script only for that subsystem.

You can use scripts to compile the required device libraries and system design files in the correct order and elaborate or load the top-level system for simulation.

Table 26. Simulation Script Variables

The simulation scripts provide variables that allow flexibility in your simulation environment.

Variable	Description
`TOP_LEVEL_NAME`	If the testbench Platform Designer system is not the top-level instance in your simulation environment because you instantiate the Platform Designer testbench within your own top-level simulation file, set the `TOP_LEVEL_NAME` variable to the top-level hierarchy name.
`QSYS_SIMDIR`	If the simulation files generated by Platform Designer are not in the simulation working directory, use the `QSYS_SIMDIR` variable to specify the directory location of the Platform Designer simulation files.
`QUARTUS_INSTALL_DIR`	Points to the Quartus installation directory that contains the device family library.

Example 3. Top-Level Simulation HDL File for a Testbench System

The example below shows the `pattern_generator_tb` generated for a Platform Designer system called `pattern_generator`. The `top.sv` file defines the top-level module that instantiates the `pattern_generator_tb` simulation model, as well as a custom SystemVerilog test program with BFM transactions, called `test_program`.

```
module top();
 pattern_generator_tb tb();
 test_program pgm();
endmodule
```

Related Information

qsys-generate Command-Line Options on page 444

1.17.1. Using the Qrun Flow

The Quartus Prime Pro Edition software now supports a new Qrun flow for IP generation. The Qrun flow optionally creates simulation files, including the functional simulation model, and any testbench (or example design).

The Qrun flow, for use with only the QuestaSim* and Questa Intel FPGA Edition simulators, is an enhancement over the traditional flow that can automatically combine the compile, optimize, and simulate functions into a single step.

This section describes how to specify the Qrun settings, generate the system or component simulation model and simulator setup scripts, and generate the testbench and example design.

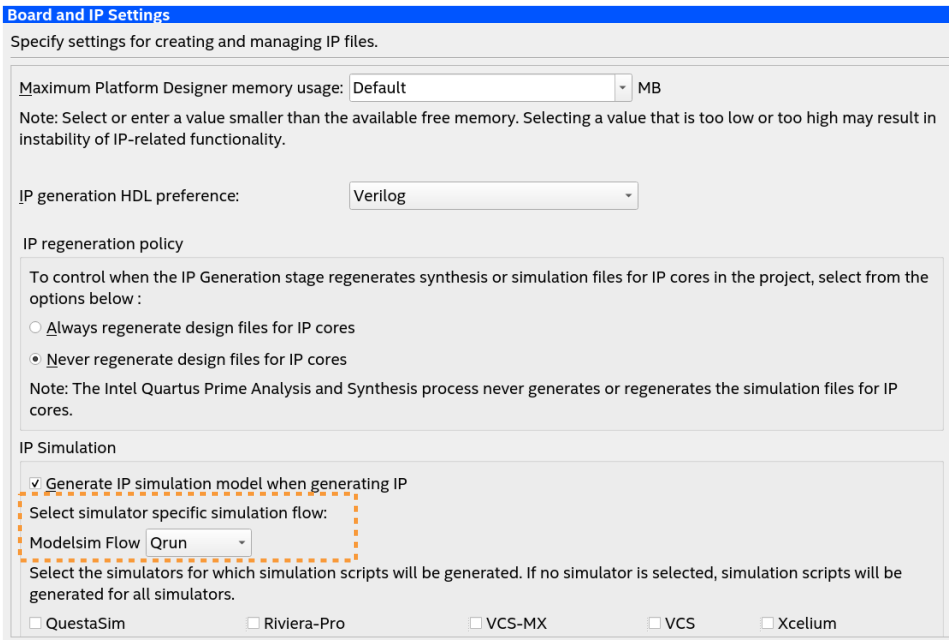
1.17.1.1. Specifying Simulation File Generation Settings

Before generating simulation files using the Qrun flow, you specify your supported simulator and other options for simulation file generation. These setting impact the generation of simulation files when generating HDL for IP in your project.

To specify simulation file generation settings, follow these steps:

1. In the Quartus Prime Pro Edition software, click **Assignments ➤ Settings ➤ Board and IP Settings**. The **Board and IP Settings** dialog box appears.
2. Under **IP Simulation**, turn on **Generate IP simulation model when generating IP**. Turning on this option enables the remaining settings.
3. For **Select simulator specific simulation flow**, make sure **Qrun** is selected to enable the Qrun flow. The alternative setting runs the **Traditional** flow.

Figure 90. Board and IP Settings Page of Settings Dialog Box



4. To specify one or more specific simulators for which to generate simulation files, enable the checkbox for those simulators. To enable generation for all supported simulators, leave all checkboxes disabled (default setting).

To generate the simulation model and simulator setup scripts for your Platform Designer system or IP component in batch mode, use this command:

```
ip-make-simscript [args] --modelsim_flow=QRUN
```

Type `ip-make-simscript -help` for all available arguments (`[args]`).

1.17.1.2. Generating the Simulation Model and Setup Scripts

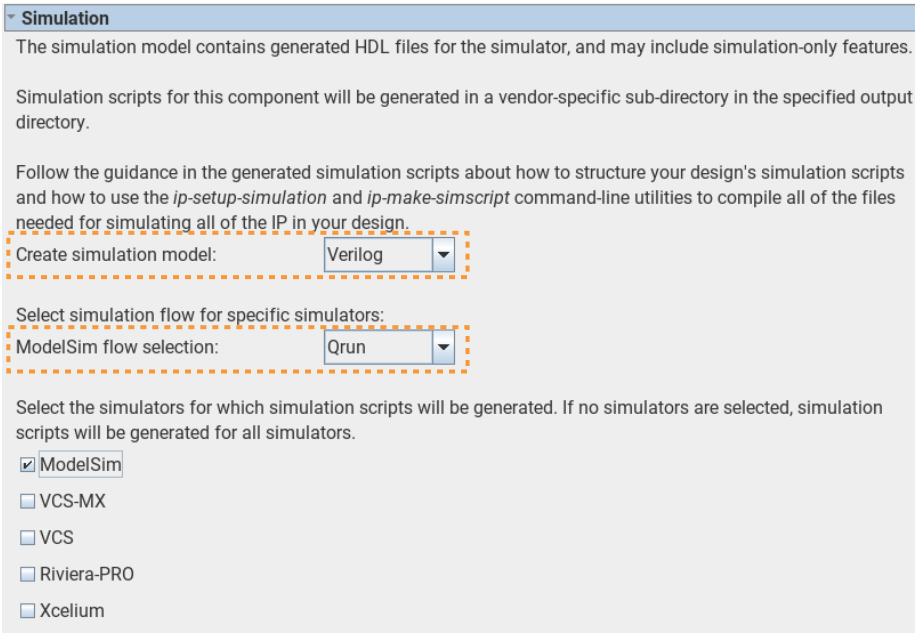
You generate the simulation model and setup scripts for IP components and Platform Designer systems when generating HDL for these IP in your project.

Platform Designer generates the simulation model and setup scripts according to your specifications in Specifying Simulation File Generation Settings.

To generate the simulation model and simulator setup scripts for your Platform Designer system or IP component, follow these steps:

1. In the Quartus Prime Pro Edition software, click **Tools ➤ Platform Designer** and open or create an IP variant or Platform Designer system.
2. After specifying any IP component or system parameters in the parameter editor, click the **Generate HDL** button. The **Generation** dialog box appears.
3. Under **Simulation**, select either **Verilog** or **VHDL** for **Create Simulation Model**. Selecting one of these options makes the **Modelsim flow selection** setting editable.
4. For **Modelsim flow selection**, make sure **Qrun** is selected to enable the Qrun flow. The alternative setting runs the **Traditional** flow.

Figure 91. Generation Dialog Box Settings



5. To specify one or more specific simulators for which to generate simulation files, enable the checkbox for those simulators. To enable generation for all supported simulators, leave all checkboxes disabled (default setting).
6. Click **Generate**. Platform Designer generates the simulation models and setup scripts for your system or IP component in the *<project>*/*<IP name>*/sim/<vendor> directory.

To generate the simulation model and simulator setup scripts for your Platform Designer system or IP component in batch mode, use this command:

```
qsys-generate <file> [args] --modelsim_flow=QRUN
```

1.17.1.3. Generating the Testbench System

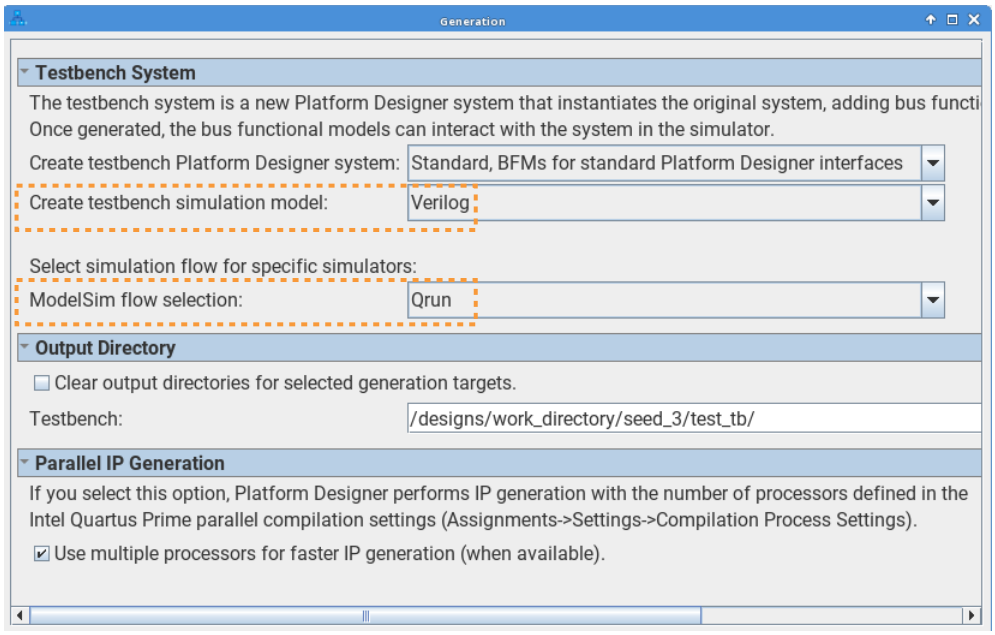
You can optionally generate a testbench system that instantiates the original system, adding bus functional models to drive the top-level interfaces. Once generated, the bus functional models can interact with the system or IP in the simulator.

Platform Designer generates the simulation model and setup scripts according to your specifications in Specifying Simulation File Generation Settings.

To generate the testbench system for a Platform Designer system or IP component, follow these steps:

1. In the Quartus Prime Pro Edition software, click **Tools ➤ Platform Designer** and open or create an IP variant or Platform Designer system.
2. After specifying any IP component or system parameters in the parameter editor, click the **Generate ➤ Generate Testbench System** button. The **Generation** dialog box appears.
3. Under **Testbench System**, select either **Verilog** or **VHDL** for **Create testbench simulation model**. Selecting one of these options makes the **Modelsim flow selection** setting editable.
4. For **Modelsim flow selection**, make sure **Qrun** is selected to enable the Qrun flow. The alternative setting runs the **Traditional** flow.

Figure 92. Generation Dialog Box Settings



5. Click **Generate**. Platform Designer generates the simulation models and setup scripts for your system or IP component under the specified **Output Directory**.

1.17.1.4. Generating Example Design Simulation Files

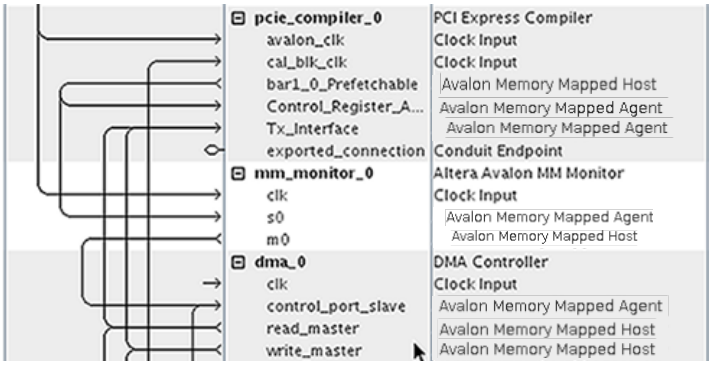
When you run **Generate ➤ Generate Example Design**, Platform Designer automatically generates the simulator setup script `msim_setup.tcl` containing `qrun` commands.

1.17.2. Adding Assertion Monitors for Simulation

You can add monitors to Avalon Memory-Mapped, AXI, and Avalon Streaming interfaces in your system to verify protocol and test coverage with a simulator that supports SystemVerilog assertions.

Figure 93. Inserting an Avalon Memory-Mapped Monitor Between an Avalon Memory-Mapped Host and Agent Interface

This example demonstrates the use of a monitor with an Avalon Memory-Mapped monitor between the `pcie_compiler bar1_0_Prefetchable` Avalon Memory-Mapped host interface, and the `dma_0 control_port_agent` Avalon Memory-Mapped agent interface.



Similarly, you can insert an Avalon Streaming monitor between Avalon Streaming source and sink interfaces.

Note: Refer to the *Nios V Processor Quick Start Guide* for information on simulating Nios V processor designs.

Related Information

Nios V Embedded Processor Design Handbook

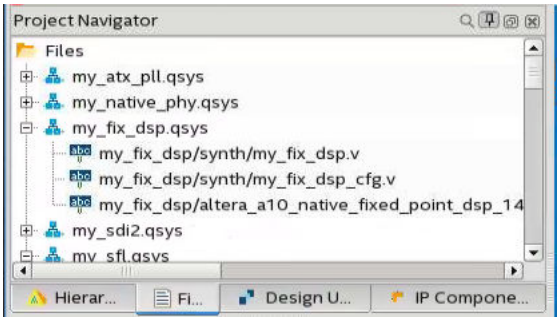
1.18. Adding a System to an Quartus Prime Project

Platform Designer requires that you to specify an associated Quartus Prime project at time of system creation. After you specify the associated project, Platform Designer automatically adds any system or IP component that you generate to that project. You can also manually add a Platform Designer system or component to a project.

To add a Platform Designer system or component to an Quartus Prime project, perform one or more of the following steps:

1. In Platform Designer, specify the associated **Quartus project** when you create a system, or click **File ➤ Select Quartus Project** to change this setting. Platform Designer automatically adds any system or IP component that you generate to the associated Quartus Prime project.
2. To manually add a Platform Designer system or component to your project, generate the system or component, and then click **Project ➤ Add/Remove Files in Project** in the Quartus Prime software.
3. Select and add the `.qsys` files to your project. The Quartus Prime Project Navigator **Files** tab lists all system and component files that you or Platform Designer add to your project.

Figure 94. Platform Designer System Files in Project



1.19. Managing Hierarchical Platform Designer Systems

Platform Designer supports hierarchical systems that include one or more Platform Designer subsystems within another Platform Designer system. Platform Designer allows you to create, explore, and edit systems and subsystems together in the same Platform Designer window. Platform Designer generates the complete system hierarchy during the top-level system's generation.

All hierarchical Platform Designer systems appear in the IP Catalog under **Project ➤ System**. You select the system from the IP Catalog to reuse the system across multiple designs. In a team-based hierarchical design flow, you can divide large designs into subsystems and allow team members develop subsystems simultaneously.

Related Information

Viewing the System Hierarchy on page 30

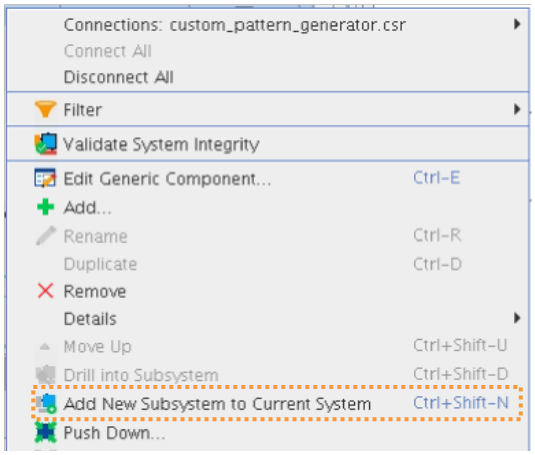
1.19.1. Adding a Subsystem to a Platform Designer System

You can add a Platform Designer system as a subsystem (child) of another Platform Designer system (parent), at any level in the parent system hierarchy.

Follow these steps to add a subsystem to a Platform Designer system:

1. Create a Platform Designer system to use as the subsystem.
2. Open a Platform Designer system to contain the subsystem.
3. On the **System View** tab, use any of the following methods to add the subsystem:
   - Right-click anywhere in the **System View** and click **Add a new subsystem to the current system**.
   - Click the **Add a new subsystem to the current system** button on the toolbar.
   - Press Ctrl+Shift+N.
4. In the **Confirm New System Name** dialog box, confirm or specify the new system file name and click **OK**. The system appears as a new subsystem in the **System View**.

Figure 95. Adding a Subsystem



1.19.2. Viewing and Traversing Subsystem Contents

You can view and traverse the elements and connections within subsystems in a hierarchical Platform Designer system.

Follow these steps to view and traverse subsystem contents:

1. Open a Platform Designer system that contains a subsystem.
2. Use any of the following methods to view the subsystem contents:
   - Use the filtering controls in the **Filter** tab to change the level of detail in the **System View**.
   - Right-click a system in the **System View** or **Schematic** tabs, and then select **Drill into Subsystem**. The subsystem opens in the **System View**.
   - Press Ctrl+Shift+D in the **System View** tab.
3. Use any of the following **System View** or **Schematic** tab toolbar buttons to traverse the system and subsystems:

Figure 96. Traversing Subsystem Contents

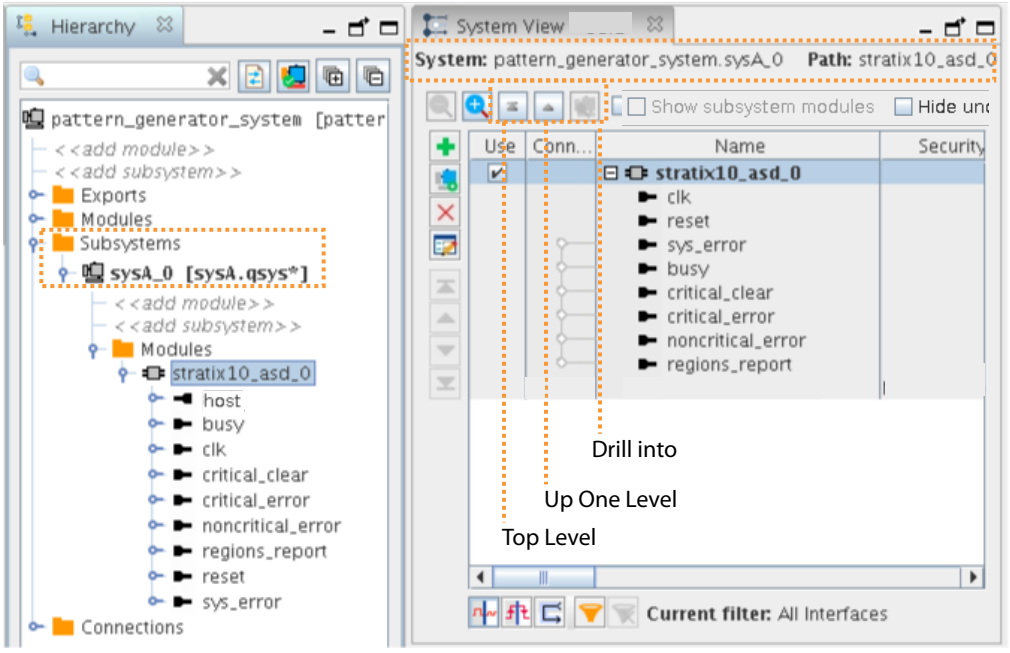


Table 27. System View and Schematic Tab Navigation Buttons

Button	Description
	**Move to the top of the hierarchy**—navigates to the top-level (parent) `.qsys` file for the system.
	**Move up one level of hierarchy**—navigates up one hierarchy level from the current selection.
	**Drill into a subsystem to explore its contents**—opens the subsystem you select in the **System View**.

Note: You can only view and traverse the contents of subsystems that you define in a `.qsys` file, not parameterizable Platform Designer systems or `_hw.tcl` files.

1.19.3. Editing a Subsystem

You can double-click a Platform Designer subsystem in the **Hierarchy** tab to edit its contents in any tab. When you make a change, open tabs refresh their content to reflect your edit. You can change the level of a subsystem, or push the system into another subsystem with commands in the **System View** tab.

Note: You can only edit subsystems that a writable `.qsys` file preserves. You cannot edit systems that you create from composed `_hw.tcl` files, or systems that define instance parameters.

Follow these steps to edit a Platform Designer subsystem:

1. Open a Platform Designer system that contains a subsystem.
2. In the **System View** or **Schematic** tabs, use the **Move Up**, **Move Down**, **Move to Top**, and **Move to Bottom** toolbar buttons to navigate the system level you want to edit. Platform Designer updates to reflect your selection.
3. To edit a system, double-click the system in the **Hierarchy** tab. The system opens and is available for edit in all Platform Designer views.
4. In the **System View** tab, you can rename any element, add, remove, or duplicate connections, and export interfaces, as appropriate.

   Note: Changes to a subsystem affect all instances. Platform Designer identifies unsaved changes to a subsystem with an asterisk next to the subsystem in the **Hierarchy** tab.

1.19.4. Saving a Subsystem

When you save a subsystem as part of a Platform Designer system, Platform Designer confirms the new subsystem name in the **Confirm New System Filenames** dialog box. By default, Platform Designer suggests the same name as the subsystem `.qsys` file and saves in the project's `/ip` directory.

Follow these steps to save a subsystem:

1. Open a Platform Designer system that contains a subsystem.
2. Click **File ➤ Save** to save your Platform Designer design.
3. In the **Confirm New System Filenames** dialog box, click **OK** to accept the subsystem file names.

   Note: If you have not yet saved your top-level system, or multiple subsystems, you can type a new name, and then press **Enter**, to move to the next un-named system.
4. In the **Confirm New System Filenames** dialog box, to edit the name of a subsystem, click the subsystem, and then type the new name.

1.19.5. Changing a Component's Hierarchy Level

You can change the hierarchical level of components in your system.

You can lower the hierarchical level of a component, even into its own subsystem, which can simplify the top-level system view. You can also raise the level of a component or subsystem to share the component or subsystem between two unique subsystems. Management of hierarchy levels facilitates system optimization and can reduce complex connectivity in your subsystems.

Follow these steps to change a component's hierarchy level:

1. Open a Platform Designer system that contains a subsystem.
2. In the **System View** tab, to group and change the hierarchy level of multiple components that share a system-level component, multi-select the components, right-click, and then click **Push down into new subsystem**. Platform Designer pushes the components into their own subsystem and re-establishes the exported signals and connectivity in the new location.
3. In the **System View** tab, to pull a component up out of a subsystem, select the component, and then click **Pull up**. Platform Designer pulls the component up out of the subsystem and re-establishes the exported signals and connectivity in the new location.

1.20. Saving and Archiving Platform Designer Systems

You can save your system in Platform Designer for later modification and reuse. Alternatively, Platform Designer can archive your entire system into a single compressed `.zip` or Tcl script (`.tcl`) file for easy storage and restoration.

If saving a Platform Designer system for external revision control systems, saving as a Tcl script may be preferred because that creates a single, clear text file that you can diff with a previous version to indicate changes.

You can also archive an entire Quartus Prime project, including any Platform Designer system or IP, within in a single, compressed Quartus Prime Archive File (`.qar`). The `.qar` preserves the project and setting files, design files, IP and system files, programming files, and all other files needed to restore the project (and system).

The `qsys-archive` utility provides command-line options for system archive, including system extraction and system dependency reporting. The following describe Platform Designer system saving and archiving in detail:

- Saving Platform Designer Systems on page 112
- Archiving Platform Designer Systems on page 113
- Including Platform Designer Systems in Project Archives on page 115
- Project Files to Include In External Revision Control on page 116
- Archive and Extract Platform Designer Systems with qsys-archive on page 457

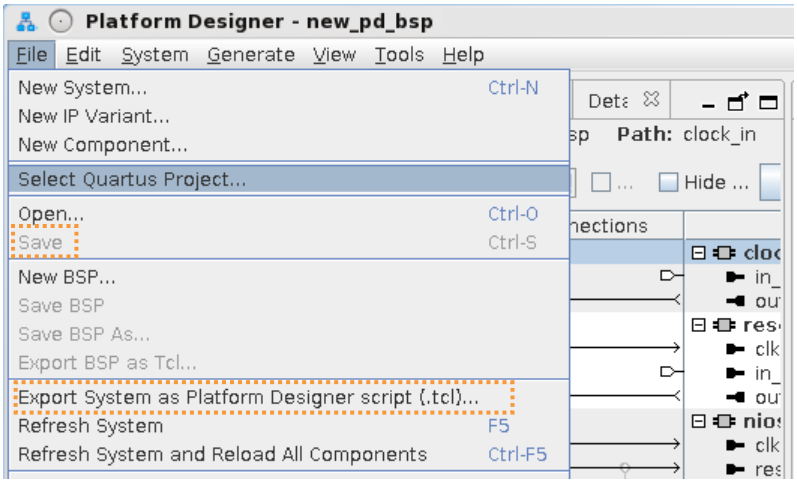
1.20.1. Saving Platform Designer Systems

Platform Designer prompts you to save any changes to your system before generating or closing. You can use any of the following methods to save your Platform Designer system:

- To save a Platform Designer system, click **File ➤ Save** in Platform Designer.
- To save a Platform Designer system as a Tcl script, click **File ➤ Export System as Platform Designer script**.

Note: The generated Tcl scripts also include any pin constraints that you set by applying presets to a Platform Designer system.

Figure 97. Saving A Platform Designer System



Restore this system by executing the `.tcl` file from the **System Scripting** tab, or with the `qsys-script` command.

Note: Restoring with `qsys-script` generates default project (`.qpf`) and settings (`.qsf`) files that contain only basic information. The `.qsf` includes no project-specific assignments from the original project's `.qsf`. You can click **File ➤ Select Quartus Project** in Platform Designer to associate a system with any Quartus Prime project.

Related Information

Generate a Platform Designer System with qsys-script on page 451

1.20.2. Archiving Platform Designer Systems

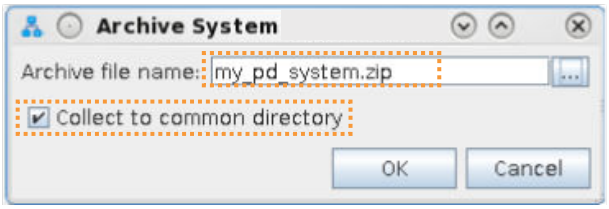
The Platform Designer GUI supports archiving an entire Platform Designer system to a single, compressed `.zip` file, and then restoring the archive in another instance of Platform Designer.

Alternatively, use the `qsys-archive` command to archive and restore Platform Designer systems at the command line.

To archive a Platform Designer system to a single, compressed `.zip` file:

1. Open a Platform Designer system.
2. In Platform Designer, click **File ➤ Archive System**. The **Archive System** dialog box appears.

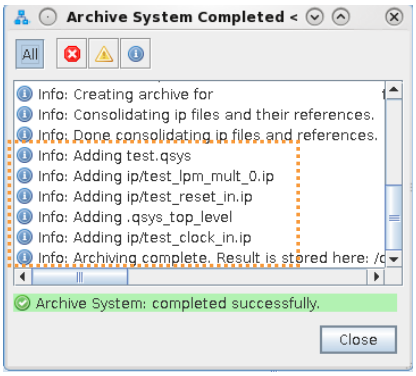
Figure 98. Archive System Dialog Box



3. Specify a name for **Archive file name**.

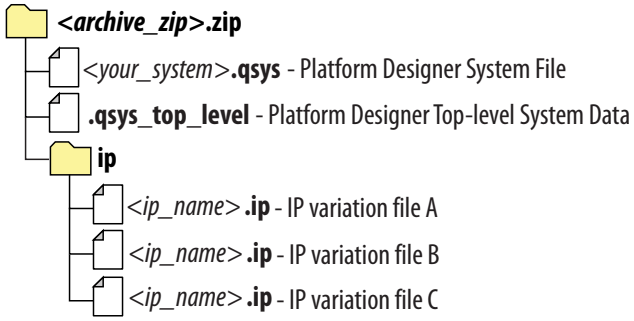
4. Enable or disable **Collect to common directory**. When enabled, Platform Designer collects the system's `.qsys` files in the root directory, and the `.ip` files in a single `ip` directory, while updating all references. Disable this option to maintain the current system's directory structure.
5. Click **OK**. Platform Designer generates the archive.

Figure 99. Archive System Complete



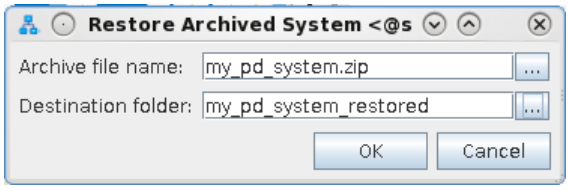
Note: Platform Designer automatically identifies the `.qsys` and `.ip` files needed for system archiving when using **Archive System**. You do not manually specify any files for archiving. **Archive System** does not include custom IP and related files in the archive by default.

Figure 100. System Archive Directory (Collect to common directory)



6. To restore the archived system, click **File ➤ Restore Archived System**. Select the **Archive file name**, and **Destination folder** to extract the restored files.

Figure 101. Restore Archived System



After restoration is complete, Platform Designer automatically launches the **Open System** dialog box, with the extracted project preloaded.

1.20.3. Including Platform Designer Systems in Project Archives

You can optionally save the elements of an Quartus Prime project—including any Platform Designer system or IP—in a single, compressed Quartus Prime Archive File (`.qar`). The `.qar` can preserve the project and settings files, source design files, IP and system files, programming output files, and all other files required to fully restore the project in the Quartus Prime software.

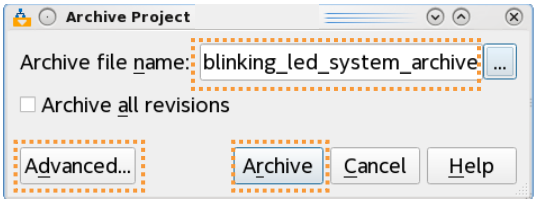
The archive `.qar` allows you to easily share projects between designers, or to transfer your project to a new version of the Quartus Prime software, or to Intel customer support. You can optionally include compilation reports, Platform Designer system files, and EDA tool integration files in the project archive.

You can fully customize the list of files that the archive includes, to ensure that your archive captures all custom IP and other files that you want to preserve. The **Archive Project** dialog box includes preset **File sets** that automatically include the appropriate detected files for **Source control**, **Service requests**, and other archiving scenarios.

By default, the **Archive Project** command includes detected Platform Designer system and IP files that are part of your project. Follow these steps to confirm that your project archive includes the Platform Designer system and IP files that you want:

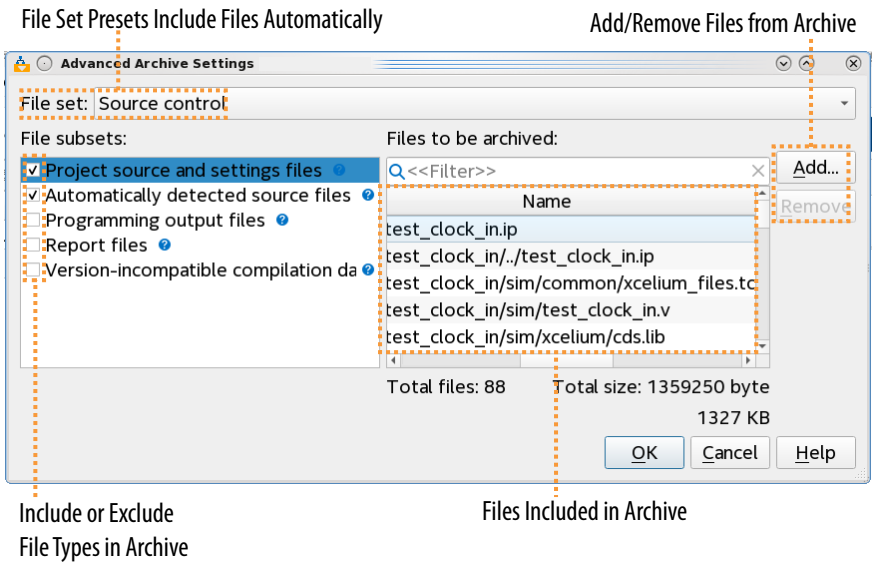
1. Open an Quartus Prime project (`.qpf`) that includes your Platform Designer system and IP.
2. Click **Project ➤ Archive Project** and specify an **Archive file name**.

Figure 102. Archive Project Dialog Box



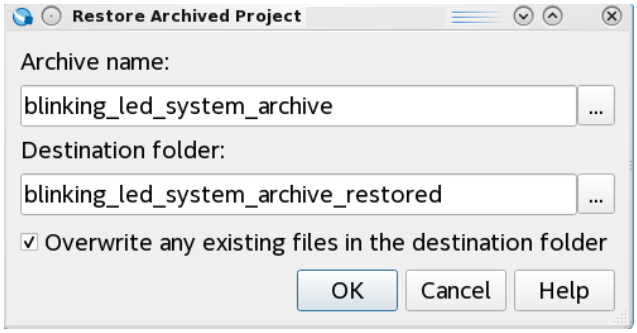
3. Click the **Advanced** button. The **Advanced Archive Settings** dialog box appears.
4. Select **Source control**, **Service requests**, or **Compilation Database and output** for the **File set**. All of these **File sets** include detected Platform Designer system and IP files in the archive automatically. Turn on or off the **File subsets** you want in the archive.
5. To customize the **Files to be archived** list, click the **Add** or **Remove** buttons to include or remove specific files.
6. To save the archive settings, click **OK**.

Figure 103. Advanced Archive Settings Dialog Box



7. To generate the project archive file, click the **Archive** button.
8. To restore the archived project (including the Platform Designer system and IP), click **Project ➤ Restore Archived Project**. Select the **Archive name**, and **Destination folder** to extract the restored files.

Figure 104.



1.20.3.1. Project Files to Include In External Revision Control

When archiving Quartus Prime projects for external source control, The **Source control** setting in **Advanced Archive Settings** dialog box is preset to include all appropriate file types for source control automatically.

Figure 105. Advanced Archive Settings Dialog Box

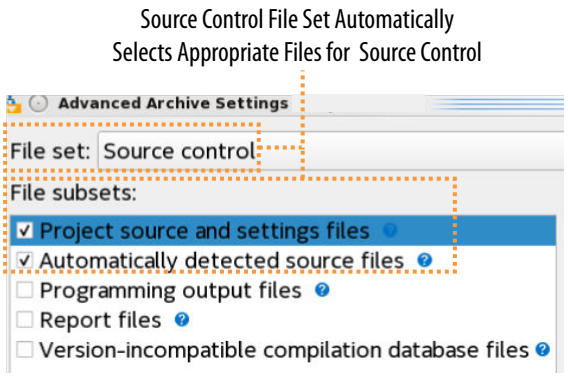


Table 28. Project Files to Include In External Revision Control

File Type	Description
Quartus Prime project setting and assignment files	• Quartus Prime Project Files (`.qpf`) • Quartus Prime Settings Files (`.qsf`) • Quartus Prime Pin Planner File (`.ppf`)
Timing constraint files	Synopsys Design Constraint Files (`.sdc`)
Design files	• Verilog HDL Design Files (`.v`) • SystemVerilog Design Files (`.sv`) • VHDL Design Files (`.vhd`) • Block Symbol Files (`.bsf`) • Verilog Quartus Mapping Files (`.vqm`) • Platform Designer System Files (`.qsys`) • State Machine Editor Files (`.smf`) • Tcl Script Design Files (`.tcl`)
System and IP files	• IP variation file (`.ip`) • Verilog IP design files (`.v`) • SystemVerilog IP design files (`.sv`) • VHDL IP design files (`.sv`) • VHDL Component Declaration Files (`.cmp`) • Quartus Prime IP file (`.qip`) • Quartus Prime Simulation IP File (`.sip`) • Platform Designer System Files (`.qsys`) • Platform Designer connection and parameterization files (`.sopcinfo`) • IP upgrade status files (`.csv`) • IP synthesis parameters files (`.qgsynthc`) • IP simulation parameters files (`.qgsimc`) • Platform Designer system exported as (`.tcl`).
EDA tool integration files	• Verilog HDL Output Files (`.vo`) • VHDL Output Files (`.vho`) • VHDL simulation model files (`.vhd`) • Verilog HDL simulation model files (`.v`) • Simulation library files (`cds.lib`, `hdl.var`) • Simulation setup scripts (`_setup.sh`, `.tcl`, `.spd`, `.txt`)

1.21. Sharing Platform Designer Packaged Subsystems

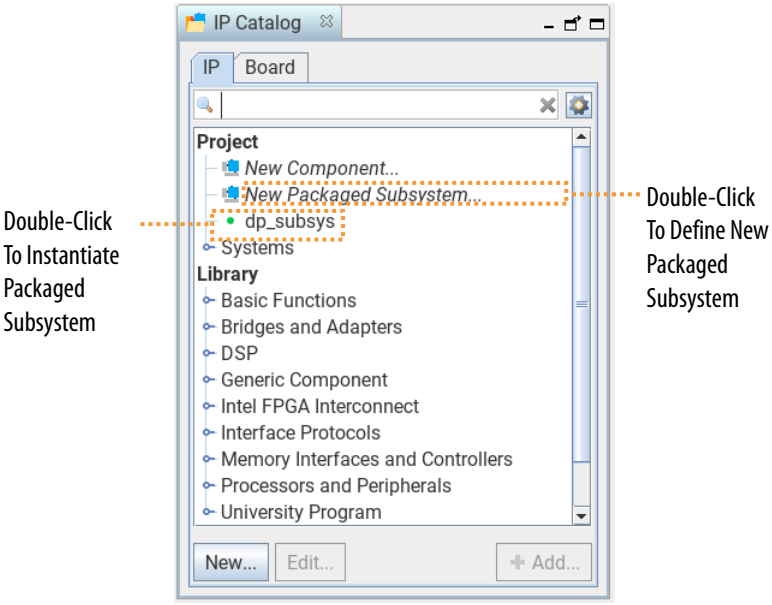
You can readily share or reuse a Platform Designer system by creating a packaged subsystem. The packaged subsystem combines everything about the pre-verified and parameterized system into a single, compressed, and portable `.qcp` file for reuse in other Platform Designer systems.

You or another packaged subsystem user can instantiate the packaged subsystem into another Platform Designer system to comprise the complete or partial system. The packaged subsystem author can disable viewing or modification by other users. This packaged subsystem flow simplifies the reuse and sharing of subsystems across multiple projects or designers.

The packaged subsystem author first defines all properties of the packaged subsystem in Platform Designer, including system components, connections, parameters, and supporting files. The packaged subsystem author next uses the **New Packaged Subsystem** command in Platform Designer's IP Catalog to save the current open system as a packaged subsystem. You can optionally include supporting RTL or other files in the packaged subsystem.

Once created, the packaged subsystem appears under **Project** in IP Catalog and the `.qcp` file appears in the location you specify. You can reuse and share the packaged subsystem by simply sharing the `.qcp` file.

Figure 106. Packaged Subsystem Available in IP Catalog for Instantiation



The following procedures describe how to create, instantiate, and revise a packaged subsystem. For detailed instructions using an example design, refer to *AN 1002: Sharing Platform Designer Packaged Subsystems*.

Related Information

AN 1002: Sharing Platform Designer Packaged Subsystems

1.21.1. User Personas for Packaged Subsystems

The packaged subsystem flow defines the following user personas and flows that this document describes in detail:

- Packaged subsystem author—the packaged subsystem author creates and saves the packaged subsystem `.qcp` file in Platform Designer. The packaged subsystem author defines the components, connections, parameters, and the external interfaces of the packaged subsystem. The packaged subsystem author can specify desired component parameters, and whether the packaged subsystem can be unlocked for modification, or just divable which allows the packaged subsystem user to dive in and view the internals of the packaged subsystem.
- Packaged subsystem user—the packaged subsystem user reuses the packaged subsystem by instantiating and connecting it to other components in another Platform Designer system. The packaged subsystem user may be able to modify the parameters or unlock the packaged subsystem for full editing control, depending on the packaged subsystem author specifications. The packaged subsystem author also determines whether the packaged subsystem is divable, which allows users to view the internals of the packaged subsystem.

1.21.2. Terminology for Packaged Subsystems

Table 29. Packaged Subsystems Terminology

Term	Description
Packaged Subsystem	A packaged subsystem combines everything about a Platform Designer system into a single, compressed `.qcp` file for sharing and reuse in other Platform Designer systems. The packaged subsystem author can optionally lock the packaged subsystem for viewing or modification by the packaged subsystem user.
Packaged Subsystem Author	The creator of a Platform Designer packaged subsystem that saves a system or subsystem as a packaged subsystem (`.qcp`) for sharing and reuse. The packaged subsystem author can set the `UNLOCKABLE` property to prevent or permit packaged subsystem editing for packaged subsystem users.
Packaged Subsystem Sharing	A packaged subsystem author can share a package subsystem with a packaged subsystem user by sharing the packaged subsystem `.qcp` file or by providing the IP search path for the user to specify when launching Platform Designer.
Packaged Subsystem User	Reuses a packaged subsystem by instantiating and connecting it to other components in another Platform Designer system. The packaged subsystem user may be able to modify the parameters or unlock the packaged subsystem for full editing control, depending on the packaged subsystem author specifications.
Package-level parameters	Parameters that appear in the parameter editor GUI when the packaged subsystem user instantiates or selects the packaged subsystem.
run_system_script	An important command for modifying the internal system inside a subsystem, `run_system_script` runs Platform Designer scripting commands such that all commands within curly braces run as separate scripts.
Subsystem	A standard unpackaged subsystem that you create in Platform Designer of the file type `.qsys`.
Subcomponent parameters	Parameters of the components of a packaged subsystem.

continued...

Term	Description
System	A standard top-level system that you create in Platform Designer of the file type `.qsys`.
Divable	The packaged subsystem author can use the `DIVABLE` property to specify whether the packaged subsystem user can dive in and view the internals of the packaged subsystem.
Unlockable	The packaged subsystem author can use the `UNLOCKABLE` property to specify whether the packaged subsystem user can unlock the packaged subsystem for full editing control.

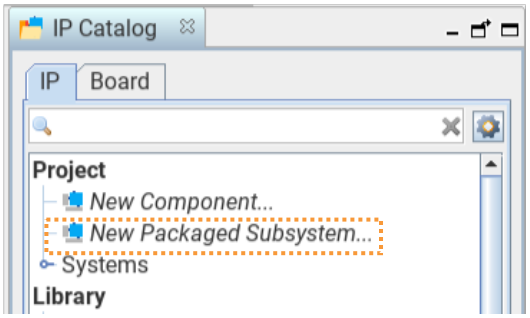
1.21.3. Creating a New Packaged Subsystem

In the packaged subsystem author flow, the packaged subsystem author creates a regular Platform Designer system, and then bundles the system into a packaged subsystem represented as a `.qcp` file. You can then provide the `.qcp` file to one or more packaged subsystem users.

Follow these steps to save an open Platform Designer system as a packaged subsystem `.qcp` file for reuse or sharing in other Platform Designer systems.

1. Define all properties of the system in the Platform Designer **System View** tab, including the system components, connections, parameters, and supporting files that you want to include in the packaged subsystem.
2. In Platform Designer's IP Catalog, click **New Packaged Subsystem**. The **New Packaged Subsystem** dialog box appears for specification of the packaged subsystem properties.

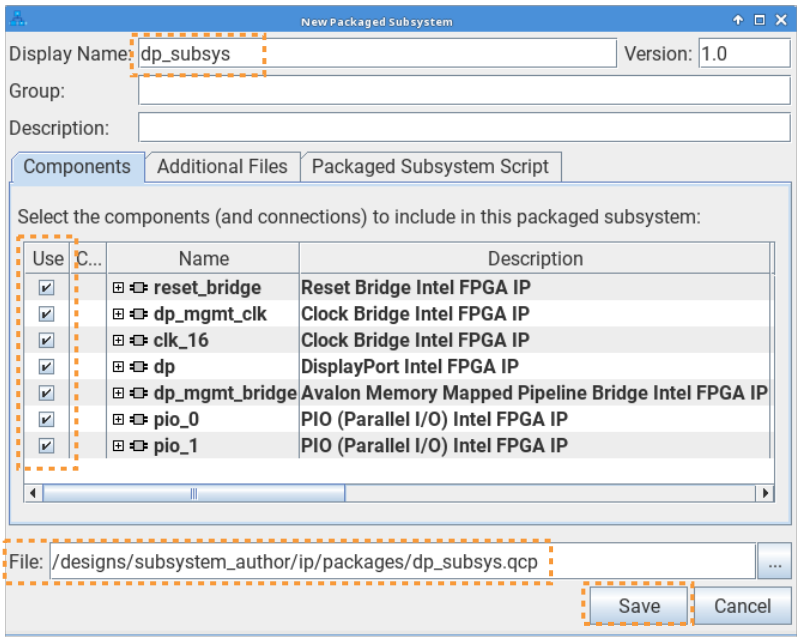
Figure 107. New Packaged Subsystem Command in IP Catalog



3. In the **Components** tab, specify a name for the packaged subsystem in **Display Name**. Refer to the image in New Packaged Subsystem Dialog Box
4. Optionally specify the **Group**, **Version** number, and **Description** to help you identify the packaged subsystem.
5. Under **Select the components (and connections) to include in this package** disable (uncheck) any connection, component, or node that you want to omit from the packaged subsystem in the **Use** column.

6. In the **File** box, specify the location to save the packaged subsystem file. The default path is `<project_directory>/ip/packages/<subsystem_name>.qcp`.
7. Optionally specify subsystem files and package script settings, as Specifying Additional Packaged Subsystem Files on page 121 and Modifying the Packaged Subsystem Script on page 122 describe.
8. When the packaged subsystem is complete, click **Save** in the **New Package** dialog box. The `.qcp` file saves to the location that you specify, and the packaged subsystem appears under **Project** in IP Catalog.

Figure 108. New Packaged Subsystem Dialog Box



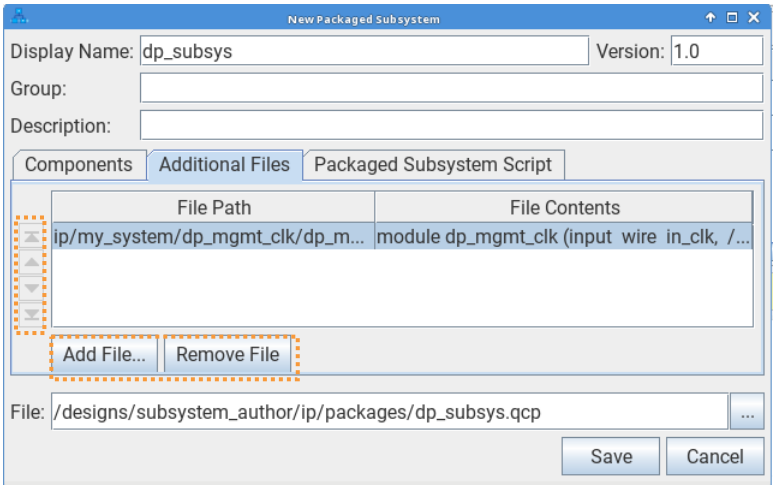
Related Information

AN 1002: Sharing Platform Designer Packaged Subsystems

1.21.4. Specifying Additional Packaged Subsystem Files

Follow these steps if you want to specify additional files to include with a Platform Designer packaged subsystem. You can include supporting files for your packaged subsystem, such as RTL for custom IP components.

Figure 109. Specifying Additional Files for a Packaged Subsystem



1. In the **Components** tab of the **New Packaged Subsystem** dialog box, define the basic properties of the new packaged subsystem, as Creating a New Platform Designer Packaged Subsystem describes.
2. Click the **Additional Files** tab.
3. To add a new file to the packaged subsystem, click the **Add File** button and select the supporting files you want to add.
4. To remove any additional files from the packaged subsystem, select the file and click the **Remove File** button.
5. To reorder the list of additional files, click the arrow buttons to move the files up or down in the list.
6. Optionally modify packaged subsystem script settings, as Modifying the Packaged Subsystem Script describes.
7. When the packaged subsystem is complete, click **Save** in the **New Package** dialog box. The `.qcp` file saves to the location that you specify, and the packaged subsystem appears under **Project** in IP Catalog.

Related Information

AN 1002: Sharing Platform Designer Packaged Subsystems

1.21.5. Modifying the Packaged Subsystem Script

The packaged subsystem infrastructure uses a Tcl script file to specify the packaged subsystem properties. You can modify the packaged subsystem script on the **Packaged Subsystem Script** tab to control the following in the packaged subsystem:

- Add parameters to enable or disable individual IP components in the packaged subsystem.
- Lock or unlock packaged subsystem editing for packaged subsystem users.
- Add packaged subsystem-level parameters that set parameter values of internal components.
- Modify the internal `.qsys` system file.

For example, when you enable or disable components on the **Components** tab, Platform Designer modifies the default script lines correspondingly in the packaged subsystem script when you right-click in the **Packaged Subsystem Script** tab and click **Reset with Default Script**. The packaged subsystem author can optionally modify the packaged subsystem script directly on the **Packaged Subsystem Script** tab.

For example, the following code creates two checkbox controls that are visible in the parameter editor GUI of the packaged subsystem for packaged subsystem users. These controls are linked to the RX and TX packaged subsystem level parameters. The RX and TX parameters are of type boolean and are asserted false by default.

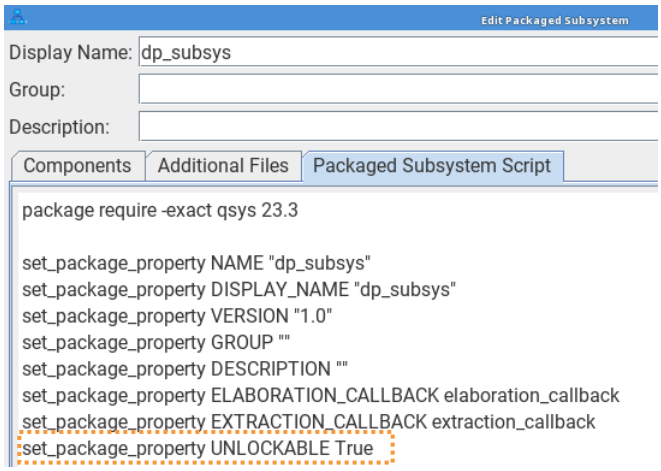
```
add_parameter TX BOOLEAN false "Enable transmitter"
add_parameter RX BOOLEAN false "Enable receiver"
```

Note: For details on these commands, refer to Parameters.

To modify the packaged subsystem script, follow these steps:

1. In the **Components** tab of the **New Packaged Subsystem** dialog box, define the basic properties of a the packaged subsystem, as Creating a New Platform Designer Packaged Subsystem describes.
2. Click the **Packaged Subsystem Script** tab.
3. Modify any of the script in the **Packaged Subsystem Script** tab to match your deployment preferences. For example, the following modification allows the packaged subsystem user to unlock the packaged subsystem for full control.

Figure 110. Packaged Subsystem Script Change (Subsystem Can Be Unlocked)



4. When the packaged subsystem is complete, click **Save** in the **New Package** dialog box. The `.qcp` file saves to the location that you specify, and the packaged subsystem appears under **Project** in IP Catalog.

Related Information

AN 1002: Sharing Platform Designer Packaged Subsystems

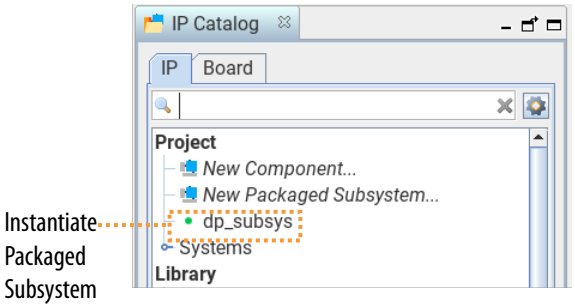
1.21.6. Instantiating a Packaged Subsystem

As a packaged subsystem user, you can instantiate a packaged subsystem in another Platform Designer system. For example, you can share a packaged subsystem `.qcp` file with another designer who can then instantiate and connect the packaged subsystem in their own Platform Designer system. The packaged subsystem author determines which elements of the packaged subsystem are editable in the packaged subsystem.

To instantiate a packaged subsystem within a Platform Designer system, follow these steps:

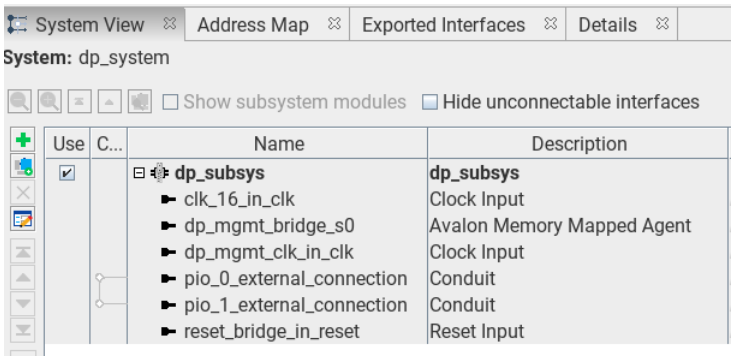
1. The packaged subsystem author creates the packaged subsystem, as Creating a New Platform Designer Packaged Subsystem describes.
2. The packaged subsystem user opens or creates the Platform Designer system that will instantiate the packaged subsystem, as Creating or Opening a Platform Designer System describes.
3. The packaged subsystem user places the subsystem `.qcp` file in the Quartus Prime software's IP search path. The packaged subsystem now appears under **Projects** in Platform Designer's IP Catalog.

Figure 111. Packaged Subsystem Available in IP Catalog for Instantiation



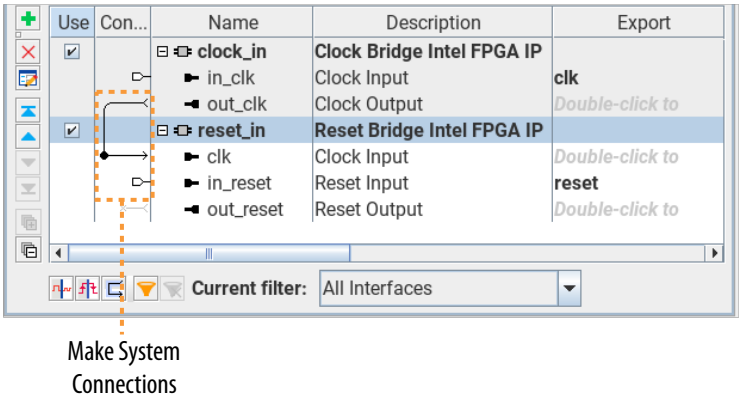
4. To instantiate the packaged subsystem in the open Platform Designer system, the packaged subsystem user double-clicks the packaged subsystem name in IP Catalog. The packaged subsystem now appears as a single IP component in the **System View** tab, according to the deployment options that the packaged subsystem author specifies.

Figure 112. Packaged Subsystem Instantiated in Platform Designer System



5. Connect the packaged subsystem to other system components, including clock and reset signals.

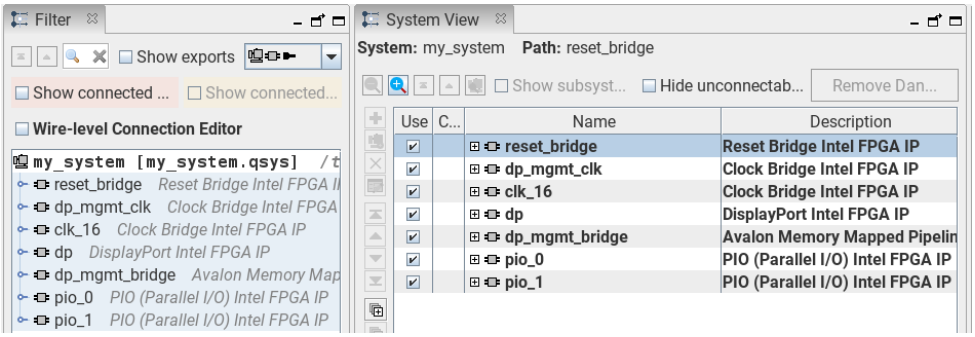
Figure 113. Connecting System Components



6. Depending on options that the packaged subsystem author specifies, you may be able to perform one or more of the following actions on the packaged subsystem:

- **Right-Click ➤ Dive Into Package**—when the `DIVABLE` property is set to `True` (the default setting) in the packaged subsystem script, you can dive into the packaged subsystem to view the details of the packaged subsystem components, connections, and parameters in another instance of Platform Designer.

Figure 114. Dive Into Package Shows Contents of the Packaged Subsystem



- **Right-Click ➤ Unlock**—when the `UNLOCKABLE` property is set to `True` in the packaged subsystem script you can unlock the packaged subsystem and interact with it like any other Platform Designer system.

  Note: This action cannot be undone.

Related Information

AN 1002: Sharing Platform Designer Packaged Subsystems

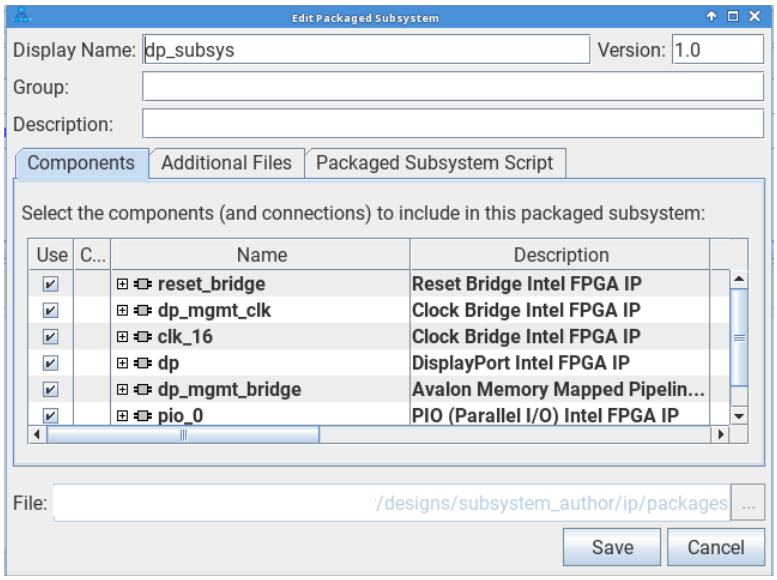
1.21.7. Revising a Packaged Subsystem

As the packaged subsystem author, you can revise a packaged subsystem that you have previously created. You can open the existing packaged subsystem in Platform Designer, allow unlock of the packaged subsystem for other users, and specify other system changes in the **Packaged Subsystem Script** tab. You can then save the updated packaged subsystem (`.qcp`) with the same name.

To revise a packaged subsystem that you previously created in Platform Designer, follow these steps:

1. Open the Platform Designer system that contains the packaged subsystem, as Creating or Opening a Platform Designer System describes.
2. In Platform Designer's IP Catalog, right-click the packaged subsystem under **Project** and click **Edit**. The **Edit Packaged Subsystem** dialog box appears.

Figure 115. Edit Packaged Subsystem Dialog Box



3. Make your desired revisions in the **Components**, **Additional Files**, and **Packaged Subsystem Scripts** tabs, as Creating a New Packaged Subsystem on page 120 describes.
4. When the packaged subsystem is complete, click **Save** in the **Edit Packaged Subsystem** dialog box. The `.qcp` file saves to the location that you specify, and the packaged subsystem appears under **Project** in IP Catalog.

Related Information

AN 1002: Sharing Platform Designer Packaged Subsystems

1.21.8. New Packaged Subsystem Dialog Box Options and Controls

The following settings and controls are available in the **New Packaged Subsystem** dialog box. These settings and options are also available in the **Edit Packaged Subsystem** dialog box unless otherwise noted.

Table 30. Component Tab Options and Controls

Option Name	Description
Display Name	Specifies a name for the new packaged subsystem you are creating. When the packaged subsystem is complete, this named packaged subsystem appears as a single IP in the Platform Designer IP Catalog. This option requires a value.
Version	Specifies the version number of the packaged subsystem. The default value is `1.0`. This setting is optional.
Group	Specifies the IP group of the packaged subsystem. This setting is optional.
Description	Specifies descriptive details about the packaged subsystem to help you identify it later.
Components	Species the components in the packaged subsystem, their connections, and whether they should be visible in the packaged subsystem for other users.
Use	Specifies whether the component should appear in the packaged subsystem or not. Turn on the checkbox to include the component in the packaged subsystem. Turn off the checkbox to exclude the component from the packaged subsystem. By default, **Use** is on for all components in the current system.
File	Specifies the path for saving the packaged subsystem `.qcp` file. The default path is `<project_directory>/ip/packages/<subsystem_name>.qcp`. Using the default path ensures that IP Catalog finds the packaged subsystem without modifying the IP search path. This option is read only in **Edit Packaged Subsystem** dialog box.
Save	Saves the `.qcp` file to the default location or a location that you specify, and the packaged subsystem appears under **Project** in IP Catalog.

Table 31. Additional Files Tab Options and Controls

Option Name	Description
File Path	Lists the path and filename of all files that you add to the packaged subsystem with **Add File**.
File Contents	Provides a description of the file types that you add to the packaged subsystem with **Add File**.
Add File	Allows you to browse for and add supplementary files to include in the packaged subsystem.
Remove File	Removes one or more files from the files list so the file is not added to the packaged subsystem.
Move to the top	Moves the selected file to the top of the files list.
Move up	Moves the selected file up one level in the files list.
Move down	Moves the selected file down one level in the files list.
Move to the bottom	Moves the selected file down to the bottom of the files list.

Table 32. Package Script Tab Options

Option	Description
Package script	Displays the editable packaged subsystem script that defines the packaged subsystem properties, parameters, and callbacks. You can directly edit this script to match your preferences.
Right-Click ➤ Reset with default script	Resets the current packaged subsystem script with the default packaged subsystem script for all subsystems.
Right-Click ➤ Preview the GUI	Displays a preview of the parameterization GUI that appears when users double-click the packaged subsystem in IP catalog.

1.22. Comparing Platform Designer Systems and IP components

Platform Designer includes an integrated System Diff Tool that highlights the differences between two Platform Designer systems or IP components (`.qsys` or `.ip` files). You can use the System Diff Tool to quickly identify the differences between two versions of systems or IP components.

The Platform Designer System Diff Tool supports the following use cases:

- Compare two versions of the same Platform Designer system (`.qsys`) on disk. View the modifications to the system.
- Compare the currently open Platform Designer system (`.qsys`) with a system on disk. View the differences between the systems.
- Compare a Platform Designer system (`.qsys`) file before and after a version upgrade. View the updated settings.
- Compare a Platform Designer system (`.qsys`) file with different device settings. View the setting differences.
- Compare a `.ip` component file before and after parameter changes. View the changes to any component interfaces.

The System Diff Tool uses color coding to highlight differences for any of following items added or removed in the system:

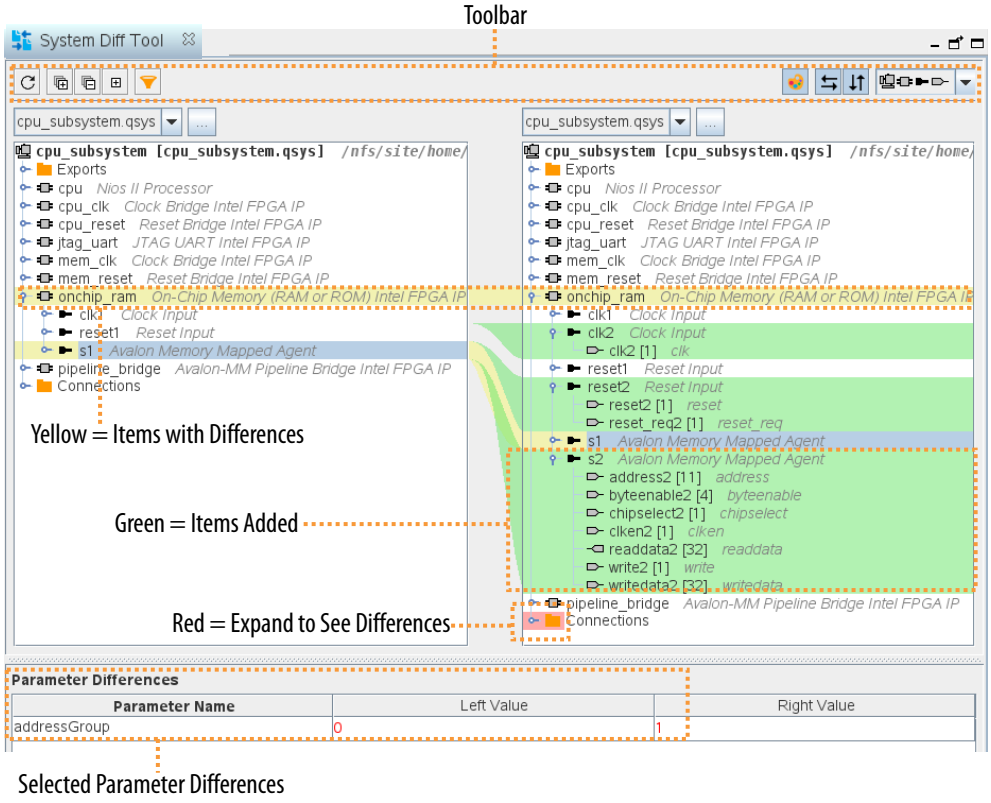
- Exports
- Modules
- Interfaces
- Ports
- Connections
- Parameters
- Assignments
- Properties

1.22.1. Using the System Diff Tool

You can open the System Diff Tool GUI from Platform Designer (**View ➤ System Diff Tool**) to compare Platform Designer systems (`.qsys`) or IP component files (`.ip`).

The System Diff Tool GUI displays the file comparison hierarchically, using color coding to display the differences in systems, modules, interfaces, ports, exports, and connections side-by-side in the top two panes. The bottom pane also displays the selected parameter differences, or you can right-click to **Show All Values** for the selected item.

Figure 116. Platform Designer System Diff Tool

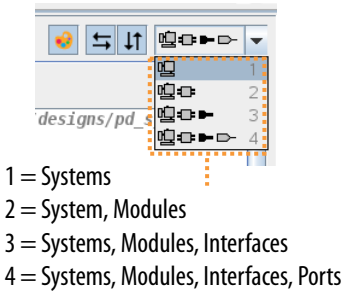


To run the System Diff Tool from Platform Designer:

1. Click **View ➤ System Diff Tool**.
2. In the Current System list at the top of each pane, specify the items for comparison. The System Diff Tool GUI then highlights the differences in each file. Selections and scrolling synchronize between the two panes:
   - Removed items appear in purple highlight.
   - Added items appear in green highlight.
   - Items with differences appear in yellow highlight.(5)
   - Items with collapsed children with differences are highlighted in red.
3. Optionally perform any of the following to refine the comparison view:

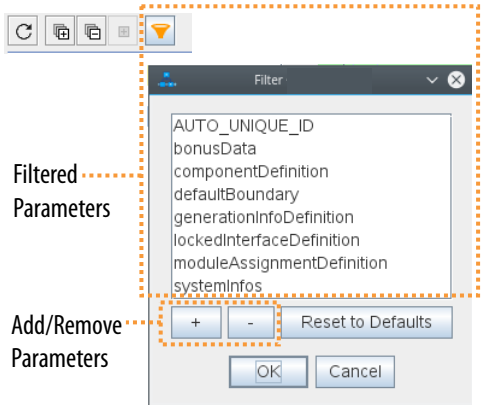
- To filter the comparison view by system, module, instance, or port hierarchy, select the filter icon that corresponds with the level of hierarchy that you want to display.

Figure 117. Filter the Comparison by Hierarchy



- To filter the comparison view by parameter name, click the Filter button to hide or show various parameters in the comparison. By default, this filter is set to exclude internal parameters that do not affect system behavior.

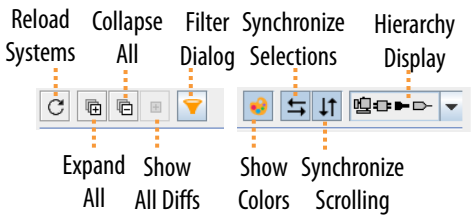
Figure 118. Filter the Comparison by Parameter



- To reload the systems for comparison after making changes to a system, click the **Reload Systems** button on the toolbar.
- To expand or collapse the comparison hierarchy, click the **Expand All** or **Collapse All** button.
- To expand the hierarchy to show all differences, click the **Show All Diffs** button.
- To show the comparison color coding, click the **Show Colors** button.
- To synchronize the scrolling or selections between the comparison panes, click the **Synchronize Scrolling** or **Synchronize Selections** button. You can use **Synchronize Selections** to compare the parameters of any two selected modules. (normally, items are diffed if they have the same name.)

(5) Item comparison is strictly based on naming. If an item on the left and right have the same name, they are compared. Otherwise, the item is marked as added or removed.

Figure 119. System Diff Toolbar



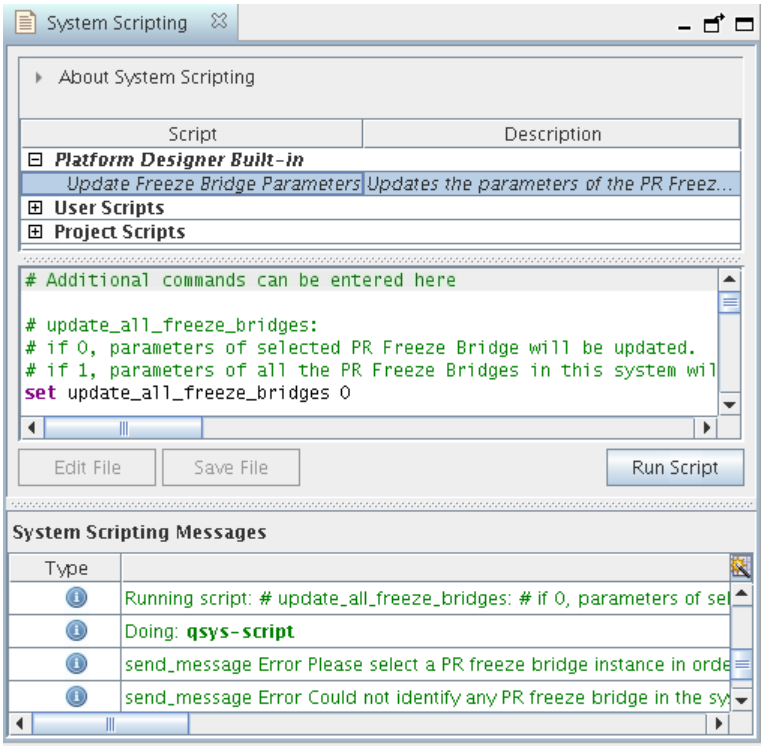
1.23. Running System Scripts

The **System Scripting** tab allows you to enter, save, and execute Tcl scripts on your Platform Designer system. The tab includes a selection of provided scripts, as well as support for storage and retrieval of your own scripts.

Follow these steps to enter, save, and execute Tcl scripts on your Platform Designer system:

1. To open the **System Scripting** tab, click **View ➤ System Scripting**.

Figure 120. System Scripting Tab



2. For **User Scripts** or **Project Scripts**, click **<<add script>>** to add a new script file to this entry. You can drag items between the **Project Scripts** and **User Scripts** fields.
3. To add additional commands to run before the script, right-click the column header and enable **Additional Commands**. Selecting this option displays a third column, in addition to **File** and **Description**. Double-click the entry in this field to add

commands to execute before running your script. Alternatively, you can add the additional commands to your script, directly through the display pane in the middle, in the specified section.

The **System Scripting** tab provides the following fields:

Table 33. System Scripting Tab Options

Name	Description
Platform Designer Built-in Scripts	Lists non-editable scripts that Platform Designer provides.
User Scripts	You can add your own scripts to this entry. Platform Designer saves these scripts to your user preference file, available in your home directory. The scripts that you add to this entry are available every time you open Platform Designer.
Project Scripts	You can add your own scripts to this entry. Platform Designer saves these scripts to your current system. The scripts that you add to this entry are available only when you open this specific Platform Designer system.
Edit File	Selecting the script in the **File** field displays the script in the pane below. Click **Edit File** to edit the script.
Revert File	Discards all your changes to the edited file.
Save File	Saves your changes to the edited file.
Run Script	Executes the selected script.
System Scripting Messages	Displays the warning and error messages when running the script.

1.24. Creating a System with Platform Designer Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout. • Updated *Changing the Target Board for a System* topic to describe alternative methods. • Updated *Create New Board Dialog Box Options* topic to describe additional preset options. • Updated *Generating Board and Preset Files for Existing Systems* section to describe alternative methods. • Updated *Customizing IP Presets* topic to describe board settings. • Updated *Creating IP Presets* topic to describe board settings. • Added new *Applying Presets After Migrating a Board* section. • Added new *Using the Qrun Flow in Platform Designer* section. • Updated *Specifying IP Component Instantiation Options* topic to remove HLS options. • Updated *Saving Platform Designer Systems* topic to describe generated Tcl scripts also include any preset pin constraints. • Added new *Add IP RTL Core Generated from the Intel oneAPI Base Toolkit* topic.
2023.12.20	23.4	• Updated *Synchronizing System Component Information* topic to explain synchronizing behavior for "Different Items" versus "Missing Items."
2023.10.02	23.3	• Updated *What's New In This Version* topic for packaged subsystems. • Revised *Viewing a Platform Designer System* for the latest GUI layout description. • Added new *Sharing Platform Designer Packaged Subsystems* section to describe new ability to package and share a subsystem.
2023.06.26	23.2	• Updated *Generating Simulation Files for NoC Designs* topic for latest NoC design flows. • Updated *Generating a Simulation Registration Include File for RTL Simulation of NoC Designs* topic for latest NoC design flows.
2023.04.03	23.1	• Added *Generating Presets for Existing Systems with Multiple Instances* topic. • Added more examples to *Generating Board and Presets for Existing Systems Using Command Line* topic. • Added *Preset Files Saved* topic. • Added *Generating Simulation Files for NoC Designs* topic. • Added *Generating a Simulation Registration Include File in the Platform Designer Flow* topic. • Added *Contents of Simulation Registration Include File* topic. • Added *Connecting NoC IP* topic. • The product family name is updated to "Intel Agilex 7" to reflect the different family members.
2022.12.12	22.4	• Updated *What's New in This Version* topic for board-aware flow support. • Revised *Creating or Opening a Platform Designer System* topic to reference board-aware GUI. • Updated *Specifying the Target Intel FPGA Device or Board for a System* topic for board-aware GUI. • Added new *Using the Board-Aware Flow in Platform Designer* section. • Added new *Creating IP Presets Targeting Specific Boards* section. • Removed limitation statement about no support for assertion monitors in Questa Intel FPGA Edition simulator. This simulator does support assertion monitors.

continued...

Document Version	Quartus Prime Version	Changes
2022.09.26	22.3	• Added clarifying note about the default agent selection to *Specifying a Default Avalon Agent or AXI Subordinate* topic. • Updated screenshot in *Specifying Interconnect Parameters* topic for new **Response FIFO Type** option. • Revised *Interconnect Parameters* topic for new **Response FIFO Type** option.
2022.06.20	22.2	• Updated *What's New In This Version* topic for latest changes in Platform Designer.
2022.04.02	22.1	• Added Top FAQs navigation and *What's New In This Version* topic. • Added new *Correcting Platform Designer System Timing Issues* topic. • Updated entire chapter for new AXI "manager" and AXI "subordinate" replacement terms. Refer to the AMBA® AXI and ACE Protocol Specification.
2021.10.04	21.3	• Added new *Preserving a System Module, Interface, or Port for Debugging* topic. • Added new *Changing the Platform Designer Font* topic. • Added new *Comparing Platform Designer Systems and IP Components* section. • Updated *Generation Dialog Box Options* topic note for Questa Intel FPGA Edition simulator. • Added references to the Nios V processor and documentation throughout.
2021.03.29	21.1	• Converted to "host" and "agent" inclusive terminology for Avalon memory mapped interface descriptions and related GUI elements throughout. • Added new *Saving and Archiving Platform Designer Systems* overview. • Revised *Saving Platform Designer Systems* for more detail, screenshot, and links about Export System as Platform Designer script (.tcl). • Revised *Archiving Platform Designer Systems* for more detail, screenshots, and links about using qsys-archive command. • Added new *Including Platform Designer Systems in Project Archives* topic. • Added new *Project Files to Include in External Revision Control* topic. • Updated *Generation Dialog Box Options* topic for new simulation options. • Updated *Simulating Platform Designer Systems* for new simulation options and images.
2020.12.14	20.4	• Updated "Specifying Interconnect Parameters" topic for latest GUI options and methods. • Updated "Interconnect Parameters" table for latest parameters and names. • Updated all System View tab screenshots for latest filter options. • Referenced Linux limitation for HLS generic component types. • Revised "Files generated for IP cores and Platform Designer Systems" diagram variable names.
2020.09.28	20.3	• Removed reference to obsolete Read/Write Waveforms option from "Modifying IP Parameters" topic. • Removed reference to obsolete System Information tab and Implementation Templates tab from "Specifying IP Component Instantiation Options" topic. • Removed reference to obsolete Direction option from "Changing a Conduit to a Reset" topic. • Added details about filter controls to "Filtering the System View" topic.
2020.01.31	19.1	• Removed obsolete "Implementing Performance Monitoring" topic.

continued...

Document Version	Quartus Prime Version	Changes
2019.10.02	19.1	• Updated location of interconnect parameters security setting in "Configuring Platform Designer System Security" topic.
2019.09.30	19.1	• Removed reference to obsolete Bus Analyzer Toolkit from "Implementing Performance Monitoring" topic.
2019.06.24	19.1	• Removed obsolete Interconnect Type parameter from "Interconnect Parameters" topic.
2019.04.30	19.1	• Corrected typographical error in "Interconnect Parameters" topic.
2019.04.01	19.1	• Described new Domains tab for specifying system-wide or domain-specific interconnect parameters. • Described new default use of synchronous reset option for Stratix® 10 designs in "Interconnect Parameters." • Described new Schematic tab in "Previewing the System Interconnect."
2018.12.15	18.1	• Replaced references to System Contents tab with new System View tab. • Described new Filter tab in Filtering the "Filtering the System View." • Updated "Disabling or Enabling Parallel IP Generation" to indicate option is now on by default and describe optional settings. • Moved command-line utility information into new "Platform Designer Command-Line Interface" chapter. • Removed "Creating a Combined Simulation Script" topic that does not apply to Platform Designer. • Revised headings and re-organized content into user task-based sections. • Updated screenshots for latest version.
2018.09.24	18.1	• Removed duplicated topic: *Manually Control Pipelining in the Platform Design Interconnect*. The topic is now in the *Platform Design Interconnect* chapter. • Added statement about supported standards for IP-XACT. • Divided topic: *Specify Implementation Type for IP Components* into *Configure the System Representation of an IP Core* and *Implementation Type*. • Reorganized information about associating Intel Quartus Prime projects to Platform Designer systems. • Grouped information regarding definition and management of IP cores in Platform Designer under topic: *IP Cores in Platform Designer*, and updated contents. • Expanded description of parallel IP generation. • In topic *64-Bit Addressing Support*, added link to information about the auto base assignment feature.
2018.06.15	18.0	• Updated description of *Enable ECC protection* in table: *System-Wide Interconnect Requirements*. • Updated example in topic: *Generate a Platform Design System with qsys-script*.
2018.05.07	18.0	• Added support for hierarchical simscripts, and the Xcelium Parallel Simulator in . • Added support for `--debug` command used with `qsys-edit`. • Added support for wire-level expressions and connectivity. • Added `_hw.tcl` commands to support wire-level expressions.
2017.11.06	17.1	• Changed instances of *Qsys Pro* to Platform Designer
2017.05.06	17.0	• Updated the topic - *Create/Open Project in Qsys Pro* • Updated the topic - *Modify the Target Device* • Updated the topic - *Modify the IP Search Path*

Document Version	Quartus Prime Version	Changes
November 2013	13.1	• Added *Integrating with the .qsys File*. • Added *Using the Hierarchy Tab*. • Added *Managing Interconnect Requirements*. • Added *Viewing Qsys Interconnect*.
May 2013	13.0	• Added AMBA APB support. • Added qsys-generate utility. • Added VHDL BFM ID support. • Added *Creating Secure Systems (TrustZones)* . • Added *CMSIS Support for Qsys Systems With An HPS Component*. • Added VHDL language support options.
November 2012	12.1	• Added AMBA AXI4 support.
June 2012	12.0	• Added AMBA AX3I support. • Added Preset Editor updates. • Added command-line utilities, and scripts.
November 2011	11.1	• Added Synopsys VCS and VCS MX Simulation Shell Script. • Added Cadence Incisive Enterprise (NCSIM) Simulation Shell Script. • Added *Using Instance Parameters and Example Hierarchical System Using Parameters*.
May 2011	11.0	• Added simulation support in Verilog HDL and VHDL. • Added testbench generation support. • Updated simulation and file generation sections.
December 2010	10.1	Initial release.

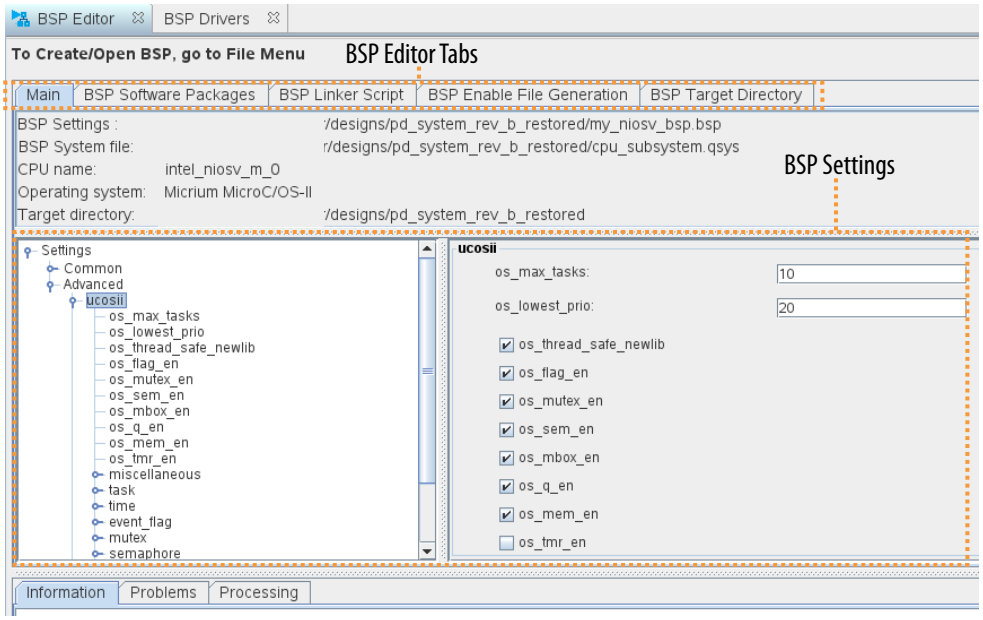
2. Creating a Board Support Package with BSP Editor

Platform Designer includes the BSP Editor board support package editing tool. A board support package (BSP) provides a software runtime environment for embedded systems, such as Nios II processor and Nios V processor systems.

The BSP simplifies your interface with connected hardware by providing the Intel FPGA hardware abstraction layer (HAL), an optional RTOS, and device drivers. BSP Editor is also available from the Nios II Embedded Design Suite (EDS).

The BSP Editor is a GUI tool that you can launch from Platform Designer to configure BSP contents. The BSP Editor allows you to specify the Harvard architecture CPU for your BSP, based on your Platform Designer system's `.qsys` file, or based on a `.sopcinfo` file that stores the target hardware definition. The `.sopcinfo` file generates during Platform Designer system HDL generation.

Figure 121. BSP Editor



The BSP isolates your application from system-specific details such as the memory map, available devices, and processor configuration. You decide the placement of the application's program code and data, depending on the memory devices that you connect to the CPU's instruction bus.

For each peripheral IP that you connect to the selected CPU's data bus, the BSP Editor automatically includes the matching driver for each peripheral IP as part of the BSP. The BSP Editor packages each driver using the `sw.tcl` API. The `sw.tcl` API defines

the collection of driver source files for the matching IP component type accessible by the CPU's data bus. Each driver may define software settings for configuring driver implementation or behavior.

You can use BSP Editor in the following modes. The BSP **System file** that you specify determines the mode.

Table 34. BSP Editor Modes in Platform Designer

	BSP Editor Integrated Mode	BSP Editor Stand-Alone Mode
Description	Generate a BSP directly for a Platform Designer system (`.qsys`). Any changes that you make in the **System View** automatically update in the BSP. Nios V processor designs require Integrated Mode.	BSP Editor is not fully integrated with Platform Designer, requiring manual update of the BSP for any changes that you make to the system using the `.sopcinfo` file. Nios II processor designs require Stand-Alone Mode.
Processor Support	Nios V Processor[6]	Nios II Processor
To Launch (BSP System File)	Specifying a `.qsys` file as **System file** launches BSP Editor in integrated mode.	Specifying a `.sopcinfo` as **System file** launches BSP Editor in stand-alone mode.

Note: For complete information about how to develop a BSP for a Nios II processor system or Nios V processor system, refer to the *Nios II Software Developer Handbook* or the *Nios V Processor Quick Start Guide*, respectively.

- Nios V Processor Reference Guide

2.1. Creating a BSP from Platform Designer

You can launch the BSP Editor from Platform Designer to define a new BSP for a Platform Designer system or other hardware design. You can launch the BSP Editor in either integrated or stand-alone mode, depending on the **System file** that you specify for the BSP in Platform Designer.

When you create a BSP from Platform Designer, the BSP Editor stores your BSP definition in a BSP Settings File (`.bsp`) for later retrieval. You can reopen an existing BSP by opening the `.bsp` file in Platform Designer. The BSP generally includes a `.a` file, header files (for example, `system.h`), and a linker script (`linker.x`). You use these BSP files when creating an application.

Launching BSP Editor in Integrated Mode

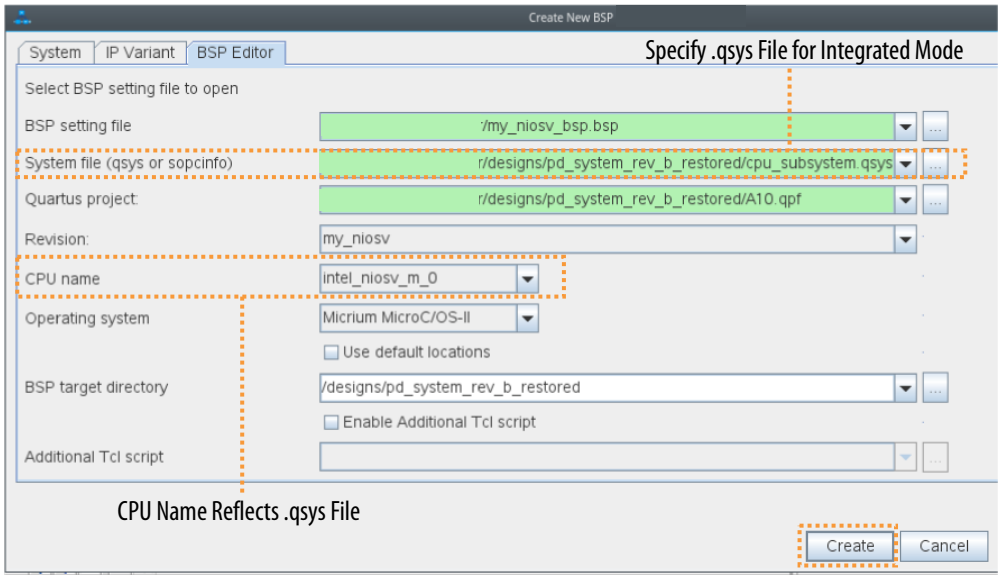
In integrated mode, BSP Editor automatically updates for any changes that you make to your system in Platform Designer. You launch BSP Editor in integrated mode by specifying your Platform Designer system's `.qsys` file as the main input to the BSP generation. Nios V processor designs require integrated mode. Nios II processor designs require stand-alone mode.

[6] The Nios V processor does not support stand-alone mode. The Nios II processor does not support integrated mode.

To launch BSP Editor in integrated mode:

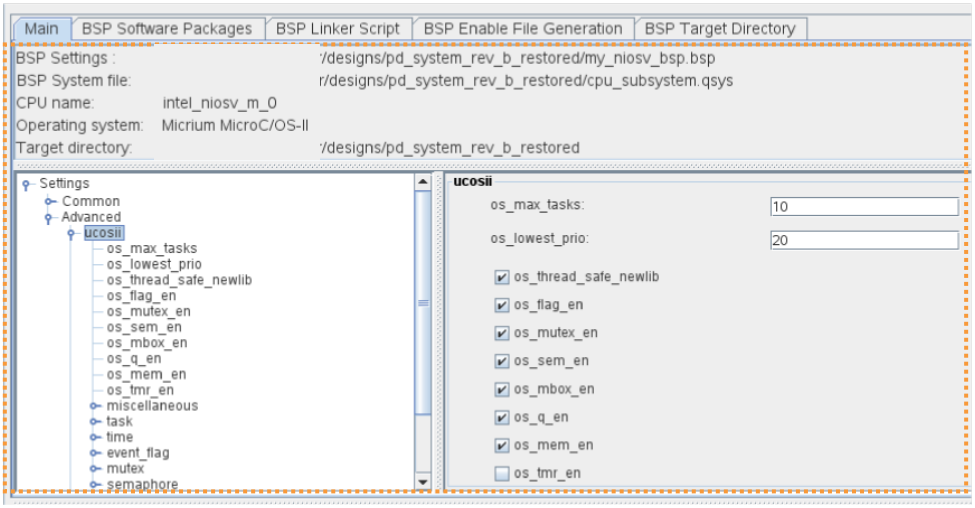
1. Open a Platform Designer system, as Creating or Opening a Platform Designer System on page 14 describes.
2. In Platform Designer, click **File ➤ New BSP**.
3. Specify the name and location for the new BSP settings file, and click the **Create** button. The **Create New BSP** dialog box opens.
4. For **System file**, specify the `.qsys` file that defines the target hardware platform for the current Platform Designer system. The **CPU name** and **BSP target directory** reflect the values in the `.qsys` file.

Figure 122. Create New BSP Dialog Box (Integrated Mode)



5. Specify options for the **Operating System** and **BSP target directory**, as Create New BSP Dialog Box on page 143 describes.
6. To create the BSP, click the **Create** button. The BSP Editor opens and displays the BSP Editor's **Main** tab in Platform Designer.

Figure 123. BSP Editor Main Tab



7. To configure the BSP, specify settings and options on the BSP Editor tabs. Refer to BSP Editor GUI on page 145 for details on these settings.
8. To generate the files for the BSP according to your specifications, click the **Generate BSP** button in BSP Editor. BSP Editor files do not automatically generate when you generate Platform Designer system files.

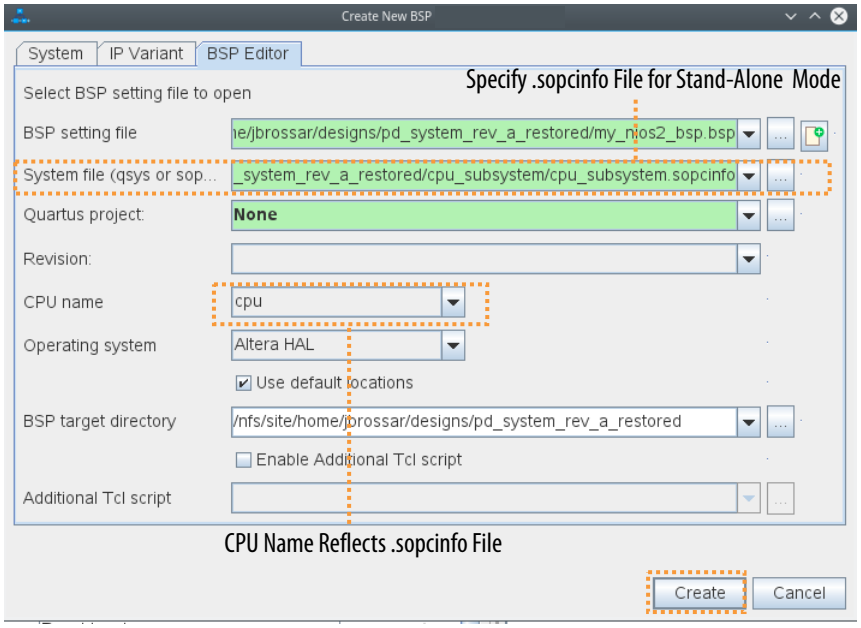
Launching BSP Editor in Stand-Alone Mode

Platform Designer generates a `<system_name>/.sopcinfo` file during HDL generation of the system. You can specify a `.sopcinfo` file and other BSP file saving options when defining a new BSP in stand-alone mode. Stand-alone mode is required for Nios II processor designs, and is not supported for Nios V processor designs.

Note: If you make any changes to your Platform Designer system after creating a BSP in stand-alone mode, you must regenerate the system's HDL and `.sopcinfo` files and create a new BSP to reflect any changes. The BSP does not update automatically with changes that you make to a Platform Designer system in stand-alone mode.

1. Open a Platform Designer system, as Creating or Opening a Platform Designer System on page 14 describes.
2. If generating a BSP for a Platform Designer system, click **Generate HDL** to generate the HDL and `.sopcinfo` files defining the target hardware for the system.
3. In Platform Designer, click **File ➤ New BSP**.
4. Specify the name and location for the new BSP settings file, and click the **Create** button. The **New Platform Designer BSP** dialog box opens.
5. For the **SOPC Information File name** option, specify the `.sopcinfo` file that step 2 generates. The **CPU name** and **BSP target directory** reflect the values in the `.sopcinfo` file.

Figure 124. Create New BSP Dialog Box (Stand-Alone Mode)



6. You can specify options for the **Operating System** and BSP file output, as Create New BSP Dialog Box on page 143 describes.
7. To create the BSP, click the **Create** button. The BSP Editor opens and displays the BSP Editor's **Main** tab in Platform Designer.
8. To configure the BSP, specify settings and options on the BSP Editor tabs. Refer to BSP Editor GUI on page 145.
9. To generate the files for the BSP according to your specifications, click the **Generate** button in BSP Editor.

2.1.1. Create New BSP Dialog Box

The **Create New BSP** dialog box allows you to specify the following options to define a new BSP:

Table 35. Create New BSP Dialog Box Settings

Name	Description
BSP setting file	Specifies the directory that contains the BSP settings file following BSP generation. By default: • `<project>/software/hal_bsp/settings.bsp` (HAL) • `<project>/software/ucOS_bsp/settings.bsp` (Micrium MicroC/OS-II)
System file (qsys or sopcinfo)	Specifies an existing `.qsys` or `.sopcinfo` file that defines the target hardware platform for a Platform Designer system or other hardware design. Platform Designer generates the `.qsys` file at system or component creation, and the `.sopcinfo` file during HDL generation of the system.
CPU name	Specifies the system CPU name if the **System file** defines a CPU, such as the Nios II processor. If the **System file** does not define a CPU, this setting is read-only. If the **System file** defines more than one CPU, you can select the CPU for this BSP.

continued...

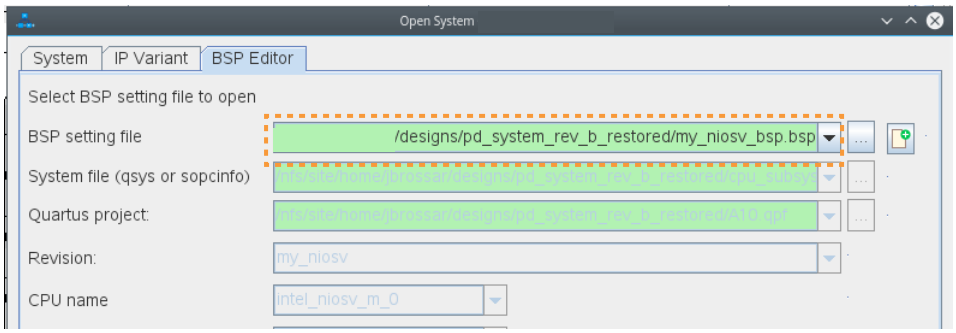
Name	Description
Operating System	Specifies the operating system of the **CPU name**. The operating system can be either **Altera HAL** or **Micrium MicroC/OS-II**. The BSP file output corresponds to your selection. You cannot change the **Operating system** for an existing BSP. Rather, you must create a new BSP that specifies a new **Operating System**.
Use default locations	Specifies whether BSP Editor uses default or custom file locations for the **BSP target directory** and **BSP settings file** storage. Disable this option to specify a custom location.
BSP target directory	Specifies the directory that contains the BSP files following BSP generation. By default: • `<project>/software/hal_bsp/` (HAL) • `<project>/software/ucOS_bsp/` (Micrium MicroC/OS-II)
Enable additional Tcl script file	Specifies an additional Tcl script (`.tcl`) that you can run to specify the BSP settings.

2.2. Opening a BSP from Platform Designer

To open and modify an existing BSP from within Platform Designer:

1. In Platform Designer, click **File ➤ Open**, and then click the **BSP Editor** tab.
2. For **BSP setting file**, click the **...** button to select the `.bsp` file for the BSP you want to open.

Figure 125. Open BSP Settings File



3. Click Open. The BSP loads in BSP Editor within Platform Designer.

2.3. Saving a BSP from Platform Designer

To save an existing BSP from within Platform Designer:

1. In Platform Designer, open an existing BSP (`.bsp`), as Opening a BSP from Platform Designer on page 144 describes.
   - Click **File ➤ Save** to save changes to the `.bsp` file to the current location.
   - Click **File ➤ Save BSP As** to save the `.bsp` file to a different location.

2.4. Exporting a BSP as Tcl from Platform Designer

You can export a BSP as a Tcl file from within Platform Designer. You can then run the Tcl script to load the BSP settings.

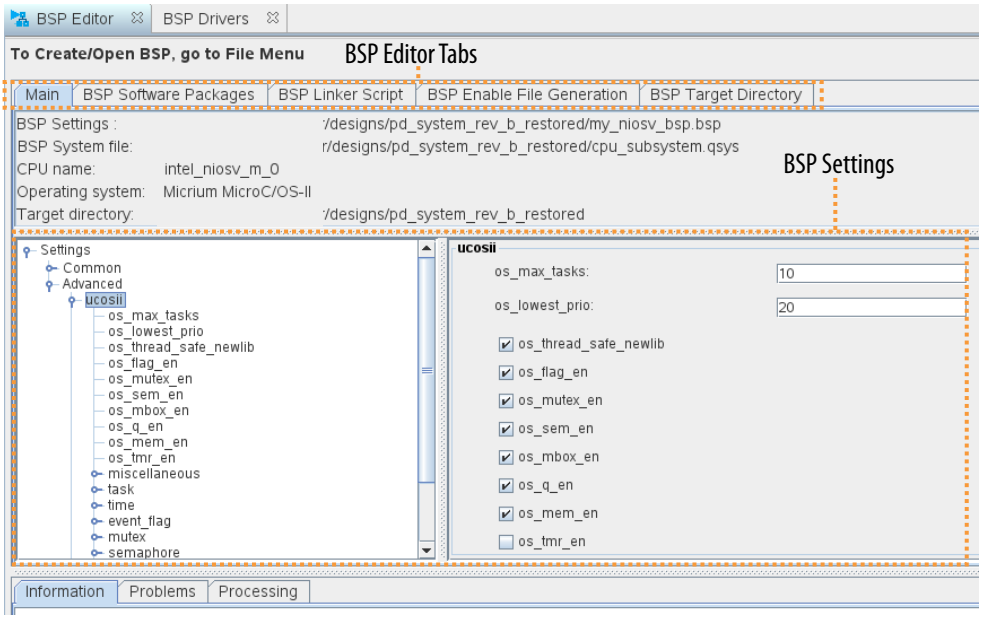
To export a BSP from Platform Designer as Tcl:

1. In Platform Designer, open an existing BSP (`.bsp`), as Opening a BSP from Platform Designer on page 144 describes.
2. Click **File ➤ Export BSP as Tcl**.
3. Specify the filename and location of the BSP Tcl file and click the **Save** button.
4. To reload the BSP, run the Tcl script file.

2.5. BSP Editor GUI

The BSP Editor GUI provides all the tools you need to create even the most complex BSPs. The BSP Editor GUI is divided into two sections. The top section contains the BSP Editor tabs for specifying the settings and other parameters that define the BSP. The **Messages** displays Information, Problems, and Processing messages about your actions in the BSP Editor.

Figure 126. BSP Editor GUI



Each tab of the BSP Editor GUI allows you to view and edit a particular aspect of the BSP, along with relevant command-line parameters and Tcl scripts. The settings that appear on the **Main**, **BSP Software Packages**, and **BSP Drivers** tabs correspond to the related command-line settings.

- Main Tab on page 146
- BSP Software Packages Tab on page 147
- BSP Drivers Tab on page 147
- BSP Linker Script Tab on page 148
- BSP Enable File Generation Tab on page 150
- BSP Target Directory Tab on page 151
- Messages Tabs on page 151

Note: For complete information about how to develop a BSP for a Nios II processor system or Nios V processor system, refer to the *Nios II Software Developer Handbook* or the *Nios V Processor Quick Start Guide*, respectively.

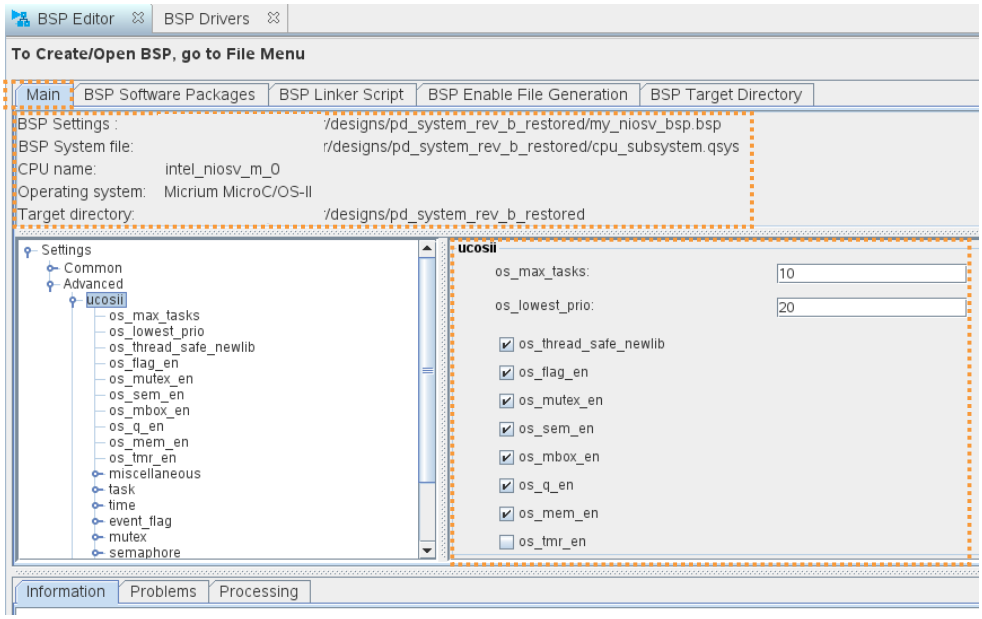
Related Information

- Nios II Software Developer Handbook
- Nios V Embedded Processor Design Handbook
- Nios V Processor Reference Guide

2.5.1. Main Tab

The **Main** tab presents general settings and parameters, and operating system settings, for the BSP. The BSP includes the following settings and parameters:

Figure 127. BSP Editor Main Tab



- The path to the `.qsys` or `.sopcinfo` file specifying the target hardware
- The CPU name
- The operating system and version

Note: You cannot change the operating system in an existing BSP. You must create a new BSP if you want to change the operating system.

- The **BSP target directory**—the destination for files that the BSP Editor copies and creates for your BSP
- BSP settings

The BSP settings appear in a tree structure. The settings are organized into **Common** and **Advanced** categories. Settings are further organized into functional groups. The available settings depend on the operating system.

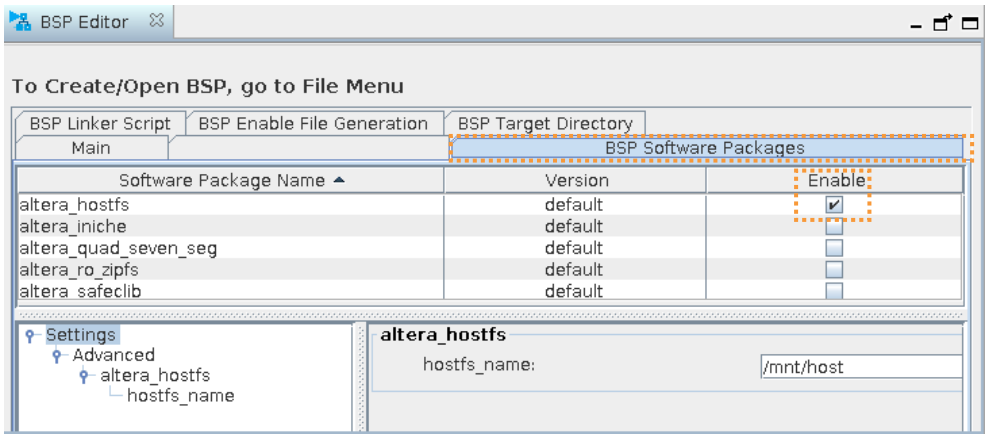
When you select a group of settings, the controls for those settings appear in the pane to the right of the tree. When you select a single setting, the pane shows the setting control, the full setting name, and the setting description.

2.5.2. BSP Software Packages Tab

The **BSP Software Packages** tab allows you to insert and remove software packages in your BSP, and control software package settings.

At the top of the **BSP Software Packages** tab is the software package table, listing each available software package. The table allows you to select the software package version, and enable or disable the software package. The operating system determines which software packages are available.

Figure 128. BSP Software Packages Tab



Many software packages define settings that you can control in your BSP. When you enable a software package, the available settings appear in a tree structure, organized into **Common** and **Advanced** settings.

When you select a group of settings, the controls for those settings appear in the pane to the right of the tree. When you select a single setting, the pane shows the setting control, the full setting name, and the setting description.

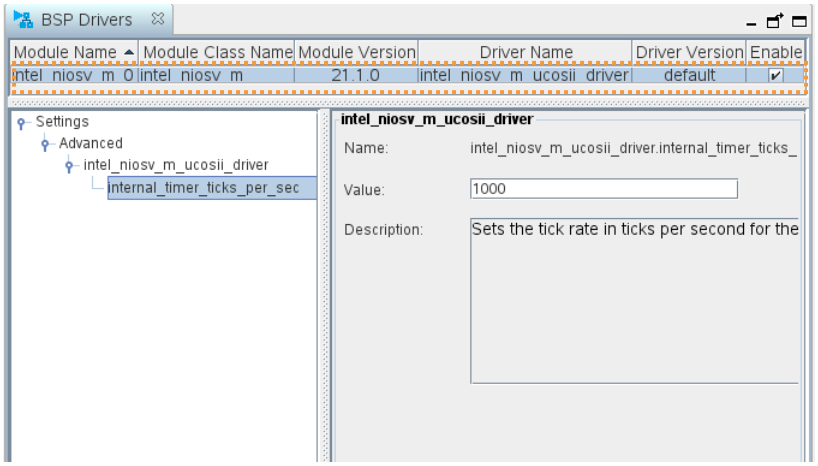
Enabling and disabling software packages and editing software package settings can have a profound impact on BSP behavior. Refer to the documentation for the specific software package for details.

2.5.3. BSP Drivers Tab

The **BSP Drivers** tab allows you to select, enable, and disable drivers for devices in your system, and control driver settings.

At the top of the **BSP Drivers** tab is the driver table, mapping components in the hardware system to drivers. The driver table shows components with driver support. Each component has a module name, module version, module class name, driver name, and driver version, determined by the contents of the hardware system. The table allows you to select the driver by name and version, as well as to enable or disable each driver.

Figure 129. BSP Drivers Tab



When you select a driver version, all instances of that driver in the BSP are set to the version you select. Only one version of a given driver can be used in an individual BSP.

Many drivers define settings that you can control in your BSP. Available driver settings appear in a tree structure below the driver table, organized into **Common** and **Advanced** settings.

When you select a group of settings, the controls for those settings appear in the pane to the right of the tree. When you select a single setting, the pane shows the setting control, the full setting name, and the setting description.

Enabling and disabling device drivers, changing drivers and driver versions, and editing driver settings, can have a profound impact on BSP behavior. Refer to the relevant component documentation and driver information for details.

Related Information

Embedded Peripherals IP User Guide
For more information about Intel FPGA components.

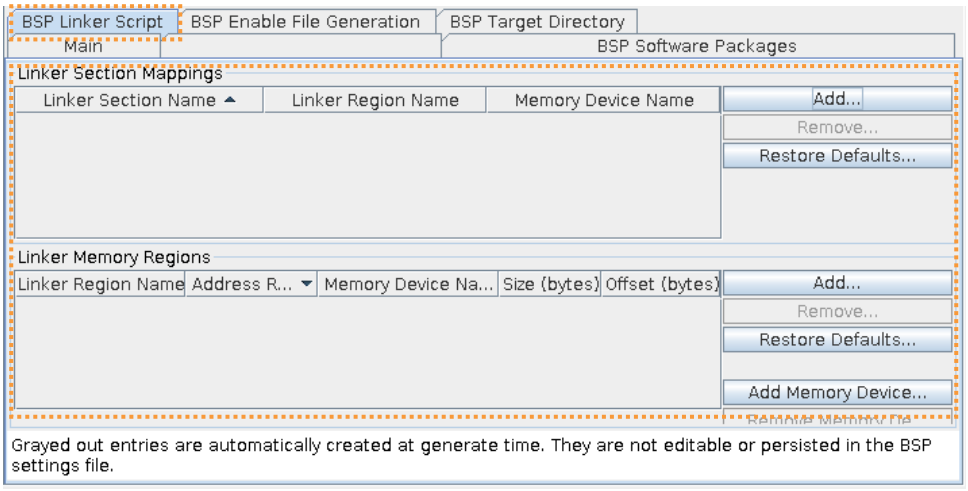
2.5.4. BSP Linker Script Tab

The **BSP Linker Script** tab allows you to view available memory in your hardware system, and examine and modify the arrangement and usage of linker regions in memory.

When you make a change to the memory configuration, the software build tools (SBT) validate your change.

Note: Rearranging linker regions and linker section mappings can have a significant impact on BSP behavior.

Figure 130. BSP Linker Script Tab



2.5.4.1. Linker Section Mappings

At the top of the **Linker Script** tab, the **Linker Section Mappings** table shows the mapping from linker sections to linker regions. You can edit the BSP linker section mappings using the following buttons located next to the linker section table:

- **Add**—Adds a linker section mapping to an existing linker region. The **Add** button opens the **Add Section Mapping** dialog box, where you specify a new section name and an existing linker region.
- **Remove**—Removes a mapping from a linker section to a linker region.
- **Restore Defaults**—Restores the section mappings to the default configuration set up at the time of BSP creation.

2.5.4.2. Linker Regions

At the bottom of the **Linker Script** tab, the **Linker Memory Regions** table shows all defined linker regions. Each row of the table shows one linker region, with its address range, memory device name, size, and offset into the selected memory device.

You reassign a defined linker region to a different memory device by selecting a different device name in the **Memory Device Name** column. The **Size** and **Offset** columns are editable. You can also edit the list of linker regions using the following buttons located next to the linker region table.

Note: Ensure that you specify the correct base address and memory size. If the base address or size of an external memory changes, you must edit the BSP manually to match. The SBT does not automatically detect changes in external memory devices, even if you update the BSP by creating a new settings file.

Table 36. Linker Memory Regions Table Buttons

Name	Description
Add	Adds a linker region in unused space on any existing device. The **Add** button opens the **Add Memory Region** dialog box, where you specify the memory device, the new memory region name, the region size, and the region's offset from the device base address.
Remove	Removes a linker region definition. Removing a region frees the region's memory space to be used for other regions.
Add Memory Device	Creates a linker region representing a memory device that is outside the hardware system. The button opens the **Add Memory Device** dialog box, where you can specify the device name, memory size, and base address. After you add the device, it appears in the linker region table, the **Memory Device Usage Table** dialog box, and the **Memory Map** dialog box. This functionality is equivalent to the `add_memory_device` Tcl command.

- **Restore Defaults**—restores the memory regions to the default configuration set up at the time of BSP creation.
- **Memory Usage**—Opens the **Memory Device Usage Table**. The **Memory Device Usage Table** allows you to view memory device usage by defined memory region. As memory regions are added, removed, and adjusted, each device's free memory, used memory, and percentage of available memory are updated. The rightmost column is a graphical representation of the device's usage, according to the memory regions assigned to it.
- **Memory Map**—Opens the **Memory Map** dialog box. The memory map allows you to view a map of system memory in the processor address space. The **Device** table is a read-only reference showing memories in the hardware system that are hosted by the selected processor. Devices are listed in memory address order.

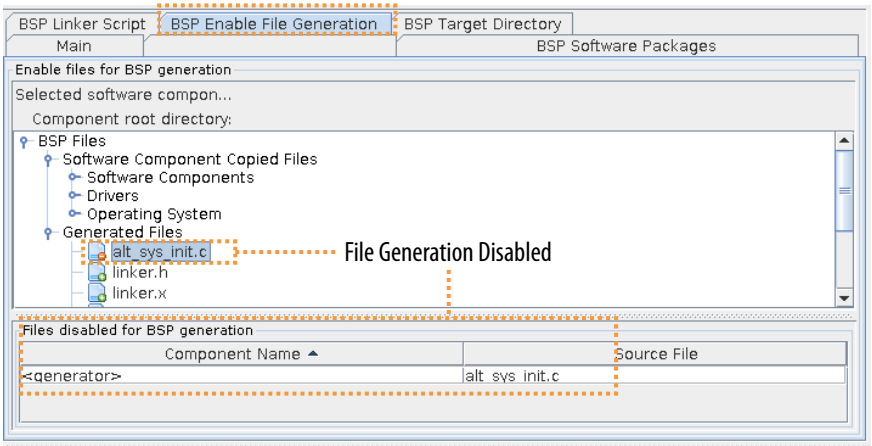
  To the right of the **Device** table is a graphical representation of the processor's memory space, showing the locations of devices in the table. Gaps indicate unmapped address space.

Note: This gap representation is not to scale.

2.5.5. BSP Enable File Generation Tab

The **BSP Enable File Generation** tab allows you to take ownership of specific BSP files that are normally generated by the SBT.

Figure 131. BSP Enable File Generation Tab



When you take ownership of a BSP file, you can modify it, and prevent the SBT from overwriting your modifications. The **BSP Enable File Generation** tab shows a tree view of all target files to be generated or copied when the BSP is generated. To disable generation of a specific file, expand the software component containing the file, expand any internal directory folders, select the file, and right-click. Each disabled file appears in a list at the bottom of the tab. This functionality is equivalent to the `set_ignore_file` Tcl command.

Note: If you take ownership of a BSP file, the SBT can no longer update it to reflect future changes in the underlying hardware. If you change the hardware, be sure to update the file manually.

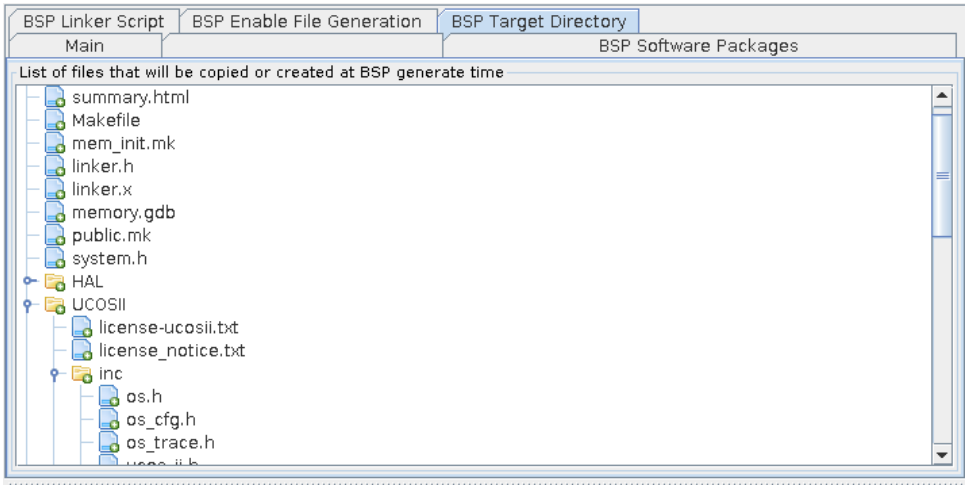
2.5.6. BSP Target Directory Tab

The **BSP Target Directory** tab is a read-only reference showing you what output to expect when the BSP is generated.

It does not depict the actual file system, but rather the files and directories to be created or copied when the BSP is generated. Each software component, including the operating system, drivers, and software packages, specifies source code to be copied into the BSP target directory. The files are generated in the directory specified on the **Main** tab.

When you generate the BSP, existing BSP files are overwritten, unless you disable generation of the file in the **BSP Enable File Generation** tab.

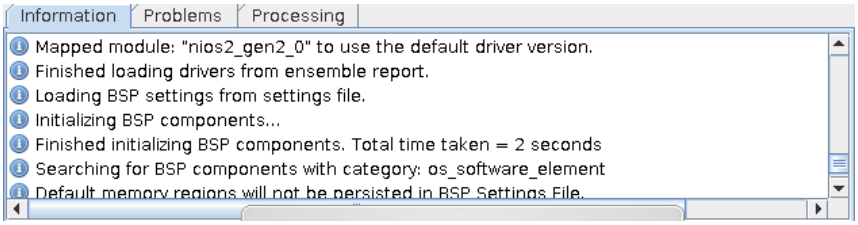
Figure 132. BSP Target Directory Tab



2.5.7. Messages Tabs

The messages area shows messages about the settings and commands that you select in the BSP Editor GUI. The messages area consists of the following tabs:

Figure 133. The Messages Area



- The **Information** tab—displays information messages about settings and commands.
- The **Problems** tab—displays problems to correct before BSP generation.
- The **Processing** tab—displays BSP Editor processing status messages.

Note: For complete information about how to develop a BSP for a Nios II processor system or Nios V processor system, refer to the *Nios II Software Developer Handbook* or the *Nios V Processor Quick Start Guide*, respectively.

2.6. Creating a Board Support Package with BSP Editor Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2023.04.03	23.1	• The product family name is updated to "Intel Agilex 7" to reflect the different family members.
2021.10.04	21.3	• Added *Launching BSP Editor in Integrated Mode* section to *Creating a BSP from Platform Designer* topic. • Updated *Creating a Board Support Package with BSP Editor* topic for Integrated Mode. • Updated *Create New BSP Dialog Box* topic for Integrated Mode. • Updated *Main Tab* topic for Integrated Mode. • Updated command name in *Saving a BSP from Platform Designer* topic. • Updated screenshot in *Opening a BSP from Platform Designer* topic. • Added references to the Nios V processor and documentation throughout.
2021.03.29	21.1	First version of chapter.

3. Creating Platform Designer Components

You can create and package IP components for use in a Platform Designer system. You can use a `_hw.tcl` file to describe IP components, interfaces and HDL files. Platform Designer provides the Component Editor to help you create a simple `_hw.tcl` file.

Related Information

- Avalon Interface Specifications
- Protocol Specifications
- Demo AXI Memory Example

3.1. Platform Designer Components

A Platform Designer component includes the following elements:

- Information about the component type, such as name, version, and author.
- HDL description of the component's hardware, including SystemVerilog, Verilog HDL, or VHDL files, or a blackbox implementation.
- A Synopsys® Design Constraints File `.sdc` that defines the component for synthesis and simulation.
- For _hw.tcl components, an `.ip` file that defines the component's parameters.
- A component's interfaces, including I/O signals.

3.1.1. Platform Designer Interface Support

Platform Designer is most effective when you use standard interfaces available in the IP Catalog to design custom IP. Standard interfaces operate efficiently with Intel FPGA IP components, and you can take advantage of the bus functional models (BFMs), monitors, and other verification IP that the IP Catalog provides.

Platform Designer also supports connections between Avalon and AXI interfaces by generating the interconnect logic. This logic enables you to handle the protocol difference. Platform Designer creates the interconnect logic by converting all the protocols to a proprietary packet format. Then, the tool routes the packet through network switches to the appropriate agents. Here, the packet converts to the agent's protocol.(7)

(7) This document now refers to the Avalon "host" and "agent," and the AXI "manager" and "subordinate," to replace formerly used terms. Refer to the current *AMBA AXI and ACE Protocol Specification* for the latest AMBA AXI and ACE protocol terminology.

Platform Designer supports the following interface specifications:

- Intel FPGA Avalon Memory-Mapped and Streaming
- Arm AMBA 3 AXI (version 1.0)
- Arm AMBA 4 AXI (version 2.0)
- Arm AMBA 4 AXI-Lite (version 2.0)
- Arm AMBA 4 AXI-Stream (version 1.0)
- Arm AMBA 3 APB (version 1.0)

IP components (IP Cores) can have any number of interfaces in any combination. Each interface represents a set of signals that you can connect within a Platform Designer system, or export outside of a Platform Designer system.

Platform Designer IP components can include the following interface types:

Table 37. IP Component Interface Types

Interface Type	Description
Memory-Mapped	Connects memory-referencing host devices with agent memory devices. Host devices can be processors and DMAs, while agent memory devices can be RAMs, ROMs, and control registers. Data transfers between Avalon Memory Mapped host and agent may be uni-directional (read only or write only), or bi-directional (read and write).
Streaming	Connects Avalon Streaming sources and sinks that stream unidirectional data, as well as high-bandwidth, low-latency IP components. Streaming creates datapaths for unidirectional traffic, including multichannel streams, packets, and DSP data. The Avalon interconnect is flexible and can implement on-chip interfaces for industry standard telecommunications and data communications cores, such as Ethernet, Interlaken, and video. You can define bus widths, packets, and error conditions.
Interrupts	Connects interrupt senders to interrupt receivers. Platform Designer supports individual, single-bit interrupt requests (IRQs). In the event that multiple senders assert their IRQs simultaneously, the receiver logic (typically under software control) determines which IRQ has highest priority, then responds appropriately.
Clocks	Connects clock output interfaces with clock input interfaces. Clock outputs can fan-out without the use of a bridge. A bridge is required only when a clock from an external (exported) source connects internally to more than one source.
Resets	Connects reset sources with reset input interfaces. If your system requires a particular positive-edge or negative-edge synchronized reset, Platform Designer inserts a reset controller to create the appropriate reset signal. If you design a system with multiple reset inputs, the reset controller ORs all reset inputs and generates a single reset output.
Conduits	Connects point-to-point conduit interfaces, or represent signals that you export from the Platform Designer system. Platform Designer uses conduits for component I/O signals that are not part of any supported standard interface. You can connect two conduits directly within a Platform Designer system as a point-to-point connection. Alternatively, you can export conduit interfaces and bring the interfaces to the top-level of the system as top-level system I/O. You can use conduits to connect to external devices, for example external DDR SDRAM memory, and to FPGA logic defined outside of the Platform Designer system.

Related Information

Exporting HDL Parameters to a System on page 189

3.1.2. Component Structure

Intel provides components automatically installed with the Quartus Prime software. To obtain a list of all Platform Designer-compliant components available from third-party IP developers, follow these steps:

1. Navigate to the Intel FPGA Find IP web page.
2. In the Find IP search results, click the **Platform Designer (Qsys) Compliant** column filter to show all Platform Designer-compliant components.
3. Further refine the search results by selecting the **End Market**, **Technology**, **Devices**, or **Provider** search filter. The **Provider** filter allows you to select specific third-party IP partners.

Every Platform Designer-compliant component is defined with a *<component_name>*_hw.tcl file. This file is a text file written in the Tcl scripting language that describes the component to Platform Designer. When you design your own custom component, you can create the _hw.tcl file manually, or by using the Platform Designer Component Editor.

The Component Editor simplifies the process of creating _hw.tcl files by creating a file that you can edit outside of the Component Editor to add advanced procedures. When you edit a previously saved _hw.tcl file, Platform Designer automatically backs up the earlier version as _hw.tcl~.

You can move component files into a new directory, such as a network location, so that other users can use the component in their systems. The _hw.tcl file contains relative paths to the other files, so if you move an _hw.tcl file, you should also move all the HDL and other files associated with it.

There are four component types:

- **Static**— static components always generate the same output, regardless of their parameterization. Components that instantiate static components must have only static children.
- **Generated**—generated component's fileset callback allows an instance of the component to create unique HDL design files based on the instance's parameter values.
- **Composed**—composed components are subsystems constructed from instances of other components. You can use a composition callback to manage the subsystem in a composed component.
- **Generic**—generic components allow instantiation of IP components without an HDL implementation. Generic components enable hierarchical isolation between system interconnect and IP components.

- Create a Composed Component or Subsystem on page 196
- Add Component Instances to a Static or Generated Component on page 198

3.1.3. Component File Organization

A typical component uses the following directory structure where the names of the directories are not significant:

<component_directory>/

- *<hdl>/*—Contains the component HDL design files, for example `.v`, `.sv`, or `.vhd` files that contain the top-level module, along with any required constraint files.
- *<component_name>*`_hw.tcl`—The component description file.
- *<component_name>*`_sw.tcl`—The software driver configuration file. This file specifies the paths for the `.c` and `.h` files associated with the component, when required.
- *<software>/*—Contains software drivers or libraries related to the component.

Note: Refer to the *Nios V Processor Quick Start* for information about writing a device driver or software package suitable for use with the Nios V processor.

Related Information

  Refer to the "Nios II Software Build Tools" and "Overview of the Hardware Abstraction Layer" chapters.
- Nios V Embedded Processor Design Handbook

3.1.4. Component Versions

Platform Designer systems support multiple versions of the same component within the same system; you can create and maintain multiple versions of the same component.

If you have multiple `_hw.tcl` files for components with the same NAME module properties and different VERSION module properties, both versions of the component are available.

If multiple versions of the component are available in the IP Catalog, you can add a specific version of a component by right-clicking the component, and then selecting **Add version** *<version_number>*.

3.1.4.1. Upgrade IP Components to the Latest Version

When you open a Platform Designer design, if Platform Designer detects IP components that require regeneration, the **Upgrade IP Cores** dialog box appears and allows you to upgrade outdated components.

Components that you must upgrade in order to successfully compile your design appear in red. Status icons indicate whether a component is currently being regenerated, the component is encrypted, or that there is not enough information to determine the status of component. To upgrade a component, in the **Upgrade IP Cores** dialog box, select the component that you want to upgrade, and then click **Upgrade**. The Quartus Prime software maintains a list of all IP components associated with your design on the **Components** tab in the Project Navigator.

3.2. Design Phases of an IP Component

When you define a component with the Platform Designer Component Editor, or a custom `_hw.tcl` file, you specify the information that Platform Designer requires to instantiate the component in a Platform Designer system and to generate the appropriate output files for synthesis and simulation.

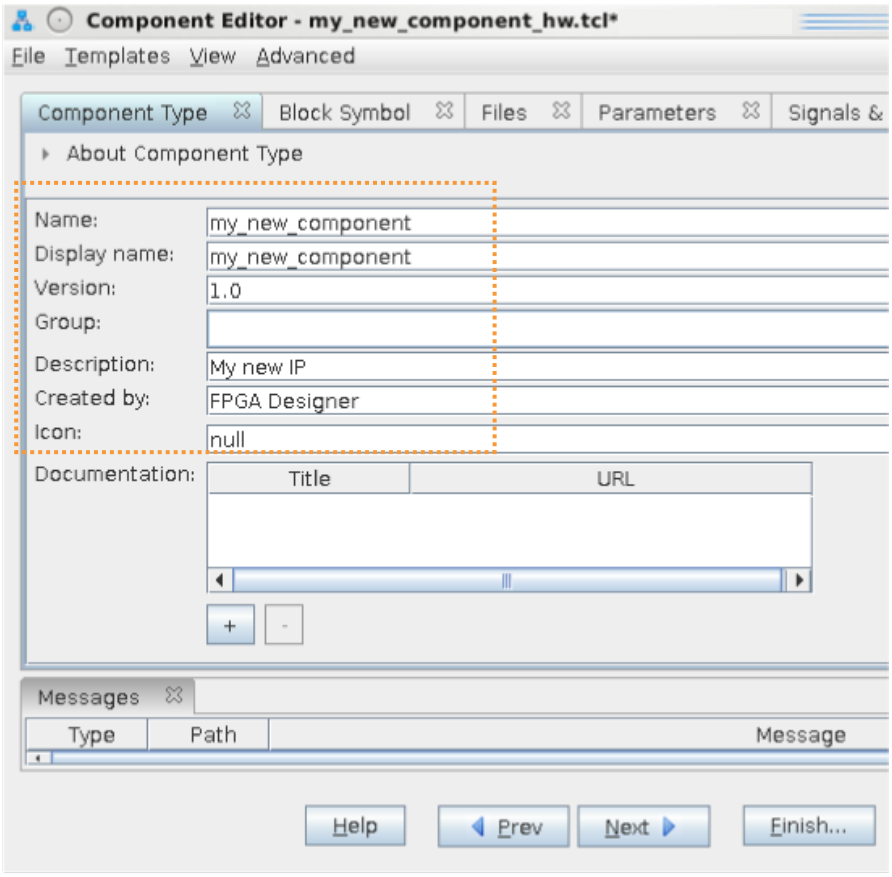
The following phases describe the process when working with components in Platform Designer:

- **Discovery**—During the discovery phase, Platform Designer reads the `_hw.tcl` file to identify information that appears in the IP Catalog, such as the component's name, version, and documentation URLs. Each time you open Platform Designer, the tool searches for the following file types using the default search locations and entries in the **IP Search Path**:
  - `_hw.tcl` files—Each `_hw.tcl` file defines a single component.
  - IP Index (`.ipx`) files—Each `.ipx` file indexes a collection of available components, or a reference to other directories to search.
- **Static Component Definition**—During the static component definition phase, Platform Designer reads the `_hw.tcl` file to identify static parameter declarations, interface properties, interface signals, and HDL files that define the component. At this stage of the life cycle, the component interfaces may be only partially defined.
- **Parameterization**—During the parameterization phase, after an instance of the component is added to a Platform Designer system, the user of the component specifies parameters with the component's parameter editor.
- **Validation**—During the validation phase, Platform Designer validates the values of each instance's parameters against the allowed ranges specified for each parameter. You can use callback procedures that run during the validation phase to provide validation messages. For example, if there are dependencies between parameters where only certain combinations of values are supported, you can report errors for the unsupported values.
- **Elaboration**—During the elaboration phase, Platform Designer queries the component for its interface information. Elaboration is triggered when an instance of a component is added to a system, when its parameters are changed, or when a system property changes. You can use callback procedures that run during the elaboration phase to dynamically control interfaces, signals, and HDL files based on the values of parameters. For example, interfaces defined with static declarations can be enabled or disabled during elaboration. When elaboration is complete, the component's interfaces and design logic must be completely defined.
- **Composition**—During the composition phase, a component can manipulate the instances in the component's subsystem. The **_hw.tcl** file uses a callback procedure to provide parameterization and connectivity of sub-components.
- **Generation**—During the generation phase, Platform Designer generates synthesis or simulation files for each component in the system into the appropriate output directories, as well as any additional files that support associated tools.

3.3. Creating IP Components in the Component Editor

The Platform Designer Component Editor allows you to create and package an IP component and parameterization GUI. When you use the Component Editor to define a component, Platform Designer writes the information to an `_hw.tcl` file.

Figure 134. Component Editor



The Platform Designer Component Editor allows you to perform the following tasks:

- Specify component's identifying information, such as name, version, author, etc.
- Specify the SystemVerilog, Verilog HDL, VHDL files, and constraint files that define the component for synthesis and simulation.
- Create an HDL template to define a component's interfaces, signals, and parameters.
- Set parameters on interfaces and signals that can alter the component's structure or functionality.

If you do not have a top-level HDL component file, you can use the Platform Designer Component Editor to add interfaces, signals, and parameters. In the Component Editor, the order in which the tabs appear reflects the recommended design flow for component development. You can use the **Prev** and **Next** buttons to guide you through the tabs.

In a Platform Designer system, the interfaces of a component are connected in the system, or exported as top-level signals from the system.

If the component is not based on an existing HDL file, enter the parameters, signals, and interfaces first, and then return to the **Files** tab to create the top-level HDL file template. When you click **Finish**, Platform Designer creates the component `_hw.tcl` file with the details that you enter in the Component Editor.

When you save the component, it appears in the IP Catalog.

If you require custom features that the Platform Designer Component Editor does not support, for example, an elaboration callback, use the Component Editor to create the `_hw.tcl` file, and then manually edit the file to complete the component definition.

Note: If you add custom coding to a component, do not open the component file in the Platform Designer Component Editor. The Platform Designer Component Editor overwrites your custom edits.

Example 4. Platform Designer Creates an _hw.tcl File from Entries in the Component Editor

```
#
# connection point clock
#
add_interface clock clock end
set_interface_property clock clockRate 0
set_interface_property clock ENABLED true

add_interface_port clock clk clk Input 1

#
# connection point reset
#
add_interface reset reset end
set_interface_property reset associatedClock clock
set_interface_property reset synchronousEdges DEASSERT
set_interface_property reset ENABLED true

add_interface_port reset reset_n reset_n Input 1

#
# connection point streaming
#
add_interface streaming avalon_streaming start
set_interface_property streaming associatedClock clock
set_interface_property streaming associatedReset reset
set_interface_property streaming dataBitsPerSymbol 8
set_interface_property streaming errorDescriptor ""
set_interface_property streaming firstSymbolInHighOrderBits true
set_interface_property streaming maxChannel 0
set_interface_property streaming readyLatency 0
set_interface_property streaming ENABLED true

add_interface_port streaming aso_data data Output 8
add_interface_port streaming aso_valid valid Output 1
add_interface_port streaming aso_ready ready Input 1

#
```

Component Interface Tcl Reference on page 666

3.3.1. Save an IP Component and Create the _hw.tcl File

You save a component by clicking **Finish** in the Platform Designer Component Editor. The Component Editor saves the component as <*component_name*> `_hw.tcl` file.

You can use IP components with other applications, such as the C compiler and a board support package (BSP) generator. Intel recommends that you move `_hw.tcl` files and their associated files to an `ip/` directory within your Quartus Prime project directory.

When changing file locations, ensure that the file paths in the `_hw.tcl` file always point to the HDL code correctly. The Component Editor places the `_hw.tcl` file in the location of the `.qsys` file, rather than in the location of the HDL files. There can be a disconnect if you move the files without updating references. Check the `ADD_FILESET_FILE` property setting in the `_hw.tcl`.

Refer to *Creating a System with Platform Designer* for information on how to search for and add components to the IP Catalog for use in your designs.

Related Information

Creating a System with Platform Designer on page 11

3.3.2. Edit an IP Component with the Platform Designer Component Editor

In Platform Designer, you make changes to a component by right-clicking the component in the **System View** tab, and then clicking **Edit**. After making changes, click **Finish** to save the changes to the `_hw.tcl` file.

You can open an `_hw.tcl` file in a text editor to view the hardware Tcl for the component. If you edit the `_hw.tcl` file to customize the component with advanced features, you cannot use the Component Editor to make further changes without over-writing your customized file.

You cannot use the Component Editor to edit components installed with the Quartus Prime software, such as Intel-provided components. If you edit the HDL for a component and change the interface to the top-level module, you must edit the component to reflect the changes you make to the HDL.

3.3.3. Specify IP Component Type Information

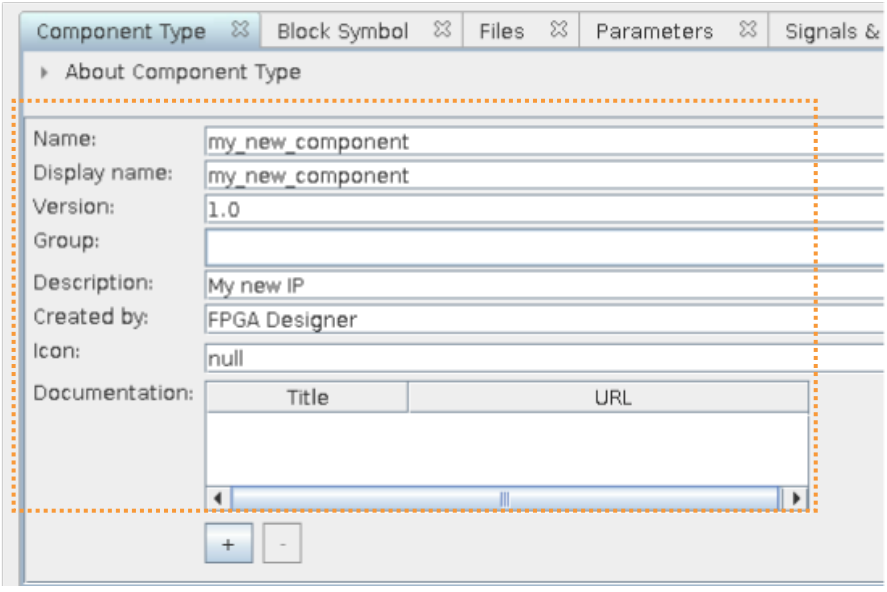
The **Component Type** tab in the Platform Designer Component Editor allows you to specify the following information about the component:

- **Name**—specifies the `_hw.tcl` filename, as well as in the top-level module name when you create a synthesis wrapper file for a non HDL-based component.
- **Display name**—identifies the component in the parameter editor, which you use to configure an instance of the component, and also appears in the IP Catalog under **Project** and on the **System View** tab.
- **Version**—specifies the component version number.

- **Group**—represents the category of the component in the list of available components in the IP Catalog. You can select an existing group from the list, or define a new group by typing a name in the **Group** box. Separating entries in the **Group** box with a slash defines a subcategory. For example, if you type **Memories and Memory Controllers/On-Chip**, the component appears in the IP Catalog under the **On-Chip** group, which is a subcategory of the **Memories and Memory Controllers** group. If you save the component in the project directory, the component appears in the IP Catalog in the group you specified under **Project**. Alternatively, if you save the component in the Quartus Prime installation directory, the component appears in the specified group under **IP Catalog**.
- **Description**—allows you to describe the component. This description appears when the user views the component details.
- **Created By**—specifies the component author name.
- **Icon**—specifies the relative path to an icon file (`.gif`, `.jpg`, or `.png` format) that represents the component and appears as the header in the parameter editor for the component. The default image is the Intel FPGA IP function icon.
- **Documentation**—specifies links to documentation for the component, and appears when you right-click the component in the IP Catalog, and then select **Details**.
  - To specify an Internet file, begin your path with `http://`, for example: `http://mydomain.com/datasheets/my_memory_controller.html`.
  - To specify a file in the file system, begin your path with `file:///` for Linux, and `file:////` for Windows; for example (Windows): `file:////company_server/datasheets my_memory_controller.pdf`.

Figure 135. Component Type Tab in the Component Editor

The **Display name**, **Group**, **Description**, **Created by**, **Icon**, and **Documentation** entries are optional.



When you use the Component Editor to create a component, it writes this basic component information in the _hw.tcl file. The `package require` command specifies the Quartus Prime software version that Platform Designer uses to create the _hw.tcl file, and ensures compatibility with this version of the Platform Designer API in future releases.

Example 5. _hw.tcl Created from Entries in the Component Type Tab

The component defines its basic information with various module properties using the `set_module_property` command. For example, `set_module_property NAME` specifies the name of the component, while `set_module_property VERSION` allows you to specify the version of the component. When you apply a version to the _hw.tcl file, it allows the file to behave exactly the same way in future releases of the Quartus Prime software.

```
# request TCL package from ACDS 14.0

package require -exact qsys 14.0

# demo_axi_memory

set_module_property DESCRIPTION \
"Demo AXI-3 memory with optional Avalon streaming port"

set_module_property NAME demo_axi_memory
set_module_property VERSION 1.0
set_module_property GROUP "My Components"
set_module_property AUTHOR Altera
set_module_property DISPLAY_NAME "Demo AXI Memory"
```

Related Information

Component Interface Tcl Reference on page 666

3.3.4. Create an HDL File in the Platform Designer Component Editor

If you do not have an HDL file for your component, you can use the Platform Designer Component Editor to define the component signals, interfaces, and parameters of your component, and then create a simple top-level HDL file.

You can then edit the HDL file to add the logic that describes the component's behavior.

1. In the Platform Designer Component Editor, specify the information about the component in the **Signals & Interfaces**, and **Interfaces**, and **Parameters** tabs.
2. Click the **Files** tab.
3. Click **Create Synthesis File from Signals**.
   The Component Editor creates an HDL file from the specified signals, interfaces, and parameters, and the .v file appears in the **Synthesis File** table.

Related Information

Specify Synthesis and Simulation Files in the Platform Designer Component Editor on page 167

3.3.5. Defining HDL Parameters in _hw.tcl

Platform Designer supports the ability to reconfigure features of parameterized modules, such as data bus width or FIFO depth. Platform Designer creates an HDL wrapper when you perform **Generate HDL**. By modifying your `_hw.tcl` files to specify parameter attributes and port properties, you can use Platform Designer to generate reusable RTL.

1. To define an alterable HDL parameter, you must declare the following two attributes for the parameter:
   - `set_parameter_property <parameter_name> HDL_PARAMETER true`
   - `set_parameter_property <parameter_name> AFFECTS_GENERATION false`
2. To have parameterized ports created in the instantiation wrapper, you can either set the width expression when adding a port to an interface, or set the width expression in the port property in `_hw.tcl`:
   - To set the width expression when adding a port:

     ```
     add_interface_port <interface> <port> <signal_type> <direction>
     <width_expression>
     ```

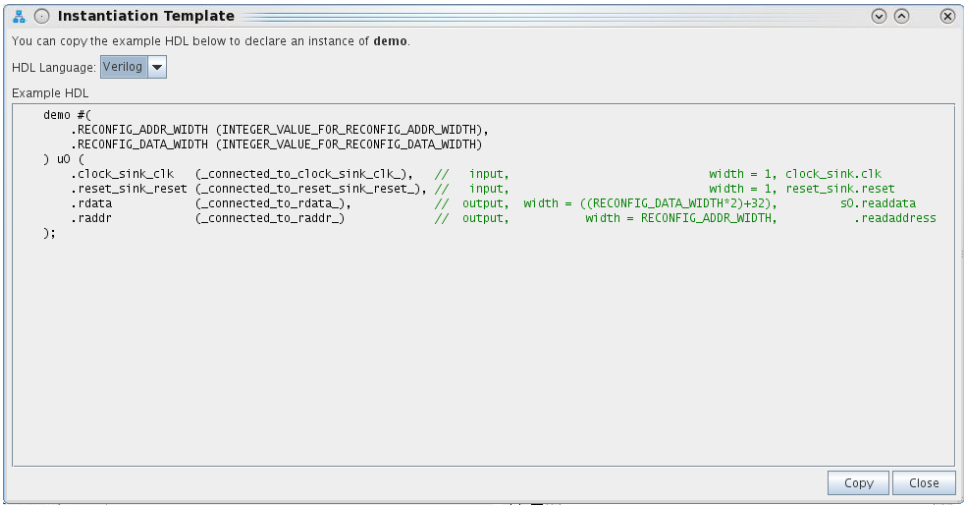
   - To set the width expression in the port property:

     ```
     set_port_property <port> WIDTH_EXPR <width_expression>
     ```

3. To create and generate the IP component in Platform Designer editor, click the **Open System ➤ IP Variant** tab, specify the new IP variant name in the **IP Variant** field and choose the `_hw.tcl` file that defines user alterable HDL parameters in the **Component type** field.
4. Click **Generate HDL** to generate the IP core. Platform Designer generates a parameterized HDL module for you directly.

To instantiate the IP component in your HDL file, click **Generate ➤ Show Instantiation Template** in the Platform Designer editor to display an instantiation template in Verilog or VHDL. Now you can instantiate the IP core in your top-level design HDL file with the template code.

Figure 136. Instantiation Template Dialog Box



The following sample contains _hw.tcl to set exportable width values:

Example 6. Sample _hw.tcl Component with User Alterable Expressions

```
package require -exact qsys 17.1

set_module_property NAME demo
set_module_property DISPLAY_NAME "Demo"
set_module_property ELABORATION_CALLBACK elaborate

# add exportable hdl parameter RECONFIG_DATA_WIDTH
add_parameter RECONFIG_DATA_WIDTH INTEGER 48
set_parameter_property RECONFIG_DATA_WIDTH AFFECTS_GENERATION false
set_parameter_property RECONFIG_DATA_WIDTH HDL_PARAMETER true

# add exportable hdl parameter RECONFIG_ADDR_WIDTH
add_parameter RECONFIG_ADDR_WIDTH INTEGER 32
set_parameter_property RECONFIG_ADDR_WIDTH AFFECTS_GENERATION false
set_parameter_property RECONFIG_ADDR_WIDTH HDL_PARAMETER true

# add non-exportable hdl parameter
add_parameter l_addr INTEGER 32
set_parameter l_addr HDL_PARAMETER false

# add interface
add_interface s0 conduit end

proc elaborate {} {
   add_interface_port s0 rdata readdata output "reconfig_data_width*2 + l_addr"
   add_interface_port s0 raddr readaddress output [get_parameter_value
RECONFIG_ADDR_WIDTH]
   set_port_property raddr WIDTH_EXPR "RECONFIG_ADDR_WIDTH"
}
```

3.3.6. Declaring SystemVerilog Interfaces in _hw.tcl

Platform Designer supports interfaces written in SystemVerilog.

The following example is `_hw.tcl` for a module with a SystemVerilog interface. The sample code is divided into parts 1 and 2.

Part 1 defines the normal array of parameters, Platform Designer interface, and ports

Example 7. Example Part 1: Parameters, Platform Designer Interface, and Ports in _hw.tcl

```
# request TCL package from ACDS 23.1
#
package require -exact qsys 23.1
#
# module ram_ip_sv_ifc_hw
#
set_module_property DESCRIPTION ""
set_module_property NAME ram_ip_sv_ifc_hw
set_module_property VERSION 1.0
set_module_property INTERNAL false
set_module_property OPAQUE_ADDRESS_MAP true
set_module_property AUTHOR ""
set_module_property DISPLAY_NAME ram_ip_hw_with_SV_d0
set_module_property INSTANTIATE_IN_SYSTEM_MODULE true
set_module_property EDITABLE true
set_module_property REPORT_TO_TALKBACK false
set_module_property ALLOW_GREYBOX_GENERATION false
set_module_property REPORT_HIERARCHY false

# Part 1 – Add parameter, platform designer interface and ports
# Adding parameter
add_parameter my_interface_parameter STRING "" "I am an interface parameter"

# Adding platform designer interface clk
add_interface clk clock end
set_interface_property clk clockRate 0
# Adding ports to clk interface
add_interface_port clk clk clk Input 1

# Adding platform designer interface reset
add_interface reset reset end
set_interface_property reset associatedClock clk
#Adding ports to reset interface
add_interface_port reset reset reset Input 1

# Adding platform designer interface avalon_slave
add_interface avalon_slave avalon end
set_interface_property avalon_slave addressUnits WORDS
set_interface_property avalon_slave associatedClock clk
set_interface_property avalon_slave associatedReset reset
# Adding ports to avalon_slave interface
add_interface_port avalon_slave address address Input 8
add_interface_port avalon_slave write write Input 1
add_interface_port avalon_slave readdata readdata Output 32
add_interface_port avalon_slave writedata writedata Input 32
```

Part 2 defines the interface name, ports, and parameters of the SystemVerilog interface.

Example 8. Example Part 2: SystemVerilog Interface Parameters in _hw.tcl

```
# Part 2 – Adding SV interface and its properties.
# Adding SV interface
add_sv_interface bus mem_ifc

set_sv_interface_property bus USE_ALL_PORTS True
# Setting the parameter property to add SV interface parameters
set_parameter_property my_interface_parameter SV_INTERFACE_PARAMETER bus
# Setting the port properties to add them to SV interface port
set_port_property clk SV_INTERFACE_PORT bus
```

```
set_port_property reset SV_INTERFACE_PORT bus

# Setting the port properties to add them as signals inside SV interface
set_port_property address SV_INTERFACE_SIGNAL bus
set_port_property write SV_INTERFACE_SIGNAL bus
set_port_property writedata SV_INTERFACE_SIGNAL bus
set_port_property readdata SV_INTERFACE_SIGNAL bus

#Adding the SV Interface File
#Adding ram_ip files
add_fileset synthesis_fileset QUARTUS_SYNTH
set_fileset_property synthesis_fileset TOP_LEVEL ram_ip
add_fileset_file ram_ip.sv SYSTEM_VERILOG PATH ram_ip.sv
add_fileset_file mem_ifc.sv SYSTEM_VERILOG PATH \
     mem_ifc.sv SYSTEMVERILOG_INTERFACE
```

Related Information

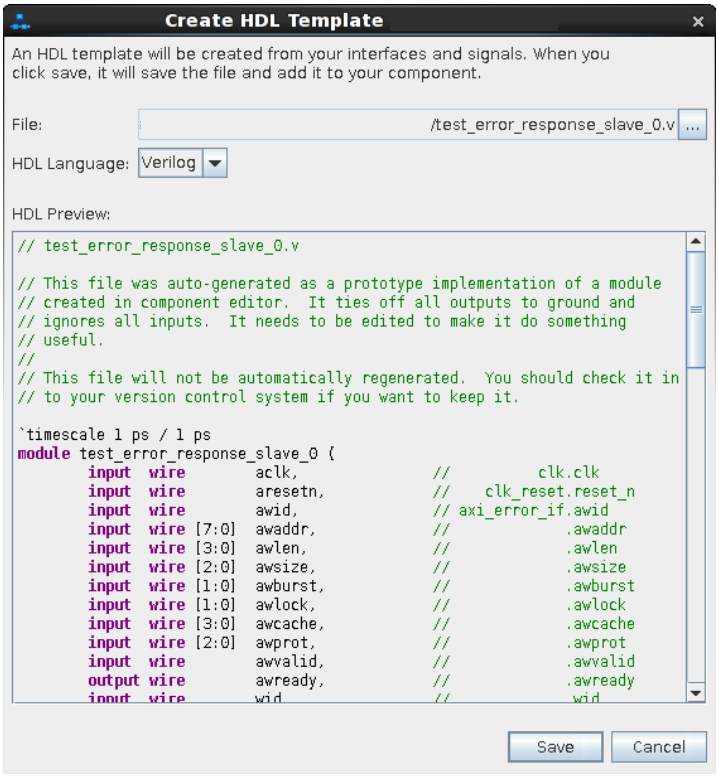
SystemVerilog Interface Commands on page 753

3.3.7. Create an HDL File Using a Template in the Platform Designer Component Editor

You can use a template to create interfaces and signals for your Platform Designer component

1. In Platform Designer, click **New Component** in the IP Catalog.
2. On the **Component Type** tab, define your component information in the **Name**, **Display Name**, **Version**, **Group**, **Description**, **Created by**, **Icon**, and **Documentation** boxes.
3. Click **Finish**.
   Your new component appears in the IP Catalog under the category that you define for "Group".
4. In Platform Designer, right-click your new component in the IP Catalog, and then click **Edit**.
5. In the Platform Designer Component Editor, click any interface from the Templates drop-down menu.
   The Component Editor fills the **Signals** and **Interfaces** tabs with the component interface template details.
6. On the **Files** tab, click **Create Synthesis File from Signals**.
7. Do the following in the **Create HDL Template** dialog box as shown below:
   a. Verify that the correct files appears in **File** path, or browse to the location where you want to save your file.
   b. Select the HDL language.
   c. Click **Save** to save your new interface, or **Cancel** to discard the new interface definition.

Create HDL Template Dialog Box



8. Verify the ***<component_name>*.v** file appears in the **Synthesis Files** table on the **Files** tab.

Related Information

Specify Synthesis and Simulation Files in the Platform Designer Component Editor on page 167

3.3.8. Specify Synthesis and Simulation Files in the Platform Designer Component Editor

The **Files** tab in the Platform Designer Component Editor allows you to specify synthesis and simulation files for your custom component.

If you already have an HDL file that describes the behavior and structure of your component, you can specify those files on the **Files** tab.

If you do not yet have an HDL file, you can specify the signals, interfaces, and parameters of the component in the Component Editor, and then use the **Create Synthesis File from Signals** option on the **Files** tab to create the top-level HDL file. The Component Editor generates the `_hw.tcl` commands to specify the files.

Note: After you analyze the component's top-level HDL file (on the **Files** tab), you cannot add or remove signals or change the signal names on the **Signals & Interfaces** tab. If you need to edit signals, edit your HDL source, and then click **Create Synthesis File from Signals** on the **Files** tab to integrate your changes.

A component uses filesets to specify the different sets of files that you can generate for an instance of the component. The supported fileset types are: `QUARTUS_SYNTH`, for synthesis and compilation in the Quartus Prime software, `SIM_VERILOG`, for Verilog HDL simulation, and `SIM_VHDL`, for VHDL simulation.

In an `_hw.tcl` file, you can add a fileset with the `add_fileset` command. You can then list specific files with the `add_fileset_file` command. The `add_fileset_property` command allows you to add properties such as `TOP_LEVEL`.

You can populate a fileset with a fixed list of files, add different files based on a parameter value, or even generate an HDL file with a custom HDL generator function outside of the `_hw.tcl` file.

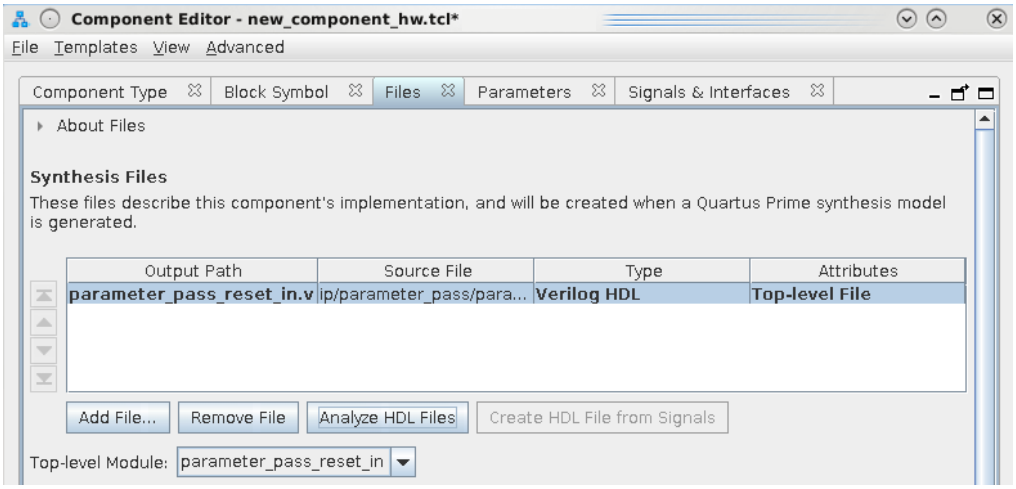
Related Information

- Create an HDL File in the Platform Designer Component Editor on page 162
- Create an HDL File Using a Template in the Platform Designer Component Editor on page 166

3.3.8.1. Specify HDL Files for Synthesis in the Platform Designer Component Editor

In the Platform Designer Component Editor, you can add HDL files and other support files with options on the `Files` tab.

Figure 137. Using HDL Files to Define a Component



A component must specify an HDL file as the top-level file. The top-level HDL file contains the top-level module. The **Synthesis Files** list may also include supporting HDL files, such as timing constraints, or other files required to successfully synthesize and compile in the Quartus Prime software. The synthesis files for a component are copied to the generation output directory during Platform Designer system generation.

3.3.8.2. Analyze Synthesis Files in the Platform Designer Component Editor

After you specify the top-level HDL file in the Platform Designer Component Editor, click **Analyze Synthesis Files** to analyze the parameters and signals in the top-level, and then select the top-level module from the **Top Level Module** list. If there is a single module or entity in the HDL file, Platform Designer automatically populates the **Top-level Module** list.

Once analysis is complete and the top-level module is selected, you can view the parameters and signals on the **Parameters** and **Signals & Interfaces** tabs. The Component Editor may report errors or warnings at this stage, because the signals and interfaces are not yet fully defined.

Note: At this stage in the Component Editor flow, you cannot add or remove parameters or signals created from a specified HDL file without editing the HDL file itself.

The synthesis files are added to a fileset with the name `QUARTUS_SYNTH` and type `QUARTUS_SYNTH` in the `_hw.tcl` file created by the Component Editor. The top-level module is used to specify the `TOP_LEVEL` fileset property. Each synthesis file is individually added to the fileset. If the source files are saved in a different directory from the working directory where the `_hw.tcl` is located, you can use standard fixed or relative path notation to identify the file location for the `PATH` variable.

Example 9. _hw.tcl Created from Entries in the Files tab in the Synthesis Files Section

```
# file sets

add_fileset QUARTUS_SYNTH QUARTUS_SYNTH "" ""
set_fileset_property QUARTUS_SYNTH TOP_LEVEL demo_axi_memory

add_fileset_file demo_axi_memory.sv
SYSTEM_VERILOG PATH demo_axi_memory.sv

add_fileset_file single_clk_ram.v VERILOG PATH single_clk_ram.v
```

Related Information

- Specify HDL Files for Synthesis in the Platform Designer Component Editor on page 168
- Component Interface Tcl Reference on page 666

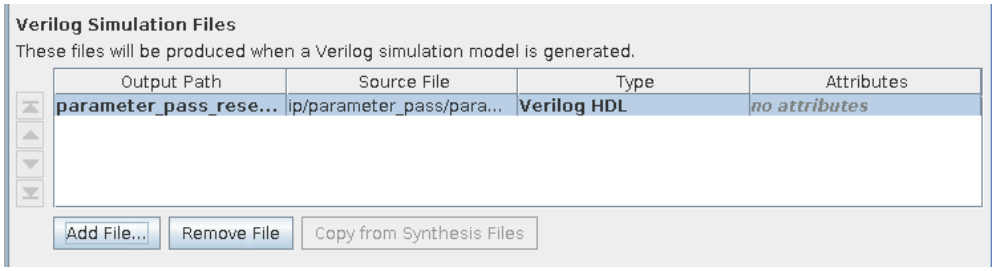
3.3.8.3. Specify Files for Simulation in the Component Editor

To support Platform Designer system generation for your custom component, you must specify VHDL or Verilog simulation files.

You can choose to generate Verilog or VHDL simulation files. In most cases, these files are the same as the synthesis files. If there are simulation-specific HDL files or simulation models, you can use them in addition to, or in place of the synthesis files. To use your synthesis files as your simulation files, click **Copy From Synthesis Files** on the **Files** tab in the Platform Designer Component Editor.

Note: The order that you add files to the fileset determines the order of compilation. For VHDL filesets with VHDL files, you must add the files bottom-up, adding the top-level file last.

Figure 138. Specifying the Simulation Output Files on the Files Tab



You specify the simulation files in a similar way as the synthesis files with the fileset commands in a `_hw.tcl` file. The code example below shows `SIM_VERILOG` and `SIM_VHDL` filesets for Verilog and VHDL simulation output files. In this example, the same Verilog files are used for both Verilog and VHDL outputs, and there is one additional SystemVerilog file added. This method works for designers of Verilog IP to support users who want to generate a VHDL top-level simulation file when they have a mixed-language simulation tool and license that can read the Verilog output for the component.

Example 10. _hw.tcl Created from Entries in the Files tab in the Simulation Files Section

```
add_fileset SIM_VERILOG SIM_VERILOG "" ""
set_fileset_property SIM_VERILOG TOP_LEVEL demo_axi_memory
add_fileset_file single_clk_ram.v VERILOG PATH single_clk_ram.v

add_fileset_file verbosity_pkg.sv SYSTEM_VERILOG PATH \
verification_lib/verbosity_pkg.sv

add_fileset_file demo_axi_memory.sv SYSTEM_VERILOG PATH \
demo_axi_memory.sv

add_fileset SIM_VHDL SIM_VHDL "" ""
set_fileset_property SIM_VHDL TOP_LEVEL demo_axi_memory
set_fileset_property SIM_VHDL ENABLE_RELATIVE_INCLUDE_PATHS false

add_fileset_file demo_axi_memory.sv SYSTEM_VERILOG PATH \
demo_axi_memory.sv

add_fileset_file single_clk_ram.v VERILOG PATH single_clk_ram.v

add_fileset_file verbosity_pkg.sv SYSTEM_VERILOG PATH \
verification_lib/verbosity_pkg.sv
```

Related Information

Component Interface Tcl Reference on page 666

3.3.8.4. Include an Internal Register Map Description in the .svd for Agent Interfaces Connected to an HPS Component

Platform Designer supports the ability for IP component designers to specify register map information on their agent interfaces. This allows components with agent interfaces that are connected to an HPS component to include their internal register description in the generated `.svd` file.

To specify their internal register map, the IP component designer must write and generate their own `.svd` file and attach it to the agent interface using the following command:

`set_interface_property` <*agent interface*> `CMSIS_SVD_FILE` <*file path*>

The `CMSIS_SVD_VARIABLES` interface property allows for variable substitution inside the `.svd` file. You can dynamically modify the character data of the `.svd` file by using the `CMSIS_SVD_VARIABLES` property.

Example 11. Setting the CMSIS_SVD_VARIBLES Interface Property

For example, if you set the `CMSIS_SVD_VARIABLES` in the `_hw tcl` file, then in the `.svd` file if there is a variable `{width}` that describes the element `<size>${width}</size>`, it is replaced by `<size>23</size>` during generation of the `.svd` file. Note that substitution works only within character data (the data enclosed by <element>...</element>) and not on element attributes.

```
set_interface_property <interface name> \
CMSIS_SVD_VARIABLES "{width} {23}"
```

3.3.9. Add Signals and Interfaces in the Platform Designer Component Editor

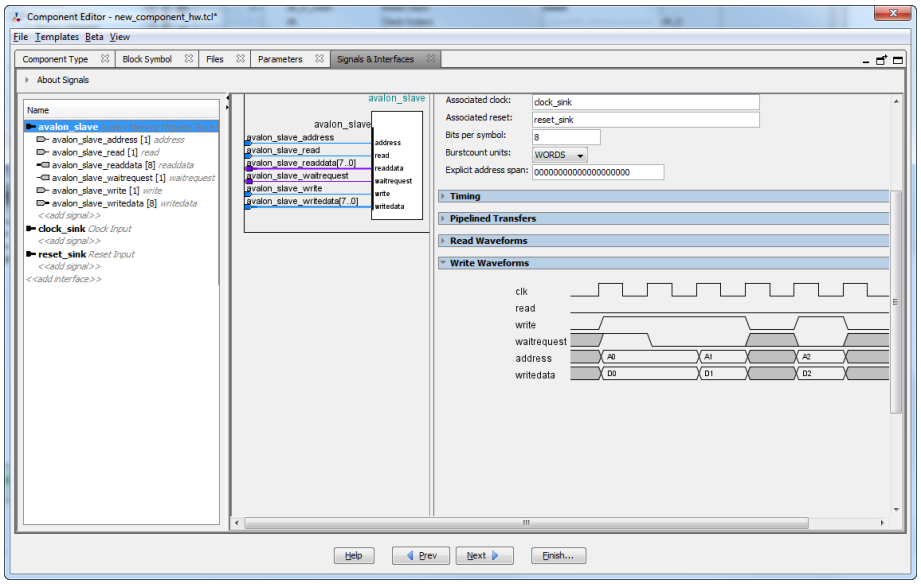
In the Platform Designer Component Editor, the **Signals & Interfaces** tab allows you to add signals and interfaces for your custom IP component.

As you select interfaces and associated signals, you can customize the parameters. Messages appear as you add interfaces and signals to guide you when customizing the component. In the parameter editor, a block diagram displays for each interface. Some interfaces display waveforms to show the timing of the interface. If you update timing parameters, the waveforms update automatically.

1. In Platform Designer, click ***New Component*** in the IP Catalog.
2. In the Platform Designer Component Editor, click the **Signals & Interfaces** tab.
3. To add an interface, click <<*add interface*>> in the left pane.
   A drop-down list appears where you select the interface type.
4. Select an interface from the drop-down list.
   The selected interface appears in the parameter editor where you can specify its parameters.
5. To add signals for the selected interface click <<*add signal*>> below the selected interface.
6. To move signals between interfaces, select the signal, and then drag it to another interface.
7. To rename a signal or interface, select the element, and then press **F2**.
8. To remove a signal or interface, right-click the element, and then click **Remove**.

Alternatively, to remove an signal or interface, you can select the element, and then press **Delete**. When you remove an interface, Platform Designer also removes all of its associated signals.

Figure 139. Platform Designer Signals & Interfaces tab



3.3.10. Specify Parameters in the Platform Designer Component Editor

Components can include parameterized HDL, which allow users of the component flexibility in meeting their system requirements. For example, a component with a configurable memory size or data width, allows using one HDL implementation in different systems, each with unique parameters values.

The **Parameters** tab allows you specify the parameters that are used to configure instances of the component in a Platform Designer system. You can specify various properties for each parameter that describe how to display and use the parameter. You can also specify a range of allowed values that are checked during the validation phase. The **Parameters** table displays the HDL parameters that are declared in the top-level HDL module. If you have not yet created the top-level HDL file, the top-level synthesis file template created from the **Files** tab include the parameters that you create on the **Parameters** tab.

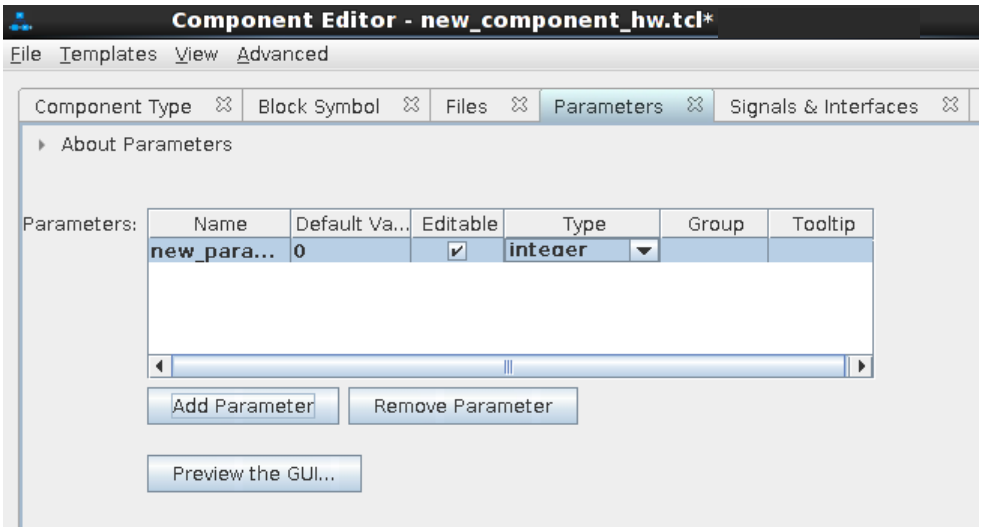
When the component includes HDL files, the parameters match those defined in the top-level module, and you cannot add or remove them on the **Parameters** tab. To add or remove the parameters, edit your HDL source, and then re-analyze the file.

If you create a top-level template HDL file for synthesis with the Component Editor, you can remove the newly-created file from the **Synthesis Files** list on the **Files** tab, make your parameter changes, and then re-analyze the top-level synthesis file.

You can use the **Parameters** table to specify the following information about each parameter:

- **Name**—specifies the parameter name.
- **Default Value**—sets the default value for new instances of the component.
- **Editable**—specifies if the user can edit the parameter value.
- **Type**—defines the parameter type as string, integer, boolean, std_logic, logic vector, natural, or positive.
- **Group**—groups parameters in the parameter editor.
- **Tooltip**—adds a description of the parameter that appears when the user of the component points to the parameter in the editor.

Figure 140. Parameters Tab in the Platform Designer Components Editor



On the **Parameters** tab, you can click **Preview the GUI** at any time to see how the declared parameters appear in the parameter editor. Parameters with their default values appear with checks in the **Editable** column. Editable parameters cannot contain computed expressions. You can group parameters under a common heading or section in the editor with the **Group** column, and a tooltip helps users of the component understand the function of the parameter. Various parameter properties allow you to customize the component's parameter editor, such as specifying parameter option controls, or displaying an image.

Example 12. _hw.tcl Created from Entries in the Parameters Tab

In this example, the first `add_parameter` command includes commonly-specified properties. The `set_parameter_property` command specifies each property individually. The **Tooltip** column on the **Parameters** tab maps to the `DESCRIPTION` property, and there is an additional unused `UNITS` property created in the code. The `HDL_PARAMETER` property specifies that the value of the parameter is specified in the HDL instance wrapper when creating instances of the component. The **Group** column in the **Parameters** tab maps to the display items section with the `add_display_item` commands. If you want to expose the HDL parameter so that you can overwrite the value when you instantiate the module, set `AFFECTS_GENERATION` to false.

Note: If a parameter <*n*> defines the width of a signal, the signal width must follow the format <*n*-1> : 0.

```
#
# parameters
#
add_parameter AXI_ID_W INTEGER 4 "Width of ID fields"
set_parameter_property AXI_ID_W DEFAULT_VALUE 4
set_parameter_property AXI_ID_W DISPLAY_NAME AXI_ID_W
set_parameter_property AXI_ID_W TYPE INTEGER
set_parameter_property AXI_ID_W UNITS None
set_parameter_property AXI_ID_W DESCRIPTION "Width of ID fields"
set_parameter_property AXI_ID_W HDL_PARAMETER true
add_parameter AXI_ADDRESS_W INTEGER 12
set_parameter_property AXI_ADDRESS_W DEFAULT_VALUE 12

add_parameter AXI_DATA_W INTEGER 32
...
#
# display items
#
add_display_item "AXI Port Widths" AXI_ID_W PARAMETER ""
```

Note: If an AXI subordinate's ID bit width is smaller than required for your system, the AXI subordinate response may not reach all AXI managers. The formula of an AXI subordinate ID bit width is calculated as follows:

```
maximum_manager_id_width_in_the_interconnect + log2 = <value>
```

For example, if an AXI subordinate connects to three AXI managers and the maximum AXI manager ID length of the three managers is 5 bits, then the AXI subordinate ID is 7 bits, and is calculated as follows:

$$5 \text{ bits} + 2 \text{ bits } (\log_2(3 \text{ managers})) = 7$$

Platform Designer refers to AXI interface parameters to build AXI interconnect. If these parameter settings are incompatible with the component's HDL behavior, Platform Designer interconnect and transactions may not work correctly. To prevent unexpected interconnect behavior, you must set the AXI component parameters.

Table 38. AXI Manager Parameters

AXI Manager Parameters	Description
`readIssuingCapability`	The maximum number of outstanding read transactions for a manager.
`writeIssuingCapability`	The maximum number of outstanding write transactions for a manager.
`combinedIssuingCapability`	The maximum number of outstanding transactions for a manager.

Table 39. AXI Subordinate Parameters

AXI Subordinate Parameters	Description
`readAcceptanceCapability`	The maximum number of outstanding read commands that a subordinate can accept.
`writeAcceptanceCapability`	The maximum number of outstanding write transactions that a subordinate can accept.
`combinedAcceptanceCapability`	The maximum number of outstanding transactions that a subordinate can accept.
`readDataReorderingDepth`	The number of outstanding read transactions for which a subordinate interface can transmit data. If `readDataReorderingDepth = 1`, the subordinate processes all transactions in order.

Component Interface Tcl Reference on page 666

3.3.10.1. Valid Ranges for Parameters in the _hw.tcl File

In the `_hw.tcl` file, you can specify valid ranges for parameters.

Platform Designer validation checks each parameter value against the `ALLOWED_RANGES` property. If the values specified are outside of the allowed ranges, Platform Designer displays an error message. Specifying choices for the allowed values enables users of the component to choose the parameter value from controls in the parameter editor GUI, instead of entering a value.

The `ALLOWED_RANGES` property is a list of valid ranges, where each range is a single value, or a range of values defined by a start and end value.

Table 40. ALLOWED_RANGES Property

ALLOWED_RANGES Property	Values
`{a b c}`	a, b, or c
`{"No Control" "Single Control" "Dual Controls"}`	Unique string values. Quotation marks are required if the strings include spaces .
`{1 2 4 8 16}`	1, 2, 4, 8, or 16
`{1:3}`	1 through 3, inclusive.
`{1 2 3 7:10}`	1, 2, 3, or 7 through 10 inclusive.

Related Information

Declare Parameters with Custom _hw.tcl Commands on page 177

3.3.10.2. Types of Platform Designer Parameters

Platform Designer uses the following parameter types: user parameters, system information parameters, and derived parameters.

Platform Designer User Parameters on page 176
Platform Designer System Information Parameters on page 176
Parameterized Parameter Widths on page 176

Platform Designer Derived Parameters on page 176

Related Information

Declare Parameters with Custom _hw.tcl Commands on page 177

3.3.10.2.1. Platform Designer User Parameters

User parameters are parameters that users of a component can control, and appear in the parameter editor for instances of the component. User parameters map directly to parameters in the component HDL. For user parameter code examples, such as AXI_DATA_W and ENABLE_STREAM_OUTPUT, refer to *Declaring Parameters with Custom hw.tcl Commands*.

3.3.10.2.2. Platform Designer System Information Parameters

A SYSTEM_INFO parameter is a parameter whose value is set automatically by the Platform Designer system. When you define a SYSTEM_INFO parameter, you provide an `information type`, and additional arguments.

For example, you can configure a parameter to store the clock frequency driving a clock input for your component. To do this, define the parameter as SYSTEM_INFO of type CLOCK_RATE:

```
set_parameter_property <param> SYSTEM_INFO CLOCK_RATE
```

You then set the name of the clock interface as the SYSTEM_INFO argument:

```
set_parameter_property <param> SYSTEM_INFO_ARG <clkname>
```

3.3.10.2.3. Parameterized Parameter Widths

Platform Designer allows a `std_logic_vector` parameter to have a width that is defined by another parameter, similar to derived parameters. The width can be a constant or the name of another parameter.

3.3.10.2.4. Platform Designer Derived Parameters

Derived parameter values are calculated from other parameters during the Elaboration phase, and are specified in the `_hw.tcl` file with the DERIVED property. Derived parameter values are calculated from other parameters during the Elaboration phase, and are specified in the `_hw.tcl` file with the DERIVED property. For example, you can derive a clock period parameter from a data rate parameter. Derived parameters are sometimes used to perform operations that are difficult to perform in HDL, such as using logarithmic functions to determine the number of address bits that a component requires.

Related Information

Declare Parameters with Custom _hw.tcl Commands on page 177

3.3.10.3. Obtaining Device Trait Information Using PART_TRAIT System Information Parameter

Within Platform Designer, an IP core can obtain information on the particular traits of a device using the PART_TRAIT system info parameter. This system info parameter takes an argument corresponding to the desired part trait. The requested trait must match the trait name as specified in the device database.

Note: Using this API declares your IP core as dependent on the requested trait.

To get the part number setting of Platform Designer system, use the value DEVICE, with the SYSTEM_INFO_ARG parameter property:

```
add_parameter part_trait_device string ""
set_parameter_property part_trait_device SYSTEM_INFO_TYPE PART_TRAIT
set_parameter_property part_trait_device SYSTEM_INFO_ARG DEVICE
```

To get the base device of the part number setting of Platform Designer system, use the value BASE_DEVICE, with the SYSTEM_INFO_ARG parameter property:

```
add_parameter part_trait_bd string ""
set_parameter_property part_trait_bd SYSTEM_INFO_TYPE PART_TRAIT
set_parameter_property part_trait_bd SYSTEM_INFO_ARG BASE_DEVICE
```

To get the device speed-grade of the part number setting of Platform Designer system, use the value DEVICE_SPEEDGRADE, with the SYSTEM_INFO_ARG parameter property:

```
add_parameter part_trait_sg string ""
set_parameter_property part_trait_sg SYSTEM_INFO_TYPE PART_TRAIT
set_parameter_property part_trait_sg SYSTEM_INFO_ARG DEVICE_SPEEDGRADE
```

3.3.10.4. Declare Parameters with Custom _hw.tcl Commands

The example below illustrates a custom _hw.tcl file, with more advanced parameter commands than those generated when you specify parameters in the Component Editor. Commands include the ALLOWED_RANGES property to provide a range of values for the AXI_ADDRESS_W (**Address Width**) parameter, and a list of parameter values for the AXI_DATA_W (**Data Width**) parameter. This example also shows the parameter AXI_NUMBYTES (**Data width in bytes**) parameter; that uses the DERIVED property. In addition, these commands illustrate the use of the GROUP property, which groups some parameters under a heading in the parameter editor GUI. You use the ENABLE_STREAM_OUTPUT_GROUP (**Include Avalon streaming source port**) parameter to enable or disable the optional Avalon Streaming interface in this design, and is displayed as a check box in the parameter editor GUI because the parameter is of type BOOLEAN. Refer to figure below to see the parameter editor GUI resulting from these _hw.tcl commands.

Example 13. Parameter Declaration

In this example, the AXI_NUMBYTES parameter is derived during the Elaboration phase based on another parameter, instead of being assigned to a specific value. AXI_NUMBYTES describes the number of bytes in a word of data. Platform Designer calculates the AXI_NUMBYTES parameter from the DATA_WIDTH parameter by dividing by 8. The _hw.tcl code defines the AXI_NUMBYTES parameter as a derived

parameter, since its value is calculated in an elaboration callback procedure. The AXI_NUMBYTES parameter value is not editable, because its value is based on another parameter value.

```
add_parameter AXI_ADDRESS_W INTEGER 12

set_parameter_property AXI_ADDRESS_W DISPLAY_NAME \
"AXI Subordinate Address Width"

set_parameter_property AXI_ADDRESS_W DESCRIPTION \
"Address width."

set_parameter_property AXI_ADDRESS_W UNITS bits
set_parameter_property AXI_ADDRESS_W ALLOWED_RANGES 4:16
set_parameter_property AXI_ADDRESS_W HDL_PARAMETER true

set_parameter_property AXI_ADDRESS_W GROUP \
"AXI Port Widths"

add_parameter AXI_DATA_W INTEGER 32
set_parameter_property AXI_DATA_W DISPLAY_NAME "Data Width"

set_parameter_property AXI_DATA_W DESCRIPTION \
"Width of data buses."

set_parameter_property AXI_DATA_W UNITS bits

set_parameter_property AXI_DATA_W ALLOWED_RANGES \
{8 16 32 64 128 256 512 1024}

set_parameter_property AXI_DATA_W HDL_PARAMETER true
set_parameter_property AXI_DATA_W GROUP "AXI Port Widths"

add_parameter AXI_NUMBYTES INTEGER 4
set_parameter_property AXI_NUMBYTES DERIVED true

set_parameter_property AXI_NUMBYTES DISPLAY_NAME \
"Data Width in bytes; Data Width/8"

set_parameter_property AXI_NUMBYTES DESCRIPTION \
"Number of bytes in one word"

set_parameter_property AXI_NUMBYTES UNITS bytes
set_parameter_property AXI_NUMBYTES HDL_PARAMETER true
set_parameter_property AXI_NUMBYTES GROUP "AXI Port Widths"

add_parameter ENABLE_STREAM_OUTPUT BOOLEAN true

set_parameter_property ENABLE_STREAM_OUTPUT DISPLAY_NAME \
"Include Avalon Streaming Source Port"

set_parameter_property ENABLE_STREAM_OUTPUT DESCRIPTION \
"Include optional Avalon streaming source (default),\
or hide the interface"

set_parameter_property ENABLE_STREAM_OUTPUT GROUP \
"Streaming Port Control"

...
```

3.3.10.5. Validate Parameter Values with a Validation Callback

You can use a validation callback procedure to validate parameter values with more complex validation operations than the ALLOWED_RANGES property allows. You define a validation callback by setting the VALIDATION_CALLBACK module property to the name of the Tcl callback procedure that runs during the validation phase. In the validation callback procedure, the current parameter values is queried, and warnings or errors are reported about the component's configuration.

Example 14. Demo AXI Memory Example

If the optional Avalon streaming interface is enabled, then the control registers must be wide enough to hold an AXI RAM address, so the designer can add an error message to ensure that the user enters allowable parameter values.

```
set_module_property VALIDATION_CALLBACK validate
proc validate {} {
if {
  [get_parameter_value ENABLE_STREAM_OUTPUT ] &&
  ([get_parameter_value AXI_ADDRESS_W] >
  [get_parameter_value AV_DATA_W])
}
send_message error "If the optional Avalon streaming port\
is enabled, the AXI Data Width must be equal to or greater\
than the Avalon control port Address Width"
}
}
```

3.4. Creating Generic Components in a System

Platform Designer allows you to add generic components with the implementation defined in `_hw.tcl` (**IP** type), in an HDL file (**HDL** type), or with only a partially defined implementation (**Blackbox** type). The generic component enables hierarchical isolation of the IP components by separating the component instantiation from the component implementation. This generic component is available as **Generic Component** in the Platform Designer IP Catalog.

When you generate a system containing a generic component, the system's RTL instantiates the component, but does not provide the implementation for the component. Rather, you must provide the implementation for the component in a downstream compiler such as Quartus Prime software or in RTL code.

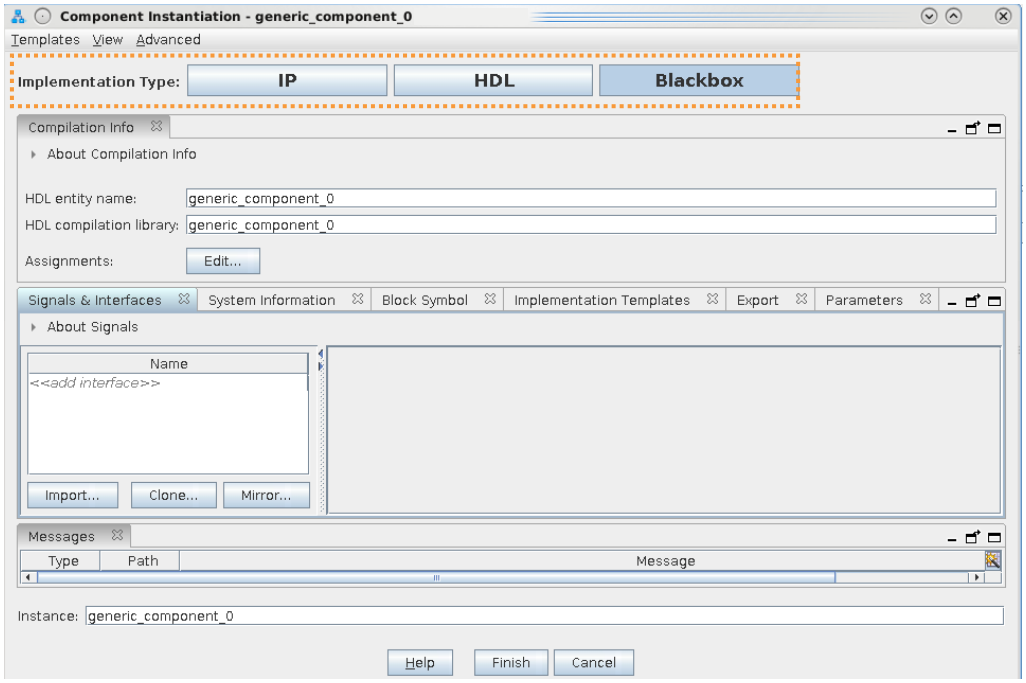
The following generic component **Implementation Type**s are available in the **Component Instantiation** editor, depending on your use case:

Table 41. Component Implementation Type Options

Implementation Type	Description
IP	The default implementation type that defines the component in `_hw.tcl` and preserves the component as a `.ip` file. Platform Designer automatically manages components with the **Implementation Type** of **IP** in the following ways: • Runs background checks against the port widths between the IP component and the `.ip` file to ensure continuity. • Scans the `.ip` file for the error flag to determine if any component has parameterization errors. • Checks for system-info mismatches between the IP file and the IP component in the system, and prompts resolution with IP instantiation warnings in the **Instantiation Messages** tab.
HDL	Defines a generic component from existing RTL. You can load the signals, interfaces, and parameters of the generic component from the HDL file containing the RTL. The HDL parameters are represented as constants local to a module, which you can redefine when instantiating the module. Generic HDL components have no `.ip` file.
Blackbox	Defines a generic component that represents only the signal and interface boundary of an entity, without providing the component's implementation. You then provide the implementation of the component for processing with the Quartus Prime software or an RTL simulator. Generic blackbox components have no `.ip` file.

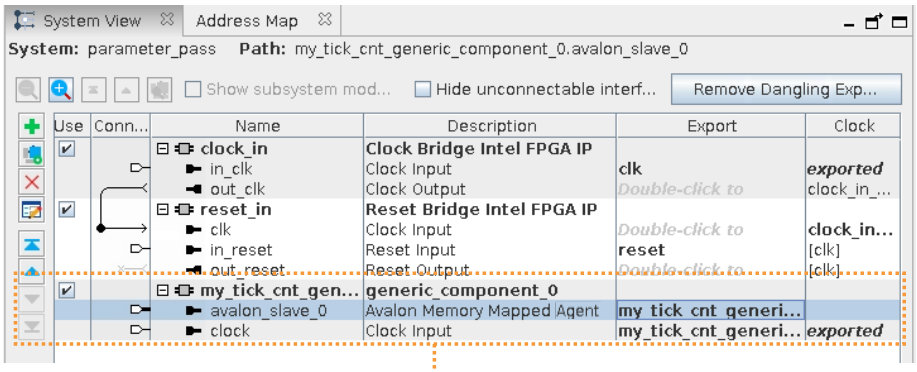
1. From the Platform Designer IP Catalog, double-click **Generic Component**. The **Component Instantiation** editor appears.
2. For **Implementation Type**, click **IP**, **HDL**, **Blackbox**, or **HLS** for your generic component. Refer to Component Implementation Type Options.
3. Add parameters to the generic component, as applicable:
   - To add parameters to a generic **HDL** component, click the **Add File** button under **Implementation Files** to specify the RTL that defines your generic component, as Adding Generic HDL Component Parameters describes.
   - To add parameters to a generic **Blackbox** component, click the **Parameters** tab, and then **Add Parameter** button to define the parameters for your generic component, as Adding Generic Blackbox Component Parameters describes.

Figure 142. Component Instantiation Editor



4. Add interfaces and signals to the generic component, as Adding Generic Component Interfaces and Signals describes.
5. Click **Finish**, the generic component appears in the **System View**.
6. In the **System View**, select the generic component that you create in step 5.

Figure 143. New Generic Component in System View



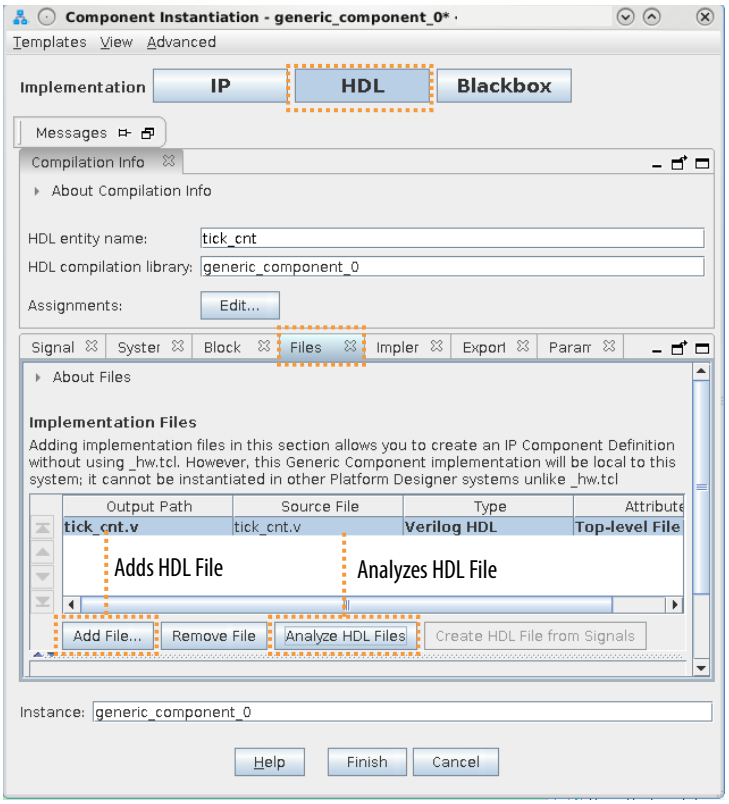
New Generic Component in System View

7. In the **System View** tab, double-click the **Export** column to export the signal(s) when you generate the system HDL.
8. In the **Parameters** tab for the component, modify the default parameter values as needed.
9. In Platform Designer, click the **Generate HDL** button. Platform Designer generates the HDL for the system and generic component according to your specifications.

3.4.1. Adding Generic HDL Component Parameters

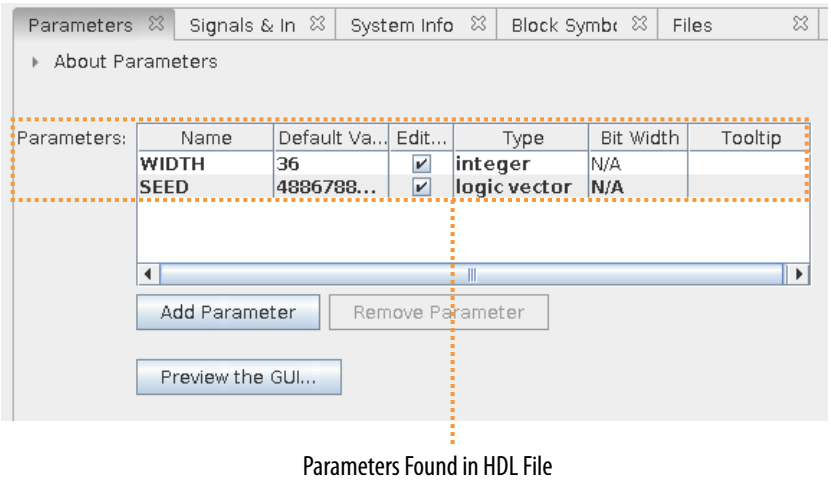
You can specify and modify HDL parameters for generic components that have an **HDL** implementation. This technique allows you to reuse the HDL component in another context with different parameter values. Platform Designer analyzes the HDL implementation, identifies the HDL parameters present, and loads the HDL parameters into the **Component Instantiation** editor where you can modify them. To add parameters in **HDL** mode, follow these steps:

Figure 144. HDL Implementation Type in Component Instantiation Editor



1. Add a generic HDL component, as Creating Generic Components in a System on page 180 describes.
2. In the **Component Instantiation** editor **Files** tab, click the **Add File** button to select the HDL file that contains the component definition.
3. Under **Implementation Files**, select the HDL file, and then click **Analyze HDL files**. The signals and interfaces found in the HDL component appear in the **Signals & Interfaces** tab. The parameters found in the HDL component appear in the **Parameters** tab.
4. On the **Parameters** tab, modify the parameter **Name**, **Value**, **Type**, **Bit Width**, and whether **Editable**.

Figure 145. Parameters Tab for HDL Instantiation



5. View the interfaces and signals, as Adding Generic Component Interfaces and Signals on page 184 describes.
6. When you are done adding parameters and interfaces, click **Finish** in the **Component Instantiation** editor. The component appears in the **System View** tab.

Note: You must treat a generic component with an **Implementation Type** of **HDL** as custom RTL, specific to your current system. When you set a generic component's **Implementation Type** to **HDL**, the output of any RTL that you add to the component is within the system's output directory.

Related Information

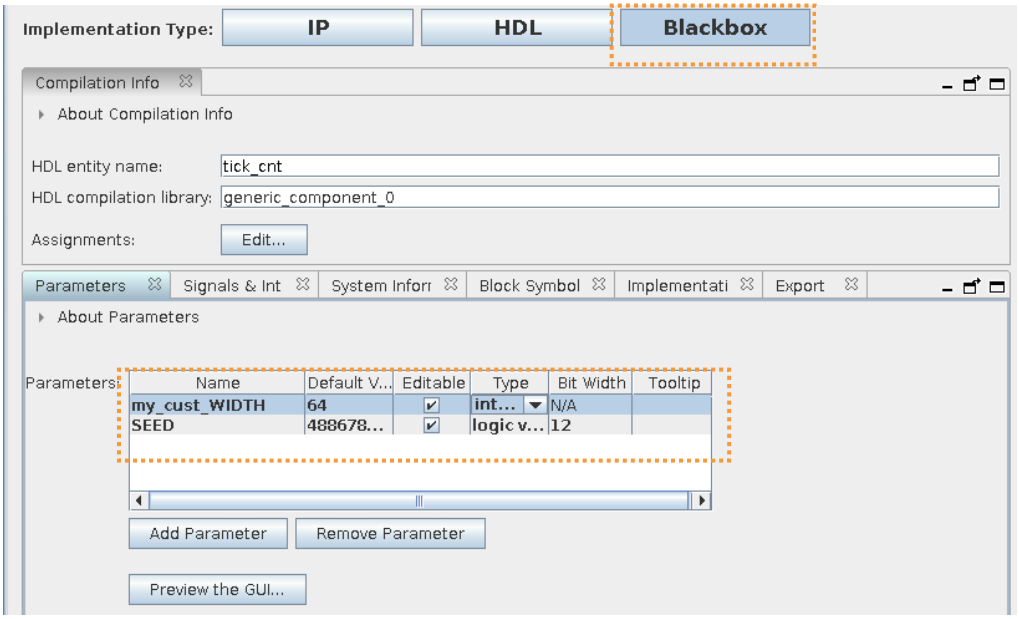
Exporting HDL Parameters to a System on page 189

3.4.2. Adding Generic Blackbox Component Parameters

You can specify and modify parameters for generic components that have a **Blackbox** implementation. This technique allows you to instantiate a component that defines only the signal and interface boundary of an entity, without providing the component's implementation at this stage. You can then add parameters and define their default properties in the **Component Instantiation** editor.

1. Define a generic blackbox component, as Creating Generic Components in a System on page 180 describes.
2. In the **Component Instantiation** editor, click the **Parameters** tab.

Figure 146. Parameters Tab in Component Instantiation Editor (Blackbox Mode)



3. Click the **Add Parameter** button to add and specify default values for the parameter **Name**, **Value**, **Type**, **Bit Width**, and whether **Editable**.
4. Add signals and interfaces on the **Signals and Interfaces** tab, as Adding Generic Component Interfaces and Signals on page 184 describes.
5. When you are done adding parameters and interfaces, click **Finish** in the **Component Instantiation** editor. The component appears in the **System View** tab.

Related Information

Exporting HDL Parameters to a System on page 189

3.4.3. Adding Generic Component Interfaces and Signals

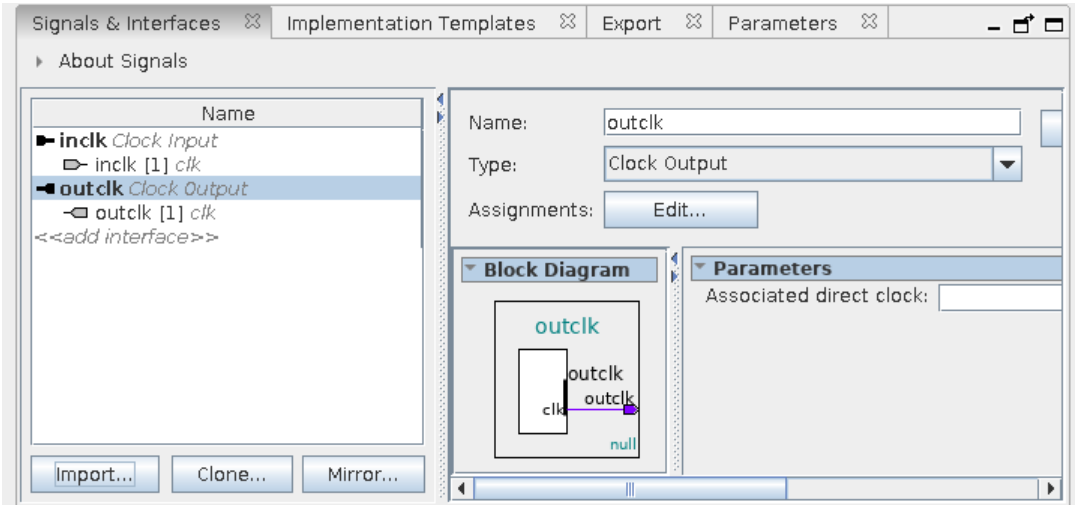
The **Signals & Interfaces** tab of the **Component Instantiation** editor allows you to customize signals and interfaces for your generic component:

1. Double-click **Generic Component** in the IP Catalog.
2. In the **Component Instantiation** editor, click the **Signals & Interfaces** tab, as Adding Generic Component Interfaces and Signals on page 184 describes.
3. To add an interface, click <<*add interface*>> in the left pane and select the interface. The selected interface appears in the parameter editor to the right, where you specify its parameters.
4. To add signals to the selected interface, click <<*add signal*>> below the selected interface.

5. To move signals between interfaces, select the signal and drag it to another interface.
6. To rename a signal or interface, select the element, and then press F2.
7. To remove a signal or interface, right-click the element, and then click **Remove**.

   Note: Alternatively, to remove a signal or interface, select the element and press **Delete**. When you remove an interface, Platform Designer also removes all of its associated signals.

Figure 147. Creating Custom Interfaces



Note: To add existing template interfaces to your generic component, select the interface from the **Templates** menu in the **Component Instantiation** editor.

3.4.3.1. Mirroring Interfaces in a Generic Component

To mirror existing signals and interfaces from an IP component to your generic component:

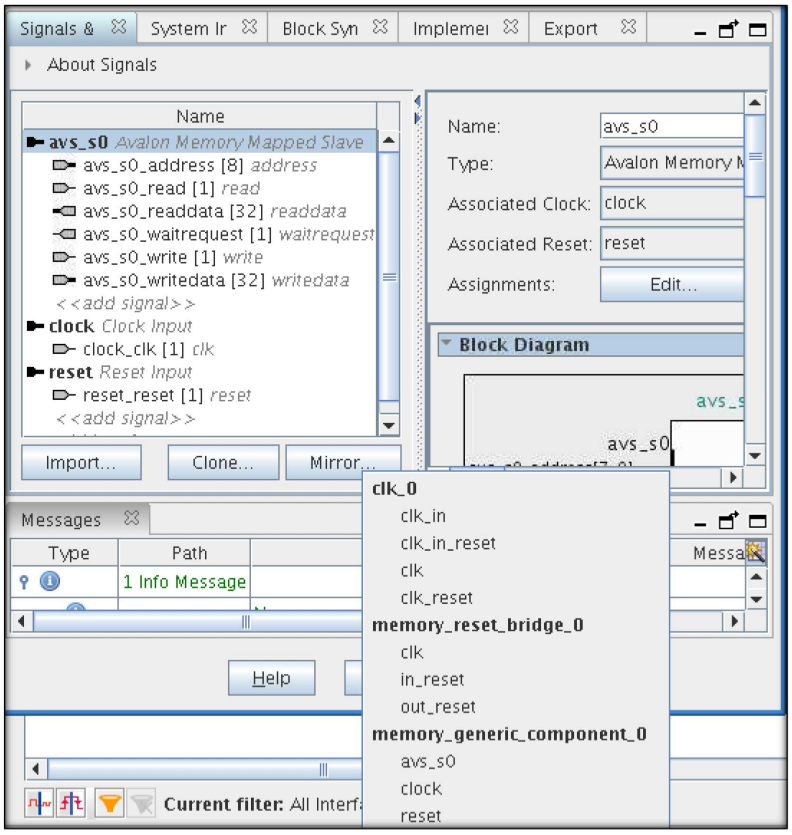
1. Double-click **Generic Component** in the IP Catalog.
2. In the **Component Instantiation** editor, click the **Signals & Interfaces** tab.
3. Click the **Mirror** button. A list appears which lists all the available components in the system and their associated interfaces.
4. Select the desired interface. Platform Designer mirrors the interface and its associated signals and adds the mirrored interfaces and signals to the **Signals & Interfaces** tab of the generic component.

Example 15. Mirroring Interfaces in a Generic Component Example

Selected Interface	Mirrored Interface
Avalon Memory-Mapped Host (`avalon_host`)	Avalon Memory-Mapped Agent (`avalon_agent`)

Signals of the Selected Interface	Signals of the Mirrored Interface
waitrequest(Input 1)	waitrequest(Output 1)
readdata(Input 32)	readdata(Output 32)
readdatavalid(Input 1)	readdatavalid(Output 1)
burstcount(Output 32)	burstcount(Input 32)

Figure 148. Mirroring Interfaces

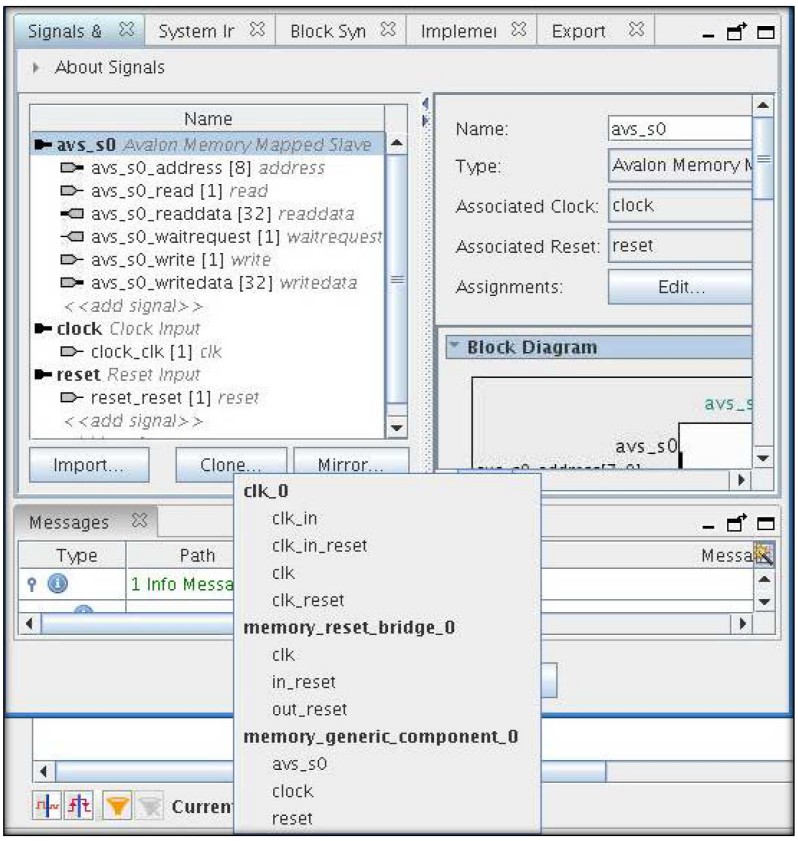


3.4.3.2. Cloning Interfaces in a Generic Component

To clone existing signals and interfaces from an IP component to your generic component:

1. Double-click **Generic Component** in the IP Catalog.
2. In the **Component Instantiation** editor, click the **Signals & Interfaces** tab.
3. Click the **Clone** button. A list appears which lists all the available components in the system and their associated interfaces.
4. Select the desired interface. Platform Designer clones the interface and adds an exact replica of the interface and its associated signals to the **Signals & Interfaces** tab of the generic component.

Figure 149. Cloning Interfaces



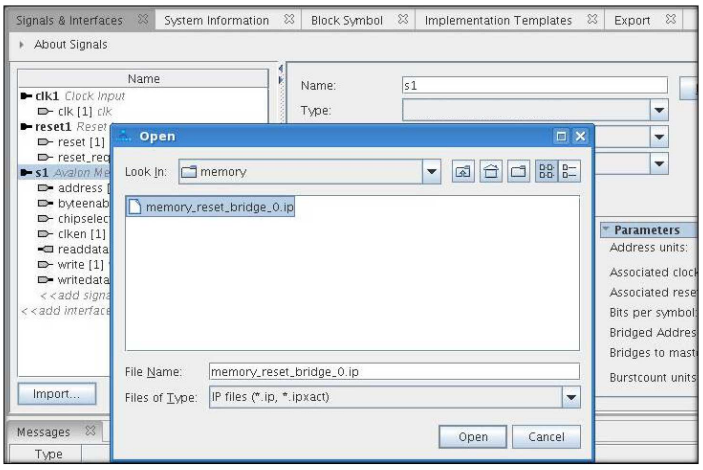
3.4.3.3. Importing Interfaces to a Generic Component

To import interfaces from an existing IP or IP-XACT[8] file to a generic component:

1. Double-click **Generic Component** in the IP Catalog.
2. In the **Component Instantiation** editor, click the **Signals & Interfaces** tab.
3. Click the **Import** button..
   A dialog box appears from where you choose the IP/IP-XACT file to import to the generic component
4. Select the interface.
   Platform Designer populates the **Signals & Interfaces** tab with the signals and interfaces defined in the selected file.

(8) Platform Designer supports importing and exporting files in IP-XACT 2009 format and exporting IP-XACT files in 2014 format.

Figure 150. Importing Interfaces

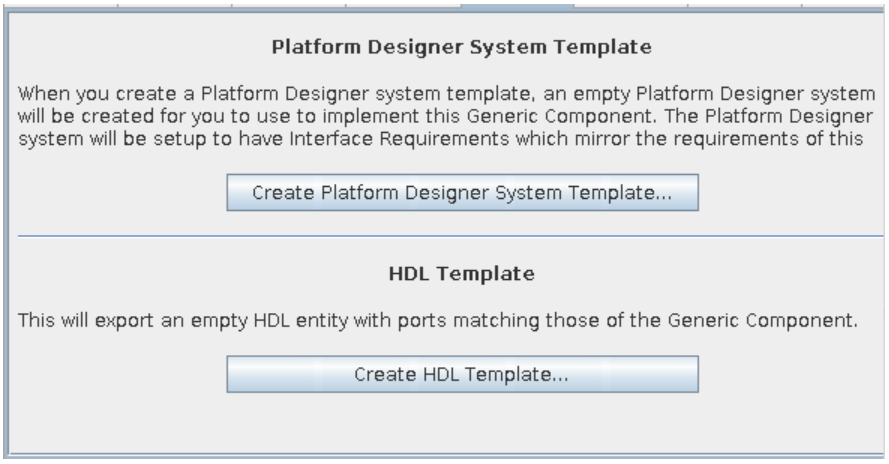


3.4.4. Creating a System Template for a Generic Component

To create a Platform Designer system template:

1. Double-click **Generic Component** in the IP Catalog.
2. In the **Component Instantiation** editor, add the interfaces and signals for the new component in the **Signals & Interfaces** tab, as .
3. Select the **Implementation Templates** tab.
4. Click **Create Platform Designer System Template** button. This option creates an empty Platform Designer system and saves the template as a `.qsys` file to implement this generic component.

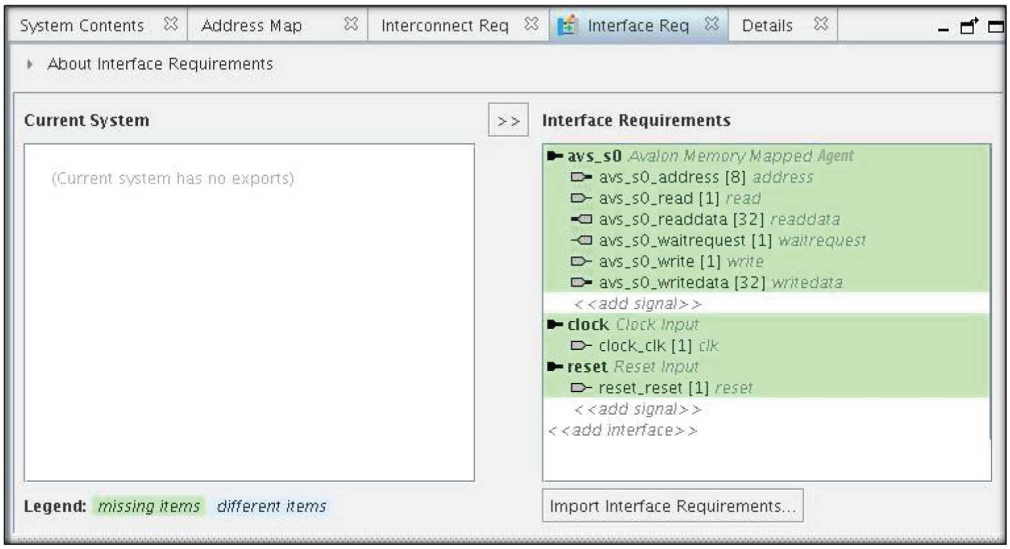
Figure 151. Creating System templates



To implement this component:

1. To open the template Platform Designer system, click **File ➤ Open** and choose the specific `.qsys` file.
2. Add either or both IP components and generic components then export their interfaces to satisfy the specified interface requirements.
3. To view the exported interfaces in the **Interface Requirements** tab, select **View ➤ Interface Requirements**.

Figure 152. Viewing the Interface Requirements from the System Template



3.4.5. Exporting a Generic Component

You can export a generic component as a `.ipxact` file as well as `_hw.tcl` file:

1. Double-click **Generic Component** in the IP Catalog.
2. Select the **Export** tab.
3. To export generic component as an IP-XACT file, click **Export IP-XACT File** and select the location to save your IP-XACT file.
4. To export generic component as a `_hw.tcl` file, click **Export _hw.tcl File** and select the location to save your `_hw.tcl` file.

3.5. Exporting HDL Parameters to a System

You can define and export Platform Designer component HDL parameters to make the parameters accessible to a higher-level system. After adding system HDL parameters, you can map the HDL parameters to components instantiated within the system.

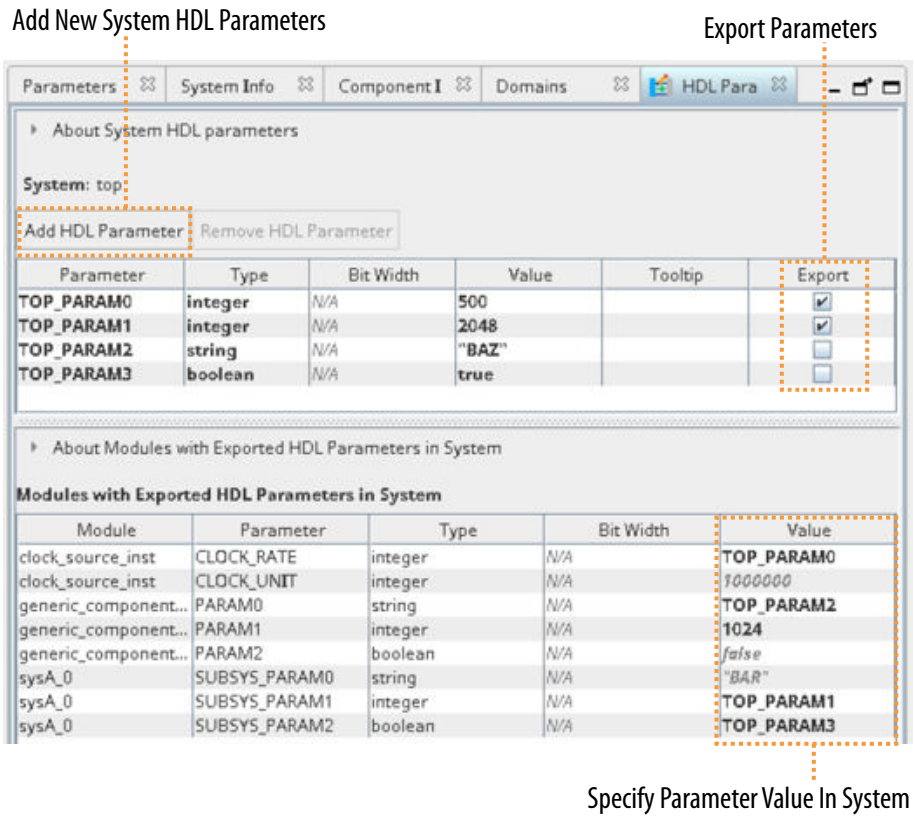
This technique allows you to set a component's parameter values outside of the immediate subsystem that contains the component, and propagate the HDL parameters upward. When you generate the system HDL, the HDL includes the parameters and mapping that you specify.

Note: Parameterization of ports is not supported.

To export an instantiated component's HDL parameters to a system, follow these steps:

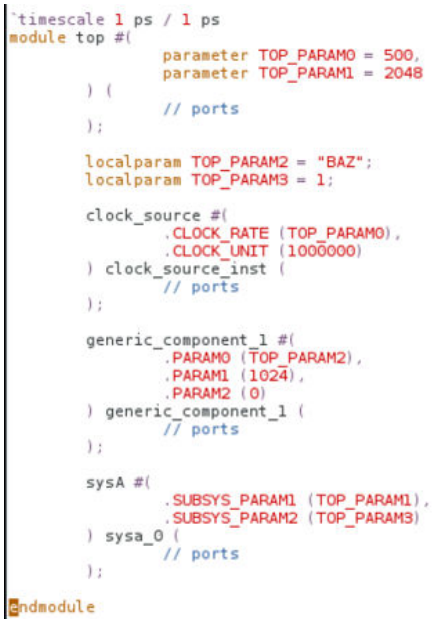
1. Instantiate a component in a Platform Designer system, as any of the following describe:
   - Creating IP Components in the Component Editor on page 158
   - Adding Generic HDL Component Parameters on page 182
   - Adding Generic Blackbox Component Parameters on page 183
2. In Platform Designer, click **View ➤ HDL Parameters**. The **HDL Parameters** tab allows you to define system HDL parameters, and overwrite instantiated components' HDL parameter values in the current system.
3. To add a new HDL parameter to the current system, click the **Add HDL Parameter** button and specify values for the parameter name, **Type**, **Width**, **Value**, and **Tooltip** options that apply to the HDL parameter. Refer to HDL Parameters Tab Settings and Controls on page 192.
4. To export the parameter during system HDL generation, thereby exposing the HDL parameter to a higher-level system, enable the **Export** option.

Figure 153. Specifying HDL Parameters



5. To change the parameter value for **Modules with Exported HDL Parameters**, select the **Value** that you want to implement during HDL generation. You can specify any of the added parameters as the value, as Figure 153 on page 191 shows with any of the TOP_PARAMx parameters.
6. To generate the HDL that includes exported parameters, click the **Generate HDL** button in Platform Designer.

Figure 154. Generated HDL for Parameters Specified in Figure 81



```
`timescale 1 ps / 1 ps
module top #(
		parameter TOP_PARAM0 = 500,
		parameter TOP_PARAM1 = 2048
	) (
		// ports
	);

	localparam TOP_PARAM2 = "BAZ";
	localparam TOP_PARAM3 = 1;

	clock_source #(
		.CLOCK_RATE (TOP_PARAM0),
		.CLOCK_UNIT (1000000)
	) clock_source_inst (
		// ports
	);

	generic_component_1 #(
		.PARAM0 (TOP_PARAM2),
		.PARAM1 (1024),
		.PARAM2 (0)
	) generic_component_1 (
		// ports
	);

	sysA #(
		.SUBSYS_PARAM1 (TOP_PARAM1),
		.SUBSYS_PARAM2 (TOP_PARAM3)
	) sysa_0 (
		// ports
	);

endmodule
```

When you generate the HDL, Platform Designer instantiates the IP or generic components with the inline parameters set to the system HDL parameter values, or set to constant values if applicable:

- **For IP components with parameters defined in _hw.tcl and subsystems**—the generated system HDL only writes out inline parameters for those HDL parameters that you overwrite for the system in the **HDL Parameters** tab (or with the `set_exposed_hdl_parameter_value` scripting command).
- **For generic HDL or Blackbox components**—the generated system HDL writes out all HDL parameters in the instantiation. The generated system HDL prioritizes setting HDL parameter values you specify in the **HDL Parameters** tab (or with the `set_exposed_hdl_parameter_value` scripting command). If the component's HDL parameter value is not overwritten in the **HDL Parameters** tab or with `set_exposed_hdl_parameter_value`, the HDL parameter's default value applies.

Note: If instantiating your component in `_hw.tcl`, rather than using the GUI, you must set `HDL_PARAMETER` to `true` and `AFFECTS_GENERATION` to `false`.

3.5.1. HDL Parameters Tab Settings and Controls

The Platform Designer **HDL Parameters** tab allows you to define system HDL parameters, and overwrite instantiated components' HDL parameter values in the current system.

The following settings and controls are available in the **HDL Parameters** tab:

Table 42. Component Implementation Type Options

Setting/Control	Description
System HDL Parameters	
Add HDL Parameter	Inserts a new HDL parameter with editable name and default settings. Specify the parameter name and default value for applicable parameter properties.
Remove HDL Parameter	Removes the selected system HDL parameter from the **HDL Parameters** tab.
Parameter	Specifies the name of a system HDL parameter. By default, Platform Designer names new HDL parameters sequentially with `new_parameter_0`, `new_parameter_1`, and so on. Double-click any parameter name to rename.
Type	Specifies the type of HDL parameter, which determines availability of other properties. The following **Types** are available: **boolean**, **integer**, **logic vector**, **natural**, **positive**, **std logic**, and **string**.
Width	Specifies the width of signals for the **logic vector** HDL parameter **Type**. The value of this property is N/A for other **Type**s.
Value	The default value of the HDL parameter.
Tooltip	Alphanumeric text that provides brief guidance about the HDL parameter to the end user in the form of a tooltip.
Export	Specifies that the HDL parameter should be exported, allowing it to be overwritten in a higher level system.
Modules with Exported HDL Parameters in System	
Value	Specifies the value of exported HDL parameters in the current Platform Designer system. The value that you specify overwrites the current parameter value when you **Generate HDL** for the system. Select an added HDL parameter with the **Export** option enabled to allow an upper-level system to overwrite the value.

3.6. Scripting Wire-Level Expressions

Platform Designer supports system scripting commands to apply wire-level expressions to input ports in IP components.

The following commands function with the `qsys-script` utility or in a `_hw.tcl` file to set, retrieve, or remove an expression on a port:

```
set_wirelevel_expression <instance_or_port_bit> <expression>
get_wirelevel_expressions <instance_or_port_bit>
remove_wirelevel_expressions <instance_or_port_bit
```

These commands require a string that you compose from the left-handed and right-handed components of the expression. Platform Designer reports errors in syntax, existence, or system hierarchy.

- set_wirelevel_expression on page 633
- get_wirelevel_expressions on page 634
- remove_wirelevel_expressions on page 635

3.7. Control Interfaces Dynamically with an Elaboration Callback

You can allow user parameters to dynamically control your component's behavior with an elaboration callback procedure during the elaboration phase. Using an elaboration callback allows you to change interface properties, remove interfaces, or add new interfaces as a function of a parameter value. You define an elaboration callback by setting the module property ELABORATION_CALLBACK to the name of the Tcl callback procedure that runs during the elaboration phase. In the callback procedure, you can query the parameter values of the component instance, and then change the interfaces accordingly.

Example 16. Avalon Streaming Source Interface Optionally Included in a Component Specified with an Elaboration Callback

```
set_module_property ELABORATION_CALLBACK elaborate

proc elaborate {} {

   # Optionally disable the Avalon streaming data output

    if{[ get_parameter_value ENABLE_STREAM_OUTPUT] == "false" }{
       set_port_property aso_data    termination true
       set_port_property aso_valid   termination true
       set_port_property aso_ready   termination true
       set_port_property aso_ready   termination_value 0
    }
  # Calculate the Data Bus Width in bytes

    set bytewidth_var [expr [get_parameter_value AXI_DATA_W]/8]
    set_parameter_value AXI_NUMBYTES $bytewidth_var
}
```

3.8. Control File Generation Dynamically with Parameters and a Fileset Callback

You can use a fileset callback to control which files are created in the output directories during the generation phase based on parameter values, instead of providing a fixed list of files. In a callback procedure, you can query the values of the parameters and use them to generate the appropriate files. To define a fileset callback, you specify a callback procedure name as an argument in the `add_fileset` command. You can use the same fileset callback procedure for all of the filesets, or create separate procedures for synthesis and simulation, or Verilog and VHDL.

Example 17. Fileset Callback Using Parameters to Control Filesets in Two Different Ways

The RAM_VERSION parameter chooses between two different source files to control the implementation of a RAM block. For the top-level source file, a custom Tcl routine generates HDL that optionally includes control and status registers, depending on the value of the CSR_ENABLED parameter.

During the generation phase, Platform Designer creates a top-level Platform Designer system HDL wrapper module to instantiate the component top-level module, and applies the component's parameters, for any parameter whose parameter property HDL_PARAMETER is set to true.

```
#Create synthesis fileset with fileset_callback and set top level

add_fileset my_synthesis_fileset QUARTUS_SYNTH fileset_callback

set_fileset_property my_synthesis_fileset TOP_LEVEL \
demo_axi_memory

# Create Verilog simulation fileset with same fileset_callback
# and set top level

add_fileset my_verilog_sim_fileset SIM_VERILOG fileset_callback

set_fileset_property my_verilog_sim_fileset TOP_LEVEL \
demo_axi_memory

# Add extra file needed for simulation only

add_fileset_file verbosity_pkg.sv SYSTEM_VERILOG PATH \
verification_lib/verbosity_pkg.sv

# Create VHDL simulation fileset (with Verilog files
# for mixed-language VHDL simulation)

add_fileset my_vhdl_sim_fileset SIM_VHDL fileset_callback
set_fileset_property my_vhdl_sim_fileset TOP_LEVEL demo_axi_memory

add_fileset_file verbosity_pkg.sv SYSTEM_VERILOG PATH
verification_lib/verbosity_pkg.sv

# Define parameters required for fileset_callback

add_parameter RAM_VERSION INTEGER 1
set_parameter_property RAM_VERSION ALLOWED_RANGES {1 2}
set_parameter_property RAM_VERSION HDL_PARAMETER false
add_parameter CSR_ENABLED BOOLEAN enable
set_parameter_property CSR_ENABLED HDL_PARAMETER false

# Create Tcl callback procedure to add appropriate files to
# filesets based on parameters

proc fileset_callback { entityName } {
  send_message INFO "Generating top-level entity $entityName"
  set ram [get_parameter_value RAM_VERSION]
  set csr_enabled [get_parameter_value CSR_ENABLED]

  send_message INFO "Generating memory
  implementation based on RAM_VERSION $ram    "

      if {$ram == 1} {
          add_fileset_file single_clk_ram1.v VERILOG PATH \
    single_clk_ram1.v
      } else     {
          add_fileset_file single_clk_ram2.v VERILOG PATH \
    single_clk_ram2.v
    }

send_message INFO "Generating top-level file for \
CSR_ENABLED $csr_enabled"

generate_my_custom_hdl $csr_enabled demo_axi_memory_gen.sv

add_fileset_file demo_axi_memory_gen.sv VERILOG PATH \
demo_axi_memory_gen.sv
}
```

3.9. Create a Composed Component or Subsystem

A composed component is a subsystem containing instances of other components. Unlike an HDL-based component, a composed component's HDL is created by generating HDL for the components in the subsystem, in addition to the Platform Designer interconnect to connect the subsystem instances.

You can add child instances in a composition callback of the `_hw.tcl` file.

With a composition callback, you can also instantiate and parameterize sub-components as a function of the composed component's parameter values. You define a composition callback by setting the `COMPOSITION_CALLBACK` module property to the name of the composition callback procedures.

A composition callback replaces the validation and elaboration phases. HDL for the subsystem is generated by generating all of the sub-components and the top-level that combines them.

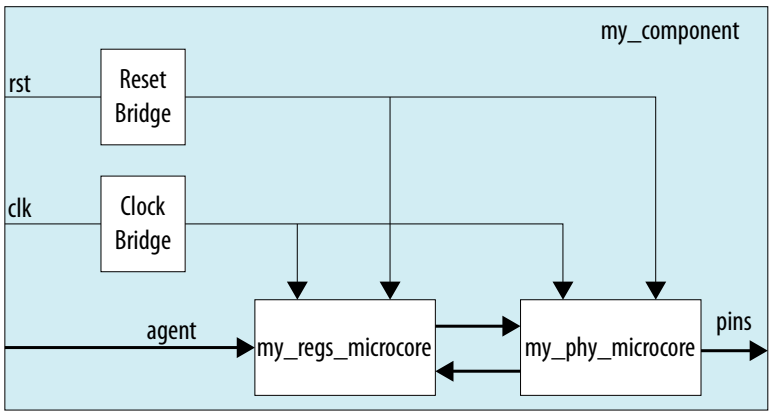
To connect instances of your component, you must define the component's interfaces. Unlike an HDL-based component, a composed component does not directly specify the signals that are exported. Instead, interfaces of submodules are chosen as the external interface, and each internal interface's ports are connected through the exported interface.

Exporting an interface means that you are making the interface visible from the outside of your component, instead of connecting it internally. You can set the `EXPORT_OF` property of the externally visible interface from the main program or the composition callback, to indicate that it is an exported view of the submodule's interface.

Exporting an interface is different than defining an interface. An exported interface is an exact copy of the subcomponent's interface, and you are not allowed to change properties on the exported interface. For example, if the internal interface is a 32-bit or 64-bit host without bursting, then the exported interface is the same. An interface on a subcomponent cannot be exported and also connected within the subsystem.

When you create an exported interface, the properties of the exported interface are copied from the subcomponent's interface without modification. Ports are copied from the subcomponent's interface with only one modification; the names of the exported ports on the composed component are chosen to ensure that they are unique.

Figure 155. Top-Level of a Composed Component



Example 18. Composed _hw.tcl File that Instantiates Two Sub-Components

Platform Designer connects the components, and also connects the clocks and resets. Note that clock and reset bridge components are required to allow both sub-components to see common clock and reset inputs.

```
package require -exact qsys 14.0
set_module_property name my_component
set_module_property COMPOSITION_CALLBACK composed_component

proc composed_component {} {
  add_instance clk altera_clock_bridge
  add_instance reset altera_reset_bridge
  add_instance regs my_regs_microcore
  add_instance phy my_phy_microcore

  add_interface clk clock end
  add_interface reset reset end
  add_interface agent avalon agent
  add_interface pins conduit end

  set_interface_property clk EXPORT_OF clk.in_clk
  set_instance_parameter_value reset synchronous_edges deassert
  set_interface_property reset EXPORT_OF reset.in_reset
  set_interface_property subordinate EXPORT_OF regs.subordinate
  set_interface_property pins  EXPORT_OF phy.pins

  add_connection clk.out_clk reset.clk
  add_connection clk.out_clk regs.clk
  add_connection clk.out_clk phy.clk
  add_connection reset.out_reset regs.reset
  add_connection reset.out_reset phy.clk_reset
  add_connection regs.output phy.input
  add_connection phy.output regs.input
}
```

3.10. Add Component Instances to a Static or Generated Component

You can create nested components by adding component instances to an existing component. Both static and generated components can create instances of other components. You can add child instances of a component in a `_hw.tcl` using elaboration callback.

With an elaboration callback, you can also instantiate and parameterize sub-components with the `add_hdl_instance` command as a function of the parent component's parameter values.

When you instantiate multiple nested components, you must create a unique variation name for each component with the `add_hdl_instance` command. Prefixing a variation name with the parent component name prevents conflicts in a system. The variation name can be the same across multiple parent components if the generated parameterization of the nested component is exactly the same.

Note: If you do not adhere to the above naming variation guidelines, Platform Designer validation-time errors occur, which are often difficult to debug.

Related Information

- Static IP Components on page 198
- Generated Components on page 199

3.10.1. Static IP Components

Static IP components always generate the same output, regardless of their parameterization. Components that instantiate static components must have only static children.

A design file that is static between all parameterizations of a component can only instantiate other static design files. Since static IPs always render the same HDL regardless of parameterization, Platform Designer generates static IPs only once across multiple instantiations, meaning they have the same top-level name set.

Example 19. Typical Usage of the add_hdl_instance Command for Static Components

```
package require -exact qsys 14.0

set_module_property name add_hdl_instance_example
add_fileset synth_fileset QUARTUS_SYNTH synth_callback
set_fileset_property synth_fileset TOP_LEVEL basic_static
set_module_property elaboration_callback elab

proc elab {} {
  # Actual API to instantiate an IP Core
  add_hdl_instance emif_instance_name altera_mem_if_ddr3_emif

  # Make sure the parameters are set appropriately
  set_instance_parameter_value emif_instance_name SPEED_GRADE {7}
  ...
  }
proc synth_callback { output_name } {
  add_fileset_file "basic_static.v" VERILOG PATH basic_static.v
}
```

Example 20. Top-Level HDL Instance and Wrapper File Created by Platform Designer

In this example, Platform Designer generates a wrapper file for the instance name specified in the _hw.tcl file.

```
//Top Level Component HDL
module basic_static (input_wire, output_wire, inout_wire);
input [31:0] input_wire;
output [31:0] output_wire;
inout [31:0] inout_wire;

// Instantiation of the instance added via add_hdl_instance
// command. This is an example of how the instance added via
// the add_hdl_instance command can be used
// in the top-level file of the component.

emif_instance_name fixed_name_instantiation_in_top_level(
.pll_ref_clk (input_wire), // pll_ref_clk.clk
.global_reset_n (input_wire), // global_reset.reset_n
.soft_reset_n (input_wire), // soft_reset.reset_n
...
... );
endmodule

//Wrapper for added HDL instance
// emif_instance_name.v
// Generated using ACDS version 14.0

`timescale 1 ps / 1 ps
module emif_instance_name (
input wire pll_ref_clk, // pll_ref_clk.clk
input wire global_reset_n, // global_reset.reset_n
input wire soft_reset_n, // soft_reset.reset_n
output wire afi_clk, // afi_clk.clk
...
...);
example_addhdlinstance_system
_add_hdl_instance_example_0_emif_instance
_name_emif_instance_name emif_instance_name (

.pll_ref_clk (pll_ref_clk), // pll_ref_clk.clk
.global_reset_n (global_reset_n), // global_reset.reset_n
.soft_reset_n (soft_reset_n), // soft_reset.reset_n
...
...);
endmodule
```

3.10.2. Generated Components

A generated component's fileset callback allows an instance of the component to create unique HDL design files based on the instance's parameter values. For example, you can write a fileset callback to include a control and status interface based on the value of a parameter. The callback overcomes a limitation of HDL languages, which do not allow run-time parameters.

Generated components change their generation output (HDL) based on their parameterization. If a component is generated, then any component that may instantiate it with multiple parameter sets must also be considered generated, since its HDL changes with its parameterization. This case has an effect that propagates up to the top-level of a design.

Since generated components are generated for each unique parameterized instantiation, when implementing the `add_hdl_instance` command, you cannot use the same fixed name (specified using `instance_name`) for the different variants of

the child HDL instances. To facilitate unique naming for the wrapper of each unique parameterized instantiation of child HDL instances, you must use the following command so that Platform Designer generates a unique name for each wrapper. You can then access this unique wrapper name with a fileset callback so that the instances are instantiated inside the component's top-level HDL.

- To declare auto-generated fixed names for wrappers, use the command:

```
set_instance_property instance_name HDLINSTANCE_USE_GENERATED_NAME \
true
```

  Note: You can only use this command with a generated component in the global context, or in an elaboration callback.

- To obtain auto-generated fixed name with a fileset callback, use the command:

```
get_instance_property instance_name HDLINSTANCE_GET_GENERATED_NAME
```

  Note: You can only use this command with a fileset callback. This command returns the value of the auto-generated fixed name, which you can then use to instantiate inside the top-level HDL.

Example 21. Typical Usage of the add_hdl_instance Command for Generated Components

Platform Designer generates a wrapper file for the instance name specified in the `_hw.tcl` file.

```
package require -exact qsys 14.0
set_module_property name generated_toplevel_component
set_module_property ELABORATION_CALLBACK elaborate
add_fileset QUARTUS_SYNTH QUARTUS_SYNTH generate
add_fileset SIM_VERILOG SIM_VERILOG generate
add_fileset SIM_VHDL SIM_VHDL generate

proc elaborate {} {

 # Actual API to instantiate an IP Core
 add_hdl_instance emif_instance_name altera_mem_if_ddr3_emif

 # Make sure the parameters are set appropriately
 set_instance_parameter_value emif_instance_name SPEED_GRADE {7}
 ...
 # instruct Platform Designer to use auto generated fixed name
 set_instance_property emif_instance_name \
 HDLINSTANCE_USE_GENERATED_NAME 1
}

proc generate { entity_name } {

 # get the autogenerated name for emif_instance_name added
 # via add_hdl_instance

 set autogeneratedfixedname [get_instance_property \
 emif_instance_name HDLINSTANCE_GET_GENERATED_NAME]

 set fileID [open "generated_toplevel_component.v" r]
 set temp ""

 # read the contents of the file

 while {[eof $fileID] != 1} {
 gets $fileID lineInfo

 # replace the top level entity name with the name provided
 # during generation

 regsub -all "substitute_entity_name_here" $lineInfo \
```

```
 "${entity_name}" lineInfo

 # replace the autogenerated name for emif_instance_name added
 # via add_hdl_instance

 regsub -all "substitute_autogenerated_emifinstancename_here" \
 $lineInfo"${autogeneratedfixedname}" lineInfo \
 append temp "${lineInfo}\n"
}

# adding a top level component file

add_fileset_file ${entity_name}.v VERILOG TEXT $temp
}
```

Example 22. Top-Level HDL Instance and Wrapper File Created By Platform Designer

```
// Top Level Component HDL

module substitute_entity_name_here (input_wire, output_wire,
inout_wire);

input [31:0] input_wire;
output [31:0] output_wire;
inout [31:0] inout_wire;

// Instantiation of the instance added via add_hdl_instance
// command. This is an example of how the instance added
// via add_hdl_instance command can be used
// in the top-level file of the component.

substitute_autogenerated_emifinstancename_here
fixed_name_instantiation_in_top_level (
.pll_ref_clk (input_wire), // pll_ref_clk.clk
.global_reset_n (input_wire), // global_reset.reset_n
.soft_reset_n (input_wire), // soft_reset.reset_n
...
... );
endmodule

// Wrapper for added HDL instance
// generated_toplevel_component_0_emif_instance_name.v is the
// auto generated //emif_instance_name
// Generated using ACDS version 13.

`timescale 1 ps / 1 ps
module generated_toplevel_component_0_emif_instance_name (
input wire pll_ref_clk, // pll_ref_clk.clk
input wire global_reset_n, // global_reset.reset_n
input wire soft_reset_n, // soft_reset.reset_n
output wire afi_clk, // afi_clk.clk
...
...);
example_addhdlinstance_system_add_hdl_instance_example_0_emif
_instance_name_emif_instance_name emif_instance_name (

.pll_ref_clk (pll_ref_clk), // pll_ref_clk.clk
.global_reset_n (global_reset_n), // global_reset.reset_n
.soft_reset_n (soft_reset_n), // soft_reset.reset_n
...
...);
endmodule
```

Control File Generation Dynamically with Parameters and a Fileset Callback on page 194

3.10.3. Design Guidelines for Adding Component Instances

In order to promote standard and predictable results when generating static and generated components, follow these best-practices:

- For two different parameterizations of a component, a component must never generate a file of the same name with different instantiations. The contents of a file of the same name must be identical for every parameterization of the component.
- If a component generates a nested component, it must never instantiate two different parameterizations of the nested component using the same instance name. If the parent component's parameterization affects the parameters of the nested component, the parent component must use a unique instance name for each unique parameterization of the nested component.
- Static components that generate differently based on parameterization have the potential to cause problems in the following cases:
  - Different file names with the same entity names, results in same entity conflicts at compilation-time
  - Different contents with the same file name results in overwriting other instances of the component, and in either file, compile-time conflicts or unexpected behavior.
- Generated components that generate files not based on the output name and that have different content results in either compile-time conflicts, or unexpected behavior.
- If preserving a custom component as part of an Quartus Prime Archive (`.qar`), you must first explicitly add the component `_hw.tcl` file to the project to ensure that the `.qar` includes the component. Click **Project ➤ Add/Remove Files in Project** to add files to your project.

3.11. Add IP RTL Core Generated from the Intel oneAPI Base Toolkit

The Intel oneAPI Base Toolkit is a core set of tools and libraries for developing high-performance, data-centric applications across diverse architectures. The toolkit features the Intel oneAPI DPC++/C++ Compiler that implements SYCL*, an evolution of C++ for heterogeneous computing. The compiler uses SYCL* code to generate RTL IP cores, depending on the compilation target that you specify.

For RTL IP cores, you set the compilation target to a supported Intel FPGA device family or part number instead of a specific acceleration platform. Users of the Intel HLS Compiler are encouraged to migrate existing designs to the Intel oneAPI Base Toolkit, as Intel HLS Compiler is planned for deprecation after Quartus Prime Pro Edition version 23.4.

To learn more about the Intel oneAPI FPGA flows in Platform Designer that use SYCL HLS, refer to the *Intel oneAPI FPGA Handbook* and the *Platform Designer Sample Tutorial*.

3.12. Creating Platform Designer Components Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout. • Added new *Add IP RTL Core Generated from the Intel oneAPI Base Toolkit* topic. • Removed deprecated "Adding Generic HLS Components" section.
2023.06.26	23.2	• Corrected code sample typo in *Create a Composed Component or Subsystem* topic.
2023.04.03	23.1	• Updated examples in *Declaring SystemVerilog Interfaces in _hw.tcl* topic. • Removed *Name HDL Signals for Automatic Interface and Type Recognition* topic as this feature is not currently supported. • The product family name is updated to "Intel Agilex 7" to reflect the different family members.
2022.04.02	22.1	• Updated entire chapter for new AXI "manager" and AXI "subordinate" replacement terms. Refer to the AMBA® AXI and ACE Protocol Specification.
2021.03.29	21.1	• Converted to "host" and "agent" inclusive terminology for Avalon memory mapped interface descriptions and related GUI elements throughout.
2020.12.14	20.4	• Added new "Exporting HDL Parameters to a System" topic. • Added new "HDL Parameters Tab Settings and Controls" topic.
2020.09.28	20.3	• Revised "Adding Generic Components to a System" to describes all implementations and refer to substeps for HDL and Blackbox parameters. • Revised "Adding Generic HDL Component Parameters" for latest steps and screenshot. • Added new "Adding Generic Blackbox Component Parameters" topic. • Added statement about `AFFECTS_GENERATION` to "Specify Parameters in the Platform Designer Component Editor" topic. • Reorganized the order of some topic to group similar items.
2020.05.01	20.1	• Added note about `.qar` file requirements to "Design Guidelines for Component Instances" topic.
2020.04.06	18.1.0	• Updated links and web page names in "Component Structure" and "Creating Platform Designer Components" topics.
2019.06.19	18.1.0	• Added descriptions of AXI parameters in "Specify Parameters in the Platform Designer Component Editor."
2018.12.15	18.1.0	• Replaced references to System Contents tab with new System View tab.
2018.05.07	18.0	• Added scripting support for wire-level expressions.
2017.11.06	17.1.0	• Changed instances of *Qsys Pro* to *Platform Designer* • Replaced mentions of altera_axi_default_slave to altera_error_response_slave • Added support for SystemVerilog interfaces with `_hw.tcl`. • Added support for user alterable HDL parameters with `_hw.tcl`. • Added support for High Level Synthesis file compilation.
2017.05.08	17.0.0	• Updated Figure: Address Span Extender

continued...

Document Version	Quartus Prime Version	Changes
2016.10.31	16.1.0	• Implemented Intel rebranding. • Implemented Qsys rebranding. • Added topics for Generic Component.
2015.11.02	15.1.0	Changed instances of *Quartus II* to *Quartus Prime*.
2015.05.04	15.0.0	• Updated screen shots **Files** tab, Qsys Component Editor. • Added topic: *Specify Interfaces and Signals in the Qsys Component Editor*. • Added topic: *Create an HDL File in the Qsys Component Editor*. • Added topic: *Create an HDL File Using a Template in the Qsys Component Editor*.
November 2013	13.1.0	• `add_hdl_instance` • Added *Creating a Component With Differing Structural Qsys View and Generated Output Files*.
May 2013	13.0.0	• Consolidated content from other Qsys chapters. • Added *Upgrading IP Components to the Latest Version*. • Updated for AMBA APB support.
November 2012	12.1.0	• Added AMBA AXI4 support. • Added the **demo_axi_memory** example with screen shots and example `_hw.tcl` code.
June 2012	12.0.0	• Added new tab structure for the Component Editor. • Added AXI 3 support.
November 2011	11.1.0	Template update.
May 2011	11.0.0	• Removed beta status. • Added Avalon Tri-state Conduit (Avalon-TC) interface type. • Added many interface templates for Nios custom instructions and Avalon-TC interfaces.
December 2010	10.1.0	Initial release.

4. Optimizing Platform Designer System Performance

Platform Designer provides tools that allow you to optimize the performance of the system interconnect for Intel FPGA designs. This chapter presents techniques that leverage the available tools and the trade offs of each implementation.

The foundation of any system is the interconnect logic that connects hardware blocks or components. Creating interconnect logic is time consuming and prone to errors, and existing interconnect logic is difficult to modify when design requirements change. The Platform Designer system integration tool addresses these issues and provides an automatically generated and optimized interconnect designed to satisfy the system requirements.

Platform Designer supports Avalon, AMBA 3 AXI (version 1.0), AMBA 4 AXI (version 2.0), AMBA 4 AXI-Lite (version 2.0), AMBA 4 AXI-Stream (version 1.0), and AMBA 3 APB (version 1.0) interface specifications.

Note: Recommended Intel practices may improve clock frequency, throughput, logic utilization, or power consumption of a Platform Designer design. When you design a Platform Designer system, use your knowledge of the design intent and goals to further optimize system performance beyond the automated optimization available in Platform Designer.

Related Information

- Creating a System with Platform Designer on page 11
- Creating Platform Designer Components on page 153
- Platform Designer Interconnect on page 251
- Avalon Interface Specifications
- AMBA Protocol Specifications

4.1. Designing with Avalon and AXI Interfaces

The Avalon and AXI interconnects for memory-mapped interfaces are flexible, partial crossbar logic. For AXI, the interconnect connects the AXI manager to the AXI subordinate interfaces. Similarly, the interconnect connects the Avalon host to the agent interfaces.(9)

Avalon Streaming links connect point-to-point, unidirectional interfaces and are typically used in data stream applications. Each pair of components is connected without any requirement to arbitrate between the data source and sink.

(9) This document now refers to the Avalon "host" and "agent," and the AXI "manager" and "subordinate," to replace formerly used terms. Refer to the current *AMBA AXI and ACE Protocol Specification* for the latest AMBA AXI and ACE protocol terminology.

Because Platform Designer supports multiplexed memory-mapped and streaming connections, you can implement systems that use multiplexed logic for control and streaming for data in a single design.

Related Information

Creating Platform Designer Components on page 153

4.1.1. Designing Streaming Components

When you design streaming component interfaces, you must consider integration and communication for each component in the system. One common consideration is buffering data internally to accommodate latency between components.

For example, if the component's Avalon streaming output or source of streaming data is back-pressured because the ready signal is deasserted, then the component must back-pressure its input or sink interface to avoid overflow.

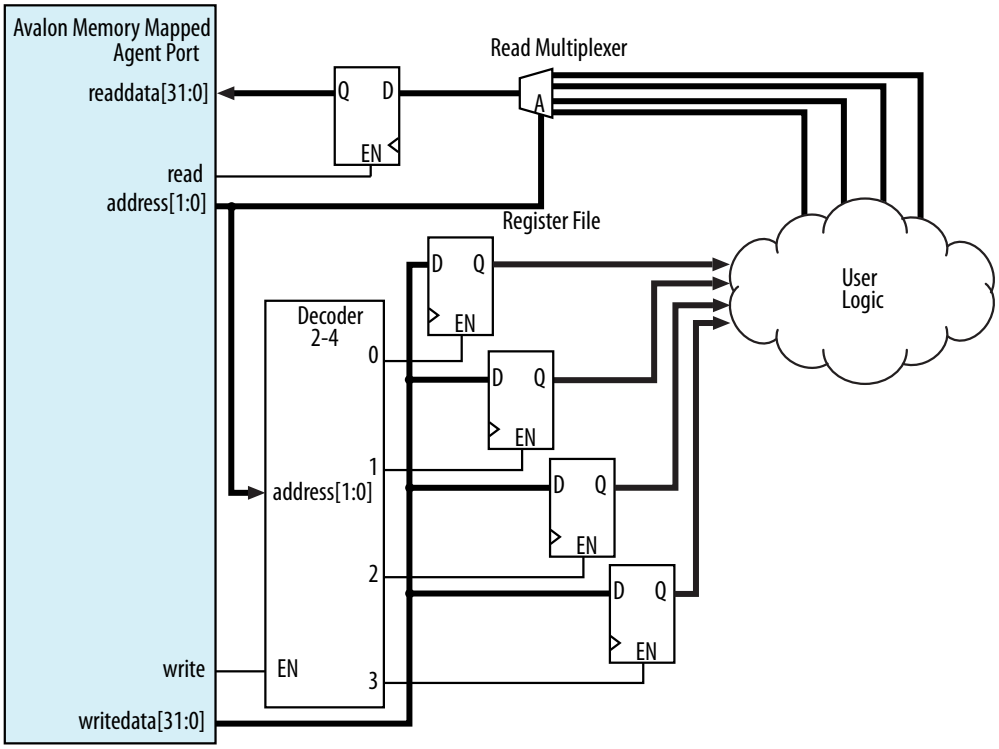
You can use a FIFO to back-pressure internally on the output side of the component so that the input can accept more data even if the output is back-pressured. Then, you can use the FIFO almost full flag to back-pressure the sink interface or input data when the FIFO has only enough space to satisfy the internal latency. You can drive the data valid signal of the output or source interface with the FIFO not empty flag when that data is available.

4.1.2. Designing Memory-Mapped Components

When designing with memory-mapped components, you can implement any component that contains multiple registers mapped to memory locations, for example, a set of four output registers to support software read back from logic. Components that implement read and write memory-mapped transactions require three main building blocks: an address decoder, a register file, and a read multiplexer.

The decoder enables the appropriate 32-bit or 64-bit register for writes. For reads, the address bits drive the multiplexer selection bits. The read signal registers the data from the multiplexer, adding a pipeline stage so that the component can achieve a higher clock frequency.

Figure 156. Control and Status Registers (CSR) in an Agent Component



This agent component has four write wait states and one read wait state. Alternatively, if you want high throughput, you may set both the read and write wait states to zero, and then specify a read latency of one, because the component also supports pipelined reads.

4.2. Using Hierarchy in Systems

You can use hierarchy to sub-divide a system into smaller subsystems that you can then connect in a top-level Platform Designer system. Additionally, if a design contains one or more identical functional units, the functional unit can be defined as a subsystem and instantiated multiple times within a top-level system.

Hierarchy can simplify verification control of agents connected to each host in a memory-mapped system. Before you implement subsystems in your design, you should plan the system hierarchical blocks at the top-level, using the following guidelines:

- **Plan shared resources**—Determine the best location for shared resources in the system hierarchy. For example, if two subsystems share resources, add the components that use those resources to a higher-level system for easy access.
- **Plan shared address space between subsystems**—Planning the address space ensures you can set appropriate sizes for bridges between subsystems.
- **Plan how much latency you may need to add to your system**—When you add an Avalon Memory Mapped Pipeline Bridge between subsystems, you may add latency to the overall system. You can reduce the added latency by parameterizing the bridge with zero cycles of latency, and by turning off the pipeline command and response signals.

Figure 157. Avalon Memory Mapped Pipeline Bridge

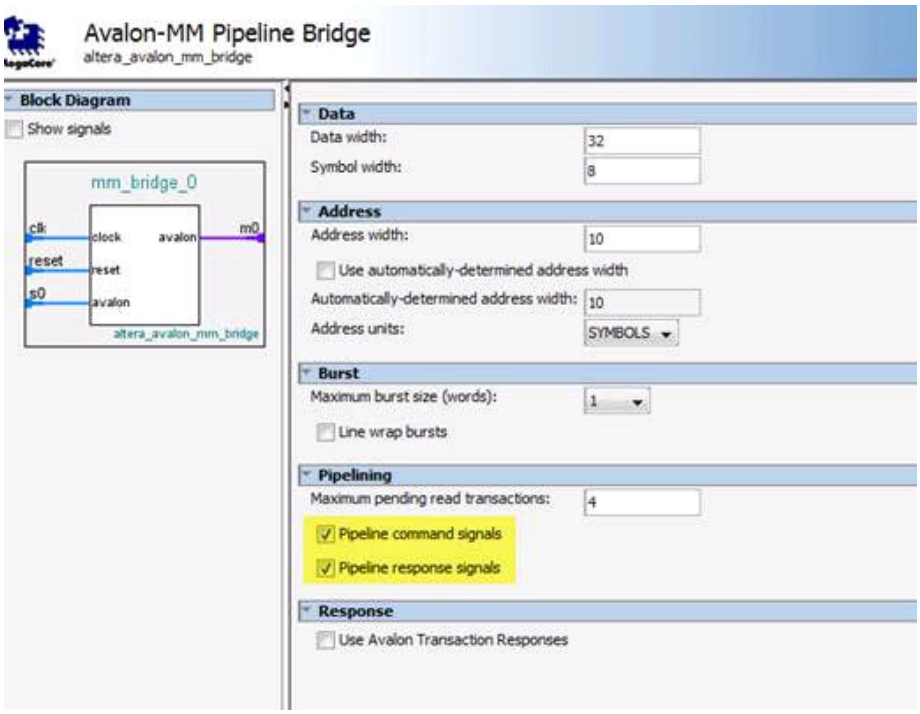


Figure 158. Passing Messages Between Subsystems

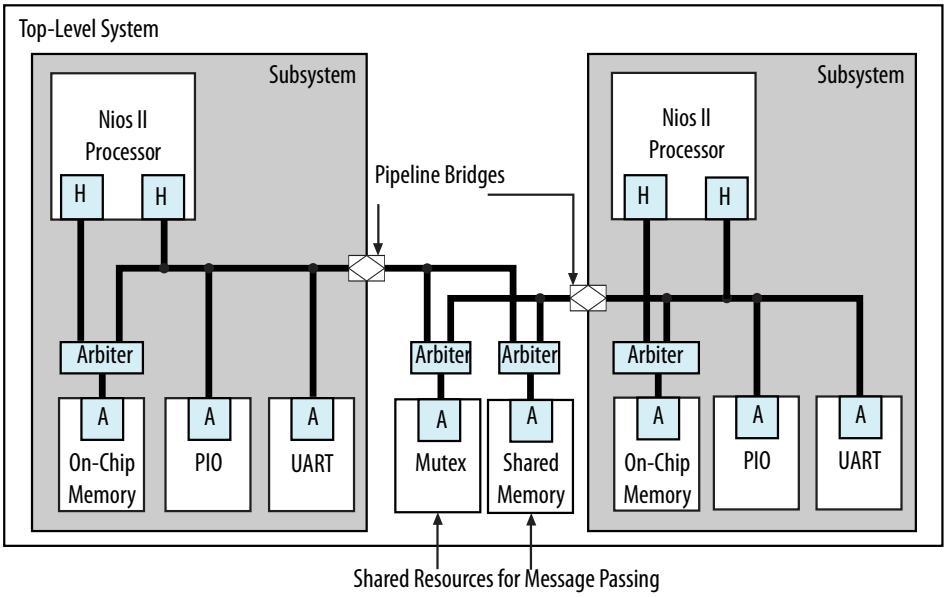
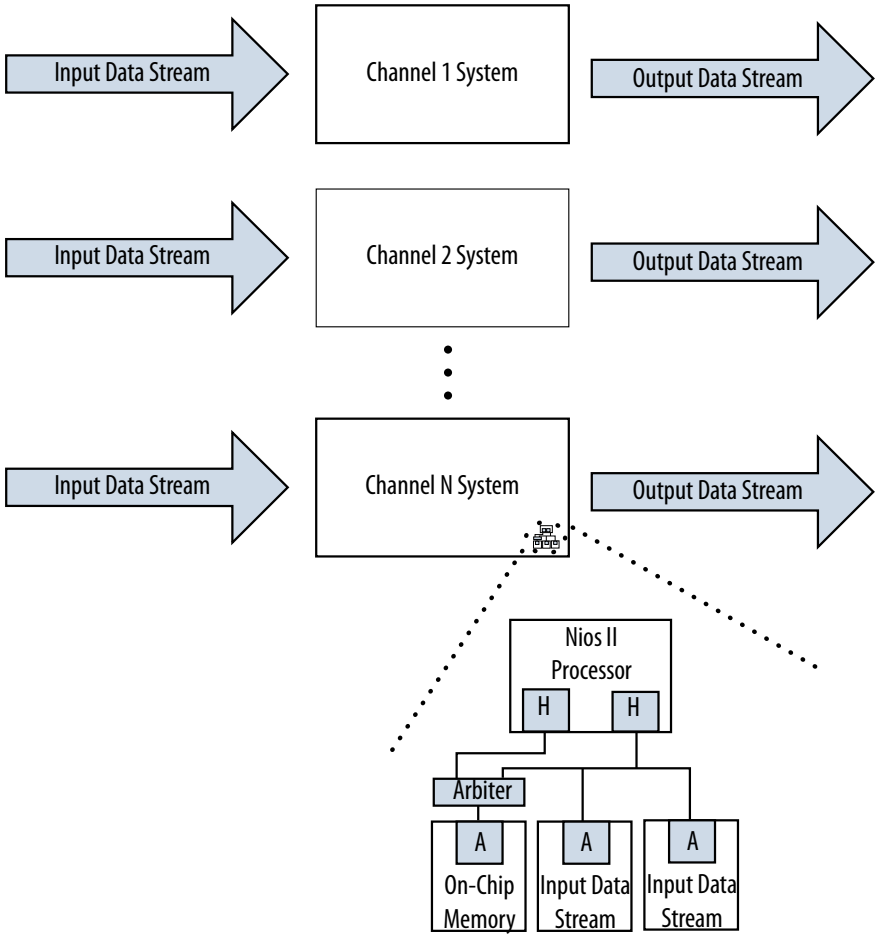


In this example, two Nios II processor subsystems share resources for message passing. Bridges in each subsystem export the Nios II data host to the top-level system that includes the mutex (mutual exclusion component) and shared memory component (which could be another on-chip RAM, or a controller for an off-chip RAM device).

Figure 159. Multi Channel System



You can also design systems that process multiple data channels by instantiating the same subsystem for each channel. This approach is easier to maintain than a larger, non-hierarchical system. Additionally, such systems are easier to scale because you can calculate the required resources as a multiple of the subsystem requirements.

4.3. Using Concurrency in Memory-Mapped Systems

Platform Designer interconnect uses parallel hardware in FPGAs, which allows you to design concurrency into your system and process transactions simultaneously.

4.3.1. Implementing Concurrency With Multiple Hosts

Implementing concurrency requires multiple hosts in a Platform Designer system. Systems that include a processor contain at least two host interfaces because the processors include separate instruction and data hosts. You can categorize host components as follows:

- General purpose processors, such as Nios II processors
- DMA (direct memory access) engines
- Communication interfaces, such as PCI Express

Because Platform Designer generates an interconnect with agent-side arbitration, every host interface in a system can issue transfers concurrently, if they are not posting transfers to the same agent. Concurrency is limited by the number of host interfaces sharing any particular agent interface. If a design requires higher data throughput, you can increase the number of host and agent interfaces to increase the number of transfers that occur simultaneously. The example below shows a system with three host interfaces.

Figure 160. Avalon Multiple Host Parallel Access

In this Avalon example, the DMA engine operates with Avalon memory mapped read and write hosts. The yellow lines represent active simultaneous connections.

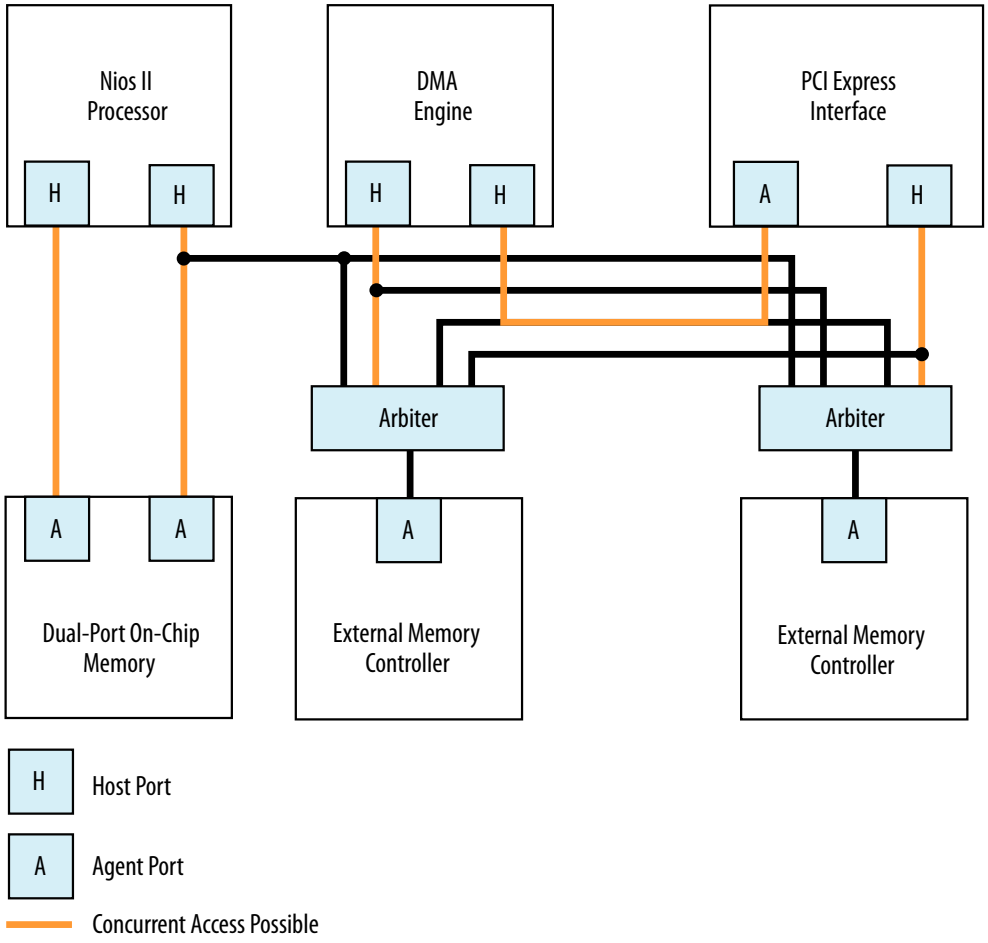


Figure 161. AXI Multiple Manager Parallel Access

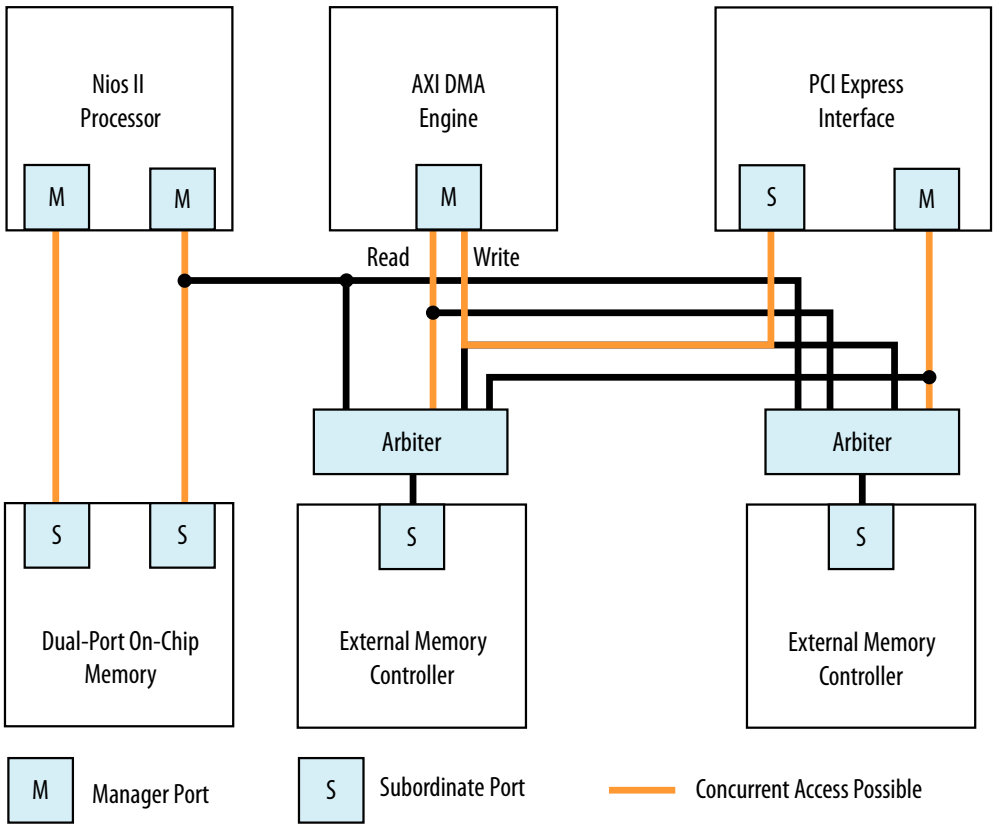
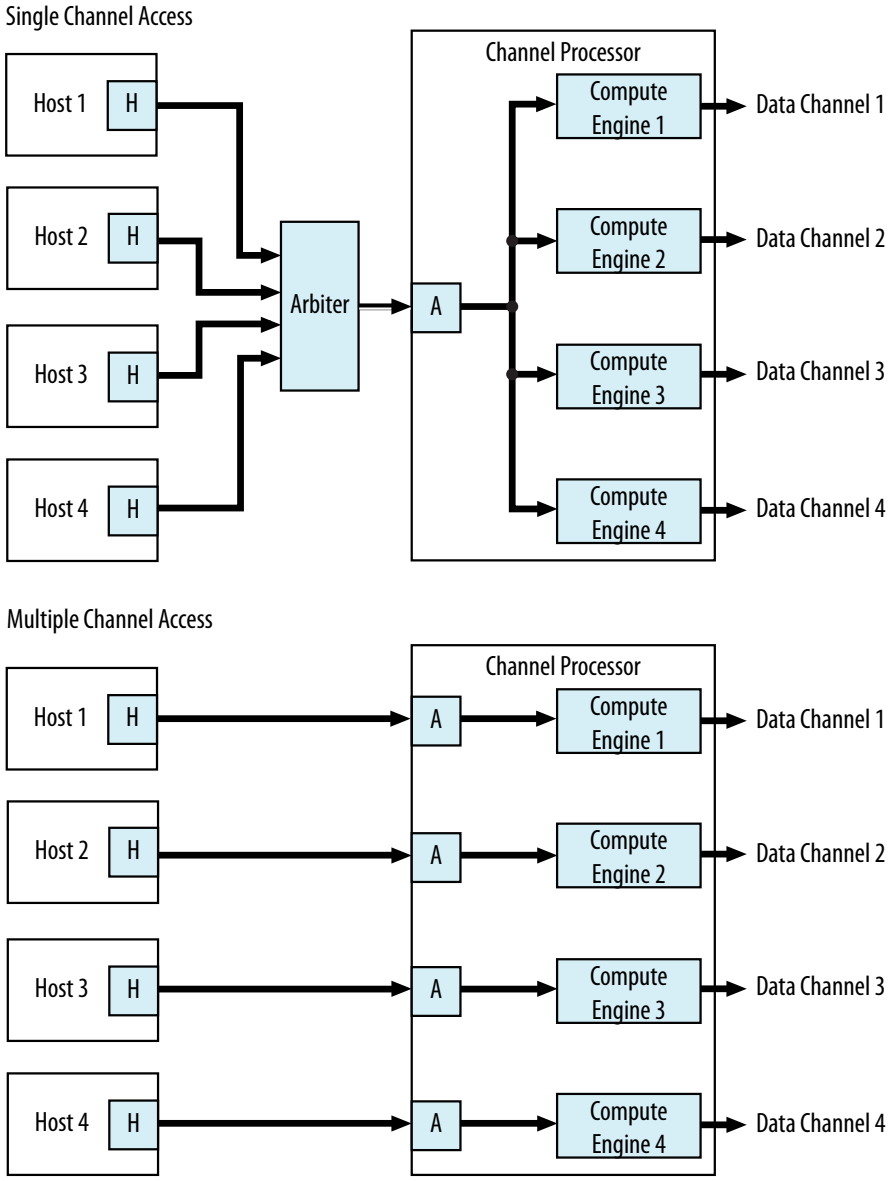
In this example, the DMA engine operates with a single manager, because in AXI, the write and read channels on the manager are independent and can process transactions simultaneously. There is concurrency between the read and write channels, with the yellow lines representing concurrent datapaths.



4.3.2. Implementing Concurrency With Multiple Agents

You can create multiple agent interfaces for a particular function to increase concurrency in your design.

Figure 162. Single Interface Versus Multiple Interfaces



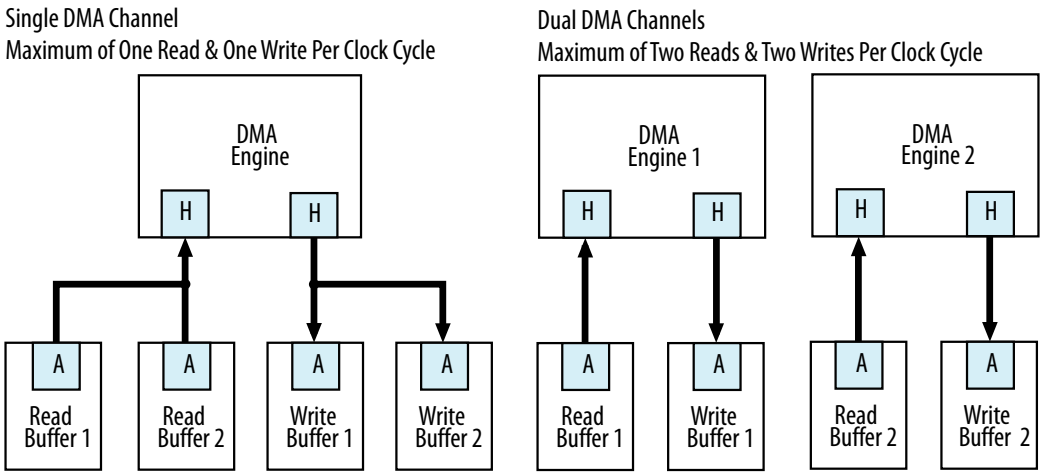
In this example, there are two channel processing systems. In the first, four hosts must arbitrate for the single agent interface of the channel processor. In the second, each host drives a dedicated agent interface, allowing all host interfaces to simultaneously access the agent interfaces of the component. Arbitration is not necessary when there is a single host and agent interface.

4.3.3. Implementing Concurrency with DMA Engines

In some systems, you can use DMA engines to increase throughput. You can use a DMA engine to transfer blocks of data between interfaces, which then frees the CPU from doing this task. A DMA engine transfers data between a programmed start and

end address without intervention, and the data throughput is dictated by the components connected to the DMA. Factors that affect data throughput include data width and clock frequency.

Figure 163. Single or Dual DMA Channels



In this example, the system can sustain more concurrent read and write operations by including more DMA engines. Accesses to the read and write buffers in the top system are split between two DMA engines, as shown in the Dual DMA Channels at the bottom of the figure.

The DMA engine operates with Avalon memory mapped write and read hosts. An AXI DMA typically has only one manager, because in AXI, the write and read channels on the manager are independent and can process transactions simultaneously.

4.4. Inserting Pipeline Stages to Increase System Frequency

Adding pipeline stages may increase the f_{MAX} of the design by reducing the combinational logic depth, at the cost of additional latency and logic utilization.

Platform Designer provides the **Limit interconnect pipeline stages to** option on the **Interconnect Requirements** tab to automatically add pipeline stages to the Platform Designer interconnect when you generate a system.

The **Limit interconnect pipeline stages to** parameter in the **Interconnect Requirements** tab allows you to define the maximum Avalon streaming pipeline stages that Platform Designer can insert during generation. You can specify between 0 to 4 pipeline stages, where 0 means that the interconnect has a combinational datapath. You can specify a unique interconnect pipeline stage value for each subsystem.

For more information, refer to *Interconnect Pipelining*.

4.5. Using Bridges

You can use bridges to increase system frequency, minimize generated Platform Designer logic, minimize adapter logic, and to structure system topology when you want to control where Platform Designer adds pipelining. You can also use bridges with arbiters when there is concurrency in the system.

An Avalon bridge has an Avalon memory mapped agent interface and an Avalon memory mapped host interface. You can have many components connected to the bridge agent interface, or many components connected to the bridge host interface. You can also have a single component connected to a single bridge agent or host interface.

You can configure the data width of the bridge, which can affect how Platform Designer generates bus sizing logic in the interconnect. Both interfaces support Avalon memory mapped pipelined transfers with variable latency, and can also support configurable burst lengths.

Transfers to the bridge agent interface are propagated to the host interface, which connects to components downstream from the bridge. Bridges can provide more control over interconnect pipelining than the **Limit interconnect pipeline stages to** option.

Note: You can use Avalon bridges between AXI interfaces, and between Avalon domains. Platform Designer automatically creates interconnect logic between the AXI and Avalon interfaces, so you do not have to explicitly instantiate bridges between these domains. For more discussion about the benefits and disadvantages of shared and separate domains, refer to the *Platform Designer Interconnect*.

4.5.1. Using Bridges to Increase System Frequency

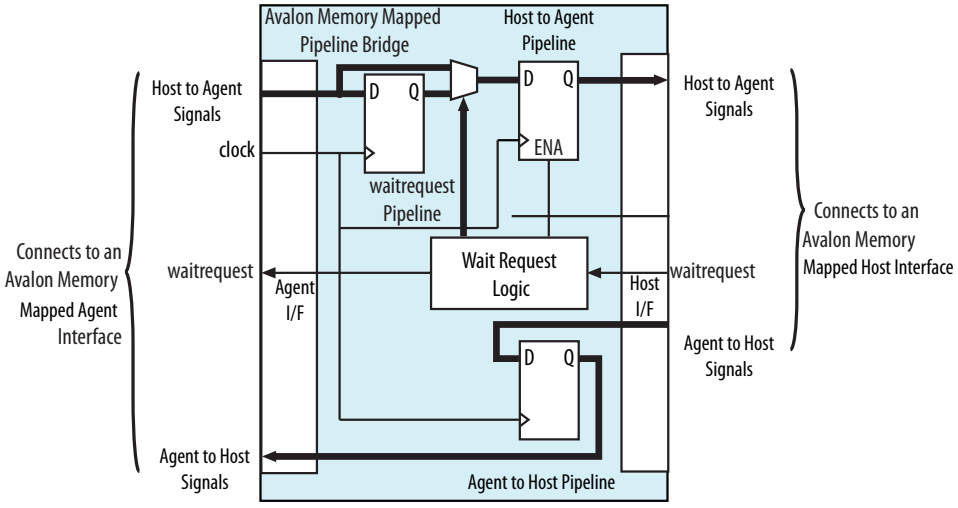
In Platform Designer, you can introduce interconnect pipeline stages or pipeline bridges to increase clock frequency in your system. Bridges control the system interconnect topology and allow you to subdivide the interconnect, giving you more control over pipelining and clock crossing functionality.

4.5.1.1. Inserting Pipeline Bridges

You can insert an Avalon memory mapped pipeline bridge to insert registers in the path between the bridges and its host and agents. If a critical register-to-register delay occurs in the interconnect, a pipeline bridge can help reduce this delay and improve system f_{MAX}.

The Avalon memory mapped pipeline bridge component integrates into any Platform Designer system. The pipeline bridge options can increase logic utilization and read latency. The change in topology may also reduce concurrency if multiple hosts arbitrate for the bridge. You can use the Avalon memory mapped pipeline bridge to control topology without adding a pipeline stage. A pipeline bridge that does not add a pipeline stage is optimal in some latency-sensitive applications. For example, a CPU may benefit from minimal latency when accessing memory.

Figure 164. Avalon Memory Mapped Pipeline Bridge

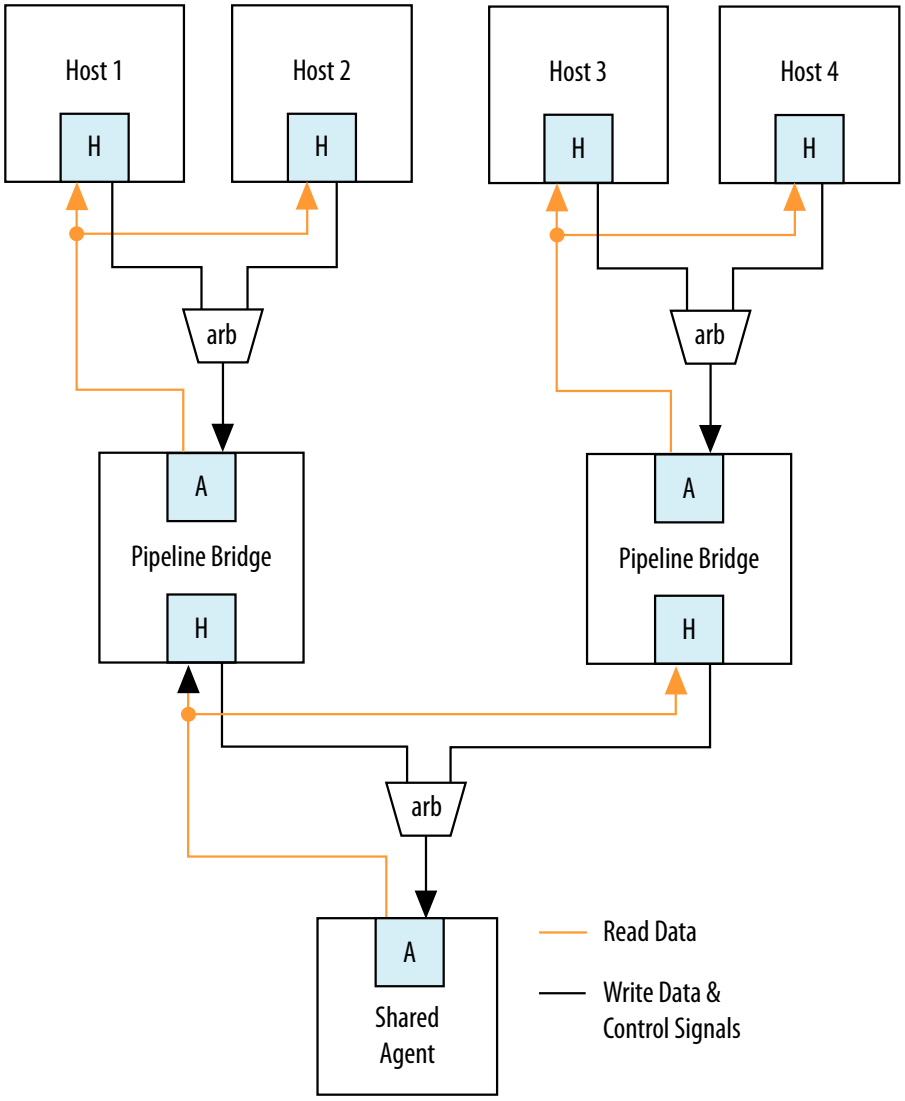


4.5.1.1.1. Implementing Command Pipelining (Host-to-Agent)

When multiple hosts share an agent device, you can use command pipelining to improve performance.

The arbitration logic for the agent interface must multiplex the `address`, `writedata`, and `burstcount` signals. The multiplexer width increases proportionally with the number of hosts connecting to a single agent interface. The increased multiplexer width may become a timing critical path in the system. If a single pipeline bridge does not provide enough pipelining, you can instantiate multiple instances of the bridge in a tree structure to increase the pipelining and further reduce the width of the multiplexer at the agent interface.

Figure 165. Tree of Bridges



4.5.1.1.2. Implementing Response Pipelining (Agent-to-Host)

When hosts connect to multiple agents that support read transfers, you can use agent-to-host pipelining to improve performance.

The interconnect inserts a multiplexer for every read datapath back to the host. As the number of agents supporting read transfers connecting to the host increases, the width of the read data multiplexer also increases. If the performance increase is insufficient with one bridge, you can use multiple bridges in a tree structure to improve f_{MAX}.

4.5.1.2. Using Clock Crossing Bridges

The clock crossing bridge contains a pair of clock crossing FIFOs, which isolate the host and agent interfaces in separate, asynchronous clock domains. Transfers to the agent interface are propagated to the host interface.

When you use a FIFO clock crossing bridge for the clock domain crossing, you add data buffering. Buffering allows pipelined read hosts to post multiple reads to the bridge, even if the agents downstream from the bridge do not support pipelined transfers.

You can also use a clock crossing bridge to place high and low frequency components in separate clock domains. If you limit the fast clock domain to the portion of your design that requires high performance, you may achieve a higher f_{MAX} for this portion of the design. For example, the majority of processor peripherals in embedded designs do not need to operate at high frequencies, therefore, you do not need to use a high-frequency clock for these components. When you compile a design with the Quartus Prime software, compilation may take more time when the clock frequency requirements are difficult to meet because the Fitter needs more time to place registers to achieve the required f_{MAX}. To reduce the amount of effort that the Fitter uses on low priority and low performance components, you can place these behind a clock crossing bridge operating at a lower frequency, allowing the Fitter to increase the effort placed on the higher priority and higher frequency datapaths.

4.5.2. Using Bridges to Minimize Design Logic

Bridges can reduce interconnect logic by reducing the amount of arbitration and multiplexer logic that Platform Designer generates. This reduction occurs because bridges limit the number of concurrent transfers that can occur.

4.5.2.1. Avoiding Speed Optimizations That Increase Logic

You can add an additional pipeline stage with a pipeline bridge between hosts and agents to reduce the amount of combinational logic between registers, which can increase system performance. If you can increase the f_{MAX} of your design logic, you may be able to turn off the Quartus Prime software optimization settings, such as the **Perform register duplication** setting. Register duplication creates duplicate registers in two or more physical locations in the FPGA to reduce register-to-register delays. You may also want to choose **Speed** for the optimization method, which typically results in higher logic utilization due to logic duplication. By making use of the registers or FIFOs available in the bridges, you can increase the design speed and avoid needless logic duplication or speed optimizations, thereby reducing the logic utilization of the design.

4.5.2.2. Limiting Concurrency

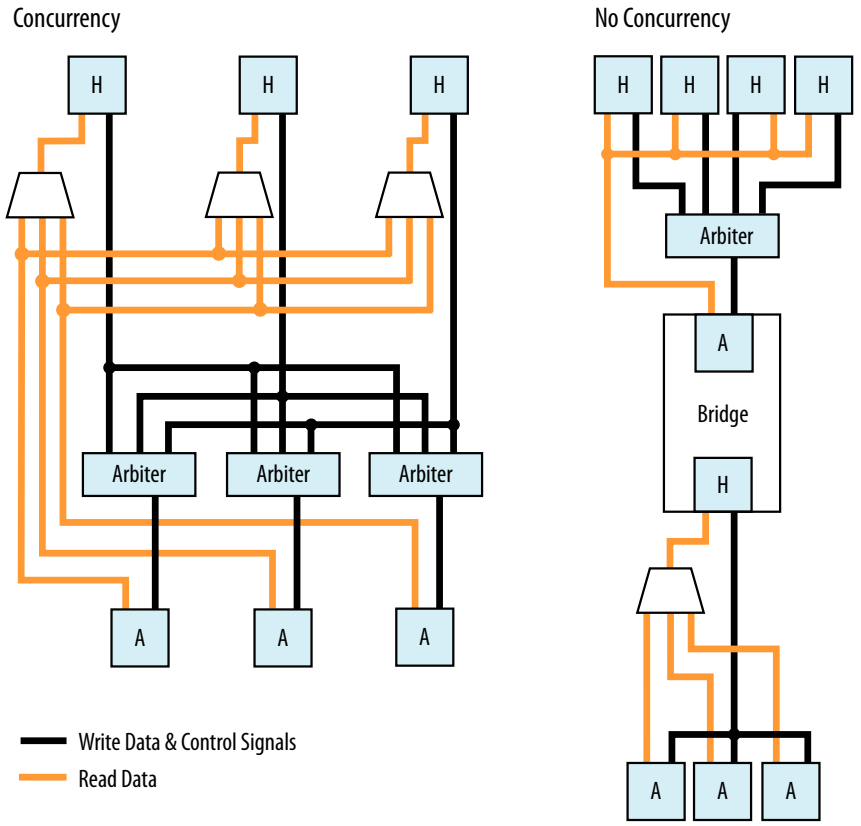
The amount of logic generated for the interconnect often increases as the system becomes larger because Platform Designer creates arbitration logic for every agent interface that is shared by multiple host interfaces. Platform Designer inserts multiplexer logic between host interfaces that connect to multiple agent interfaces if both support read datapaths.

Most embedded processor designs contain components that are either incapable of supporting high data throughput, or do not need to be accessed frequently. These components can contain host or agent interfaces. Because the interconnect supports concurrent accesses, you may want to limit concurrency by inserting bridges into the datapath to limit the amount of arbitration and multiplexer logic generated.

For example, if a system contains three host and three agent interfaces that are interconnected, Platform Designer generates three arbiters and three multiplexers for the read datapath. If these hosts do not require a significant amount of simultaneous throughput, you can reduce the resources that your design consumes by connecting the three hosts to a pipeline bridge. The bridge controls the three agent interfaces and reduces the interconnect into a bus structure. Platform Designer creates one arbitration block between the bridge and the three hosts, and a single read datapath multiplexer between the bridge and three agents, and prevents concurrency. This implementation is similar to a standard bus architecture.

You should not use this method for high throughput datapaths to ensure that you do not limit overall system performance.

Figure 166. Differences Between Systems With and Without a Pipeline Bridge



4.5.3. Using Bridges to Minimize Adapter Logic

Platform Designer generates adapter logic for clock crossing, width adaptation, and burst support when there is a mismatch between the clock domains, widths, or bursting capabilities of the host and agent interface pairs.

Platform Designer creates burst adapters when the maximum burst length of the host is greater than the host burst length of the agent. The adapter logic creates extra logic resources, which can be substantial when your system contains host interfaces connected to many components that do not share the same characteristics. By placing bridges in your design, you can reduce the amount of adapter logic that Platform Designer generates.

4.5.3.1. Determining Effective Placement of Bridges

To determine the effective placement of a bridge, you should initially analyze each host in your system to determine if the connected agent devices support different bursting capabilities or operate in a different clock domain. The maximum burstcount of a component is visible as the `burstcount` signal in the HDL file of the component. The maximum burst length is $2^{(\text{width(burstcount -1)})}$, therefore, if the `burstcount` width is four bits, the maximum burst length is eight. If no `burstcount` signal is present, the component does not support bursting or has a burst length of 1.

To determine if the system requires a clock crossing adapter between the host and agent interfaces, check the **Clock** column for the host and agent interfaces. If the clock is different for the host and agent interfaces, Platform Designer inserts a clock crossing adapter between them. To avoid creating multiple adapters, you can place the components containing agent interfaces behind a bridge so that Platform Designer creates a single adapter. By placing multiple components with the same burst or clock characteristics behind a bridge, you limit concurrency and the number of adapters.

You can also use a bridge to separate AXI and Avalon domains to minimize burst adaptation logic. For example, if there are multiple Avalon agents that are connected to an AXI manager, you can consider inserting a bridge to access the adaptation logic once before the bridge, instead of once per agent. This implementation results in latency, and you would also lose concurrency between reads and writes.

4.5.3.2. Changing the Response Buffer Depth

When you use automatic clock-crossing adapters, Platform Designer determines the required depth of FIFO buffering based on the agent properties. If an agent has a high **Maximum Pending Reads** parameter, the resulting deep response buffer FIFO that Platform Designer inserts between the host and agent can consume a lot of device resources. To control the response FIFO depth, you can use a clock crossing bridge and manually adjust its FIFO depth to trade off throughput with smaller memory utilization.

For example, if you have hosts that cannot saturate the agent, you do not need response buffering. Using a bridge reduces the FIFO memory depth and reduces the **Maximum Pending Reads** available from the agent.

4.5.4. Considering the Effects of Using Bridges

Before you use pipeline or clock crossing bridges in a design, you should carefully consider their effects. Bridges can have any combination of consequences on your design, which could be positive or negative. Benchmarking your system before and after inserting bridges can help you determine the impact to the design.

4.5.4.1. Increased Latency

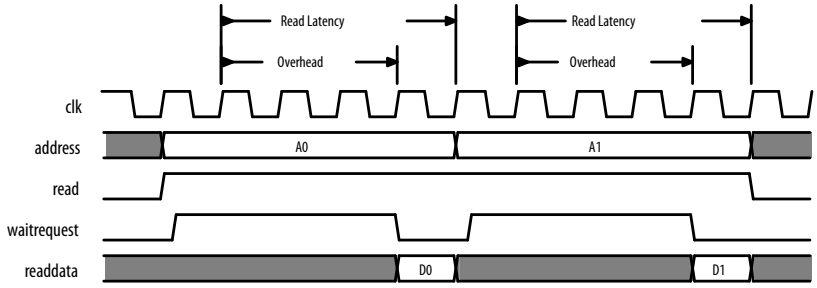
Adding a bridge to a design has an effect on the read latency between the host and the agent. Depending on the system requirements and the type of host and agent, this latency increase may not be acceptable in your design.

4.5.4.1.1. Acceptable Latency Increase

For a pipeline bridge, Platform Designer adds a cycle of latency for each pipeline option that is enabled. The buffering in the clock crossing bridge also adds latency. If you use a pipelined or burst host that posts many read transfers, the increase in latency does not impact performance significantly because the latency increase is very small compared to the length of the data transfer.

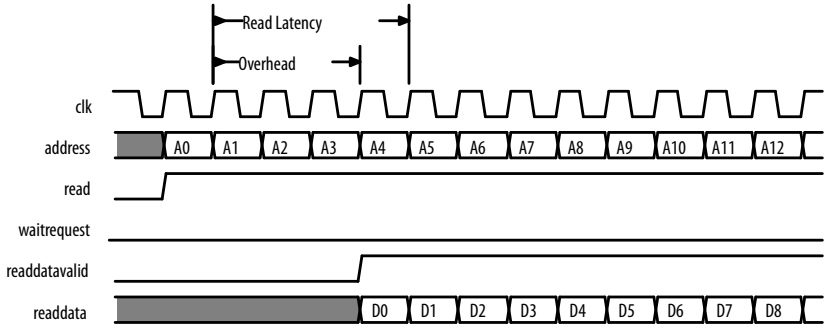
For example, if you use a pipelined read host such as a DMA controller to read data from a component with a fixed read latency of four clock cycles, but only perform a single word transfer, the overhead is three clock cycles out of the total of four. This is true when there is no additional pipeline latency in the interconnect. The read throughput is only 25%.

Figure 167. Low-Efficiency Read Transfer



However, if 100 words of data are transferred without interruptions, the overhead is three cycles out of the total of 103 clock cycles. This corresponds to a read efficiency of approximately 97% when there is no additional pipeline latency in the interconnect. Adding a pipeline bridge to this read path adds two extra clock cycles of latency. The transfer requires 105 cycles to complete, corresponding to an efficiency of approximately 94%. Although the efficiency decreased by 3%, adding the bridge may increase the f_{MAX} by 5%. For example, if the clock frequency can be increased, the overall throughput would improve. As the number of words transferred increases, the efficiency increases to nearly 100%, whether or not a pipeline bridge is present.

Figure 168. High Efficiency Read Transfer

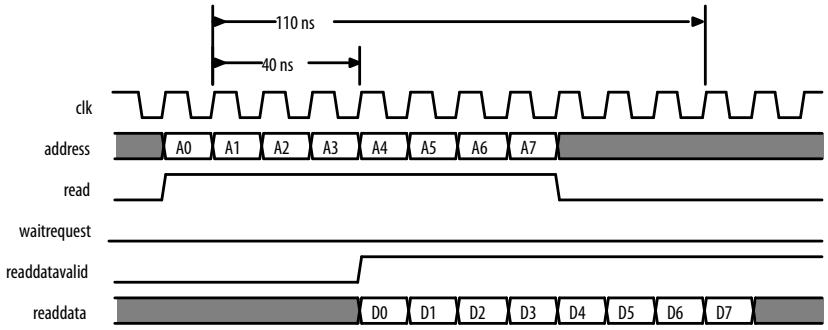


4.5.4.1.2. Unacceptable Latency Increase

Processors are sensitive to high latency read times and typically retrieve data for use in calculations that cannot proceed until the data arrives. Before adding a bridge to the datapath of a processor instruction or data host, determine whether the clock frequency increase justifies the added latency.

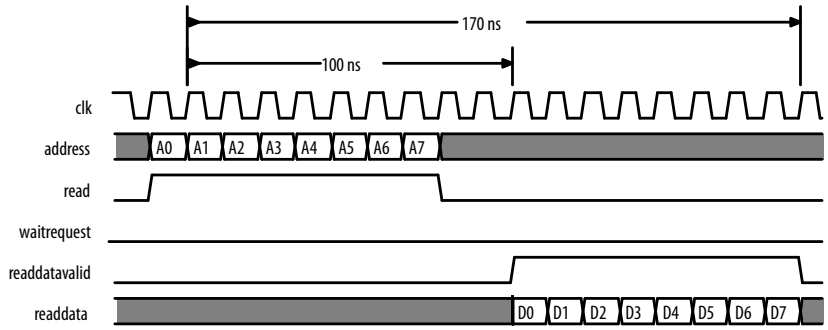
A Nios II processor instruction master has a cache memory with a read latency of four cycles, which is eight sequential words of data return for each read. At 100 MHz, the first read takes 40 ns to complete. Each successive word takes 10 ns so that eight reads complete in 110 ns.

Figure 169. Performance of a Nios II Processor and Memory Operating at 100 MHz



Adding a clock crossing bridge allows the memory to operate at 125 MHz. However, this increase in frequency is negated by the increase in latency because if the clock crossing bridge adds six clock cycles of latency at 100 MHz, then the memory continues to operate with a read latency of four clock cycles. Consequently, the first read from memory takes 100 ns, and each successive word takes 10 ns because reads arrive at the frequency of the processor, which is 100 MHz. In total, eight reads complete after 170 ns. Although the memory operates at a higher clock frequency, the frequency at which the host operates limits the throughput.

Figure 170. Performance of a Nios II Processor and Eight Reads with Ten Cycles Latency



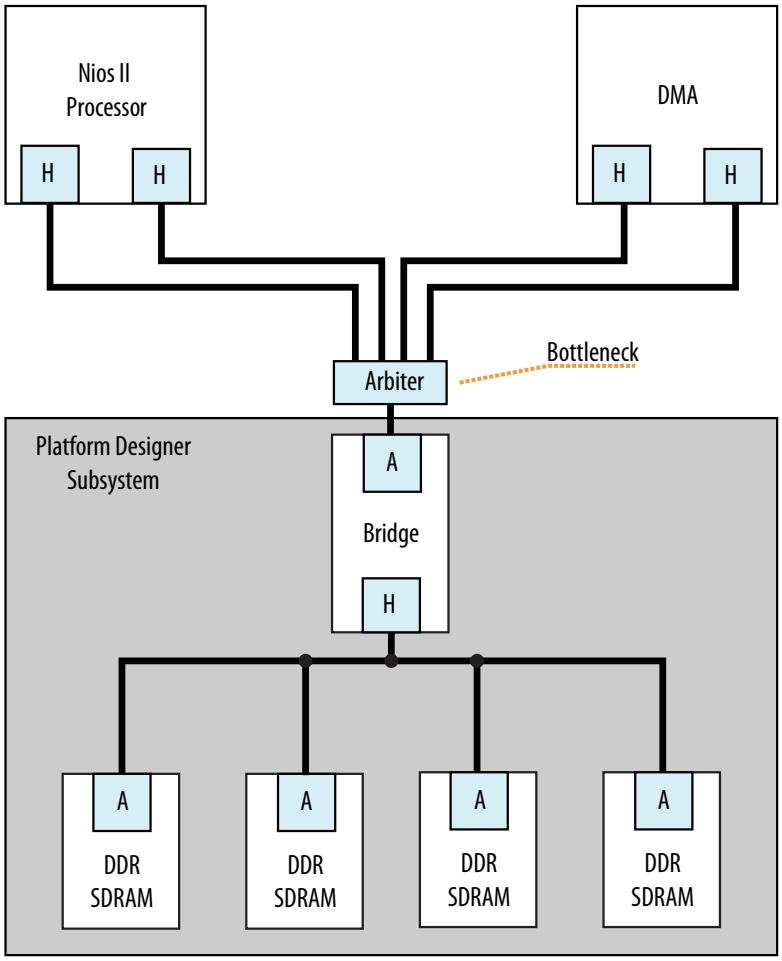
4.5.4.2. Limited Concurrency

Placing a bridge between multiple host and agent interfaces limits the number of concurrent transfers your system can initiate. This limitation is the same when connecting multiple host interfaces to a single agent interface. The agent interface of

the bridge is shared by all the hosts and, as a result, Platform Designer creates arbitration logic. If the components placed behind a bridge are infrequently accessed, this concurrency limitation may be acceptable.

Bridges can have a negative impact on system performance if you use them inappropriately. For example, if multiple memories are used by several hosts, you should not place the memory components behind a bridge. The bridge limits memory performance by preventing concurrent memory accesses. Placing multiple memory components behind a bridge can cause the separate agent interfaces to appear as one large memory to the hosts accessing the bridge; all hosts must access the same agent interface.

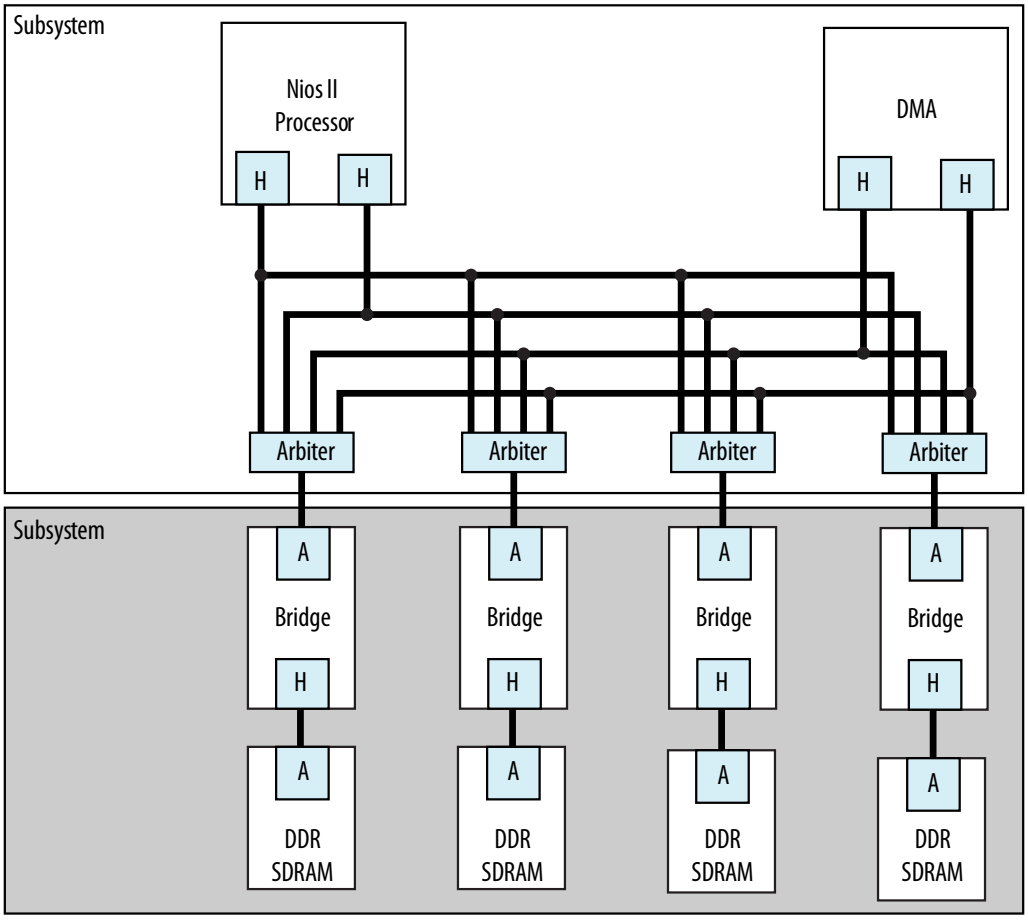
Figure 171. Inappropriate Use of a Bridge in a Hierarchical System



A memory subsystem with one bridge that acts as a single agent interface for the Avalon memory mapped Nios II and DMA hosts, which results in a bottleneck architecture. The bridge acts as a bottleneck between the two hosts and the memories.

If the f_{MAX} of your memory interfaces is low and you want to use a pipeline bridge between subsystems, you can place each memory behind its own bridge, which increases the f_{MAX} of the system without sacrificing concurrency.

Figure 172. Efficient Memory Pipelining Without a Bottleneck in a Hierarchical System

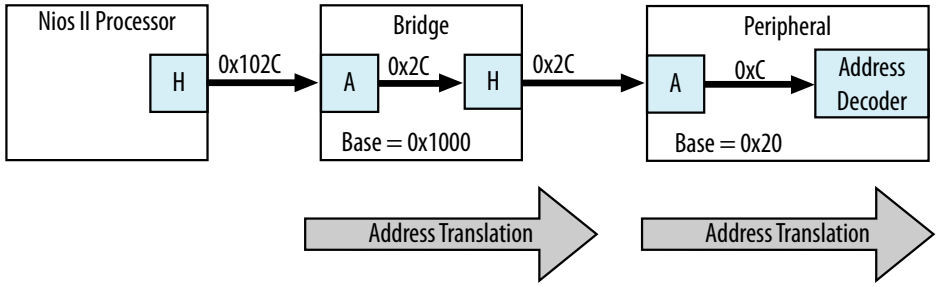


4.5.4.3. Address Space Translation

The agent interface of a pipeline or clock crossing bridge has a base address and address span. You can set the base address, or allow Platform Designer to set it automatically. The address of the agent interface is the base offset address of all the components connected to the bridge. The address of components connected to the bridge is the sum of the base offset and the address of that component.

The host interface of the bridge drives only the address bits that represent the offset from the base address of the bridge agent interface. Any time a host accesses an agent through a bridge, both addresses must be added together, otherwise the transfer fails. The **Address Map** tab displays the addresses of the agents connected to each host and includes address translations caused by system bridges.

Figure 173. Bridge Address Translation

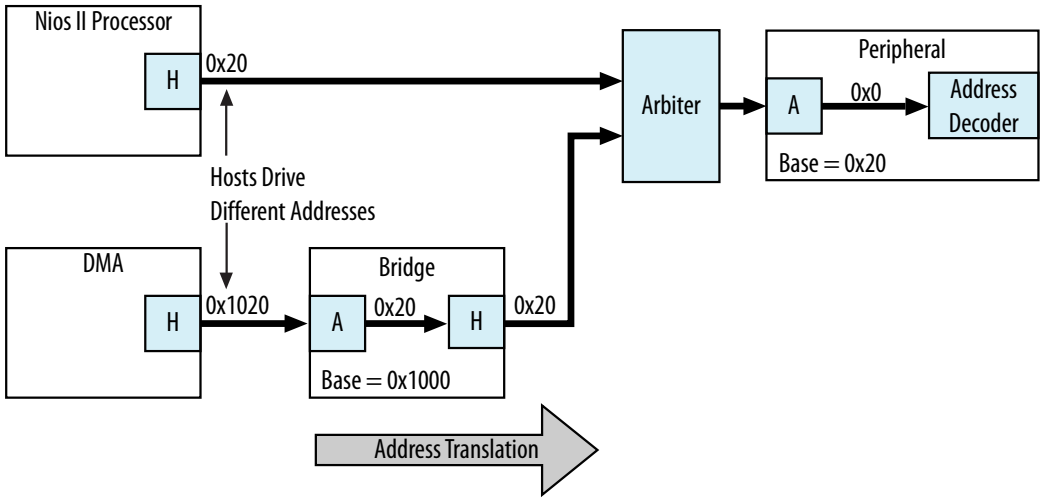


In this example, the Nios II processor connects to a bridge located at base address 0x1000, an agent connects to the bridge host interface at an offset of 0x20, and the processor performs a write transfer to the fourth 32-bit or 64-bit word within the agent. Nios II drives the address 0x102C to interconnect, which is within the address range of the bridge. The bridge host interface drives 0x2C, which is within the address range of the agent, and the transfer completes.

4.5.4.4. Address Coherency

To simplify the system design, all hosts should access agents at the same location. In many systems, a processor passes buffer locations to other hosting components, such as a DMA controller. If the processor and DMA controller do not access the agent at the same location, Platform Designer must compensate for the differences.

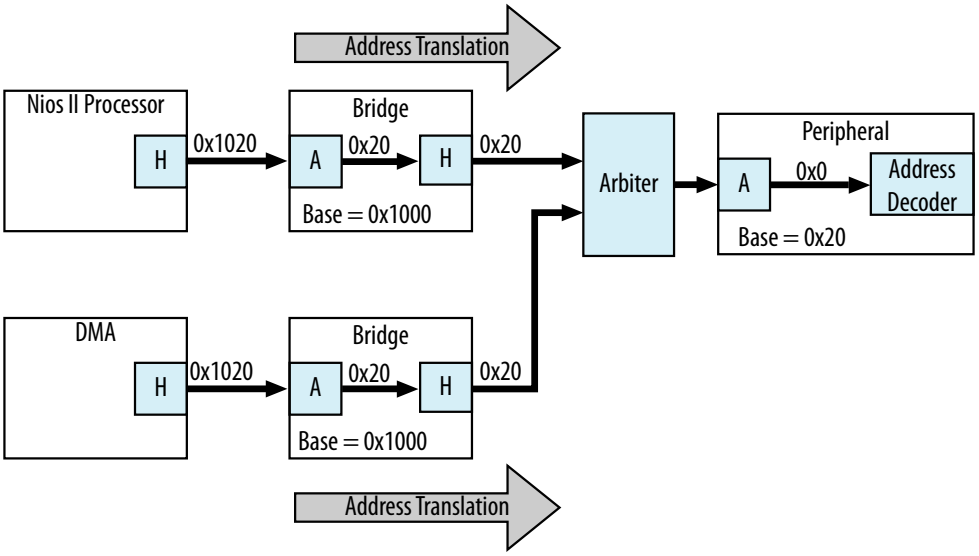
Figure 174. Agents at Different Addresses and Complicating the System



A Nios II processor and DMA controller access an agent interface located at address 0x20. The processor connects directly to the agent interface. The DMA controller connects to a pipeline bridge located at address 0x1000, which then connects to the agent interface. Because the DMA controller accesses the pipeline bridge first, it must drive 0x1020 to access the first location of the agent interface. Because the processor accesses the agent from a different location, you must maintain two base addresses for the agent device.

To avoid the requirement for two addresses, you can add an additional bridge to the system, set its base address to 0x1000, and then disable all the pipelining options in the second bridge so that the bridge has minimal impact on system timing and resource utilization. Because this second bridge has the same base address as the original bridge, the processor and DMA controller access the agent interface with the same address range.

Figure 175. Address Translation Corrected With Bridge



4.6. Increasing Transfer Throughput

Increasing the transfer efficiency of the host and agent interfaces in your system increases the throughput of your design. Designs with strict cost or power requirements benefit from increasing the transfer efficiency because you can then use less expensive, lower frequency devices. Designs requiring high performance also benefit from increased transfer efficiency because increased efficiency improves the performance of frequency–limited hardware.

Throughput is the number of symbols (such as bytes) of data that Platform Designer can transfer in a given clock cycle. Read latency is the number of clock cycles between the address and data phase of a transaction. For example, a read latency of two means that the data is valid two cycles after the address is posted. If the host must wait for one request to finish before the next begins, such as with a processor, then the read latency is very important to the overall throughput.

You can measure throughput and latency in simulation by observing the waveforms, or using the verification IP monitors.

- Avalon Interface Specifications
- Siemens EDA* AXI Verification IP Suite

4.6.1. Using Pipelined Transfers

Pipelined transfers increase the read efficiency by allowing a host to post multiple reads before data from an earlier read returns. Hosts that support pipelined transfers post transfers continuously, relying on the `readdatavalid` signal to indicate valid data. Agents support pipelined transfers by including the `readdatavalid` signal or operating with a fixed read latency.

AXI managers declare how many outstanding writes and reads it can issue with the `writeIssuingCapability` and `readIssuingCapability` parameters. In the same way, an agent can declare how many reads it can accept with the `readAcceptanceCapability` parameter. AXI managers with a read issuing capability greater than one are pipelined in the same way as Avalon hosts and the `readdatavalid` signal.

4.6.1.1. Using the Maximum Pending Reads Parameter

If you create a custom component with an agent interface supporting variable-latency reads, you must specify the **Maximum Pending Reads** parameter in the Component Editor. Platform Designer uses this parameter to generate the appropriate interconnect and represent the maximum number of read transfers that your pipelined agent component can process. If the number of reads presented to the agent interface exceeds the **Maximum Pending Reads** parameter, then the agent interface must assert `waitrequest`.

Optimizing the value of the **Maximum Pending Reads** parameter requires an understanding of the latencies of your custom components. This parameter should be based on the component's highest read latency for the various logic paths inside the component. For example, if your pipelined component has two modes, one requiring two clock cycles and the other five, set the **Maximum Pending Reads** parameter to 5 to allow your component to pipeline five transfers, and eliminating dead cycles after the initial five-cycle latency.

You can also determine the correct value for the **Maximum Pending Reads** parameter by monitoring the number of reads that are pending during system simulation or while running the hardware. To use this method, set the parameter to a high value and use a host that issues read requests on every clock. You can use a DMA for this task if the data is written to a location that does not frequently assert `waitrequest`. If you implement this method, you can observe your component with a logic analyzer or built-in monitoring hardware.

Choosing the correct value for the **Maximum Pending Reads** parameter of your custom pipelined read component is important. If you underestimate the parameter value, you may cause a host interface to stall with a `waitrequest` until the agent responds to an earlier read request and frees a FIFO position.

The **Maximum Pending Reads** parameter controls the depth of the response FIFO inserted into the interconnect for each host connected to the agent. This FIFO does not use significant hardware resources. Overestimating the **Maximum Pending Reads** parameter results in a slight increase in hardware utilization. For these reasons, if you are not sure of the optimal value, you should overestimate this value.

If your system includes a bridge, you must set the **Maximum Pending Reads** parameter on the bridge as well. To allow maximum throughput, this value should be equal to or greater than the **Maximum Pending Reads** value for the connected agent that has the highest value. You can limit the maximum pending reads of an

agent and reduce the buffer depth by reducing the parameter value on the bridge if the high throughput is not required. If you do not know the **Maximum Pending Reads** value for all the agent components, you can monitor the number of reads that are pending during system simulation while running the hardware. To use this method, set the **Maximum Pending Reads** parameter to a high value and use a host that issues read requests on every clock, such as a DMA. Then, reduce the number of maximum pending reads of the bridge until the bridge reduces the performance of any hosts accessing the bridge.

4.6.2. Arbitration Shares and Bursts

Arbitration shares provide control over the arbitration process. By default, the arbitration algorithm allocates evenly, with all hosts receiving one share.

You can adjust the arbitration process by assigning a larger number of shares to hosts that need greater throughput. The larger the arbitration share, the more transfers are allocated to the host to access an agent. The hosts gets uninterrupted access to the agent for its number of shares when the host is reading or writing.

If a host cannot post a transfer, and other hosts are waiting to gain access to a particular agent, the arbiter grants access to another host. This mechanism prevents a host from wasting arbitration cycles if it cannot post back-to-back transfers. A bursting transaction contains multiple beats (or words) of data, starting from a single address. Bursts allow a host to maintain access to an agent for more than a single word transfer. If a bursting host posts a write transfer with a burst length of eight, it is guaranteed arbitration for eight write cycles.

You can assign arbitration shares to an Avalon memory mapped bursting host and AXI hosts (which are always considered a bursting host). Each share consists of one burst transaction (such as multi cycle write), and allows a host to complete a number of bursts before arbitration switches to the next host.

Related Information

Arbitration on page 264

4.6.2.1. Differences Between Arbitration Shares and Bursts

The following three key characteristics distinguish arbitration shares and bursts:

- Arbitration Lock
- Sequential Addressing
- Burst Adapters

Arbitration Lock

When a host posts a burst transfer, the arbitration is locked for that host; consequently, the bursting host should be capable of sustaining transfers for the duration of the locked period. If, after the fourth write, the host deasserts the write signal (Avalon memory mapped write or AXI `wvalid`) for fifty cycles, all other hosts continue to wait for access during this stalled period.

To avoid wasted bandwidth, your host designs should wait until a full burst transfer is ready before requesting access to an agent device. Alternatively, you can avoid wasted bandwidth by posting `burstcounts` equal to the amount of data that is ready. For example, if you create a custom bursting write host with a maximum `burstcount`

of eight, but only three words of data are ready, you can present a `burstcount` of three. This strategy does not result in optimal use of the system band width if the agent is capable of handling a larger burst; however, this strategy prevents stalling and allows access for other hosts in the system.

Sequential Addressing

An Avalon memory mapped burst transfer includes a base address and a `burstcount`, which represents the number of words of data that are transferred, starting from the base address and incrementing sequentially. Burst transfers are common for processors, DMAs, and buffer processing accelerators; however, sometimes a host must access non-sequential addresses. Consequently, a bursting host must set the `burstcount` to the number of sequential addresses, and then reset the `burstcount` for the next location.

The arbitration share algorithm has no restrictions on addresses; therefore, your custom host can update the address it presents to the interconnect for every read or write transaction.

Burst Adapters

Platform Designer allows you to create systems that mix bursting and non-bursting host and agent interfaces. This design strategy allows you to connect bursting host and agent interfaces that support different maximum burst lengths, with Platform Designer generating burst adapters when appropriate.

Platform Designer inserts a burst adapter whenever a host interface burst length exceeds the burst length of the agent interface, or if the host issues a burst type that the agent cannot support. For example, if you connect an AXI manager to an Avalon agent, a burst adapter is inserted. Platform Designer assigns non-bursting hosts and agent interfaces a burst length of one. The burst adapter divides long bursts into shorter bursts. As a result, the burst adapter adds logic to the address and `burstcount` paths between the host and agent interfaces.

4.6.2.2. Choosing Avalon Memory Mapped Interface Types

To avoid inefficient Avalon memory mapped transfers, custom host or agent interfaces must use the appropriate simple, pipelined, or burst interfaces.

4.6.2.2.1. Simple Avalon Memory Mapped Interfaces

Simple interface transfers do not support pipelining or bursting for reads or writes; consequently, their performance is limited. Simple interfaces are appropriate for transfers between hosts and infrequently used agent interfaces. In Platform Designer, the PIO, UART, and Timer include agent interfaces that use simple transfers.

4.6.2.2.2. Pipelined Avalon Memory Mapped Interfaces

Pipelined read transfers allow a pipelined host interface to start multiple read transfers in succession without waiting for prior transfers to complete. Pipelined transfers allow host-agent pairs to achieve higher throughput, even though the agent port may require one or more cycles of latency to return data for each transfer.

In many systems, read throughput becomes inadequate if simple reads are used and pipelined transfers can increase throughput. If you define a component with a fixed read latency, Platform Designer automatically provides the pipelining logic necessary

to support pipelined reads. You can use fixed latency pipelining as the default design starting point for agent interfaces. If your agent interface has a variable latency response time, use the `readdatavalid` signal to indicate when valid data is available. The interconnect implements read response FIFO buffering to handle the maximum number of pending read requests.

To use components that support pipelined read transfers, and to use a pipelined system interconnect efficiently, your system must contain pipelined hosts. You can use pipelined hosts as the default starting point for new host components. Use the `readdatavalid` signal for these host interfaces.

Because host and agents sometimes have mismatched pipeline latency, the interconnect contains logic to reconcile the differences.

Table 43. Pipeline Latency in a Host-Agent Pair

Host	Agent	Pipeline Management Logic Structure
No pipeline	No pipeline	Platform Designer interconnect does not instantiate logic to handle pipeline latency.
No pipeline	Pipelined with fixed or variable latency	Platform Designer interconnect forces the host to wait through any agent-side latency cycles. This host-agent pair gains no benefits from pipelining, because the host waits for each transfer to complete before beginning a new transfer. However, while the host is waiting, the agent can accept transfers from a different host.
Pipelined	No pipeline	Platform Designer interconnect carries out the transfer as if neither host nor agent were pipelined, causing the host to wait until the agent returns data. An example of a non-pipeline agent is an asynchronous off-chip interface.
Pipelined	Pipelined with fixed latency	Platform Designer interconnect allows the host to capture data at the exact clock cycle when data from the agent is valid, to enable maximum throughput. An example of a fixed latency agent is an on-chip memory.
Pipelined	Pipelined with variable latency	The agent asserts a signal when its `readdata` is valid, and the host captures the data. The host-agent pair can achieve maximum throughput if the agent has variable latency. Examples of variable latency agents include SDRAM and FIFO memories.

4.6.2.2.3. Burst Avalon Memory Mapped Interfaces

Burst transfers are commonly used for latent memories such as SDRAM and off-chip communication interfaces, such as PCI Express. To use a burst-capable agent interface efficiently, you must connect to a bursting host. Components that require bursting to operate efficiently typically have an overhead penalty associated with short bursts or non-bursting transfers.

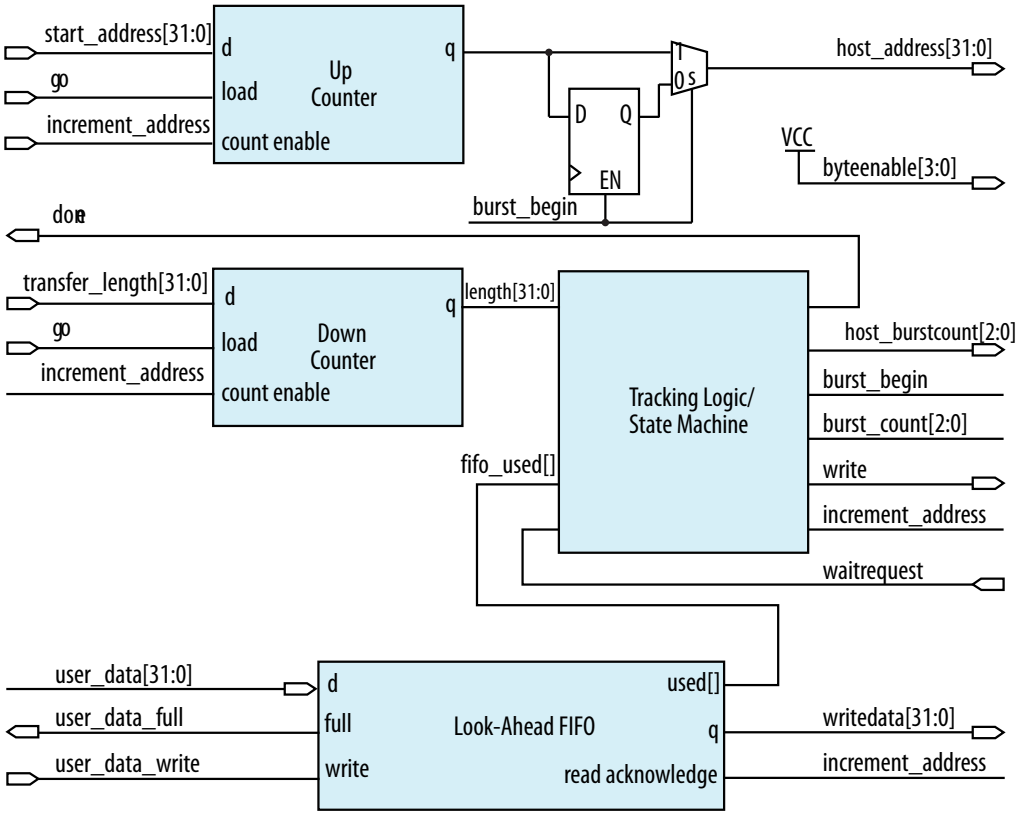
You can use a burst-capable agent interface if you know that your component requires sequential transfers to operate efficiently. Because SDRAM memories incur a penalty when switching banks or rows, performance improves when SDRAM memories are accessed sequentially with bursts.

Architectures that use the same signals to transfer address and data also benefit from bursting. Whenever an address is transferred over shared address and data signals, the throughput of the data transfer is reduced. Because the address phase adds overhead, using large bursts increases the throughput of the connection.

4.6.2.3. Avalon Memory Mapped Burst Host Example

Figure 176. Avalon Bursting Write Host

This example shows the architecture of a bursting write host that receives data from a FIFO and writes the contents to memory. You can use a bursting host as a starting point for your own bursting components, such as custom DMAs, hardware accelerators, or off-chip communication interfaces.



The host performs word accesses and writes to sequential memory locations. When `go` is asserted, the `start_address` and `transfer_length` are registered. On the next clock cycle, the control logic asserts `burst_begin`, which synchronizes the internal control signals in addition to the `host_address` and `host_burstcount` presented to the interconnect. The timing of these two signals is important because during bursting write transfers `byteenable` and `burstcount` must be held constant for the entire burst.

To avoid inefficient writes, the host posts a burst when enough data is buffered in the FIFO. To maximize the burst efficiency, the host should stall only when an agent asserts `waitrequest`. In this example, the FIFO's used signal tracks the number of words of data that are stored in the FIFO and determines when enough data has been buffered.

The `address` register increments after every word transfer, and the `length` register decrements after every word transfer. The address remains constant throughout the burst. Because a transfer is not guaranteed to complete on burst boundaries, additional logic is necessary to recognize the completion of short bursts and complete the transfer.

4.7. Reducing Logic Utilization

You can minimize logic size of Platform Designer systems. Typically, there is a trade-off between logic utilization and performance. Reducing logic utilization applies to both Avalon and AXI interfaces.

4.7.1. Minimizing Interconnect Logic to Reduce Logic Unitization

In Platform Designer, changes to the connections between host and agent reduce the amount of interconnect logic required in the system.

Related Information

Limited Concurrency on page 222

4.7.1.1. Creating Dedicated Host and Agent Connections to Minimize Interconnect Logic

You can create a system where a host interface connects to a single agent interface. This configuration eliminates address decoding, arbitration, and return data multiplexing, which simplifies the interconnect. Dedicated host-to-agent connections attain the same clock frequencies as Avalon streaming connections.

Typically, these one-to-one connections include an Avalon memory-mapped bridge or hardware accelerator. For example, if you insert a pipeline bridge between an agent and all other host interfaces, the logic between the bridge host and agent interface is reduced to wires. If a hardware accelerator connects only to a dedicated memory, no system interconnect logic is generated between the host and agent pair.

4.7.1.2. Removing Unnecessary Connections to Minimize Interconnect Logic

The number of connections between host and agent interfaces affects the f_{MAX} of your system. Every host interface that you connect to an agent interface increases the width of the multiplexer width. As a multiplexer width increases, so does the logic depth and width that implements the multiplexer in the FPGA. To improve system performance, connect hosts and agents only when necessary.

When you connect a host interface to many agent interfaces, the multiplexer for the read data signal grows. Avalon typically uses a `readdata` signal. AXI read data signals add a response status and last indicator to the read response channel using `rdata`, `rresp`, and `rlast`. Additionally, bridges help control the depth of multiplexers.

Related Information

Implementing Command Pipelining (Host-to-Agent) on page 216

4.7.1.3. Simplifying Address Decode Logic

If address code logic is in the critical path, you may be able to change the address map to simplify the decode logic. Experiment with different address maps, including a one-hot encoding, to see if results improve.

4.7.2. Minimizing Arbitration Logic by Consolidating Multiple Interfaces

As the number of components in a design increases, the amount of logic required to implement the interconnect also increases. The number of arbitration blocks increases for every agent interface that is shared by multiple host interfaces. The width of the read data multiplexer increases as the number of agent interfaces supporting read transfers increases on a per host interface basis. For these reasons, consider implementing multiple blocks of logic as a single interface to reduce interconnect logic utilization.

4.7.2.1. Logic Consolidation Trade-Offs

You should consider the following trade-offs before making modifications to your system or interfaces:

- Consider the impact on concurrency that results when you consolidate components. When a system has four host components and four agent interfaces, it can initiate four concurrent accesses. If you consolidate the four agent interfaces into a single interface, then the four hosts must compete for access. Consequently, you should only combine low priority interfaces such as low speed parallel I/O devices if the combination does not impact the performance.
- Determine whether consolidation introduces new decode and multiplexing logic for the agent interface that the interconnect previously included. If an interface contains multiple read and write address locations, the interface already contains the necessary decode and multiplexing logic. When you consolidate interfaces, you typically reuse the decoder and multiplexer blocks already present in one of the original interfaces; however, combining interfaces may simply move the decode and multiplexer logic, rather than eliminate duplication.
- Consider whether consolidating interfaces makes the design complicated. If so, you should not consolidate interfaces.

Related Information

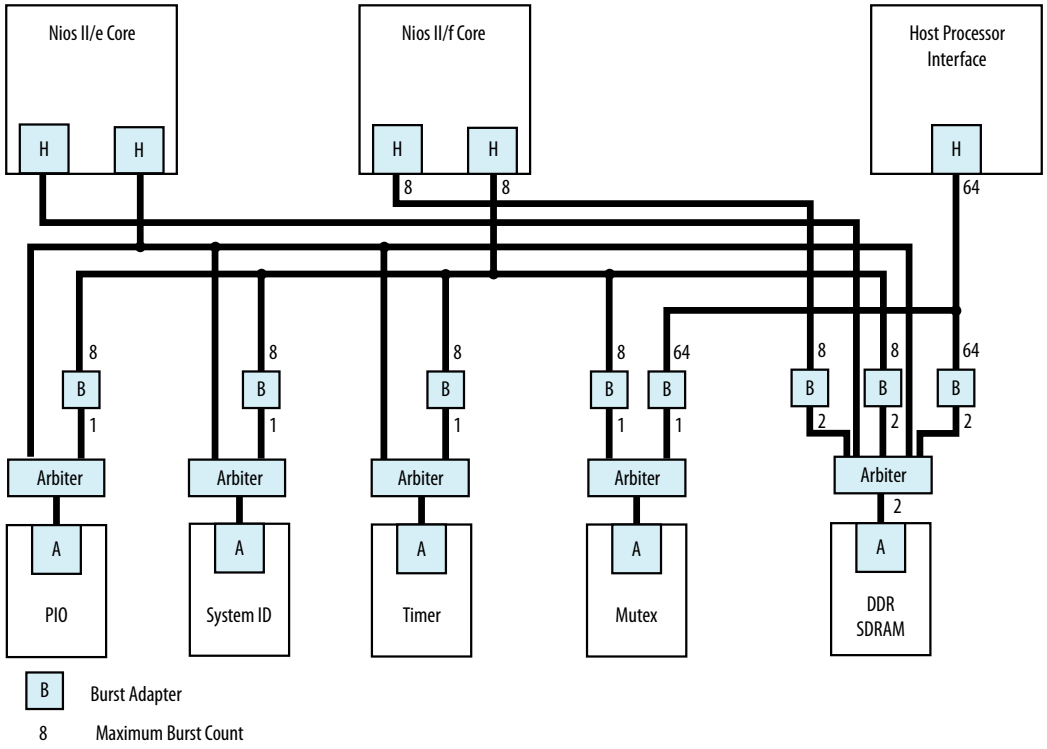
Using Concurrency in Memory-Mapped Systems on page 210

4.7.2.2. Consolidating Interfaces

The following example shows a system with a mix of components, each having different burst capabilities: a Nios II/e core, a Nios II/f core, and an external processor, which off-loads some processing tasks to the Nios II/f core.

The Nios II/f core supports a maximum burst size of eight. The external processor interface supports a maximum burst length of 64. The Nios II/e core does not support bursting. The memory in the system is SDRAM with an Avalon maximum burst length of two.

Figure 177. Mixed Bursting System

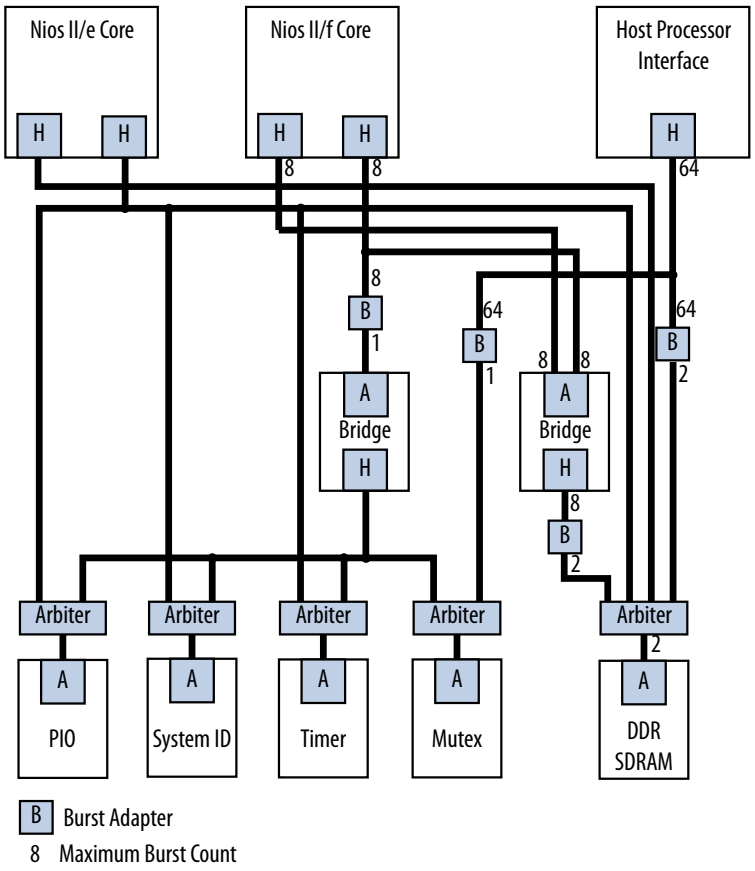


Platform Designer automatically inserts burst adapters to compensate for burst length mismatches. The adapters reduce bursts to a single transfer, or the length of two transfers. For the external processor interface connecting to DDR SDRAM, a burst of 64 words is divided into 32 burst transfers, each with a burst length of two. When you generate a system, Platform Designer inserts burst adapters based on maximum `burstcount` values; consequently, the interconnect logic includes burst adapters between hosts and agent pairs that do not require bursting, if the host is capable of bursts.

In this example, Platform Designer inserts a burst adapter between the Nios II processors and the timer, system ID, and PIO peripherals. These components do not support bursting and the Nios II processor performs a single word read and write accesses to these components.

Figure 178. Mixed Bursting System with Bridges

To reduce the number of adapters, you can add pipeline bridges. The pipeline bridge, between the Nios II/f core and the peripherals that do not support bursts, eliminates three burst adapters from the previous example. A second pipeline bridge between the Nios II/f core and the DDR SDRAM, with its maximum burst size set to eight, eliminates another burst adapter, as shown below.



4.7.3. Reducing Logic Utilization With Multiple Clock Domains

You specify clock domains in Platform Designer on the **System View** tab. Clock sources can be driven by external input signals to Platform Designer, or by PLLs inside Platform Designer. Clock domains are differentiated based on the name of the clock. You can create multiple asynchronous clocks with the same frequency.

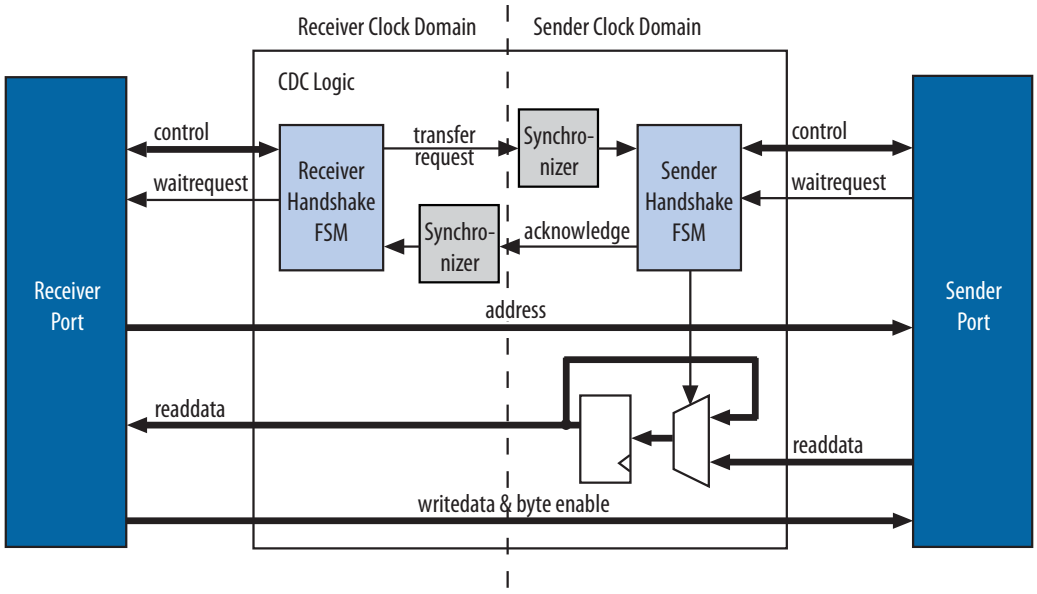
Platform Designer generates Clock Domain Crossing (CDC) logic that hides the details of interfacing components operating in different clock domains. The interconnect supports the memory-mapped protocol with each port independently, and therefore hosts do not need to incorporate clock adapters in order to interface to agents on a different domain. Platform Designer interconnect logic propagates transfers across clock domain boundaries automatically.

Clock-domain adapters provide the following benefits:

- Allows component interfaces to operate at different clock frequencies.
- Eliminates the need to design CDC hardware.
- Allows each memory-mapped port to operate in only one clock domain, which reduces design complexity of components.
- Enables hosts to access any agent without communication with the agent clock domain.
- Allows you to focus performance optimization efforts on components that require fast clock speed.

A clock domain adapter consists of two finite state machines (FSM), one in each clock domain, that use a hand-shaking protocol to propagate transfer control signals (`read_request`, `write_request`, and the host `waitrequest` signals) across the clock boundary.

Figure 179. Clock Crossing Adapter



This example illustrates a clock domain adapter between one host and one agent. The synchronizer blocks use multiple stages of flipflops to eliminate the propagation of meta-stable events on the control signals that enter the handshake FSMs. The CDC logic works with any clock ratio.

The typical sequence of events for a transfer across the CDC logic is as follows:

- The host asserts address, data, and control signals.
- The host handshake FSM captures the control signals and immediately forces the host to wait. The FSM uses only the control signals, not address and data. For example, the host simply holds the address signal constant until the agent side has safely captured it.
- The host handshake FSM initiates a transfer request to the agent handshake FSM.
- The transfer request is synchronized to the agent clock domain.

- The agent handshake FSM processes the request, performing the requested transfer with the agent.
- When the agent transfer completes, the agent handshake FSM sends an acknowledge back to the host handshake FSM. The acknowledge is synchronized back to the host clock domain.
- The host handshake FSM completes the transaction by releasing the host from the wait condition.

Transfers proceed as normal on the agent and the host side, without a special protocol to handle crossing clock domains. From the perspective of an agent, there is nothing different about a transfer initiated by a host in a different clock domain. From the perspective of a host, a transfer across clock domains simply requires extra clock cycles. Similar to other transfer delay cases (for example, arbitration delay or wait states on the agent side), the Platform Designer forces the host to wait until the transfer terminates. As a result, pipeline host ports do not benefit from pipelining when performing transfers to a different clock domain.

Platform Designer automatically determines where to insert CDC logic based on the system and the connections between components, and places CDC logic to maintain the highest transfer rate for all components. Platform Designer evaluates the need for CDC logic for each host and agent pair independently, and generates CDC logic wherever necessary.

4.7.4. Duration of Transfers Crossing Clock Domains

CDC logic extends the duration of host transfers across clock domain boundaries. In the worst case, which is for reads, each transfer is extended by five host clock cycles and five agent clock cycles. Assuming the default value of 2 for the host domain synchronizer length and the agent domain synchronizer length, the components of this delay are the following:

- Four additional host clock cycles, due to the host-side clock synchronizer.
- Four additional agent clock cycles, due to the agent-side clock synchronizer.
- One additional clock in each direction, due to potential metastable events as the control signals cross clock domains.

Note: Systems that require a higher performance clock should use the Avalon memory mapped clock crossing bridge instead of the automatically inserted CDC logic. The clock crossing bridge includes a buffering mechanism so that multiple reads and writes can be pipelined. After paying the initial penalty for the first read or write, there is no additional latency penalty for pending reads and writes, increasing throughput by up to four times, at the expense of added logic resources.

4.8. Reducing Power Consumption

Platform Designer provides various low power design changes that enable you to reduce the power consumption of the interconnect and custom components.

4.8.1. Reducing Power Consumption With Multiple Clock Domains

When you use multiple clock domains, you should put non-critical logic in the slower clock domain. Platform Designer automatically reconciles data crossing over asynchronous clock domains by inserting clock crossing logic (handshake or FIFO).

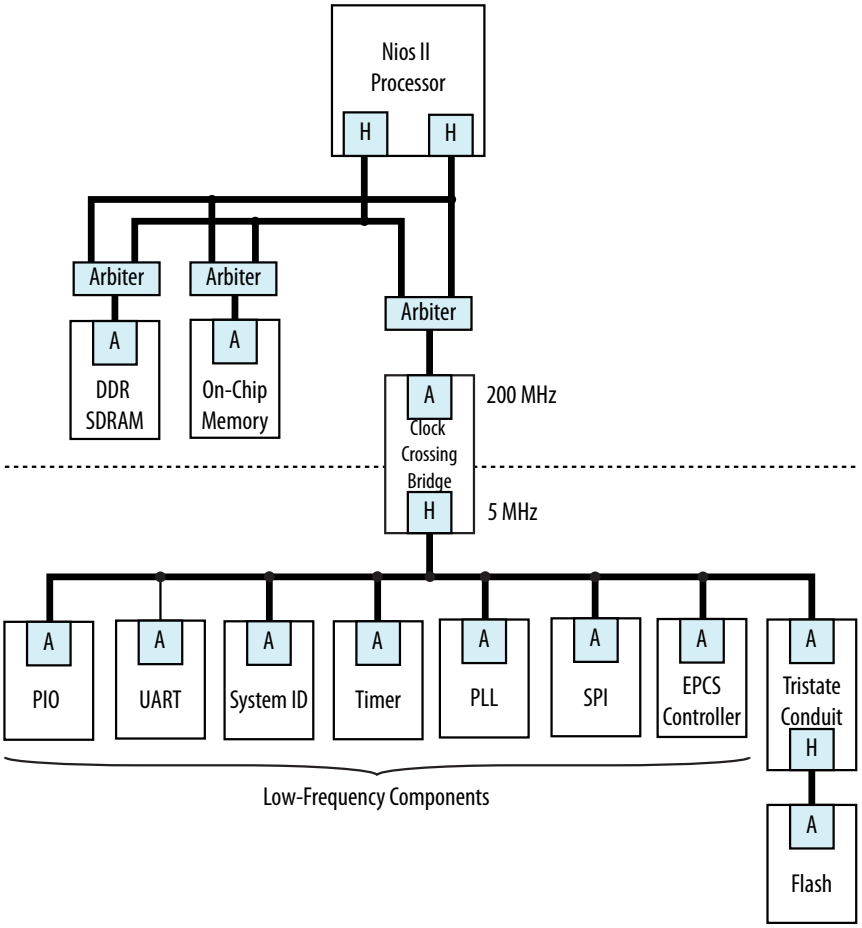
You can use clock crossing in Platform Designer to reduce the clock frequency of the logic that does not require a high frequency clock, which allows you to reduce power consumption. You can use either handshaking clock crossing bridges or handshaking clock crossing adapters to separate clock domains.

You can use the clock crossing bridge to connect host interfaces operating at a higher frequency to agent interfaces running at a lower frequency. Only connect low throughput or low priority components to a clock crossing bridge that operates at a reduced clock frequency. The following are examples of low throughput or low priority components:

- PIOs
- UARTs (JTAG or RS-232)
- System identification (SysID)
- Timers
- PLL (instantiated within Platform Designer)
- Serial peripheral interface (SPI)
- EPCS controller
- Tristate bridge and the components connected to the bridge

By reducing the clock frequency of the components connected to the bridge, you reduce the dynamic power consumption of the design. Dynamic power is a function of toggle rates and decreasing the clock frequency decreases the toggle rate.

Figure 180. Reducing Power Utilization Using a Bridge to Separate Clock Domains



Platform Designer automatically inserts clock crossing adapters between host and agent interfaces that operate at different clock frequencies. You can choose the type of clock crossing adapter in the Platform Designer **Project Settings** tab. Adapters do not appear in the **Connections** column because you do not insert them. The following clock crossing adapter types are available in Platform Designer:

- **Handshake**—Uses a simple handshaking protocol to propagate transfer control signals and responses across the clock boundary. This adapter uses fewer hardware resources because each transfer is safely propagated to the target domain before the next transfer begins. The Handshake adapter is appropriate for systems with low throughput requirements.
- **FIFO**—Uses dual-clock FIFOs for synchronization. The latency of the FIFO adapter is approximately two clock cycles more than the handshake clock crossing component, but the FIFO-based adapter can sustain higher throughput because it supports multiple transactions simultaneously. The FIFO adapter requires more resources, and is appropriate for memory-mapped transfers requiring high throughput across clock domains.
- **Auto**—Platform Designer specifies the appropriate FIFO adapter for bursting links and the Handshake adapter for all other links.

Because the clock crossing bridge uses FIFOs to implement the clock crossing logic, it buffers transfers and data. Clock crossing adapters are not pipelined, so that each transaction is blocking until the transaction completes. Blocking transactions may lower the throughput substantially; consequently, if you want to reduce power consumption without limiting the throughput significantly, you should use the clock crossing bridge or the FIFO clock crossing adapter. However, if the design requires single read transfers, a clock crossing adapter is preferable because the latency is lower.

The clock crossing bridge requires few logic resources other than on-chip memory. The number of on-chip memory blocks used is proportional to the address span, data width, buffering depth, and bursting capabilities of the bridge. The clock crossing adapter does not use on-chip memory and requires a moderate number of logic resources. The address span, data width, and the bursting capabilities of the clock crossing adapter determine the resource utilization of the device.

When you decide to use a clock crossing bridge or clock crossing adapter, you must consider the effects of throughput and memory utilization in the design. If on-chip memory resources are limited, you may be forced to choose the clock crossing adapter. Using the clock crossing bridge to reduce the power of a single component may not justify using more resources. However, if you can place all of the low priority components behind a single clock crossing bridge, you may reduce power consumption in the design.

4.8.2. Reducing Power Consumption by Minimizing Toggle Rates

A Platform Designer system consumes power whenever logic transitions between on and off states. When the state is held constant between clock edges, no charging or discharging occurs. You can use the following design methodologies to reduce the toggle rates of your design:

- Registering component boundaries
- Using clock enable signals
- Inserting bridges

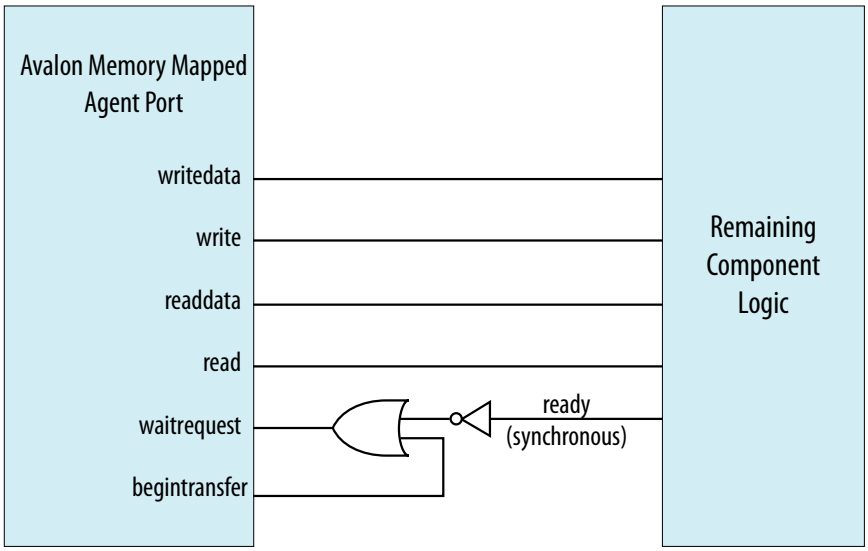
Platform Designer interconnect is uniquely combinational when no adapters or bridges are present and there is no interconnect pipelining. When an agent interface is not selected by a host, various signals may toggle and propagate into the component. By registering the boundary of your component at the host or agent interface, you can minimize the toggling of the interconnect and your component. In addition, registering boundaries can improve operating frequency. When you register the signals at the interface level, you must ensure that the component continues to operate within the interface standard specification.

Avalon memory mapped `waitrequest` is a difficult signal to synchronize when you add registers to your component. The `waitrequest` signal must be asserted during the same clock cycle that a host asserts read or write to in order to prolong the transfer. A host interface can read the `waitrequest` signal too early and post more reads and writes prematurely.

Note: There is no direct AXI equivalent for `waitrequest` and `burstcount`, though the *AMBA Protocol Specification* implies that the AXI `ready` signal cannot depend combinationally on the AXI `valid` signal. Therefore, Platform Designer typically buffers AXI component boundaries for the `ready` signal.

For agent interfaces, the interconnect manages the `begintransfer` signal, which is asserted during the first clock cycle of any read or write transfer. If the `waitrequest` is one clock cycle late, you can logically OR the `waitrequest` and the `begintransfer` signals to form a new `waitrequest` signal that is properly synchronized. Alternatively, the component can assert `waitrequest` before it is selected, guaranteeing that the `waitrequest` is already asserted during the first clock cycle of a transfer.

Figure 181. Variable Latency



Using Clock Enables

You can use clock enables to hold the logic in a steady state, and the `write` and `read` signals as clock enables for agent components. Even if you add registers to your component boundaries, the interface can potentially toggle without the use of clock enables. You can also use the clock enable to disable combinational portions of the component.

For example, you can use an active high clock enable to mask the inputs into the combinational logic to prevent it from toggling when the component is inactive. Before preventing inactive logic from toggling, you must determine if the masking causes the circuit to function differently. If masking causes a functional failure, it may be possible to use a register stage to hold the combinational logic constant between clock cycles.

Inserting Bridges

You can use bridges to reduce toggle rates, if you do not want to modify the component by using boundary registers or clock enables. A bridge acts as a repeater where transfers to the agent interface are repeated on the host interface. If the bridge is not accessed, the components connected to its host interface are also not accessed. The host interface of the bridge remains idle until a host accesses the bridge agent interface.

Bridges can also reduce the toggle rates of signals that are inputs to other host interfaces. These signals are typically `readdata`, `readdatavalid`, and `waitrequest`. Subordinate interfaces that support read accesses drive the

`readdata`, `readdatavalid`, and `waitrequest` signals. A bridge inserts either a register or clock crossing FIFO between the agent interface and the host to reduce the toggle rate of the host input signals.

4.8.3. Reducing Power Consumption by Disabling Logic

There are typically two types of low power modes: volatile and non-volatile. A volatile low power mode holds the component in a reset state. When the logic is reactivated, the previous operational state is lost. A non-volatile low power mode restores the previous operational state. You can use either software-controlled or hardware-controlled sleep modes to disable a component in order to reduce power consumption.

Software-Controlled Sleep Mode

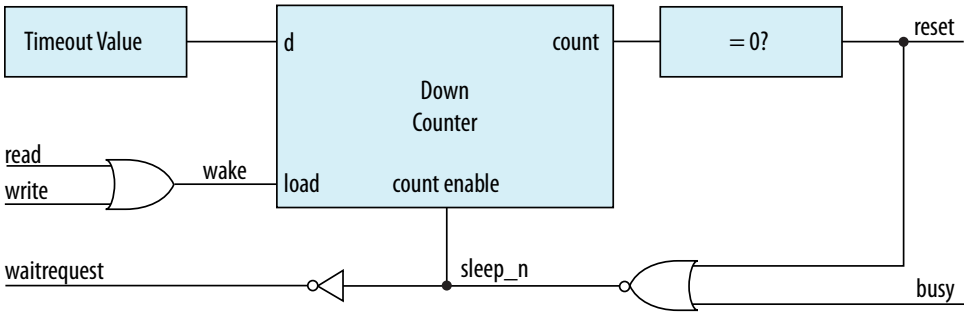
To design a component that supports software-controlled sleep mode, create a single memory-mapped location that enables and disables logic by writing a zero or one. You can use the register's output as a clock enable or reset, depending on whether the component has non-volatile requirements. The agent interface must remain active during sleep mode so that the enable bit is set when the component needs to be activated.

If multiple hosts can access a component that supports sleep mode, you can use the Mutex Intel FPGA IP to provide mutually exclusive accesses to your component. You can also build in the logic to re-enable the component on the very first access by any host in your system. If the component requires multiple clock cycles to re-activate, then it must assert a wait request to prolong the transfer as it exits sleep mode.

Hardware-Controlled Sleep Mode

Alternatively, you can implement a timer in your component that automatically causes the component to enter a sleep mode based on a timeout value specified in clock cycles between read or write accesses. Each access resets the timer to the timeout value. Each cycle with no accesses decrements the timeout value by one. If the counter reaches zero, the hardware enters sleep mode until the next access.

Figure 182. Hardware-Controlled Sleep Components



This example provides a schematic for the hardware-controlled sleep mode. If restoring the component to an active state takes a long time, use a long timeout value so that the component is not continuously entering and exiting sleep mode. The agent interface must remain functional while the rest of the component is in sleep mode. When the component exits sleep mode, the component must assert the `waitrequest` signal until it is ready for read or write accesses.

4.9. Reset Polarity and Synchronization in Platform Designer

When you add a component interface with a reset signal, Platform Designer defines its polarity as `reset`(active-high) or `reset_n` (active-low).

You can view the polarity status of a reset signal by selecting the signal in the **Hierarchy** tab, and then view its expanded definition in the open **Parameters** and **Block Symbol** tabs. When you generate your component, Platform Designer interconnect automatically inverts polarities as needed.

Figure 183. Reset Signal (Active-High)

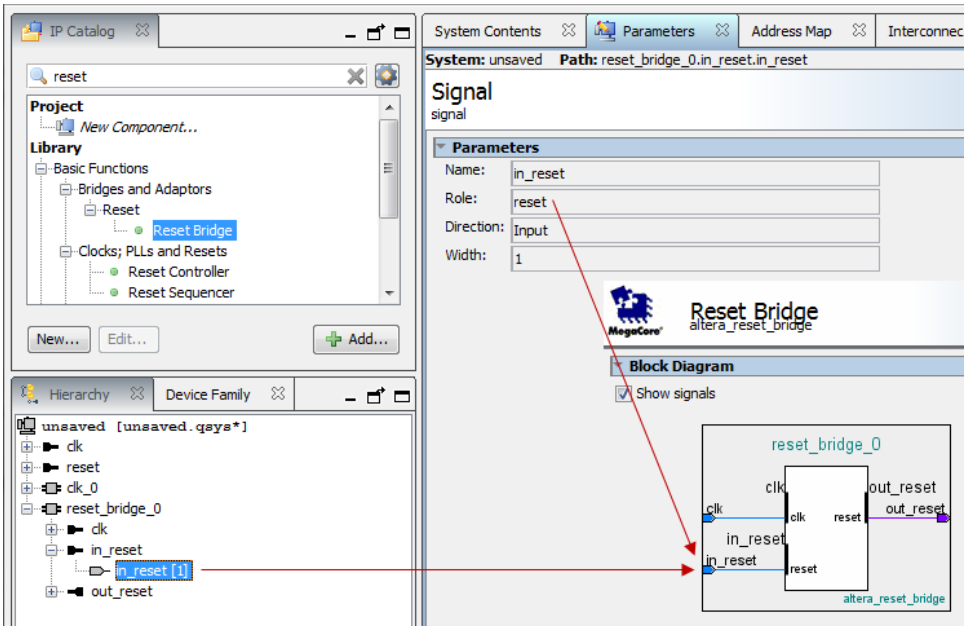

Figure 184. Reset Signal Active-Low

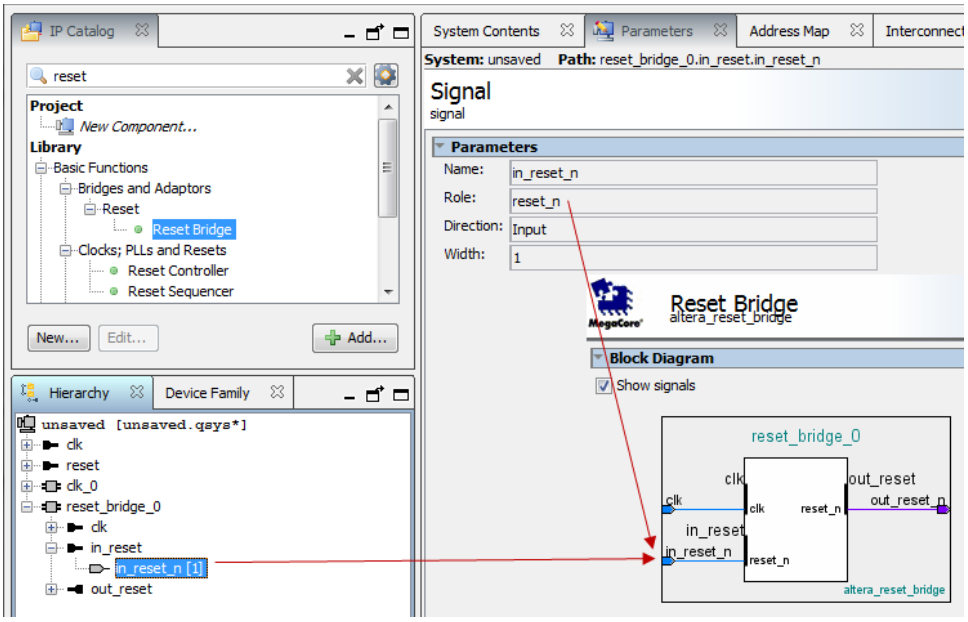
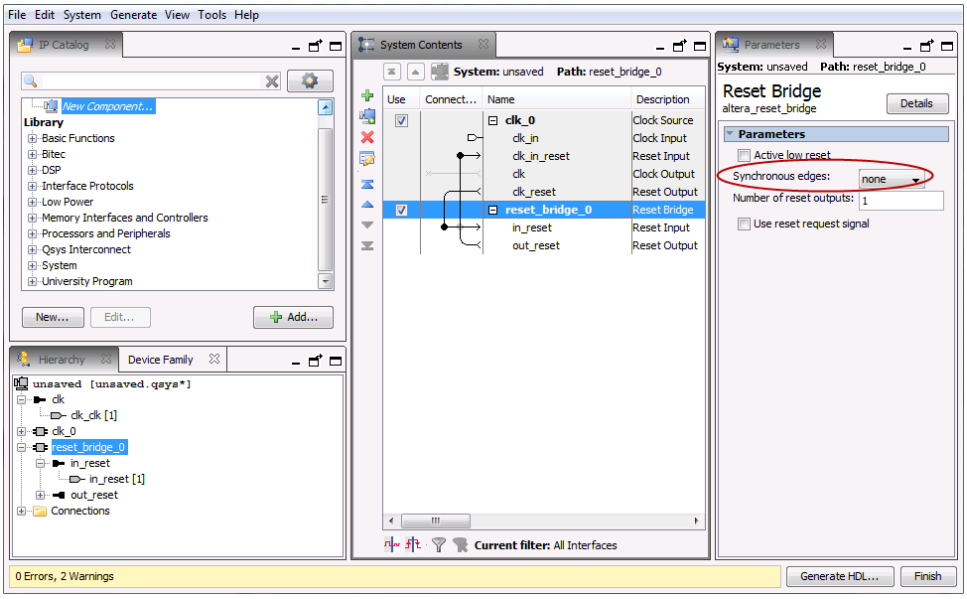


Each Platform Designer component has its own requirements for reset synchronization. Some blocks have internal synchronization and have no requirements, whereas other blocks require an externally synchronized reset. You can define how resets are synchronized in your Platform Designer system with the **Synchronous edges** parameter. In the clock source or reset bridge component, set the value of the **Synchronous edges** parameter to one of the following, depending on how the reset is externally synchronized:

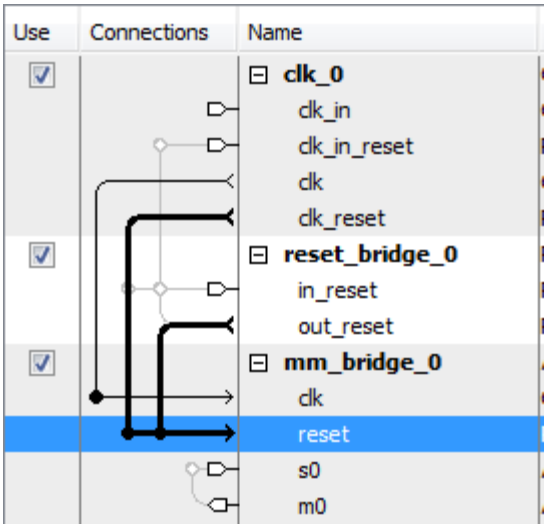
- **None**—There is no synchronization on this reset.
- **Both**—The reset is synchronously asserted and deasserted with respect to the input clock.
- **Deassert**—The reset is synchronously asserted with respect to the input clock, and asynchronously deasserted.

Figure 185. Synchronous Edges Parameter



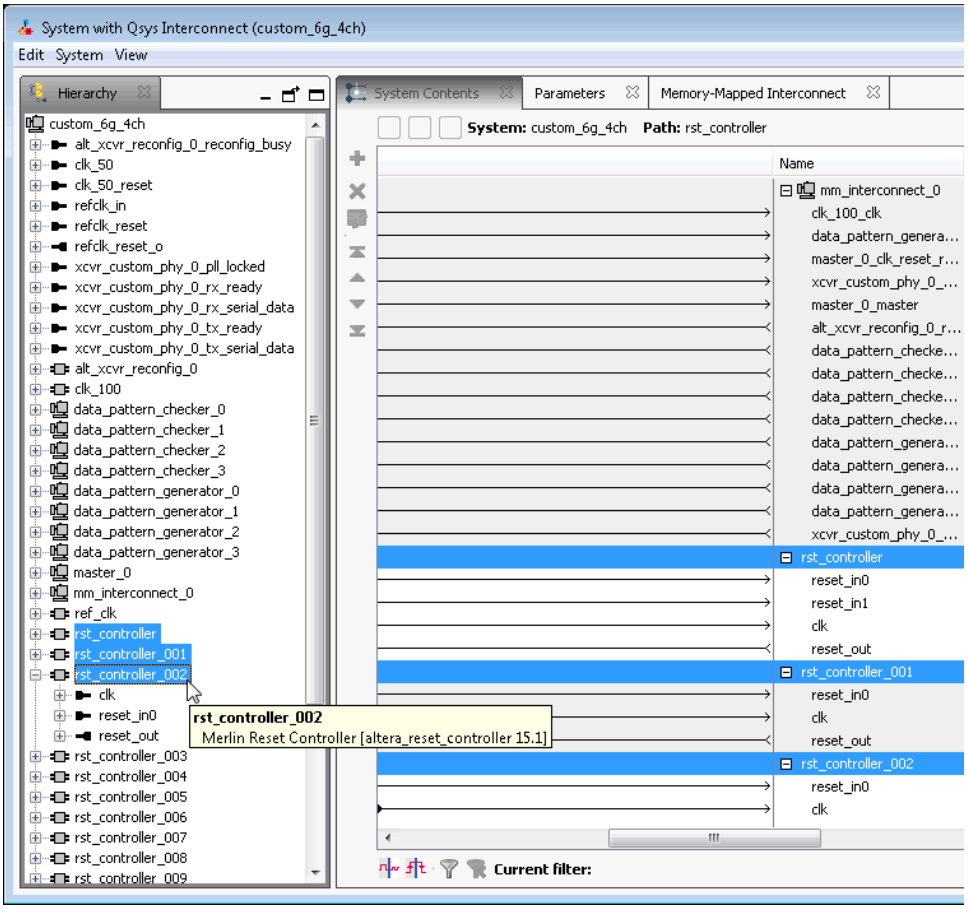
You can combine multiple reset sources to reset a particular component.

Figure 186. Combine Multiple Reset Sources



When you generate your component, Platform Designer inserts adapters to synchronize or invert resets if there are mismatches in polarity or synchronization between the source and destination. You can view inserted adapters on the **Memory-Mapped Interconnect** tab with the **System ➤ Show System with Platform Designer Interconnect** command.

Figure 187. Platform Designer Interconnect



4.10. Optimizing Platform Designer System Performance Design Examples

Avalon Pipelined Read Host Example on page 246

Multiplexer Examples on page 248

4.10.1. Avalon Pipelined Read Host Example

For a high throughput system using the Avalon memory mapped standard, you can design a pipelined read host that allows a system to issue multiple read requests before data returns. Pipelined read hosts hide the latency of read operations by posting reads as frequently as every clock cycle. You can use this type of host when the address logic is not dependent on the data returning.

4.10.1.1. Avalon Pipelined Read Host Example Design Requirements

You must carefully design the logic for the control and datapaths of pipelined read hosts. The control logic must extend a read cycle whenever the `waitrequest` signal is asserted. This logic must also control the host `address`, `byteenable`, and `read`

signals. To achieve maximum throughput, pipelined read hosts should post reads continuously while `waitrequest` is deasserted. While `read` is asserted, the address presented to the interconnect is stored.

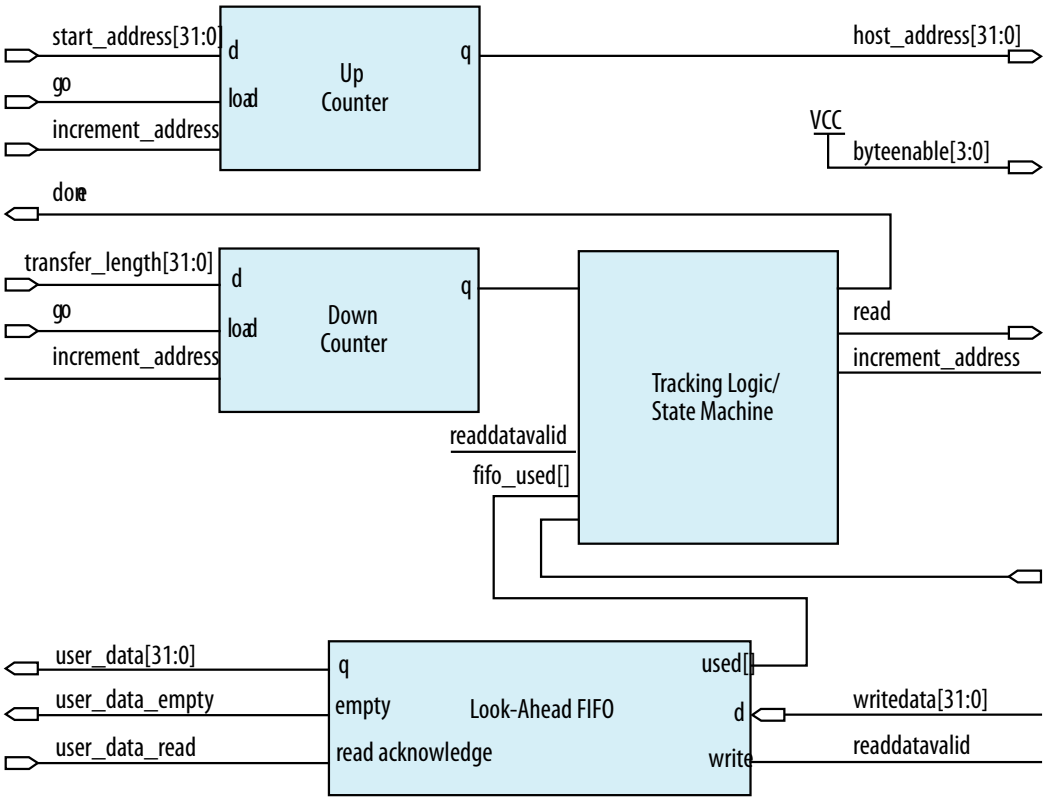
The datapath logic includes the `readdata` and `readdatavalid` signals. If your host can accept data on every clock cycle, you can register the data with the `readdatavalid` as an enable bit. If your host cannot process a continuous stream of read data, it must buffer the data in a FIFO. The control logic must stop issuing reads when the FIFO reaches a predetermined fill level to prevent FIFO overflow.

4.10.1.2. Expected Throughput Improvement

The throughput improvement that you can achieve with a pipelined read host is typically directly proportional to the pipeline depth of the interconnect and the agent interface. For example, if the total latency is two cycles, you can double the throughput by inserting a pipelined read host, assuming the agent interface also supports pipeline transfers. If either the host or agent does not support pipelined read transfers, then the interconnect asserts `waitrequest` until the transfer completes. You can also gain throughput when there are some cycles of overhead before a read response.

Where reads are not pipelined, the throughput is reduced. When both the host and agent interfaces support pipelined read transfers, data flows in a continuous stream after the initial latency. You can use a pipelined read host that stores data in a FIFO to implement a custom DMA, hardware accelerator, or off-chip communication interface.

Figure 188. Pipelined Read Host



This example shows a pipelined read host that stores data in a FIFO. The host performs word accesses that are word-aligned and reads from sequential memory addresses. The transfer length is a multiple of the word size.

When the `go` bit is asserted, the host registers the `start_address` and `transfer_length` signals. The host begins issuing reads continuously on the next clock cycle until the length register reaches zero. In this example, the word size is four bytes so that the address always increments by four, and the length decrements by four. The `read` signal remains asserted unless the FIFO fills to a predetermined level. The address register increments and the length register decrements if the length has not reached 0 and a read is posted.

The host posts a read transfer every time the `read` signal is asserted and the `waitrequest` is deasserted. The host issues reads until the entire buffer has been read or `waitrequest` is asserted. An optional tracking block monitors the `done` bit. When the length register reaches zero, some reads are outstanding. The tracking logic prevents assertion of `done` until the last read completes, and monitors the number of reads posted to the interconnect so that it does not exceed the space remaining in the `readdata` FIFO. This example includes a counter that verifies that the following conditions are met:

- If a read is posted and `readdatavalid` is deasserted, the counter increments.
- If a read is not posted and `readdatavalid` is asserted, the counter decrements.

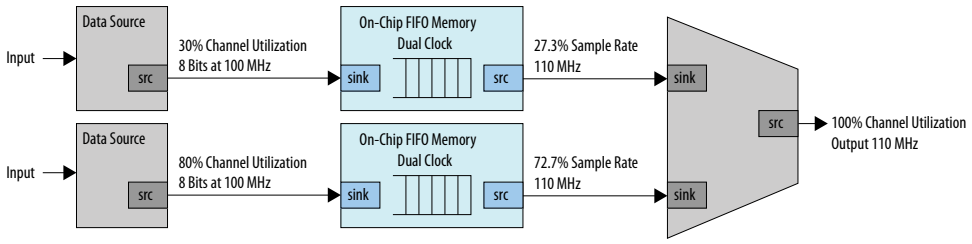
When the `length` register and the tracking logic counter reach zero, all the reads have completed and the `done` bit is asserted. The `done` bit is important if a second host overwrites the memory locations that the pipelined read host accesses. This bit guarantees that the reads have completed before the original data is overwritten.

4.10.2. Multiplexer Examples

You can combine adapters with streaming components to create datapaths whose input and output streams have different properties. The following examples demonstrate datapaths in which the output stream exhibits higher performance than the input stream.

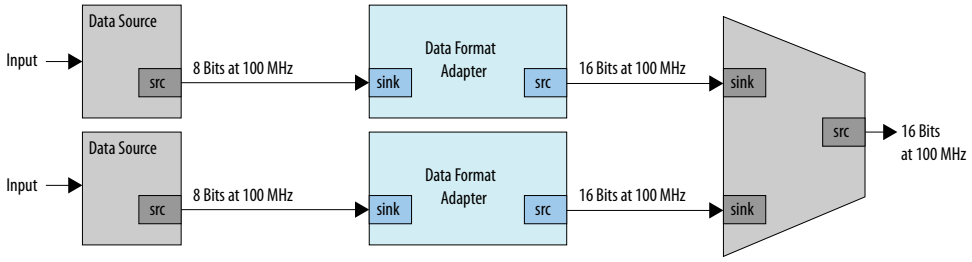
The diagram below illustrates a datapath that uses the dual clock version of the on-chip FIFO memory to boost the frequency of input data from 100 MHz to 110 MHz by sampling two input streams at differential rates. The on-chip FIFO memory has an input clock frequency of 100 MHz, and an output clock frequency of 110 MHz. The channel multiplexer runs at 110 MHz and samples one input stream 27.3 percent of the time, and the second 72.7 percent of the time. You must know what the typical and maximum input channel utilizations are before for this type of design. For example, if the first channel hits 50% utilization, the output stream exceeds 100% utilization.

Figure 189. Datapath that Doubles the Clock Frequency



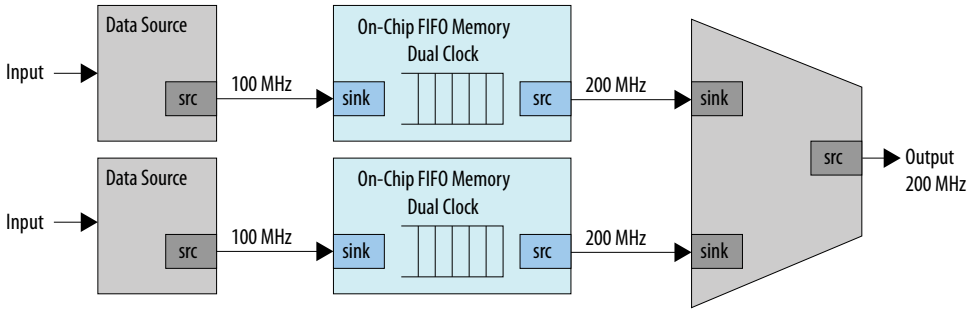
The diagram below illustrates a datapath that uses a data format adapter and Avalon streaming channel multiplexer to merge the 8-bit 100 MHz input from two streaming data sources into a single 16-bit 100 MHz streaming output. This example shows an output with double the throughput of each interface with a corresponding doubling of the data width.

Figure 190. Datapath to Double Data Width and Maintain Original Frequency



The diagram below illustrates a datapath that uses the dual clock version of the on-chip FIFO memory and Avalon streaming channel multiplexer to merge the 100 MHz input from two streaming data sources into a single 200 MHz streaming output. This example shows an output with double the throughput of each interface with a corresponding doubling of the clock frequency.

Figure 191. Datapath to Boost the Clock Frequency



4.11. Optimizing Platform Designer System Performance Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2022.04.02	22.1	• Updated entire chapter for new AXI "manager" and AXI "subordinate" replacement terms. Refer to the AMBA® AXI and ACE Protocol Specification.
2021.03.29	21.1	• Converted to "host" and "agent" inclusive terminology for Avalon memory mapped interface descriptions and related GUI elements throughout.
2018.12.15	18.1.0	• Replaced references to System Contents tab with new System View tab.
2017.11.06	17.1.0	• Changed instances of *Qsys Pro* to *Platform Designer*
2016.10.31	16.1.0	• Implemented Intel rebranding. • Implemented Qsys rebranding.
2015.11.02	15.1.0	• Added:*Reset Polarity and Synchronization in Qsys*. • Changed instances of *Quartus II* to *Quartus Prime*.
2015.05.04	15.0.0	*Multiplexer Examples*, rearranged description text for the figures.
May 2013	13.0.0	AMBA APB support.
November 2012	12.1.0	AMBA AXI4 support.
June 2012	12.0.0	AMBA AXI3 support.
November 2011	11.1.0	New document release.

5. Platform Designer Interconnect

Platform Designer interconnect is a high-bandwidth structure that allows you to connect IP components to other IP components with various interfaces.

Platform Designer allows you to establish connections between Avalon and AXI interfaces by generating an interconnect logic. This logic enables you to handle the protocol differences. Platform Designer creates the interconnect logic by converting all the protocols to a proprietary packet format. Then, the tool routes the packet through network switches to the appropriate AXI subordinates or Avalon agents. Here, the packet converts to the subordinate's protocol.(10)

Platform Designer supports Avalon, AMBA 3 AXI (version 1.0), AMBA 4 AXI (version 2.0), AMBA 4 AXI-Lite (version 2.0), AMBA 4 AXI-Stream (version 1.0), and AMBA 3 APB (version 1.0) interface specifications.

The video *AMBA AXI and Intel Avalon Interoperation Using Platform Designer* describes seamless integration of IP components using the AMBA AXI and the Intel Avalon interfaces.

Synchronous Reset Support

Platform Designer interconnect supports synchronous reset of registers in the interconnect. Use of synchronous reset can result in higher performance for Stratix 10 designs because Stratix 10 Hyper-Registers lack a reset signal. If a register in your Stratix 10 design uses asynchronous reset, the Compiler cannot implement the register as a Hyper-Register, potentially reducing performance.

When **Use synchronous reset** is set to **True** in the **Domains** tab, all registers in the interconnect use synchronous reset. The **Use synchronous reset** option is enabled by default for Stratix 10 devices, but is disabled by default for all other devices.

Note: In Platform Designer systems with no clock domain crossing, the initial reset requires asserting for at least 16 cycles. This action prevents the propagation of incorrect values that the reset tree skew may generate during the initial reset release, ensuring the resetting of all the Platform Designer components and interconnect. If system has multiple clocks, reset must be held high for at least 16 slowest clock cycles.

- Specifying Interconnect Parameters on page 71

5.1. Memory-Mapped Interfaces

Platform Designer supports the implementation of memory-mapped interfaces for Avalon, AXI, and APB protocols.

Platform Designer interconnect transmits memory-mapped transactions between hosts and agents in packets. The command network transports read and write packets from host interfaces to agent interfaces. The response network transports response packets from agent interfaces to host interfaces.

For each component interface, Platform Designer interconnect manages memory-mapped transfers and interacts with signals on the connected interface. Host and agent interfaces can implement different signals based on interface parameterizations, and Platform Designer interconnect provides any necessary adaptation between them. In the path between host and agents, Platform Designer interconnect may introduce registers for timing synchronization, finite state machines for event sequencing, or nothing at all, depending on the services required by the interfaces.

Platform Designer interconnect supports the following implementation scenarios:

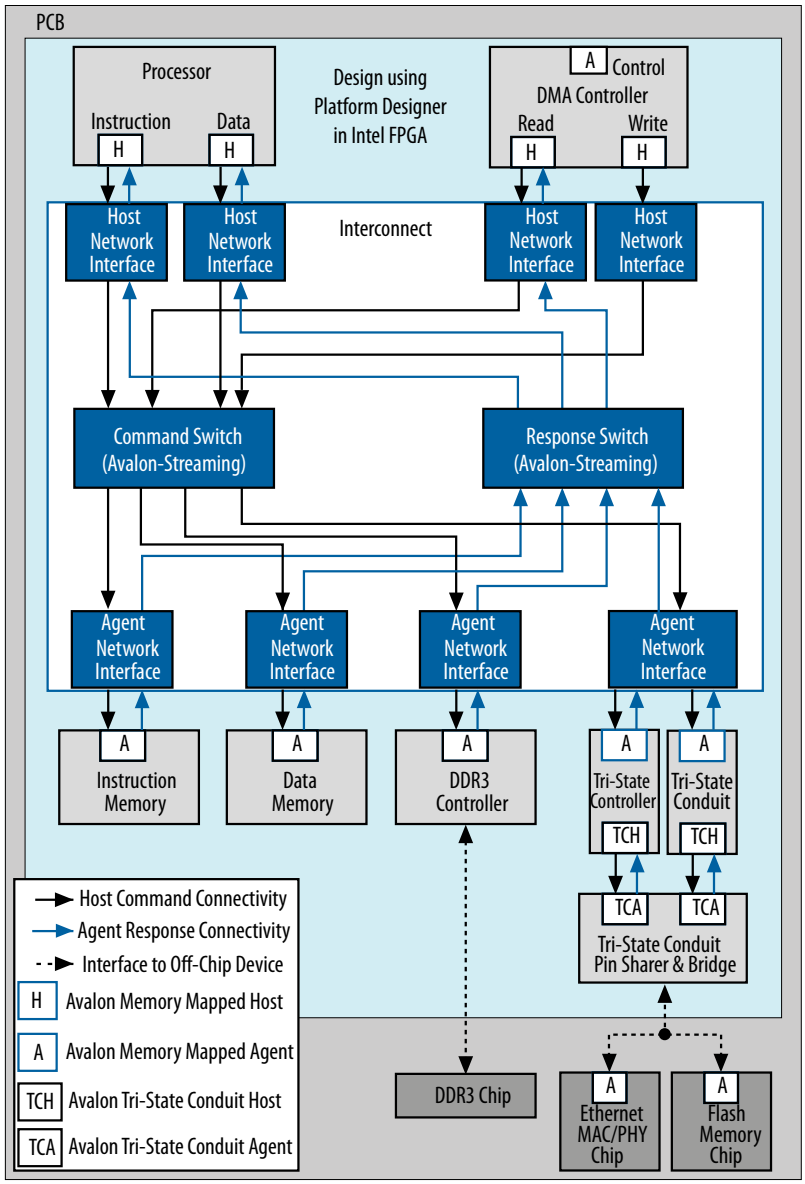
- Any number of components with host and agent interfaces. The host-to-agent relationship can be one-to-one, one-to-many, many-to-one, or many-to-many.
- Hosts and agents of different data widths.
- Hosts and agents operating in different clock domains.
- IP Components with different interface properties and signals. Platform Designer adapts the component interfaces so that interfaces with the following differences can be connected:
  - Avalon and AXI interfaces that use active-high and active-low signaling. AXI signals are active high, except for the reset signal.
  - Interfaces with different burst characteristics.
  - Interfaces with different latencies.
  - Interfaces with different data widths.
  - Interfaces with different optional interface signals.

    Note: Since interface connections between AMBA 3 AXI and AMBA 4 AXI declare a fixed set of signals with variable latency, there is no need for adapting between active-low and active-high signaling, burst characteristics, different latencies, or port signatures. Adaptation might be necessary between Avalon interfaces.

In this example, there are two components hosting the system, a processor and a DMA controller, each with two host interfaces. The hosts connect through the Platform Designer interconnect to agents in the Platform Designer system.

The dark blue blocks represent interconnect components. The dark gray boxes indicate items outside of the Platform Designer system and the Quartus Prime software design, and show how to export component interfaces and how to connect these interfaces to external devices.

Figure 192. Platform Designer interconnect for an Avalon Memory Mapped System with Multiple Hosts



5.1.1. Platform Designer Packet Format

The Platform Designer packet format supports Avalon, AXI, and APB transactions. Memory-mapped transactions between hosts and agents are encapsulated in Platform Designer packets. For Avalon systems without AXI or APB interfaces, some fields are ignored or removed.

5.1.1.1. Fields in the Platform Designer Packet Format

The fields of the Platform Designer packet format are of variable length to minimize resource usage. However, if most components in a design have a single data width, for example 32-bits, and a single component has a data width of 64-bits, Platform Designer inserts a width adapter to accommodate 64-bit transfers.

Table 44. Platform Designer Packet Format for Memory-Mapped Host and Agent Interfaces

Command	Description
`Address`	Specifies the byte address for the lowest byte in the current cycle. There are no restrictions on address alignment.
`Size`	Encodes the run-time size of the transaction. In conjunction with address, this field describes the segment of the payload that contains valid data for a beat within the packet.
`Address Sideband`	Carries "address" sideband signals. The interconnect passes this field from host to agent. This field is valid for each beat in a packet, even though it is only produced and consumed by an address cycle. Up to 8-bit sideband signals are supported for both read and write address channels.
`Cache`	Carries the AXI cache signals.
`Transaction (Exclusive)`	Indicates whether the transaction has exclusive access.
`Transaction (Posted)`	Used to indicate non-posted writes (writes that require responses).
`Data`	For command packets, carries the data to be written. For read response packets, carries the data that has been read.
`Byteenable`	Specifies which symbols are valid. AXI can issue or accept any byteenable pattern. For compatibility with Avalon, Intel recommends that you use the following legal values for 32-bit data transactions between Avalon hosts and agents: • **1111**—Writes full 32 bits • **0011**—Writes lower 2 bytes • **1100**—Writes upper 2 bytes • **0001**—Writes byte 0 only • **0010**—Writes byte 1 only • **0100**—Writes byte 2 only • **1000**—Writes byte 3 only
`Source_ID`	The ID of the host or agent that initiated the command or response.
`Destination_ID`	The ID of the host or agent to which the command or response is directed.
`Response`	Carries the AXI response signals.
`Thread ID`	Carries the AXI transaction ID values.
`Byte count`	The number of bytes remaining in the transaction, including this beat. Number of bytes requested by the packet.

continued...

Command	Description
`Burstwrap`	The burstwrap value specifies the wrapping behavior of the current burst. The burstwrap value is of the form $2^{<n>}$ -1. The following types are defined: • Variable wrap–Variable wrap bursts can wrap at any integer power of 2 value. When the burst reaches the wrap boundary, it wraps back to the previous burst boundary so that only the low order bits are used for addressing. For example, a burst starting at address 0x1C, with a burst wrap boundary of 32 bytes and a burst size of 20 bytes, would write to addresses 0x1C, 0x0, 0x4, 0x8, and 0xC. • For a burst wrap boundary of size <*m*>, `Burstwrap` = <*m*> - 1, or for this case `Burstwrap` = (32 - 1) = 31 which is 2^5 -1. • For AXI managers, the burstwrap boundary value (m) is based on the different AXBURST: — Burstwrap set to all 1's. For example, for a 6-bit burstwrap, burstwrap is `6'b111111`. — For `WRAP` bursts, burstwrap = AXLEN * size – 1. — For `FIXED` bursts, burstwrap = size – 1. — Sequential bursts increment the address for each transfer in the burst. For sequential bursts, the `Burstwrap` field is set to all 1s. For example, with a 6-bit `Burstwrap` field, the value for a sequential burst is 6'b111111 or 63, which is 2^6 - 1. For Avalon hosts, Platform Designer adaptation logic sets a hardwired value for the burstwrap field, according to the declared host burst properties. For example, for a host that declares sequential bursting, the burstwrap field is set to ones. Similarly, hosts that declare burst have their burstwrap field set to the appropriate constant value. AXI managers choose their burst type at run-time, depending on the value of the `AW` or ARBURST signal. The interconnect calculates the burstwrap value at run-time for AXI managers.(11)
`Protection`	Access level protection. When the lowest bit is 0, the packet has normal access. When the lowest bit is 1, the packet has privileged access. For Avalon memory mapped interfaces, this field maps directly to the privileged access signal, which allows a memory-mapped host to write to an on-chip memory ROM instance. The other bits in this field support AXI secure accesses and uses the same encoding, as described in the AXI specification.
`QoS`	QoS (Quality of Service Signaling) is a 4-bit field that is part of the AMBA 4 AXI interface that carries QoS information for the packet from the AXI manager to the AXI subordinate. Transactions from AMBA 3 AXI and Avalon hosts have the default value `4'b0000`, that indicates that they are not participating in the QoS scheme. QoS values are dropped for agents that do not support QoS.
`Data sideband`	Carries data sideband signals for the packet. On a write command, the data sideband directly maps to `WUSER`. On a read response, the data sideband directly maps to RUSER. On a write response, the data sideband directly maps to BUSER.

5.1.1.2. Transaction Types for Memory-Mapped Interfaces

Table 45. Transaction Types for Memory-Mapped Interfaces

The table below describes the information that each bit transports in the packet format's transaction field.

Bit	Name	Definition
`0`	`PKT_TRANS_READ`	When asserted, indicates a read transaction.
`1`	`PKT_TRANS_COMPRESSED_READ`	For read transactions, specifies whether the read command can be expressed in a single cycle (all `byteenables` asserted on every cycle).

continued...

(11) This document refers to the new AXI "manager" and AXI "subordinate" inclusive terms to replace outmoded terms, as the latest version of the AMBA® AXI and ACE Protocol Specification describes.

Bit	Name	Definition
2	PKT_TRANS_WRITE	When asserted, indicates a write transaction.
3	PKT_TRANS_POSTED	When asserted, no response is required.
4	PKT_TRANS_LOCK	When asserted, indicates arbitration is locked. Applies to write packets.

5.1.1.3. Platform Designer Transformations

The memory-mapped host and agent components connect to network interface modules that encapsulate the transaction in Avalon streaming packets. The memory-mapped interfaces have no information about the encapsulation or the function of the layer transporting the packets. The interfaces operate in accordance with memory-mapped protocol and use the read and write signals and transfers.

Figure 193. Transformation when Generating a System with Memory-Mapped Components

Platform Designer components that implement the blocks appear shaded.

5.1.2. Interconnect Domains

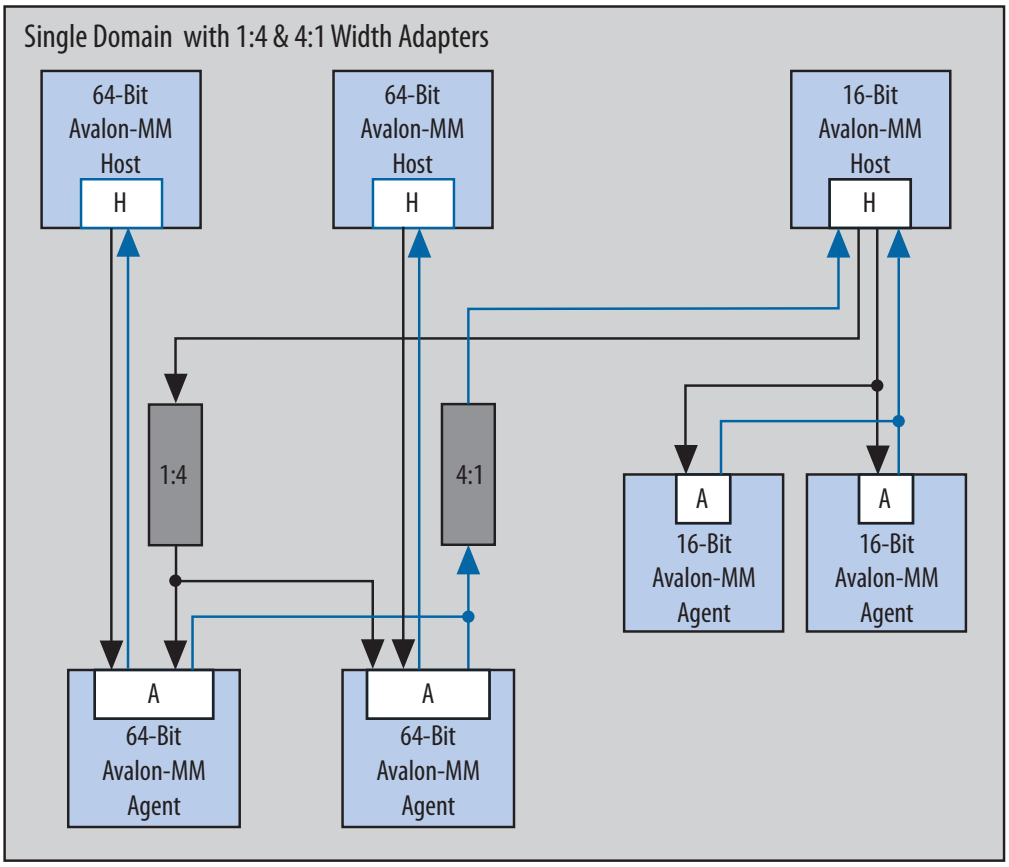
An interconnect domain is a group of connected memory-mapped hosts and agents that share the same interconnect. The components in a single interconnect domain share the same packet format.

5.1.2.1. Using One Domain with Width Adaptation

When one of the hosts in a system connects to all the agents, Platform Designer creates a single domain with two packet formats: one with 64-bit data, and one with 16-bit data. A width adapter manages accesses between the 16-bit host and 64-bit

agents. In the following example, two 64-bit hosts access two 64-bit agents. One 16-bit host, accesses two 16-bit agents and two 64-bit agents. The 16-bit Avalon host connects through a 1:4 adapter, then a 4:1 adapter to reach its 16-bit agents.

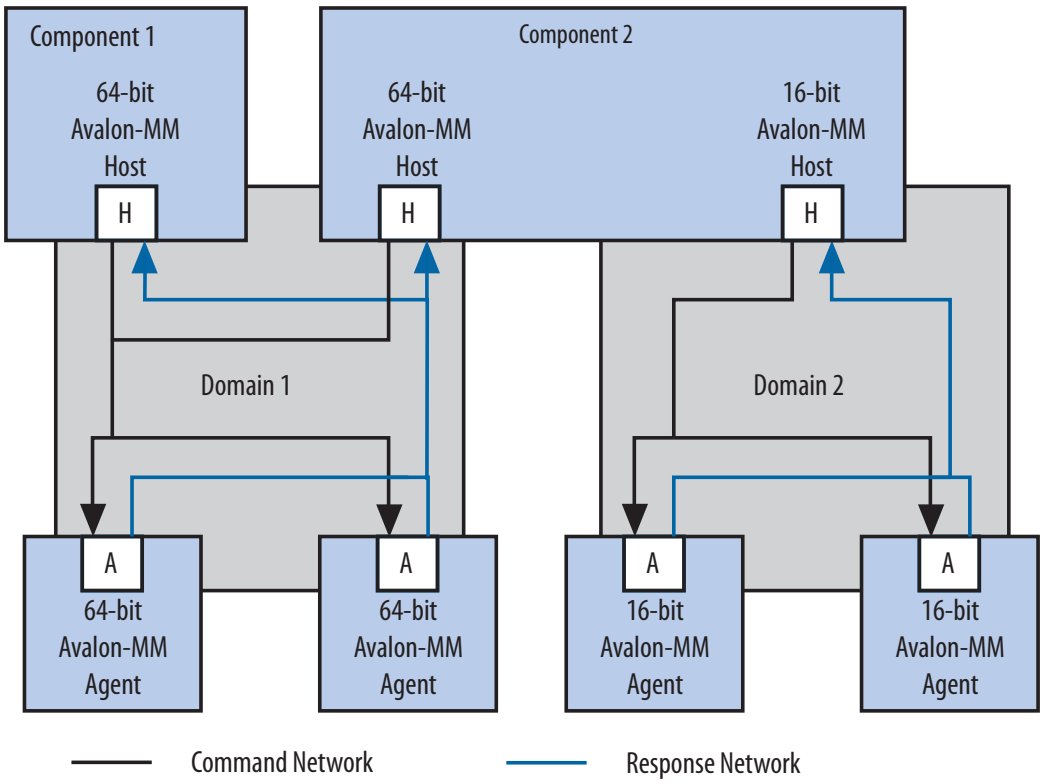
Figure 194. One Domain with 1:4 and 4:1 Width Adapters



5.1.2.2. Using Two Separate Domains

In the following example, Platform Designer uses two separate domains. The first domain includes two 64-bit hosts connected to two 64-bit agents. A second domain includes one 16-bit host connected to two 16-bit agents. Because the interfaces in Domain 1 and Domain 2 do not share any connections, Platform Designer can optimize the packet format for the two separate domains. In this example, the first domain uses a 64-bit data width and the second domain uses 16-bit data.

Figure 195. Two Separate Domains

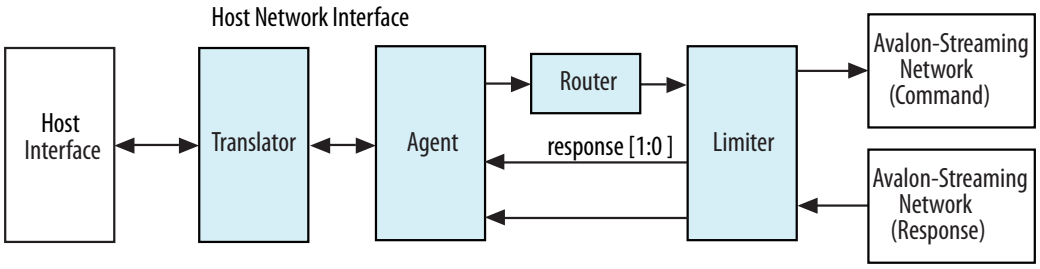


5.1.3. Avalon Host and AXI Manager Network Interfaces

Figure 196. Avalon Memory Mapped Host Network Interface

Avalon network interfaces drive default values for the QoS and BUSER, WUSER, and RUSER packet fields in the host agent, and drop the packet fields in the agent.

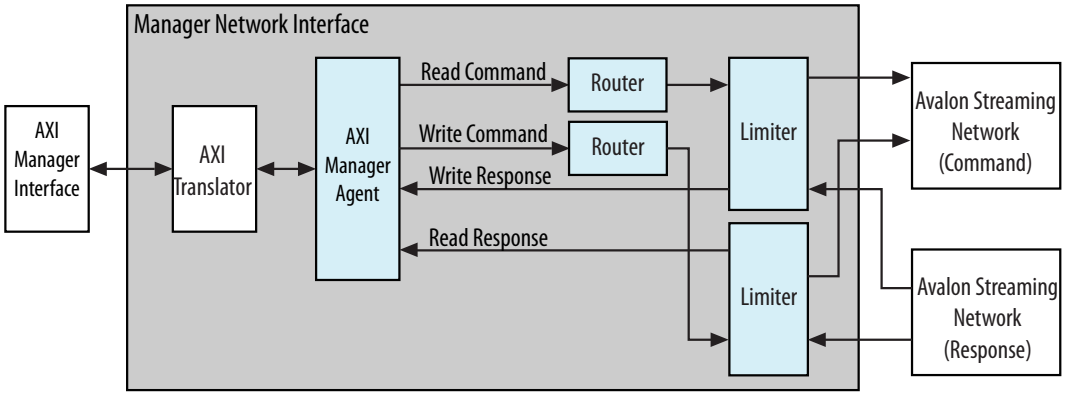
Note: The `response` signal from the Limiter to the Agent is optional.



An AMBA 4 AXI manager supports `INCR` bursts up to 256 beats, QoS signals, and data sideband signals.(12)

(12) This document refers to the new AXI "manager" and AXI "subordinate" inclusive terms to replace outmoded terms, as the latest version of the AMBA® AXI and ACE Protocol Specification describes.

Figure 197. AXI Manager Network Interface



Note: For a complete definition of the optional read response signal, refer to *Avalon Memory-Mapped Interface Signal Types* in the *Avalon Interface Specifications*.

Related Information

- Avalon Interface Specifications
- Creating a System with Platform Designer on page 11

5.1.3.1. Avalon Memory Mapped Host Agent

The Avalon Memory Mapped Host Agent translates Avalon memory mapped host transactions into Platform Designer command packets and translates the Platform Designer Avalon memory mapped agent response packets into Avalon memory mapped responses.

5.1.3.2. Avalon Memory Mapped Host Translator

The Avalon Memory Mapped Host Translator interfaces with an Avalon memory mapped host component and converts the Avalon memory mapped host interface to a simpler representation for use in Platform Designer.

The Avalon Memory Mapped Host translator performs the following functions:

- Translates active-low signaling to active-high signaling
- Inserts wait states to prevent an Avalon memory mapped host from reading invalid data
- Translates word and symbol addresses
- Translates word and symbol burst counts
- Manages re-timing and re-sequencing bursts
- Removes unnecessary address bits

5.1.3.3. AXI Manager Agent

An AXI Manager Agent accepts AXI commands and produces Platform Designer command packets. It also accepts Platform Designer response packets and converts those into AXI responses. This component has separate packet channels for read

commands, write commands, read responses, and write responses. The Avalon host agent drives the QoS and BUSER, WUSER, and RUSER packet fields with default values AXQO and b0000, respectively.

Note: For signal descriptions, refer to *Platform Designer Packet Format*.

Related Information

Fields in the Platform Designer Packet Format on page 254

5.1.3.4. AXI Translator

AMBA 4 AXI allows omitting signals from interfaces. The translator bridges between these "incomplete" AMBA 4 AXI interfaces and the "complete" AMBA 4 AXI interface on the network interfaces.

Attention: If you connect an Avalon agent or to a host, or connect an AXI subordinate to a manager, without response ports, the interconnect could ignore transaction responses, such as SLAVEERROR or DECODEERROR. This situation could lead to returning invalid data to the manager or host.

The AXI translator is inserted for both AXI managers and subordinates and performs the following functions:

- Matches ID widths between the manager and subordinates in 1x1 systems.
- Drives default values as defined in the *AMBA Protocol Specifications* for missing signals.
- Performs lock transaction bit conversion when an AMBA 3 AXI manager connects to an AMBA 4 AXI subordinate in 1x1 systems.

Related Information

Arm AMBA Protocol Specifications

5.1.3.5. APB Manager Agent

An APB manager agent accepts APB commands and produces or generates Platform Designer command packets. It also converts Platform Designer response packets to APB responses.

5.1.3.6. APB Subordinate Agent

An APB subordinate agent issues resulting transaction to the APB interface. It also accepts creates Platform Designer response packets.

5.1.3.7. APB Translator

An APB peripheral does not require pslverr signals to support additional signals for the APB debug interface.

The APB translator is inserted for both the manager and subordinate and performs the following functions:

- Sets the response value default to OKAY if the APB subordinate does not have a `pslverr` signal.
- Turns on or off additional signals between the APB debug interface, which is used with HPS (Intel SoC's Hard Processor System).

5.1.3.8. AHB Subordinate Agent

The Platform Designer interconnect supports non-bursting Advanced High-performance Bus (AHB) subordinate interfaces.

5.1.3.9. Memory-Mapped Router

The Memory-Mapped Router routes command packets from the host to the agent, and response packets from the agent to the host. For host command packets, the router uses the address to set the `Destination_ID` and Avalon streaming channel. For the agent response packet, the router uses the `Destination_ID` to set the Avalon streaming channel. The demultiplexers use the Avalon streaming channel to route the packet to the correct destination.

5.1.3.10. Memory-Mapped Traffic Limiter

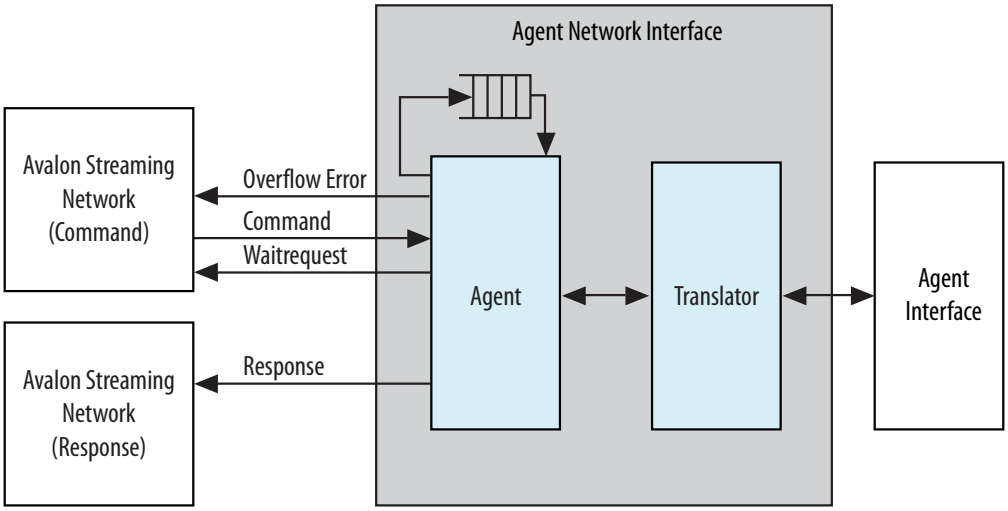
The Memory-Mapped Traffic Limiter ensures the responses arrive in order. It prevents any command from being sent if the response could conflict with the response for a command that has already been issued. By guaranteeing in-order responses, the Traffic Limiter simplifies the response network.

5.1.4. Avalon Agent and AXI Subordinate Network Interfaces

5.1.4.1. Avalon Memory Mapped Agent Translator

The Avalon Memory Mapped Agent Translator converts the Avalon memory mapped agent interface to a simplified representation that the Platform Designer network can use.

Figure 198. Avalon Memory Mapped Agent Network Interface



An Avalon Memory Mapped Agent Translator performs the following functions:

- Drives the `beginbursttransfer` and `byteenable` signals.
- Supports Avalon memory mapped agents that operate using fixed timing and or agents that use the `readdatavalid` signal to identify valid data.
- Translates the `read`, `write`, and `chipselect` signals into the representation that the Avalon streaming agent response network uses.
- Converts active low signals to active high signals.
- Translates word and symbol addresses and burstcounts.
- Handles burstcount timing and sequencing.
- Removes unnecessary address bits.

Related Information

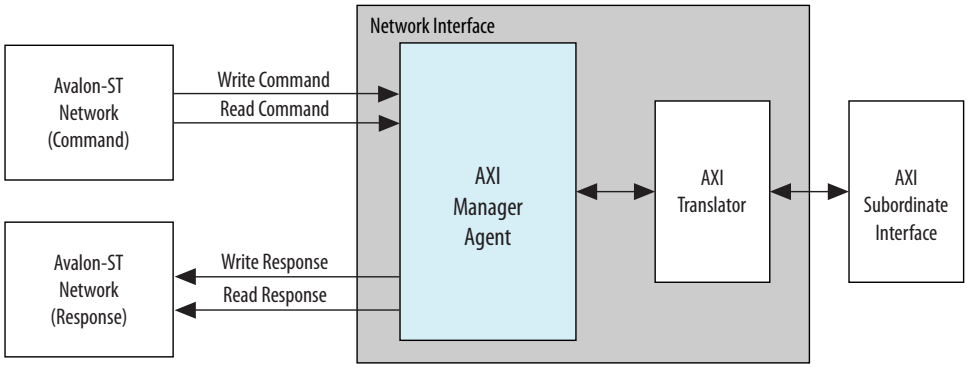
Avalon Agent and AXI Subordinate Network Interfaces on page 261

5.1.4.2. AXI Translator

AMBA 4 AXI allows omitting signals from interfaces. The translator bridges between these "incomplete" AMBA 4 AXI interfaces and the "complete" AMBA 4 AXI interface on the network interfaces.

Figure 199. AXI Subordinate Network Interface

An AMBA 4 AXI subordinate supports up to 256 beat INCR bursts, QoS signals, and data sideband signals.



The AXI translator is inserted for both AMBA 4 AXI manager and subordinate, and performs the following functions:

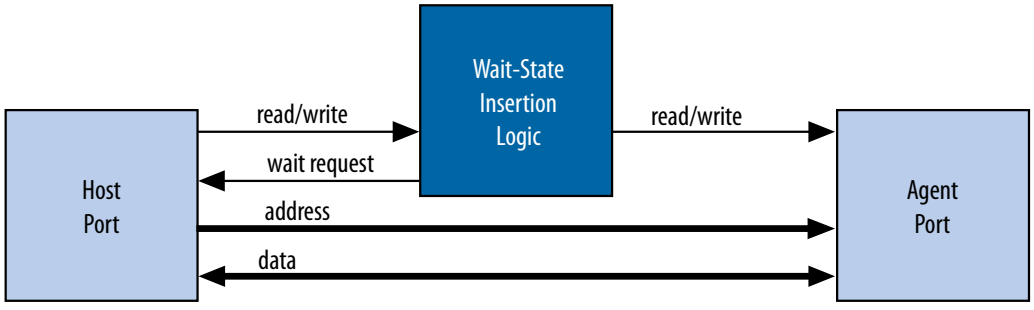
- Matches ID widths between manager and subordinate in 1x1 systems.
- Drives default values as defined in the *AMBA Protocol Specifications* for missing signals.
- Performs lock transaction bit conversion when an AMBA 3 AXI manager connects to an AMBA 4 AXI subordinate in 1x1 systems.

5.1.4.3. Wait State Insertion

Wait states extend the duration of a transfer by one or more cycles. Wait state insertion logic accommodates the timing needs of each agent, and causes the host to wait until the agent can proceed. Platform Designer interconnect inserts wait states into a transfer when the target agent cannot respond in a single clock cycle, as well as in cases when agent `read` and `write` signals have setup or hold time requirements.

Wait state insertion logic is a small finite-state machine that translates control signal sequencing between the agent side and the host side. Platform Designer interconnect can force a host to wait for the wait state needs of an agent; for example, arbitration logic in a multi-host system. Platform Designer generates wait state insertion logic based on the properties of all agents in the system.

Figure 200. Wait State Insertion Logic for One Host and One Agent



5.1.4.4. Avalon Memory Mapped Agent Component

The Avalon Memory Mapped Agent component accepts command packets and issues the resulting transactions to the Avalon interface. For pipelined agents, an Avalon streaming FIFO stores information about pending transactions. The size of this FIFO is the maximum number of pending responses that you specify when creating the agent component. The Avalon Memory Mapped Agent component also `backpressures` the Avalon memory mapped host command interface when the FIFO is full if the agent component includes the `waitrequest` signal.

5.1.4.5. AXI Subordinate Agent

An AXI subordinate Agent works like a reverse AXI manager agent. The AXI subordinate Agent accepts Platform Designer command packets to create AXI commands, and accepts AXI responses to create Platform Designer response packets. This component has separate packet channels for read commands, write commands, read responses, and write responses.

5.1.5. Arbitration

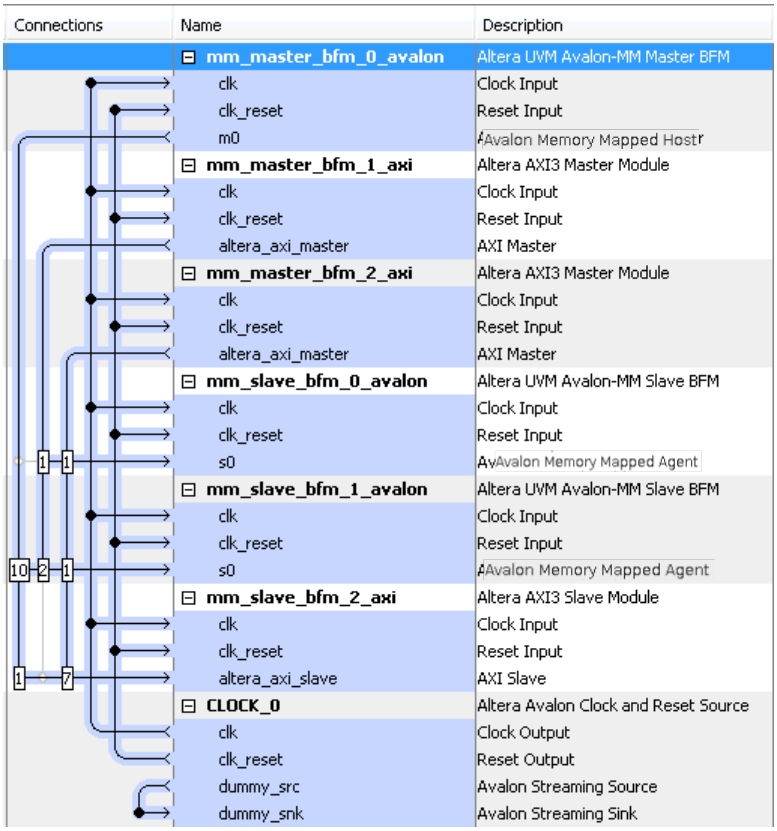
When multiple hosts contend for access to an agent, Platform Designer automatically inserts arbitration logic, which grants access in fairness-based, round-robin order. You can alternatively choose to designate an agent as a fixed priority arbitration agent, and then manually assign priorities in the Platform Designer GUI.

5.1.5.1. Round-Robin Arbitration

When multiple hosts contend for access to an agent, Platform Designer automatically inserts arbitration logic which grants access in fairness-based, round-robin order.

In a fairness-based arbitration protocol, each host has an integer value of transfer *shares* with respect to an agent. One share represents permission to perform one transfer. The default arbitration scheme is equal share round-robin that grants equal, sequential access to all requesting hosts. You can change the arbitration scheme to weighted round-robin by specifying a relative number of arbitration shares to the hosts that access a given agent. AXI subordinates have separate arbitration for their independent read and write channels, and the **Arbitration Shares** setting affects both the read and write arbitration. To display arbitration settings, right-click an instance on the **System View** tab, and then click **Show Arbitration Shares**.

Figure 201. Arbitration Shares in the Connections Column



5.1.5.1.1. Fairness-Based Shares

In a fairness-based arbitration scheme, each host-to-agent connection provides a transfer share count. This count is a request for the arbiter to grant a specific number of transfers to this host before giving control to a different host. One share represents permission to perform one transfer.

Figure 202. Arbitration of Continuous Transfer Requests from Two Hosts

Consider a system with two hosts connected to a single agent. Host 1 has its arbitration shares set to three, and Host 2 has its arbitration shares set to four. Host 1 and Host 2 continuously attempt to perform back-to-back transfers to the agent. The arbiter grants Host 1 access to the agent for three transfers, and then grants Host 2 access to the agent for four transfers. This cycle repeats indefinitely. The figure below describes the waveform for this scenario.

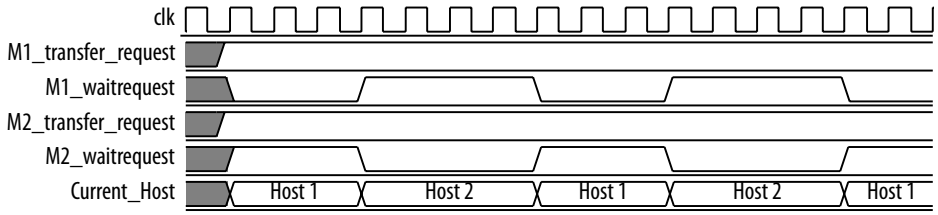


Figure 203. Arbitration of Two Hosts with a Gap in Transfer Requests

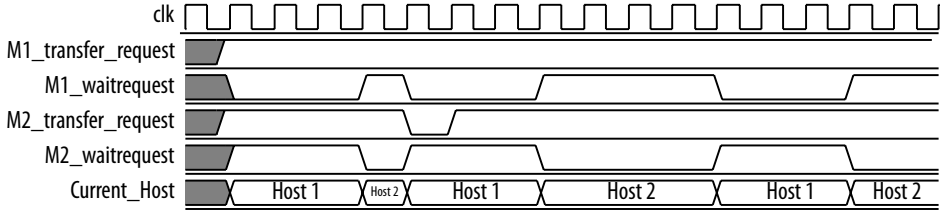
If a host stops requesting transfers before it exhausts its shares, it forfeits all its remaining shares, and the arbiter grants access to another requesting host. After completing one transfer, Host 2 stops requesting for one clock cycle. As a result, the arbiter grants access back to Host 1, which gets a replenished supply of shares.



5.1.5.1.2. Round-Robin Scheduling

When multiple hosts contend for access to an agent, the arbiter grants shares in round-robin order. Platform Designer includes only requesting hosts in the arbitration for each agent transaction.

5.1.5.2. Fixed Priority Arbitration

Fixed priority arbitration is an alternative arbitration scheme to the default round-robin scheme.

You can selectively apply fixed priority arbitration to any agent in a Platform Designer system. You can design Platform Designer systems where a subset of agents use the default round-robin arbitration, and other agents use fixed priority arbitration. Fixed priority arbitration uses a fixed priority algorithm to grant access to an agent amongst its connected hosts.

Set a fixed priority agent arbitration under **Interconnect Parameters** in the **Domains** tab. You can then assign an arbitration priority number for each host connected to a fixed priority agent in the **System View** tab, where the highest numeric value receives the highest priority. When multiple hosts request access to a fixed priority arbitrated agent, the arbiter gives the host with the highest priority first access to the agent.

For example, when a fixed priority agent receives requests from three hosts on the same cycle, the arbiter grants the host with highest assigned priority first access to the agent, and backpressures the other two hosts.

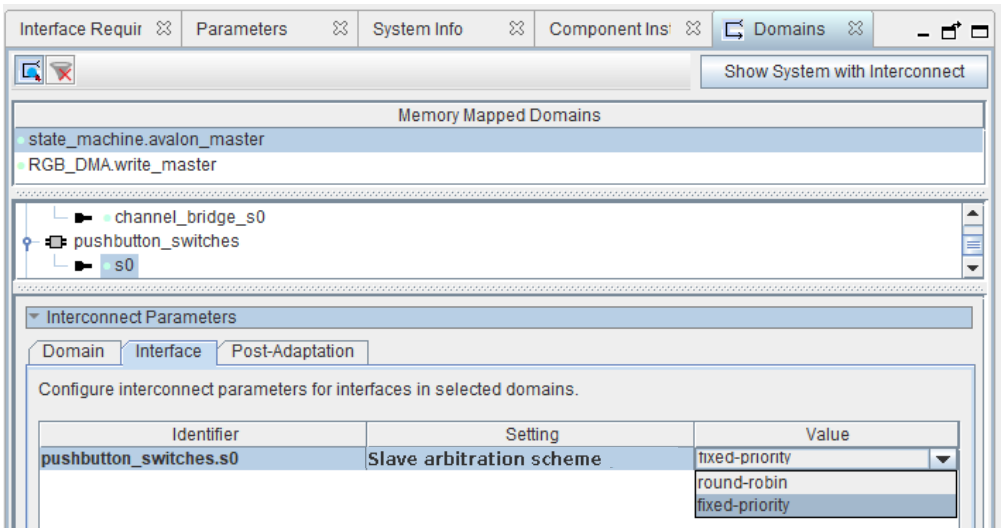
Note: When you connect an AXI manager to an Avalon memory mapped agent designated to use a fixed priority arbitrator, the interconnect instantiates a command-path intermediary round-robin multiplexer in front of the designated agent.

5.1.5.2.1. Designate a Platform Designer Agent to Use Fixed Priority Arbitration

You can designate any agent in your Platform Designer system to use fixed priority arbitration. You must assign each host connected to a fixed priority agent a numeric priority. The host with the highest higher priority receives first access to the agent. No two hosts can have the same priority.

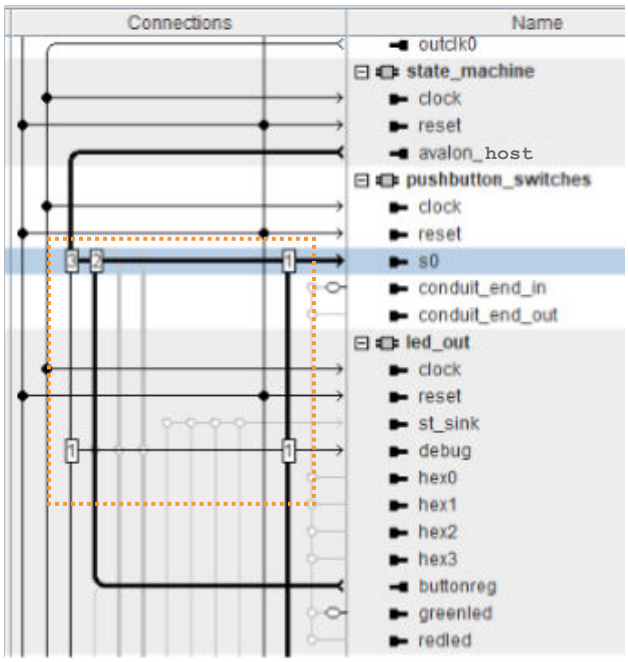
1. In Platform Designer, click **View ➤ Domains**.
2. Under **Interconnect Parameters**, click **Add** on the **Interface** tab to add a new requirement.
3. In the **Identifier** column, select the agent for fixed priority arbitration.

Figure 204. Interface Tab of Domains Tab



4. In the **Setting** column, select **Slave arbitration scheme**.
5. In the **Value** column, select **fixed-priority**.
6. Navigate to the **System View** tab.
7. In the **System View** tab, right-click the designated fixed priority agent, and then select **Show Arbitration Shares**.
8. For each host connected to the fixed priory arbitration agent, type a numerical arbitration priority in the box that appears in place of the connection circle.

Figure 205. Arbitration Priority Box



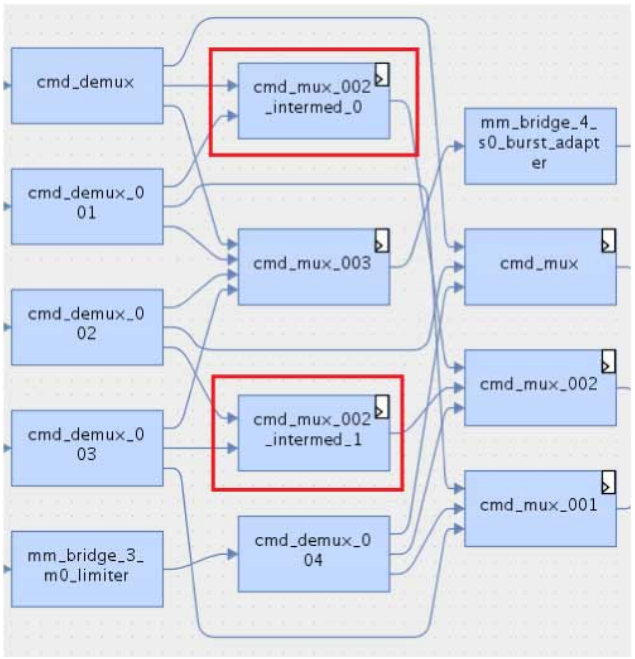
9. Right click the designated fixed priority agent and uncheck **Show Arbitration Shares** to return to the connection circles.

5.1.5.2.2. Fixed Priority Arbitration with AXI Managers and Avalon Memory Mapped Agents

When an AXI manager is connected to a designated fixed priority arbitration Avalon memory mapped agent, Platform Designer interconnect automatically instantiates an intermediary multiplexer in front of the Avalon memory mapped agent.

Since AXI managers have separate read and write channels, each channel appears as two separate managers to the Avalon memory mapped agent. To support fairness between the AXI manager's read and write channels, the instantiated round-robin intermediary multiplexer arbitrates between simultaneous read and write commands from the AXI manager to the fixed-priority Avalon memory mapped agent.

Figure 206. Intermediary Multiplexer Between AXI Manager and Avalon Memory Mapped Agent



When an AXI manager is connected to a fixed priority AXI subordinate, the manager's read and write channels are directly connected to the AXI subordinate's fixed-priority multiplexers. In this case, there is one multiplexer for the read command, and one multiplexer for the write command and therefore an intermediary multiplexer is not required.

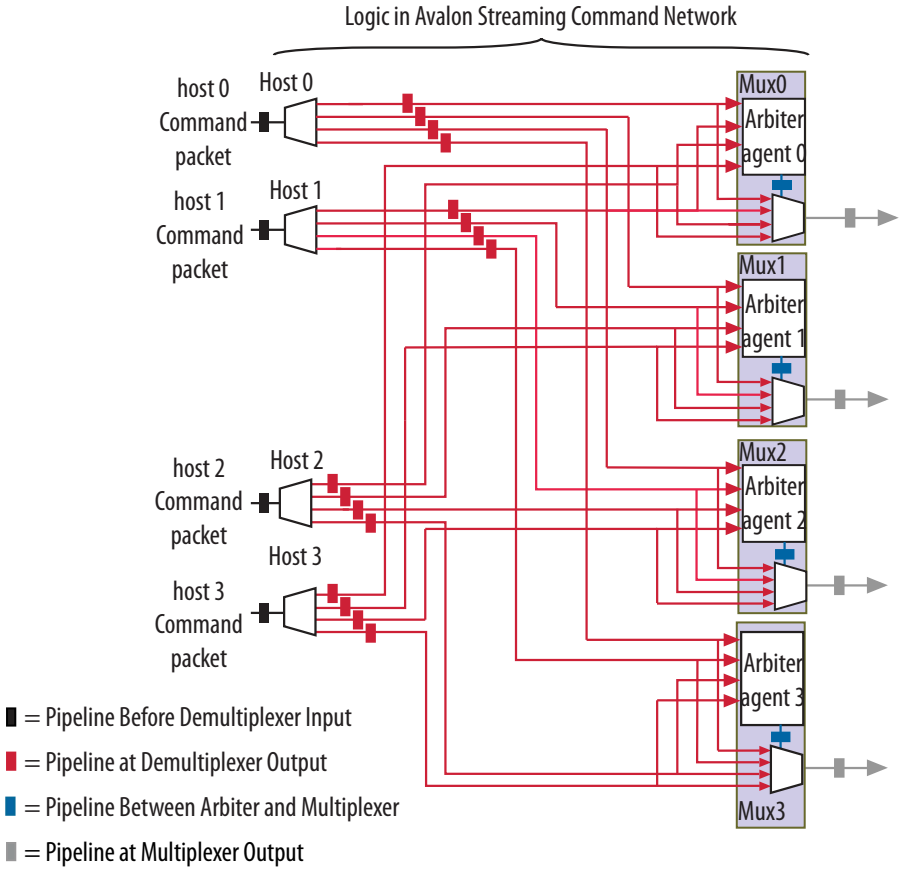
The red rectangles indicate placement of the intermediary multiplexer between the AXI manager and Avalon memory mapped agent due to the separate read and write channels of the AXI manager.

5.1.6. Memory-Mapped Arbiter

The input to the Memory-Mapped Arbiter is the command packet for all hosts requesting access to a specific agent. The arbiter outputs the channel number for the selected host. This channel number controls the output of a multiplexer that selects the agent device.

Figure 207. Arbitration Logic

In this example, four Avalon memory-mapped hosts connect to four Avalon memory-mapped agents. In each cycle, an arbiter positioned in front of each Avalon memory-mapped agent selects among the requesting Avalon memory-mapped hosts.



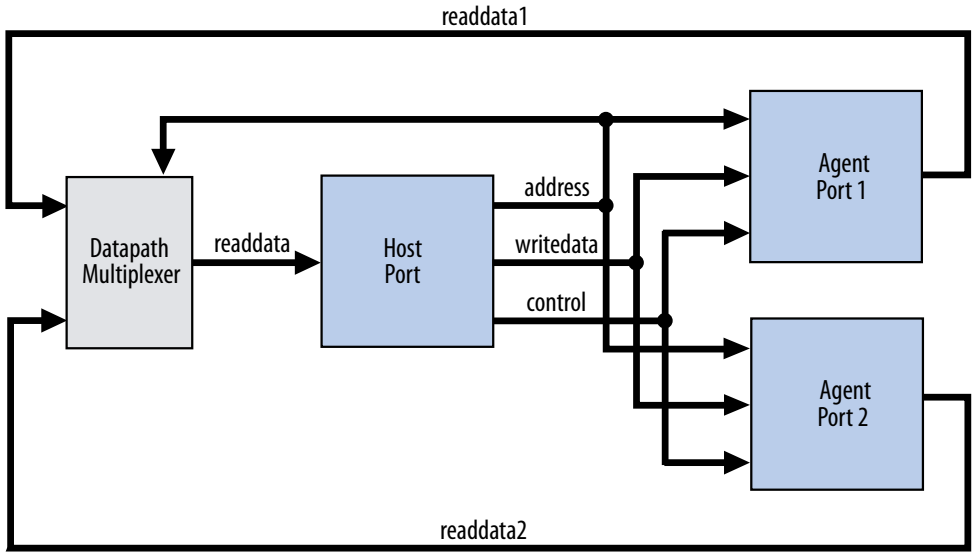
Note: If you specify a **Limit interconnect pipeline stages to** parameter greater than zero, the output of the Arbiter is registered. Registering this output reduces the amount of combinational logic between the host and the interconnect, increasing the f_{MAX} of the system.

Note: You can use the Memory-Mapped Arbiter for both round-robin and fixed priority arbitration.

5.1.7. Datapath Multiplexing Logic

Datapath multiplexing logic drives the `writedata` signal from the granted host to the selected agent, and the `readdata` signal from the selected agent back to the requesting host. Platform Designer generates separate datapath multiplexing logic for every host in the system (`readdata`), and for every agent in the system (`writedata`). Platform Designer does not generate multiplexing logic if it is not needed.

Figure 208. Datapath Multiplexing Logic for One Host and Two Agents



5.1.8. Width Adaptation

Platform Designer width adaptation converts between Avalon memory-mapped host and agents with different data and byte enable widths, and manages the run-time size requirements of AXI. Width adaptation for AXI to Avalon interfaces is also supported.

5.1.8.1. Memory-Mapped Width Adapter

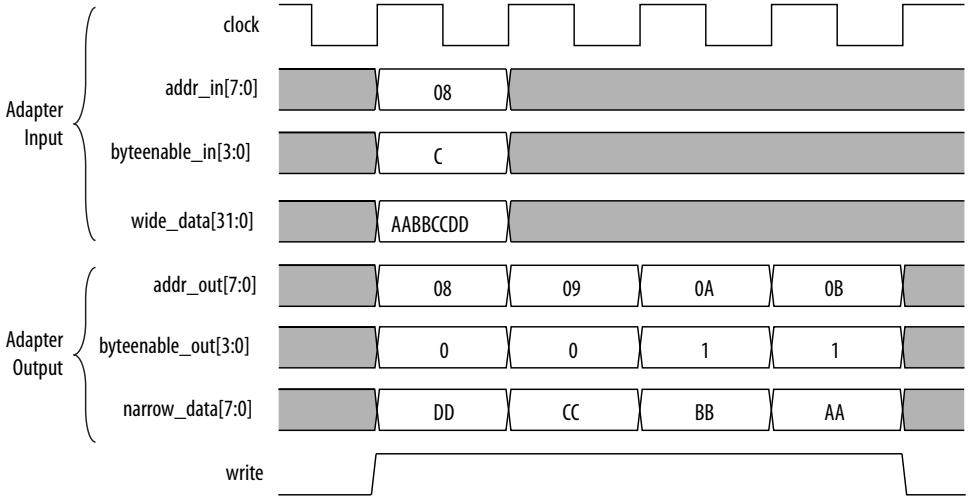
The Memory-Mapped Width Adapter is used in the Avalon streaming domain and operates with information contained in the packet format.

The memory-mapped width adapter accepts packets on its sink interface with one data width and produces output packets on its source interface with a different data width. The ratio of the narrow data width must be a power of two, such as 1:4, 1:8, and 1:16. The ratio of the wider data width to the narrower width must also be a power of two, such as 4:1, 8:1, and 16:1 These output packets may have a different size if the input size exceeds the output data bus width, or if data packing is enabled.

When the width adapter converts from narrow data to wide data, each input beat's data and byte enables are copied to the appropriate segment of the wider output data and byte enables signals.

Figure 209. Width Adapter Timing for a 4:1 Adapter

This adapter assumes that the field ordering of the input and output packets is the same, with the only difference being the width of the data and accompanying byte enable fields. When the width adapter converts from wide data to narrow data, the narrower data is transmitted over several beats. The first output beat contains the lowest addressed segment of the input data and byte enables.



5.1.8.1.1. AXI Wide-to-Narrow Adaptation

For all cases of AXI wide-to-narrow adaptation, read data is re-packed to match the original size. Responses are merged, with the following error precedence: DECERR, SLVERR, 0KAY, and EX0KAY.

Table 46. AXI Wide-to-Narrow Adaptation (Downsizing)

Burst Type	Behavior
Incrementing	If the transaction size is less than or equal to the output width, the burst is unmodified. Otherwise, it is converted to an incrementing burst with a larger length and size equal to the output width. If the resulting burst is unsuitable for the subordinate, the burst is converted to multiple sequential bursts of the largest allowable lengths. For example, for a 2:1 downsizing ratio, an `INCR9` burst is converted into `INCR16 + INCR2` bursts. This is true if the maximum burstcount a subordinate can accept is 16, which is the case for AMBA 3 AXI subordinates. Avalon subordinates have a maximum burstcount of 64.
Wrapping	If the transaction size is less than or equal to the output width, the burst is unmodified. Otherwise, it is converted to a wrapping burst with a larger length, with a size equal to the output width. If the resulting burst is unsuitable for the subordinate, the burst is converted to multiple sequential bursts of the largest allowable lengths; respecting wrap boundaries. For example, for a 2:1 downsizing ratio, a `WRAP16` burst is converted into two or three `INCR` bursts, depending on the address.
Fixed	If the transaction size is less than or equal to the output width, the burst is unmodified. Otherwise, it is converted into repeated sequential bursts over the same addresses. For example, for a 2:1 downsizing ratio, a FIXED single burst is converted into an `INCR2` burst.

5.1.8.1.2. AXI Narrow-to-Wide Adaptation

Table 47. AXI Narrow-to-Wide Adaptation (Upsizing)

Burst Type	Behavior
Incrementing	The burst (and its response) passes through unmodified. Data and write strobes are placed in the correct output segment.
Wrapping	The burst (and its response) passes through unmodified.
Fixed	The burst (and its response) passes through unmodified.

5.1.9. Burst Adapter

Platform Designer interconnect uses the memory-mapped burst adapter to accommodate the burst capabilities of each interface in the system, including interfaces that do not support burst transfers.

The maximum burst length for each interface is a property of the interface and is independent of other interfaces in the system. Therefore, a specific host may be capable of initiating a burst longer than an agent's maximum supported burst length. In this case, the burst adapter translates the large host burst into smaller bursts, or into individual agent transfers if the agent does not support bursting. Until the host completes the burst, arbiter logic prevents other hosts from accessing the target agent. For example, if a host initiates a burst of 16 transfers to an agent with maximum burst length of 8, the burst adapter initiates 2 bursts of length 8 to the agent.

Avalon memory mapped burst transactions allow a host uninterrupted access to an agent for a specified number of transfers. The host specifies the number of transfers when it initiates the burst. Once a burst begins between a host and agent, arbiter logic is locked until the burst completes. For burst hosts, the length of the burst is the number of cycles that the host has access to the agent, and the selected arbitration shares have no effect.

Note: AXI managers can issue burst types that Avalon cannot accept, for example, fixed bursts. In this case, the burst adapter converts the fixed burst into a sequence of transactions to the same address.

Note: For AMBA 4 AXI subordinates, Platform Designer allows 256-beat `INCR` bursts. You must ensure that 256-beat narrow-sized `INCR` bursts are shortened to 16-beat narrow-sized INCR bursts for AMBA 3 AXI subordinates.

Avalon memory mapped hosts always issue addresses that are aligned to the size of the transfer. However, when Platform Designer uses a narrow-to-wide width adaptation, the resulting address may be unaligned. For unaligned addresses, the burst adapter issues the maximum sized bursts with appropriate byte enables. This brings the burst-in-progress up to an aligned agent address. Then, it completes the burst on aligned addresses.

The burst adapter supports variable wrap or sequential burst types to accommodate different properties of memory-mapped hosts. Some bursting hosts can issue more than one burst type.

Burst adaptation is available for Avalon to Avalon, Avalon to AXI, and AXI to Avalon, and AXI to AXI connections. For information about AXI-to-AXI adaptation, refer to *AXI Wide-to-Narrow Adaptation*

Note: For AMBA 4 AXI to AMBA 3 AXI connections, Platform Designer follows an AMBA 4 AXI 256 burst length to AMBA 3 AXI 16 burst length.

5.1.9.1. Burst Adapter Implementation Options

Platform Designer automatically inserts burst adapters into your system depending on your host and agent connections, and properties. You can select burst adapter implementation options on the **Interconnect Requirements** tab.

To access the implementation options, you must select the **Burst adapter implementation** setting for the `$system` identifier.

- **Generic converter (slower, lower area)**—Default. Controls all burst conversions with a single converter that can adapt incoming burst types. This results in an adapter that has lower f_{MAX}, but smaller area.
- **Per-burst-type converter (faster, higher area)**—Controls incoming bursts with a specific converter, depending on the burst type. This results in an adapter that has higher f_{MAX}, but higher area. This setting is useful when you have AXI managers or subordinates and you want a higher f_{MAX}.

Note: For more information about the **Interconnect Requirements** tab, refer to *Creating a System with Platform Designer*.

Related Information

Creating a System with Platform Designer on page 11

5.1.9.2. Burst Adaptation: AXI to Avalon

The following entries specify the behavior when converting between AXI and Avalon burst types.

Table 48. Burst Adaptation: AXI to Avalon

Burst Type	Behavior
Incrementing	**Sequential Subordinate** Bursts that exceed `slave_max_burst_length` are converted to multiple sequential bursts of a length less than or equal to the `slave_max_burst_length`. Otherwise, the burst is unconverted. For example, for an Avalon agent with a maximum burst length of 4, an `INCR7` burst is converted to `INCR4 + INCR3`. **Wrapping Subordinate** Bursts that exceed the `slave_max_burst_length` are converted to multiple sequential bursts of length less than or equal to the `slave_max_burst_length`. Bursts that exceed the wrapping boundary are converted to multiple sequential bursts that respect the Avalon agent's wrapping boundary.
Wrapping	**Sequential Subordinate** A WRAP burst is converted to multiple sequential bursts. The sequential bursts are less than or equal to the `max_burst_length` and respect the transaction's wrapping boundary **Wrapping Subordinate** If the WRAP transaction's boundary matches the Avalon agent's boundary, then the burst passes through. Otherwise, the burst is converted to sequential bursts that respect both the transaction and Avalon agent wrap boundaries.
Fixed	Fixed bursts are converted to sequential bursts of length 1 that repeatedly access the same address.
Narrow	All narrow-sized bursts are broken into multiple bursts of length 1.

5.1.9.3. Burst Adaptation: Avalon to AXI

The following entries specify the behavior when converting between Avalon and AXI burst types.

Note: The Platform Designer-generated interconnect that adapts between an Avalon memory-mapped interface host and a connected AXI subordinate does not account for the AXI3 or AXI4 4KB boundary restriction for burst transactions. When connecting an Avalon memory-mapped interface FPGA host to an AXI subordinate in Platform Designer, you must ensure that the bursts do not exceed the AXI3 or AXI4 4KB boundary restriction for burst transactions.

Table 49. Burst Adaptation: Avalon to AXI

Burst Type	Definition
Sequential	Bursts of length greater than 16 are converted to multiple `INCR` bursts of a length less than or equal to 16. Bursts of length less than or equal to 16 are not converted.
Wrapping	Only Avalon hosts with `alwaysBurstMaxBurst = true` are supported. The WRAP burst is passed through if the length is less than or equal to 16. Otherwise, it is converted to two or more `INCR` bursts that respect the transaction's wrap boundary.
`GENERIC_CONVERTER`	Controls all burst conversions with a single converter that adapts all incoming burst types, resulting in an adapter that has smaller area, but lower f_{MAX}.

5.1.10. Waitrequest Allowance Adapter

The Waitrequest Allowance Adapter allows a connection between a host and an agent interface with different `waitrequestAllowance` properties.

The Waitrequest Allowance adapter provides the following features:

- The adapter is used in the memory-mapped domain and operates with signals on the memory-mapped interface.
- Signal widths and all properties other than `waitrequestAllowance` are identical on host and agent interfaces.
- The adapter does not modify any command properties such as data width, burst type, or burst count.
- The adapter is inserted by the Platform Designer interconnect software when a host and agent with different `waitrequestAllowance` property are connected.

When the agent has a `waitrequestAllowance = n` the host must deassert `read` or `write` signals after <*n*> transfers when `waitrequest` is asserted.

Table 50. Interconnect Scenarios Requiring waitrequestAllowance

Host *(m)* / Agent *(n)* waitrequestAllowance	Adaptation Required	Description	Adapter Function
m = *n*	No	The host `waitrequestAllowance` is equal to the agent's `waitrequestAllowance`.	All signals are passed through.
m = 0; *n* > 0	Yes	The host cannot send when `waitrequest=1`, but holds the value on the bus. This would result in the agent receiving multiple copies.	The adapter deasserts `valid` when input `waitrequest` is asserted.

continued...

Host *(m)* / Agent *(n)* waitrequestAllowance	Adaptation Required	Description	Adapter Function
		Requires adaptation to prevent.	
m < *n*; *m* != 0	No	The host can send <*m*> transfers after `waitrequest` is asserted. The agent receives fewer than <*n*> transfers, which is acceptable.	All signals are passed through.
m > *n*; *n* = 0	Yes	The agent cannot accept transfers when `waitrequest` is asserted. Transfers sent when `waitrequest=1` can be lost. Prevention requires adaptation in the form of transfer buffering.	If the input `waitrequest` is asserted, the adapter buffers the input data.
m > *n*; *n* > 0	Yes	The agent cannot accept more than <*n*> transfers after `waitrequest` is asserted, however the host can send up to <*m*> transfers. Transfers (<*m*> – <*n*>) can be lost. Prevention requires adaptation in the form of transfer buffering.	The adapter buffers the input data.

5.1.11. Read and Write Responses

Platform Designer merges write responses if a write is converted (burst adapted) into multiple bursts. Platform Designer requires read response merging for a downsized (wide-to-narrow width adapted) read.

Platform Designer merges responses based on the following precedence rule:

```
DECERR > SLVERR > OKAY > EXOKAY
```

Adaptation between a host with write responses and an agent without write responses can be costly, especially if there are multiple agents, or if the agent supports bursts. To minimize the cost of logic between agents, consider placing the agents that do not have write responses behind a bridge so that the write response adaptation logic cost is only incurred once, at the bridge's agent interface.

The following table describes what happens when there is a mismatch in response support between the host and agent.

Table 51. Response Support for Mismatched Host and Agent

	Agent with Response	Agent Without Response
Host with Response	Interconnect delivers response from the agent to the host. Response merging or duplication may be necessary for bus sizing.	Interconnect delivers an OKAY response to the host
Host without Response	Host ignores responses from the agent	No need for responses. Host, agent and interconnect operate without response support.

Note: If there is a bridge between the host and the endpoint agent, and the responses must come from the endpoint agent, ensure that the bridge passes the appropriate response signals through from the endpoint agent to the host.

If the bridge does not support responses, then the responses are generated by the interconnect at the agent interface of the bridge, and responses from the endpoint agent are ignored.

For the response case where the transaction violates security settings or uses an illegal address, the interconnect routes the transactions to the default agent. For information about Platform Designer system security, refer to Manage System Security. For information about specifying a default agent, refer to *Error Response Agent* in *Platform Designer System Design Components*.

Note: Avalon memory mapped agents without a `response` signal are not able to notify a connected host that a transaction has not completed successfully. As a result, Platform Designer interconnect generates an OKAY response on behalf of the Avalon memory mapped agent.

- Error Correction Coding (ECC) in Platform Designer Interconnect on page 331

5.1.12. Platform Designer Address Decoding

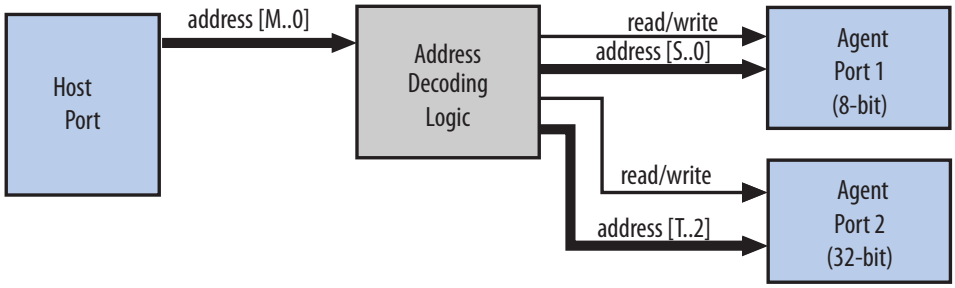
Address decoding logic forwards appropriate addresses to each agent.

Address decoding logic simplifies component design in the following ways:

- The interconnect selects an agent whenever it is being addressed by a host. Agent components do not need to decode the address to determine when they are selected.
- Agent addresses are properly aligned to the agent interface.
- Changing the system memory map does not involve manually editing HDL.

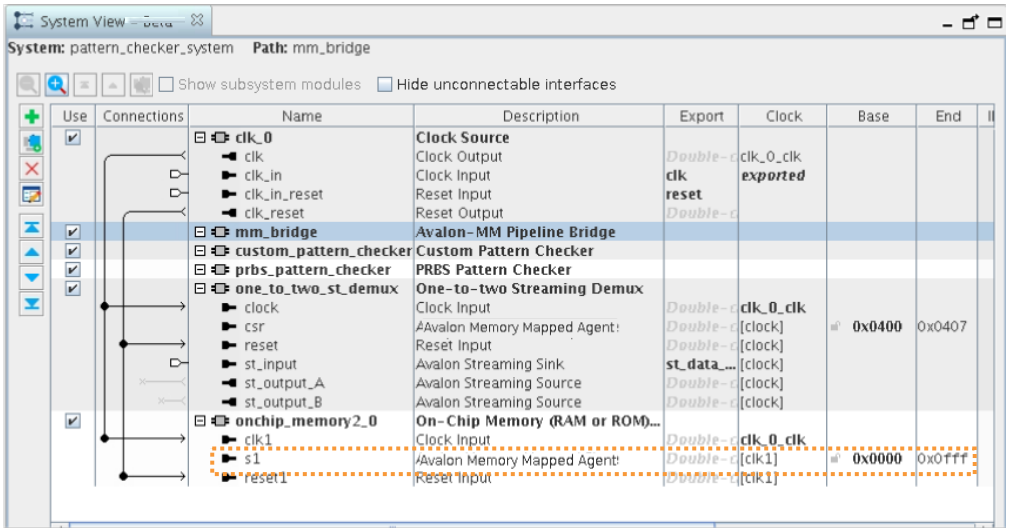
Figure 210. Address Decoding for One Host and Two Agents

In this example, Platform Designer generates separate address decoding logic for each host in a system. The address decoding logic processes the difference between the host address width (<M>) and the individual agent address widths (<S>) and (<T>). The address decoding logic also maps only the necessary host address bits to access words in each agent's address space.



Platform Designer controls the base addresses with the **Base** setting of active components on the **System View** tab. The base address of an agent component must be a multiple of the address span of the component. This restriction is part of the Platform Designer interconnect to allow the address decoding logic to be efficient, and to achieve the best possible f_{MAX}.

Figure 211. Address Decoding Base Settings



5.2. Avalon Streaming Interfaces

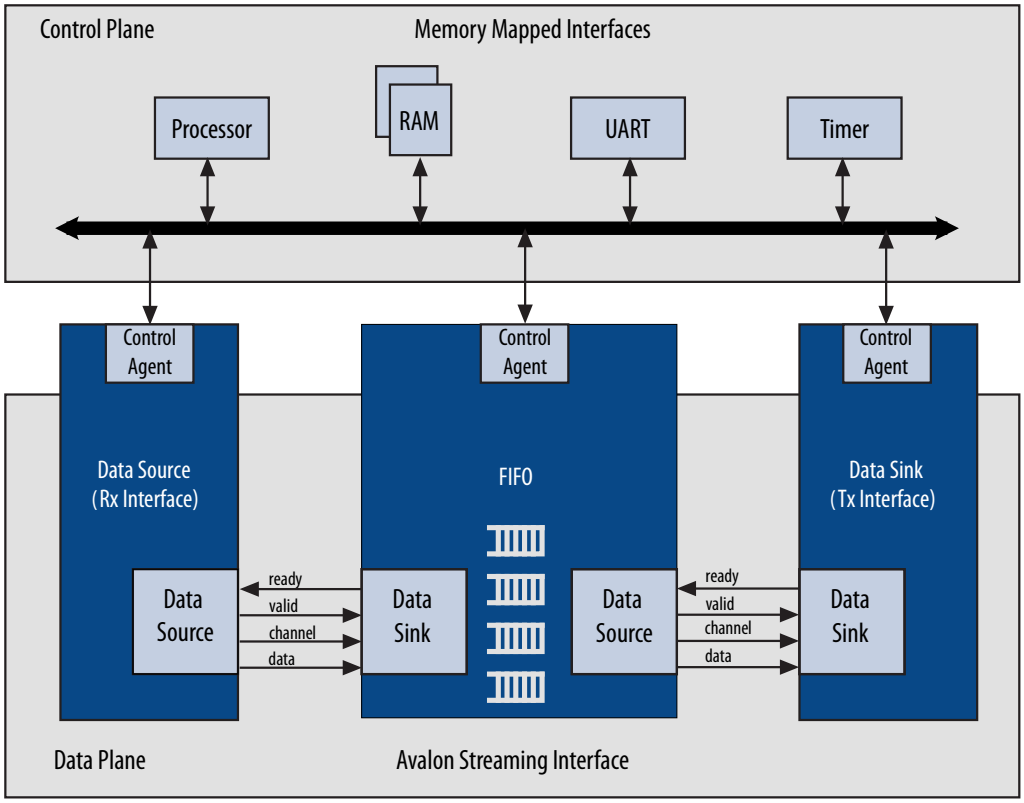
High bandwidth components with streaming data typically use Avalon streaming interfaces for the high throughput datapath. Streaming interfaces can also use memory-mapped connection interfaces to provide an access point for control. In contrast to the memory-mapped interconnect, the Avalon streaming interconnect always creates a point-to-point connection between a single data source and data sink.

Figure 212 on page 279 contains the following connection pairs:

- Data source in the Rx Interface transfers data to the data sink in the FIFO.
- Data source in the FIFO transfers data to the `Tx Interface` data sink.

The memory-mapped interface allows a processor to access the data source, FIFO, or data sink to provide system control. If your source and sink interfaces have different formats, for example, a 32-bit source and an 8-bit sink, Platform Designer automatically inserts the necessary adapters. You can view the adapters on the **System View** tab by clicking **System ➤ Show System with Platform Designer Interconnect**.

Figure 212. Avalon Memory-Mapped and Avalon Streaming Interfaces



The following diagram shows a source-sink pair that includes only the `data` signal. The sink must be able to receive data as soon as the source interface comes out of reset.

Figure 213. Avalon Streaming Connection Between the Source and Sink

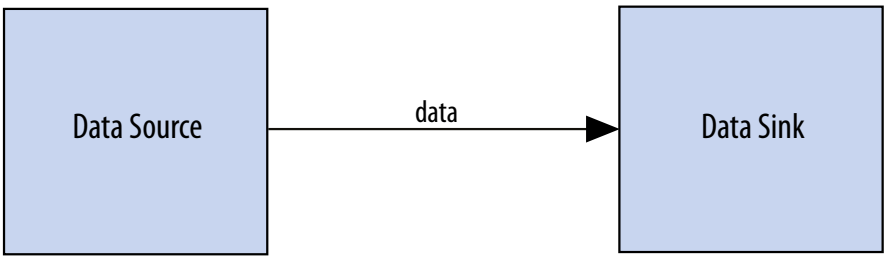


Figure 214. Signals Indicating the Start and End of Packets, Channel Numbers, Error Conditions, and Backpressure

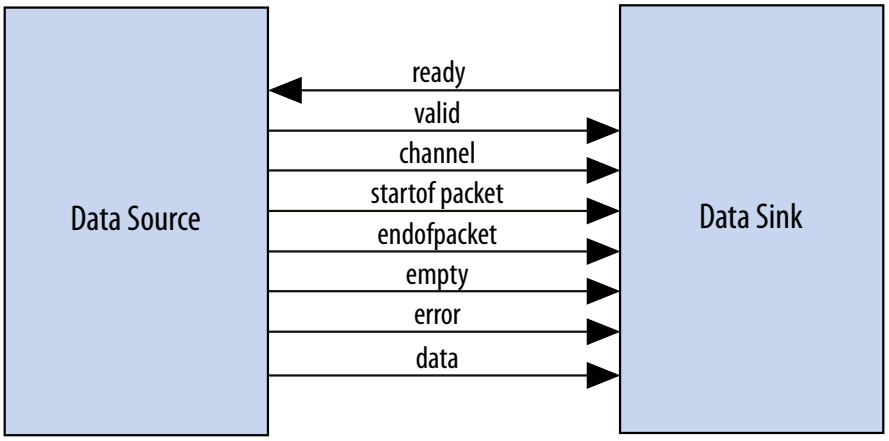
All data transfers using Avalon streaming interconnect occur synchronously on the rising edge of the associated clock interface. Throughput and frequency of a system depends on the components and how they are connected.



The IP Catalog includes Avalon streaming components that you can use to create datapaths, including datapaths whose input and output streams have different properties. Generated systems that include memory-mapped host and agent components may also use these Avalon streaming components because Platform Designer generation creates interconnect with a structure similar to a network topology, as described in *Platform Designer Transformations*. The following sections introduce the Avalon streaming components.

Related Information

Platform Designer Transformations on page 256

5.2.1. Avalon Streaming Adapters

Platform Designer automatically adds Avalon streaming adapters between two components during system generation when it detects mismatched interfaces. If you connect mismatched Avalon streaming sources and sinks, for example, a 32-bit source and an 8-bit sink, Platform Designer inserts the appropriate adapter type to connect the mismatched interfaces.

After generation, you can view the inserted adapters selecting **System ➤ Show System With Platform Designer Interconnect**. For each mismatched source-sink pair, Platform Designer inserts an Avalon streaming adapter. The adapter instantiates the necessary adaptation logic as sub-components. You can review the logic for each adapter instantiation in the Hierarchy view by expanding each adapter's source and sink interface and comparing the relevant ports. For example, to determine why a channel adapter is inserted, expand the channel adapter's sink and source interfaces and review the channel port properties for each interface.

You can turn off the auto-inserted adapters feature by adding the `qsys_enable_avalon_streaming_transform=off` command to the `quartus.ini` file. When you turn off the auto-inserted adapters feature, if mismatched interfaces are detected during system generation, Platform Designer does not insert adapters and reports the mismatched interface with validation error message.

Note: The auto-inserted adapters feature does not work for video IP connections.

5.2.1.1. Avalon Streaming Adapter

The Avalon streaming adapter combines the logic of the channel, error, data format, and timing adapters. The Avalon streaming adapter provides adaptations between interfaces that have mismatched Avalon streaming endpoints. Based on the source and sink interface parameterizations for the Avalon streaming adapter, Platform Designer instantiates the necessary adapter logic (channel, error, data format, or timing) as hierarchal sub-components.

5.2.1.1.1. Avalon Streaming Adapter Parameters Common to Source and Sink Interfaces

Table 52. Avalon Streaming Adapter Parameters Common to Source and Sink Interfaces

Parameter Name	Description
Symbol Width	Width of a single symbol in bits.
Use Packet	Indicates whether the source and sink interfaces connected to the adapter's source and sink interfaces include the `startofpacket` and `endofpacket` signals, and the optional `empty` signal.

5.2.1.1.2. Avalon Streaming Adapter Upstream Source Interface Parameters

Table 53. Avalon Streaming Adapter Upstream Source Interface Parameters

Parameter Name	Description
Source Data Width	Controls the data width of the source interface `data` port.
Source Top Channel	Maximum number of output channels allowed.
Source Channel Port Width	Sets the bit width of the source interface `channel` port. If set to 0, there is no `channel` port on the sink interface.
Source Error Port Width	Sets the bit width of the source interface `error` port. If set to 0, there is no `error` port on the sink interface.
Source Error Descriptors	A list of strings that describe the error conditions for each bit of the source interface `error` signal.
Source Uses Empty Port	Indicates whether the source interface includes the `empty` port, and whether the sink interface should also include the `empty` port.
Source Empty Port Width	Indicates the bit width of the source interface `empty` port, and sets the bit width of the sink interface `empty` port.
Source Uses Valid Port	Indicates whether the source interface connected to the sink interface uses the `valid` port, and if set, configures the sink interface to use the `valid` port.
Source Uses Ready Port	Indicates whether the sink interface uses the `ready` port, and if set, configures the source interface to use the `ready` port.
Source Ready Latency	Specifies what ready latency to expect from the source interface connected to the adapter's sink interface.

5.2.1.1.3. Avalon Streaming Adapter Downstream Sink Interface Parameters

Table 54. Avalon Streaming Adapter Downstream Sink Interface Parameters

Parameter Name	Description
Sink Data Width	Indicates the bit width of the `data` port on the sink interface connected to the source interface.
Sink Top Channel	Maximum number of output channels allowed.
Sink Channel Port Width	Indicates the bit width of the `channel` port on the sink interface connected the source interface.
Sink Error Port Width	Indicates the bit width of the `error` port on the sink interface connected to the adapter's source interface. If set to zero, there is no error port on the source interface.
Sink Error Descriptors	A list of strings that describe the error conditions for each bit of the `error` port on the sink interface connected to the source interface.
Sink Uses Empty Port	Indicates whether the sink interface connected to the source interface uses the `empty` port, and whether the source interface should also use the `empty` port.
Sink Empty Port Width	Indicates the bit width of the `empty` port on the sink interface connected to the source interface, and configures a corresponding `empty` port on the source interface.
Sink Uses Valid Port	Indicates whether the sink interface connected to the source interface uses the `valid` port, and if set, configures the source interface to use the `valid` port.
Sink Uses Ready Port	Indicates whether the `ready` port on the sink interface is connected to the source interface , and if set, configures the sink interface to use the ready port.
Sink Ready Latency	Specifies what ready latency to expect from the source interface connected to the sink interface.

5.2.1.2. Channel Adapter

The channel adapter provides adaptations between interfaces that have different channel signal widths.

Table 55. Channel Adapter Adaptations

Condition	Description of Adapter Logic
The source uses channels, but the sink does not.	Platform Designer gives a warning at generation time. The adapter provides a simulation error and signals an error for data for any channel from the source other than 0.
The sink has channel, but the source does not.	Platform Designer gives a warning at generation time, and the channel inputs to the sink are all tied to a logical 0.
The source and sink both support channels, and the source's maximum channel number is less than the sink's maximum channel number.	The source's channel is connected to the sink's channel unchanged. If the sink's channel signal has more bits, the higher bits are tied to a logical 0.
The source and sink both support channels, but the source's maximum channel number is greater than the sink's maximum channel number.	The source's channel is connected to the sink's channel unchanged. If the source's channel signal has more bits, the higher bits are left unconnected. Platform Designer gives a warning that channel information may be lost. An adapter provides a simulation error message and an error indication if the value of channel from the source is greater than the sink's maximum number of channels. In addition, the `valid` signal to the sink is deasserted so that the sink never sees data for channels that are out of range.

5.2.1.2.1. Avalon Streaming Channel Adapter Input Interface Parameters

Table 56. Avalon Streaming Channel Adapter Input Interface Parameters

Parameter Name	Description
Channel Signal Width (bits)	Width of the input channel signal in bits
Max Channel	Maximum number of input channels allowed.

5.2.1.2.2. Avalon Streaming Channel Adapter Output Interface Parameters

Table 57. Avalon Streaming Channel Adapter Output Interface Parameters

Parameter Name	Description
Channel Signal Width (bits)	Width of the output channel signal in bits.
Max Channel	Maximum number of output channels allowed.

5.2.1.2.3. Avalon Streaming Channel Adapter Common to Input and Output Interface Parameters

Table 58. Avalon Streaming Channel Adapter Common to Input and Output Interface Parameters

Parameter Name	Description
Data Bits Per Symbol	Number of bits for each symbol in a transfer.
Include Packet Support	When the Avalon Streaming Channel adapter supports packets, the `startofpacket`, `endofpacket`, and optional `empty` signals are included on its sink and source interfaces.
Include Empty Signal	Indicates whether an `empty` signal is required.
Data Symbols Per Beat	Number of symbols per transfer.
Support Backpressure with the ready signal	Indicates whether a `ready` signal is required.
Ready Latency	Specifies the ready latency to expect from the sink connected to the module's source interface.
Error Signal Width (bits)	Bit width of the `error` signal.
Error Signal Description	A list of strings that describes what each bit of the `error` signal represents.

5.2.1.3. Data Format Adapter

The data format adapter allows you to connect interfaces that have different values for the parameters defining the `data` signal, or interfaces where the source does not use the `empty` signal, but the sink does use the `empty` signal. One of the most common uses of this adapter is to convert data streams of different widths.

Table 59. Data Format Adapter Adaptations

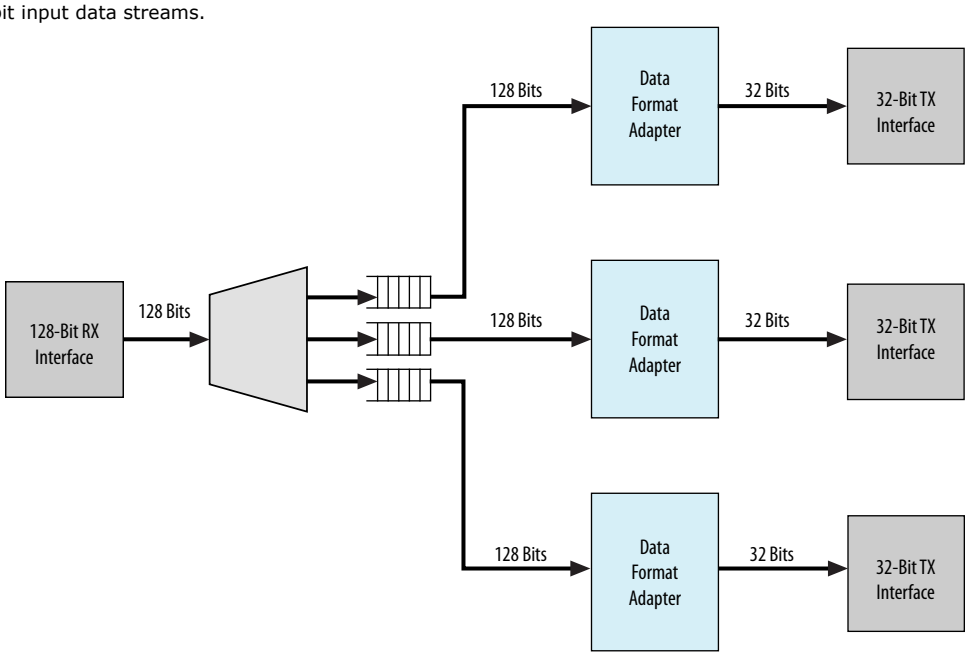
Condition	Description of Adapter Logic
The source and sink's bits per symbol parameters are different.	The connection cannot be made.
The source and sink have a different number of symbols per beat.	The adapter converts the source's width to the sink's width.

continued...

Condition	Description of Adapter Logic
	If the adaptation is from a wider to a narrower interface, a beat of data at the input corresponds to multiple beats of data at the output. If the input `error` signal is asserted for a single beat, it is asserted on output for multiple beats. If the adaptation is from a narrow to a wider interface, multiple input beats are required to fill a single output beat, and the output `error` is the logical OR of the input `error` signal.
The source uses the `empty` signal, but the sink does not use the `empty` signal.	Platform Designer cannot make the connection.

Figure 215. Avalon Streaming Interconnect with Data Format Adapter

In this example, the data format adapter allows a connection between a 128-bit output data stream and three 32-bit input data streams.



5.2.1.3.1. Avalon Streaming Data Format Adapter Input Interface Parameters

Table 60. Avalon Streaming Data Format Adapter Input Interface Parameters

Parameter Name	Description
Data Symbols Per Beat	Number of symbols per transfer.
Include Empty Signal	Indicates whether an `empty` signal is required.

5.2.1.3.2. Avalon Streaming Data Format Adapter Output Interface Parameters

Table 61. Avalon Streaming Data Format Adapter Output Interface Parameters

Parameter Name	Description
Data Symbols Per Beat	Number of symbols per transfer.
Include Empty Signals	Indicates whether an `empty` signal is required.

5.2.1.3.3. Avalon Streaming Data Format Adapter Common to Input and Output Interface Parameters

Table 62. Avalon Streaming Data Format Adapter Common to Input and Output Interface Parameters

Parameter Name	Description
Data Bits Per Symbol	Number of bits for each symbol in a transfer.
Include Packet Support	When the Avalon Streaming Data Format adapter supports packets, Platform Designer uses `startofpacket`, `endofpacket`, and `empty` signals.
Channel Signal Width (bits)	Width of the output channel signal in bits.
Max Channel	Maximum number of channels allowed.
Read Latency	Specifies the ready latency to expect from the sink connected to the module's source interface.
Error Signal Width (bits)	Width of the `error` signal output in bits.
Error Signal Description	A list of strings that describes what each bit of the `error` signal represents.

5.2.1.4. Error Adapter

The error adapter ensures that per-bit-error information provided by the source interface is correctly connected to the sink interface's input error signal. Error conditions that both source and sink can process are connected. If the source has an `error` signal representing an error condition that is not supported by the sink, the signal is left unconnected; the adapter provides a simulation error message and an error indication if the error is asserted. If the sink has an error condition that is not supported by the source, the sink's input error bit corresponding to that condition is set to 0.

Note: The output interface error signal descriptor accepts an error set with an `other` descriptor. Platform Designer assigns the bit-wise `ORing` of all input error bits that are unmatched, to the output interface error bits set with the `other` descriptor.

5.2.1.4.1. Avalon Streaming Error Adapter Input Interface Parameters

Table 63. Avalon Streaming Error Adapter Input Interface Parameters

Parameter Name	Description
Error Signal Width (bits)	The width of the `error` signal. Valid values are 0–256 bits. Type `0` if the `error` signal is not used.
Error Signal Description	The description for each of the error bits. If scripting, separate the description fields by commas. For a successful connection, the description strings of the error bits in the source and sink must match and are case sensitive.

5.2.1.4.2. Avalon Streaming Error Adapter Output Interface Parameters

Table 64. Avalon Streaming Error Adapter Output Interface Parameters

Parameter Name	Description
Error Signal Width (bits)	The width of the `error` signal. Valid values are 0–256 bits. Type `0` if you do not need to send error values.
Error Signal Description	The description for each of the error bits. Separate the description fields by commas. For successful connection, the description of the error bits in the source and sink must match, and are case sensitive.

5.2.1.4.3. Avalon Streaming Error Adapter Common to Input and Output Interface Parameters

Table 65. Avalon Streaming Error Adapter Common to Input and Output Interface Parameters

Parameter Name	Description
Support Backpressure with the ready signal	Turn on this option to add the backpressure functionality to the interface.
Ready Latency	When the `ready` signal is used, the value for `ready_latency` indicates the number of cycles between when the ready signal is asserted and when valid data is driven.
Channel Signal Width (bits)	The width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is eight bits. Set to 0 if channels are not used.
Max Channel	The maximum number of channels that the interface supports. Valid values are 0–255.
Data Bits Per Symbol	Number of bits per symbol.
Data Symbols Per Beat	Number of symbols per active transfer.
Include Packet Support	Turn on this option if the connected interfaces support a packet protocol, including the `startofpacket`, `endofpacket` and `empty` signals.
Include Empty Signal	Turn this option on if the cycle that includes the `endofpacket` signal can include empty symbols. This signal is not necessary if the number of symbols per beat is 1.

5.2.1.5. Timing Adapter

The timing adapter allows you to connect component interfaces that require a different number of cycles before driving or receiving data. This adapter inserts a FIFO buffer between the source and sink to buffer data or pipeline stages to delay the back-pressure signals. You can also use the timing adapter to connect interfaces that support the `ready` signal, and those that do not. The timing adapter treats all signals other than the `ready` and `valid` signals as payload, and simply drives them from the source to the sink.

Table 66. Timing Adapter Adaptations

Condition	Adaptation
The source has `ready`, but the sink does not.	In this case, the source can respond to `backpressure`, but the sink never needs to apply it. The `ready` input to the source interface is connected directly to logical 1.
The source does not have `ready`, but the sink does.	The sink may apply `backpressure`, but the source is unable to respond to it. There is no logic that the adapter can insert that prevents data loss when the source asserts `valid` but the sink is not ready. The adapter provides simulation time error messages if data is lost. The user is presented with a warning, and the connection is allowed.
The source and sink both support backpressure, but the sink's ready latency is greater than the source's.	The source responds to `ready` assertion or deassertion faster than the sink requires it. The number of pipeline stages equal to the difference in ready latency are inserted in the `ready` path from the sink back to the source, causing the source and the sink to see the same cycles as `ready` cycles.
The source and sink both support backpressure, but the sink's ready latency is less than the source's.	The source cannot respond to `ready` assertion or deassertion in time to satisfy the sink. A FIFO whose depth is equal to the difference in ready latency is inserted to compensate for the source's inability to respond in time.

5.2.1.5.1. Avalon Streaming Timing Adapter Input Interface Parameters

Table 67. Avalon Streaming Timing Adapter Input Interface Parameters

Parameter Name	Description
Support Backpressure with the ready signal	Indicates whether a `ready` signal is required.
Read Latency	Specifies the ready latency to expect from the sink connected to the module's source interface.
Include Valid Signal	Indicates whether the sink interface requires a valid signal.

5.2.1.5.2. Avalon Streaming Timing Adapter Output Interface Parameters

Table 68. Avalon Streaming Timing Adapter Output Interface Parameters

Parameter Name	Description
Support Backpressure with the ready signal	Indicates whether a `ready` signal is required.
Read Latency	Specifies the ready latency to expect from the sink connected to the module's source interface.
Include Valid Signal	Indicates whether the sink interface requires a valid signal.

5.2.1.5.3. Avalon Streaming Timing Adapter Common to Input and Output Interface Parameters

Table 69. Avalon Streaming Timing Adapter Common to Input and Output Interface Parameters

Parameter Name	Description
Data Bits Per Symbol	Number of bits for each symbol in a transfer.
Include Packet Support	Turn this option on if the connected interfaces support a packet protocol, including the `startofpacket`, `endofpacket` and `empty` signals.
Include Empty Signal	Turn this option on if the cycle that includes the `endofpacket` signal can include empty symbols. This signal is not necessary if the number of symbols per beat is 1.

continued...

Parameter Name	Description
Data Symbols Per Beat	Number of symbols per active transfer.
Channel Signal Width (bits)	Width of the output channel signal in bits.
Max Channel	Maximum number of output channels allowed.
Error Signal Width (bits)	Width of the output `error` signal in bits.
Error Signal Description	A list of strings that describes errors.

5.3. Avalon Streaming Credit Interfaces

Avalon Streaming Credit interfaces are for use with components that drive high-bandwidth, low-latency, unidirectional data. Typical applications include multiplexed streams, packets, and DSP data. The Avalon Streaming Credit interface signals can describe traditional streaming interfaces supporting a single stream of data, without knowledge of channels or packet boundaries. The interface can also support more complex protocols capable of burst and packet transfers with packets interleaved across multiple channels.

All Avalon Streaming Credit source and sink interfaces are not necessarily interoperable. However, if two interfaces provide compatible functions for the same application space, adapters are available to allow them to interoperate.

You can also connect an Avalon Streaming Credit source to an Avalon Streaming sink via an adapter. Similarly, you can connect an Avalon Streaming source to an Avalon Streaming Credit sink via an adapter.

Avalon Streaming Credit interfaces support datapaths requiring the following features:

- Low-latency, high-throughput point-to-point data transfer
- Multiple channel support with flexible packet interleaving
- Sideband signaling of channel, error, and start and end of packet delineation
- Support for data bursting
- Sideband signals for user-defined functionality

5.3.1. Terms and Concepts

The Avalon Streaming Credit interface protocol defines the following terms and concepts:

- **Avalon Streaming Credit System**—an Avalon Streaming Credit system contains one or more Avalon Streaming Credit connections that transfer data from a source interface to a sink interface.
- **Avalon Streaming Credit Components**—a typical system using Avalon Streaming credit interfaces combines multiple functional modules, called components. The system designer configures the components and connects them together to implement a system.
- **Source and Sink Interfaces and Connections**—when two components are connected, credits flow from the sink to the source; and the data flows from the source interface to the sink interface. The combination of a source interface connected to a sink interface is referred to as a connection.
- **Transfers**—a transfer results in data and control propagation from a source interface to a sink interface. For data interfaces, sources can start data transfers only if they have credits available. Similarly, sinks can accept data only if they have outstanding credits.
- **Symbol**—a symbol is the smallest unit of data as defined for the interface. One or more symbols make up the single unit of data transferred in a clock cycle. The default symbol size is 8 bits.
- **Beat**—a beat is a single cycle transfer between a source and sink interface made up of one or more symbols.
- **Packet**—a packet is an aggregation of data and control signals that is transmitted together. A packet may contain a header to help routers and other network devices direct the packet to the correct destination. The packet format is defined by the application, not this specification. Avalon Streaming packets can be variable in length and can be interleaved across a connection. With an Avalon Streaming Credit interface, the use of packets is optional.

5.3.2. Avalon Streaming Credit Adapters

Avalon Streaming Credit adapters perform data width conversion when the Avalon Streaming Credit source and Avalon Streaming Credit sink have different data widths. For example, if an Avalon Streaming Credit source and Avalon Streaming Credit sink have different data widths, you can insert the Avalon Streaming Credit Wide to Narrow Adapter, or the Avalon Streaming Credit Narrow to Wide Adapter, for data width conversion.

Platform Designer interconnect supports the following data format adapters for Avalon Streaming Credit interfaces:

5.3.2.1. Avalon Streaming Credit Wide to Narrow Adapter

The Avalon Streaming Credit Wide to Narrow Adapter has the following blocks for performing primary functions.

Table 70. Avalon Streaming Credit Wide to Narrow Adapter Blocks

Adapter Block	Function
Data Management	Accepts incoming wide data and converts the wide data to narrow data for the sink.
Credit Management	Accepts incoming credits from the sink and sends credits to the source. However, credits received from the sink do not directly transfer to the source. Internally, this adapter implements credit management logic. The adapter sends data out if there are credits and data available. If all the credits from the sink are serviced, then the adapter holds the incoming data from the source side until the adapter receives more credits from the sink.
Packet Management	Accepts the `startofpacket`, `endofpacket`, and `empty` packet management signals and drives them appropriately, while maintaining packet and data integrity, on the output.
User Signal Management	Accepts user-defined signals (such as `channel`, `error`, `user_signal_per_packet`, `user_signal_per_symbol`) and sends the signals to the source side, in accordance with the wide-to-narrow conversion.

The adapter is available for parameterization as the **Avalon Streaming Credit Wide to Narrow Adapter Intel FPGA IP** in the Platform Designer IP Catalog.

Figure 216. Avalon Streaming Credit Wide to Narrow Adapter

5.3.2.1.1. Avalon Streaming Credit Wide to Narrow Adapter Interface Parameters

You can specify the following parameters for the Avalon Streaming Credit Wide to Narrow Adapter by double-clicking **Avalon Streaming Credit Wide to Narrow Adapter Intel FPGA IP** in the Platform Designer IP Catalog:

Note: The source data width must be an integer multiple of the sink data width.

Table 71. Avalon Streaming Credit Wide to Narrow Adapter Interface Parameters

Parameter Name	Description	Legal Values
fifo depth	Specifies the number of words the adapter can save for transformation. Also dictates the maximum number of credits the sink can request from the upstream source side.	**8**
Maximum Credit Allowed (Sink Interface)	Specifies the maximum number of credits allowed by the sink interface. The default value is 8.	**8**

continued...

Parameter Name	Description	Legal Values
Number of symbols	Specifies the maximum number of symbols that can transfer.	**1-8192**
Symbol width	Specifies the number of data bits per symbol.	**1-8192**
Width of Channel Port	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is disabled.	**1-128**
Width of Error Port	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is disabled.	**1-1024**
Width of Empty Port	The width of the `empty` signal on the output interfaces. A value of 0 indicates that the empty signal is not in use. This parameter is disabled when **Use Empty** is disabled.	**1-1024**
Maximum Credit Allowed (Source Interface)	Specifies the maximum number of credits allowed by the source interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128, 256**
Use Packets	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.	**On|Off**
Use Empty	Enables or disables the `empty` signal.	**On|Off**
Use Channel	Enables or disables the `channel` signal.	**On|Off**
Use Error	Enables or disables the `error` signal.	**On|Off**
Enable User Signals	Allows you to specify the name, width, and type of user signals.	**On|Off**

Avalon Streaming Credit Interface Signal Roles on page 355

5.3.2.2. Avalon Streaming Credit Narrow to Wide Adapter

The Avalon Streaming Credit Narrow to Wide Adapter has the following blocks for performing primary functions:

Table 72. Avalon Streaming Credit Narrow to Wide Adapter Blocks

Adapter Block	Function
Data Management	Accepts incoming narrow data and converts the narrow data to wide data for the sink.
Credit Management	Accepts incoming credits from the sink and sends credits to the source. However, credits received from the sink do not directly transfer to the source. Internally, this adapter implements credit management logic. The adapter sends data out if there are credits and data available. If all the credits from the sink are serviced, then the adapter holds the incoming data from the source side until the adapter receives more credits from the sink.
Packet Management	Accepts the `startofpacket`, `endofpacket`, and `empty` package management signals and drives them appropriately, while maintaining packet and data integrity, on the output.
User Signal Management	Accepts user-defined signals (such as `channel`, `error`, `user_signal_per_packet`, `user_signal_per_symbol`) and sends the signal to the source side, in accordance with the narrow-to-wide conversion.

The adaptor is available for parameterization as the **Avalon Streaming Credit Narrow to Wide Adapter Intel FPGA IP** in the Platform Designer IP Catalog.

Figure 218. Avalon Streaming Credit Narrow to Wide Adapter

5.3.2.2.1. Avalon Streaming Credit Narrow to Wide Adapter Interface Parameters

You can specify the following parameters for the Avalon Streaming Credit Narrow to Wide Adapter by double-clicking **Avalon Streaming credit narrow to wide adapter Intel FPGA IP** in the Platform Designer IP Catalog.

Note: The sink data width must be an integer multiple of the source data width.

Table 73. Avalon Streaming Credit Narrow to Wide Adapter Interface Parameters

Parameter Name	Description	Legal Values
Maximum Credit Allowed (Sink Interface)	Specifies the maximum number of credits allowed by the sink interface. The legal value is 32.	**32**
Number of symbols	Specifies the maximum number of symbols that can transfer.	**1-8192**
Symbol width	Specifies the number of data bits per symbol.	**1-8192**
Width of Channel Port	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is disabled.	**1-128**
Width of Error Port	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is disabled.	**1-1024**
Width of Empty Port	The width of the `empty` signal on the output interfaces. A value of 0 indicates that the empty signal is not in use. This parameter is disabled when **Use Empty** is disabled.	**1-1024**
Maximum Credit Allowed (Source Interface)	Specifies the maximum number of credits allowed by the source interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128, 256**
Use Packets	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.	**On|Off**
Use Empty	Enables or disables the `empty` signal.	**On|Off**
Use Channel	Enables or disables the `channel` signal.	**On|Off**
Use Error	Enables or disables the `error` signal.	**On|Off**
Enable User Signals	Allows you to specify the name, width, and type of user signals.	**On|Off**

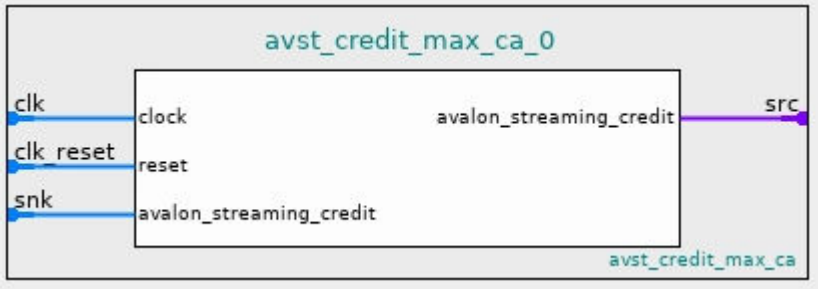
5.3.2.3. Avalon Streaming Credit Max Credit Adapter

The Avalon Streaming Max Credit Adapter facilitates credit flow integrity when the source's **Maximum Credit Allowed** (`maxCredit`) parameter value is less than the sink's **Maximum Credit Allowed** (`maxCredit`) value. The adaptor is available for parameterization as the **Avalon Streaming Credit Max Credit Adapter Intel FPGA IP** from the Platform Designer IP Catalog.

Figure 220. Avalon Streaming Credit Max Credit Adapter



This adapter can accept up to the `maxCredit` of sink credits from the sink, and then supply credits to the source according to the source's `maxCredit` property.

For example, if the source's `maxCredit` is 4 and the sink's `maxCredit` is 8, and the sink provides a value of 8 on the credit bus, the adapter sends 4 credits to the source. When the adapter receives 4 valid beats from the source, the adapter releases the remaining 4 credits to the source. This adapter does not modify data from the source.

5.3.2.3.1. Avalon Streaming Credit Max Credit Adapter Interface Parameters

You can specify the following parameters for the Avalon Streaming Credit Max Credit Adapter by double-clicking **Avalon Streaming Credit Max Credit Adapter Intel FPGA IP** in the Platform Designer IP Catalog:

Table 74. Avalon Streaming Credit Max Credit Adapter Interface Parameters

Parameter Name	Description	Legal Values
Maximum Credit Allowed (Sink Interface)	Specifies the maximum number of credits allowed by the sink interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128, 256**
Number of symbols	Specifies the maximum number of symbols that can transfer.	**1-8192**
Symbol width	Specifies the number of data bits per symbol.	**1-8192**
Width of Channel Port	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is disabled.	**1-128**
Width of Error Port	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is disabled.	**1-1024**
Width of Empty Port	The width of the `empty` signal on the output interfaces. A value of 0 indicates that the empty signal is not in use. This parameter is disabled when **Use Empty** is disabled.	**1-1024**
Maximum Credit Allowed (Source Interface)	Specifies the maximum number of credits allowed by the source interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128, 256**
Use Packets	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.	**On|Off**
Use Empty	Enables or disables the `empty` signal.	**On|Off**
Use Channel	Enables or disables the `channel` signal.	**On|Off**
Use Error	Enables or disables the `error` signal.	**On|Off**
Enable User Signals	Allows you to specify the name, width, and type of user signals.	**On|Off**

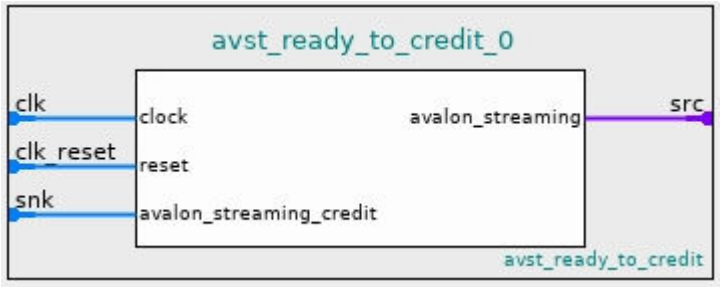
5.3.2.4. Avalon Streaming Ready to Credit Adapter

The Avalon Streaming Ready to Credit Adapter facilitates connectivity between an Avalon Streaming sink and an Avalon Streaming Credit source.

The Avalon Streaming Ready to Credit adapter:

- Outputs credits on the Avalon Streaming Credit sink interface.
- Outputs data on the Avalon Streaming source interface
- Accepts `ready` and asserts `valid` on the Avalon Streaming source interface.
- Supports the `readyLatency` property on the Avalon Streaming sink interface.
- Is available as the **Avalon Streaming Ready to Credit Intel FPGA IP** from the Platform Designer IP Catalog.

Figure 222. Avalon Streaming Ready to Credit Adapter



5.3.2.4.1. Avalon Streaming Ready to Credit Adapter Interface Parameters

You can specify the following parameters for the Avalon Streaming Ready to Credit Adapter by double-clicking **Avalon Streaming Ready to Credit Intel FPGA IP** in the Platform Designer IP Catalog:

Table 75. Avalon Streaming Ready to Credit Adapter Interface Parameters

Parameter Name	Description	Legal Values
Maximum Credit Allowed (Sink Interface)	Specifies the maximum number of credits allowed by the sink interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128, 256**
Number of symbols	Specifies the maximum number of symbols that can transfer.	**1-8192**
Symbol width	Specifies the number of data bits per symbol.	**1-8192**
Width of Channel Port	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is disabled.	**1-128**
Width of Error Port	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is disabled.	**1-1024**
Width of Empty Port	The width of the `empty` signal on the output interfaces. A value of 0 indicates that the empty signal is not in use. This parameter is disabled when **Use Empty** is disabled.	**1-1024**
Ready Latency	Specifies the ready latency to expect from the sink connected to the module's source interface.	**0-32**
synchronous reset	Specifies that the adapter should have a synchronous reset.	**On|Off**
Use Packets	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.	**On|Off**
Use Empty	Enables or disables the `empty` signal.	**On|Off**
Use Channel	Enables or disables the `channel` signal.	**On|Off**
Use Error	Enables or disables the `error` signal.	**On|Off**

5.3.2.5. Avalon Streaming Credit to Ready Adapter

The Avalon Streaming Credit to Ready Adapter facilitates connectivity between an Avalon Streaming Credit sink and an Avalon Streaming source.

The Avalon Streaming Credit to Ready adapter:

- Receives credits on the Avalon Streaming Credit source interface.
- Asserts `ready` and accepts `valid` on the Avalon Streaming sink interface.
- Supports the **Ready Latency** (`readyLatency`) parameter on the Avalon Streaming sink interface.
- Is available as the **Avalon Streaming Credit to Ready Intel FPGA IP** from the Platform Designer IP Catalog.

Figure 224. Avalon Streaming Credit to Ready Adapter

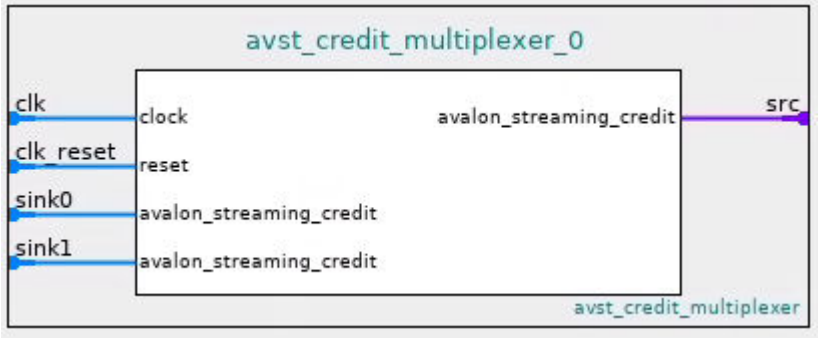
5.3.3. Avalon Streaming Credit Multiplexer

The Avalon Streaming Credit Multiplexer allows multiple sources to access a single sink.

The Avalon Streaming Credit Multiplexer:

- Supports round-robin arbitration.
- Receives credits from the sink, and ensures credits supplied to sources are independent.
- Implements separate credit management logic on both source and sink interfaces.
- Maintains packet integrity from a source.
- Is available as the **Avalon Streaming Credit Multiplexer Intel FPGA IP** from the Platform Designer IP Catalog.

Figure 226. Avalon Streaming Credit Multiplexer



5.3.3.1. Avalon Streaming Credit Multiplexer Parameters

You can specify the following parameters for the Avalon Streaming Credit Multiplexer by double-clicking **Avalon Streaming Credit Multiplexer Intel FPGA IP** in the Platform Designer IP Catalog:

Table 77. Avalon Streaming Credit Multiplexer Parameters

Parameter Name	Description	Legal Values
Number of mux inputs	Specifies the number of inputs to the multiplexer.	N/A
Use Packets	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.	**On|Off**
Use Empty	Enables or disables the `empty` signal.	**On|Off**
Use Channel	Enables or disables the `channel` signal.	**On|Off**
Use Error	Enables or disables the `error` signal.	**On|Off**
Maximum Credit Allowed (Source Interface)	Specifies the maximum number of credits allowed by the source interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128,256**
Number of symbols	Specifies the maximum number of symbols that can transfer.	**1-8192**
Symbol width	Specifies the number of data bits per symbol.	**1-8192**
Width of Channel Port	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is disabled.	**1-128**
Width of Error Port	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is disabled.	**1-1024**
Width of Empty Port	The width of the `empty` signal on the output interfaces. A value of 0 indicates that the empty signal is not in use. This parameter is disabled when **Use Empty** is disabled.	**1-1024**
Use channel on Sink interface	Enables or disables the `channel` signal on the sink interlace.	**On|Off**
Sink channel width	Specifies the width of the sink channel when **Use channel on Sink interface** is **On**.	**1-128**

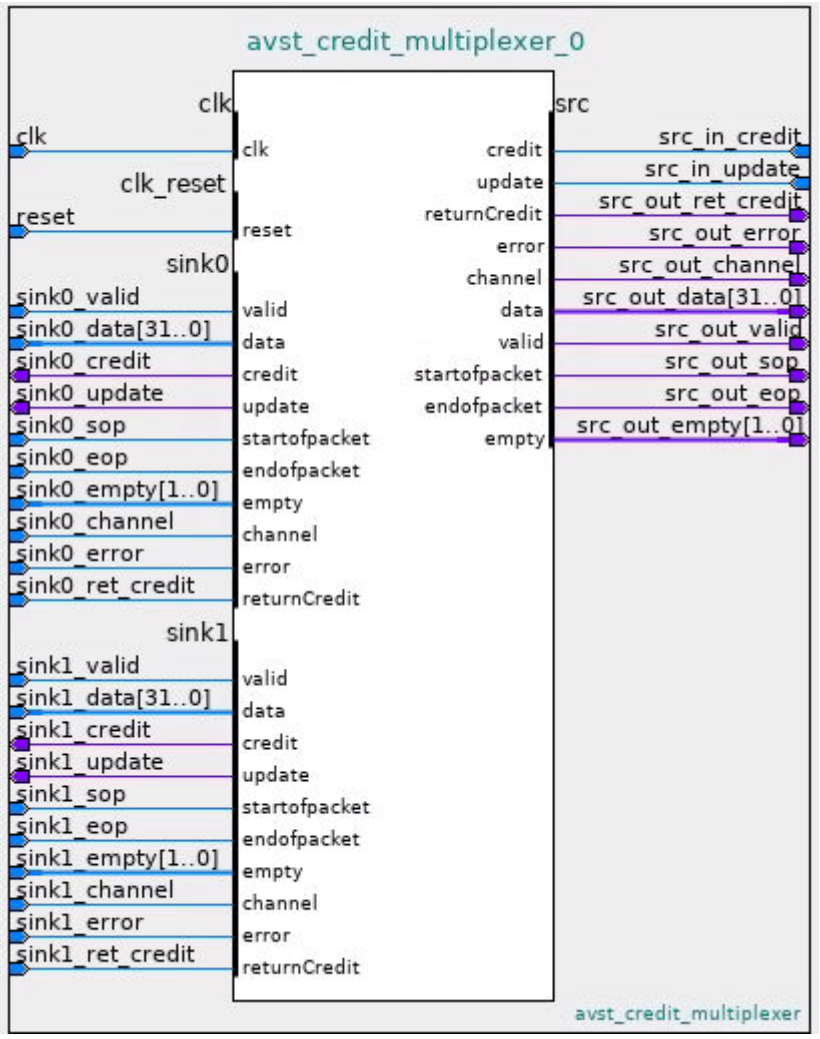
Figure 227. Avalon Streaming Credit Multiplexer Interface Signals



Related Information

Avalon Streaming Credit Interface Signal Roles on page 355

5.3.4. Avalon Streaming Credit Demultiplexer

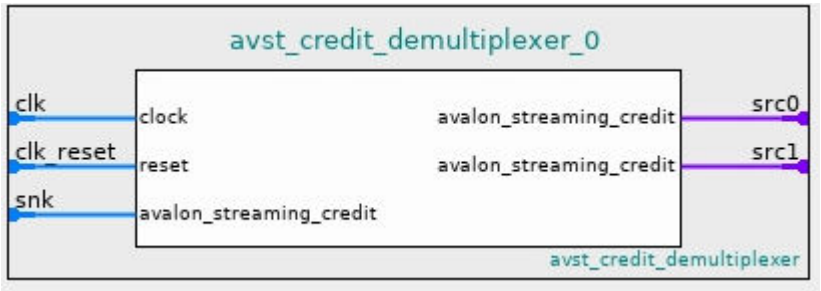
The Avalon Streaming Credit Demultiplexer allows one source to access multiple sinks.

The Avalon Streaming Credit Demultiplexer:

- Must have a channel signal from the source as an input.
- The channel input from the source must be at least `ceil(log2 (NUM_SINKS))` wide, where `NUM_SINKS` is the number of sinks.

  For example, if the source connects to 6 sinks, the channel signal from the source must be at least 3 bits. The least significant `ceil(log2(NUM_SINKS))` bits route data from the source to the appropriate sink. For example, if the demultiplexer connects to 5 sinks (`sink0`, `sink1`, `sink2`, `sink3`, `sink4`), and the channel signal is 8 bits wide, with a value on the channel bus of `00010010`, data routes to `sink2`.
- The source is responsible for maintaining packet integrity to any sink.
- During a packet transmission, the source must not change the lower order channel bits. Otherwise, the sinks may receive incomplete or invalid packets.
- Is available as the **Avalon Streaming Credit Demultiplexer Intel FPGA IP** from the Platform Designer IP Catalog.

Figure 228. Avalon Streaming Credit Demultiplexer



5.3.4.1. Avalon Streaming Credit Demultiplexer Parameters

You can specify the following parameters for the Avalon Streaming Credit Demultiplexer by double-clicking **Avalon Streaming Credit Demultiplexer Intel FPGA IP** in the Platform Designer IP Catalog:

Table 78. Avalon Streaming Credit Demultiplexer Parameters

Parameter Name	Description	Legal Values
Number of demux outputs	Specifies the number of outputs from the demultiplexer.	N/A
Maximum Credit Allowed (Sink Interface)	Specifies the maximum number of credits allowed by the sink interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128,256**
Number of symbols	Specifies the maximum number of symbols that can transfer.	**1-8192**
Symbol width	Specifies the number of data bits per symbol.	**1-8192**
Width of Error Port	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is disabled.	**1-1024**

continued...

Parameter Name	Description	Legal Values
Width of Empty Port	The width of the `empty` signal on the output interfaces. A value of 0 indicates that the empty signal is not in use. This parameter is disabled when **Use Empty** is disabled.	**1-1024**
Use Channel	Enables the `channel` signal. (always on)	**On**
Width of Channel Port	The width of the `channel` signal on the sink interface based on the number of demux outputs.	**1-128**
Use Packets	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.	**On|Off**
Use Empty	Enables or disables the `empty` signal.	**On|Off**
Use Error	Enables or disables the `error` signal.	**On|Off**
Enable User Signals	Allows you to specify the name, width, and type of user signals.	**On|Off**
Use channel on Source interface	Enables or disables the `channel` signal on the source interface.	**On|Off**
Source channel width	Specifies the width of the source channel when **Use channel on Source interface** is **On**.	**1-128**

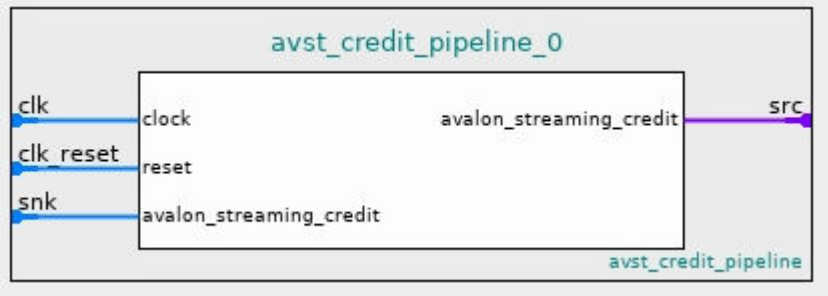
Avalon Streaming Credit Interface Signal Roles on page 355

5.3.5. Avalon Streaming Credit Pipeline Bridge

The Avalon Streaming Credit Pipeline Bridge allows you to insert an arbitrary number of pipeline stages on both the credit and data paths. The number of pipeline stages on the credit path, from sink to source, need not be equal to the number of pipeline stages on the data path, from source to sink.

This bridge is available as the **Avalon Streaming Credit Pipeline Bridge Intel FPGA IP** from the Platform Designer IP Catalog.

Figure 230. Avalon Streaming Credit Pipeline Bridge



5.3.5.1. Avalon Streaming Credit Pipeline Bridge Parameters

You can specify the following parameters for the Avalon Streaming Credit Pipeline Bridge by double-clicking **Avalon Streaming Credit Pipeline Bridge Intel FPGA IP** in the Platform Designer IP Catalog:

Table 79. Avalon Streaming Credit Pipeline Bridge Parameters

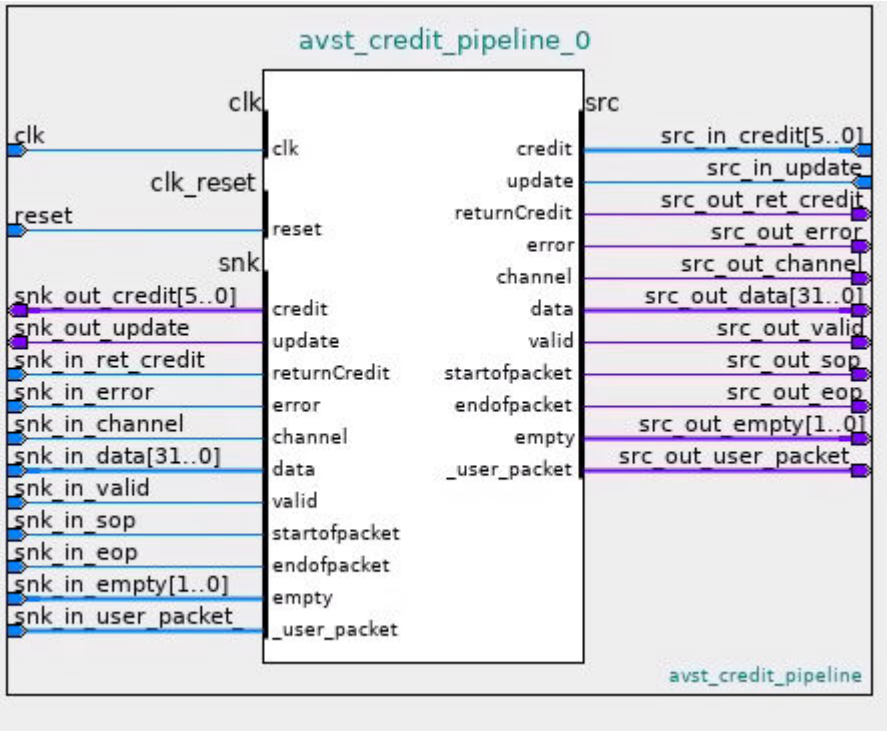
Parameter Name	Description	Legal Values
Data Pipeline Depth	Specifies the depth (size) of the data pipeline.	**1-16**
Credit Pipeline Depth	Specifies the depth (size) of the credit pipeline.	**1-16**
Maximum Credit Allowed (Source Interface)	Specifies the maximum number of credits allowed by the source interface. Legal values are from 1 to 256.	**1,2,4,8,16,32,64,128, 256**
Number of symbols	Specifies the maximum number of symbols that can transfer.	**1-8192**
Symbol width	Specifies the number of data bits per symbol.	**1-8192**
Width of Channel Port	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is disabled.	**1-128**
Width of Error Port	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is disabled.	**1-1024**
Width of Empty Port	The width of the `empty` signal on the output interfaces. A value of 0 indicates that the empty signal is not in use. This parameter is disabled when **Use Empty** is disabled.	**1-1024**

continued...

Parameter Name	Description	Legal Values
Use Packets	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.	**On|Off**
Use Empty	Enables or disables the `empty` signal.	**On|Off**
Use Channel	Enables or disables the `channel` signal.	**On|Off**
Use Error	Enables or disables the `error` signal.	**On|Off**
Enable User Signals	Allows you to specify the name, width, and type of user signals.	**On|Off**

5.3.5.2. Avalon Streaming Credit Pipeline Bridge Interface Signals

Figure 231. Avalon Streaming Credit Pipeline Bridge Interface Signals



Related Information

Avalon Streaming Credit Interface Signal Roles on page 355

5.4. Interrupt Interfaces

Using individual requests, the interrupt logic can process up to 2048 IRQ inputs connected to each interrupt receiver. With this logic, the interrupt sender connected to interrupt `receiver0` is the highest priority with sequential receivers being successively lower priority. You can redefine the priority of interrupt senders by instantiating the IRQ mapper component. For more information, refer to IRQ Mapper on page 309.

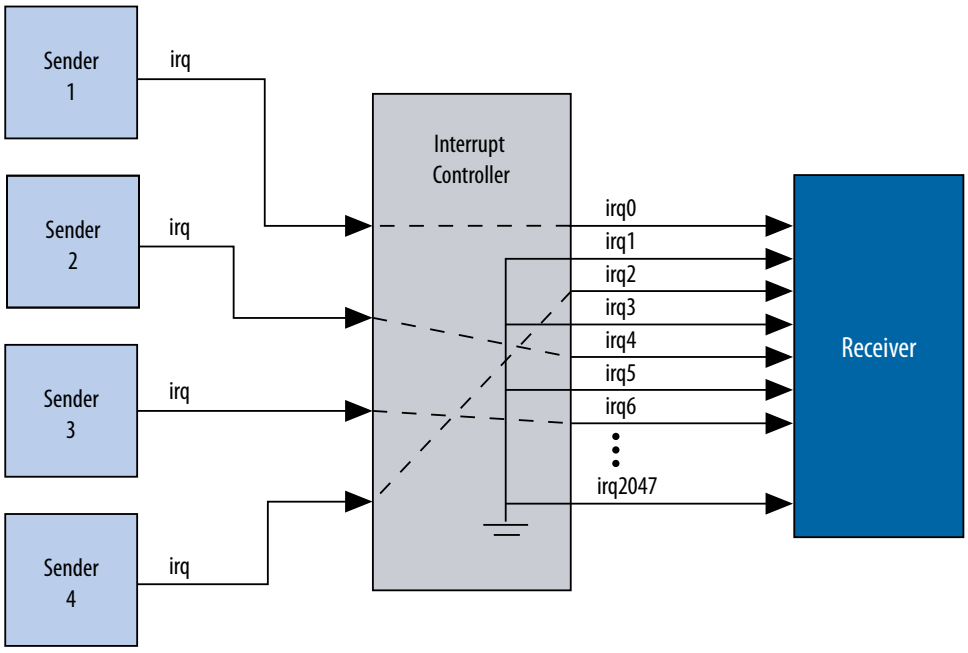
You can define the interrupt sender interface as asynchronous with no associated clock or reset interfaces. You can also define the interrupt receiver interface as asynchronous with no associated clock or reset interfaces. As a result, the receiver does its own synchronization internally. Platform Designer does not insert interrupt synchronizers for such receivers.

For clock crossing adaptation on interrupts, Platform Designer inserts a synchronizer. This synchronizer is clocked with the interrupt end point interface clock when the corresponding starting point interrupt interface has no clock or a different clock (than the end point). Platform Designer inserts the adapter if there is any kind of mismatch between the start and end points. Platform Designer does not insert the adapter if the interrupt receiver does not have an associated clock.

5.4.1. Individual Requests IRQ Scheme

In the individual requests IRQ scheme, Platform Designer interconnect passes IRQs directly from the sender to the receiver, without making assumptions about IRQ priority. If multiple senders assert their IRQs simultaneously, the receiver logic determines which IRQ has highest priority, and then responds appropriately.

Figure 232. Interrupt Controller Mapping IRQs



Using individual requests, the interrupt controller can process up to 2048 IRQ inputs. The interrupt controller generates a 2048-bit signal `irq[2047:0]` to the receiver, and maps agent IRQ signals to the bits of `irq[2047:0]`. Any unassigned bits of `irq[2047:0]` are disabled.

5.4.2. Assigning IRQs in Platform Designer

You assign IRQ connections on the **System View** tab of Platform Designer. After adding all components to the system, you connect interrupt senders and receivers.

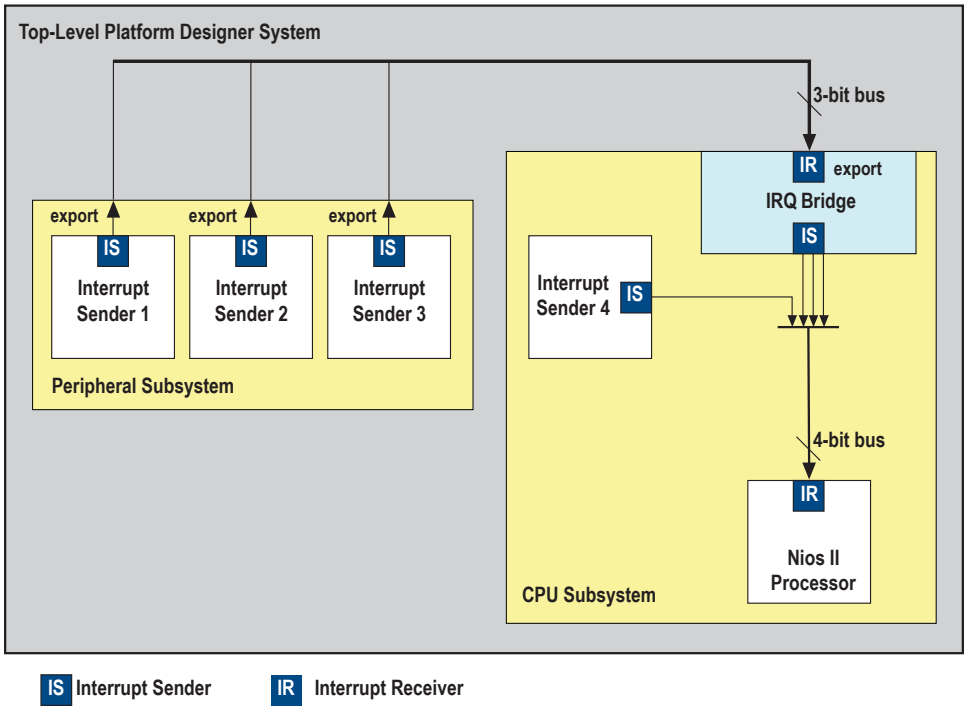
You can use the **IRQ** column to specify an IRQ number with respect to each receiver, or to specify a receiver's IRQ as unconnected. Platform Designer uses the following components to implement interrupt handling: IRQ Bridge, IRQ Mapper, IRQ Clock Crosser, and IRQ Fanout.

5.4.2.1. IRQ Bridge

The IRQ Bridge Intel FPGA IP allows you to route interrupt wires between Platform Designer subsystems.

Figure 233. Platform Designer IRQ Bridge Application

The peripheral subsystem example below has three interrupt senders that are exported to the top-level of the subsystem. The interrupts are then routed to the CPU subsystem using the IRQ bridge.



Note: Nios II BSP tools support the IRQ Bridge. Interrupts connected via an IRQ Bridge appear in the generated `system.h` file. You can use the following properties with the IRQ Bridge, which do not effect Platform Designer interconnect generation. Platform Designer uses these properties to generate the correct IRQ information for downstream tools:

- `set_interface_property <sender port> bridgesToReceiver <receiver port>`— The <*sender port*> of the IP generates a signal that is received on the IP's <*receiver port*>. Sender ports are single bits. Receive ports can be multiple bits. Platform Designer requires the `bridgedReceiverOffset` property to identify the <*receiver port*> bit that the <*sender port*> sends.
- `set_interface_property <sender port> bridgedReceiverOffset <port number>`— Indicates the <*port number*> of the receiver port that the <*sender port*> sends.

5.4.2.2. IRQ Mapper

Platform Designer inserts the IRQ Mapper Intel FPGA IP automatically during generation. The IRQ Mapper converts individual interrupt wires to a bus, and then maps the appropriate IRQ priority number onto the bus.

You can specify the following parameter values:

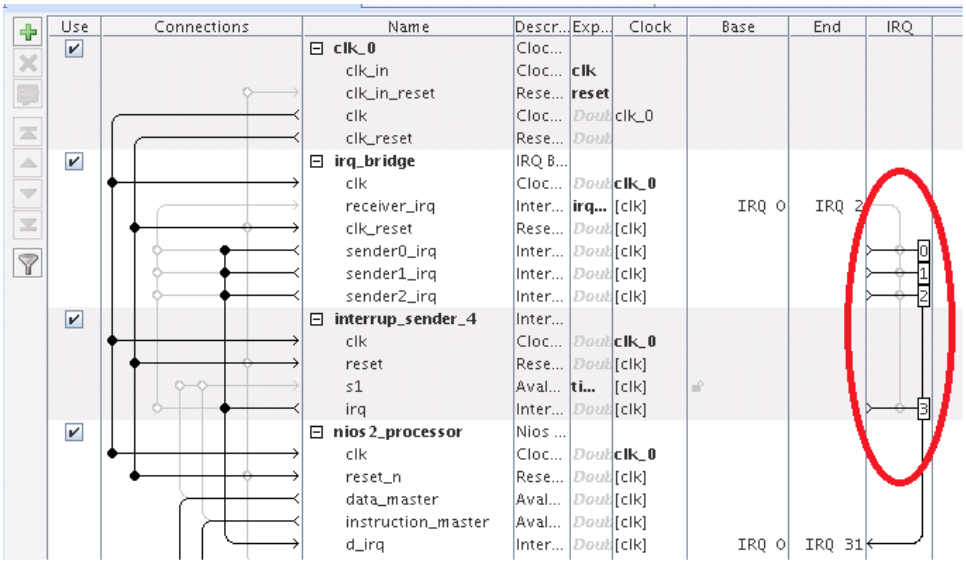
Table 80. IRQ Mapper Parameters

Parameter	Values	Description
Number of receivers	1-2048	Specifies the number of Avalon receiver signals on the bus.
Sender interrupt width	1-2048	Specifies the width of the Avalon sender signal bus.
Use synchronous resets	On|Off	Resets signal synchronously. This option is Off by default.
Remove Clock and Reset Ports	On|Off	Removes the clock and reset ports from the component. If both **Use synchronous resets** and **Remove Clock and Reset Ports** are on, Platform Designer displays an error.

By default, the interrupt sender connected to the `receiver0` interface of the IRQ mapper is the highest priority, and sequential receivers are successively lower priority. You can modify the interrupt priority of each IRQ wire by modifying the IRQ priority number in Platform Designer under the **IRQ** column. The modified priority is reflected in the **IRQ_MAP** parameter for the auto-inserted IRQ Mapper.

Figure 234. IRQ Column in Platform Designer

Circled in the **IRQ** column are the default interrupt priorities allocated for the CPU subsystem.



5.4.2.3. IRQ Clock Crosser

The IRQ Clock Crosser Intel FPGA IP synchronizes interrupt senders and receivers that are in different clock domains. To use this component, connect the clocks for both the interrupt sender and receiver, and for both the interrupt sender and receiver interfaces. Platform Designer automatically inserts this component when it is required.

5.4.2.4. IRQ Fanout

The IRQ Fanout Intel FPGA IP allows you to specify a value for the **Number of senders** parameter that controls the number of interrupt senders exported to the top level of the system. Platform Designer automatically inserts this component when the system requires.

5.5. Clock Interfaces

Clock interfaces define the clocks used by a component. Components can have clock inputs, clock outputs, or both. To update the clock frequency of the component, use the **Parameters** tab for the clock source.

The **Clock Source** parameters allows you to set the following options:

- **Clock frequency**—the frequency of the output clock from this clock source.
- **Clock frequency is known**— when turned on, the clock frequency is known. When turned off, the frequency is set from outside the system. Turning off this option is useful for cases when a subsystem receives a clock from a higher level system.

  Note: If turned off, system generation may fail because the components do not receive the necessary clock information. For best results, turn this option on before system generation.

For more information about synchronous design practices, refer to *Quartus Prime Pro Edition User Guide: Design Recommendations*.

5.5.1. (High Speed Serial Interface) HSSI Clock Interfaces

You can use HSSI Serial Clock and HSSI Bonded Clock interfaces in Platform Designer to enable high speed serial connectivity between clocks that are used by certain IP protocols.

5.5.1.1. HSSI Serial Clock Interface

You can connect the HSSI Serial Clock interface with only similar type of interfaces, for example, you can connect a HSSI Serial Clock Source interface to a HSSI Serial Clock Sink interface.

5.5.1.1.1. HSSI Serial Clock Source

The HSSI Serial Clock interface includes a source in the **Start** direction.

You can instantiate the HSSI Serial Clock Source interface in the **_hw.tcl** file as:

```
add_interface <name> hssi_serial_clock start
```

You can connect the HSSI Serial Clock Source to multiple HSSI Serial Clock Sinks because the HSSI Serial Clock Source supports multiple fan-outs. This Interface has a single **clk** port role limited to a 1 bit width, and a **clockRate** parameter, which is the frequency of the clock driven by the HSSI Serial Clock Source interface.

An unconnected and unexported HSSI Serial Source is valid and does not generate error messages.

Table 81. HSSI Serial Clock Source Port Roles

Name	Direction	Width	Description
clk	Output	1 bit	A single bit wide port role, which provides synchronization for internal logic.

Table 82. HSSI Serial Clock Source Parameters

Name	Type	Default	Derived	Description
clockRate	long	0	No	The frequency of the clock driven byte HSSI Serial Clock Source interface.

5.5.1.1.2. HSSI Serial Clock Sink

The HSSI Serial Clock interface includes a sink in the **End** direction.

You can instantiate the HSSI Serial Clock Sink interface in the **_hw.tcl** file as:

```
add_interface <name> hssi_serial_clock end
```

You can connect the HSSI Serial Clock Sink interface to a single HSSI Serial Clock Source interface; you cannot connect it to multiple sources. This Interface has a single **clk** port role limited to a 1 bit width, and a **clockRate** parameter, which is the frequency of the clock driven by the HSSI Serial Clock Source interface.

An unconnected and unexported HSSI Serial Sink is invalid and generates error messages.

Table 83. HSSI Serial Clock Sink Port Roles

Name	Direction	Width	Description
clk	Output	1	A single bit wide port role, which provides synchronization for internal logic

Table 84. HSSI Serial Clock Sink Parameters

Name	Type	Default	Derived	Description
clockRate	long	0	No	The frequency of the clock driven by the HSSI Serial Clock Source interface. When you specify a **clockRate** greater than 0, then this interface can be driven only at that rate.

5.5.1.1.3. HSSI Serial Clock Connection

The HSSI Serial Clock Connection defines a connection between a HSSI Serial Clock Source connection point, and a HSSI Serial Clock Sink connection point.

A valid HSSI Serial Clock Connection exists when all the following criteria are satisfied. If the following criteria are not satisfied, Platform Designer generates error messages and the connection is prohibited.

- The starting connection point is an HSSI Serial Clock Source with a single port role **clk** and maximum 1 bit in width. The direction of the starting port is **Output**.
- The ending connection point is an HSSI Serial Clock Sink with a single port role **clk**, and maximum 1 bit in width. The direction of the ending port is **Input**.
- If the parameter, **clockRate** of the HSSI Serial Clock Sink is greater than 0, the connection is only valid if the **clockRate** of the HSSI Serial Clock Source is the same as the **clockRate** of the HSSI Serial Clock Sink.

5.5.1.1.4. HSSI Serial Clock Example

Example 23. HSSI Serial Clock Interface Example

You can make connections to declare the HSSI Serial Clock interfaces in the **_hw.tcl**.

```
package require -exact qsys 14.0

set_module_property name hssi_serial_component
set_module_property ELABORATION_CALLBACK elaborate

add_fileset QUARTUS_SYNTH QUARTUS_SYNTH generate
add_fileset SIM_VERILOG SIM_VERILOG generate
add_fileset SIM_VHDL SIM_VHDL generate

set_fileset_property QUARTUS_SYNTH TOP_LEVEL \
"hssi_serial_component"

set_fileset_property SIM_VERILOG TOP_LEVEL "hssi_serial_component"
set_fileset_property SIM_VHDL TOP_LEVEL "hssi_serial_component"

proc elaborate {} {
    # declaring HSSI Serial Clock Source
    add_interface my_clock_start hssi_serial_clock start
    set_interface_property my_clock_start  ENABLED true

    add_interface_port my_clock_start  hssi_serial_clock_port_out \
 clk Output 1

    # declaring HSSI Serial Clock Sink
    add_interface my_clock_end hssi_serial_clock end
    set_interface_property my_clock_end  ENABLED true
```

```
    add_interface_port my_clock_end  hssi_serial_clock_port_in clk \
 Input 1
}

proc generate { output_name } {

    add_fileset_file hssi_serial_component.v VERILOG PATH \
 "hssi_serial_component.v"
}
```

Example 24. HSSI Serial Clock Instantiated in a Composed Component

If you use the components in a hierarchy, for example, instantiated in a composed component, you can declare the connections as illustrated in this example.

```
add_instance myinst1 hssi_serial_component
add_instance myinst2 hssi_serial_component
# add connection from source of myinst1 to sink of myinst2

add_connection myinst1.my_clock_start myinst2.my_clock_end \
hssi_serial_clock

# adding connection from source of myinst2 to sink of myinst1

add_connection myinst2.my_clock_start myinst2.my_clock_end \
hssi_serial_clock
```

5.5.1.2. HSSI Bonded Clock Interface

You can connect the HSSI Bonded Clock interface only with similar type of interfaces, for example, you can connect a HSSI Bonded Clock Source interface to a HSSI Bonded Clock Sink interface.

5.5.1.2.1. HSSI Bonded Clock Source

The HSSI Bonded Clock interface includes a source in the **Start** direction.

You can instantiate the HSSI Bonded Clock Source interface in the **_hw.tcl** file as:

```
add_interface <name> hssi_bonded_clock start
```

You can connect the HSSI Bonded Clock Source to multiple HSSI Bonded Clock Sinks because the HSSI Serial Clock Source supports multiple fanouts. This Interface has a single **clk** port role limited to a width range of 1 to 1024 bits. The HSSI Bonded Clock Source interface has two parameters: **clockRate** and **serializationFactor**. **clockRate** is the frequency of the clock driven by the HSSI Bonded Clock Source interface, and the **serializationFactor** is the parallel data width that operates the HSSI TX serializer. The serialization factor determines the required frequency and phases of the individual clocks within the HSSI Bonded Clock interface

An unconnected and unexported HSSI Bonded Source is valid, and does not generate error messages.

Table 85. HSSI Bonded Clock Source Port Roles

Name	Direction	Width	Description
clk	Output	1 to 24 bits	A multiple bit wide port role which provides synchronization for internal logic.

Table 86. HSSI Bonded Clock Source Parameters

Name	Type	Default	Derived	Description
clockRate	long	0	No	The frequency of the clock driven byte HSSI Serial Clock Source interface.
serialization	long	0	No	The serialization factor is the parallel data width that operates the HSSI TX serializer. The serialization factor determines the necessary frequency and phases of the individual clocks within the HSSI Bonded Clock interface.

5.5.1.2.2. HSSI Bonded Clock Sink

The HSSI Bonded Clock interface includes a sink in the **End** direction.

You can instantiate the HSSI Bonded Clock Sink interface in the **_hw.tcl** file as:

```
add_interface <name> hssi_bonded_clock end
```

You can connect the HSSI Bonded Clock Sink interface to a single HSSI Bonded Clock Source interface; you cannot connect it to multiple sources. This Interface has a single **clk** port role limited to a width range of 1 to 1024 bits. The HSSI Bonded Clock Source interface has two parameters: **clockRate** and **serializationFactor**. **clockRate** is the frequency of the clock driven by the HSSI Bonded Clock Source interface, and the serialization factor is the parallel data width that operates the HSSI TX serializer. The serialization factor determines the required frequency and phases of the individual clocks within the HSSI Bonded Clock interface

An unconnected and unexported HSSI Bonded Sink is invalid and generates error messages.

Table 87. HSSI Bonded Clock Source Port Roles

Name	Direction	Width	Description
clk	Output	1 to 24 bits	A multiple bit wide port role which provides synchronization for internal logic.

Table 88. HSSI Bonded Clock Source Parameters

Name	Type	Default	Derived	Description
clockRate	long	0	No	The frequency of the clock driven byte HSSI Serial Clock Source interface.
serialization	long	0	No	The serialization factor is the parallel data width that operates the HSSI TX serializer. The serialization factor determines the necessary frequency and phases of the individual clocks within the HSSI Bonded Clock interface.

5.5.1.2.3. HSSI Bonded Clock Connection

The HSSI Bonded Clock Connection defines a connection between a HSSI Bonded Clock Source connection point, and a HSSI Bonded Clock Sink connection point.

A valid HSSI Bonded Clock Connection exists when all the following criteria are satisfied. If the following criteria are not satisfied, Platform Designer generates error messages and the connection is prohibited.

- The starting connection point is an HSSI Bonded Clock Source with a single port role **clk** with a width range of 1 to 24 bits. The direction of the starting port is **Output**.
- The ending connection point is an HSSI Bonded Clock Sink with a single port role **clk** with a width range of 1 to 24 bits. The direction of the ending port is **Input**.
- The width of the starting connection point **clk** must be the same as the width of the ending connection point.
- If the parameter, **clockRate** of the HSSI Bonded Clock Sink greater than 0, then the connection is only valid if the **clockRate** of the HSSI Bonded Clock Source is same as the **clockRate** of the HSSI Bonded Clock Sink.
- If the parameter, **serializationFactor** of the HSSI Bonded Clock Sink is greater than 0, Platform Designer generates a warning if the **serializationFactor** of HSSI Bonded Clock Source is not same as the **serializationFactor** of the HSSI Bonded Clock Sink.

5.5.1.2.4. HSSI Bonded Clock Example

Example 25. HSSI Bonded Clock Interface Example

You can make connections to declare the HSSI Bonded Clock interfaces in the **_hw.tcl** file.

```
package require -exact qsys 14.0

set_module_property name hssi_bonded_component
set_module_property ELABORATION_CALLBACK elaborate

add_fileset synthesis QUARTUS_SYNTH generate
add_fileset verilog_simulation SIM_VERILOG generate

set_fileset_property synthesis TOP_LEVEL "hssi_bonded_component"

set_fileset_property verilog_simulation TOP_LEVEL \
"hssi_bonded_component"

proc elaborate {} {
    add_interface my_clock_start hssi_bonded_clock start
    set_interface_property my_clock_start  ENABLED true

    add_interface_port my_clock_start  hssi_bonded_clock_port_out \
 clk Output 1024

    add_interface my_clock_end hssi_bonded_clock end
    set_interface_property my_clock_end  ENABLED true

    add_interface_port my_clock_end  hssi_bonded_clock_port_in \
 clk Input 1024
}

proc generate { output_name } {
    add_fileset_file hssi_bonded_component.v VERILOG PATH \
 "hssi_bonded_component.v"}
```

If you use the components in a hierarchy, for example, instantiated in a composed component, you can declare the connections as illustrated in this example.

Example 26. HSII Bonded Clock Instantiated in a Composed Component

```
add_instance myinst1 hssi_bonded_component
add_instance myinst2 hssi_bonded_component
# add connection from source of myinst1 to sink of myinst2

add_connection myinst1.my_clock_start myinst2.my_clock_end \
hssi_bonded_clock

# adding connection from source of myinst2 to sink of myinst1

add_connection myinst2.my_clock_start myinst2.my_clock_end \
hssi_bonded_clock
```

5.6. Reset Interfaces

Reset interfaces provide both soft and hard reset functionality. Soft reset logic typically re-initializes registers and memories without powering down the device. Hard reset logic initializes the device after power-on.

You can define separate reset sources for each clock domain, a single reset source for all clocks, or any combination in between. You can choose to create a single global reset domain by clicking **System ➤ Create Global Reset Network**. If your design requires more than one reset domain, you can implement your own reset logic and connectivity. The IP Catalog includes a reset controller, reset sequencer, and a reset bridge to implement the reset functionality. You can also design your own reset logic.

Platform Designer interconnect now supports synchronous reset of registers in the interconnect. Use of synchronous reset can result in higher performance for Stratix 10 designs because although Stratix 10 Hyper-Registers lack a reset signal, they can make use of the synchronous reset from an adjacent LAB. If a register in your Stratix 10 design uses asynchronous reset, the Compiler cannot implement the register as a Hyper-Register, potentially reducing performance.

When **Use synchronous reset** is set to **True** in the **Domains** tab, all registers in the interconnect use synchronous reset. The **Use synchronous reset** option is enabled by default for Stratix 10 designs, but is disabled by default for all other designs.

Note: If you design your own reset circuitry, you must carefully consider situations which may result in system lockup. For example, if an Avalon memory mapped agent is reset in the middle of a transaction, the Avalon memory mapped host may lockup.

Related Information

Specifying Interconnect Parameters on page 71

5.6.1. Single Global Reset Signal Implemented by Platform Designer

When you select **System ➤ Create Global Reset Network**, the Platform Designer interconnect creates a global reset bus. All the reset requests are ORed together, synchronized to each clock domain, and fed to the reset inputs. The duration of the reset signal is at least one clock period.

The Platform Designer interconnect inserts the system-wide reset under the following conditions:

- The global reset input to the Platform Designer system is asserted.
- Any component asserts its `resetrequest` signal.

5.6.2. Reset Controller

Platform Designer automatically inserts a reset controller block if the input reset source does not have a reset request, but the connected reset sink requires a reset request.

The Reset Controller has the following parameters that you can specify to customize its behavior:

- **Number of inputs**— Indicates the number of individual reset interfaces the controller ORs to create a signal reset output.
- **Output reset synchronous edges**—Specifies the level of synchronization. You can select one the following options:
  - **None**—The reset is asserted and deasserted asynchronously. You can use this setting if you have designed internal synchronization circuitry that matches the reset style required for the IP in the system.
  - **Both**—The reset is asserted and deasserted synchronously.
  - **Deassert**—The reset is deasserted synchronously and asserted asynchronously.
- **Synchronization depth**—Specifies the number of register stages the synchronizer uses to eliminate the propagation of metastable events.
- **Reset request**—Enables reset request generation, which is an early signal that is asserted before reset assertion. The reset request is used by blocks that require protection from asynchronous inputs, for example, M20K blocks.

Platform Designer automatically inserts reset synchronizers under the following conditions:

- More than one reset source is connected to a reset sink
- There is a mismatch between the reset source's synchronous edges and the reset sinks' synchronous edges

5.6.3. Reset Bridge

The Reset Bridge allows you to use a reset signal in two or more subsystems of your Platform Designer system. You can connect one reset source to local components, and export one or more to other subsystems, as required.

The Reset Bridge parameters are used to describe the incoming reset and include the following options:

- **Active low reset**—When turned on, reset is asserted low.
- **Synchronous edges**—Specifies the level of synchronization and includes the following options:
  - **None**—The reset is asserted and deasserted asynchronously. Use this setting if you have internal synchronization circuitry.
  - **Both**—The reset is asserted and deasserted synchronously.
  - **Deassert**—The reset is deasserted synchronously, and asserted asynchronously.
- **Number of reset outputs**—The number of reset interfaces that are exported.

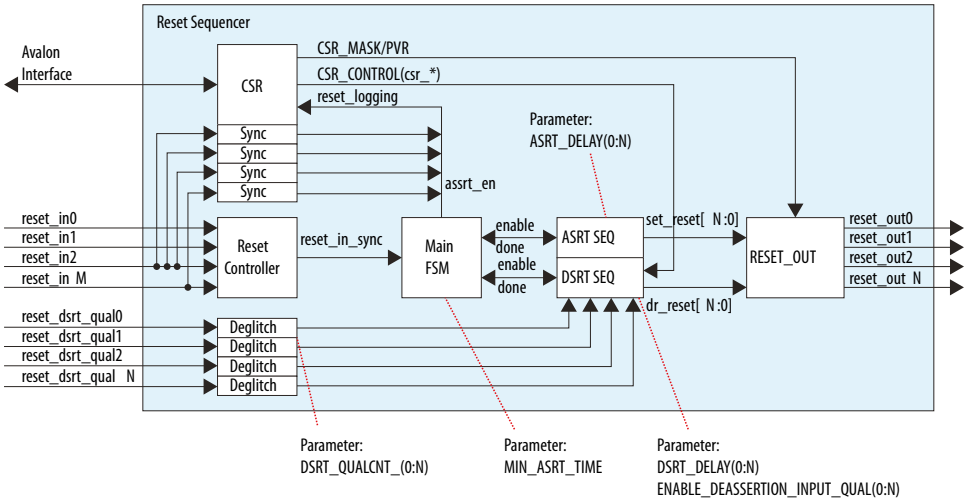
Note: Platform Designer supports multiple reset sink connections to a single reset source interface. However, there are situations in composed systems where an internally generated reset must be exported from the composed system in addition to being used to connect internal components. In this situation, you must declare one reset output interface as an export, and use another reset output to connect internal components.

5.6.4. Reset Sequencer

The Reset Sequencer allows you to control the assertion and deassertion sequence for Platform Designer system resets.

The Parameter Editor displays the expected assertion and deassertion sequences based on the current settings. You can connect multiple reset sources to the reset sequencer, and then connect the outputs of the Reset Sequencer to components in the system.

Figure 235. Elements and Flow of a Reset Sequencer



- Reset Controller—Reused reset controller block. It synchronizes the reset inputs into one and feeds into the main FSM of the sequencer block.
- Sync—Synchronization block (double flipflop).
- Deglitch—Deglitch block. This block waits for a signal to be at a level for X clocks before propagating the input to the output.
- CSR—This block contains the CSR Avalon interface and related CSR register and control block in the sequencer.
- Main FSM—Main sequencer. This block determines when assertion/deassertion and assertion hold timing occurs.
- [A/D]SRT SEQ—Generic sequencer block that sequences out assertion/deassertion of reset from 0:N. The block has multiple counters that saturate upon reaching count.
- RESET_OUT—Controls the end output via:
  - Set/clear from the ASRT_SEQ/DSRT_SEQ.
  - Masking/forcing from CSR controls.
  - Remap of numbering (parameterization).

5.6.4.1. Reset Sequencer Parameters

Table 89. Reset Sequencer Parameters

Parameter	Description
Number of reset outputs	Sets the number of output resets to be sequenced, which is the number of output reset signals defined in the component with a range of 2 to 10.
Number of reset inputs	Sets the number of input reset signals to be sequenced, which is the number of input reset signals defined in the component with a range of 1 to 10.
Minimum reset assertion time	Specifies the minimum assertion cycles between the assertion of the last sequenced reset, and the deassertion of the first sequenced reset. The range is 0 to 1023.
Enable Reset Sequencer CSR	Enables CSR functionality of the Reset Sequencer through an Avalon interface.
reset_out#	Lists the reset output signals. Set the parameters in the other columns for each reset signal in the table.
ASRT Seq#	Determines the order of reset assertion. Enter the values 1, 2, 3, etc. to specify the required non-overlapping assertion order. This value determines the ASRT_REMAP value in the component HDL.
ASRT Cycle#	Number of cycles to wait before assertion of the reset. The value set here corresponds to the ASRT_DELAY value in the component HDL. The range is 0 to 1023.
DSRT Seq#	Determines the reset order of reset deassertion. Enter the values 1, 2, 3, etc. to specify the required non-overlapping deassertion order. This value determines the DSRT_REMAP value in the component HDL.
DSRT Cycle#/Deglitch#	Number of cycles to wait before deasserting or deglitching the reset. If the **USE_DRST_QUAL** parameter is set to 0, specifies the number of cycles to wait before deasserting the reset. If **USE_DSRT_QUAL** is set to1, specifies the number of cycles to deglitch the input `reset_dsrt_qual` signal. This value determines either the DSRT_DELAY, or the DSRT_QUALCNT value in the component HDL, depending on the **USE_DSRT_QUAL** parameter setting. The range is 0 to 1023.
USE_DSRT_QUAL	If you set **USE_DSRT_QUAL** to 1, the deassertion sequence waits for an external input signal for sequence qualification instead of waiting for a fixed delay count. To use a fixed delay count for deassertion, set this parameter to 0.

5.6.4.2. Reset Sequencer Timing Diagrams

Figure 236. Basic Sequencing

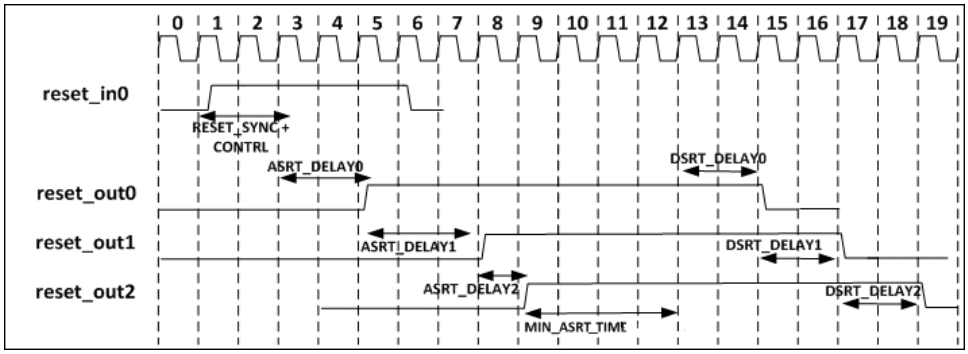


Figure 237. Sequencing with USE_DSRT_QUAL Set

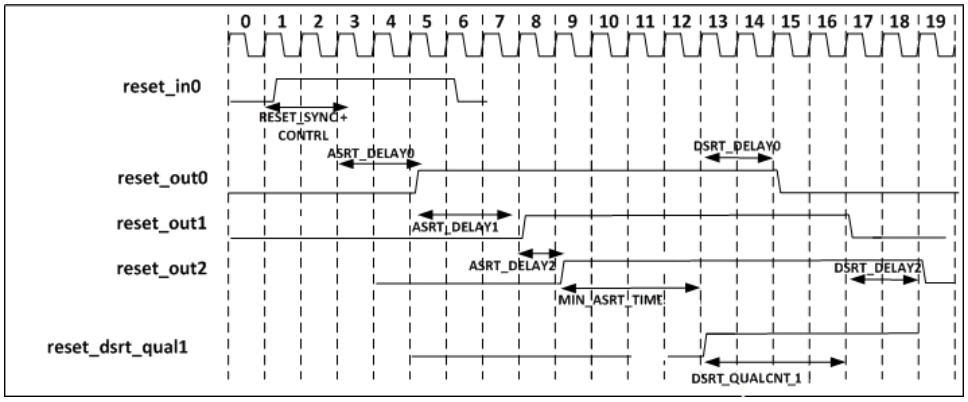


5.6.4.3. Reset Sequencer CSR Registers

The Reset Sequencer's CSR registers provide the following functionality:

- **Support reset logging**
  - Ability to identify which reset is asserted.
  - Ability to determine whether any reset is currently active.
- **Support software triggered resets**
  - Ability to generate reset by writing to the register.
  - Ability to disable assertion or deassertion sequence.
- **Support software sequenced reset**
  - Ability for the software to fully control the assertion/deassertion sequence by writing to registers and stepping through the sequence.
- **Support reset override**
  - Ability to assert a specific component reset through software.

Table 90. Reset Sequencer CSR Register Map

Register	Offset	Width	Reset Value	Description
`Status Register`	`0x00`	32	`0x0`	The `Status` register indicates which sources are allowed to cause a reset.
`Interrupt Enable Register`	`0x04`	32	`0x0`	The `Interrupt Enable` register bits enable events triggering the IRQ of the reset sequencer.
`Control Register`	`0x08`	32	`0x0`	The `Control` register allows you to control the Reset Sequencer.
`Software Sequenced Reset Assert Control Register`	`0x0C`	32	`0x3FF`	You can program the `Software Sequenced Reset Assert` control register to control the reset assertion sequence.

continued...

Register	Offset	Width	Reset Value	Description
Software Sequenced Reset Deassert Control Register	0x10	32	0x3FF	You can program the Software Sequenced Reset Deassert register to control the reset deassertion sequence.
Software Direct Controlled Resets	0x14	32	0X0	You can write a bit to 1 to assert the reset_outN signal, and to 0 to deassert the reset_outN signal.
Software Reset Masking	0x18	32	0x0	Masking off (writing 1) to a reset_outN "Reset Mask Enable" signal prevents the corresponding reset from being asserted. Writing a bit to 0 to a reset mask enable signal allows assertion of reset_outN.

5.6.4.3.1. Reset Sequencer Status Register

The Status register indicates which sources are allowed to cause a reset.

You can clear bits by writing 1 to the bit location. The Reset Sequencer ignores attempts to write bits with a value of 0. If the sequencer is reset (power-on-reset), all bits are cleared, except the power-on-reset bit.

Table 91. Values for the Status Register at Offset 0x00

Bit	Attribute	Default	Description
31	RO	0	Reset Active—Indicates that the sequencer is currently active in reset sequence (assertion or deassertion).
30	RW1C	0	Reset Asserted and waiting for SW to proceed—Set when there is an active reset assertion, and the next sequence is waiting for the software to proceed. Only valid when the Enable SW sequenced reset assert option is turned on.
29	RW1C	0	Reset Deasserted and waiting for SW to proceed—Set when there is an active reset deassertion, and the next sequence is waiting for the software to proceed. Only valid when the Enable SW sequenced reset deassert option is turned on.
28:26	Reserved.		
25:16	RW1C	0	Reset deassertion input qualification signal reset_dsrt_qual [9:0] status—Indicates that the reset deassertion's input signal qualification signal is set. This bit is set on the detection of assertion of the signal.
15:12	Reserved.		
11	RW1C	0	reset_in9 was triggered—Indicates that reset_in9 triggered the reset. Software clears this bits by writing 1 to this location.
10	RW1C	0	reset_in8 was triggered—Indicates that reset_in8 triggered the reset. Software clears this bit by writing 1 to this location.
9	RW1C	0	reset_in7 was triggered—Indicates that reset_in7 triggered the reset. Software clears this bit by writing 1 to this location.
8	RW1C	0	reset_in6 was triggered—Indicates that reset_in6 triggered the reset. Software clears this bit by writing 1 to this location.

continued...

Bit	Attribute	Default	Description
7	RW1C	0	reset_in5 was triggered—Indicates that reset_in5 triggered the reset. Software clears this bit by writing 1 to this location.
6	RW1C	0	reset_in4 was triggered—Indicates that reset_in4 triggered the reset. Software clears this bit by writing 1 to this location.
5	RW1C	0	reset_in3 was triggered—Indicates that reset_in3 triggered the reset. Software clears this bit by writing 1 to this location.
4	RW1C	0	reset_in2 was triggered—Indicates that reset_in2 triggered the reset. Software clears this bit by writing 1 to this location.
3	RW1C	0	reset_in1 was triggered—Indicates that reset_in1 triggered the reset. Software clears this bit by writing 1 to this location.
2	RW1C	0	reset_in0 was triggered—Indicates that reset_in0 triggered. Software clears this bit by writing 1 to this location.
1	RW1C	0	Software-triggered reset—Indicates that the software-triggered reset is set by the software, and triggering a reset.
0	RW1C	0	Power-on-reset was triggered—Asserted whenever the reset to the sequencer is triggered. This bit is NOT reset when sequencer is reset. Software clears this bit by writing 1 to this location.

5.6.4.3.2. Reset Sequencer Interrupt Enable Register

The Interrupt Enable register bits enable events triggering the IRQ of the reset sequencer.

Table 92. Values for the Interrupt Enable Register at Offset 0x04

Bit	Attribute	Default	Description
31	Reserved.		
30	RW	0	Interrupt on Reset Asserted and waiting for SW to proceed enable. When set, the IRQ is set when the sequencer is waiting for the software to proceed in an assertion sequence.
29	RW	0	Interrupt on Reset Deasserted and waiting for SW to proceed enable. When set, the IRQ is set when the sequencer is waiting for the software to proceed in a deassertion sequence.
28:26	Reserved.		
25:16	RW	0	Interrupt on Reset deassertion input qualification signal reset_dsrt_qual_[9:0] status— When set, the IRQ is set when the reset_dsrt_qual[9:0] status bit (per bit enable) is set.
15:12	Reserved.		
11	RW	0	Interrupt on reset_in9 Enable—When set, the IRQ is set when the reset_in9 trigger status bit is set.
10	RW	0	Interrupt on reset_in8 Enable—When set, the IRQ is set when the reset_in8 trigger status bit is set.
9	RW	0	Interrupt on reset_in7 Enable—When set, the IRQ is set when the reset_in7 trigger status bit is set.
8	RW	0	Interrupt on reset_in6 Enable—When set, the IRQ is set when the reset_in6 trigger status bit is set.

continued...

Bit	Attribute	Default	Description
7	RW	0	Interrupt on reset_in5 Enable—When set, the IRQ is set when the reset_in5 trigger status bit is set.
6	RW	0	Interrupt on reset_in4 Enable—When set, the IRQ is set when the reset_in4 trigger status bit is set.
5	RW	0	Interrupt on reset_in3 Enable—When set, the IRQ is set when the reset_in3 trigger status bit is set.
4	RW	0	Interrupt on reset_in2 Enable—When set, the IRQ is set when the reset_in2 trigger status bit is set.
3	RW	0	Interrupt on reset_in1 Enable—When set, the IRQ is set when the reset_in1 trigger status bit is set.
2	RW	0	Interrupt on reset_in0 Enable—When set, the IRQ is set when the reset_in0 trigger status bit is set.
1	RW	0	Interrupt on Software triggered reset Enable—When set, the IRQ is set when the software triggered reset status bit is set.
0	RW	0	Interrupt on Power-On-Reset Enable—When set, the IRQ is set when the power-on-reset status bit is set.

5.6.4.3.3. Reset Sequencer Control Register

The Control register allows you to control the Reset Sequencer.

Table 93. Values for the Control Register at Offset 0x08

Bit	Attribute	Default	Description
31:3	Reserved.		
2	RW	0	Enable SW sequenced reset assert—Enable a software sequenced reset assert sequence. Timer delays and input qualification are ignored, and only the software can sequence the assert.
1	RW	0	Enable SW sequenced reset deassert—Enable a software sequenced reset deassert sequence. Timer delays and input qualification are ignored, and only the software can sequence the deassert.
0	WO	0	Initiate Reset Sequence—To trigger the hardware sequenced warm reset, the Reset Sequencer writes this bit to 1 a single time. The Reset Sequencer verifies that Reset Active is 0 before setting this bit, and always reads the value 0. To monitor this sequence, verify that Reset Active is asserted, and then subsequently deasserted.

5.6.4.3.4. Reset Sequencer Software Sequenced Reset Assert Control Register

You can program the Software Sequenced Reset Assert control register to control the reset assertion sequence.

When the corresponding enable bit is set, the sequencer stops when the desired reset asserts, and then sets the Reset Asserted and waiting for SW to proceed bit. The Reset Sequencer proceeds only after the Reset Asserted and waiting for SW to proceed bit is cleared.

Table 94. Values for the Reset Sequencer Software Sequenced Reset Assert Control Register at Offset 0x0C

Bit	Attribute	Default	Description
31:10	Reserved.		
9:0	RW	0x3FF	Per-reset SW sequenced reset assert enable—This is a per-bit enable for SW sequenced reset assert. If the register's bitN is set, the sequencer sets the bit30 of the status register when a resetN is asserted. It then waits for the bit30 of the status register to clear before proceeding with the sequence. By default, all bits are enabled (fully SW sequenced).

5.6.4.3.5. Reset Sequencer Software Sequenced Reset Deassert Control Register

You can program the Software Sequenced Reset Deassert register to control the reset deassertion sequence.

When the corresponding enable bit is set, the sequencer stops when the desired reset asserts, and then sets the Reset Deasserted and waiting for SW to proceed bit. The Reset Sequencer proceeds only after the Reset Deasserted and waiting for SW to proceed bit is cleared.

Table 95. Values for the Reset Sequencer Software Sequenced Reset Deassert Control Register at Offset 0x10

Bit	Attribute	Default	Description
31:10	Reserved.		
9:0	RW	0x3FF	Per-reset SW sequenced reset deassert enable—This is a per-bit enable for SW-sequenced reset deassert. If bitN of this register is set, the sequencer sets bit29 of the Status Register when a resetN is asserted. It then waits for the bit29 of the status register to clear before proceeding with the sequence. By default, all bits are enabled (fully SW sequenced).

5.6.4.3.6. Reset Sequencer Software Direct Controlled Resets

You can write a bit to 1 to assert the reset_outN signal, and to 0 to deassert the reset_outN signal.

Table 96. Values for the Software Direct Controlled Resets at Offset 0x14

Bit	Attribute	Default	Description
31:26	Reserved.		
25:16	WO	0	Reset Overwrite Trigger Enable—This is a per-bit control trigger bit for the overwrite value to take effect.
15:10	Reserved.		
9:0	WO	0	reset_outN Reset Overwrite Value—This is a per-bit control of the reset_out bit. The Reset Sequencer can use this to forcefully drive the reset to a specific value. A value of 1 sets the reset_out. A value of 0 clears the reset_out. A write to this register only takes effect if the corresponding trigger bit in this register is set.

5.6.4.3.7. Reset Sequencer Software Reset Masking

Masking off (writing 1) to a `reset_outN "Reset Mask Enable"` signal prevents the corresponding reset from being asserted. Writing a bit to `0` to a reset mask enable signal allows assertion of `reset_outN`.

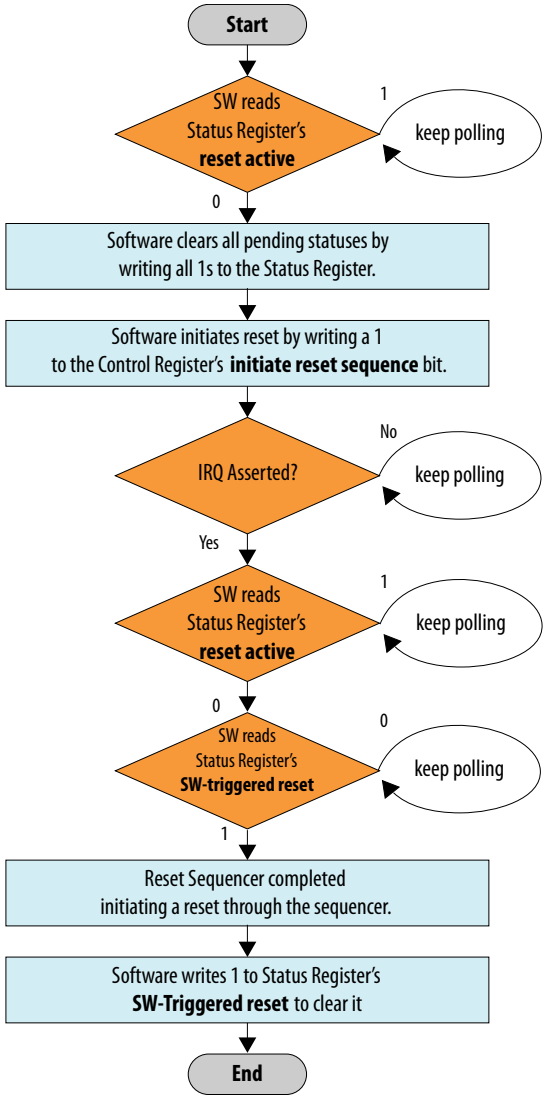
Table 97. Values for the Reset Sequencer Software Reset Masking at Offset 0x18

Bit	Attribute	Default	Description
31:10	Reserved.		
9:0	RW	0	`reset_outN "Reset Mask Enable"`—This is a per-bit control to mask off the `reset_outN` bit. Software Reset Masking prevents the reset bit from being asserted during a reset assertion sequence. If `reset_out` is already asserted, it does not deassert the reset.

5.6.4.4. Reset Sequencer Software Flows

5.6.4.4.1. Reset Sequencer (Software-Triggered) Flow

Figure 238. Reset Sequencer (Software-Triggered) Flow Diagram



Related Information

- Reset Sequencer Status Register on page 321
- Reset Sequencer Control Register on page 323

5.6.4.4.2. Reset Assert Flow

The following flow sequence occurs for a Reset Assert Flow:

- A reset is triggered either by the software, or when input resets to the Reset Sequencer are asserted.
- The IRQ is asserted, if the IRQ is enabled.
- Software reads the Status register to determine which reset was triggered.

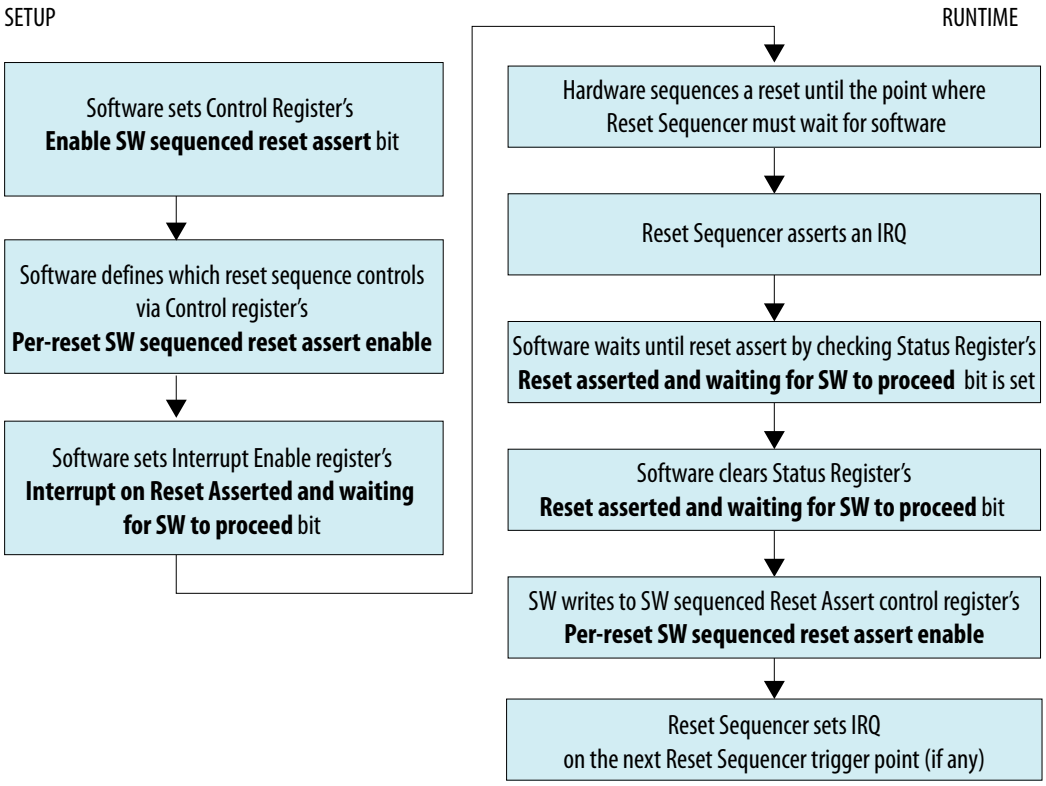
5.6.4.4.3. Reset Deassert Flow

The following flow sequence occurs for a Reset Deassert Flow:

- When a reset source is deasserted, or when the reset assert sequence has completed without pending resets asserted, the deassertion flow is initiated.
- The IRQ is asserted, if the IRQ is enabled.
- Software reads the Status Register to determine which reset was triggered.

5.6.4.4.4. Reset Assert (Software Sequenced) Flow

Figure 239. Reset Assert (Software Sequenced) Flow



Related Information

- Reset Sequencer Control Register on page 323
- Reset Sequencer Software Sequenced Reset Assert Control Register on page 323
- Reset Sequencer Interrupt Enable Register on page 322

- Reset Sequencer Status Register on page 321

5.6.4.4.5. Reset Deassert (Software Sequenced) Flow

The sequence and flow is similar to the `Reset Assert (SW Sequenced)` flow, though, this flow uses the `reset deassert` registers/bits instead of the `reset assert` registers/bits.

Related Information

Reset Assert (Software Sequenced) Flow on page 327

5.7. Conduits

You can use the conduit interface type for interfaces that do not fit any of the other interface types, and to group any arbitrary collection of signals. Like other interface types, you can export or connect conduit interfaces.

The PCI Express-to-Ethernet example in *Creating a System with Platform Designer* is an example of using a conduit interface for export. You can declare an associated clock interface for conduit interfaces in the same way as memory-mapped interfaces with the `associatedClock`.

To connect two conduit interfaces inside Platform Designer, the following conditions must be met:

- The interfaces must match exactly with the same signal roles and widths.
- The interfaces must be the opposite directions.
- Clocked conduit connections must have matching `associatedClocks` on each of their endpoint interfaces.

Note: To connect a conduit output to more than one input conduit interface, you can create a custom component. The custom component could have one input that connects to two outputs, and you can use this component between other conduits that you want to connect. For information about the Avalon Conduit interface, refer to the *Avalon Interface Specifications*

Related Information

- Avalon Interface Specifications
- Creating a System with Platform Designer on page 11

5.8. Interconnect Pipelining

You can use pipeline stages within the interconnect to increase a design's f_{MAX}. Insertion of pipeline stages reduces the combinational logic depth, while incurring additional latency and logic use.[13]

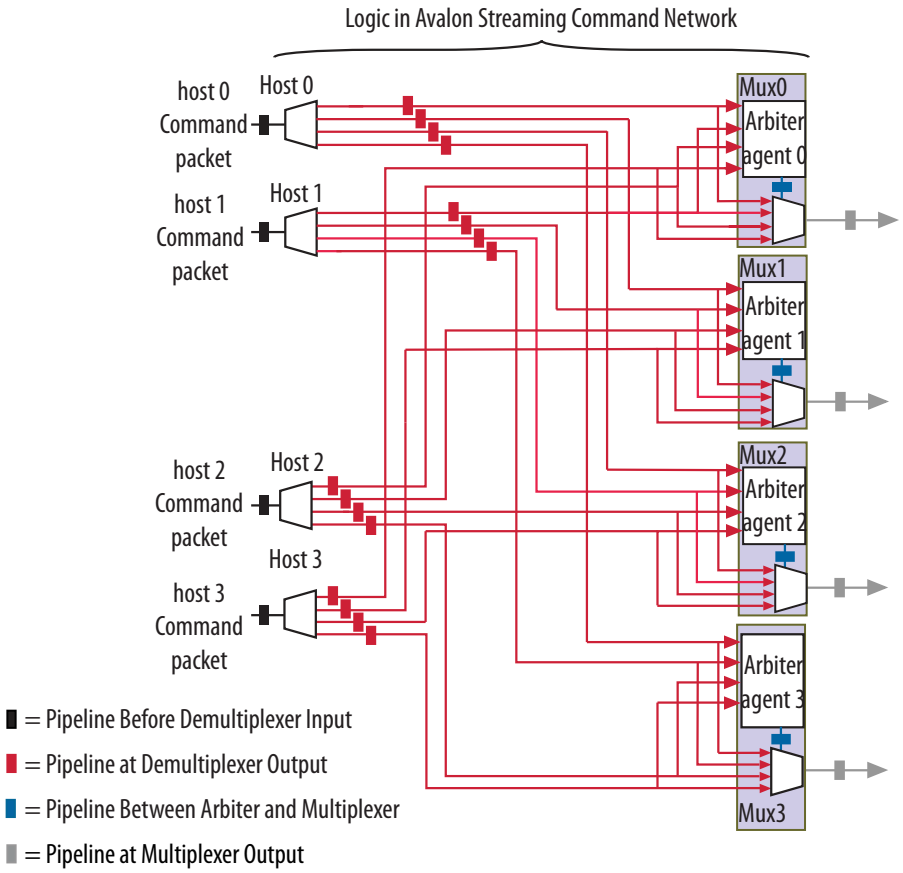
[13] Each pipeline stage requires two registers and some control logic to store write data, address, and control signals on the command path, as well as response, data, and control signals on the response path.

The **Limit interconnect pipeline stages to** option on the **Domains** tab allows you to specify the maximum number of fixed location Avalon pipeline stages that Platform Designer can automatically insert in the command and response path, as Figure 240 on page 329 illustrates. You can specify between 0 to 4 pipeline stages, where 0 means that the interconnect has a combinational datapath. Choosing 3 or 4 pipeline stages can significantly increase the logic utilization of the system. **Limit interconnect pipeline stages to** is specific to each Platform Designer system or subsystem.

Note: Enabling **Limit interconnect pipeline stages to** only *allows* insertion up to the limit you specify. However, the actual insertion of pipelines depends upon the existence of certain interconnect components. For example, single-agent systems do not have multiplexers; therefore, multiplexer pipelining does not occur. In an extreme case of a single-host to single-agent system, no pipelining occurs, regardless of the value of the **Limit interconnect pipeline stages to** option.

Figure 240. Pipeline Placement in Arbitration Logic for Command Path

The following example shows the location of up to four potential pipeline stages in the interconnect command path. Platform Designer can potentially place pipeline stages before the input to the demultiplexer, at the output of the demultiplexer, between the arbiter and the multiplexer, and at the output of the multiplexer. The response path has one less potential pipeline location than the command path.



If the **Limit interconnect pipeline stages to** setting does not provide enough fine control over the placement of pipelines, you can explicitly adjust the number of pipeline stages by clicking **Show System with Interconnect** on the **Domains** tab, as Add Pipeline Stages to the Interconnect Schematic on page 330 describes.

Related Information

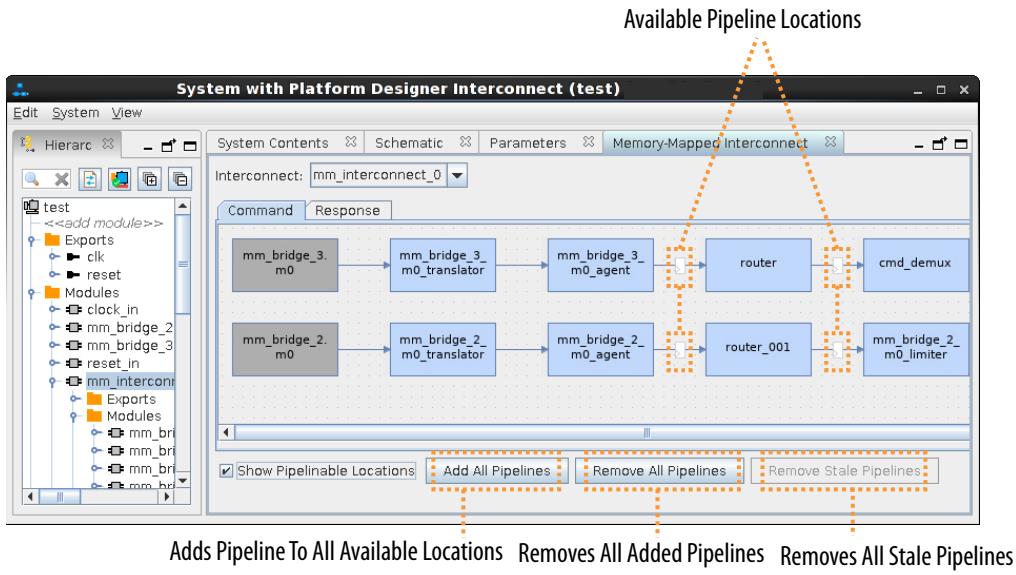
- Previewing the System Interconnect on page 74
- Inserting Pipeline Stages to Increase System Frequency on page 214

5.8.1. Add Pipeline Stages to the Interconnect Schematic

You can view and enable pipelinable locations in a graphical schematic of the Platform Designer interconnect. The **Memory-Mapped Interconnect** tab allows you to adjust pipeline connections in the Platform Designer command and response interconnect.

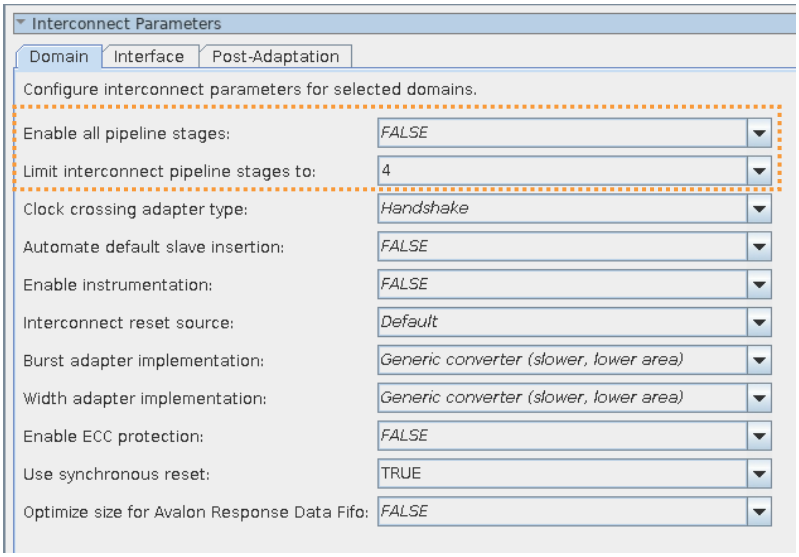
Note: You can specify the **Limit interconnect pipeline stages to** option to automatically insert from zero to a maximum of four pipeline stages, rather than adding pipeline stages explicitly in the schematic. Use the schematic if you require finer control than the option provides. Add pipelines to the interconnect schematic only for complete systems. When **Enable all pipeline stages** is set to **TRUE**, the **Limit interconnect pipeline stages to** option is disabled, and you cannot edit pipelines in the schematic.

Figure 241. Available Pipeline Locations in Memory Mapped Interconnect Schematic



1. In the Platform Designer software, open a system that includes two Avalon memory mapped pipeline bridge instances, with one instance functioning as the host, and the other instance functioning as the agent.
2. Click **View ➤ Domains**. The **Domains** tab displays the memory mapped domains in the system.
3. Under **Interconnect Parameters**, ensure that **Enable all pipeline stages** is set to **False**. When set to **True**, this option disables manual pipeline insertion.

Figure 242. Domains Tab



4. In the **Domains** tab, click **Show System With Interconnect**. The System with Platform Designer Interconnect window displays the available pipeline locations on the **Command** and **Response** tabs.
5. Specify the placement of pipeline stages in the interconnect schematic:
   - To view all locations that can accept a pipeline stage, enable **Show Pipelinable Locations**.
   - To add a pipeline to an available location, right-click the location and enable **Pipelined**.
   - To add pipelines at all available locations, click **Add All Pipelines**.
   - To remove all pipelines you add, click **Remove All Pipelines**.
   - To remove pipelines that have become stale due to changes since enabling a pipeline, click **Remove Stale Pipelines**. If you make changes to the original system's connectivity after manually pipelining an interconnect, the inserted pipelines may become invalid. Platform Designer displays warning messages when you generate the system if invalid pipeline stages are detected. You can remove invalid pipeline stages with the **Remove Stale Pipelines** option in the **Memory-Mapped Interconnect** tab. Do not make changes to the system's connectivity after manual pipeline insertion.

Note: Review manually-inserted pipelines when upgrading to newer versions of Platform Designer. Manually-inserted pipelines in one version of Platform Designer may not be valid in a future version.

5.9. Error Correction Coding (ECC) in Platform Designer Interconnect

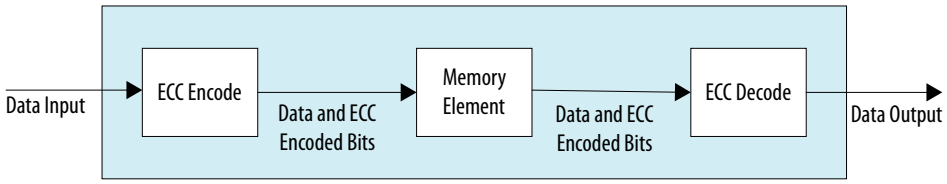
Error Correction Coding (ECC) logic allows the Platform Designer interconnect to detect and correct errors. Enabling ECC improves data integrity in memory blocks. Platform Designer supports ECC protection for Read Data FIFO (`rdata_FIFO`) instances only.

As transistors become smaller, computer hardware is more susceptible to data corruption. Data corruption causes Single Event Upsets (SEUs), and increases the probability of Failures in Time (FIT) rates in computer systems. SEU events without error notification can cause the system to be stuck in an unknown response status, and increase the FIT rate.

Before writing data to the memory device, the ECC logic encodes the data bus with a Hamming code. Then, the ECC logic decodes and performs error checking on the data output.

Platform Designer interconnect sends uncorrectable errors arising from memory as DECODEERROR (DECERR) on the Avalon response bus.

Figure 243. High-Level Implementation of rdata_FIFO with ECC Enabled



Note: Enabling ECC logic may increase logic utilization and cause lower f_{MAX}.

Read and Write Responses on page 276

5.10. AMBA 3 AXI Protocol Specification Support (version 1.0)

Platform Designer allows memory-mapped connections between AMBA 3 AXI components, AMBA 3 AXI and AMBA 4 AXI components, and AMBA 3 AXI and Avalon interfaces with unique or exceptional support.

Refer to the *AMBA 3 Protocol Specifications* on the ARM website for more information. (14)

Related Information

- Arm AMBA Protocol Specifications
- Avalon Agent and AXI Subordinate Network Interfaces on page 261

5.10.1. Channels

Platform Designer has the following support and restrictions for AMBA 3 AXI channels.

(14) This document now refers to the AXI "manager" and "subordinate" to replace the former terms, as the latest AMBA® AXI and ACE Protocol Specification describes.

5.10.1.1. Read and Write Address Channels

Most signals are allowed. However, the following limitations are present in Platform Designer 14.0:

- Supports 64-bit addressing.
- ID width limited to 18-bits.
- HPS-FPGA host interface has a 12-bit ID.

5.10.1.2. Write Data, Write Response, and Read Data Channels

Most signals are allowed. However, the following limitations are present in Platform Designer 14.0:

- Data widths limited to a maximum of 1024-bits
- Limited to a fixed byte width of 8-bits

5.10.1.3. Low Power Channel

Low power extensions are not supported in Platform Designer, version 14.0.

5.10.2. Cache Support

AWCACHE and ARCACHE are passed to an AXI subordinate unmodified. (15)

5.10.2.1. Bufferable

Platform Designer interconnect treats AXI transactions as non-bufferable. All responses must come from the terminal subordinate.

When connecting to Avalon memory mapped agents, since they do not have write responses, the following exceptions apply:

- For Avalon memory mapped agents, the write response is generated by the AXI subordinate agent once the write transaction is accepted by the subordinate. The following limitation exists for an Avalon bridge:
- For an Avalon bridge, the response is generated before the write reaches the endpoint. Be aware of this limitation and avoid multiple paths past the bridge to any endpoint subordinate, or only perform bufferable transactions to an Avalon bridge.

5.10.2.2. Cacheable (Modifiable)

Platform Designer interconnect acknowledges the cacheable (modifiable) attribute of AXI transactions.

(15) This document now refers to the AXI "manager" and "subordinate" to replace the former outmoded terms. Refer to the *AMBA AXI and ACE Protocol Specification*.

It does not change the address, burst length, or burst size of non-modifiable transactions, with the following exceptions:

- Platform Designer considers a wide transaction to a narrow agent as modifiable because the size requires reduction.
- Platform Designer may consider AXI read and write transactions as modifiable when the destination is an Avalon agent. The AXI transaction may be split into multiple Avalon transactions if the agent is unable to accept the transaction. This may occur because of burst lengths, narrow sizes, or burst types.

Platform Designer ignores all other bits, for example, read allocate or write allocate because the interconnect does not perform caching. By default, Platform Designer considers Avalon host transactions as non-bufferable and non-cacheable, with the allocate bits tied low.

5.10.3. Security Support

TrustZone refers to the security extension of the ARM architecture, which includes the concept of "secure" and "non-secure" transactions, and a protocol for processing between the designations.

The interconnect passes the AWPROT and ARPROT signals to the endpoint subordinate without modification. It does not use or modify the PROT bits.

Refer to *Manage System Security* in *Creating a System with Platform Designer* for more information about secure systems and the TrustZone feature.

Related Information

Configuring Platform Designer System Security on page 79

5.10.4. Atomic Accesses

Exclusive accesses are supported for AXI subordinates by passing the lock, transaction ID, and response signals from manager to subordinate, with the limitation that subordinates that do not reorder responses. Avalon agents do not support exclusive accesses, and always return OKAY as a response. Locked accesses are also not supported.

5.10.5. Response Signaling

Full response signaling is supported. Avalon agents always return OKAY as a response.

5.10.6. Ordering Model

Platform Designer interconnect provides responses in the same order as the commands are issued.

To prevent reordering, for subordinates that accept reordering depths greater than 1, Platform Designer does not transfer the transaction ID from the manager, but provides a constant transaction ID of 0. For subordinates that do not reorder, Platform Designer allows the transaction ID to be transferred to the subordinate. To avoid cyclic dependencies, Platform Designer supports a single outstanding subordinate scheme for both reads and writes. Changing the targeted subordinate before all responses have returned stalls the manager, regardless of transaction ID.

5.10.6.1. AXI and Avalon Ordering

There is a potential read-after-write risk when Avalon hosts transact to AXI subordinates.

According to the *AMBA Protocol Specifications*, there is no ordering requirement between reads and writes. However, Avalon has an implicit ordering model that requires transactions from a host to the same AXI subordinate to be in order. The Avalon interconnect always processes the transactions in order. The interconnect blocks transactions if required. The interconnect prevents writing to the AXI subordinate when read is pending.

5.10.7. Data Buses

Narrow bus transfers are supported. AXI write strobes can have any pattern that is compatible with the address and size information. Intel recommends that transactions to Avalon agents follow Avalon `byteenable` limitations for maximum compatibility.

Note: Byte `0` is always bits `[7:0]` in the interconnect, following AXI's and Avalon's byte (address) invariance scheme.

5.10.8. Unaligned Address Commands

Unaligned address commands are commands with addresses that do not conform to the data width of a subordinate. Since Avalon memory mapped subordinates accept only aligned addresses, Platform Designer modifies unaligned commands from AXI managers to the correct data width. Platform Designer must preserve commands issued by AXI managers when passing the commands to AXI subordinates.

Note: Unaligned transfers are aligned if downsizing occurs. For example, when downsizing to a bus width narrower than that required by the transaction size, `AWSIZE` or `ARSIZE`, the transaction must be modified.

5.10.9. Avalon and AXI Transaction Support

Platform Designer supports transactions between Avalon and AXI interfaces with the following limitations in this section.

Related Information

Avalon Interface Specifications

5.10.9.1. Transaction Cannot Cross 4KB Boundaries

When an Avalon host issues a transaction to an AXI subordinate, the transaction cannot cross 4KB boundaries. Non-bursting Avalon hosts already follow this boundary restriction.

When connecting an Avalon memory-mapped interface FPGA host to an AXI subordinate in Platform Designer, you must ensure that the bursts do not exceed the AXI3 or AXI4 4KB boundary restriction for burst transactions.

5.10.9.2. Adjacent Bytelanes with Partial Width Transactions

The following limitations apply to Avalon to AXI partial width transactions with use of adjacent bytelanes:

- Avalon interfaces only support adjacent bytelanes if the interface requires more than one byte enable. For example: `1100`, `0011`.
- AXI fully supports use of bytelanes that are not adjacent. For example: `1010`, `0101`.

Related Information

Avalon Interface Specifications

5.10.9.3. Handling Read Side Effects

Read side effects can occur when more bytes than necessary are read from the subordinate, and the unwanted data that are read are later inaccessible on subsequent reads. For write commands, the correct byteenable paths are asserted based on the size of the transactions. For read commands, narrow-sized bursts are broken up into multiple non-bursting commands, and each command with the correct byteenable paths asserted.

Platform Designer always assumes that the byteenable is asserted based on the size of the command, not the address of the command. The following scenarios are examples:

- For a 32-bit AXI manager that issues a read command with an unaligned address starting at address `0x01`, and a burstcount of 2 to a 32-bit Avalon agent, the starting address is: `0x00`.
- For a 32-bit AXI manager that issues a read command with an unaligned address starting at address `0x01`, with 4-bytes to an 8-bit AXI subordinate, the starting address is: `0x00`.

5.11. AMBA 3 APB Protocol Specification Support (version 1.0)

APB (Advanced Peripheral Bus) interface is optimized for minimal power consumption and reduced interface complexity. You can use APB to interface to peripherals which are low-bandwidth and do not require the high performance of a pipelined bus interface. Signal transitions are sampled at the rising edge of the clock to enable the integration of APB peripherals easily into any design flow.

Platform Designer allows connections between APB components, and AMBA 3 AXI, AMBA 4 AXI, and Avalon memory-mapped interfaces. The following sections describe unique or exceptional APB support in the Platform Designer software. (16)

Related Information

Arm AMBA Protocol Specifications

5.11.1. Bridges

With APB, you cannot use bridge components that use multiple PSELx in Platform Designer. As a workaround, you can group PSELx, and then send the packet to the subordinate directly.

(16) This document now refers to the AXI "manager" and "subordinate" to replace the former terms, as the latest AMBA® AXI and ACE Protocol Specification describes.

Intel recommends as an alternative that you instantiate the APB bridge and all the APB subordinates in Platform Designer. You should then connect the subordinate side of the bridge to any high speed interface and connect the manager side of the bridge to the APB subordinates. Platform Designer creates the interconnect on either side of the APB bridge and creates only one PSEL signal.

Alternatively, you can connect a bridge to the APB bus outside of Platform Designer. Use an AXI bridge to export the AXI manager to the top-level, and then connect this AXI interface to the subordinate side of the APB bridge. Alternatively, instantiate the APB bridge in Platform Designer and export APB manager to the top- level, and from there connect to APB bus outside of Platform Designer.

5.11.2. Burst Adaptation

APB is a non-bursting interface. Therefore, for any AXI manager or Avalon host with bursting support, a burst adapter is inserted before the agent or subordinate interface, and the burst transaction is translated into a series of non-bursting transactions before reaching the APB subordinate or agent.

5.11.3. Width Adaptation

Platform Designer allows different data width connections with APB. When connecting a wider manager to a narrower APB subordinate, the width adapter converts the wider transactions to a narrower transaction to fit the APB subordinate data width. APB does not support Write Strobe. Therefore, when you connect a narrower transaction to a wider APB subordinate, the subordinate cannot determine which byte lane to write. In this case, the subordinate data may be overwritten or corrupted.

5.11.4. Error Response

Error responses are returned to the manager. Platform Designer performs error mapping if the manager is an AMBA 3 AXI or AMBA 4 AXI manager, for example, RRESP/BRESP= SLVERR. For the case when the subordinate does not use SLVERR signal, an OKAY response is sent back to manager by default.

5.12. AMBA 4 AXI Memory-Mapped Interface Support (version 2.0)

Platform Designer allows memory-mapped connections between AMBA 4 AXI components, AMBA 4 AXI and AMBA 3 AXI components, and AMBA 4 AXI and Avalon interfaces with unique or exceptional support. [17]

5.12.1. Burst Support

Platform Designer supports `INCR` bursts up to 256 beats. Platform Designer converts long bursts to multiple bursts in a packet with each burst having a length less than or equal to `MAX_BURST` when going to AMBA 3 AXI or Avalon agents.

For narrow-sized transfers, bursts with Avalon agents as destinations are shortened to multiple non-bursting transactions in order to transmit the correct address to the agents, since Avalon agents always perform full-sized `datawidth` transactions.

[17] This document now refers to the AXI "manager" and "subordinate" to replace the former terms, as the latest AMBA® AXI and ACE Protocol Specification describes.

Bursts with AMBA 3 AXI subordinates as destinations are shortened to multiple bursts, with each burst length less than or equal to 16. Bursts with AMBA 4 AXI subordinates as destinations are not shortened.

5.12.2. QoS

Platform Designer routes 4-bit QoS signals (Quality of Service Signaling) on the read and write address channels directly from the AXI manager or Avalon host to the AXI subordinate or Avalon agent, respectively.

Transactions from AXI managers and Avalon hosts have a default value of `4'b0000`, which indicates that the transactions are not part of the QoS flow. QoS values are not used for subordinates or agents that do not support QoS.

There are no programmable QoS registers or compile-time QoS options for a manager or host that overrides its real or default value.

5.12.3. Regions

AMBA 4 AXI subordinates with `AXREGION` signals are allowed. `AXREGION` signals are driven with the default value of `0x0`, and are limited to one entry in a manager's address map.

5.12.4. Write Response Dependency

Write response dependency as specified in the *Arm AMBA Protocol Specifications* for AMBA 4 AXI is not supported.

Related Information

Arm AMBA Protocol Specifications

5.12.5. AWCACHE and ARCACHE

For AMBA 4 AXI, Platform Designer meets the requirement for modifiable and non-modifiable transactions. The modifiable bit refers to `ARCACHE[1]`and `AWCACHE[1]`.

5.12.6. Width Adaptation and Data Packing in Platform Designer

Data packing applies only to systems where the data width of Avalon hosts or AXI managers is less than the data width of Avalon agents or AXI subordinates, respectively.

The following rules apply:

- Data packing is supported when hosts and agents are Avalon memory mapped.
- Data packing is not supported when any manager or subordinate is an AMBA 3 AXI, AMBA 4 AXI, or APB component.

For example, for a read/write command with a 32-bit host connected to a 64-bit agent, and a transaction of 2 burstcounts, Platform Designer sends 2 separate read/write commands to access the 64-bit data width of the agent.

5.12.7. Ordering Model

Platform Designer does not support out of order command response. Platform Designer processes AXI subordinates as device non-bufferable memory types.

The following describes the required behavior for the device non-bufferable memory type:

- Write response must be obtained from the final destination.
- Read data must be obtained from the final destination
- Transaction characteristics must not be modified.
- Reads must not be pre-fetched. Writes must not be merged.
- Non-modifiable read and write transactions.

(`AWCACHE[1] = 0 or ARCACHE[1] = 0`) from the same ID to the same subordinate must remain ordered. The interconnect always provides responses in the same order as the commands issued. subordinates that support reordering provide a constant transaction ID to prevent reordering. AXI subordinates that do not reorder are provided with transaction IDs, which allows exclusive accesses for such subordinates.

5.12.8. Read and Write Allocate

Read and write allocate does not apply to Platform Designer interconnect, which does not have caching features, and always receives responses from an endpoint.

5.12.9. Locked Transactions

Locked transactions are not supported for Platform Designer, version 14.0.

5.12.10. Memory Types

For AMBA 4 AXI, Platform Designer processes transactions as though the endpoint is a device memory type. For device memory types, using non-bufferable transactions to force previous bufferable transactions to finish is irrelevant, because Platform Designer interconnect always identifies transactions as being non-bufferable.

5.12.11. Mismatched Attributes

There are rules for how multiple managers issue cache values to a shared memory region. The interconnect meets requirements if signals are not modified.

5.12.12. Signals

Platform Designer supports up to 64-bits for the BUSER, WUSER and RUSER sideband signals. AMBA 4 AXI allows some signals to be omitted from interfaces by aligning them with the default values as defined in the *AMBA Protocol Specifications* on the ARM website.

Related Information

Arm AMBA Protocol Specifications

5.13. AMBA 4 AXI Streaming Interface Support (version 1.0)

5.13.1. Connection Points

Platform Designer allows you to connect an AMBA 4 AXI-Stream interface to another AMBA 4 AXI-Stream interface.

The connection is point-to-point without adaptation and must be between an `axi4stream_manager` and `axi4stream_subordinate`. Connected interfaces must have the same port roles and widths.

Non matching manager to subordinate connections, and multiple managers to multiple subordinates connections are not supported. (18)

5.13.1.1. AMBA 4 AXI Streaming Connection Point Parameters

Table 98. AMBA 4 AXI Streaming Connection Point Parameters

Name	Type	Description
`associatedClock`	string	Name of associated clock interface.
`associatedReset`	string	Name of associated reset interface

5.13.1.2. AMBA 4 AXI Streaming Connection Point Signals

Table 99. AMBA 4 AXI-Stream Connection Point Signals

Port Role	Width	Manager Direction	Subordinate Direction	Required
`tvalid`	1	Output	Input	Yes
`tready`	1	Input	Output	No
`tdata`(19)	8:4096	Output	Input	No
`tstrb`	1:512	Output	Input	No
`tkeep`	1:512	Output	Input	No
`tid`(20)	1:8	Output	Input	No

continued...

(18) This document refers to the new AXI "manager" and AXI "subordinate" inclusive terms to replace outmoded terms, as the latest version of the AMBA® AXI and ACE Protocol Specification describes.

(19) integer in multiple of bytes

(20) maximum 8-bits

Port Role	Width	Manager Direction	Subordinate Direction	Required
tdest[21]	1:4	Output	Input	No
tuser[22]	1:4096	Output	Input	No
tlast	1	Output	Input	No

5.13.2. Adaptation

AMBA 4 AXI-Stream adaptation support is not available. AMBA 4 AXI-Stream manager and subordinate interface signals and widths must match.

5.14. AMBA 4 AXI-Lite Protocol Specification Support (version 2.0)

AMBA 4 AXI-Lite is a sub-set of AMBA 4 AXI. It is suitable for simpler control register-style interfaces that do not require the full functionality of AMBA 4 AXI. [23]

Platform Designer supports the following AMBA 4 AXI-Lite features:

- Transactions with a burst length of 1.
- Data accesses use the full width of a data bus (32- bit or 64-bit) for data accesses, and no narrow-size transactions.
- Non-modifiable and non-bufferable accesses.
- No exclusive accesses.

5.14.1. AMBA 4 AXI-Lite Signals

Platform Designer supports all AMBA 4 AXI-Lite interface signals. Signals that are optional in AMBA 4 are also optional in AMBA 4 AXI-Lite.

Table 100. AMBA 4 AXI-Lite Signals

Global	Write Address Channel	Write Data Channel	Write Response Channel	Read Address Channel	Read Data Channel
ACLK	AWVALID	WVALID	BVALID	ARVALID	RVALID
ARESETn	AWREADY	WREADY	BREADY	ARREADY	RREADY
-	AWADDR	WDATA	BRESP	ARADDR	RDATA
-	AWPROT	WSTRB	-	ARPROT	RRESP

(21) maximum 4-bits

(22) number of bits in multiple of the number of bytes of tdata

(23) This document refers to the new AXI "manager" and AXI "subordinate" inclusive terms to replace outmoded terms, as the latest version of the AMBA® AXI and ACE Protocol Specification describes.

5.14.2. AMBA 4 AXI-Lite Optional Port Support and Interconnect

Platform Designer permits you to omit optional ports on the AMBA 4 AXI-Lite interface. However, the Platform Designer interconnect does not support the optional AMBA 4 AXI-Lite signals. The interconnect-facing AMBA 4 AXI-Lite interface must include all signals in AMBA 4 AXI-Lite Signals.

5.14.3. AMBA 4 AXI-Lite Bus Width

AMBA 4 AXI-Lite managers or subordinates must have either 32-bit or 64-bit bus widths. Platform Designer interconnect inserts a width adapter if a manager and subordinate pair have different widths.

5.14.4. AMBA 4 AXI-Lite Outstanding Transactions

AXI-Lite supports outstanding transactions. The options to control outstanding transactions is set in the parameter editor for the selected component.

5.14.5. AMBA 4 AXI-Lite IDs

AMBA 4 AXI-Lite does not support IDs. Platform Designer performs ID reflection inside the AXI subordinate agent.

5.14.6. Connections Between AMBA 3 AXI,AMBA 4 AXI and AMBA 4 AXI-Lite

5.14.6.1. AMBA 4 AXI-Lite Subordinate Requirements

For an AMBA 4 AXI-Lite subordinate side, the host or manager can be any interface type, such as an Avalon (with bursting), AMBA 3 AXI, or AMBA 4 AXI. Platform Designer allows the following connections and inserts adapters, if needed.

- **Burst adapter**—Avalon and AMBA 3 AXI and AMBA 4 AXI bursting host or manager require a burst adapter to shorten the burst length to 1 before sending a transaction to an AMBA 4 AXI-Lite subordinate.
- Platform Designer interconnect uses a width adapter for mismatched data widths.
- Platform Designer interconnect performs ID reflection inside the subordinate agent.
- An AMBA 4 AXI-Lite subordinate must have an address width of at least 12-bits.
- AMBA 4 AXI-Lite does not have the AXSIZE parameter. Narrow manager to a wide AMBA 4 AXI-Lite subordinate is not supported. For managers that support narrow-sized bursts, for example, AMBA 3 AXI and AMBA 4 AXI, a burst to an AMBA 4 AXI-Lite subordinate must have a burst size equal to or greater than the subordinate's burst size.

5.14.6.2. AMBA 4 AXI-Lite Data Packing

Platform Designer interconnect does not support AMBA 4 AXI-Lite data packing.

5.14.7. AMBA 4 AXI-Lite Response Merging

When Platform Designer interconnect merges SLVERR and DECERR, the error responses are not sticky. The response is based on priority and the manager always sees a DECERR. When SLVERR and DECERR are merged, it is based on their priorities, not stickiness. DECERR receives priority in this case, even if SLVERR returns first.

5.15. Port Roles (Interface Signal Types)

Each interface defines signal roles and their behavior. Many signal roles are optional, allowing IP component designers the flexibility to select only the signal roles necessary to implement the required functionality.

5.15.1. AXI Manager Interface Signal Types

Table 101. AXI Manager Interface Signal Types

5.15.6. AMBA 4 AXI-Lite Signal Support and Limitations

ACE-Lite is a sub-set of AMBA 4 AXI that consists of an AMBA 4 AXI interface with additional signals on the read address and write address channels. ACE-Lite signals indicate transactions meant for cache coherence, cache maintenance, and other functions.

Table 106. ACE-Lite Interface Signal Roles

Name	Width	Manager Direction	Subordinate Direction	Required
arsnoop	4 bits	Output	Input	Yes
ardomain	2 bits	Output	Input	Yes
arbar	2 bits	Output	Input	Yes
awsnoop	3 bits	Output	Input	Yes
awdomain	2 bits	Output	Input	Yes
awbar	2 bits	Output	Input	Yes
awunique	1 bit	Output	Input	Yes

Note: Platform Designer's ACE-Lite interface does comprise of all the signals specified in the AMBA 4 AXI specification. The following sections describe the Platform Designer support and limitations for ACE-Lite transactions.

5.15.6.1. ACE-Lite Transaction Support and Limitations

Platform Designer's ACE-Lite interface does currently comprise of all the signals specified in the AMBA 4 AXI specification. Therefore, there are limitations on the extent of transactional support that Platform Designer interconnect provides for ACE-Lite transactions. The signals are present for point-to-point (1-manager, 1-subordinate) and non-point-to-point Interconnects, when the manager and subordinate ACE-Lite interfaces are not identical and require adaptation.

Table 107. Supported ACE-Lite Transactions

Transaction Type	Supported Transactions
Non-snoop transactions	WriteNoSnoop, ReadNoSnoop
Coherent transactions	WriteUnique, ReadOnce

Table 108. Unsupported ACE-Lite Transactions

Transaction Type	Unsupported Transactions
Barrier transactions	ReadBarrier, WriteBarrier
Cache Maintenance transactions	CleanShared, CleanInvalid, MakeInvalid
Coherent transactions	WriteLineUnique

Note: Unsupported ACE-Lite transaction interconnect behavior is non-deterministic. Use of unsupported transactions can cause a system failure or data corruption.

The following describes the ACE-Lite signal connectivity in various manager-subordinate combinations for the Platform Designer interconnect:

Table 109. ACE-Lite Signal Connectivity in Various Manager-Subordinate Combinations

Manager/Subordinate Combination	ACE-Lite Signal Connectivity
ACE-Lite manager to Avalon memory mapped agent.	ACE-Lite interface signals drop from the interconnect.
AXI manager to ACE-Lite subordinate	The ACE-Lite subordinate receives default values for ACE-Lite interface signals from the manager agent, by virtue of ACE-Lite interface being unsupported on the manager. The values are as follows: • `ARDOMAIN/AWDOMAIN = 2'b11` • `ARSNOOP/AWSNOOP = 0` • `ARBAR/AWBAR = 0` The above transactions indicate non-snooping `ReadNoSnoop/WriteNoSnoop` transactions. `AWUNIQUE = 0` indicates that `AWUNIQUE` is unsupported.
ACE-Lite manager to AXI subordinate	The subordinate agent sends out default values for ACE-Lite interface signals because the subordinate does not support the interface. The values are as follows: • `ARDOMAIN/AWDOMAIN = 2'b11` • `ARSNOOP/AWSNOOP = 0` • `ARBAR/AWBAR = 0` The above transactions indicate non-snooping `ReadNoSnoop/WriteNoSnoop` transactions. `AWUNIQUE = 0` indicates that `AWUNIQUE` is unsupported.
ACE-Lite manager to ACE-Lite subordinate	The ACE-Lite interface signals are sent through the interconnect as pass through.

5.15.7. APB Interface Signal Types

Table 110. APB Interface Signal Types

Name	Width	Direction APB Manager	Direction APB Subordinate	Required

`pwrite`	1	output	input	yes
`pwdata`	[1:32]	output	input	yes
`prdata`	[1:32]	input	output	yes
`pslverr`	1	input	output	no
`pready`	1	input	output	yes
`paddr31`	1	output	input	no

5.15.8. Avalon Memory Mapped Interface Signal Roles

Signal roles define the signal types that Avalon memory mapped host and agent ports allow.

This specification does not require all signals to exist in an Avalon memory mapped interface. There is no one signal that is always required. The minimum requirements for an Avalon memory mapped interface are `readdata` for a read-only interface, or `writedata` and `write` for a write-only interface.

The following table lists signal roles for the Avalon memory mapped interface:

Table 111. Avalon Memory Mapped Signal Roles

Some Avalon memory mapped signals can be active high or active low. When active low, the signal name ends with _n.

Signal Role	Width	Direction	Required	Description
Fundamental Signals				
`address`	1 - 64	Host → Agent	No	Hosts: By default, the `address` signal represents a byte address. The value of the address must align to the data width. To write to specific bytes within a data word, the host must use the `byteenable` signal. Refer to the `addressUnits` interface property for word addressing. Agents: By default, the interconnect translates the byte address into a word address in the agent's address space. From the perspective of the agent, each agent access is for a word of data. For example, `address = 0` selects the first word of the agent. `address = 1` selects the second word of the agent. Refer to the `addressUnits` interface property for byte addressing.
`byteenable` `byteenable_n`	2, 4, 8, 16, 32, 64, 128	Host → Agent	No	Enables one or more specific byte lanes during transfers on interfaces of width greater than 8 bits. Each bit in `byteenable` corresponds to a byte in `writedata` and `readdata`. The host bit <n> of `byteenable` indicates whether byte <n> is being written to. During writes, `byteenables` specify which bytes are being written to. Other bytes should be ignored by the agent. During reads, `byteenables` indicate which bytes the host is reading. Agents that simply return `readdata` with no side effects are free to ignore `byteenables` during reads. If an interface does not have a `byteenable` signal, the transfer proceeds as if all `byteenables` are asserted. When more than one bit of the `byteenable` signal is asserted, all asserted lanes are adjacent.
`debugaccess`	1	Host → Agent	No	When asserted, allows the Nios II processor to write on-chip memories configured as ROMs.
`read` `read_n`	1	Host → Agent	No	Asserted to indicate a `read` transfer. If present, `readdata` is required.
`readdata`	8, 16, 32, 64, 128, 256, 512, 1024	Agent → Host	No	The `readdata` driven from the agent to the host in response to a `read` transfer. Required for interfaces that support reads.
`response [1:0]`	2	Agent → Host	No	The `response` signal is an optional signal that carries the response status. *Note:* Because the signal is shared, an interface cannot issue or accept a write response and a read response in the same clock cycle.

continued...

Signal Role	Width	Direction	Required	Description
				• 00: OKAY—Successful response for a transaction. • 01: RESERVED—Encoding is reserved. • 10: SLVERR—Error from an endpoint agent. Indicates an unsuccessful transaction. • 11: DECODEERROR—Indicates attempted access to an undefined location. For read responses: • One response is sent with each readdata. A read burst length of N results in N responses. Fewer responses are not valid, even in the event of an error. The response signal value may be different for each readdata in the burst. • The interface must have read control signals. Pipeline support is possible with the readdatavalid signal. • On read errors, the corresponding readdata is "don't care". For write responses: • One write response must be sent for each write command. A write burst results in only one response, which must be sent after the final write transfer in the burst is accepted. • If writeresponsevalid is present, all write commands must be completed with write responses.
write write_n	1	Host → Agent	No	Asserted to indicate a write transfer. If present, writedata is required.
writedata	8, 16, 32, 64, 128, 256, 512, 1024	Host → Agent	No	Data for write transfers. The width must be the same as the width of readdata if both are present. Required for interfaces that support writes.
Wait-State Signals				
lock	1	Host → Agent	No	lock ensures that once a host wins arbitration, the winning host maintains access to the agent for multiple transactions. Lock asserts coincident with the first read or write of a locked sequence of transactions. Lock deasserts on the final transaction of a locked sequence of transactions. lock assertion does not guarantee that arbitration is won. After the lock-asserting host has been granted, that host retains grant until lock is deasserted. A host equipped with lock cannot be a burst host. Arbitration priority values for lock-equipped hosts are ignored. lock is particularly useful for read-modify-write (RMW) operations. The typical read-modify-write operation includes the following steps: 1. Host A asserts lock and reads 32-bit data that has multiple bit fields. 2. Host A deasserts lock, changes one bit field, and writes the 32-bit data back. lock prevents host B from performing a write between Host A's read and write.
waitrequest waitrequest_n	1	Agent → Host	No	An agent asserts waitrequest when unable to respond to a read or write request. Forces the host to wait until the interconnect is ready to proceed with the transfer. At the start of all transfers, a host initiates the transfer and waits until waitrequest is deasserted. A host must make no assumption about the assertion state of waitrequest when the host is idle: waitrequest may be high or low, depending on system properties.

continued...

Signal Role	Width	Direction	Required	Description
				When `waitrequest` is asserted, host control signals to the agent must remain constant except for `beginbursttransfer`. For a timing diagram illustrating the `beginbursttransfer` signal, refer to the figure in *Read Bursts*. An Avalon memory mapped agent may assert `waitrequest` during idle cycles. An Avalon memory mapped host may initiate a transaction when `waitrequest` is asserted and wait for that signal to be deasserted. To avoid system lockup, an agent device should assert `waitrequest` when in reset.
Pipeline Signals				
`readdatavalid` `readdatavalid_n`	1	Agent → Host	No	Used for variable-latency, pipelined `read` transfers. When asserted, indicates that the `readdata` signal contains valid data. For a read burst with burstcount value <*n*>, the `readdatavalid` signal must be asserted <*n*> times, once for each readdata item. There must be at least one cycle of latency between acceptance of the `read` and assertion of `readdatavalid`. For a timing diagram illustrating the `readdatavalid` signal, refer to *Pipelined Read Transfer with Variable Latency*. An agent may assert `readdatavalid` to transfer data to the host independently of whether the agent is stalling a new command with `waitrequest`. Required if the host supports pipelined reads. Bursting hosts with read functionality must include the `readdatavalid` signal.
`writeresponsevalid`	1	Agent → Host	No	An optional signal. If present, the interface issues write responses for write commands. When asserted, the value on the response signal is a valid write response. `Writeresponsevalid` is only asserted one clock cycle or more after the write command is accepted. There is at least a one clock cycle latency from command acceptance to assertion of `writeresponsevalid`. A write command is considered accepted when the last beat of the burst is issued to the agent and `waitrequest` is low. `writeresponsevalid` can be asserted one or more clock cycles after the last beat of the burst has been issued.
Burst Signals				

continued...

Signal Role	Width	Direction	Required	Description
burstcount	1 – 11	Host → Agent	No	Used by bursting hosts to indicate the number of transfers in each burst. The value of the maximum burstcount parameter must be a power of 2. A burstcount interface of width <n> can encode a max burst of size $2^{(<n>-1)}$. For example, a 4-bit burstcount signal can support a maximum burst count of 8. The minimum burstcount is 1. The constantBurstBehavior property controls the timing of the burstcount signal. Bursting hosts with read functionality must include the readdatavalid signal. For bursting hosts and agents using byte addresses, the following restriction applies to the width of the address: *<address_w> >= <burstcount_w> + log2(<symbols_per_word_of_interface>)* For bursting hosts and agents using word addresses, the $\log_2$ term above is omitted.
beginbursttransfer	1	Interconnect → Agent	No	Asserted for the first cycle of a burst to indicate when a burst transfer is starting. This signal is deasserted after one cycle regardless of the value of waitrequest. For a timing diagram illustrating beginbursttransfer, refer to the figure in *Read Bursts*. beginbursttransfer is optional. An agent can always internally calculate the start of the next write burst transaction by counting data transfers. ***Warning:*** *do not* use this signal. This signal exists to support legacy memory controllers.

5.15.9. Avalon Streaming Interface Signal Roles

Each signal in an Avalon streaming source or sink interface corresponds to one Avalon streaming signal role. An Avalon streaming interface may contain only one instance of each signal role. All Avalon streaming signal roles apply to both sources and sinks and have the same meaning for both.

Table 112. Avalon Streaming Interface Signals

In the following table, all signal roles are active high.

Signal Role	Width	Direction	Required	Description
Fundamental Signals				
channel	1 – 128	Source → Sink	No	The channel number for data being transferred on the current cycle. If an interface supports the channel signal, the interface must also define the maxChannel parameter.
data	1 – 8,192	Source → Sink	No	The data signal from the source to the sink, typically carries the bulk of the information being transferred. Parameters further define the contents and format of the data signal.
error	1 – 256	Source → Sink	No	A bit mask to mark errors affecting the data being transferred in the current cycle. A single bit of the error signal masks each of the errors the component recognizes. The errorDescriptor defines the error signal properties.

continued...

Signal Role	Width	Direction	Required	Description
`ready`	1	Sink → Source	No	Asserts high to indicate that the sink can accept data. `ready` is asserted by the sink on cycle <n> to mark cycle <*n* + `readyLatency`> as a ready cycle. The source may only assert `valid` and transfer data during `ready` cycles. Sources without a `ready` input do not support backpressure. Sinks without a `ready` output never need to backpressure.
`valid`	1	Source → Sink	No	The source asserts this signal to qualify all other source to sink signals. The sink samples data and other source-to-sink signals on ready cycles where `valid` is asserted. All other cycles are ignored. Sources without a `valid` output implicitly provide valid data on every cycle that a sink is not asserting backpressure. Sinks without a `valid` input expect valid data on every cycle that they are not backpressuring.
Packet Transfer Signals				
`empty`	1 – 10	Source → Sink	No	Indicates the number of symbols that are empty, that is, do not represent valid data. The `empty` signal is not necessary on interfaces where there is one symbol per beat.
`endofpacket`	1	Source → Sink	No	Asserted by the source to mark the end of a packet.
`startofpacket`	1	Source → Sink	No	Asserted by the source to mark the beginning of a packet.

5.15.10. Avalon Streaming Credit Interface Signal Roles

Each signal in an Avalon Streaming Credit source or sink interface corresponds to one Avalon Streaming Credit signal role. An Avalon Streaming Credit interface may contain only one instance of each signal role. All Avalon Streaming Credit signal roles apply to both sources and sinks and have the same meaning for both.

Table 113. Avalon Streaming Credit Interface Signals

Signal Name	Direction	Width	Optional / Required	Description
`update`	Sink to source	1	Required	Sink sends `update` and source updates the available credit counter. Sink sends `update` to source when a transaction is popped from its buffer. Credit counter in source is increased by the value on the credit bus from sink to source.
`credit`	Sink to source	1-9	Required	Indicates additional credit available at sink when update is asserted. This bus carries a value as specified by the sink. Width of the `credit` bus is $ceilog_2$(MAX_CREDIT + 1). Sink sends available credit value on this bus which indicates the number of transactions it can accept. Source captures **`credit`** value only if **`update`** signal is asserted.

continued...

Signal Name	Direction	Width	Optional / Required	Description
return_credit	Source to sink	1	Required	Asserted by source to return 1 credit back to sink. *Note:* For more details, refer to Section 6.2.3 *Returning the Credits*.
data	Source to sink	1-8192	Required	Data is divided into symbols as per existing Avalon Streaming definition.
valid	Source to sink	1	Required	Asserted by the source to qualify all other source to sink signals. Source can assert `valid` only when the credit available to it is greater than 0.
error	Source to sink	1-256	Optional	A bit mask used to mark errors affecting the data being transferred in the current cycle. A single bit in error is used for each of the errors recognized by the component, as defined by the `errorDescriptor` property.
channel	Source to sink	1-128	Optional	The channel number for data being transferred on the current cycle. If an interface supports the `channel` signal, it must also define the `maxChannel` parameter.
Packet Transfer Signals				
startofpacket	Source to sink	1	Optional	Asserted by the source to mark the start of a packet.
endofpacket	Source to sink	1	Optional	Asserted by the source to mark the end of a packet.
empty	Source to sink	ceil(log2(NUM_SYMBOLS))	Optional	Indicates the number of symbols that are empty, that is, do not represent valid data. The `empty` signal is not used on interfaces where there is one symbol per beat.
User Signals				
<Per-Packet User Signals>	Source to sink	1-8192	Optional	Any number of per-packet user signals can be present on source and sink interfaces. Source sets value of this signal when `startofpacket` is asserted. Source should not change the value of this signal until start of new packet. More details are in the User Signal section.
<Per-Symbol User Signals>	Source to sink	1-8192	Optional	Any number of per-symbol user signals can be present on source and sink. More details are in the User Signal section.

5.15.10.1. Synchronous Interface

All transfers of an Avalon Streaming connection occur synchronous to the rising edge of the associated clock signal. All outputs from a source interface to a sink interface, including the `data`, `channel`, and `error` signals, must be registered on the rising edge of clock. Inputs to a sink interface do not have to be registered. Registering signals at the source facilitates high-frequency operation.

Table 114. Avalon Streaming Credit Interface Properties

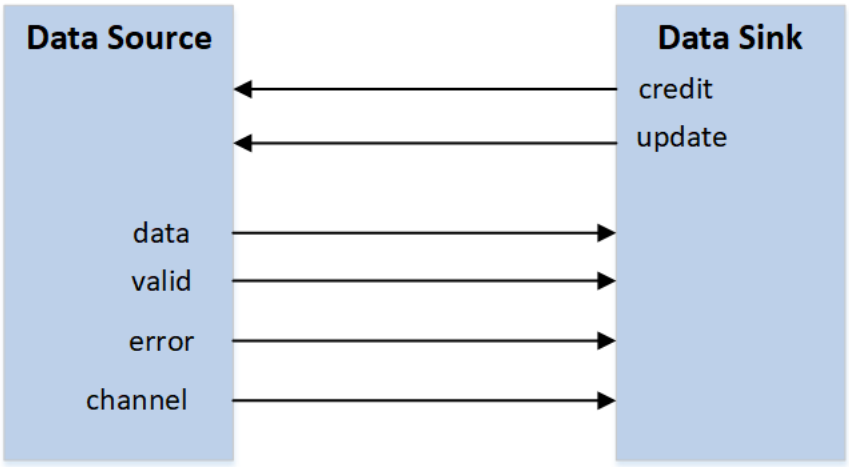
Property Name	Default Value	Legal Value	Description
associatedClock	1	Clock interface	The name of the Avalon Clock interface to which this Avalon Streaming interface is synchronous.
associatedReset	1	Reset interface	The name of the Avalon Reset interface to which this Avalon Streaming interface is synchronous.
dataBitsPerSymbol	8	1 – 8192	Defines the number of bits per symbol. For example, byte-oriented interfaces have 8-bit symbols. This value is not restricted to be a power of 2.
symbolsPerBeat	1	1 – 8192	The number of symbols that are transferred on every valid cycle.
maxCredit	256	1-256	The maximum number of credits that a data interface can support.
errorDescriptor	0	List of strings	A list of words that describe the error associated with each bit of the error signal. The length of the list must be the same as the number of bits in the error signal. The first word in the list applies to the highest order bit. For example, "crc, overflow" means that bit[1] of error indicates a CRC error. Bit[0] indicates an overflow error.
firstSymbolInHighOrderBits	true	true, false	When true, the first-order symbol is driven to the most significant bits of the data interface. The highest-order symbol is labeled D0 in this specification. When this property is set to false, the first symbol appears on the low bits. D0 appears at data[7:0]. For a 32-bit bus, if true, D0 appears on bits[31:24].
maxChannel	0	0	The maximum number of channels that a data interface can support.

5.15.10.2. Typical Data Transfers

This section defines the transfer of data from a source interface to a sink interface. In all cases, the data source and the data sink must comply with the specification. It is not the responsibility of the data sink to detect source protocol errors.

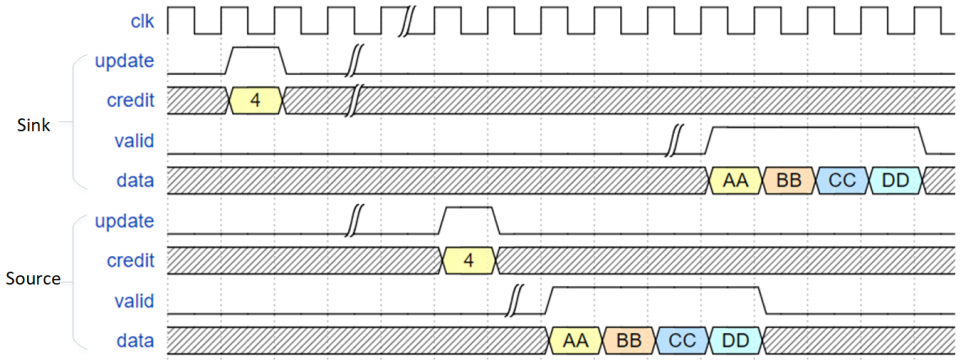
The below figure shows the signals that are typically used in an Avalon Streaming Credit interface.

Figure 244. Typical Avalon Streaming Credit Signals



As this figure indicates, a typical Avalon Streaming Credit source interface drives the `valid`, `data`, `error`, and `channel` signals to the sink. The sink drives `update` and `credit` signals.

Figure 245. Typical Credit and Data Transfer



The above figure shows a typical credit and data transfer between source and sink. There can be an arbitrary delay between the sink asserting `update` and source receiving the `update`. Similarly, there can be an arbitrary delay between source asserting `valid` for data and sink receiving that data. Delay on credit path from sink to source and data path from source to sink need not be equal. These delays can be 0 cycle as well, i.e. when the sink asserts `update`, it is seen by the source in the same cycle. Conversely, when the source asserts `valid`, it is seen by the sink in the same cycle. If source has zero credits, it cannot assert `valid`. Transferred credits are cumulative. If sink has transferred credits equal to its maxCredit property, and has not received any data, it cannot assert `update` until it receives at least 1 data or has received a `return_credit` pulse from the source.

Sink cannot backpressure data from source if sink has provided credits to the source, i.e. sink must accept data from source if there are outstanding credits. Source cannot assert `valid` if it has not received any credit or exhausted the credits received, i.e. already sent the data in lieu of credits received.

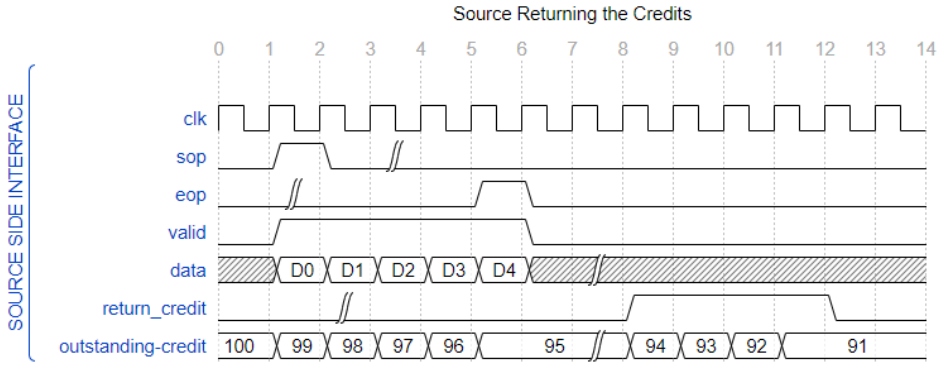
If source has zero credits, source cannot start the data transfer in the same cycle it receives credits. Similarly, if sink has transferred credits equal to its maxCredit property and it receives data, sink cannot send an update in the same cycle as it received data. These restrictions have been put in place to avoid combinational loops in the implementation.

5.15.10.3. Returning the Credits

Avalon Streaming Credit protocol supports a `return_credit` signal. This is used by source to return the credits back to sink. Every cycle this signal is asserted, it indicates source is giving back 1 credit. If source wants to return multiple credits, this signal needs to be asserted for multiple cycles. For example, if source wants to return 10 outstanding credits, it asserts `return_credit` signal for 10 cycles. Sink should account for returned credits in its internal credit maintenance counters. Credits can be returned by source at any point in time as long as it has credits greater than 0.

The below figure exemplifies source returning credits. As shown in the figure, *outstanding_credit* is an internal counter for the source. When source returns credits, this counter is decremented.

Figure 246. Source Returning Credits



Note: Although the diagram above shows the returning of credits when `valid` is deasserted, `return_credit` can also be asserted while `valid` is asserted. In this case, source effectively spends 2 credits: one for `valid`, and one for `return_credit`.

5.15.11. Avalon Streaming Credit User Signals

User signals are optional sideband signals which flow along with data. They are considered valid only when data is valid. Given that user signals do not have any defined meaning or purpose, caution must be used while using these signals. It is the responsibility of the system designer to make sure that two IPs connected to each other agree on the roles of the user signals.

Two types of user signals are being proposed: per-symbol user signals and per-packet user signals.

5.15.11.1. Per-Symbol User Signal

As the name suggests, the data defines a per-symbol user signal (`symbol_user`) per symbol. Each symbol in the data can have a user signal. For example, if the number of symbols in the data is 8, and `symbol_user` width is 2 bits, the total width of the `symbol_user` signal is 16 bits.

`Symbol_user` is valid only when data is valid. Source can change this signal every cycle when data is valid. Sink can disregard the value of `symbol_user` bits for empty symbols.

If a source which has this signal is connected to a sink which does not have this signal on its interface, the signal from source remains dangling in the generated interconnect.

If a source which does not have this signal is connected to a sink which has this signal on its interface, the sink's input user signal ties to 0.

If both source and sink have equal number of symbols in the data, then the user signals for both must have equal widths. Otherwise, they cannot be connected.

If a wide source is connected to a narrow sink, and both have per-symbol user signals, then both must have equal bits of user signal associated with each symbol. For example, if a 16-symbol source has 2 bits of user signal associated with each symbol (for a total of 32 bits of user signal), then a 4-symbol sink must have an 8-bit wide user signal (2 bits associated with each symbol). A data format adapter can convert the 16-symbol source data to 4-symbol sink data, and 32-bit user signal to 8-bit user signal. The data format adapter maintains the association of symbols with corresponding user signal bits.

Similarly, if a narrow source is connected to a wide sink, and both have per-symbol user signals, then both must have equal bits of user signal associated with each symbol. For example, if a 4-symbol source has 2 bits of user signal associated with each symbol (for a total of 8 bits of user signal), then a 16-symbol sink must have a 32-bit wide user signal (2 bits associated with each symbol). A data format adapter can convert the 4-symbol source data to 16-symbol sink data, and 8-bit user signal to 32-bit user signal. The data format adapter maintains the association of symbols with corresponding user signal bits. If the packet is smaller than the ratio of data widths, the data format adapter sets the value of empty accordingly. Sink should disregard the value of user bits associated with empty symbols.

5.15.11.2. Per-Packet User Signal

In addition to `symbol_user`, per-packet user signals (`packet_user`) can also be declared on the interface. `Packet_user` can be of arbitrary width. Unlike `symbol_user`, `packet_user` must remain constant throughout the packet, i.e. its value should be set at the start of the packet and must remain the same until the end of the packet. This restriction makes the implementation of the data format adapter simpler as it eliminates the option to replicate or chop (wide source, narrow sink) or concatenate (narrow source, wide sink) `packet_user`.

If a source has `packet_user` and sink does not, the `packet_user` from source remains dangling. In such a case, the system designer must be careful and not transmit any critical control information on this signal as it is completely or partially ignored.

If a source does not have `packet_user` and the sink does, the `packet_user` to sink is tied to 0.

5.15.12. Avalon Clock Source Signal Roles

An Avalon Clock source interface drives a clock signal out of a component.

Table 115. Clock Source Signal Roles

Signal Role	Width	Direction	Required	Description
`clk`	1	Output	Yes	An output clock signal.

5.15.13. Avalon Clock Sink Signal Roles

A clock sink provides a timing reference for other interfaces and internal logic.

Table 116. Clock Sink Signal Roles

Signal Role	Width	Direction	Required	Description
`clk`	1	Input	Yes	A clock signal. Provides synchronization for internal logic and for other interfaces.

5.15.14. Avalon Conduit Signal Roles

Table 117. Conduit Signal Roles

Signal Role	Width	Direction	Description
<any>	<*n*>	In, out, or bidirectional	A conduit interface consists of one or more input, output, or bidirectional signals of arbitrary width. Conduits can have any user-specified role. You can connect compatible Conduit interfaces inside a Platform Designer system provided the roles and widths match and the directions are opposite.

5.15.15. Avalon Tristate Conduit Signal Roles

The following table lists the signal defined for the Avalon Tristate Conduit interface. All Avalon-TC signals apply to both hosts and agents and have the same meaning for both.

Table 118. Tristate Conduit Interface Signal Roles

Signal Role	Width	Direction	Required	Description
`request`	1	Host → Agent	Yes	The meaning of `request` depends on the state of the `grant` signal, as the following rules dictate. When `request` is asserted and `grant` is deasserted, `request` is requesting access for the current cycle. When `request` is asserted and `grant` is asserted, `request` is requesting access for the next cycle. Consequently, `request` should be deasserted on the final cycle of an access. The `request` signal deasserts in the last cycle of a bus access. The `request` signal can reassert immediately following the final cycle of a transfer.

continued...

Signal Role	Width	Direction	Required	Description
				This protocol makes both rearbitration and continuous bus access possible if no other hosts are requesting access. Once asserted, `request` must remain asserted until granted. Consequently, the shortest bus access is 2 cycles. Refer to *Tristate Conduit Arbitration Timing* for an example of arbitration timing.
`grant`	1	Agent → Host	Yes	When asserted, indicates that a tristate conduit host has access to perform transactions. The `grant` signal asserts in response to the `request` signal. The `grant` signal remains asserted until 1 cycle following the deassertion of `request`.
<*name*>_in	1 – 1024	Agent → Host	No	The input signal of a logical tristate signal.
<*name*>_out	1 – 1024	Host → Agent	No	The output signal of a logical tristate signal.
<*name*>_outen	1	Host → Agent	No	The output enable for a logical tristate signal.

5.15.16. Avalon Tri-State Agent Interface Signal Types

Table 119. Tri-state Agent Interface Signal Types

Name	Width	Direction	Required	Description
`address`	1 - 32	input	No	Address lines to the agent port. Specifies a byte offset into the agent's address space.
`read` `read_n`	1	input	No	Read-request signal. Not required if the agent port never outputs data. If present, data must also be used.
`write` `write_n`	1	input	No	Write-request signal. Not required if the agent port never receives data from a host. If present, data must also be present, and `writebyteenable` cannot be present.
`chipselect` `chipselect_n`	1	input	No	When present, the agent port ignores all Avalon memory mapped signals unless `chipselect` is asserted. `chipselect` is always present in combination with read or write
`outputenable` `outputenable_n`	1	input	Yes	Output-enable signal. When deasserted, a tri-state agent port must not drive its data lines otherwise data contention may occur.
`data`	8,16, 32, 64, 128, 256, 512, 1024	bidir	No	Bidirectional data. During write transfers, the FPGA drives the data lines. During read transfers the agent device drives the data lines, and the FPGA captures the data signals and provides them to the host.
`byteenable` `byteenable_n`	2, 4, 8,16, 32, 64, 128	input	No	Enables specific byte lanes during transfers. Each bit in byteenable corresponds to a byte lane in data. During writes, `byteenables` specify which bytes the host is writing to the agent. During

continued...

Name	Width	Direction	Required	Description
				reads, `byteenables` indicates which bytes the host is reading. Agents that simply return data with no side effects are free to ignore `byteenables` during reads. When more than one byte lane is asserted, all asserted lanes are guaranteed to be adjacent. The number of adjacent lines must be a power of 2, and the specified bytes must be aligned on an address boundary for the size of the data. The following are legal values for a 32-bit agent: `1111 writes full 32 bits` `0011 writes lower 2 bytes` `1100 writes upper 2 bytes` `0001 writes byte 0 only` `0010 writes byte 1 only` `0100 writes byte 2 only` `1000 writes byte 3 only`
`writebyteenable` `writebyteenable_n`	2,4,8,16, 32, 64,128	input	No	Equivalent to the logical AND of the `byteenable` and write signals. When used, the write signal is not used.
`begintransfer1`	1	input	No	Asserted for the first cycle of each transfer.
Note: All Avalon signals are active high. Avalon signals that can also be asserted low list both versions in the **Signal Role** column.				

5.15.17. Avalon Interrupt Sender Signal Roles

Table 120. Interrupt Sender Signal Roles

Signal Role	Width	Direction	Required	Description
irq irq_n	1-2048	Output	Yes	Interrupt Request. An interrupt sender drives an interrupt signal to an interrupt receiver.

5.15.18. Avalon Interrupt Receiver Signal Roles

Table 121. Interrupt Receiver Signal Roles

Signal Role	Width	Direction	Required	Description
irq	1–2048	Input	Yes	irq is an <*n*>-bit vector, where each bit corresponds directly to one IRQ sender with no inherent assumption of priority.

5.16. Platform Designer Interconnect Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2023.10.02	23.3	• Removed misplaced Reset Synchronous Edges description from *Clock Interfaces* topic. • Removed obsolete upper limit from *IRQ Fan-Out* topic.
2023.04.03	23.1	• The product family name is updated to "Intel Agilex 7" to reflect the different family members.
2022.06.20	22.2	• Added new *IRQ Fanout* topic. • Updated *IRQ Mapper* topic to describe Remove Clock and Reset Ports parameters. • Updated legal IRQ width from 32 to 2048 in the following topics: — *Interrupt Interfaces* — *Individual Requests IRQ Scheme* — *Avalon Interrupt Sender Signal Roles* — *Avalon Interrupt Receiver Signal Roles*
2022.04.02	22.1	• Updated entire chapter for new AXI "manager" and AXI "subordinate" replacement terms. Refer to the AMBA® AXI and ACE Protocol Specification. • Updated parameter values for all *Avalon Streaming Credit* IPs. • Revised wording in *Terms and Concepts* topic for greater clarity. • Revised AMBA 4 AXI-Lite Signals topic for optional signals information. • Added new AMBA 4 AXI-Lite Optional Port Support and Interconnect topic describing optional port support details.
2021.03.29	21.1	• Converted to "host" and "agent" inclusive terminology for Avalon memory mapped interface descriptions and related GUI elements throughout.

continued...

Document Version	Quartus Prime Version	Changes
2020.12.14	20.4	• Revised "Interconnect Pipelining" for clarity and latest GUI. • Revised "Fixed Priority Arbitration" for latest GUI. • Revised "Add Pipeline Stages in the Interconnect Schematic" for Add All Pipelines and Remove All Pipelines controls. • Revised statement in "Ordering Model" topic to clarify applies to all versions. • Revised "Pipeline Placement in Arbitration Logic" diagram color coding.
2020.06.26	20.1	Removed incorrect statement about compile time option to enforce strict ordering from the "AXI and Avalon Ordering" topic.
2020.05.08	20.1	Added some clarification for the timing behavior of the signal `writeresponsevalid` to the *Avalon Memory-Mapped Interface Signal Roles* section. Updated the bus widths for the `data` and `empty` signals in the *Avalon Streaming Interface Signal Roles* section.
2020.05.01	20.1	• Updated "Avalon Streaming Credit Interface Signal Roles" to indicate that return_credit is required. • Added "Avalon Streaming Credit Interfaces" section. • Added "Avalon Streaming Credit Interface Signal Roles" topic. • Added "Avalon Streaming Credit User Signals" topic.
2019.11.11	19.1.0	• Added note to "Burst Adaptation: AXI to Avalon" about AXI3 and AXI4 4KB boundary restriction for burst transactions. • Added "Adjacent Bytelanes with Partial Width Transactions" topic.
2019.06.19	19.1.0	• Corrected statement about preventing reordering in "Ordering Model."
2019.04.01	19.1.0	• Described new default use of synchronous reset option for Stratix 10 designs in "Reset Interfaces."
2018.12.10	18.1.0	• Replaced references to System Contents tab with new System View tab.
2018.09.24	18.1.0	• Updated location of **Limit interconnect pipeline stages to** option in Platform Designer GUI • In *Avalon Memory-Mapped Interface Signal Roles*, added consecutive byte-enable support. • Specified minimum duration of reset that the Platform Design Interconnect requires to work correctly.
2018.06.15	18.0.0	Clarified behavior of Error Correction Coding (ECC) in Interconnect.
2018.05.07	18.0.0	• Added support for `waitrequestAllowance` adapter. • Added support for ACE-Lite connections.
2017.11.06	17.1.0	• Changed instances of *Qsys Pro* to Platform Designer • Updated information about the Reset Sequencer.
2016.10.31	16.1.0	• Implemented Intel rebranding. • Implemented *Qsys* rebranding.
2015.11.02	15.1.0	Changed instances of *Quartus II* to *Quartus Prime*.
2015.05.04	15.0.0	• Fixed Priority Arbitration. • Added topic: *Read and Write Responses*. • Added topic: *Error Correction Coding (ECC) in Qsys Interconnect*. • Added: `response [1:0]`, *Avalon Memory-Mapped Interface Signal Roles*. • Added `writeresponsevalid`, *Avalon Memory-Mapped Interface Signal Roles*.

continued...

Document Version	Quartus Prime Version	Changes
December 2014	14.1.0	• Read error responses, Avalon Memory-Mapped Interface Signal, `response`. • Burst Adapter Implementation Options: Generic converter (slower, lower area), Per-burst-type converter (faster, higher area).
August 2014	14.0a10.0	• Updated Qsys Packet Format for Memory-Mapped Host and Agent Interfaces table, `Protection`. • Streaming Interface renamed to Avalon Streaming Interfaces. • Added *Response Merging* under *Memory-Mapped Interfaces*.
June 2014	14.0.0	• AXI4-Lite support. • AXI4-Stream support. • Avalon streaming adapter parameters. • IRQ Bridge. • Handling Read Side Effects note added.
November 2013	13.1.0	• HSSI clock support. • Reset Sequencer. • Interconnect pipelining.
May 2013	13.0.0	• AMBA APB support. • Auto-inserted Avalon streaming adapters feature. • Moved Address Span Extender to the *Qsys System Design Components* chapter.
November 2012	12.1.0	• AMBA AXI4 support.
June 2012	12.0.0	• AMBA AXI3 support. • Avalon streaming adapters. • Address Span Extender.
November 2011	11.0.1	Template update.
May 2011	11.0.0	Removed beta status.
December 2010	10.1.0	Initial release.

6. Platform Designer System Design Components

You can use Platform Designer IP components to create Platform Designer systems. Platform Designer interfaces include components appropriate for streaming high-speed data, reading and writing registers and memory, controlling off-chip devices, and transporting data between components.

Platform Designer supports Avalon, AMBA 3 AXI (version 1.0), AMBA 4 AXI (version 2.0), AMBA 4 AXI-Lite (version 2.0), AMBA 4 AXI-Stream (version 1.0), and AMBA 3 APB (version 1.0) interface specifications.

- Avalon Interface Specifications

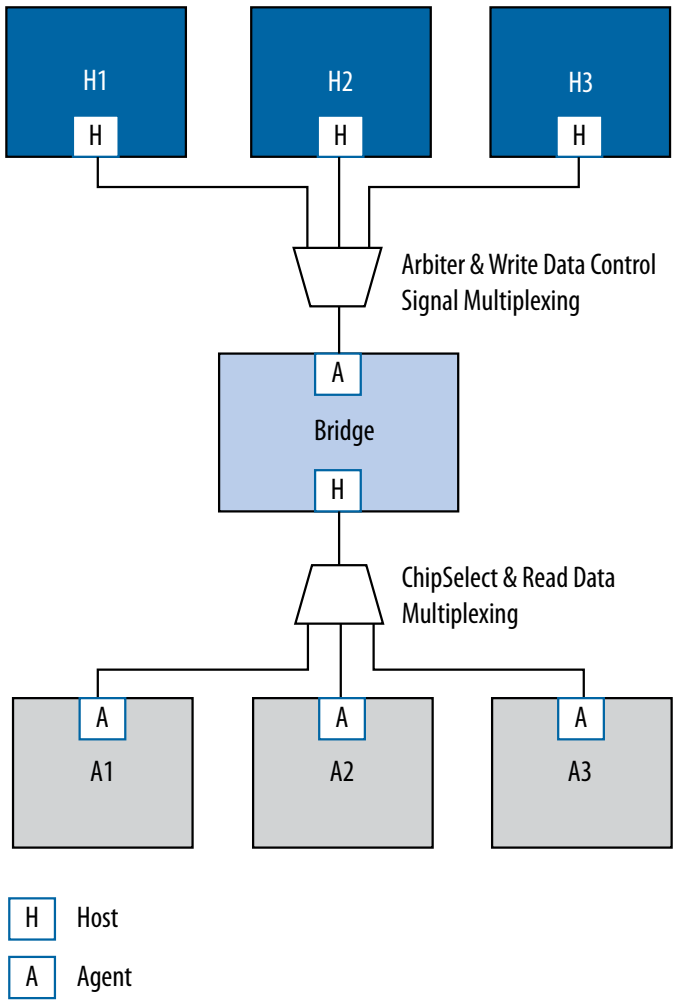
6.1. Bridges

Bridges affect the way Platform Designer transports data between components. You can insert bridges between host[24] and agent interfaces to control the topology of a Platform Designer system, which affects the interconnect that Platform Designer generates. You can also use bridges to separate components into different clock domains to isolate clock domain crossing logic.

A bridge has one agent interface and one host interface. In Platform Designer, one or more host interfaces from other components connect to the bridge agent. The bridge host connects to one or more agent interfaces on other components. In the following example, three hosts have logical connections to three agents, although physically each host connects only to the bridge. Transfers initiated to the agent propagate to the host in the same order in which the transfers are initiated on the agent.

[24] Platform Designer now replaces non-inclusive terms with "host" and "agent" inclusive terms for Avalon memory mapped interface descriptions and related GUI elements.

Figure 247. Using a Bridge in a Platform Designer System

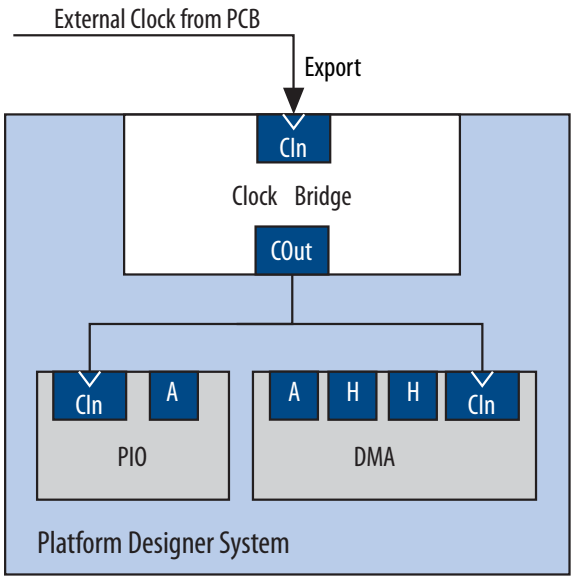


6.1.1. Clock Bridge Intel FPGA IP

The Clock Bridge Intel FPGA IP connects a clock source to multiple clock input interfaces. You can use the clock bridge to connect a clock source that is outside the Platform Designer system. Create the connection through an exported interface, and then connect to multiple clock input interfaces.

Clock outputs match fan-out performance without the use of a bridge. You require a bridge only when you want a clock from an exported source to connect internally to more than one source.

Figure 248. Clock Bridge Intel FPGA IP



6.1.2. Avalon Memory Mapped Clock Crossing Bridge Intel FPGA IP

The Avalon Memory Mapped Clock Crossing Bridge Intel FPGA IP transfers Avalon memory mapped commands and responses between different clock domains. You can also use the Avalon Memory Mapped Clock Crossing Bridge between AXI hosts and agents of different clock domains.

The Avalon Memory Mapped Clock Crossing Bridge uses asynchronous FIFOs to implement clock crossing logic. The bridge parameters control the depth of the command and response FIFOs in both the host and agent clock domains. If the number of active reads exceeds the depth of the response FIFO, the Clock Crossing Bridge stops sending reads.

To maintain throughput for high-performance applications, increase the response FIFO depth from the default minimum depth, which is twice the maximum burst size.

Note: When you use the FIFO-based clock crossing a Platform Designer system, the DC FIFO is automatically inserted in the Platform Designer system. The reset inputs for the DC FIFO connect to the reset sources for the connected host and agent components on either side of the DC FIFO. For this configuration, you must assert both the resets on the host and the agent sides at the same time to ensure the DC FIFO resets properly. Alternatively, you can drive both resets from the same reset source to guarantee that the DC FIFO resets properly.

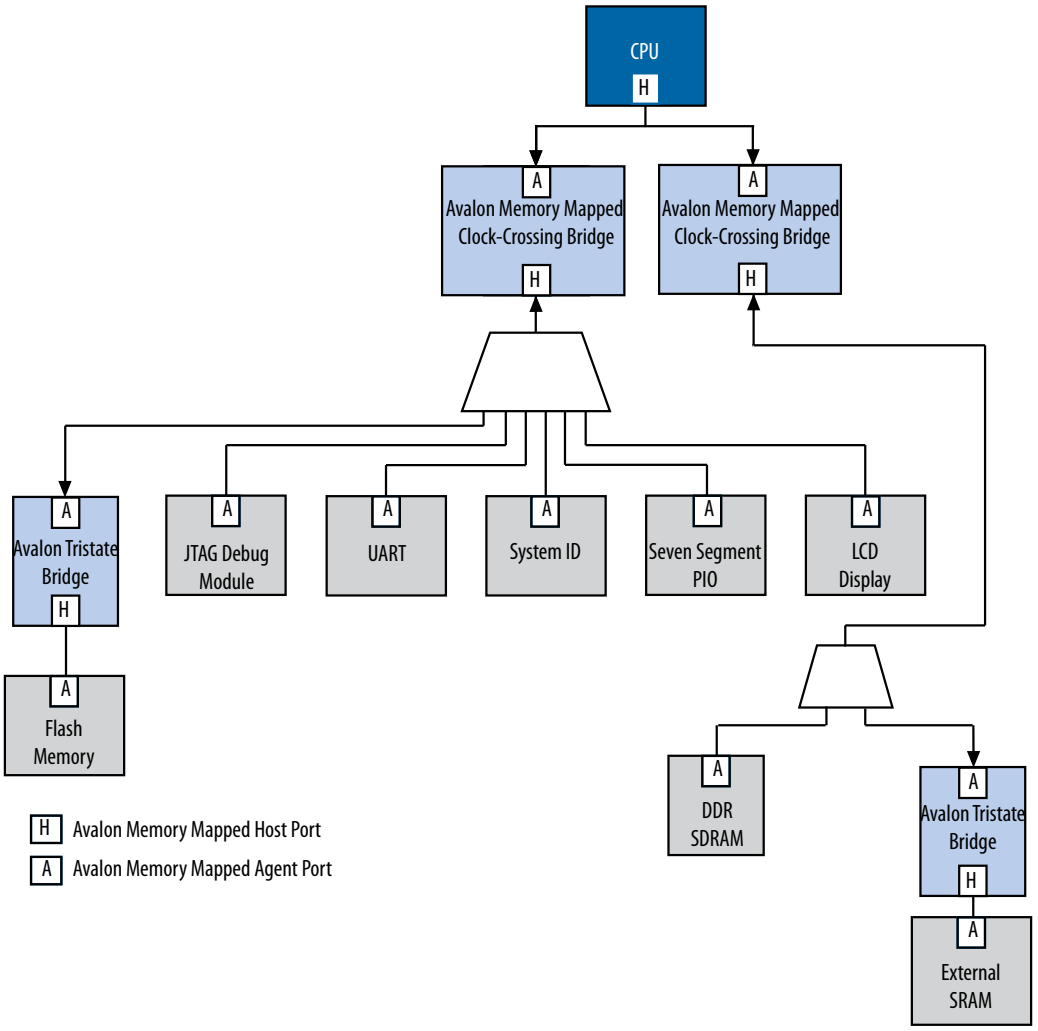
Note: The clock crossing bridge includes appropriate SDC constraints for its internal asynchronous FIFOs. For these SDC constraints to work correctly, do not set false paths on the pointer crossings in the FIFOs. Do not split the bridge's clocks into separate clock groups when you declare SDC constraints; the split has the same effect as setting false paths.

6.1.2.1. Avalon Memory Mapped Clock Crossing Bridge Example

In the example shown below, the Avalon Memory Mapped Clock Crossing bridges separate agent components into two groups. The Avalon Memory Mapped Clock Crossing Bridge places the low performance agent components behind a single bridge and clocks the components at a lower speed. The bridge places the high-performance components behind a second bridge and clocks it at a higher speed.

By inserting clock-crossing bridges, you simplify the Platform Designer interconnect and allow the Quartus Prime Fitter to optimize paths that require minimal propagation delay.

Figure 249. Avalon Memory Mapped Clock Crossing Bridge



6.1.2.2. Avalon Memory Mapped Clock Crossing Bridge Parameters

Table 122. Avalon Memory Mapped Clock Crossing Bridge Parameters

Parameters	Values	Description
Data width	8, 16, 32, 64, 128, 256, 512, 1024 bits	Determines the data width of the interfaces on the bridge, and affects the size of both FIFOs. For the highest bandwidth, set **Data width** to be as wide as the widest host that connects to the bridge.
Symbol width	1, 2, 4, 8, 16, 32, 64 (bits)	Number of bits per symbol. For example, byte-oriented interfaces have 8-bit symbols.
Address width	1-32 bits	The address bits needed to address the downstream agents.
Use automatically-determined address width	-	The minimum bridge address width that is required to address the downstream agents.
Maximum burst size	1, 2, 4, 8, 16, 32, 64, 128, 256, 512, 1024 bits	Determines the maximum length of bursts that the bridge supports.
Command FIFO depth	2, 4, 8, 16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384 bits	Command (host-to-agent) FIFO depth.
Respond FIFO depth	2, 4, 8,16, 32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, 16384 bits	agent-to-host FIFO depth.
Master clock domain synchronizer depth	2, 3, 4, 5 bits	The number of pipeline stages in the clock crossing logic in the issuing host to target agent direction. Increasing this value leads to a larger mean time between failures (MTBF). You can determine the MTBF for a design by running a timing analysis.
Slave clock domain synchronizer depth	2, 3, 4, 5 bits	The number of pipeline stages in the clock crossing logic in the target agent to host direction. Increasing this value leads to a larger meantime between failures (MTBF). You can determine the MTBF for a design by running a timing analysis.

6.1.3. Avalon Memory Mapped Pipeline Bridge Intel FPGA IP

The Avalon Memory Mapped Pipeline Bridge Intel FPGA IP inserts a register stage in the Avalon memory mapped command and response paths. The bridge accepts commands on its agent port and propagates the commands to its host port. The pipeline bridge provides separate parameters to turn on pipelining for command and response signals.

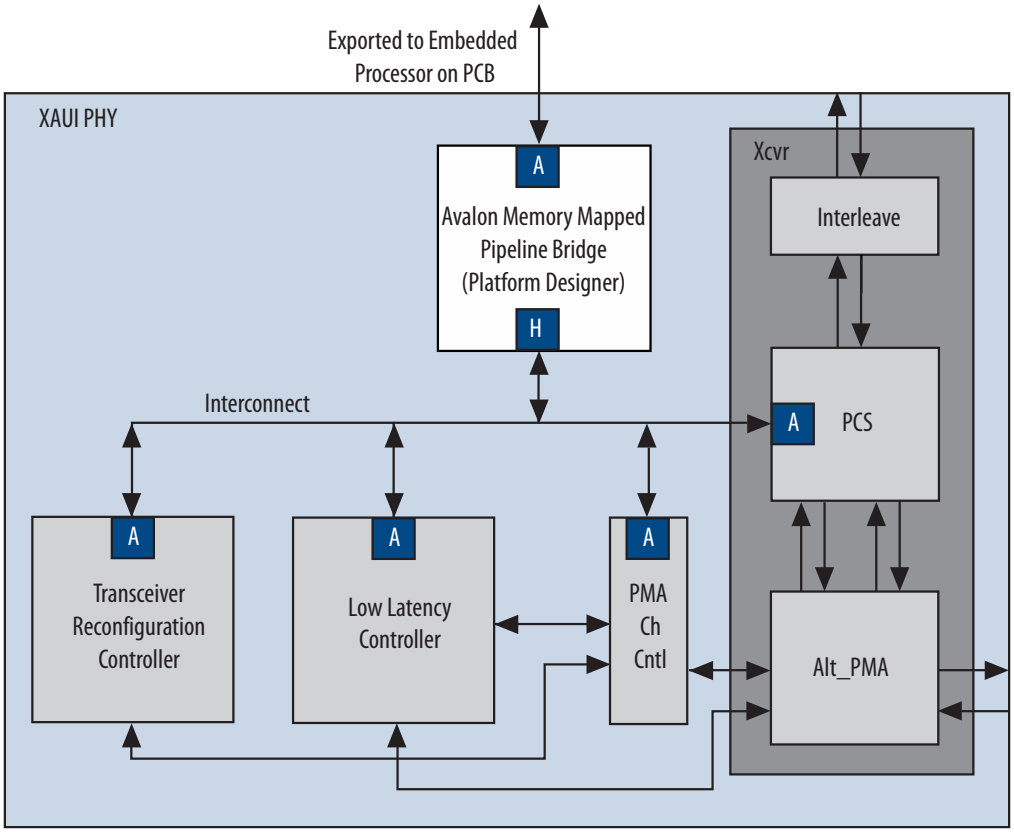
Note: The Avalon Memory Mapped Pipeline Bridge Intel FPGA IP has a `readLatency` of `0` and `readdatavalid` of `1`. Therefore, the bridge does not support fixed-latency pipelined read transfers.

The **Maximum pending read transactions** parameter is the maximum number of pending reads that the Avalon Memory Mapped bridge can queue up. To determine the best value for this parameter, review this same option for the bridge's connected agents and identify the highest value of the parameter, and then add the internal buffering requirements of the Avalon Memory Mapped bridge. In general, the value is between 4 and 32. The limit for maximum queued transactions is 64.

You can use the Avalon Memory Mapped bridge to export a single Avalon memory mapped agent interface to control multiple Avalon memory mapped agent devices. The pipelining feature is optional.

Figure 250. Avalon Memory Mapped Pipeline Bridge IP and XAUI PHY Transceiver IP

In this example, the bridge transfers commands received on its agent interface to its host port.

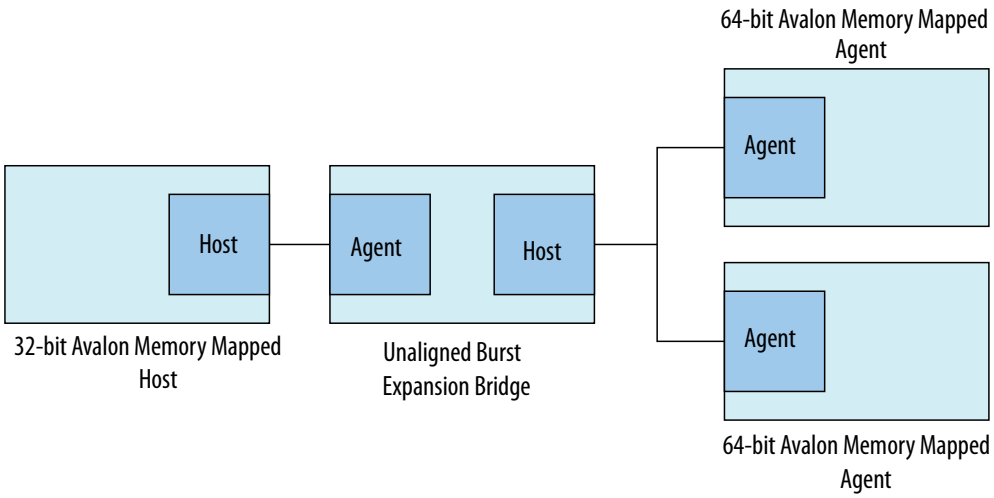


Because the agent interface is exported to the pins of the device, having a single agent port, rather than separate ports for each agent device, reduces the pin count of the FPGA. Refer to Interconnect Pipelining on page 328 for more information.

6.1.4. Avalon Memory Mapped Unaligned Burst Expansion Bridge Intel FPGA IP

The Avalon Memory Mapped Unaligned Burst Expansion Bridge Intel FPGA IP aligns read burst transactions from hosts connected to its agent interface, to the address space of agents connected to its host interface. This alignment ensures that all read burst transactions are delivered to the agent as a single transaction.

Figure 251. Avalon Memory Mapped Unaligned Burst Expansion Bridge Intel FPGA IP



You can use the Avalon Unaligned Burst Expansion Bridge to align read burst transactions from hosts that have narrower data widths than the target agents. Using the bridge for this purpose improves bandwidth utilization for the host-agent pair, and ensures that unaligned bursts are processed as single transactions rather than multiple transactions.

Note: Do not use the Avalon Memory Mapped Unaligned Burst Expansion Bridge if any connected agent has read side effects from reading addresses that are exposed to any connected host's address map. This bridge can cause read side effects due to alignment modification to read burst transaction addresses.

Note: The Avalon Memory Mapped Unaligned Burst Expansion Bridge does not support VHDL simulation.

6.1.4.1. Using the Avalon Memory Mapped Unaligned Burst Expansion Bridge

When a host sends a read burst transaction to an agent, the Avalon Memory Mapped Unaligned Burst Expansion Bridge initially determines whether the start address of the read burst transaction is aligned to the agent's memory address space. If the base address is aligned, the bridge does not change the base address. If the base address is not aligned, the bridge aligns the base address to the nearest aligned address that is less than the requested base address.

The Avalon Memory Mapped Unaligned Burst Expansion Bridge then determines whether the final word requested by the host is the last word at the agent read burst address. If a single agent address contains multiple words, all those words must be requested for a single read burst transaction to occur.

- If the final word requested by the host is the last word at the agent read burst address, the bridge does not modify the burst length of the read burst command to the agent.
- If the final word requested by the host is not the last word at the agent read burst address, the bridge increases the burst length of the read burst command to the agent. The final word requested by the modified read burst command is then the last word at the agent read burst address.

The bridge stores information about each aligned read burst command that it sends to agents connected to a host interface. When a read response is received on the host interface, the bridge determines if the base address or burst length of the issued read burst command was altered.

If the bridge alters either the base address or the burst length of the issued read burst command, it receives response words that the host did not request. The bridge suppresses words that it receives from the aligned burst response that are not part of the original read burst command from the host.

6.1.4.2. Avalon Memory Mapped Unaligned Burst Expansion Bridge Parameters

Figure 252. Avalon Memory Mapped Unaligned Burst Expansion Bridge Parameter Editor

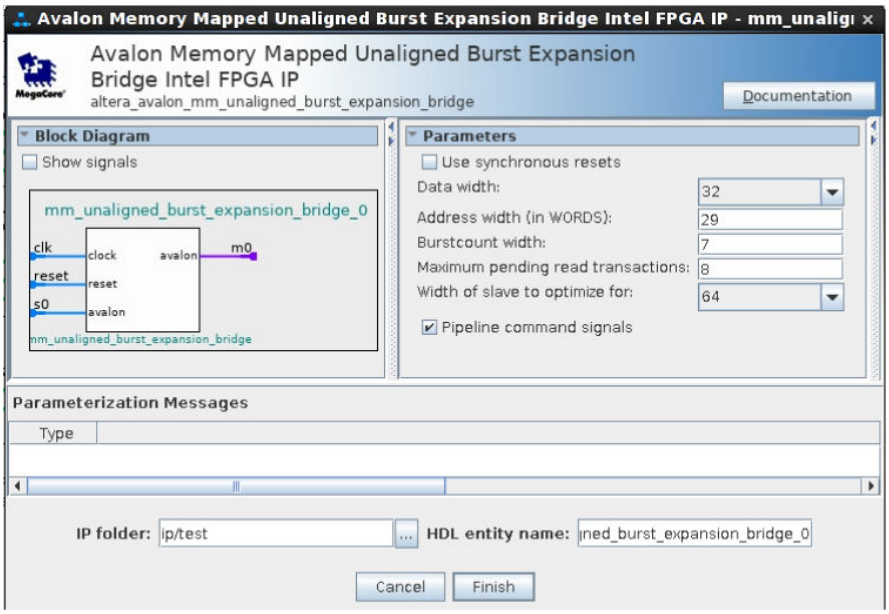


Table 123. Avalon Memory Mapped Unaligned Burst Expansion Bridge Parameters

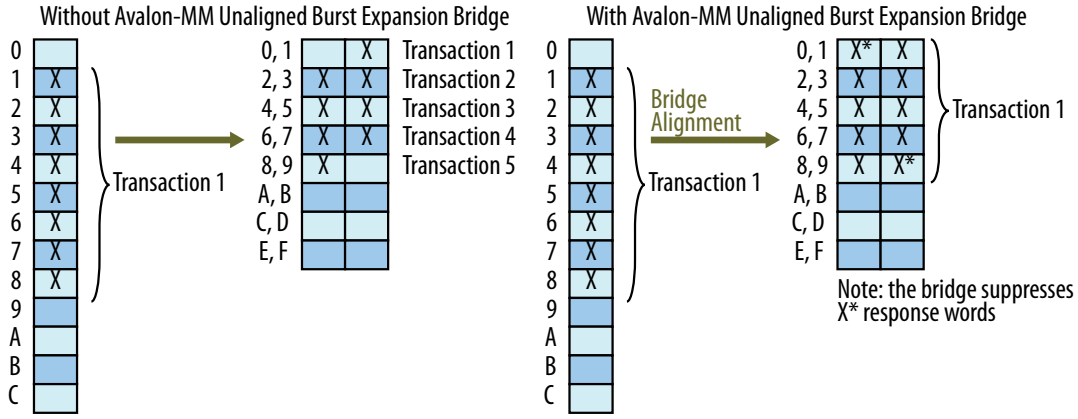
Parameter	Description
Data width	Data width of the host connected to the bridge.
Address width (in WORDS)	The address width of the host connected to the bridge.
Burstcount width	The burstcount signal width of the host connected to the bridge.
Maximum pending read transactions	The **Maximum pending read transactions** parameter is the maximum number of pending reads that the Avalon Memory Mapped bridge can queue up. To determine the best value for this parameter, review this same option for the bridge's connected agents and identify the highest value of the parameter, and then add the internal buffering requirements of the Avalon Memory Mapped bridge. In general, the value is between 4 and 32. The limit for maximum queued transactions is 64.
Width of agent to optimize for	The data width of the connected agent. Supported values are: 16, 32, 64, 128, 256, 512, 1024, 2048, and 4096 bits. *Note:* If you connect multiple agents, all agents must have the same data width.
Pipeline command signals	When turned on, the command path is pipelined, minimizing the bridge's critical path at the expense of increased logic usage and latency.

6.1.4.3. Avalon Memory Mapped Unaligned Burst Expansion Bridge Example

The following example shows an unaligned read burst command from a host that the Avalon Memory Mapped Unaligned Burst Expansion Bridge converts to an aligned request for a connected agent. The figure also shows the suppression of words due to the aligned read burst command. In this example, a 32-bit host requests an 8-beat burst of 32-bit words from a 64-bit agent with a start address that is not 64-bit aligned.

Figure 253. Unaligned Burst Expansion Bridge



Because the target agent has a 64-bit data width, address 1 is unaligned in the agent's address space. As a result, several smaller burst transactions are needed to request the data associated with the host's read burst command.

With an Avalon memory mapped Unaligned Burst Expansion Bridge in place, the bridge issues a new read burst command to the target agent beginning at address 0 with burst length 10, which requests data up to the word stored at address 9.

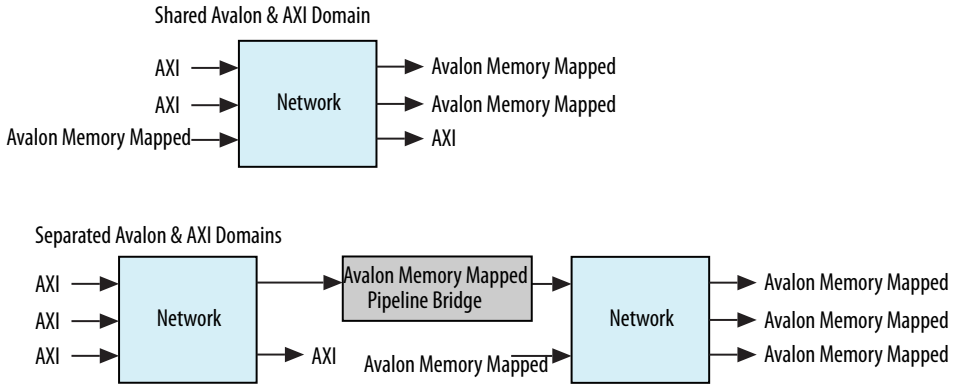
When the bridge receives the word corresponding to address 0, it suppresses it from the host, and then delivers the words corresponding to addresses 1 through 8 to the host. When the bridge receives the word corresponding to address 9, it suppresses that word from the host.

6.1.5. Bridges Between Avalon and AXI Interfaces

When designing a Platform Designer system, you can make connections between AXI and Avalon interfaces without the use of explicitly-instantiated bridges; the interconnect provides all necessary bridging logic. However, this does not prevent the use of explicit bridges to separate the AXI and Avalon domains. Using an explicit

Avalon memory mapped bridge to separate the AXI and Avalon domains reduces the amount of bridging logic in the interconnect at the expense of concurrency, as the following example shows:

Figure 254. Avalon Memory Mapped Pipeline Bridge Between Avalon Memory-Mapped and AXI Domains



6.1.6. AXI Bridge Intel FPGA IP

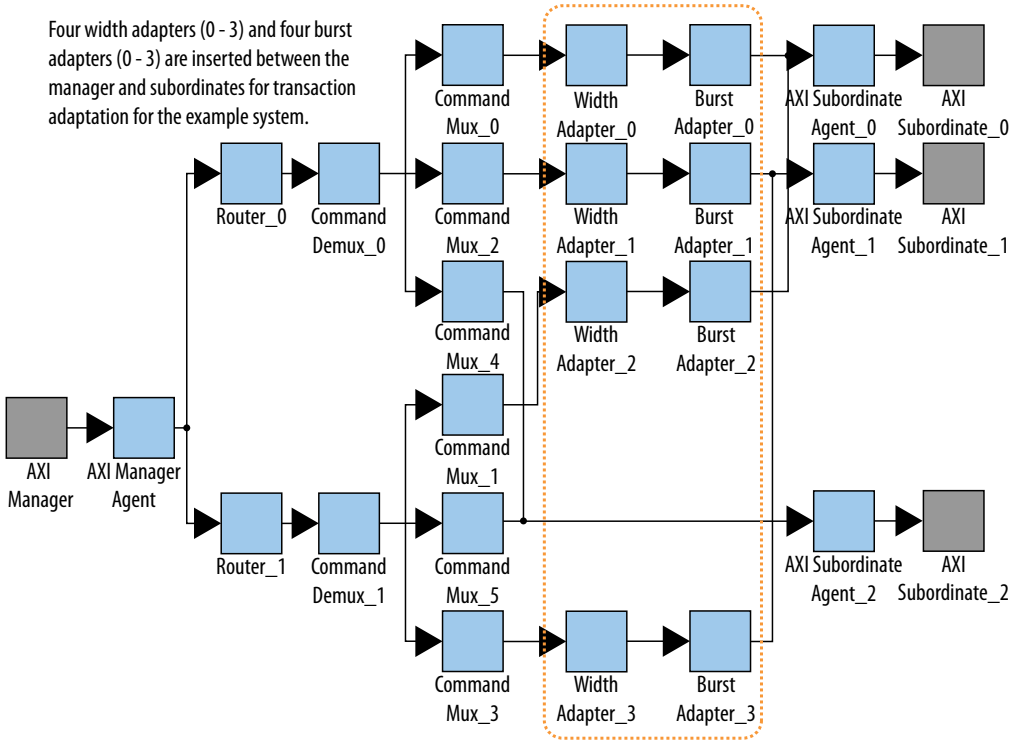
With an AXI bridge, you can influence the placement of resource-intensive components, such as the width and burst adapters. Depending on its use, an AXI bridge may reduce throughput and concurrency, in return for higher f_{MAX} and less logic.

You can use an AXI Bridge Intel FPGA IP to group different parts of your Platform Designer system. Other parts of the system can then connect to the bridge interface instead of to multiple separate manager or subordinate interfaces. You can also use an AXI bridge to export AXI interfaces from Platform Designer systems.

The AXI bridge also supports ACE-Lite interface signals when enabled on the manager or subordinate side. Platform Designer treats these ACE-Lite interface signals as pass through signals.

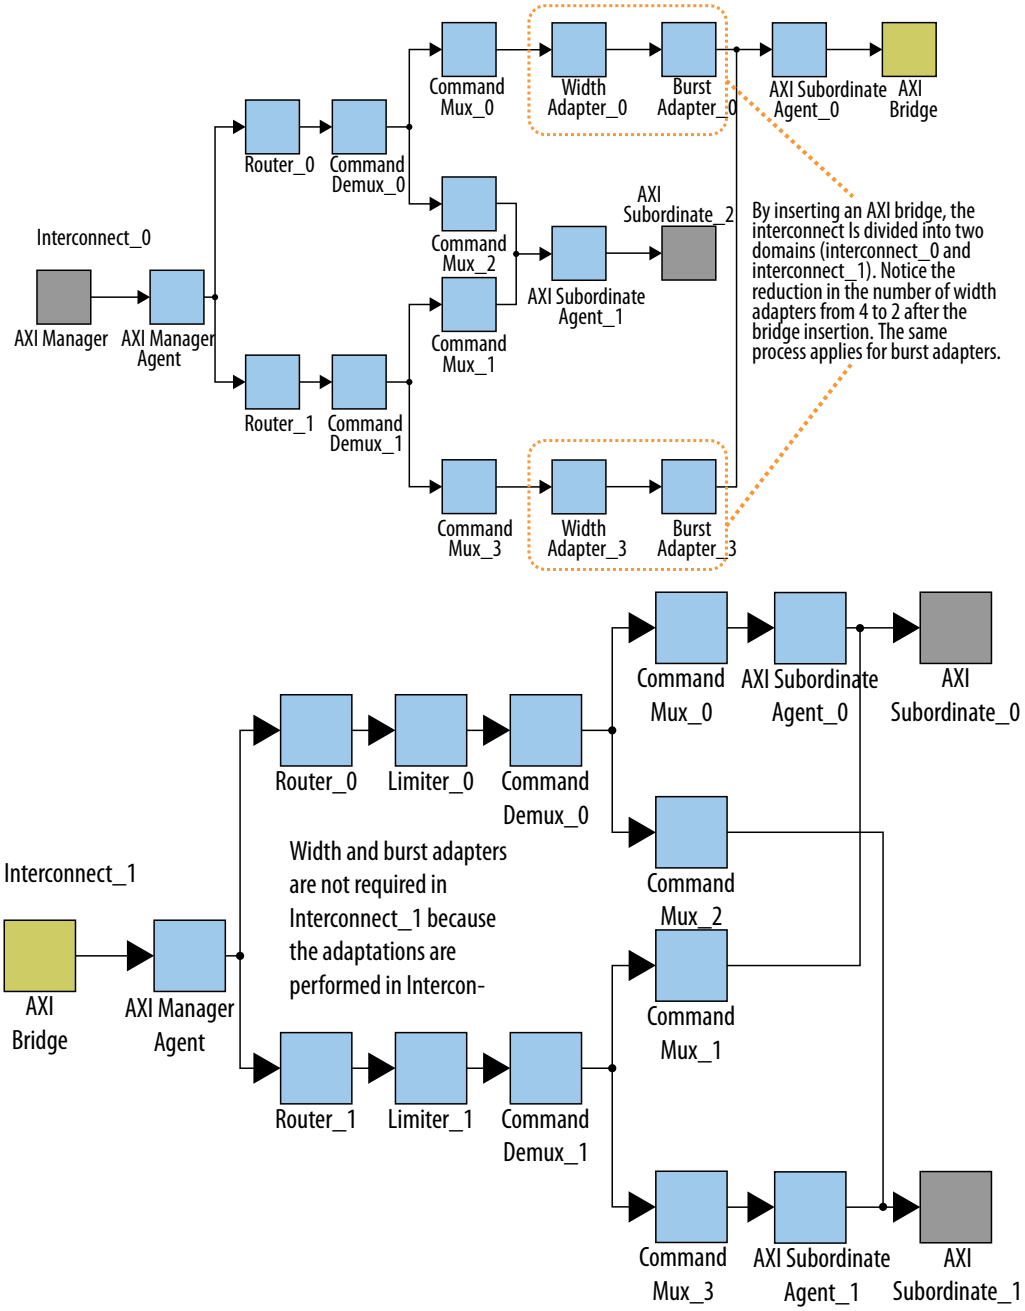
The following figure shows a system with a single AXI manager and three AXI subordinates. It also has various interconnect components, such as routers, demultiplexers, and multiplexers. Two of the subordinates have a narrower data width than the manager; 16-bit subordinates versus a 32-bit manager.

Figure 255. AXI System Without a Bridge



In this system, Platform Designer interconnect creates four width adapters and four burst adapters to access the two subordinates. You can improve resource usage by adding an AXI bridge. Then, Platform Designer needs to add only two width adapters and two burst adapters; one pair for the read channels, and another pair for the write channel.

Figure 256. Width and Burst Adapters Added to System With a Bridge



The figure shows the same system with an AXI bridge component, and the decrease in the number of width and burst adapters. Platform Designer creates only two width adapters and two burst adapters, as compared to the four width adapters and four burst adapters in the previous figure. Even though this system includes more components, the overall system performance improves because there are fewer resource-intensive width and burst adapters.

6.1.6.1. AXI Bridge Signal Types

Based on parameter selections that you make for the AXI Bridge component, Platform Designer instantiates either the AMBA 3 AXI or AMBA 4 AXI manager and subordinate interfaces into the component.

Note: In AMBA 3 AXI, `aw/aruser` accommodates sideband signal usage by hard processor systems (HPS).

Table 124. Sets of Signals for the AXI Bridge Based on the Protocol

Signal Name	AMBA 3 AXI	AMBA 4 AXI
awid / arid	yes	yes
awaddr / araddr	yes	yes
awlen / arlen	yes (4-bit)	yes (8-bit)
awsize / arsize	yes	yes
awburst / arburst	yes	yes
awlock / arlock	yes	yes (1-bit optional)
awcache / arcache	yes (2-bit)	yes (optional)
awprot / arprot	yes	yes
awuser / aruser	yes	yes
awvalid / arvalid	yes	yes
awready / arready	yes	yes
awqos / arqos	no	yes
awregion / arregion	no	yes
wid	yes	no (optional)
wdata / rdata	yes	yes
wstrb	yes	yes
wlast / rvalid	yes	yes
wvalid / rlast	yes	yes
wready / rready	yes	yes
wuser / ruser	no	yes
bid / rid	yes	yes
bresp / rresp	yes	yes (optional)
bvalid	yes	yes
bready	yes	yes

6.1.6.2. AXI Bridge Parameters

In the parameter editor, you can customize the parameters for the AXI bridge according to the requirements of your design.

Figure 257. AXI Bridge Parameter Editor

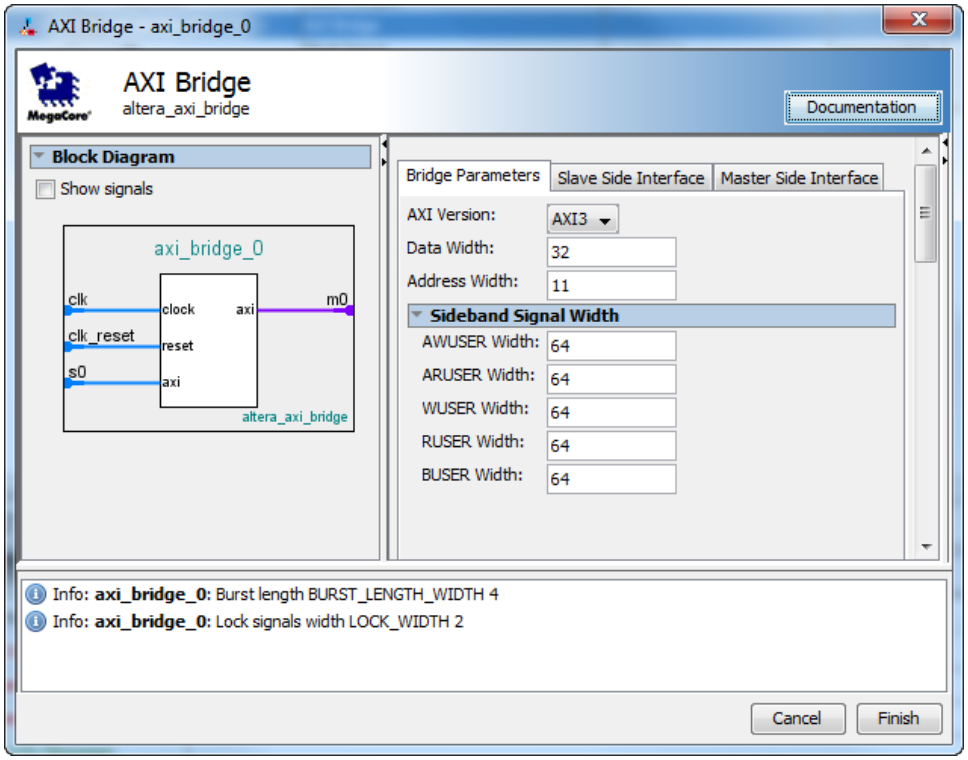


Table 125. AXI Bridge Parameters

Parameter	Type	Range	Description
AXI Version	string	AMBA 3 AXI or AMBA 4 AXI	Specifies the AXI version and signals that Platform Designer generates for the subordinate and manager interfaces of the bridge.
Data Width	integer	8:1024	Controls the width of the data for the manager and subordinate interfaces.
Address Width	integer	1-64 bits	Controls the width of the address for the manager and subordinate interfaces.
AWUSER Width	integer	1-64 bits	Controls the width of the write address channel sideband signals of the manager and subordinate interfaces.
ARUSER Width	integer	1-64 bits	Controls the width of the read address channel sideband signals of the manager and subordinate interfaces.
WUSER Width	integer	1-64 bits	Controls the width of the write data channel sideband signals of the manager and subordinate interfaces.
RUSER Width	integer	1-16 bits	Controls the width of the read data channel sideband signals of the manager and subordinate interfaces.
BUSER Width	integer	1-16 bits	Controls the width of the write response channel sideband signals of the manager and subordinate interfaces.

6.1.6.3. AXI Bridge Subordinate and Manager Interface Parameters

Table 126. AXI Bridge Subordinate and Manager Interface Parameters

Parameter	Description
ID Width	Controls the width of the thread ID of the manager and subordinate interfaces.
Write/Read/Combined Acceptance Capability	Controls the depth of the FIFO that Platform Designer needs in the interconnect agents based on the maximum pending commands that the subordinate interface accepts.
Write/Read/Combined Issuing Capability	Controls the depth of the FIFO that Platform Designer needs in the interconnect agents based on the maximum pending commands that the manager interface issues. Issuing capability must follow acceptance capability to avoid unnecessary creation of FIFOs in the bridge.

Note: Maximum acceptance/issuing capability is a model-only parameter and does not influence the bridge HDL. The bridge does not backpressure when this limit is reached. Downstream components or the interconnect must apply backpressure.

6.1.7. AXI Timeout Bridge Intel FPGA IP

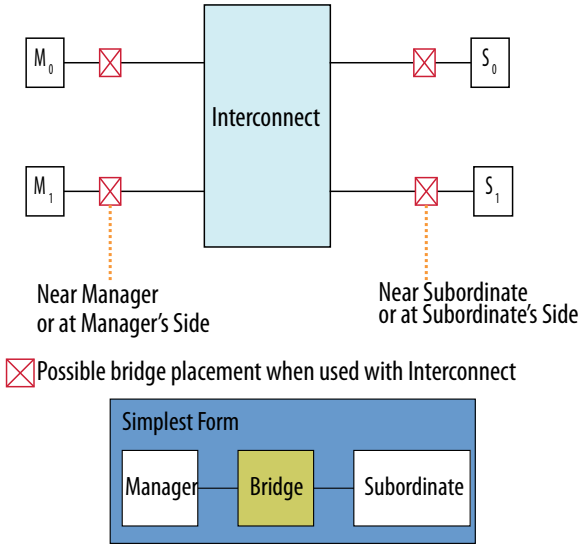
The AXI Timeout Bridge Intel FPGA IP allows your system to recover when it freezes, and facilitates debugging. You can place an AXI Timeout Bridge between a single manager and a single subordinate if you know that the subordinate may time out and cause your system to freeze. If a subordinate does not accept a command or respond to a command it accepted, its manager can wait indefinitely.

For a domain with multiple managers and subordinates, placement of an AXI Timeout Bridge in your design may be beneficial in the following scenarios:

- To recover from a freeze, place the bridge near the subordinate. If the manager attempts to communicate with a subordinate that freezes, the AXI Timeout Bridge frees the manager by generating error responses. The manager is then able to communicate with another subordinate.
- When debugging your system, place the AXI Timeout Bridge near the manager. This placement enables you to identify the origin of the burst, and to obtain the full address from the manager. Additionally, placing an AXI Timeout Bridge near the manager enables you to identify the target subordinate for the burst.

  Note: If you place the bridge at the subordinate's side and you have multiple subordinates connected to the same manager, you do not get the full address.

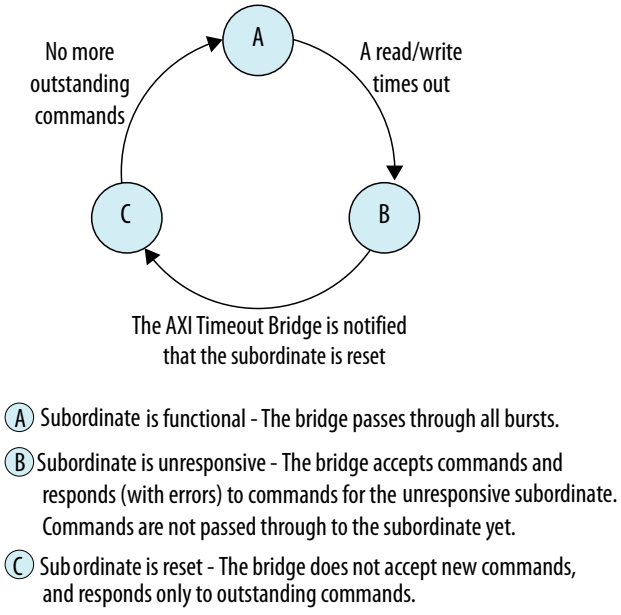
Figure 258. AXI Timeout Bridge Placement



6.1.7.1. AXI Timeout Bridge Stages

A timeout occurs when the internal timer in the bridge exceeds the specified number of cycles within which a burst must complete from start to end.

Figure 259. AXI Timeout Bridge Stages



- When a timeout occurs, the AXI Timeout Bridge asserts an interrupt and reports the burst that caused the timeout to the Configuration and Status Register (CSR).
- The bridge then generates error responses back to the manager on behalf of the unresponsive subordinate. This stage frees the manager and certifies the unresponsive subordinate as dysfunctional.
- The AXI Timeout Bridge accepts subsequent write addresses, write data, and read addresses to the dysfunctional subordinate. The bridge does not accept outstanding write responses, and read data from the dysfunctional subordinate is not passed through to the manager.
- The `awvalid`, `wvalid`, `bready`, `arvalid`, and `rready` ports are held low at the manager interface of the bridge.

Note: After a timeout, `awvalid`, `wvalid`, and `arvalid` may be dropped before they are accepted by `awready` at the manager interface. While the behavior violates the AXI specification, it occurs only on an interface connected to the subordinate which has been certified dysfunctional by the AXI Timeout Bridge.

Write channel refers to the AXI write address, data and response channels. Similarly, read channel refers to the AXI read address and data channels. AXI write and read channels are independent of each other. However, when a timeout occurs on either channel, the bridge generates error responses on both channels.

Table 127. Burst Start and End Definitions for the AXI Timeout Bridge

Channel	Start	End
Write	When an address is issued. First cycle of `awvalid`, even if data of the same burst is issued before the address (first cycle of `wvalid`).	When the response is issued. First cycle of `bvalid`.
Read	When an address is issued. First cycle of `arvalid`.	When the last data is issued. First cycle of `rvalid` and `rlast`.

The AXI Timeout Bridge has four required interfaces: manager, subordinate, Configuration and Status Register (CSR) (AMBA 3 AXI-Lite), and Interrupt. Platform Designer allows the AXI Timeout Bridge to connect to any AMBA 3 AXI, AMBA 4 AXI, or Avalon host or agent interface. Avalon hosts must utilize the bridge's interrupt output to detect a timeout.

The bridge subordinate interface accepts write addresses, write data, and read addresses, and then generates the SLVERR response at the write response and read data channels. Do not use `buser`, `rdata`, and `ruser` at this stage of processing.

To resume normal operation, the dysfunctional subordinate must be reset and the bridge notified of the change in status via the CSR. Once the CSR notifies the bridge that the subordinate is ready, the bridge does not accept new commands until all outstanding bursts are responded to with an error response.

The CSR has a 4-bit address width and a 32-bit data width. The CSR reports status and address information when the bridge asserts an interrupt.

Table 128. CSR Interrupt Status Information for the AXI Timeout Bridge

Address	Attribute	Name	Description	
0x0	write-only	Subordinate is reset	Write a 1 to this address to notify the AXI timeout bridge that the subordinate is reset and is ready. This also clears the interrupt.	
0x4	read-only	Timed out operation	Legacy behavior=1	The operation of the burst that causes the timeout: • 01: write operation • 00: read operation
			Legacy behavior=0	CSR Values: • 00: No timeout occurs • 10: Read operation causes timeout • 11: Write operation causes timeout
0x8 through 0xF	read-only	Timed out address	The address of the burst that causes the timeout. Note: If you use an ADDRESS_WIDTH of more than 32 bits, two CSR reads (from addresses 0x8 and 0xc) are required to get the complete address, given that the data width of the CSR interface is only 32 bits wide.	

6.1.7.2. AXI Timeout Bridge Parameters

Table 129. AXI Timeout Bridge Parameters

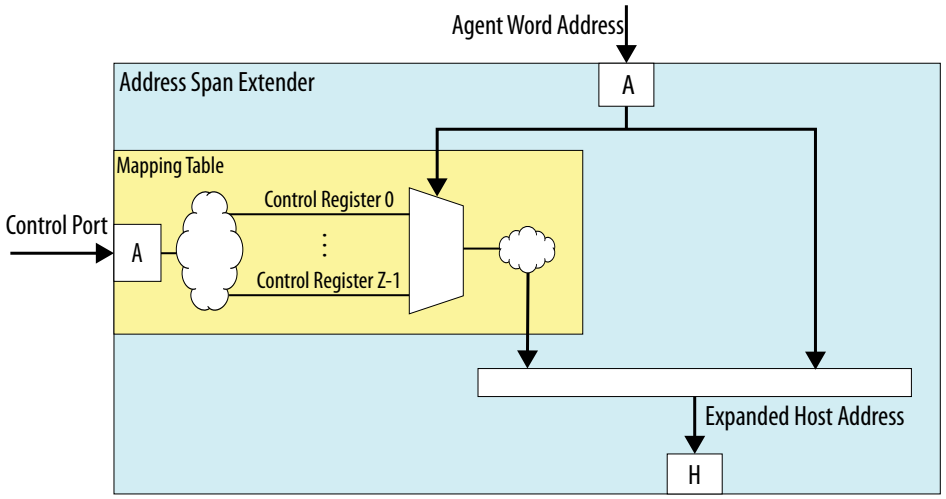
Parameter	Description
ID width	The width of awid, bid, arid, or rid.
Address width	The width of awaddr or araddr.
Data width	The width of wdata or rdata.
User width	The width of awuser, wuser, buser, aruser, or ruser.
Maximum number of outstanding writes	The expected maximum number of outstanding writes.
Maximum number of outstanding reads	The expected maximum number of outstanding reads.
Maximum number of cycles	The number of cycles within which a burst must complete.
Use synchronous resets	When this option is off (default), the IP allows asynchronous resets. When this option is on, the IP uses internal reset synchronization and allows no asynchronous resets.
Use Legacy Behavior	When this option is off, the IP uses the new behavior of the CSR and allows asynchronous resets. When this option is on, the IP uses the legacy (previous) behavior of the CSR, and you cannot access the CSR except during a timeout. For a new instance of the IP, the default **Use Legacy Behavior** is OFF. If you update the old version of the IP, the default Legacy Behavior is ON as previous behavior.

6.1.8. Address Span Extender Intel FPGA IP

The Address Span Extender Intel FPGA IP allows memory-mapped host interfaces to access a larger or smaller address map than the width of their address signals allows. The Address Span Extender IP splits the addressable space into multiple separate windows, so that the host can access the appropriate part of the memory through the window.

The Address Span Extender does not limit host and agent widths to a 32-bit and 64-bit configuration. You can use the Address Span Extender with 1-64 bit address windows.

Figure 260. Address Span Extender Intel FPGA IP



If a processor can address only 2 GB of an address span, and your system contains 4 GB of memory, the Address Span Extender can provide two, 2 GB windows in the 4 GB memory address space. This issue sometimes occurs with Intel SoC devices.

For example, an HPS subsystem in an SoC device can address only 1 GB of an address span within the FPGA, using the HPS-to-FPGA bridge. The Address Span Extender enables the SoC device to address all the address space in the FPGA using multiple 1 GB windows.

6.1.8.1. CTRL Register Layout

The control registers consist of one 64-bit register for each window, where you specify the window's base address. For example, if CTRL_BASE is the base address of the control register, and address span extender contains two windows (0 and 1), then window 0's control register starts at CTRL_BASE, and window 1's control register starts at CTRL_BASE + 8 (using byte addresses).

6.1.8.2. Address Span Extender Parameters

Table 130. Address Span Extender Parameters

Parameter	Description
Datapath Width	Width of write data and read data signals.
Expanded Master Byte Address Width	Width of the host byte address port. That is, the address span size of all the downstream agents that attach to the address span extender.
Slave Word Address Width	Width of the agent word address port. That is, the address span size of the downstream agents that the upstream host accesses.
Burstcount Width	Burst count port width of the downstream agent and the upstream host that attach to the address span extender.

continued...

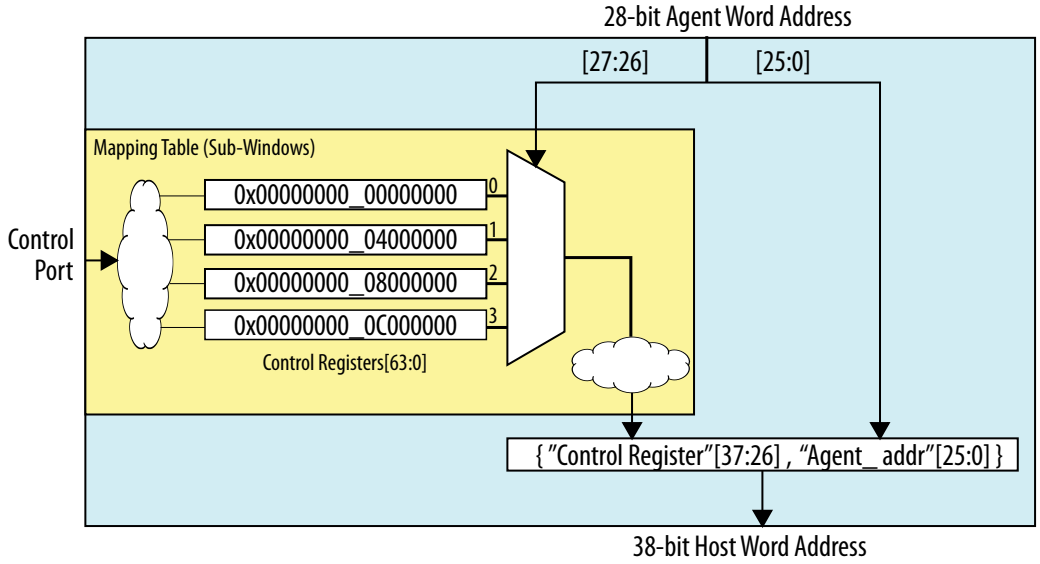
Parameter	Description
Number of sub-windows	The agent port can represent one or more windows in the host address span. You can subdivide the agent address span into *N* equal spans in *N* sub-windows. A remapping register in the CSR agent represents each sub-window, and configures the base address that each sub-window remaps to. The address span extender replaces the upper bits of the address with the stored index value in the remapping register before the host initiates a transaction.
Enable Slave Control Port	Dictates run-time control over the sub-window indexes. If you can define static re-mappings that do not need any change, you do not need to enable this CSR agent.
Maximum Pending Reads	Sets the bridge agent's `maximumPendingReadTransactions` property. In certain system configurations, you must increase this value to improve performance. This value usually aligns with the properties of the downstream agents that you attach to this bridge.

6.1.8.3. Calculating the Address Span Extender Agent Address

The diagram describes how Platform Designer calculates the agent address. In this example, the address span extender is configured with a 28-bit address space for agents. The upper 2 bits `[27:26]` are used to select the control registers.

The lower 26 bits (`[25:0]`) originate from the address span extender's data port, and are the offset into a particular window.

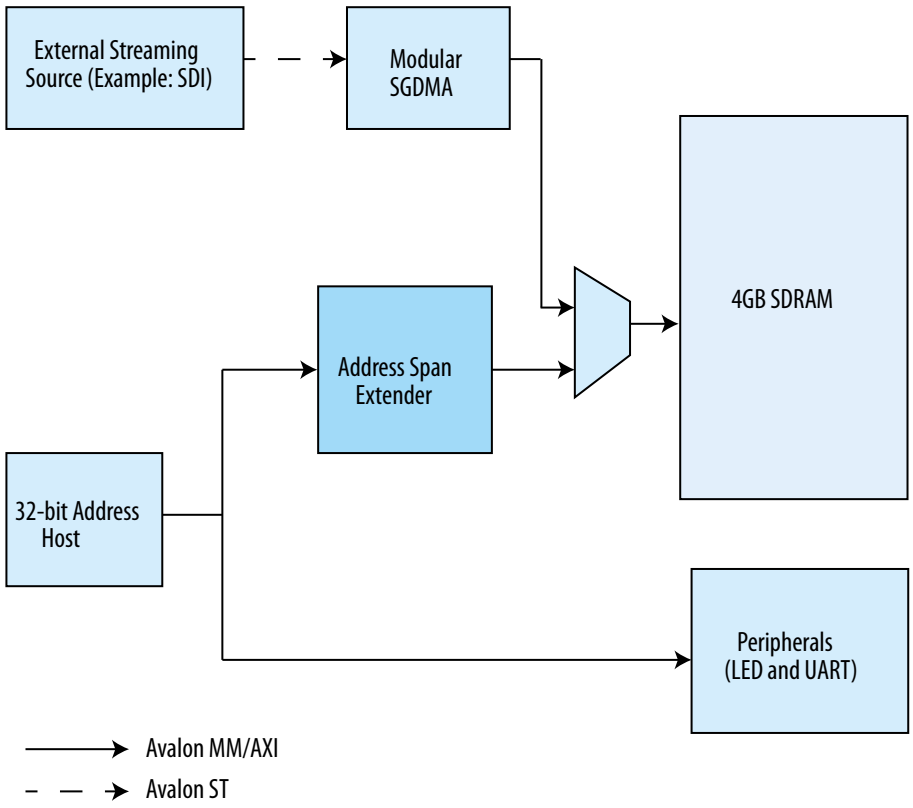
Figure 261. Address Span Extender



6.1.8.4. Using the Address Span Extender

This example shows when and how to use address span extender component in your Platform Designer design.

Figure 262. Block Diagram with Address Span Extender



In the above design, a 32-bit host shares 4 GB SDRAM with an external streaming interface. The host has the path to access streaming data from the SDRAM DDR memory. However, if you connect the whole 32-bit address bus of the host to the SDRAM DDR memory, you cannot connect the host to peripherals such as LED or UART. To avoid this situation, you can implement the address span extender between the host and DDR memory. The address span extender allows the host to access the SDRAM DDR memory and the peripherals at the same time.

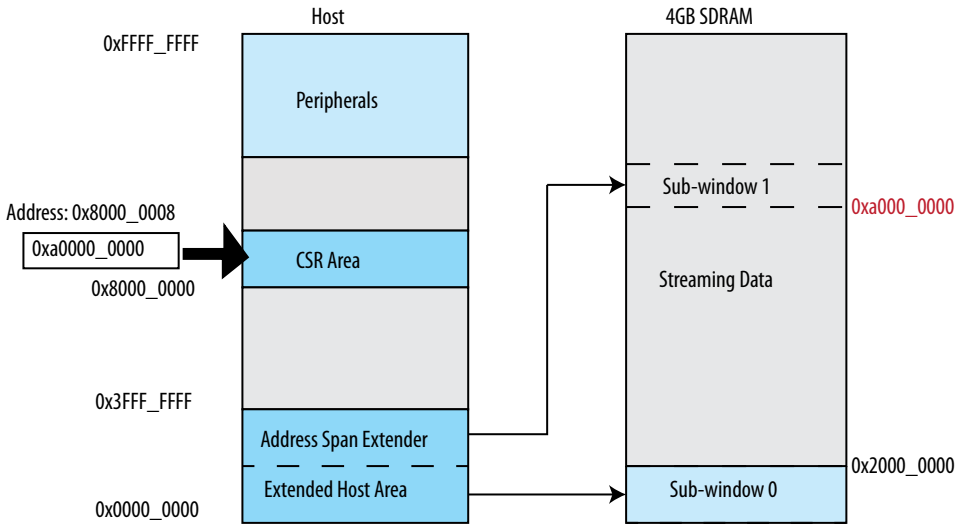
To implement address span extender for the above example, you can divide the address window of the address span extender into two sub-windows of 512 MB each. The sub-window 0 is for the host program area. You can dynamically map the sub-window 1 to any area other than the program area.

You can change the offset of the address window by setting the base address of sub-window 1 to the control register of the address span extender. However, you must make sure that the sub-window address span masks the base address. You can choose any arbitrary base address. If you set the value 0xa000_0000 to the control register, Platform Designer maps the sub-window 1 to 0xa000_0000.

Table 131. CSR Mapping Table

Address	Data
0x8000_0000	0x0000_0000
0x8000_0008	0xa000_0000

Figure 263. Memory mapping for Address Span Extender

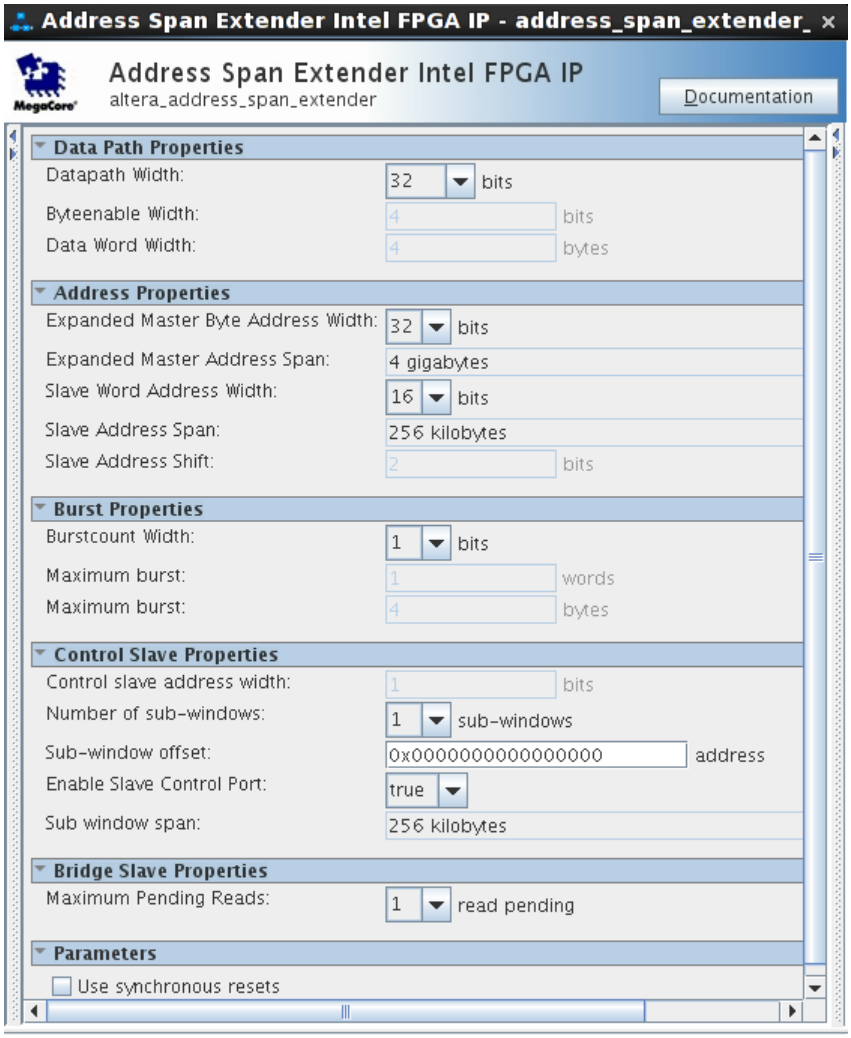


The table below indicates the Platform Designer parameter settings for this address span extender example.

Table 132. Parameter Settings for the Address Span Extender Example

Parameter	Value	Description
Datapath Width	32 bits	The CPU has 32-bits data width and the SDRAM DDR memory has 512-bits data width. Since the transaction between the host and SDRAM DDR memory is minimal, set the datapath width to align with the upstream host.
Expanded Master Byte Address	32 bits	The address span extender has a 4 GB address span.
Slave Word Address Width	18 bits	There are two 512 MB sub-windows in reserve for the host. The number of bytes over the data word width in the **Datapath Properties** (4 bytes for this example) accounts for the agent address.
Burstcount Width	4 bits	The address span extender must handle up to 8 words burst in this example.
Number of sub-windows	2	Address window of the address span extender has two sub-windows of 512 MB each.
Enable Slave Control Port	true	The address span extender component must have control to change the base address of the sub-window.
Maximum Pending Reads	4	This number is the same as SDRAM DDR memory burst count.

Figure 264. Address Span Extender Parameter Editor



Note: You can view the address span extender connections in the **System View** tab. The windowed agent port and control port connect to the host. The expanded host port connects to the SDRAM DDR memory.

6.1.8.5. Alternate Options for the Address Span Extender

You can set parameters for the address span extender with an initial fixed address value. Enter an address for the **Reset Default for Master Window** option, and select **True** for the **Disable Slave Control Port** option. This allows the address span extender to function as a fixed, non-programmable component.

Each sub-window is equal in size and stacks sequentially in the windowed agent interface's address space. To control the fixed address bits of a particular sub-window, you can write to the sub-window's register in the register control agent interface. Platform Designer structures the logic so that Platform Designer can optimize and remove bits that are not needed.

If **Burstcount Width** is greater than 1, Platform Designer processes the read burst in a single cycle, and assumes all `byteenable` signals are asserted on every cycle.

6.1.8.6. Nios II Support

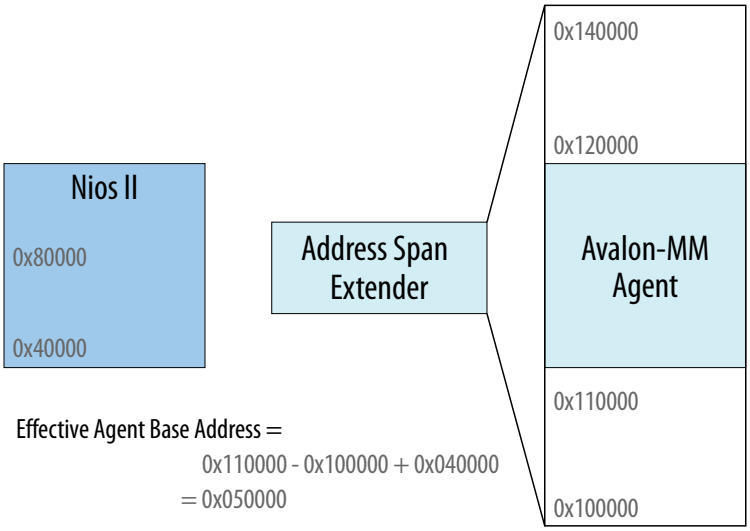
If the address span extender window is fixed, for example, the **Disable Slave Control Port** option is turned on, then the address span extender performs as a bridge. Components on the agent side of the address span extender that are within the window are visible to the Nios II processor. Components partially within a window appear to the Nios II processor as if they have a reduced span. For example, a memory partially within a window appears as having a smaller size.

You can also use the address span extender to provide a window for the Nios II processor, so that the HPS memory map is visible to the Nios II processor. This technique allows the Nios II processor to communicate with HPS peripherals.

In the example, a Nios II processor has an address span extender from address `0x40000` to `0x80000`. There is a window within the address span extender starting at `0x100000`. Within the address span extender's address space there is an agent at base address `0x1100000`. The agent appears to the Nios II processor as being at address:

```
0x110000 - 0x100000 + 0x40000 = 0x050000
```

Figure 265. Nios II Support and the Address Span Extender



The address span extender window is dynamic. For example, when the **Disable Slave Control Port** option is turned off, the Nios II processor is unable to see components on the agent side of the address span extender.

6.2. Error Response Slave Intel FPGA IP

The Error Response Slave IP provides a predictable error response service for host interfaces that attempt to access an undefined memory region.

The Error Response Slave is an AMBA 3 AXI component, and appears in the Platform Designer IP Catalog under **Platform Designer Interconnect**.

To comply with the AXI protocol, the interconnect logic must return the DECERR error response in cases where the interconnect cannot decode subordinate access. Therefore, an AXI system with address space not fully decoded to subordinate interfaces requires the Error Response Slave.(25)

The Error Response Slave behaves like any other component in the system, and connects to other components via translation and adaptation interconnect logic. Connecting an Error Response Slave to managers or hosts of different data widths, including Avalon hosts or AXI-Lite managers, can increase resource usage.

An Error Response Slave can connect to clock, reset, and IRQ signals as well as AMBA 3 AXI and AMBA 4 AXI manager interfaces without instantiating a bridge. When you connect an Error Response Slave to a manager or host, the Error Response Slave accepts cycles sent from the manager or host, and returns the DECERR error response. On the AXI interface, the Error Response Slave supports only a read and write acceptance of capability 1, and does not support write data interleaving. The Error Response Slave can return responses when simultaneously targeted by a read and write cycle, because its read and write channels are independent.

An optional Avalon interface on the Error Response Slave provides information in a set of CSR registers. CSR registers log the required information when returning an error response.

- To set the Error Response Slave as the default subordinate or agent for a manager or host interface in your system, connect the subordinate to the manager or connect the agent to the host in your Platform Designer system.
- A system can contain more than one Error Response Slave.
- As a best practice, instantiate separate Error Response Slave components for each AXI manager in your system.

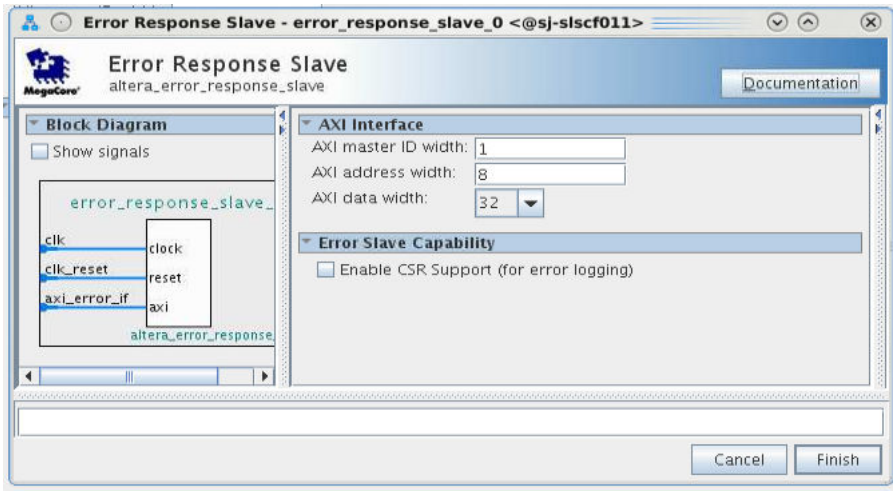
Related Information

- AMBA 3 AXI Protocol Specification Support (version 1.0) on page 332
- Designating a Default Agent on page 396

(25) This document now refers to the AXI "manager" and "subordinate" to replace the former terms. Refer to the latest *AMBA AXI and ACE Protocol Specification*.

6.2.1. Error Response Slave Parameters

Figure 266. Error Response Slave Parameter Editor



If you turn on **Enable CSR Support (for error logging)** more parameters become available.

Figure 267. Error Response Slave Parameter Editor with Enabled CSR Support

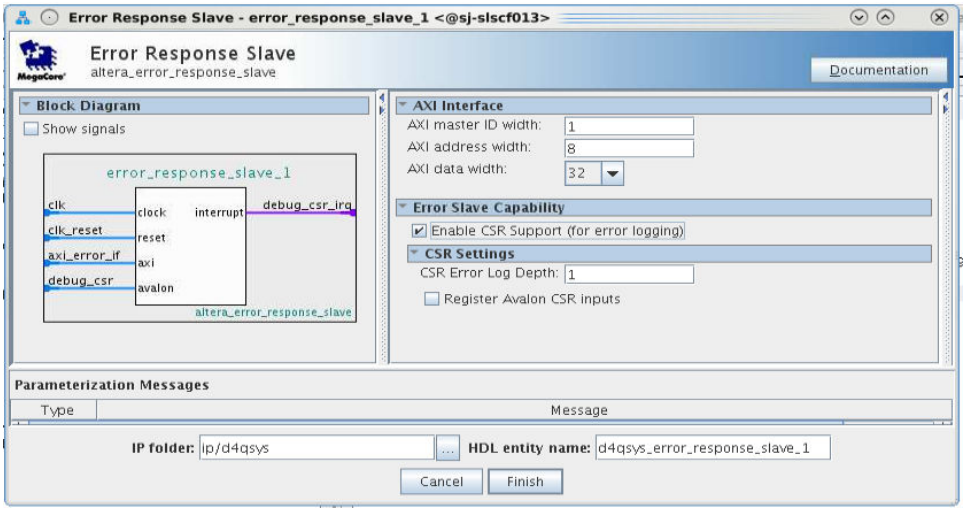


Table 133. Error Response Slave Parameters

Parameter	Value	Description
AXI master ID width	1-8 bits	Specifies the manager ID width for error logging.
AXI address width	8-64 bits	Specifies the address width for error logging. This value also affects the overall address width of the system, and should not exceed the maximum address width required in the system.

continued...

Parameter	Value	Description
AXI data width	32, 64, or 128 bits	Specifies the data width for error logging.
Enable CSR Support (for error logging)	On / Off	When turned on, instantiates an Avalon CSR interface for error logging.
CSR Error Log Depth	1-16 bits	Depth of the transaction log, for example, the number of transactions the CSR logs for cycles with errors.
Register Avalon CSR inputs	On / Off	When turned on, controls debug access to the CSR interface.

6.2.2. Error Response Slave CSR Registers

The Error Response Slave with enabled CSR support provides a service to handle access violations. This service uses CSR registers for status and logging purposes.

The sequence of actions in the access violation service is equivalent for read and write access violations, but the CSR status bits and log registers are different.

6.2.2.1. Error Response Slave Access Violation Service

When an access violation occurs, and the CSR port is enabled:

1. The Error Response Slave generates an interrupt:
   - For a read access violation, the Error Response Slave sets the `Read Access Violation Interrupt register` bit in the `Interrupt Status` register.
   - For a write access violation, the Error Response Slave sets the `Write Access Violation Interrupt register` bit in the `Interrupt Status` register.
2. The Error Response Slave transfers transaction information to the access violation log FIFO. The amount of information that the FIFO can handle is given by the **Error Log Depth** parameter.

   You define the **Error Log Depth** in the **Parameter Editor**, when you enable CSR Support.
3. Software reads entries of the access violation log FIFO until the corresponding `cycle log valid` bit is cleared, and then exits the service routine.
   - The `Read cycle log valid` bit is in the `Read Access Violation Log` CSR Registers.
   - The `Write cycle log valid` bit is in the `Write Access Violation Log` CSR Registers.
4. The Error Response Slave clears the interrupt bit when there are no access violations to report.

Some special cases are:

- If any error occurs when the FIFO is full, the Error Response Slave sets the corresponding `Access Violation Interrupt Overflow register` bit (bits 2 and 3 of the Status Register for write and read access violations, respectively). Setting this bit means that not all error entries were written to the access violation log.
- After Software reads an entry in the Access Violation log, the Error Response Slave can write a new entry to the log.
- Software can specify the number of entries to read before determining that the access violation service is taking too long to complete, and exit the routine.

6.2.2.2. CSR Interrupt Status Registers

Table 134. CSR Interrupt Status Registers

For CSR register maps: `Address = Memory Address Base + Offset`.

Offset	Bits	Attribute	Default	Description
0x00	31:4	Reserved.		
	3	RW1C	0	`Read Access Violation Interrupt Overflow register` Asserted when a read access causes the Interconnect to return a DECERR response, and the buffer log depth is full. Indicates that there is a logging error lost due to an exceeded buffer log depth. Cleared by setting the bit to 1.
	2	RW1C	0	`Write Access Violation Interrupt Overflow register` Asserted when a write access causes the Interconnect to return a DECERR response, and the buffer log depth is full. Indicates that there is a logging error lost due to an exceeded buffer log depth. Cleared by setting the bit to 1.
	1	RW1C	0	`Read Access Violation Interrupt register` Asserted when a read access causes the Interconnect to return a DECERR response. Cleared by setting the bit to 1. *Note:* Access violation are logged until the bit is cleared.
	0	RW1C	0	`Write Access Violation Interrupt register` Asserted when a write access causes the Interconnect to return a DECERR response. Cleared by setting the bit to 1. *Note:* Access violation are logged until the bit is cleared.

6.2.2.3. CSR Read Access Violation Log Registers

The CSR read access violation log settings are valid only when an associated read interrupt register is set. Read this set of registers until the validity bit is cleared.

Table 135. CSR Read Access Violation Log Registers

Offset	Bits	Attribute	Default	Description
0x100	31:13	Reserved.		
	12:11	R0	0	`Offending Read cycle burst type`: Specifies the burst type of the initiating cycle that causes the access violation.
	10:7	R0	0	`Offending Read cycle burst length`: Specifies the burst length of the initiating cycle that causes the access violation.
	6:4	R0	0	`Offending Read cycle burst size`: Specifies the burst size of the initiating cycle that causes the access violation.

continued...

Offset	Bits	Attribute	Default	Description
	3:1	R0	0	Offending Read cycle PROT: Specifies the PROT of the initiating cycle that causes the access violation.
	0	R0	0	Read cycle log valid: Specifies the validity of the read access violation log. This bit is cleared when the interrupt register is cleared.
0x104	31:0	R0	0	Offending read cycle ID: Manager ID for the cycle that causes the access violation.
0x108	31:0	R0	0	Offending read cycle target address: Target address for the cycle that causes the access violation (lower 32-bit).
0x10C	31:0	R0	0	Offending read cycle target address: Target address for the cycle that causes the access violation (upper 32-bit). Valid only if widest address in system is larger than 32 bits. *Note:* When this register is read, the current read access violation log is recovered from FIFO.

6.2.2.4. CSR Write Access Violation Log Registers

The CSR write access violation log settings are valid only when an associated write interrupt register is set. Read this set of registers until the validity bit is cleared.

Table 136. CSR Write Access Violation Log

Offset	Bits	Attribute	Default	Description
0x190	31:13	Reserved.		
	12:11	R0	0	Offending write cycle burst type: Specifies the burst type of the initiating cycle that causes the access violation.
	10:7	R0	0	Offending write cycle burst length: Specifies the burst length of the initiating cycle that causes the access violation.
	6:4	R0	0	Offending write cycle burst size: Specifies the burst size of the initiating cycle that causes the access violation.
	3:1	R0	0	Offending write cycle PROT: Specifies the PROT of the initiating cycle that causes the access violation.
	0	R0	0	Write cycle log valid: Specifies whether the log for the transaction is valid. This bit is cleared when the interrupt register is cleared.
0x194	31:0	R0	0	Offending write cycle ID: Manager ID for the cycle that causes the access violation.
0x198	31:0	R0	0	Offending write cycle target address: Write target address for the cycle that causes the access violation (lower 32-bit).
0x19C	31:0	R0	0	Offending write cycle target address: Write target address for the cycle that causes the access violation (upper 32-bit). Valid only if widest address in system is larger than 32 bits.
0x1A0	31:0	R0	0	Offending write cycle first write data: First 32 bits of the write data for the write cycle that causes the access violation. *Note:* When this register is read, the current write access violation log is recovered from FIFO, when the data width is 32 bits.

continued...

Offset	Bits	Attribute	Default	Description
0x1A4	31:0	R0	0	Offending write cycle first write data: Bits [63:32] of the write data for the write cycle that causes the access violation. Valid only if the data width is greater than 32 bits.
0x1A8	31:0	R0	0	Offending write cycle first write data: Bits [95:64] of the write data for the write cycle that causes the access violation. Valid only if the data width is greater than 64 bits.
0x1AC	31:0	R0	0	Offending write cycle first write data: The first bits [127:96] of the write data for the write cycle that causes the access violation. Valid only if the data width is greater than 64 bits. *Note:* When this register is read, the current write access violation log is recovered from FIFO.

6.2.3. Designating a Default Agent

You can designate any agent in your Platform Designer system as the error response default agent. The default agent you designate provides an error response service for hosts that attempt access to an undefined memory region.

1. In your Platform Designer system, in the **System View** tab, right-click the header and turn on **Show Default Slave Column**.
2. Select the agent that you want to designate as the default agent, and then click the checkbox for the agent in the **Default Slave** column.
3. In the **System View** tab, in the **Connections** column, connect the designated default agent to one or more hosts.

   Note: If you do not specify a value for the **Default Slave** option, and the **Automate default slave insertion** option is off, Platform Designer automatically assigns the AXI subordinate or Avalon agent in the system. Platform Designer automatically assigns the AXI subordinate or Avalon agent that has largest address span within the memory map for the issuing AXI manager or Avalon host. In the case of multiple, large AXI subordinates or Avalon agents that have the same address span, Platform Designer selects the AXI subordinate or Avalon agent at the lowest base offset.

Related Information

Specifying a Default Avalon Agent or AXI Subordinate on page 80

6.3. Tri-State Components

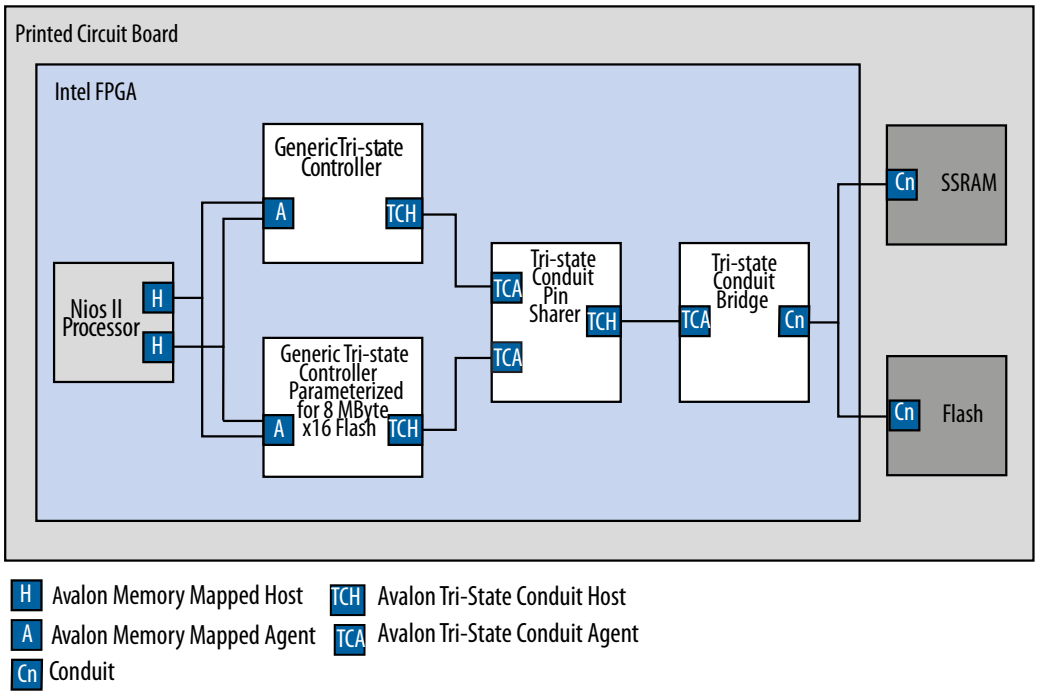
The tri-state interface type allows you to design Platform Designer subsystems that connect to tri-state devices on your PCB. You can use tri-state components to implement pin sharing, convert between unidirectional and bidirectional signals, and create tri-state controllers for devices whose interfaces can be described using the tri-state signal types.

Example 27. Tri-State Conduit System to Control Off-Chip SRAM and Flash Devices

In this example, there are two generic Tri-State Conduit Controllers. The first is customized to control a flash memory. The second is customized to control an off-chip SSRAM. The Tri-State Conduit Pin Sharer multiplexes between these two controllers, and the Tri-State Conduit Bridge converts between an on-chip encoding of tri-state

signals and true bidirectional signals. By default, the Tri-State Conduit Pin Sharer and Tri-State Conduit Bridge present byte addresses. Typically, each address location contains more than one byte of data.

Figure 268. Tri-State Conduit System to Control Off-Chip SRAM and Flash Devices

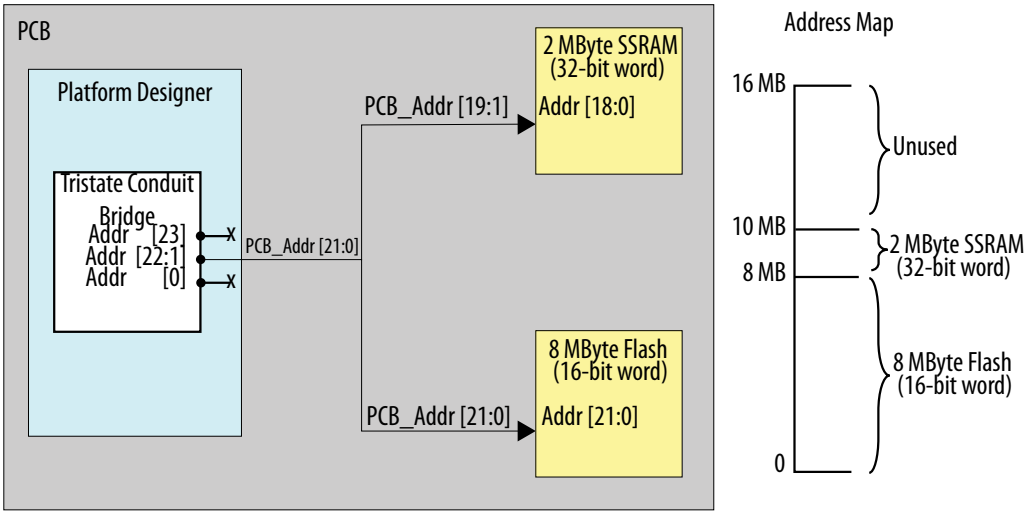


Address Connections from Platform Designer System to PCB

The flash device operates on 16-bit words and must ignore the least-significant bit of the Avalon memory mapped address. The figure shows `addr[0]`as not connected. The SSRAM memory operates on 32-bit words and must ignore the two low-order memory bits. Because neither device requires a byte address, `addr[0]` is not routed on the PCB.

The flash device responds to address range 0 MB to 8 MB-1. The SSRAM responds to address range 8 MB to 10 MB-1. The PCB schematic for the PCB connects `addr[21:0]` to `addr[18:0]` of the SSRAM device because the SSRAM responds to 32-bit word address. The 8 MB flash device accesses 16-bit words; consequently, the schematic does not connect `addr[0]`. The `chipselect` signals select between the two devices.

Figure 269. Address Connections from Platform Designer System to PCB



Note: If you create a custom tri-state conduit host with word aligned addresses, the Tri-state Conduit Pin Sharer does not change or align the address signals.

Figure 270. Tri-State Conduit System in Platform Designer

Avalon Interface Specifications

6.3.1. Generic Tri-State Controller Intel FPGA IP

The Generic Tri-State Controller Intel FPGA IP provides a template for a controller. You can customize the Generic Tri-State Controller with various parameters to reflect the behavior of an off-chip device. The following types of parameters are available for the Generic Tri-State Controller:

- Width of the address and data signals
- Read and write wait times
- Bus turnaround time
- Data hold time

Note: In calculating delays, the Generic Tri-State Controller chooses the larger of the bus turnaround time and read latency. Turnaround time is measured from the time that a command is accepted, not from the time that the previous read returned data.

The Generic Tri-State Controller includes the following interfaces:

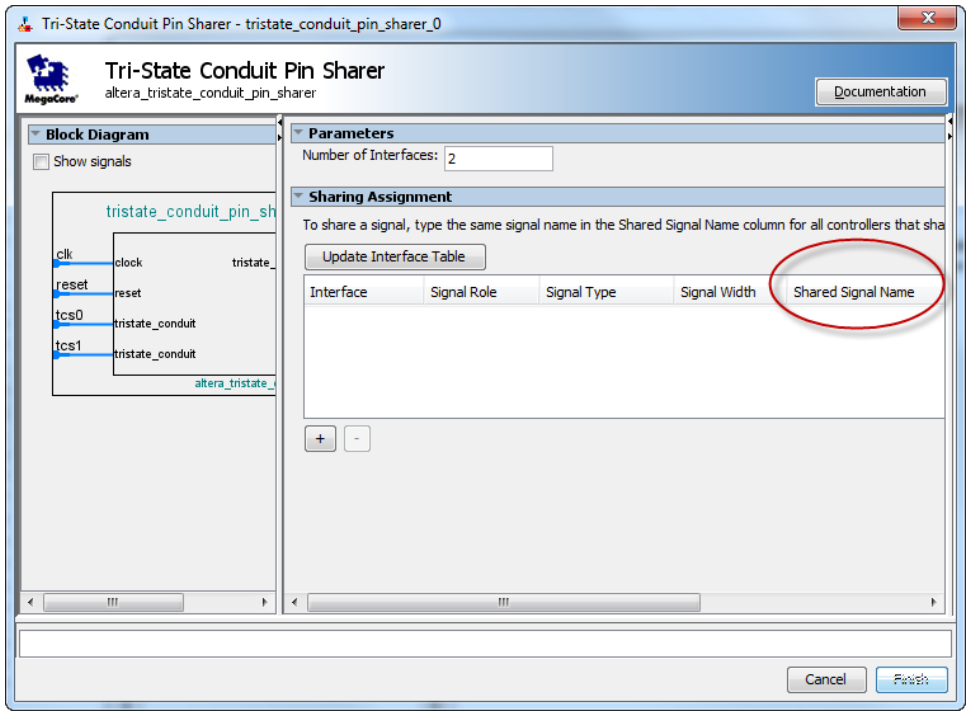
- **Memory-mapped agent interface**—This interface connects to a memory-mapped host, such as a processor.
- **Tristate Conduit Host interface**—The tri-state host interface usually connects to the tri-state conduit agent interface of the tri-state conduit pin sharer.
- **Clock sink**—The component's clock reference. You must connect this interface to a clock source.
- **Reset sink**—This interface connects to a reset source interface.

6.3.2. Tri-State Conduit Pin Sharer Intel FPGA IP

The Tri-State Conduit Pin Sharer Intel FPGA IP multiplexes between the signals of the connected tri-state controllers. You connect all signals from the tri-state controllers to the Tri-State Conduit Pin Sharer IP, and then use the parameter editor to specify the signals that are shared.

The parameter editor includes a **Shared Signal Name** column. If the widths of shared signals differ, the signals are aligned on their 0^{th} bit and the higher-order pins are driven to 0 whenever the smaller signal has control of the bus. Unshared signals always propagate through the pin sharer. The tri-state conduit pin sharer uses the round-robin arbiter to select between tri-state conduit controllers.

Figure 271. Tri-State Conduit Pin Sharer Parameter Editor



Note: All tri-state conduit components connected to a pin sharer must be in the same clock domain.

Related Information

Avalon Streaming Round Robin Scheduler Intel FPGA IP on page 423

6.3.3. Tri-State Conduit Bridge Intel FPGA IP

The Tri-State Conduit Bridge Intel FPGA IP instantiates bidirectional signals for each tri-state signal while passing all other signals straight through the component. The Tri-State Conduit Bridge registers all outgoing and incoming signals, which adds two cycles of latency for a read request. You must account for this additional pipelining when designing a custom controller. During reset, all outputs are placed in a high-impedance state. Outputs are enabled in the first clock cycle after reset is deasserted, and the output signals are then bidirectional.

6.4. Avalon Data Pattern Generator and Checker Intel FPGA IP

You can use the Avalon Data Pattern Generator IP to insert different error conditions, and then use the Avalon Data Pattern Checker IP to report these error conditions to the control interface, via an Avalon Memory-Mapped agent.

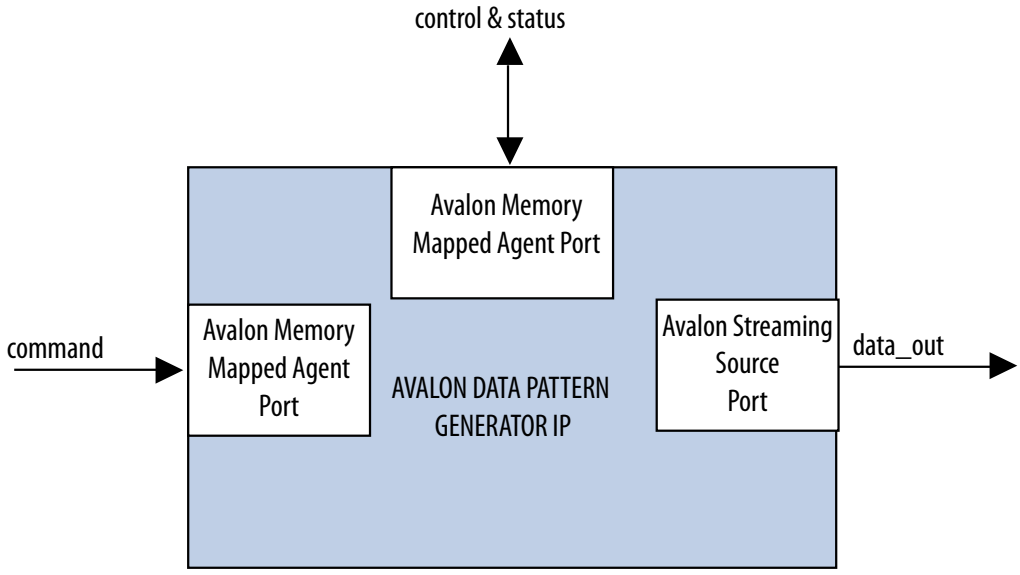
Similarly, for Avalon streaming interfaces, Avalon Data Pattern Generator IP generates data, and sends the data out on an Avalon streaming data interface. The Avalon Data Pattern Checker IP verifies the data. Optionally, you can format the data as packets, with accompanying `start_of_packet` and `end_of_packet` signals.

The **Throttle Seed** is the starting value for the throttle control random number generator. Intel recommends a unique value for each instance of the data pattern generator and checker IP cores in a system.

6.4.1. Avalon Data Pattern Generator Intel FPGA IP

The Avalon Data Pattern Generator IP accepts commands to generate data via an Avalon memory mapped command interface, and drives the generated data to an Avalon streaming data interface. You can parameterize most aspects of the Avalon streaming data interface, such as the number of error bits and data signal width, thus allowing you to test components with different interfaces.

Figure 272. Avalon Data Pattern Generator Intel FPGA IP



The data pattern is calculated as: *Symbol Value* = *Symbol Position in Packet* XOR *Data Error Mask*. Data that is not organized in packets is a single stream with no beginning or end. The Avalon Data Pattern Generator IP has a throttle register that is set via the Avalon memory mapped control interface. The Avalon Data Pattern Generator IP uses the value of the throttle register in conjunction with a pseudo-random number generator to throttle the data generation rate.

6.4.1.1. Avalon Data Pattern Generator IP Command Interface

The command interface for the Avalon Data Pattern Generator is a 32-bit Avalon memory mapped write agent that accepts data generation commands. It is connected to a 16-element deep FIFO, thus allowing a host peripheral to drive commands into the Avalon Data Pattern Generator IP.

The command interface maps to the following registers: `cmd_lo` and `cmd_hi`. The command is pushed into the FIFO when the register `cmd_lo` (address 0) is addressed. When the FIFO is full, the command interface asserts the `waitrequest` signal. You can create errors by writing to the register `cmd_hi` (address 1). The errors are cleared when 0 is written to this register, or its respective fields.

6.4.1.2. Avalon Data Pattern Generator IP Control and Status Interface

The control and status interface of the Avalon Data Pattern Generator IP is a 32-bit Avalon memory mapped agent that allows you to enable or disable the data generation, as well as set the throttle. This interface also provides generation-time information, such as the number of channels and whether data packets are supported.

6.4.1.3. Avalon Data Pattern Generator IP Output Interface

The output interface of the Avalon Data Pattern Generator IP is an Avalon streaming interface that optionally supports data packets. You can configure the output interface to align with your system requirements. Depending on the incoming stream of commands, the output data may contain interleaved packet fragments for different channels. To keep track of the current symbol's position within each packet, the Avalon Data Pattern Generator IP maintains an internal state for each channel.

You can configure the output interface of the Avalon Data Pattern Generator IP with the following parameters:

- **Number of Channels**—Number of channels that the Avalon Data Pattern Generator IP supports. Valid values are 1 to 256.
- **Data Bits Per Symbol**—Bits per symbol is related to the width of `readdata` and `writedata` signals, which must be a multiple of the bits per symbol.
- **Data Symbols Per Beat**—Number of symbols (words) that are transferred per beat. Valid values are 1 to 256.
- **Include Packet Support**—Indicates whether packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Error Signal Width (bits)**—Width of the error signal on the output interface. Valid values are 0 to 31. A value of `0` indicates that the error signal is not in use.

Note: If you change only bits per symbol, and do not change the data width, errors are generated.

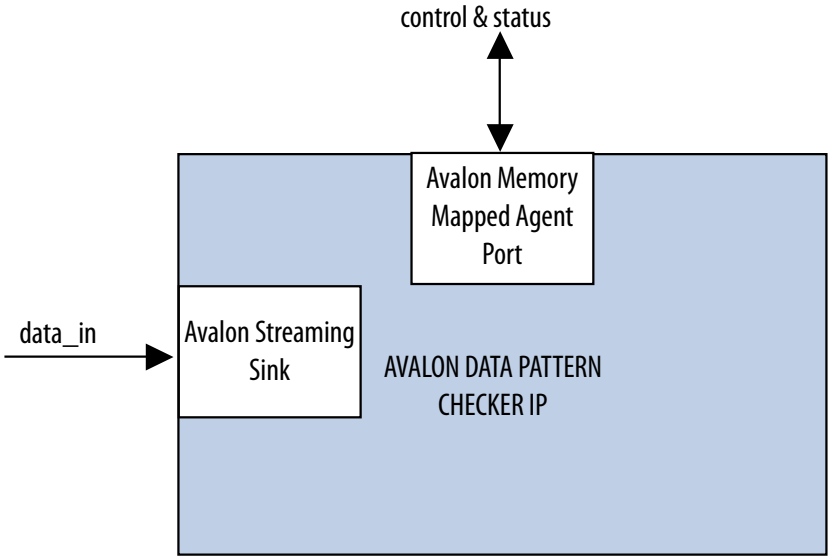
6.4.1.4. Avalon Data Pattern Generator IP Functional Parameter

The Avalon Data Pattern Generator IP functional parameter allows you to configure the Avalon Data Pattern Generator as an entire system.

6.4.2. Avalon Data Pattern Checker Intel FPGA IP

The Avalon Data Pattern Checker Intel FPGA IP accepts data via an Avalon streaming interface and verifies it against a predetermined pattern that the Avalon Data Pattern Generator Intel FPGA IP produces. The Avalon Data Pattern Checker IP reports any exceptions to the control interface. You can parameterize most aspects of the Avalon Data Pattern Checker's Avalon streaming interface, such as the number of error bits, and the data signal width. This IP allows you to test components with different interfaces. The Avalon Data Pattern Checker IP has a throttle register that is set via the Avalon memory mapped control interface. The value of the throttle register controls the rate at which data is accepted.

Figure 273. Avalon Data Pattern Checker Intel FPGA IP



The Avalon Data Pattern Checker IP detects exceptions and reports them to the control interface via a 32-element deep internal FIFO. Possible exceptions are data error, missing start-of-packet (SOP), missing end-of-packet (EOP), and signaled error.

As each exception occurs, an exception descriptor is pushed into the FIFO. If the same exception occurs more than once consecutively, only one exception descriptor is pushed into the FIFO. All exceptions are ignored when the FIFO is full. Exception descriptors are deleted from the FIFO after they are read by the control and status interface.

6.4.2.1. Avalon Data Pattern Checker IP Input Interface

The Avalon Data Pattern Checker IP input interface is an Avalon streaming interface that optionally supports data packets. You can configure the input interface to align with your system requirements. Incoming data may contain interleaved packet fragments. To keep track of the current symbol’s position, the test pattern checker maintains an internal state for each channel.

6.4.2.2. Avalon Data Pattern Checker IP Control and Status Interface

The Avalon Data Pattern Checker IP control and status interface is a 32-bit Avalon memory mapped agent that allows you to enable or disable data acceptance, as well as set the throttle. This interface provides generation-time information, such as the number of channels and whether the Avalon Data Pattern Checker supports data packets. The control and status interface also provides information on the exceptions detected by the Avalon Data Pattern Checker IP. The interface obtains this information by reading from the exception FIFO.

6.4.2.3. Avalon Data Pattern Checker IP Functional Parameter

The Avalon Data Pattern Checker IP functional parameter allows you to configure the Avalon Data Pattern Checker IP as a whole system.

6.4.2.4. Avalon Data Pattern Checker Input Parameters

You can configure the input interface of the Avalon Data Pattern Checker IP using the following parameters:

- **Data Bits Per Symbol**—Bits per symbol is related to the width of `readdata` and `writedata` signals, which must be a multiple of the bits per symbol.
- **Data Symbols Per Beat**—Number of symbols (words) that are transferred per beat. Valid values are 1 to 32.
- **Include Packet Support**—Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Number of Channels**—Number of channels that the test pattern checker supports. Valid values are 1 to 256.
- **Error Signal Width (bits)**—Width of the `error` signal on the input interface. Valid values are 0 to 31. A value of `0` indicates that the `error` signal in not in use.

Note: If you change only bits per symbol, and do not change the data width, errors are generated.

6.4.3. Avalon Data Pattern Generator and Checker IP Software Programming Model

The HAL system library support, software files, and register maps describe the software programming model for the test pattern generator and checker cores.

6.4.3.1. HAL System Library Support

For Nios II processor users, Intel provides HAL system library drivers that allow you to initialize and access the Avalon Data Pattern Generator and Checker IPs. Intel recommends you use the provided drivers to access the IPs instead of accessing the registers directly.

For Nios II IDE users, copy the provided drivers from the following installation folders to your software application directory:

- `<IP installation directory>/ip/sopc_builder_ip/altera_Avalon_data_source/HAL`
- `<IP installation directory>/ip/sopc_builder_ip/altera_Avalon_data_sink/HAL`

Note: This instruction does not apply if you use the Nios II command-line tools.

6.4.3.2. Avalon Data Pattern Generator and Checker IP Files

The following files define the low-level access to the hardware, and provide the routines for the HAL device drivers.

- Avalon Data Pattern Generator IP files in `<installation directory>/ip/sopc_builder_ip/altera_Avalon_data_source/HAL`:
  - `data_source_regs.h`—header file that defines the test pattern generator's register maps.
  - `data_source_util.h`, `data_source_util.c`—header and source code for the functions and variables required to integrate the driver into the HAL system library.
- Avalon Data Pattern Checker IP files in `<installation directory>/ip/sopc_builder_ip/altera_Avalon_data_sink/HAL`
  - `data_sink_regs.h`—header file that defines the IP register maps.
  - `data_sink_util.h`, `data_sink_util.c`—header and source code for the functions and variables required to integrate the driver into the HAL system library.

Note: Do not modify the Avalon Data Pattern Generator or Avalon Data Pattern Checker IP files.

6.4.3.3. Avalon Data Pattern Generator and Checker IP Register Maps

6.4.3.3.1. Avalon Data Pattern Generator IP Control and Status Registers

Table 137. Avalon Data Pattern Generator IP Control and Status Register Map

Each register is 32-bits wide.

Offset	Register Name
base + 0	`status`
base + 1	`control`
base + 2	`fill`

Table 138. Avalon Data Pattern Generator IP Status Register Bits

Bits	Name	Access	Description
[15:0]	ID	RO	A constant value of 0x64.
[23:16]	NUMCHANNELS	RO	The configured number of channels.
[30:24]	NUMSYMBOLS	RO	The configured number of symbols per beat.
[31]	SUPPORTPACKETS	RO	A value of 1 indicates data packet support.

Table 139. Avalon Data Pattern Generator IP Control Register Bits

Bits	Name	Access	Description
[0]	ENABLE	RW	Setting this bit to 1 enables the data pattern generator IP.
[7:1]	Reserved		
[16:8]	THROTTLE	RW	Specifies the throttle value which can be between 0–256, inclusively. The Data Pattern Generator IP uses this value in conjunction with a pseudo-random number generator to throttle the data generation rate.
[17]	SOFT RESET	RW	When this bit is set to 1, all internal counters and statistics are reset. Write 0 to this bit to exit reset.
[31:18]	Reserved		

Table 140. Avalon Data Pattern Generator IP Fill Register Bits

Bits	Name	Access	Description
[0]	BUSY	RO	A value of 1 indicates that data transmission is in progress, or that there is at least one command in the command queue.
[6:1]	Reserved		
[15:7]	FILL	RO	The number of commands currently in the command FIFO.
[31:16]	Reserved		

6.4.3.3.2. Avalon Data Pattern Generator IP Command Registers

Table 141. Avalon Data Pattern Generator IP Command Register Map

Shows the offset for the command registers. Each register is 32-bits wide.

Offset	Register Name
base + 0	cmd_lo
base + 1	cmd_hi

The cmd_lo is pushed into the FIFO only when the cmd_lo register is addressed.

Table 142. `cmd_lo` Register Bits

Bits	Name	Access	Description
[15:0]	SIZE	RW	The segment size in symbols. Except for the last segment in a packet, the size of all segments must be a multiple of the configured number of symbols per beat. If this condition is not met, the Data Pattern Generator IP inserts additional symbols to the segment to ensure the condition is fulfilled.
[29:16]	CHANNEL	RW	The channel to send the segment on. If the `channel` signal is less than 14 bits wide, the Data Pattern Generator IP uses the low order bits of this register to drive the signal.
[30]	SOP	RW	Set this bit to 1 when sending the first segment in a packet. This bit is ignored when data packets are not supported.
[31]	EOP	RW	Set this bit to 1 when sending the last segment in a packet. This bit is ignored when data packets are not supported.

Table 143. `cmd_hi` Register Bits

Bits	Name	Access	Description
[15:0]	SIGNALED ERROR	RW	Specifies the value to drive the `error` signal. A non-zero value creates a signaled error.
[23:16]	DATA ERROR	RW	The output data is XORed with the contents of this register to create data errors. To stop creating data errors, set this register to 0.
[24]	SUPPRESS SOP	RW	Set this bit to 1 to suppress the assertion of the `startofpacket` signal when the first segment in a packet is sent.
[25]	SUPRESS EOP	RW	Set this bit to 1 to suppress the assertion of the `endofpacket` signal when the last segment in a packet is sent.

6.4.3.3.3. Avalon Data Pattern Checker IP Control and Status Registers

Table 144. Avalon Data Pattern Generator and Checker IP Control and Status Register Map

Shows the offset for the control and status registers. Each register is 32 bits wide.

Offset	Register Name
base + 0	`status`
base + 1	`control`
base + 2	Reserved
base + 3	
base + 4	
base + 5	`exception_descriptor`
base + 6	`indirect_select`
base + 7	`indirect_count`

Table 145. Avalon Data Pattern Checker IP Status Register Bits

Bits	Name	Access	Description
[15:0]	ID	RO	Contains a constant value of 0x65.
[23:16]	NUMCHANNELS	RO	The configured number of channels.
[30:24]	NUMSYMBOLS	RO	The configured number of symbols per beat.
[31]	SUPPORTPACKETS	RO	A value of 1 indicates packet support.

Table 146. Avalon Data Pattern Checker IP Control Register Bits

Bits	Name	Access	Description
[0]	ENABLE	RW	Setting this bit to 1 enables the Data Pattern Checker IP.
[7:1]	Reserved		
[16:8]	THROTTLE	RW	Specifies the throttle value which can be between 0–256, inclusively. Platform Designer uses this value in conjunction with a pseudo-random number generator to throttle the data generation rate. Setting THROTTLE to 0 stops the Avalon Data Pattern Checker IP. Setting it to 256 causes the Avalon Data Pattern Checker IP to run at full throttle. Values between 0–256 result in a data rate proportional to the throttle value.
[17]	SOFT RESET	RW	When this bit is set to 1, all internal counters and statistics are reset. Write 0 to this bit to exit reset.
[31:18]	Reserved		

If there is no exception, reading the `exception_descriptor` register bit register returns 0.

Table 147. `exception_descriptor` Register Bits

Bits	Name	Access	Description
[0]	DATA ERROR	RO	A value of 1 indicates that an error is detected in the incoming data.
[1]	MISSINGSOP	RO	A value of 1 indicates missing start-of-packet.
[2]	MISSINGEOP	RO	A value of 1 indicates missing end-of-packet.
[7:3]	Reserved		
[15:8]	SIGNALLED ERROR	RO	The value of the `error` signal.
[23:16]	Reserved		
[31:24]	CHANNEL	RO	The channel on which the exception was detected.

Table 148. `indirect_select` Register Bits

Bit	Bits Name	Access	Description
[7:0]	INDIRECT CHANNEL	RW	Specifies the channel number that applies to the INDIRECT PACKET COUNT, INDIRECT SYMBOL COUNT, and INDIRECT ERROR COUNT registers.
[15:8]	Reserved		
[31:16]	INDIRECT ERROR	RO	The number of data errors that occurred on the channel specified by INDIRECT CHANNEL.

Table 149. `indirect_count` Register Bits

Bit	Bits Name	Access	Description
[15:0]	INDIRECT PACKET COUNT	RO	The number of data packets received on the channel specified by INDIRECT CHANNEL.
[31:16]	INDIRECT SYMBOL COUNT	RO	The number of symbols received on the channel specified by INDIRECT CHANNEL.

6.4.4. Avalon Data Pattern Generator IP API

The following subsections describe application programming interface (API) for the Avalon Data Pattern Generator IP.

Note: API functions are currently not available from the interrupt service routine (ISR).

6.4.4.1. data_source_reset()

Table 150. data_source_reset()

Information Type	Description
Prototype	`void data_source_reset(alt_u32 base);`
Thread-safe	No
Include	*<data_source_util.h >*
Parameters	base—Base address of the control and status agent.
Returns	void
Description	Resets the Avalon Data Pattern Generator IP, including all internal counters and FIFOs. The control and status registers are not reset by this function.

6.4.4.2. data_source_init()

Table 151. data_source_init()

Information Type	Description
Prototype	`int data_source_init(alt_u32 base, alt_u32 command_base);`
Thread-safe	No
Include	*<data_source_util.h >*
Parameters	`base`—Base address of the control and status agent. `command_base`—Base address of the command agent.
Returns	`1`—Initialization is successful. `0`—Initialization is unsuccessful.
Description	Performs the following operations to initialize the Avalon Data Pattern Generator IP: • Resets and disables the Avalon Data Pattern Generator IP. • Sets the maximum throttle. • Clears all inserted errors.

6.4.4.3. data_source_get_id()

Table 152. data_source_get_id()

Information Type	Description
Prototype	`int data_source_get_id(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	Avalon Data Pattern Generator IP identifier.
Description	Retrieves the Avalon Data Pattern Generator IP identifier.

6.4.4.4. data_source_get_supports_packets()

Table 153. data_source_get_supports_packets()

Information Type	Description
Prototype	`int data_source_init(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	`1`—Data packets are supported. `0`—Data packets are not supported.
Description	Checks if the Avalon Data Pattern Generator IP supports data packets.

6.4.4.5. data_source_get_num_channels()

Table 154. data_source_get_num_channels()

Description	Description
Prototype	`int data_source_get_num_channels(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*
Parameters	base—Base address of the control and status agent.
Returns	Number of channels supported.
Description	Retrieves the number of channels supported by the Avalon Data Pattern Generator IP.

6.4.4.6. data_source_get_symbols_per_cycle()

Table 155. data_source_get_symbols_per_cycle()

Description	Description
Prototype	`int data_source_get_symbols(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*
Parameters	base—Base address of the control and status agent.
Returns	Number of symbols transferred in a beat.
Description	Retrieves the number of symbols transferred by the Avalon Data Pattern Generator IP in each beat.

6.4.4.7. data_source_get_enable()

Table 156. data_source_get_enable()

Information Type	Description
Prototype	`int data_source_get_enable(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*
Parameters	base—Base address of the control and status agent.
Returns	Value of the ENABLE bit.
Description	Retrieves the value of the ENABLE bit.

6.4.4.8. data_source_set_enable()

Table 157. data_source_set_enable()

Information Type	Description
Prototype	`void data_source_set_enable(alt_u32 base, alt_u32 value);`
Thread-safe	No

continued...

Information Type	Description
Include	*<data_source_util.h >*
Parameters	`base`—Base address of the control and status agent. `value`— ENABLE bit set to the value of this parameter.
Returns	`void`
Description	Enables or disables the Avalon Data Pattern Generator IP. When disabled, the Avalon Data Pattern Generator IP stops data transmission but continues to accept commands and stores them in the FIFO

6.4.4.9. data_source_get_throttle()

Table 158. data_source_get_throttle()

Information Type	Description
Prototype	`int data_source_get_throttle(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	Throttle value.
Description	Retrieves the current throttle value.

6.4.4.10. data_source_set_throttle()

Table 159. data_source_set_throttle()

Information Type	Description
Prototype	`void data_source_set_throttle(alt_u32 base, alt_u32 value);`
Thread-safe	No
Include	*<data_source_util.h >*
Parameters	`base`—Base address of the control and status agent. `value`—Throttle value.
Returns	`void`
Description	Sets the throttle value, which can be between 0–256 inclusively. The throttle value, when divided by 256 yields the rate at which the Avalon Data Pattern Generator IP sends data.

6.4.4.11. data_source_is_busy()

Table 160. data_source_is_busy()

Information Type	Description
Prototype	`int data_source_is_busy(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*

continued...

Information Type	Description
Parameters	`base`—Base address of the control and status agent.
Returns	`1`—Avalon Data Pattern Generator IP is busy. `0`—Avalon Data Pattern Generator IP is not busy.
Description	Checks if the Avalon Data Pattern Generator IP is busy. The Avalon Data Pattern Generator IP is busy when it is sending data or has data in the command FIFO to be sent.

6.4.4.12. data_source_fill_level()

Table 161. data_source_fill_level()

Information Type	Description
Prototype	`int data_source_fill_level(alt_u32 base);`
Thread-safe	Yes
Include	*<data_source_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	Number of commands in the command FIFO.
Description	Retrieves the number of commands currently in the command FIFO.

6.4.4.13. data_source_send_data()

Table 162. data_source_send_data()

Information Type	Description
Prototype	`int data_source_send_data(alt_u32 cmd_base, alt_u16 channel, alt_u16 size, alt_u32 flags, alt_u16 error, alt_u8 data_error_mask);`
Thread-safe	No
Include	*<data_source_util.h >*
Parameters	`cmd_base`—Base address of the command agent. `channel`—Channel to send the data. `size`—Data size. `flags` —Specifies whether to send or suppress SOP and EOP signals. Valid values are `DATA_SOURCE_SEND_SOP`, `DATA_SOURCE_SEND_EOP`, `DATA_SOURCE_SEND_SUPRESS_SOP` and `DATA_SOURCE_SEND_SUPRESS_EOP`. `error`—Value asserted on the `error` signal on the output interface. `data_error_mask`—Parameter and the data are XORed together to produce erroneous data.
Returns	Returns 1.
Description	Sends a data fragment to the specified channel. If data packets are supported, applications must ensure consistent usage of SOP and EOP in each channel. Except for the last segment in a packet, the length of each segment is a multiple of the data width. If data packets are not supported, applications must ensure that there are no SOP and EOP indicators in the data. The length of each segment in a packet is a multiple of the data width.

6.4.5. Avalon Data Pattern Checker IP API

The following subsections describe API for the Avalon Data Pattern Checker IP. The API functions are currently not available from the ISR.

6.4.5.1. data_sink_reset()

Table 163. data_sink_reset()

Information Type	Description
Prototype	`void data_sink_reset(alt_u32 base);`
Thread-safe	No
Include	*<data_sink_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	`void`
Description	Resets the Avalon Data Pattern Checker IP, including all internal counters.

6.4.5.2. data_sink_init()

Table 164. data_sink_init()

Information Type	Description
Prototype	`int data_source_init(alt_u32 base);`
Thread-safe	No
Include	*<data_sink_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	`1`—Initialization is successful. `0`—Initialization is unsuccessful.
Description	Performs the following operations to initialize the Avalon Data Pattern Checker IP: • Resets and disables the Avalon Data Pattern Checker IP. • Sets the throttle to the maximum value.

6.4.5.3. data_sink_get_id()

Table 165. data_sink_get_id()

Information Type	Description
Prototype	`int data_sink_get_id(alt_u32 base);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	Avalon Data Pattern Checker IP identifier.
Description	Retrieves the Avalon Data Pattern Checker IP identifier.

6.4.5.4. data_sink_get_supports_packets()

Table 166. data_sink_get_supports_packets()

Information Type	Description
Prototype	`int data_sink_init(alt_u32 base);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	`1`—Data packets are supported. `0`—Data packets are not supported.
Description	Checks if the Avalon Data Pattern Checker IP supports data packets.

6.4.5.5. data_sink_get_num_channels()

Table 167. data_sink_get_num_channels()

Information Type	Description
Prototype	`int data_sink_get_num_channels(alt_u32 base);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	Number of channels supported.
Description	Retrieves the number of channels supported by the Avalon Data Pattern Checker IP.

6.4.5.6. data_sink_get_symbols_per_cycle()

Table 168. data_sink_get_symbols_per_cycle()

Information Type	Description
Prototype	`int data_sink_get_symbols(alt_u32 base);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	Number of symbols received in a beat.
Description	Retrieves the number of symbols received by the Avalon Data Pattern Checker IP in each beat.

6.4.5.7. data_sink_get_enable()

Table 169. data_sink_get_enable()

Information Type	Description
Prototype	`int data_sink_get_enable(alt_u32 base);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`base`—Base address of the control and status agent.
Returns	Value of the ENABLE bit.
Description	Retrieves the value of the ENABLE bit.

6.4.5.8. data_sink_set enable()

Table 170. data_sink_set enable()

Information Type	Description
Prototype	`void data_sink_set_enable(alt_u32 base, alt_u32 value);`
Thread-safe	No

continued...

Information Type	Description
Include	*<data_sink_util.h >*
Parameters	base—Base address of the control and status agent. value—ENABLE bit is set to the value of the parameter.
Returns	void
Description	Enables the Avalon Data Pattern Checker IP.

6.4.5.9. data_sink_get_throttle()

Table 171. data_sink_get_throttle()

Information Type	Description
Prototype	`int data_sink_get_throttle(alt_u32 base);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	base—Base address of the control and status agent.
Returns	Throttle value.
Description	Retrieves the throttle value.

6.4.5.10. data_sink_set_throttle()

Table 172. data_sink_set_throttle()

Information Type	Description
Prototype	`void data_sink_set_throttle(alt_u32 base, alt_u32 value);`
Thread-safe	No
Include:	*<data_sink_util.h >*
Parameters	base—Base address of the control and status agent. value—Throttle value.
Returns	void
Description	Sets the throttle value, which can be between 0–256 inclusively. The throttle value, when divided by 256 yields the rate at which the Avalon Data Pattern Checker IP receives data.

6.4.5.11. data_sink_get_packet_count()

Table 173. data_sink_get_packet_count()

Information Type	Description
Prototype	`int data_sink_get_packet_count(alt_u32 base, alt_u32 channel);`
Thread-safe	No
Include	*<data_sink_util.h >*
Parameters	base—Base address of the control and status agent.

continued...

Information Type	Description
	channel—Channel number.
Returns	Number of data packets received on the channel.
Description	Retrieves the number of data packets received on a channel.

6.4.5.12. data_sink_get_error_count()

Table 174. data_sink_get_error_count()

Information Type	Description
Prototype	`int data_sink_get_error_count(alt_u32 base, alt_u32 channel);`
Thread-safe	No
Include	*<data_sink_util.h >*
Parameters	base—Base address of the control and status agent. channel—Channel number.
Returns	Number of errors received on the channel.
Description	Retrieves the number of errors received on a channel.

6.4.5.13. data_sink_get_symbol_count()

Table 175. data_sink_get_symbol_count()

Information Type	Description
Prototype	`int data_sink_get_symbol_count(alt_u32 base, alt_u32 channel);`
Thread-safe	No
Include	*<data_sink_util.h >*
Parameters	base—Base address of the control and status agent. channel—Channel number.
Returns	Number of symbols received on the channel.
Description	Retrieves the number of symbols received on a channel.

6.4.5.14. data_sink_get_exception()

Table 176. data_sink_get_exception()

Information Type	Description
Prototype	`int data_sink_get_exception(alt_u32 base);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	base—Base address of the control and status agent.
Returns	First exception descriptor in the exception FIFO. 0—No exception descriptor found in the exception FIFO.
Description	Retrieves the first exception descriptor in the exception FIFO and pops it off the FIFO.

6.4.5.15. data_sink_exception_is_exception()

Table 177. data_sink_exception_is_exception()

Information Type	Description
Prototype	`int data_sink_exception_is_exception(int exception);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`exception`—Exception descriptor
Returns	`1`—Indicates an exception. `0`—No exception.
Description	Checks if an exception descriptor describes a valid exception.

6.4.5.16. data_sink_exception_has_data_error()

Table 178. data_sink_exception_has_data_error()

Information Type	Description
Prototype	`int data_sink_exception_has_data_error(int exception);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`exception`—Exception descriptor.
Returns	`1`—Data has errors. `0`—No errors.
Description	Checks if an exception indicates erroneous data.

6.4.5.17. data_sink_exception_has_missing_sop()

Table 179. data_sink_exception_has_missing_sop()

Information Type	Description
Prototype	`int data_sink_exception_has_missing_sop(int exception);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`exception`—Exception descriptor.
Returns	`1`—Missing SOP. `0`—Other exception types.
Description	Checks if an exception descriptor indicates missing SOP.

6.4.5.18. data_sink_exception_has_missing_eop()

Table 180. data_sink_exception_has_missing_eop()

Information Type	Description
Prototype	`int data_sink_exception_has_missing_eop(int exception);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`exception`—Exception descriptor.
Returns	`1`—Missing EOP. `0`—Other exception types.
Description	Checks if an exception descriptor indicates missing EOP.

6.4.5.19. data_sink_exception_signalled_error()

Table 181. data_sink_exception_signalled_error()

Information Type	Description
Prototype	`int data_sink_exception_signalled_error(int exception);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`exception`—Exception descriptor.
Returns	Signal error value.
Description	Retrieves the value of the signaled error from the exception.

6.4.5.20. data_sink_exception_channel()

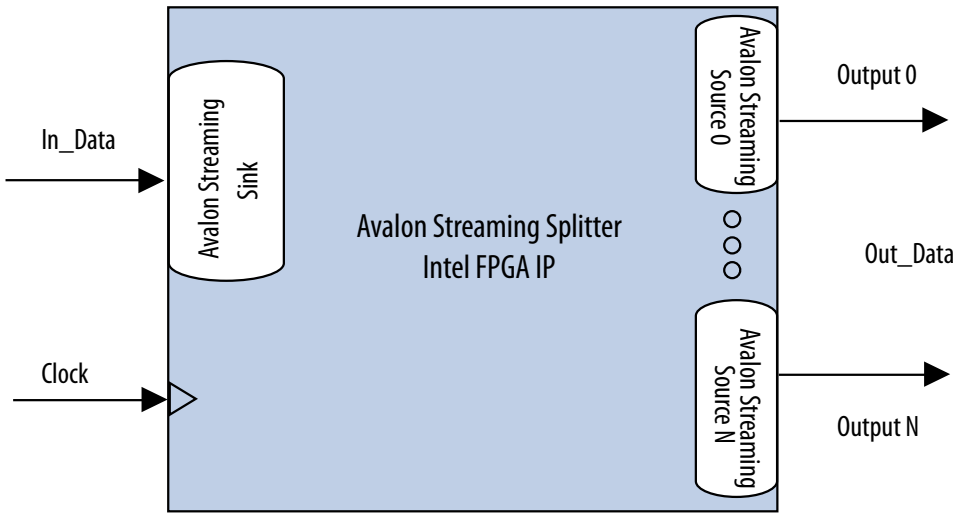
Table 182. data_sink_exception_channel()

Information Type	Description
Prototype	`int data_sink_exception_channel(int exception);`
Thread-safe	Yes
Include	*<data_sink_util.h >*
Parameters	`exception`—Exception descriptor.
Returns	Channel number on which an exception occurred.
Description	Retrieves the channel number on which an exception occurred.

6.5. Avalon Streaming Splitter Intel FPGA IP

The Avalon Streaming Splitter Intel FPGA IP allows you to replicate transactions from an Avalon streaming sink interface to multiple Avalon streaming source interfaces. This IP supports from 1 to 16 outputs.

Figure 274. Avalon Streaming Splitter Intel FPGA IP



The Avalon Streaming Splitter IP copies input signals from the input interface to the corresponding output signals of each output interface without altering the size or functionality. This includes all signals except for the `ready` signal. The IP includes a clock signal to determine the Avalon streaming interface and clock domain where the IP resides. Because the Avalon Streaming Splitter IP does not use the `clock` signal internally, latency is not introduced when using this IP.

6.5.1. Avalon Streaming Splitter Intel FPGA IP Backpressure

The Avalon Streaming Splitter Intel FPGA IP integrates with backpressure by AND-ing the `ready` signals from the output interfaces and sending the result to the input interface. As a result, if an output interface deasserts the `ready` signal, the input interface receives the deasserted `ready` signal, as well. This functionality ensures that backpressure on the output interfaces is propagated to the input interface.

When the **Qualify Valid Out** option is enabled, the `out_valid` signals on all other output interfaces are gated when backpressure is applied from one output interface. In this case, when any output interface deasserts its `ready` signal, the `out_valid` signals on the other output interfaces are also deasserted.

When the **Qualify Valid Out** option is disabled, the output interfaces have a non-gated `out_valid` signal when backpressure is applied. In this case, when an output interface deasserts its ready signal, the `out_valid` signals on the other output interfaces are not affected.

Because the logic is combinational, the Intel FPGA IP introduces no latency.

6.5.2. Avalon Streaming Splitter Intel FPGA IP Interfaces

The Avalon Streaming Splitter Intel FPGA IP supports streaming data, with optional packet, channel, and error signals. The Intel FPGA IP propagates backpressure from any output interface to the input interface.

Table 183. Avalon Streaming Splitter Intel FPGA IP Support

Feature	Support
Backpressure	Ready latency = 0.
Data Width	Configurable.
Channel	Supported (optional).
Error	Supported (optional).
Packet	Supported (optional).

6.5.3. Avalon Streaming Splitter Intel FPGA IP Parameters

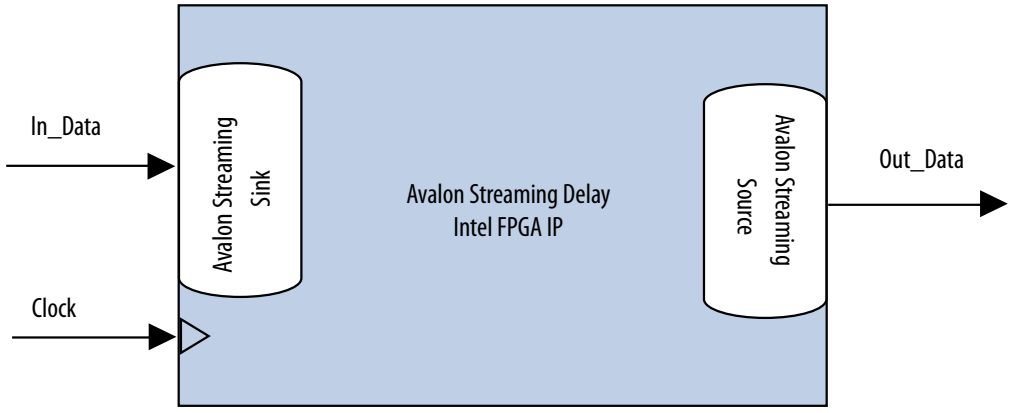
Table 184. Avalon Streaming Splitter Intel FPGA IP Parameters

Parameter	Legal Values	Default Value	Description
Number Of Outputs	1 to 16	2	The number of output interfaces. Platform Designer supports 1 for some systems where no duplicated output is required.
Qualify Valid Out	Enabled, Disabled	Enabled	If enabled, the `out_valid` signal of all output interfaces is gated when back pressure is applied.
Data Width	1–512	8	The width of the data on the Avalon streaming data interfaces.
Bits Per Symbol	1–512	8	The number of bits per symbol for the input and output interfaces. For example, byte-oriented interfaces have 8-bit symbols.
Use Packets	Enabled, Disabled	Disabled	Enable support of data packet transfers. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
Use Channel	Enabled, Disabled	Disabled	Enable the channel signal.
Channel Width	0-8	1	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is set to 0.
Max Channels	0-255	1	The maximum number of channels that a data interface can support. This parameter is disabled when **Use Channel** is set to 0.
Use Error	Enabled, Disabled	Disabled	Enable the error signal.
Error Width	0–31	1	The width of the `error` signal on the output interfaces. A value of `0` indicates that the IP is not using the `error` signal. This parameter is disabled when **Use Error** is set to `0`.

6.6. Avalon Streaming Delay Intel FPGA IP

The Avalon Streaming Delay Intel FPGA IP provides a solution to delay Avalon streaming transactions by a constant number of clock cycles. This IP supports up to 16 clock cycle delays.

Figure 275. Avalon Streaming Delay Intel FPGA IP



The Avalon Streaming Delay Intel FPGA IP adds a delay between the input and output interfaces. The IP accepts transactions presented on the input interface and reproduces them on the output interface N cycles later without changing the transaction.

The input interface delays the input signals by a constant N number of clock cycles to the corresponding output signals of the output interface. The **Number Of Delay Clocks** parameter defines the constant N, which must be from 0 to 16. The change of the `in_valid` signal is reflected on the `out_valid` signal exactly N cycles later.

6.6.1. Avalon Streaming Delay Intel FPGA IP Reset Signal

The Avalon Streaming Delay Intel FPGA IP has a `reset` signal that is synchronous to the `clk` signal. When the IP asserts the `reset` signal, the output signals are held at 0. After the `reset` signal is deasserted, the output signals are held at 0 for N clock cycles. The delayed values of the input signals are then reflected at the output signals after N clock cycles.

6.6.2. Avalon Streaming Delay Intel FPGA IP Interfaces

The Avalon Streaming Delay Intel FPGA IP supports streaming data, with optional packet, channel, and error signals. The Avalon Streaming Delay Intel FPGA IP does not support backpressure.

Table 185. Avalon Streaming Delay Intel FPGA IP Support

Feature	Support
Backpressure	Not supported.
Data Width	Configurable.
Channel	Supported (optional).
Error	Supported (optional).
Packet	Supported (optional).

6.6.3. Avalon Streaming Delay Intel FPGA IP Parameters

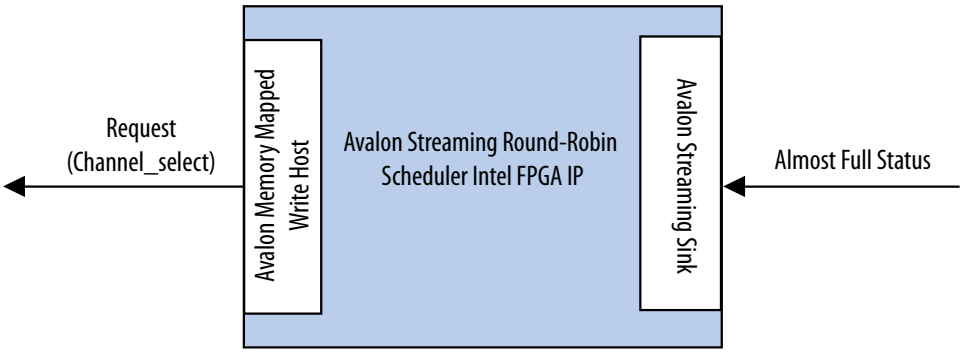
Table 186. Avalon Streaming Delay Intel FPGA IP Parameters

Parameter	Legal Values	Default Value	Description
Number Of Delay Clocks	0 to 16	1	Specifies the delay the IP introduces, in clock cycles. Platform Designer supports 0 for some systems where no delay is required.
Data Width	1–512	8	The width of the data on the Avalon streaming data interfaces.
Bits Per Symbol	1–512	8	The number of bits per symbol for the input and output interfaces. For example, byte-oriented interfaces have 8-bit symbols.
Use Packets	0 or 1	0	Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
Use Channel	0 or 1	0	The option to enable or disable the channel signal.
Channel Width	0-8	1	The width of the `channel` signal on the data interfaces. This parameter is disabled when **Use Channel** is set to 0.
Max Channels	0-255	1	The maximum number of channels that a data interface can support. This parameter is disabled when **Use Channel** is set to 0.
Use Error	0 or 1	0	The option to enable or disable the error signal.
Error Width	0–31	1	The width of the `error` signal on the output interfaces. A value of 0 indicates that the error signal is not in use. This parameter is disabled when **Use Error** is set to 0.

6.7. Avalon Streaming Round Robin Scheduler Intel FPGA IP

The Avalon Streaming Round Robin Scheduler Intel FPGA IP controls the read operations from a multi-channel Avalon streaming component that buffers data by channels. The IP reads the almost-full threshold values from the multiple channels in the multi-channel component, and then issues the read request to the Avalon streaming source according to a round-robin scheduling algorithm.

Figure 276. Avalon Streaming Round Robin Scheduler Intel FPGA IP



In a multi-channel component, the IP can store data either in the sequence that it comes in (FIFO), or in segments according to the channel. When data is stored in segments according to channels, a scheduler is needed to schedule the read operations.

6.7.1. Avalon Streaming Round Robin Scheduler IP Almost-Full Status Interface

The Almost-Full Status interface is an Avalon streaming sink interface that collects the almost-full status from the sink components for the channels in the sequence provided.

Table 187. Avalon Streaming Interface Feature Support

Feature	Property
Backpressure	Not supported
Data Width	Data width = 1; Bits per symbol = 1
Channel	Maximum channel = 32; Channel width = 5
Error	Not supported
Packet	Not supported

6.7.2. Avalon Streaming Round Robin Scheduler IP Request Interface

The Request Interface is an Avalon memory mapped write host interface that requests data from a specific channel. The Avalon Streaming Round Robin Scheduler cycles through the channels it supports and schedules data to be read.

6.7.3. Avalon Streaming Round Robin Scheduler IP Operation

If a particular channel is almost full, the Avalon Streaming Round Robin Scheduler does not schedule data to be read from that channel in the source component.

The scheduler only requests 1 bit of data from a channel at each transaction. To request 1 bit of data from channel *n*, the scheduler writes the value 1 to address (4 ×*n*). For example, if the scheduler is requesting data from channel 3, the scheduler writes 1 to address `0xC`. At every clock cycle, the scheduler requests data from the next channel. Therefore, if the scheduler starts requesting from channel 1, at the next clock cycle, it requests from channel 2. The scheduler does not request data from a particular channel if the almost-full status for the channel is asserted. In this case, the scheduler uses one clock cycle without a request transaction.

The Avalon Streaming Round Robin Scheduler cannot determine if the requested component is able to service the request transaction. The component asserts `waitrequest` when it cannot accept new requests.

Table 188. Avalon Streaming Round Robin Scheduler Ports

Signal	Direction	Description
Clock and Reset		
`clk`	In	Clock reference.
		continued...

Signal	Direction	Description
reset_n	In	Asynchronous active low reset.
Avalon Memory Mapped Request Interface		
request_address (log_2 Max_Channels–1:0)	Out	The write address that indicates which channel has the request.
request_write	Out	Write enable signal.
request_writedata	Out	The amount of data requested from the particular channel. This value is always fixed at 1.
request_waitrequest	In	Wait request signal that pauses the scheduler when the agent cannot accept a new request.
Avalon Streaming Almost-Full Status Interface		
almost_full_valid	In	Indicates that almost_full_channel and almost_full_data are valid.
almost_full_channel (Channel_Width–1:0)	In	Indicates the channel for the current status indication.
almost_full_data (log_2 Max_Channels–1:0)	In	A 1-bit signal that is asserted high to indicate that the channel indicated by almost_full_channel is almost full.

6.7.4. Avalon Streaming Round Robin Scheduler IP Parameters

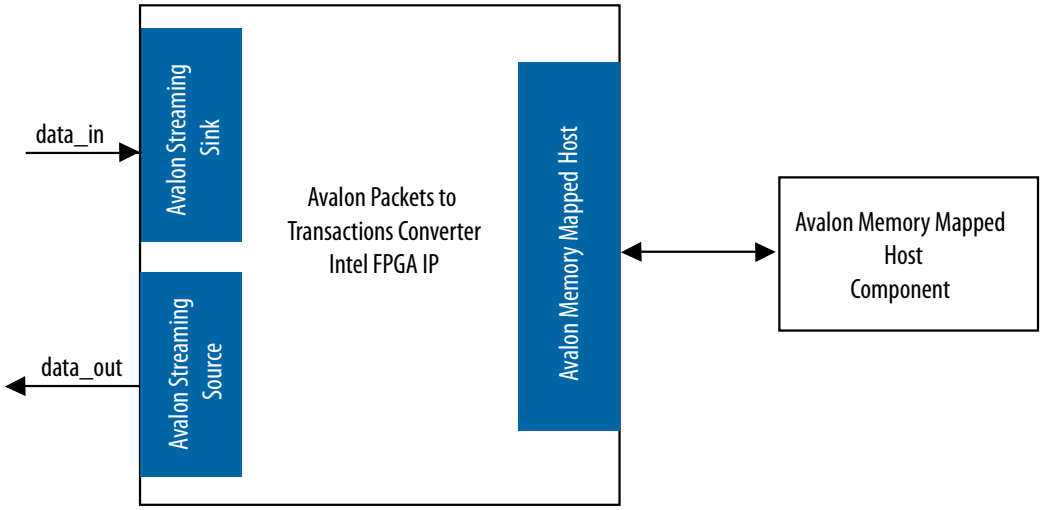
Table 189. Avalon Streaming Round Robin Scheduler IP Parameters

Parameters	Legal Values	Default Value	Description
Number of channels	2–32	2	Specifies the number of channels the Avalon Streaming Round Robin Scheduler supports.
Use almost-full status	Enabled, Disabled	Disabled	If enabled, the scheduler uses the almost-full interface. If not, the IP requests data from the next channel at the next clock cycle.

6.8. Avalon Packets to Transactions Converter Intel FPGA IP

The Avalon Packets to Transactions Converter Intel FPGA IP receives streaming data from upstream components and initiates Avalon memory mapped transactions. The IP then returns Avalon memory mapped transaction responses to the requesting components.

Figure 277. Avalon Packets to Transactions Converter Intel FPGA IP



Note: The SPI Agent to Avalon Host Bridge, and the JTAG to Avalon Host Bridge, are examples of the Packets to Transactions Converter IP. For more information, refer to the *Avalon Interface Specifications*.

Related Information

Avalon Interface Specifications

6.8.1. Avalon Packets to Transactions Converter IP Interfaces

Table 190. Properties of Avalon Streaming Interfaces

Feature	Property
Backpressure	Ready latency = 0.
Data Width	Data width = 8 bits; Bits per symbol = 8.
Channel	Not supported.
Error	Not used.
Packet	Supported.

The Avalon memory mapped host interface supports read and write transactions. The data width is set to 32 bits, and burst transactions are not supported.

6.8.2. Avalon Packets to Transactions Converter IP Operation

The Avalon Packets to Transactions Converter IP receives streams of packets on its Avalon streaming sink interface and initiates Avalon memory mapped transactions. Upon receiving transaction responses from Avalon memory mapped agents, the IP transforms the responses to packets and returns them to the requesting components via its Avalon streaming source interface. The IP does not report Avalon streaming errors.

6.8.2.1. Avalon Packets to Transactions Converter IP Data Packet Formats

A response packet is returned for every write transaction. The IP also returns a response packet if a no transaction (`0x7f`) is received. An invalid transaction code is regarded as a no transaction. For read transactions, the IP returns the data read.

The Avalon Packets to Transactions Converter IP expects incoming data streams to be in the formats shown in the table below.

Table 191. Data Packet Formats

Byte	Field	Description
Transaction Packet Format		
0	`Transaction code`	Type of transaction.
1	Reserved	Reserved for future use.
[3:2]	`Size`	Transaction size in bytes. For write transactions, the size indicates the size of the `data` field. For read transactions, the size indicates the total number of bytes to read.
[7:4]	`Address`	32-bit address for the transaction.
[n:8]	`Data`	Transaction data; data to be written for write transactions.
Response Packet Format		
0	`Transaction code`	The transaction code with the most significant bit inversed.
1	Reserved	Reserved for future use.
[4:2]	`Size`	Total number of bytes read/written successfully.

Related Information

Avalon Packets to Transactions Converter IP Interfaces on page 426

6.8.2.2. Avalon Packets to Transactions Converter IP Supported Transactions

The Avalon Packets to Transactions Converter IP supports the following Avalon memory mapped transactions:

Table 192. Avalon Packets to Transactions Converter IP Supported Transactions

Transaction Code	AvalonMemory Mapped Transaction	Description
`0x00`	Write, non-incrementing address.	Writes data to the address until the total number of bytes written to the same word address equals to the value specified in the `size` field.
`0x04`	Write, incrementing address.	Writes transaction data starting at the current address.
`0x10`	Read, non-incrementing address.	Reads 32 bits of data from the address until the total number of bytes read from the same address equals to the value specified in the `size` field.
`0x14`	Read, incrementing address.	Reads the number of bytes specified in the `size` parameter starting from the current address.
`0x7f`	No transaction.	No transaction is initiated. You can use this transaction type for testing purposes. Although no transaction is initiated on the Avalon memory mapped interface, the IP still returns a response packet for this transaction code.

The Avalon Packets to Transactions Converter IP can process only a single transaction at a time. The `ready` signal on the IP Avalon streaming sink interface is asserted only when the current transaction is completely processed.

No internal buffer is implemented on the datapaths. Data received on the Avalon streaming interface is forwarded directly to the Avalon memory mapped interface and vice-versa. Asserting the `waitrequest` signal on the Avalon memory mapped interface backpressures the Avalon streaming sink interface. In the opposite direction, if the Avalon streaming source interface is backpressured, the `read` signal on the Avalon memory mapped interface is not asserted until the backpressure is alleviated. Backpressuring the Avalon streaming source in the middle of a read can result in data loss. In this cases, the IP returns the data that is successfully received.

A transaction is considered complete when the IP receives an EOP. For write transactions, the actual data size is expected to be the same as the value of the `size` property. Whether or not both values agree, the IP always uses the end of packet (EOP) to determine the end of data.

6.8.2.3. Avalon Packets to Transactions IP Converter Malformed Packets

The following are examples of malformed packets:

- **Consecutive start of packet (SOP)**—An SOP marks the beginning of a transaction. If an SOP is received in the middle of a transaction, the IP drops the current transaction without returning a response packet for the transaction, and initiates a new transaction. This effectively processes packets without an end of packet (EOP).
- **Unsupported transaction codes**—The IP processes unsupported transactions as a no transaction.

6.9. Avalon Streaming Pipeline Stage Intel FPGA IP

The Avalon Streaming Pipeline Stage Intel FPGA IP receives data from an Avalon streaming source interface, and outputs the data to an Avalon streaming sink interface. In the absence of back pressure, the Avalon Streaming Pipeline Stage Intel FPGA IP source interface outputs data one cycle after receiving the data on its sink interface.

If the pipeline stage receives back pressure on its source interface, the pipeline stage continues to assert its source interface's current data output. While the pipeline stage is receiving back pressure on its source interface, and then receives new data on its sink interface, the pipeline stage internally buffers the new data. It then asserts back pressure on its sink interface.

After the backpressure is deasserted, the pipeline stage's source interface is deasserted and the pipeline stage asserts internally buffered data (if present). Additionally, the pipeline stage deasserts back pressure on its sink interface.

Figure 278. Pipeline Stage Simple Register

If the ready signal is not pipelined, the pipeline stage becomes a simple register.

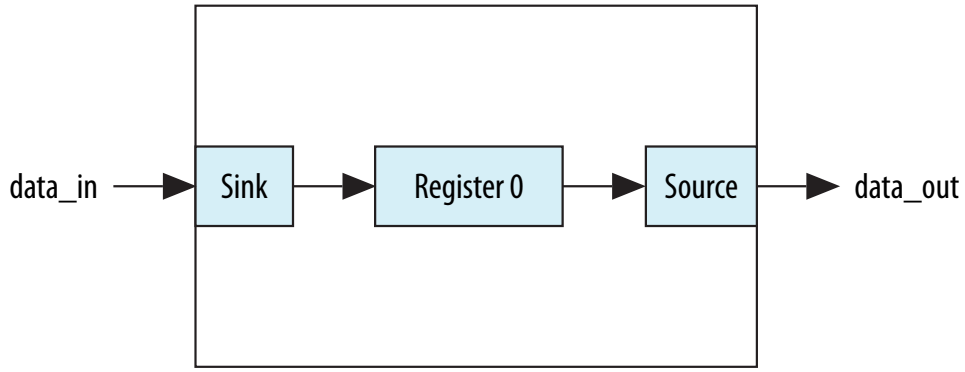


Figure 279. Pipeline Stage Holding Register

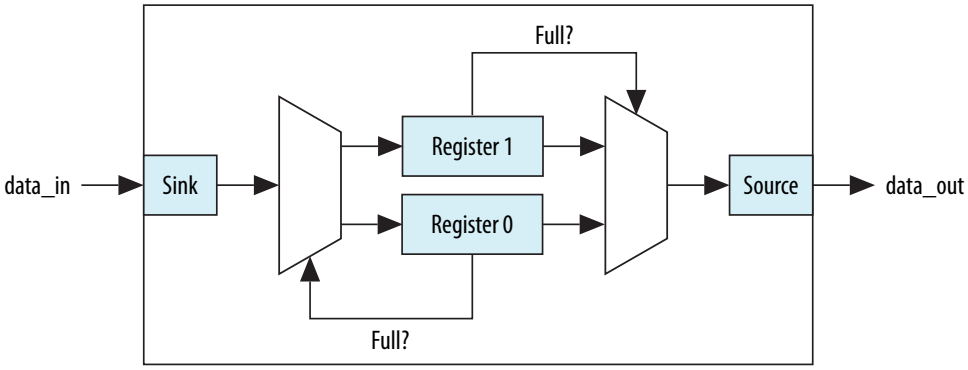
If the ready signal is pipelined, the pipeline stage must also include a second "holding" register.



6.10. Avalon Streaming Multiplexer and Demultiplexer Intel FPGA IP

The Avalon Streaming Multiplexer Intel FPGA IP receives data from various input interfaces and multiplexes the data into a single output interface, using the optional `channel` signal to indicate the origin of the data. The Avalon Streaming Multiplexer Intel FPGA IP receives data from a channelized input interface and drives that data to multiple output interfaces, where the output interface is selected by the input `channel` signal.

The Multiplexer and Demultiplexer IPs can transfer data between interfaces on that supports a unidirectional flow of data. The Multiplexer and Demultiplexer IP allow you to create multiplexed or demultiplexed datapaths without having to write custom HDL code. The Multiplexer IP includes an Avalon Streaming Round Robin Scheduler.

Related Information

Avalon Streaming Round Robin Scheduler Intel FPGA IP on page 423

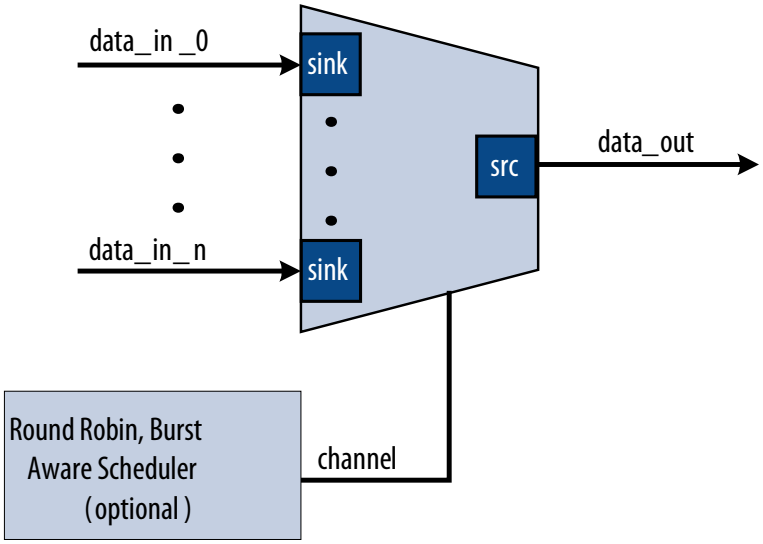
6.10.1. Avalon Streaming Multiplexer and Demultiplexer Software Programming Model

The Multiplexer and Demultiplexer IP components do not have any user-visible control or status registers. Therefore, Platform Designer cannot control or configure any aspect of the Multiplexer or Demultiplexer at run-time. These IP components cannot generate interrupts.

6.10.2. Avalon Streaming Multiplexer Intel FPGA IP

The Avalon Streaming Multiplexer Intel FPGA IP takes data from a variety of input data interfaces, and multiplexes the data onto a single output interface. The multiplexer includes a round-robin scheduler that selects from the next input interface that has data. Each input interface has the same width as the output interface, so that the other input interfaces are backpressured when the multiplexer is carrying data from a different input interface.

Figure 280. Avalon Streaming Multiplexer Intel FPGA IP



The multiplexer includes an optional channel signal that enables each input interface to carry channelized data. The output interface channel width is equal to:

(log2 (n-1)) + 1 + w

where n is the number of input interfaces, and w is the channel width of each input interface. All input interfaces must have the same channel width. These bits are appended to either the most or least significant bits of the output channel signal.

The scheduler processes one input interface at a time, selecting it for transfer. Once an input interface has been selected, data from that input interface is sent until one of the following scenarios occurs:

- The specified number of cycles have elapsed.
- The input interface has no more data to send and the `valid` signal is deasserted on a ready cycle.
- When packets are supported, `endofpacket` is asserted.

6.10.2.1. Avalon Streaming Multiplexer IP Input Interfaces

Each input interface is an Avalon streaming data interface that optionally supports packets. The input interfaces are identical; they have the same symbol and data widths, error widths, and channel widths.

6.10.2.2. Avalon Multiplexer IP Output Interface

The output interface carries the multiplexed data stream with data from the inputs. The symbol, data, and error widths are the same as the input interfaces.

The width of the `channel` signal is the same as the input interfaces, with the addition of the bits needed to indicate the origin of the data.

You can configure the following parameters for the output interface:

- **Data Bits Per Symbol**—the bits per symbol is related to the width of `readdata` and `writedata` signals, which must be a multiple of the bits per symbol.
- **Data Symbols Per Beat**—the number of symbols (words) that are transferred per beat (transfer). Valid values are 1 to 32.
- **Include Packet Support**—indicates whether packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Channel Signal Width (bits)**— the number of bits Platform Designer uses for the channel signal for output interfaces. For example, set this parameter to 1 if you have two input interfaces with no channel, or set this parameter to 2 if you have two input interfaces with a channel width of 1 bit. The input channel can have a width between 0-31 bits.
- **Error Signal Width (bits)**—The width of the `error` signal for input and output interfaces. A value of `0` means the `error` signal is not in use.

Note: If you change only bits per symbol, and do not change the data width, errors are generated.

6.10.2.3. Avalon Multiplexer IP Parameters

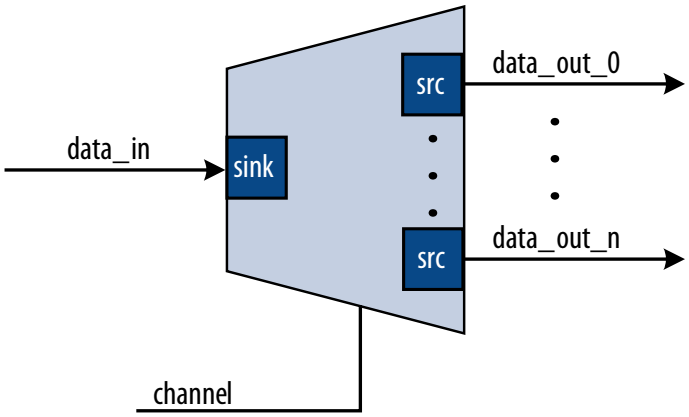
You can configure the following parameters for the multiplexer:

- **Number of Input Ports**—the number of input interfaces that the multiplexer supports. Valid values are 2 to 16.
- **Scheduling Size (Cycles)**—the number of cycles that are sent from a single channel before changing to the next channel.
- **Use Packet Scheduling**—when this parameter is turned on, the multiplexer only switches the selected input interface on packet boundaries. Therefore, packets on the output interface are not interleaved.
- **Use high bits to indicate source port**—when this parameter is turned on, the multiplexer uses the high bits of the output `channel` signal to indicate the origin of the input interface of the data. For example, if the input interfaces have 4-bit channel signals, and the multiplexer has 4 input interfaces, the output interface has a 6-bit channel signal. If this parameter is turned on, bits [5:4] of the output channel signal indicate origin of the input interface of the data, and bits [3:0] are the channel bits that were presented at the input interface.

6.10.3. Avalon Streaming Demultiplexer Intel FPGA IP

The Avalon Streaming Demultiplexer Intel FPGA IP takes data from a channelized input data interface and provides that data to multiple output interfaces, where the output interface selected for a particular transfer is specified by the input `channel` signal.

Figure 281. Avalon Streaming Demultiplexer



The data is delivered to the output interfaces in the same order it is received at the input interface, regardless of the value of `channel`, `packet`, `frame`, or any other signal. Each of the output interfaces has the same width as the input interface; each output interface is idle when the demultiplexer is driving data to a different output interface. The demultiplexer uses $\log_2$ (`num_output_interfaces`) bits of the `channel` signal to select the output for the data; the remainder of the channel bits are forwarded to the appropriate output interface unchanged.

6.10.3.1. Avalon Streaming Demultiplexer IP Input Interface

Each input interface is an Avalon streaming data interface that optionally supports packets. You can configure the following parameters for the input interface:

- **Data Bits Per Symbol**—The bits per symbol is related to the width of `readdata` and `writedata` signals, which must be a multiple of the bits per symbol.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat (transfer). Valid values are 1 to 32.
- **Include Packet Support**—Indicates whether data packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Channel Signal Width (bits)**—The number of bits for the `channel` signal for output interfaces. A value of `0` means that output interfaces do not use the optional `channel` signal.
- **Error Signal Width (bits)**—The width of the `error` signal for input and output interfaces. A value of `0` means the `error` signal is in use.

Note: If you change only bits per symbol, and do not change the data width, errors are generated.

6.10.3.2. Avalon Streaming Demultiplexer IP Output Interface

Each output interface carries data from a subset of channels from the input interface. Each output interface is identical; all have the same symbol and data widths, error widths, and channel widths. The symbol, data, and error widths are the same as the input interface. The width of the `channel` signal is the same as the input interface, without the bits that the demultiplexer uses to select the output interface.

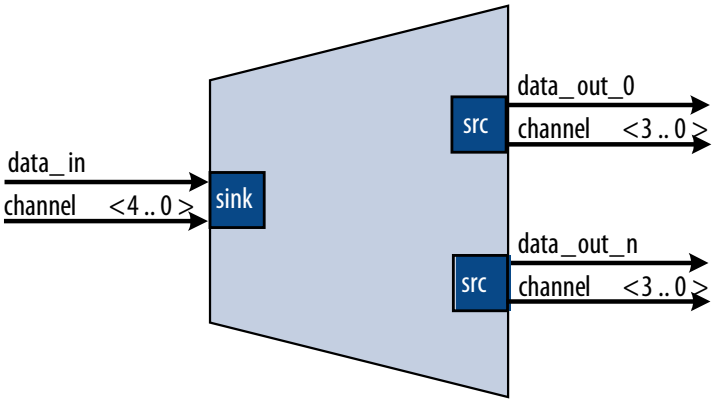
6.10.3.3. Avalon Streaming Demultiplexer IP Parameters

You can configure the following parameters for the demultiplexer:

- **Number of Output Ports**—The number of output interfaces that the multiplexer supports Valid values are 2 to 16.
- **High channel bits select output**—When this option is turned on, the demultiplexing function uses the high bits of the input `channel` signal, and the low order bits are passed to the output. When this option is turned off, the demultiplexing function uses the low order bits, and the high order bits are passed to the output.

Where you place the signals in your design affects the functionality; for example, there is one input interface and two output interfaces. If the low-order bits of the channel signal select the output interfaces, the even channels go to channel 0, and the odd channels go to channel 1. If the high-order bits of the channel signal select the output interface, channels 0 to 7 go to channel 0 and channels 8 to 15 go to channel 1.

Figure 282. Select Bits for the Demultiplexer



6.11. Avalon Streaming Single-Clock and Dual-Clock FIFO Intel FPGA IP

The Avalon Streaming Single-Clock and Avalon Streaming Dual-Clock FIFO Intel FPGA IP are FIFO buffers which operate with a common clock and independent clocks for input and output ports respectively.

Figure 283. Avalon Streaming Single Clock FIFO Intel FPGA IP

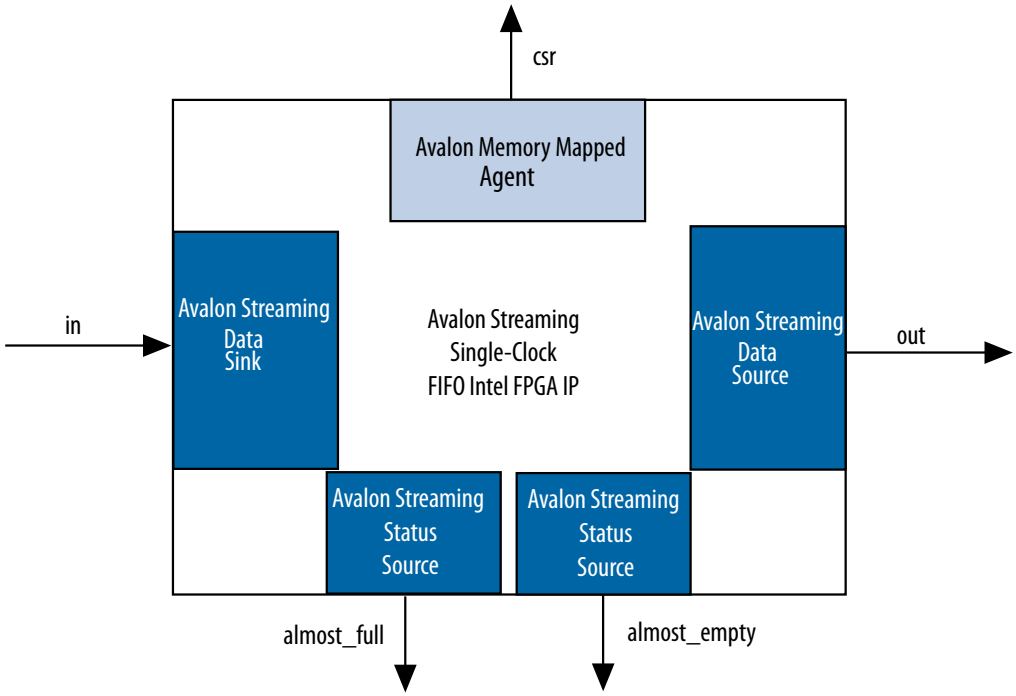


Figure 284. Avalon Streaming Dual Clock FIFO Intel FPGA IP

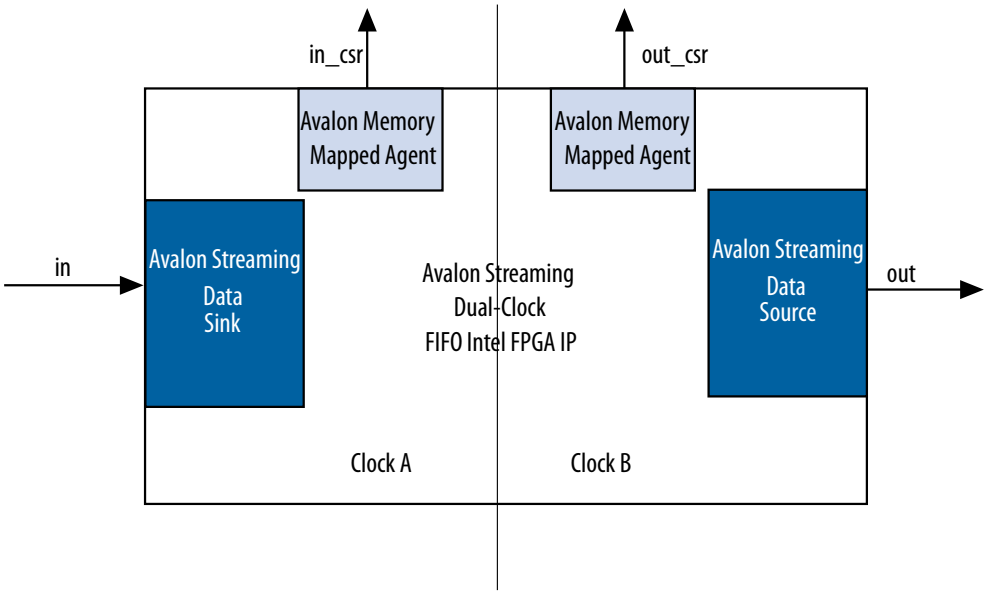

6.11.1. Interfaces Implemented in FIFO Cores

The following interfaces are implemented in FIFO Intel FPGA IP:

Avalon Streaming Data Interface on page 435

Avalon Memory Mapped Control and Status Register Interface on page 435
Avalon Streaming Status Interface on page 435

6.11.1.1. Avalon Streaming Data Interface

Each FIFO IP has an Avalon Streaming data sink and source interface. The data sink and source interfaces in the dual-clock FIFO IP are driven by different clocks.

Error	Configurable.
Packet	Configurable.

6.11.1.2. Avalon Memory Mapped Control and Status Register Interface

You can configure the single-clock FIFO IP to include an optional Avalon memory mapped interface, and the dual-clock FIFO IP to include an Avalon memory mapped interface in each clock domain. The Avalon memory mapped interface provides access to 32-bit registers, which allows you to retrieve the FIFO buffer fill level and configure the almost-empty and almost-full thresholds. In the single-clock FIFO IP, you can also configure the packet and error handling modes.

6.11.1.3. Avalon Streaming Status Interface

The single-clock FIFO IP has two optional Avalon streaming status source interfaces from which you can obtain the FIFO buffer almost-full and almost empty statuses.

6.11.2. Avalon Streaming FIFO IP Operating Modes

- **Default mode**—the IP accepts incoming data on the `in` interface (Avalon streaming data sink) and forwards it to the `out` interface (Avalon streaming data source). The IP asserts the `valid` signal on the Avalon streaming source interface to indicate that data is available at the interface.
- **Store and forward mode**—this mode applies only to the single-clock FIFO IP. The IP asserts the `valid` signal on the `out` interface only when a full packet of data is available at the interface. In this mode, you can also enable the drop-on-error feature by setting the `drop_on_error` register to 1. When this feature is enabled, the IP drops all packets received with the `in_error` signal asserted.
- **Cut-through mode**—this mode applies only to the single-clock FIFO IP. The IP asserts the `valid` signal on the `out` interface to indicate that data is available for consumption when the number of entries specified in the `cut_through_threshold` register are available in the FIFO buffer.

Note: To turn on **Cut-through mode**, the **Use store and forward** parameter must be set to 0. Turning on **Use store and forward mode** prompts the user to turn on **Use fill level**, and then the CSR appears.

6.11.3. Avalon Streaming FIFO IP Buffer Fill Level

You can obtain the fill level of the Avalon Streaming FIFO IP buffer via the optional Avalon memory mapped control and status interface. Turn on the **Use fill level** parameter (**Use sink fill level** and **Use source fill level** in the Avalon Streaming Dual-Clock FIFO IP) and read the `fill_level` register.

The Avalon Streaming Dual-Clock FIFO IP has two fill levels, one in each clock domain. Due to the latency of the clock crossing logic, the fill levels reported in the input and output clock domains may be different for any instance. In both cases, the fill level may report badly for the clock domain; that is, the fill level is reported high in the input clock domain, and low in the output clock domain.

The Avalon Streaming Dual-Clock FIFO IP has an output pipeline stage to improve f_{MAX}. This output stage is accounted for when calculating the output fill level, but not when calculating the input fill level. Therefore, the best measure of the amount of data in the FIFO is by the fill level in the output clock domain. The fill level in the input clock domain represents the amount of space available in the FIFO (`available space = FIFO depth – input fill level`).

6.11.4. Almost-Full and Almost-Empty Thresholds to Prevent Overflow and Underflow

You can use almost-full and almost-empty thresholds as a mechanism to prevent FIFO IP overflow and underflow. This feature is available only in the Avalon Streaming Single-Clock FIFO IP. To use the thresholds, turn on the **Use fill level**, **Use almost-full status**, and **Use almost-empty status** parameters. You can access the `almost_full_threshold` and `almost_empty_threshold` registers via the csr interface and set the registers to an optimal value for your application.

You can obtain the almost-full and almost-empty statuses from `almost_full` and `almost_empty` interfaces (Avalon streaming status source). The IP asserts the `almost_full` signal when the fill level is equal to or higher than the almost-full threshold. Likewise, the IP asserts the `almost_empty` signal when the fill level is equal to or lower than the almost-empty threshold.

6.11.5. Avalon Streaming Single Clock and Dual Clock FIFO IP Parameters

Table 194. Avalon Streaming Single Clock FIFO IP Parameters

Parameter	Legal Values	Description
Symbols per beat	1–32	These parameters determine the width of the FIFO. FIFO width = **Bits per symbol** * **Symbols per beat**, where: **Bits per symbol** is the number of bits in a symbol, and **Symbols per beat** is the number of symbols transferred in a beat.
Bits per symbol	1–32	
FIFO depth	2^n	The FIFO depth. An output pipeline stage is added to the FIFO to increase performance, which increases the FIFO depth by one. <n> = n=1,2,3,4 and so on.
Channel width	1–32	The width of the `channel` signal.
Error width	0–32	The width of the `error` signal.

continued...

Parameter	Legal Values	Description
Use packets	On|Off	Turn on this parameter to enable data packet support on the Avalon streaming data interfaces.
Use fill level	On|Off	Turn on this parameter to include the Avalon memory mapped control and status register interface (CSR). The CSR is enabled when **Use fill level** is set to 1.
Use store and forward	On|Off	To turn on **Cut-through mode**, **Use store and forward** must be set to 0. Turning on **Use store and forward** prompts the user to turn on **Use fill level**, and then the CSR appears.
Use almost full status	On|Off	Enables a single-bit almost-full status streaming interface
Use almost empty status	On|Off	Enables a single-bit almost-empty status streaming interface.
Enable explicit maxChannel	On|Off	Turn on this parameter to specify the maximum channel number.
Explicit maxChannel	value	Maximum channel number.
Use synchronous resets	On|Off	Turing off allows asynchronous resets. Turning on uses internal reset synchronization.

Table 195. Avalon Streaming Dual Clock FIFO IP Parameters

Parameter	Legal Values	Description
Symbols per beat	1–32	These parameters determine the width of the FIFO. FIFO width = **Bits per symbol** * **Symbols per beat**, where: **Bits per symbol** is the number of bits in a symbol, and **Symbols per beat** is the number of symbols transferred in a beat.
Bits per symbol	1–32	
FIFO depth	2^n	The FIFO depth. An output pipeline stage is added to the FIFO to increase performance, which increases the FIFO depth by one. <n> = n=1,2,3,4 and so on.
Channel width	1–32	The width of the `channel` signal.
Error width	0–32	The width of the `error` signal.
Use packets	On|Off	Turn on this parameter to enable data packet support on the Avalon streaming data interfaces.
Use sink fill level	On|Off	Turn on this parameter to include the Avalon memory mapped control and status register interface in the input clock domain.
Use source fill level	On|Off	Turn on this parameter to include the Avalon memory mapped control and status register interface in the output clock domain.
Write pointer synchronizer length	2–8	The length of the write pointer synchronizer chain. Setting this parameter to a higher value leads to better metastability while increasing the latency of the IP.
Read pointer synchronizer length	2–8	The length of the read pointer synchronizer chain. Setting this parameter to a higher value leads to better metastability.
Enable explicit maxChannel	On|Off	Turn on this parameter to specify the maximum channel number.
Explicit maxChannel	value	Maximum channel number.
Pipeline pointers	On|Off	This option enables the pipeline pointer after clock domain crossing. Enable this option for better timing closure by adding one clock cycle of latency.
Use synchronous resets	On|Off	Turing off allows asynchronous resets. Turning on uses internal reset synchronization.

Note: For more information about metastability in Intel devices, refer to *Understanding Metastability in FPGAs*. For more information about metastability analysis and synchronization register chains, refer to the *Managing Metastability* in the *Quartus Prime Pro Edition User Guide: Design Recommendations*.

6.11.6. Avalon Streaming Single-Clock FIFO IP Registers

Table 196. Avalon Streaming Single-Clock FIFO IP Registers

The CSR interface in the Avalon Streaming Single Clock FIFO IP provides access to registers.

32-Bit Word Offset	Name	Access	Reset	Description
0	`fill_level`	R	0	24-bit FIFO fill level. Bits 24 to 31 are not used.
1	Reserved	—	—	Reserved for future use.
2	`almost_full_threshold`	RW	**FIFO depth**–1	Set this register to a value that indicates the FIFO buffer is getting full.
3	`almost_empty_threshold`	RW	0	Set this register to a value that indicates the FIFO buffer is getting empty.
4	`cut_through_threshold`	RW	0	**0**—Enables store and forward mode. **Greater than 0**—Enables cut-through mode and specifies the minimum of entries in the FIFO buffer before the `valid` signal on the Avalon streaming source interface is asserted. Once the FIFO IP starts sending the data to the downstream component, it continues to do so until the end of the packet. *Note:* To turn on **Cut-through mode**, **Use store and forward** must be set to 0. Turning on **Use store and forward mode** prompts the user to turn on **Use fill level**, and then the CSR appears.
5	`drop_on_error`	RW	0	**0**—Disables drop-on error. **1**—Enables drop-on error. This register applies only when the **Use packet** and **Use store and forward** parameters are turned on.

Table 197. Register Description for Avalon Streaming Dual-Clock FIFO

The `in_csr` and `out_csr` interfaces in the Avalon Streaming Dual Clock FIFO IP reports the FIFO fill level.

32-Bit Word Offset	Name	Access	Reset Value	Description
0	`fill_level`	R	0	24-bit FIFO fill level. Bits 24 to 31 are not used.

6.12. Platform Designer System Design Components Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout.
2023.04.03	23.1	• Added note about no support for fixed-latency pipelined read transfers to *Avalon Memory Mapped Pipeline Bridge Intel FPGA IP* topic. • The product family name is updated to "Intel Agilex 7" to reflect the different family members.
2022.09.26	22.3	• Revised note about the default agent selection to *Designating a Default Agent* topic. • Revised note about the default agent selection to *Specifying a Default Avalon Agent or AXI Subordinate* topic. • Revised note about the default agent selection to *Accessing Undefined Memory Regions* topic.
2022.04.02	22.1	• Updated entire chapter for new AXI "manager" and AXI "subordinate" replacement terms. Refer to the AMBA® AXI and ACE Protocol Specification. • Updated *AXI Timeout Bridge Stages* and *AXI Timeout Bridge Parameters* topics for new CSR behavior and parameters. • Updated the *Avalon Streaming Single-Clock and Dual-Clock FIFO IP Parameters* topic for Pipeline pointers parameter.
2021.03.29	21.1	• Converted to "host" and "agent" inclusive terminology for Avalon memory mapped interface descriptions and related GUI elements throughout.
2021.01.14	20.4	• Added descriptions to *CSR Interrupt Status Information for the AXI Timeout Bridge* table.
2019.11.11	19.1	• Updated the names of Intel FPGA IP components throughout. • Updated name of Test Pattern Checker IP to Avalon Data Pattern Checker IP throughout. • Updated Address Span Extender figure bit order. • Provided directory path in Test Pattern Generator
2018.12.15	18.1	• Replaced references to System Contents tab with new System View tab.
2017.11.06	17.1	• Changed instances of *Qsys Pro* to *Platform Designer*. • Changed instances of *AXI Default Slave* to *Error Response Slave*. • Updated topics: Error Response Slave. • Updated Figure: Error Response Slave Parameter Editor. • Added Figure: Error Response Slave Parameter Editor with Enabled CSR Support. • Updated topics: CSR Registers and renamed to Error Response Slave CSR Registers. • Added topic: Error Response Slave Access Violation Service.
2016.10.31	16.1	• Implemented Intel rebranding. • Implemented Qsys rebranding.
2016.05.03	16.0	Updated Address Span Extender • Address Span Extender register mapping better explained • Address Span Extender Parameters table added • Address Span Extender example added
2015.11.02	15.1	Changed instances of *Quartus II* to *Quartus Prime*.

continued...

Document Version	Quartus Prime Version	Changes
2015.05.04	15.0	Avalon Memory Mapped Unaligned Burst Expansion Bridge and Avalon Memory Mapped Pipeline Bridge, **Maximum pending read transactions** parameter. Extended description.
December 2014	14.1	• AXI Timeout Bridge. • Added notes to *Avalon Memory Mapped Clock Crossing Bridge* pertaining to: — SDC constraints for its internal asynchronous FIFOs. — FIFO-based clock crossing.
June 2014	14.0	• AXI Bridge support. • Address Span Extender updates. • Avalon Memory Mapped Unaligned Burst Expansion Bridge support.
November 2013	13.1	• Address Span Extender
May 2013	13.0	• Added Streaming Pipeline Stage support. • Added AMBA APB support.
November 2012	12.1	• Moved relevant content from the *Embedded Peripherals IP User Guide*.

7. Platform Designer Command-Line Utilities

You can perform many of the functions available in the Platform Designer GUI at the command-line, with Platform Designer command-line utilities.

You run Platform Designer command-line executables from the Quartus Prime installation directory:

```
<Quartus Prime installation directory>\quartus\sopc_builder\bin
```

For command-line help listing of all the options for any executable, type the following command:

```
<Quartus Prime installation directory>\quartus\sopc_builder\bin
\<executable name> --help
```

Note: You must add `$QUARTUS_ROOTDIR/sopc_builder/bin/` to the PATH variable to access command-line utilities. Once you add this PATH variable, you can launch the utility from any directory location.

7.1. Run the Platform Designer Editor with qsys-edit

The `qsys-edit` utility allows you to run the Platform Designer editor from command-line.

You can use the following options with the `qsys-edit` utility:

Table 198. qsys-edit Command-Line Options

Option	Usage	Description
1st arg file	Optional	Specifies the name of the `.qsys` system or `.qvar` variation file to edit.
`--search-path[=<value>]`	Optional	If you omit this command, Platform Designer uses a standard default path. If you provide a search path, Platform Designer searches a comma-separated list of paths. To include the standard path in your replacement, use "$", for example: `/extra/dir,$` .
`--quartus-project[=<value>]`	Required	This option is mandatory if you are associating your Platform Designer system with an existing Quartus Prime project. Specifies the name of the Quartus Prime project file. If you do not provide the revision via `--rev`, Platform Designer uses the default revision as the Quartus Prime project name.

continued...

Option	Usage	Description
`--new-quartus-project[=<value>]`	Required	This option is mandatory if you are associating your Platform Designer system with a new Quartus Prime project. Specifies the name and path of the new Quartus Prime project. Creates a new Quartus Prime project at the specified path. You can also provide the revision name.
`--rev[=<value>]`	Optional	Specifies the name of the Quartus Prime project revision.
`--family[=<value>]`	Optional	Sets the device family.
`--part[=<value>]`	Optional	Sets the device part number. If set, this option overrides the `--family` option.
`--new-component-type[=<value>]`	Optional	Specifies the instance type for parameterization in a variation.
`--require-generation`	Optional	Marks the loading system as requiring generation.
`--debug`	Optional	Enables debugging features and output.
`--jvm-max-heap-size=<value>`	Optional	The maximum memory size that Platform Designer uses when running `qsys-edit`. You specify this value as `<size><unit>`, where unit is `m` (or `M`) for multiples of megabytes, or `g` (or `G`) for multiples of gigabytes. The default value is `512m`.
`--metrics-log-file=[path_to_log_file]`	Optional	This switch creates a new file containing a set of metrics, at the path you specify. This switch must be used alongside the `--record-metrics` switch, or the switch does not function. The path to the log file must exist, or the `FileDoesNotExists` error appears. Platform Designer does not create any new directories listed in the path.
`--record-metrics[=<foobar>]`	Optional	Enables metric logging. This feature logs the time Platform Designer takes to perform various operations. The other information includes: • The operation performed. • The IP instance name and its `.ip` file location. • The IP component type and its `_hw.tcl` file location. The switch does not require a value, but it does accept a string value that has no effect on the metric logging. In the absence of the `--metrics-log-file` switch, Platform Designer creates the log file in the project directory with the name of `metrics_<top-level name>.txt` by default.
`--help`	Optional	Displays help for `qsys-edit`.

Important: The options `--quartus-project` and `--new-quartus-project` are mutually exclusive. If you use `--quartus-project` you cannot use `--new-quartus-project` and vice versa.

Extended Features with the --debug Options

The `--debug` option provides powerful tools for debugging. When you launch Platform Designer with the `--debug` option enabled, you can:

- View debug messages when opening a system or generating HDL for that system.
- Add the `--verbose` argument when generating IP or a system using command-line utilities.
- Access internal library components in the IP Catalog, for example, modules used to create interconnect fabric.
- Access to debug tools and files from the **Internal** menu.

Figure 285. Internal Menu Options

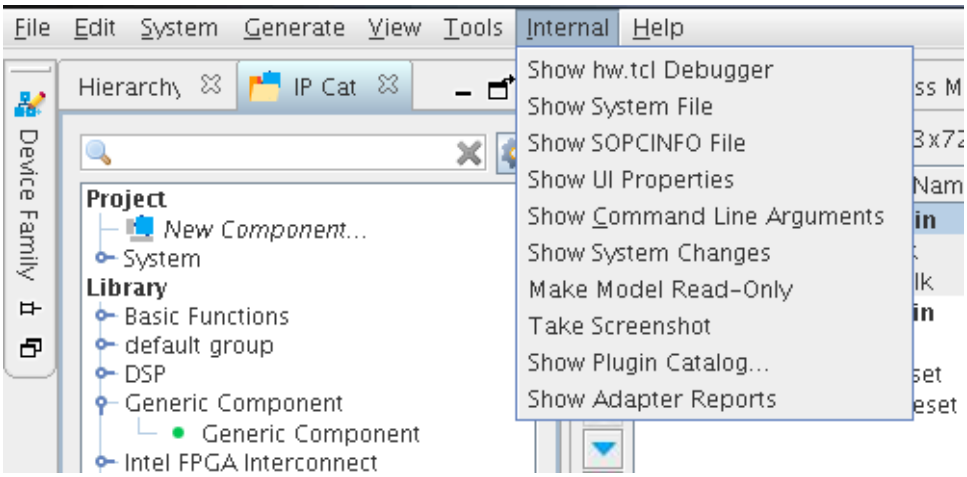

Table 199. Debug Options on the Internal Menu

Menu Item	Description
Show hw.tcl Debugger	Displays a Tcl debugger.
Show System File	Displays the current system XML in a text dialog box.
Show SOPCINFO File	Shows the SOPCINFO report XML in a text dialog box.
Show UI Properties	Displays the UI properties in a text dialog box.
Show Command Line Arguments	Displays all command-line arguments and environment variables in a text dialog box.
Show System Changes	Displays dynamic system changes in a text dialog box.
Make Model Read-only	Makes the system you are working in read-only.
Take Screenshots	Creates a `.png` file in the *<project_directory>* by default. You can navigate and save to a directory of your choice.
Show Plug-In Catalog	Displays library details such as type, version, tags, etc. for all IPs in the IP Catalog.
Show Adapter Reports	Displays adapter reports for any adapters added when transforming the system.

- You can view detailed debugging messages in the **Component Editor** while building a custom IP component.
- You can view the generated Tcl script while editing in the **Component Editor** with the **Advanced ➤ Show Tcl for Component** command.
- You can launch the System Console with debug logging.

7.2. Scripting IP Core Generation

Use the `qsys-script` and `qsys-generate` utilities to define and generate an IP core variation outside of the Quartus Prime GUI.

To parameterize and generate an IP core at command-line, follow these steps:

1. Run `qsys-script` to start a Tcl script that instantiates the IP and sets parameters:

```
qsys-script --script=<script_file>.tcl
```

2. Run `qsys-generate` to generate the IP core variation:

```
qsys-generate <IP variation file>.qsys
```

Related Information

Generate a Platform Designer System with qsys-script on page 451

7.2.1. qsys-generate Command-Line Options

Table 200. Command-Line Options for qsys-generate

Options in alphabetical order.

Option	Usage	Description
<1st arg file>	Required	Specifies the name of the `.qsys` system file to generate.
`--block-symbol-file`	Optional	Creates a Block Symbol File (`.bsf`) for the Platform Designer system.
`--bypass-quartus-project`	Optional	Override the project settings with values from the Platform Designer system, if possible. For example, if the Platform Designer system defines its own IP search path, use that path instead of the project settings IP search path. This option mainly affects the generation process.
`--clear-output-directory`	Optional	Clears the output directory corresponding to the selected target, that is, simulation or synthesis.
`--example-design=<value>`	Optional	Creates example design files. For example, `--example-design` or `--example-design=all`. The default is *All*, which generates example designs for all instances. Alternatively, choose specific filesets based on instance name and fileset name. For example `--example-design=instance0.example_design1,instance1.example_design` 2. Specify an output directory for the example design files creation.
`--family=<value>`	Optional	Sets the device family name.
`--help`	Optional	Displays help for `--qsys-generate`.

continued...

Option	Usage	Description
`--greybox`	Optional	If you are synthesizing your design with a third-party EDA synthesis tool, generate a netlist for the synthesis tool to estimate timing and resource usage for this design. *Note:* Generation of a timing and area estimation (gray box) netlist is available only for individual Intel FPGA IP, and not for Platform Designer systems.
`--ipxact`	Optional	If you specify this option, Platform Designer generates the post-generation system as an IPXACT-compatible component description. *Note:* Platform Designer supports importing and exporting files in IP-XACT 2009 format and exporting IP-XACT files in 2014 format.
`--jvm-max-heap-size=<value>`	Optional	The maximum memory size that Platform Designer uses when running `qsys-generate`. You specify the value as `<size><unit>`, where `unit` is m (or M) for multiples of megabytes or g (or G) for multiples of gigabytes. The default value is 512m.
`--metrics-log-file=[path_to_log_file]`	Optional	This switch creates a new file containing a set of metrics, at the path you specify. This switch must be used alongside the `--record-metrics` switch, or the switch does not function. The path to the log file must exist, or the `FileDoesNotExists` error appears. Platform Designer does not create any new directories listed in the path.
`--parallel[=<level>]`	Optional	Directs Platform Designer to generate in parallel mode, with the level of parallelism that you specify. If you omit the level, Platform Designer determines a number based on processor availability and number of files to be generated.
`--part=<value>`	Optional	Sets the device part number. If set, this option overrides the `--family` option.
`--record-metrics[=<foobar>]`	Optional	Enables metric logging. This feature logs the time Platform Designer takes to perform various operations. The other information includes: • The operation performed. • The IP instance name and its `.ip` file location. • The IP component type and its `_hw.tcl` file location. The switch does not require a value, but it does accept a string value that has no effect on the metric logging. In the absence of the `--metrics-log-file` switch, Platform Designer creates the log file in the project directory with the name of `metrics_<top-level name>.txt` by default.
`--search-path=<value>`	Optional	If you omit this command, Platform Designer uses a standard default path. If you provide this command, Platform Designer searches a comma-separated list of paths. To include the standard path in your replacement, use "$", for example, "`/extra/dir,$`".
`--simulation=<VERILOG|VHDL>`	Optional	Creates a simulation model for the Platform Designer system. The simulation model contains generated HDL files for the simulator, and may include simulation-only features. Specify the preferred simulation language. The default value is *VERILOG*.
`--synthesis=<VERILOG|VHDL>`	Optional	Creates synthesis HDL files that Platform Designer uses to compile the system in an Quartus Prime project. Specify the generation language for the top-level RTL file for the Platform Designer system. The default value is *VERILOG*.

continued...

Option	Usage	Description
`--testbench=<SIMPLE|STANDARD>`	Optional	Creates a testbench system that instantiates the original system, adding bus functional models (BFMs) to drive the top-level interfaces. When you generate the system, the BFMs interact with the system in the simulator. The default value is *STANDARD*.
`--testbench-simulation=<VERILOG|VHDL>`	Optional	After you create the testbench system, create a simulation model for the testbench system. The default value is *VERILOG*.
`--top-level-generation`	Optional	Only generate the top-level of the given Platform Designer system. Do not descend into hierarchy. Do not generate generic components.
`--upgrade-ip-cores`	Optional	Enables upgrading all the IP cores that support upgrade in the Platform Designer system you specify. This command has no impact on IP cores in any subsystem.
`--upgrade-variation-file`	Optional	If you set this option to true, the file argument for this command accepts a `.v` file, which contains a IP variant. This file parameterizes a corresponding instance in a Platform Designer system of the same name.

7.3. Board-Aware Flow Scripting Support

The following Tcl commands support the board-aware flow, including preset and board file management, and board and preset file export. For examples use of these commands, refer to Example 1 and Example 2.

Table 201. General Commands

Return	Command	Argument
No return value	`set_project_property`	`BOARD <board_name>`
String	`get_project_property`	`BOARD`

Table 202. Preset Commands

Return	Command	Argument
no return value	`save_component_preset`	`[<preset_file> <preset_name> <preset_description> <preset_version> <board_name> <category> <pin_file.tcl>]`
no return value	`apply_component_preset`	`<preset_name>`

Table 203. Board Commands

Return	Command	Argument
no return value	`add_board`	`<board_file> <board_name> <vendor> <device_family> <device_part> <version>`
String	`get_board_info`	`<board_name> <info_type>` <info_type> can be vendor, device_family, device_part, version
String	`get_boards`	`[<device_family> <device_part>]` Returns all board names.
no return value	`delete_board`	`<board_name>`

Table 204. Export Board and Presets from Current System Commands

Return	Command	Argument
no return value	`export_board_file`	*`<board_name> <board_file>`* `[<vendor> <version>]`
`String[] Instance_paths`	`get_quartus_instance_path_for_entity`	`[<entity_name>]` Returns a list of instance paths in hierarchical format. For example: • `quartus_top.qsys_instance_name` • `quartus_top.something.qsys_instance_name`
no return value	`load_pin_from_quartus_project`	*`<instance_path>`*
No return value	`export_system_preset`	*`[preset_directory_path]`* *Note:* By default the `preset_file_name` is `system_name.qprs`.

Example 1: Create System, Add Component, Apply Built-In Preset

```
# create the system
create_system test_system
set_project_property BOARD {Arria 10 SoC Development Kit}
set_project_property HIDE_FROM_IP_CATALOG {false}
set_use_testbench_naming_pattern 0 {}
# add component pio0
add_component pio_0 ip/test_system/test_system_pio_0.ip altera_avalon_pio pio_0
19.2.0
load_component pio_0

#assume this led4 preset file path is in the search path
apply_component_preset led4
save_component
```

Example 2: Create New Preset, Apply Preset with Pin Constraints File

Example of led4_pins.tcl file:

```
set_instance_assignment -to "led_export[0]" -name IO_STANDARD "1.8 V"
set_location_assignment -to "led_export[0]" "PIN_AR23"
set_instance_assignment -to "led_export[1]" -name IO_STANDARD "1.8 V"
set_location_assignment -to "led_export[1]" "PIN_AR22"
set_instance_assignment -to "led_export[2]" -name IO_STANDARD "1.8 V"
set_location_assignment -to "led_export[2]" "PIN_AM21"
set_instance_assignment -to "led_export[3]" -name IO_STANDARD "1.8 V"
set_location_assignment -to "led_export[3]" "PIN_AL20"
```

Script:

```
add_component pio_0 ip/sys/sys_pio_0.ip altera_avalon_pio pio_0 19.2.0
load_component pio_0
set_component_parameter_value bitClearingEdgeCapReg {0}
set_component_parameter_value bitModifyingOutReg {0}
set_component_parameter_value captureEdge {0}
set_component_parameter_value direction {Output}
set_component_parameter_value edgeType {RISING}
set_component_parameter_value generateIRQ {0}
set_component_parameter_value irqType {LEVEL}
set_component_parameter_value resetValue {0.0}
set_component_parameter_value simDoTestBenchWiring {0}
set_component_parameter_value simDrivenValue {0.0}
set_component_parameter_value width {4}
set_component_project_property HIDE_FROM_IP_CATALOG {false}
# export interface first, then only import the pin constraint tcl file
set_interface_property led EXPORT_OF pio_0.external_connection
save_component_preset led4_demo.qprs led4_demo "" ALL "Arria 10 SoC Development
Kit" "IO" led4_pins.tcl
apply_component_preset led4_demo
save_component
```

7.4. Display Available IP Components with ip-catalog

The `ip-catalog` command displays a list of available IP components relative to the current Quartus Prime project directory, as either text or XML.

You can use the following options with the `ip-catalog` utility:

Table 205. ip-catalog Command-Line Options

Option	Usage	Description
`--project-dir=<directory>`	Optional	Finds IP components relative to the Quartus Prime project directory. By default, Platform Designer uses `'.'` as the current directory. To exclude a project directory, leave the value empty.
`--type`	Optional	Provides a pattern to filter the type of available plug-ins. By default, Platform Designer shows only IP components. To look for a partial type string, surround with *, for instance, **connection**.
`--name=<value>`	Optional	Provides a pattern to filter the names of the IP components found. To show all IP components, use a * or `''`. By default, Platform Designer shows all IP components. The argument is not case sensitive. To look for a partial name, surround with *, for instance, **uart**
`--verbose`	Optional	Reports the progress of the command.
`--xml`	Optional	Generates the output in XML format, in place of colon-delimited format.
`--search-path=<value>`	Optional	If you omit this command, Platform Designer uses a standard default path. If you provide this command, Platform Designer searches a comma-separated list of paths. To include the standard path in your replacement, use "$", for example, "`/extra/dir,$`".
<1st arg value>	Optional	Specifies the directory or name fragment.
`--jvm-max-heap-size=<value>`	Optional	The maximum memory size that Platform Designer uses for when running `ip-catalog`. You specify the value as *<size><unit>*, where `unit` is m (or M) for multiples of megabytes or g (or G) for multiples of gigabytes. The default value is 512m.
`--help`	Optional	Displays help for the `ip-catalog` command.

7.5. Create an .ipx File with ip-make-ipx

The `ip-make-ipx` command creates an `.ipx` index file. This file provides a convenient way to include a collection of IP components from an arbitrary directory. You can edit the `.ipx` file to disable visibility of one or more IP components in the IP Catalog.

You can use the following options with the `ip-make-ipx` utility:

Table 206. ip-make-ipx Command-Line Options

Option	Usage	Description
`--source-directory=<directory>`	Optional	Specifies the directory containing your IP components. The default directory is `'.'`. You can provide a comma-separated list of directories.
`--output=<file>`	Optional	Specifies the name of the index file to generate. The default name is `/component.ipx`. Set as `--output=<"">` to print the output to the console.

continued...

Option	Usage	Description
`--relative-vars=<value>`	Optional	Causes the output file to include references relative to the specified variable or variables wherever possible. You can specify multiple variables as a comma-separated list.
`--thorough-descent`	Optional	If you set this option, Platform Designer searches all the component files, without skipping the sub-directories.
`--message-before=<value>`	Optional	Prints a log message at the start of reading an index file.
`--message-after=<value>`	Optional	Prints a log message at the end of reading an index file.
`--jvm-max-heap-size=<value>`	Optional	The maximum memory size Platform Designer uses when running `ipr-make-ipx`. You specify this value as `<size><unit>`, where unit is `m` (or `M`) for multiples of megabytes, or `g` (or `G`) for multiples of gigabytes. The default value is `512m`.
`--help`	Optional	Displays help for the `ip-make-ipx` command.

7.6. Generate Simulation Scripts

You can use the `ip-make-simscript` utility to generate simulation scripts for one or more simulators, given one or more **Simulation Package Descriptor** (`.spd`) files, `.qsys` files, and `.ip` files.

In Platform Designer, `ip-make-simscript` generates simulation scripts in a hierarchical structure instead of a flat view of the entire system. The `ip-make-simscript` utility uses `.spd` and system files according to the options you select:

- When targeting only `.spd` files (`ip-make-simscript --spd=<file>.spd`) the utility combines the contents of all input `.spd` files, and generates a common directory which contains a set of `<simulator>_files.tcl` files under the specified output directory.
- When targeting only system files (`ip-make-simscript --system-file=<file>`) such as `.qsys` and `.ip` files, the utility searches for instances of `<simulator>_files.tcl` files for each input system, and generates a combined simulation script which contains a list of references of `<simulator>_files.tcl`.
- When the utility uses both `--spd` and `--system-file` options, `ip-make-simscript` combines all input `.spd` files and generates a `common/<simulator>_files.tcl` in the specified output directory. The generated simulation script refers to the generated `common/<simulator>_files.tcl` first, followed by a list of Tcl files from each input system.

Table 207. ip-make-simscript Command-Line Options

Option	Usage	Description
`--spd[=<file>]`	Optional/Repeatable	The `.spd` files describe the list of HDL files for simulation, and memory models hierarchy. This argument can either be a single path to an `.spd` file or a comma-separated list of paths of `.spd` files. For instance, `--spd=ipcore_1.spd,ipcore_2.spd` The generated list is processed in the order of the input `.spd` files.

continued...

Option	Usage	Description
		Note: When this argument is used in combination with `--system-file`, the `.spd` files are parsed before the system files.
`--system-file[=<file>]`	Optional/Repeatable	Specifies the system files (`.qsys` or `.ip` files) used to generate the simulation scripts. This argument can contain either a single path to a Platform Designer system file or a comma-separated list of paths to Platform Designer system files. The simulation script is generated in the order the system files are listed. *Note:* When this argument is used in combination with `--spd`, the `.spd` files are parsed before the system files.
`--output-directory[=<directory>]`	Optional	Specifies the directory path for the location of output files. If you do not specify a directory, the output directory defaults to the directory from which `--ip-make-simscript` runs.
`--compile-to-work`	Optional	Compiles all design files to the default library - `work`.
`--use-relative-paths`	Optional	Uses relative paths whenever possible.
`--cache-file[=<file>]`	Optional	Generates cache file for managed flow.
`--quiet`	Optional	Quiet reporting mode. Does not report generated files.
`--jvm-max-heap-size=<value>`	Optional	The maximum memory size Platform Designer uses when running `ip-make-simscript`. You specify this value as `<size><unit>` where unit is `m` (or `M`) for multiples of megabytes, or `g` (or `G`) for multiples of gigabytes. The default value is `512m`.
`--search-path=<value>`	Optional	Comma-separated list of search paths. If omitted, a default path including the current working directory is used. To include the standard path in your replacement, append the $ symbol, for example:`"/extra/dir,$"`
`--device-family=<value>`	Optional	Overrides the existing device family when used.
`--top-name=<value>`	Optional	Specify a top-level entity name used in generated simulation scripts.
`--help`	Optional	Displays help for `--ip-make-simscript`.

7.7. Generate a Platform Designer System with qsys-script

You can use the `qsys-script` utility to create and manipulate a Platform Designer system with Tcl scripting commands. If you specify a system, Platform Designer loads that system before executing any of the scripting commands.

Note: You must provide a package version for the `qsys-script`. If you do not specify the `--package-version=<value>` command, you must then provide a Tcl script and request the system scripting API directly with the `package require -exact qsys<version>` command.

Example 28. Platform Designer Command-Line Scripting

```
qsys-script --script=my_script.tcl \
--system-file=fancy.qsys
```

`my_script.tcl` contains:

```
package require -exact qsys 16.0
# get all instance names in the system and print one by one
set instances [ get_instances ]
foreach instance $instances {
    send_message Info "$instance"
}
```

You can use the following options with the `qsys-script` utility:

Table 208. qsys-script Command-Line Options

Option	Usage	Description
`--system-file=<file>`	Optional	Specifies the path to a `.qsys` file. Platform Designer loads the system before running scripting commands.
`--script=<file>`	Optional	A file that contains Tcl scripting commands that you can use to create or manipulate a Platform Designer system. If you specify both `--cmd` and `--script`, Platform Designer runs the `--cmd` commands before the script specified by `--script`.
`--cmd=<value>`	Optional	A string that contains Tcl scripting commands that you can use to create or manipulate a Platform Designer system. If you specify both `--cmd` and `--script`, Platform Designer runs the `--cmd` commands before the script specified by `--script`.
`--package-version=<value>`	Optional	Specifies which Tcl API scripting version to use and determines the functionality and behavior of the Tcl commands. The Quartus Prime software supports Tcl API scripting commands. The minimum supported version is 12.0. If you do not specify the version on the command-line, your script must request the scripting API directly with the `package require -exact qsys` <*version* > command.
`--search-path=<value>`	Optional	If you omit this command, a Platform Designer uses a standard default path. If you provide this command, Platform Designer searches a comma-separated list of paths. To include the standard path in your replacement, use "$", for example, `/<directory path>/dir,$`. Separate multiple directory references with a comma.
`--quartus-project=<value>`	Optional	Specifies the path to a `.qpf` Quartus Prime project file. Utilizes the specified Quartus Prime project to add the file saved using `save_system` command. If you omit this command, Platform Designer uses the default revision as the project name.
`--new-quartus-project=<value>`	Optional	Specifies the name of the new Quartus Prime project. Creates a new Quartus Prime project at the specified path and adds the file saved using `save_system` command to the project. If you omit this command, Platform Designer uses the Quartus Prime project revision as the new Quartus Prime project name.
`--rev=<value>`	Optional	Allows you to specify the name of the Quartus Prime project revision.
`--jvm-max-heap-size=<value>`	Optional	The maximum memory size that the `qsys-script` tool uses. You specify this value as `<size><unit>`, where unit is `m` (or `M`) for multiples of megabytes, or `g` (or `G`) for multiples of gigabytes.

continued...

Option	Usage	Description
`--metrics-log-file=[path_to_log_file]`	Optional	This switch creates a new file containing a set of metrics, at the path you specify. This switch must be used alongside the `--record-metrics` switch, or the switch does not function. The path to the log file must exist, or the `FileDoesNotExists` error appears. Platform Designer does not create any new directories listed in the path.
`--record-metrics[=<foobar>]`	Optional	Enables metric logging. This feature logs the time Platform Designer takes to perform various operations. The other information includes: • The operation performed. • The IP instance name and its `.ip` file location. • The IP component type and its `_hw.tcl` file location. The switch does not require a value, but it does accept a string value that has no effect on the metric logging. In the absence of the `--metrics-log-file` switch, Platform Designer creates the log file in the project directory with the name of `metrics_<top-level name>.txt` by default.
`--help`	Optional	Displays help for the `qsys-script` utility.

Related Information

Saving Platform Designer Systems on page 112

7.8. Parameterizing an Instantiated IP Core after save_system Command

When you call the `save_system` command in your Tcl script, Platform Designer converts all the instantiated IP cores in your system to generic components.

To modify these IP cores after saving your system, you must first load the actual component within the instantiated generic component. Re-parameterize an instantiated IP core using one of the following methods:

1. Load the component in the Platform Designer system, modify the component's parameter value, and save the component:

```
…
save_system kernel_system.qsys
…
load_component cra_root
set_component_parameter_value DATA_W 64
save_component
…
```

2. Load the `.ip` file specific to the component, modify the instance's parameter value, and save the `.ip` file:

```
…
save_system kernel_system.qsys
…
load_system cra_root.ip
set_instance_parameter_value cra_root DATA_W 64
save_system
…
```

Note: To directly modify an instance parameter value after the `save_system` command, you must load the `.ip` file corresponding to the IP component.

Related Information

- set_component_parameter_value on page 584
- load_component on page 581
- save_component on page 583
- save_system on page 471

7.9. Validate the Generic Components in a System with qsys-validate

Use the `qsys-validate` utility to run IP component footprint validation on the `.qsys` file for the system.

Table 209. qsys-validate Command-Line Options

Option	Usage	Description
1st arg file	Optional	The name of the `.qsys` system file to validate.
`--search-path[=<value>]`	Optional	If omitted, Platform Designer uses a standard default path. If provided, Platform Designer searches a comma-separated list of paths. To include the standard path in your replacement, use "$", for example: `/extra/dir.$`.
`--strict`	Optional	Enables strict validation. All warnings are reported as errors
`--jvm-max-heap-size=<value>`	Optional	The maximum memory size Platform Designer uses for allocations when running `qsys-edit`. You specify this value as `<size><unit>`, where unit is `m` (or `M`) for multiples of megabytes, or `g` (or `G`) for multiples of gigabytes. The default value is `512m`.
`--help`	Optional	Display help for `qsys-validate`.

7.10. Generate an IP Component or Platform Designer System with quartus_ipgenerate

The `quartus_ipgenerate` command allows you to generate IP components or a Platform Designer system in your Quartus Prime project. Ensure that you include the IP component or the Platform Designer system you wish to generate in your Quartus Prime project.

To run the `quartus_ipgenerate` command from the Quartus Prime shell, type:

```
quartus_ipgenerate <project name> [<options>]
```

Use any of the following options with the `quartus_ipgenerate` utility:

Table 210. `quartus_ipgenerate` Command-Line Options

Option	Usage	Description
<1st arg file>	Required	Specifies the name of the Quartus Prime project file (`.qpf`). This option generates all the `.qsys` and `.ip` files in the specified Quartus Prime project (*<project name>*).
`-f [<argument file>]`	Optional	Specifies a file containing additional command-line arguments. Arguments that you specify after this option can conflict or override the options you specify in the argument file.
`--rev[=<revision name>]` or `-c[=<revision name>]`	Optional	Specifies the Quartus Prime project revision and the associated `.qsf` file to use. If you omit this option, Platform Designer uses the same revision name as your Quartus Prime project.

continued...

Option	Usage	Description
`--clear_ip_generation_dirs` or `--clean`	Optional	Clears the generation directories of all the `.qsys` or the `.ip` files in the specified Quartus Prime project. For example, to clear the generation directories in the project `test`, run the following command: `quartus_ipgenerate --clear_ip_generation_dirs test` or `quartus_ipgenerate --clean test`
`--generate_ip_file --ip_file[=<ip file name>]`	Optional	Generates the files for *<file name>*`.ip` file in the specified Quartus Prime project. Use the following optional flags with `--generate_ip_file`: • `-synthesis[=<value>]`—optional argument that specifies the synthesis target type. Specify the value as either *verilog* or *vhdl*. The default value is *verilog*. • `-simulation[=<value>]`—optional argument that specifies the simulation target type. Specify the value as either *verilog* or *vhdl*. If you omit this flag, Platform Designer does not generate any simulation files. • `--clear_ip_generation_dirs`—clears the preexisting generation directories before generation. If you omit this command, Platform Designer does not clear the generation directories. For example, to generate the files for a `test.qsys` file within the project, `test`: `quartus_ipgenerate --generate_ip_file --synthesis=vhdl --simulation=verilog --clear_ip_generation_dirs --ip_file=test.qsys test`
`--generate_project_ip_files [<project name>]`	Optional	Generates the files for all the `.qsys` and `.ip` files in the specified Quartus Prime project. Use any of the following optional flags with `--generate_project_ip_files`: • `-synthesis[=<value>]`—optional argument that specifies the synthesis target type. Specify the value as either *verilog* or *vhdl*. The default value is *verilog*. • `-simulation[=<value>]`—optional argument that specifies the simulation target type. Specify the value as either *verilog* or *vhdl*. If you omit this flag, Platform Designer does not generate any simulation files. • `--clear_ip_generation_dirs`—clears the preexisting generation directories before generation. If you omit this command, Platform Designer does not clear the generation directories. For example, to generate all the `.qsys` and `.ip` files within the project, `test`: `quartus_ipgenerate --generate_project_ip_files --synthesis=vhdl --simulation=verilog --clear_ip_generation_dirs test`
`--get_project_ip_files`	Optional	Returns a list of the `.qsys` or `.ip` files in the specified Quartus Prime project. This option displays each file in a separate Quartus Prime message line. For example, to get a list of `.qsys` files in the project `test`, and revision `rev`: `quartus_ipgenerate --get_project_ip_files test -c rev`
`--lower_priority`	Optional	Allows you to lower the priority of the current process. This option is useful if you use a single-processor computer, allowing you to use other applications more easily while the Quartus Prime software runs the command in the background.

7.11. Generate an IP Variation File with ip-deploy

Use the `ip-deploy` utility to generate an IP variation file (`.ip` file) in the specified location.

Table 211. ip-deploy Command-Line Options

Option	Usage	Description
`--component-name[=<value>]`	Required	The name of a component you instantiate.
`--output-name[=<value>]`	Optional	Name for the resulting component; defaults to the component's type name.
`--component-parameter[=<value>]`	Optional	Repeatable. A single value assignment, like `--component-param=WIDTH=11`. To assign multiple parameters, use this option several times.
`--preset[=<value>]`	Optional	Repeatable. The name of a saved preset to use in creating a variation of the IP component. Presets are additive and repeatable.
`--family[=<value>]`	Optional	Sets the device family
`--part[=<value>]`	Optional	Sets the device part number. You can also use this command to set the base device, device speed-grade, device family, and device feature's system information.
`--output-directory[=<value>]`	Optional	This directory contains the output IP variation file. Platform Designer automatically creates the directory if the directory does not exist. If you do not specify an output directory, the output directory is the current working directory.
`--search-path[=<value>]`	Optional	If you do not specify the search path, the command uses a standard default path. If you provide a search path, Platform Designer searches a comma-separated list of paths. To include the standard path in your replacement, use "`$`", like `/extra/dir,$`.
`--jvm-max-heap-size[=<value>]`	Optional	The maximum memory size Platform Designer uses for allocations when running `qsys-edit`. You specify this value as `<size><unit>`, where unit is `m` (or `M`) for multiples of megabytes, or `g` (or `G`) for multiples of gigabytes. The default value is `512m`.
`--help`	Optional	Displays help for `ip-deploy`

7.12. Archive and Extract Platform Designer Systems with qsys-archive

The `qsys-archive` command allows you to archive a system, extract an archived system, and retrieve information about the system's dependencies.

Table 212. `qsys-archive` Command-Line Options

Option	Usage	Description
<1st arg file>	Required	The filename of the root Platform Designer system, Platform Designer file archive, or the Quartus Prime project file.
`--search-path[=<value>]`	Optional	If you omit this option, Platform Designer uses a standard default path. If you specify this option, Platform Designer searches a comma-separated list of paths. To include the standard path in your replacement, use "$", for example: `/extra/dir,$`.
`--archive`	Optional	Creates a zip archive of the specified Platform Designer system or the Quartus Prime project.
`--report-file[=<value>]`	Optional	Lists the files that the Platform Designer system or the Quartus Prime project references, and writes the files list to the specified name in `.txt` format.
`--output-directory[=<file>]`	Optional	Specifies the output directory to save the archive.
`--extract`	Optional	Extracts all the files in the given archive.
`--output-name[=<value>]`	Optional	Specifies the output name to save the archive or report.
`collect-to-common-directory[=<true|false>]`	Optional	When archiving, collects all the `.qsys` files in the root directory of the archive and all `.ip` files in a single `ip` directory, and updates all the matching references. The default option is *true*.
`new-quartus-project[=<value>]`	Optional	Creates a new Quartus Prime project which contains all the `.ip` and system files referenced by the Platform Designer system or the Quartus Prime project.
`quartus-project[=<value>]`	Optional	When you use this command in combination with: • `--report-file`—adds all the referenced files to the Quartus Prime project. • `--extract`—adds all extracted files to the specified project. • `--archive`—archives all the system and `.ip` files referenced in the Quartus Prime project.
`--rev`	Optional	Specifies the name of the Quartus Prime project revision.
`--include-generated-files`	Optional	Includes all the generated files of the Platform Designer system.
`--force`	Optional	Forcefully creates the specified archive or report, overwriting any existing archives or reports.
`--jvm-max-heap-size=<value>`	Optional	Specifies the maximum memory size Platform Designer uses for allocations when running `qsys-edit`. Specify this value as `<size><unit>`, where unit is `m` (or `M`) for multiples of megabytes, or `g` (or `G`) for multiples of gigabytes. The default value is `512m`.
`--help`	Optional	Displays help for `qsys-archive`.

Alternatively, you can archive and restore your system using the Platform Designer GUI. For more information, refer to *Saving and Archiving Platform Designer Systems* section.

Related Information

Saving and Archiving Platform Designer Systems on page 112

7.13. Apply Presets to a New Board

The `get_presets` command allows you to determine if an instance has a preset that matches the current configuration. `apply_presets` allows you to apply presets to your board.

Table 213. Scripting Command to Apply Presets to New Board

Return	Command	Argument
No return value	`apply_presets`	Applies the presets that you specify to the Platform Designer system that your specify. `<systemName_ipName_presetName>` `systemName_ipName_presetName` consists of systems name, instance name, and preset name.
String[]	`get_presets`	Determines if the instance has a preset that matches the current configuration `<instance_name> <enable_board_filter> <enable_matched_preset>` `enable_matched_preset` indicates whether to perform filtering based on the module instance's parameters and/or pin assignments values.

Example 1: Change Board and Apply Built-in Preset to Components

```
$ qsys-script --script=board_migration.tcl --quartus-project=project \
--system-file=top_system.qsys
```

`board_migration.tcl` content for a single hierarchy system example:

```
package require -exact qsys 24.1

set_project_property BOARD {new board}
set_project_property DEVICE {new part}
set_project_property DEVICE_FAMILY {new family}

apply_presets {{top_system,top_ipinst0, top_ipinst0_preset0}}
```

`board_migration.tcl` content for a multiple hierarchy system example:

```
package require -exact qsys 24.1

set_project_property BOARD {new board}
set_project_property DEVICE {new part}
set_project_property DEVICE_FAMILY {new family}

apply_presets {{top_system,top_ipinst0, top_ipinst0_preset0} \
{top_system,top_ipinst1, top_ipinst1_preset1} {sub_system_name,subipinst0,
subip_preset0}}
```

Initially, you must change the board for the project in the Quartus Prime software (**Assignments ➤ Device ➤ Board**) before you can run the script.

Example 2: Determine If System Instances are Already Configured in the New Board

```
$ qsys-script --script=board_migration.tcl --quartus-project=project \
--system-file=top_system.qsys
```

`board_migration.tcl` content for a single hierarchy system example:

```
package require -exact qsys 24.1

set_project_property BOARD {new board}
```

```
set_project_property DEVICE {new part}
set_project_property DEVICE_FAMILY {new family}

set module_list [get_instances]

foreach module $module_list {
  set num_matched_preset [llength [get_presets $module true true]]
  if ($num_matched_preset > 0) {
    # do something when the instance configured
  }
}
```

`get_presets` supports the optional `enable_matched_preset` argument that allows you to determine if the instance has a preset that matches the current configuration.

7.14. Platform Designer Scripting Command Reference

Platform Designer system scripting provides Tcl commands to manipulate your system. The `qsys-script` provides a command-line alternative to the Platform Designer tool. Use the `qsys-script` commands to create and modify your system, as well as to create reports about the system.

To use the current version of the Tcl commands, include the following line at the top of your script:

```
package require -exact qsys <version>
```

For example, for the current release of the Quartus Prime software, include:

```
package require -exact qsys 18.0
```

The Platform Designer scripting commands fall under the following categories:

7.14.1. System

This section lists the commands that allow you to manipulate a Platform Designer system.

7.14.1.1. create_system

Description

Replaces the current system with a new system of the specified name.

Usage

`create_system [<name>]`

Returns

No return value.

Arguments

name (optional) The new system name.

Example

```
create_system my_new_system_name
```

Related Information

- load_system on page 470
- save_system on page 471

7.14.1.2. export_hw_tcl

Description

Allows you to save the currently open system as an `_hw.tcl` file in the project directory. The saved systems appears under the **System** category in the IP Catalog.

Usage

`export_hw_tcl`

Returns

No return value.

Arguments

No arguments

Example

```
export_hw_tcl
```

Related Information

- load_system on page 470
- save_system on page 471

7.14.1.3. get_device_families

Description

Returns the list of installed device families.

Usage

```
get_device_families
```

Returns

String[] The list of device families.

Arguments

No arguments

Example

```
get_device_families
```

Related Information

get_devices on page 465

7.14.1.4. get_devices

Description

Returns the list of installed devices for the specified family.

Usage

`get_devices <family>`

Returns

String[] The list of devices.

Arguments

family Specifies the family name to get the devices for.

Example

```
get_devices exampleFamily
```

Related Information

get_device_families on page 464

7.14.1.5. get_module_properties

Description

Returns the properties that you can manage for a top-level module of the Platform Designer system.

Usage

```
get_module_properties
```

Returns

The list of property names.

Arguments

No arguments.

Example

```
get_module_properties
```

Related Information

- get_module_property on page 467
- set_module_property on page 473

7.14.1.6. get_module_property

Description

Returns the value of a top-level system property.

Usage

`get_module_property` <*property*>

Returns

The property value.

Arguments

property The property name to query. Refer to *Module Properties*.

Example

```
get_module_property NAME
```

Related Information

- get_module_properties on page 466
- set_module_property on page 473

7.14.1.7. get_project_properties

Description

Returns the list of properties that you can query for properties pertaining to the Quartus Prime project.

Usage

```
get_project_properties
```

Returns

The list of project properties.

Arguments

No arguments

Example

```
get_project_properties
```

Related Information

- get_project_property on page 469
- set_project_property on page 474

7.14.1.8. get_project_property

Description

Returns the value of an Quartus Prime project property.

Usage

`get_project_property` <*property*>

Returns

The property value.

Arguments

property The project property name. Refer to *Project properties*.

Example

```
get_project_property DEVICE_FAMILY
```

Related Information

- get_module_properties on page 466
- get_module_property on page 467
- set_module_property on page 473
- Project Properties on page 651

7.14.1.9. load_system

Description

Loads the Platform Designer system from a file, and uses the system as the current system for scripting commands.

Usage

`load_system` <*file*>

Returns

No return value.

Arguments

file The path to the `.qsys` file.

Example

```
load_system example.qsys
```

Related Information

- create_system on page 462
- save_system on page 471

7.14.1.10. save_system

Description

Saves the current system to the specified file. If you do not specify the file, Platform Designer saves the system to the same file opened with the `load_system` command.

Usage

`save_system` <*file*>

Returns

No return value.

Arguments

file If available, the path of the `.qsys` file to save.

Example

```
save_system
```

```
save_system file.qsys
```

Related Information

- load_system on page 470
- create_system on page 462

7.14.1.11. set_design_id

Description

Specifies an alphanumeric string that identifies the system.

If you specify `set_design_id` when creating a system, the generated system includes a SOPCINFO file with a new `design_id` attribute in the EnsembleReport element:

```
<EnsembleReport
name="my_system"
kind="my_system"
design_id="my_design_id"
version="1.0"
fabric="QSYS">
```

Usage

`set_design_id` <*design-id*>

Returns

No return value.

Arguments

design-id (optional) An alphanumeric string that identifies the system.

Example

```
set_design_id foo121
```

7.14.1.12. set_module_property

Description

Specifies the Tcl procedure to evaluate changes in Platform Designer system instance parameters.

Usage

`set_module_property` <*property*> <*value*>

Returns

No return value.

Arguments

property The property name. Refer to *Module Properties*.

value The new value of the property.

Example

```
set_module_property COMPOSITION_CALLBACK "my_composition_callback"
```

Related Information

- get_module_properties on page 466
- get_module_property on page 467
- Module Properties on page 645

7.14.1.13. set_project_property

Description

Sets the project property value, such as the device family.

Usage

`set_project_property` <*property*> <*value*>

Returns

No return value.

Arguments

property The property name. Refer to *Project Properties*.

value The new property value.

Example

```
set_project_property DEVICE_FAMILY "Cyclone IV GX"
```

Related Information

- get_project_properties on page 468
- get_project_property on page 469
- Project Properties on page 651

7.14.2. Subsystems

This section lists the commands that allow you to obtain the connection and parameter information of instances in your Platform Designer subsystem.

7.14.2.1. get_composed_connections

Description

Returns the list of all connections in the subsystem for an instance that contains the subsystem of the Platform Designer system.

Usage

`get_composed_connections` <*instance*>

Returns

The list of connection names in the subsystem.

Arguments

instance The child instance containing the subsystem.

Example

```
get_composed_connections subsystem_0
```

Related Information

- get_composed_connection_parameter_value on page 477
- get_composed_connection_parameters on page 478

7.14.2.2. get_composed_connection_parameter_value

Description

Returns the parameter value of a connection in a child instance containing the subsystem.

Usage

`get_composed_connection_parameter_value` <*instance*> <*child_connection*> <*parameter*>

Returns

The parameter value.

Arguments

instance The child instance that contains the subsystem.

child_connection The connection name in the subsystem.

parameter The parameter name to query for the connection.

Example

```
get_composed_connection_parameter_value subsystem_0 cpu.data_host/memory.s0
baseAddress
```

Related Information

- get_composed_connection_parameters on page 478
- get_composed_connections on page 476

7.14.2.3. get_composed_connection_parameters

Description

Returns the list of parameters of a connection in the subsystem, for an instance that contains the subsystem.

Usage

`get_composed_connection_parameters` <*instance*> <*child_connection*>

Returns

The list of parameter names.

Arguments

instance The child instance containing the subsystem.

child_connection The name of the connection in the subsystem.

Example

```
get_composed_connection_parameters subsystem_0 cpu.data_host/memory.s0
```

Related Information

- get_composed_connection_parameter_value on page 477
- get_composed_connections on page 476

7.14.2.4. get_composed_instance_assignment

Description

Returns the assignment value of the child instance in the subsystem.

Usage

`get_composed_instance_assignment` <*instance*> <*child_instance*> <*assignment*>

Returns

The assignment value.

Arguments

instance The subsystem containing the child instance.

child_instance The child instance name in the subsystem.

assignment The assignment key.

Example

```
get_composed_instance_assignment subsystem_0 video_0
"embeddedsw.CMacro.colorSpace"
```

Related Information

- get_composed_instance_assignments on page 480
- get_composed_instances on page 483

7.14.2.5. get_composed_instance_assignments

Description

Returns the list of assignments of the child instance in the subsystem.

Usage

`get_composed_instance_assignments` <*instance*> <*child_instance*>

Returns

The list of assignment names.

Arguments

instance The subsystem containing the child instance.

child_instance The child instance name in the subsystem.

Example

```
get_composed_instance_assignments subsystem_0 cpu
```

Related Information

- get_composed_instance_assignment on page 479
- get_composed_instances on page 483

7.14.2.6. get_composed_instance_parameter_value

Description

Returns the parameter value of the child instance in the subsystem.

Usage

`get_composed_instance_parameter_value` <*instance*> <*child_instance*> <*parameter*>

Returns

The parameter value of the instance in the subsystem.

Arguments

instance The subsystem containing the child instance.

child_instance The child instance name in the subsystem.

parameter The parameter name to query on the child instance in the subsystem.

Example

```
get_composed_instance_parameter_value subsystem_0 cpu DATA_WIDTH
```

Related Information

- get_composed_instance_parameters on page 482
- get_composed_instances on page 483

7.14.2.7. get_composed_instance_parameters

Description

Returns the list of parameters of the child instance in the subsystem.

Usage

`get_composed_instance_parameters` <*instance*> <*child_instance*>

Returns

The list of parameter names.

Arguments

instance The subsystem containing the child instance.

child_instance The child instance name in the subsystem.

Example

```
get_composed_instance_parameters subsystem_0 cpu
```

Related Information

- get_composed_instance_parameter_value on page 481
- get_composed_instances on page 483

7.14.2.8. get_composed_instances

Description

Returns the list of child instances in the subsystem.

Usage

`get_composed_instances <instance>`

Returns

The list of instance names in the subsystem.

Arguments

instance The subsystem containing the child instance.

Example

```
get_composed_instances subsystem_0
```

Related Information

- get_composed_instance_assignment on page 479
- get_composed_instance_assignments on page 480
- get_composed_instance_parameter_value on page 481
- get_composed_instance_parameters on page 482

7.14.3. Domains and Interfaces

This section lists the commands that allow you to specify parameters for domains and interfaces in your system.

Related Information

Specifying Interconnect Parameters on page 71

7.14.3.1. set_domain_assignment

Description

Sets the assignment value to all connections on the given domain.

Usage

```
set_domain_assignment <element> <assignment> <value>
```

Arguments

element Connection or interface in the domain to set with assignment. If element name is $system, assigns to all the domains in the system.

assignment The name of the assignment.

value The value of the assignment.

7.14.3.2. get_domain_assignment

Description

Obtains the value for specified assignment in the given domain.

Usage

```
get_domain_assignment <element> <assignment>
```

Arguments

element Connection or interface in the domain for which you want the assignment value.

assignment The name of the assignment.

7.14.3.3. get_domain_assignments

Description

Obtains all domain assignments for the given domain as a list of strings. Each "group" of three elements in the list contains the element name, assignment name, and value (in that order). Element name in the output is the input element name. If the input element is $system, then the output element name is the connection point in the domain. For example, typical list contents appear like this:

```
[element0 name0 value0 element1 name1 value1 ... ]
```

In TCL, you'd loop over the list by writing a foreach loop:

```
foreach {element name value } $requirement_list \
     { puts " $element $name $value" }
```

Usage

```
get_domain_assignments <element>
```

Arguments

element Connection or interface in the domain for which you want to get assignments. If element is specified as $system, gives values of all the domains in the system.

7.14.3.4. set_interface_assignment

Description

Adds interconnect assignment to the interface.

Usage

```
set_interface_assignment <interface> <assignment> <value>
```

Arguments

interface Interface name.

assignment The name of the assignment.

value The value of the assignment.

7.14.3.5. get_interface_assignment

Description

Obtains the value of the named interface interconnect assignment on the specified interface.

Usage

```
get_interface_assignment <interface> <assignment>
```

Arguments

interface Interface name.

assignment The name of the assignment.

7.14.3.6. get_interface_assignments

Description

Obtains all interface interconnect assignments for the given domain as a list of strings. Each "group" of three elements in the list contains the interface name, assignment name, and value (in that order). For example, typical list contents might look like this:

```
[interface0 name0 value0 interface1 name1 value1 ... ]
```

In TCL, you'd loop over the list by writing a foreach loop:

```
foreach {interface name value } $requirement_list \
     { puts " $interface $name $value" }
```

Usage

```
get_interface_assignments <interface>
```

Arguments

interface Interface name that you want to get assignments for. If interface is specified as $system , it gives assignments of all the interfaces in the system.

assignment The name of the assignment.

7.14.3.7. set_postadaptation_assignment

Description

Adds a post adaptation interconnect assignment.

Usage

```
set_postadaptation_assignment <element> <assignment> <value>
```

Arguments

element Element name.

assignment The name of the assignment.

value The value of the assignment.

7.14.3.8. get_postadaptation_assignment

Description

Obtains the value of the named post adaptation interconnect assignment on the specified element.

Usage

```
get_postadaptation_assignment <element> <assignment>
```

Arguments

element Element name.

assignment The name of the assignment.

7.14.3.9. get_postadaptation_assignments

Description

Obtains all post adaptation interconnect assignments for the given domain as a list of strings. Each "group" of three elements in the list contains the element name, assignment name, and value (in that order). For example, typical list contents might look like this:

```
[element0 name0 value0 element1 name1 value1 ... ]
```

In TCL, you'd loop over the list by writing a foreach loop:

```
foreach {element name value } $requirement_list \
     { puts " $element $name $value" }
```

Usage

```
get_postadaptation_assignments <interface>
```

Arguments

interface Interface name that you want to get assignments for. If interface is specified as $system , it gives assignments of all the interfaces in the system.

7.14.4. Instances

This section lists the commands that allow you to manipulate the instances of IP components in your Platform Designer system.

7.14.4.1. add_instance

Description

Adds an instance of a component, referred to as a *child* or *child instance*, to the system.

Usage

`add_instance` <*name*> <*type*> [<*version*>]

Returns

No return value.

Arguments

name Specifies a unique local name that you can use to manipulate the instance. Platform Designer uses this name in the generated HDL to identify the instance.

type Refers to a kind of instance available in the IP Catalog, for example `altera_avalon_uart`.

version The required version of the specified instance type. This argument is required in Package version 19.1 and later. Before package version 19.1, when not specified the latest IP version is used.

Example

```
add_instance uart_0 altera_avalon_uart 22.2
```

Related Information

- get_instance_property on page 514
- get_instances on page 515
- remove_instance on page 517
- set_instance_parameter_value on page 518
- get_instance_parameter_value on page 509

7.14.4.2. apply_instance_preset

Description

Applies the settings in a preset to the specified instance.

Usage

`apply_instance_preset` <*preset_name*>

Returns

No return value.

Arguments

preset_name The preset name.

Example

```
apply_preset "Custom Debug Settings"
```

Related Information

set_instance_parameter_value on page 518

7.14.4.3. create_ip

Description

Creates a new IP Variation system with the given instance.

Usage

`create_ip` <*type*> [<*instance_name*> <*version*>]

Returns

No return value.

Arguments

type Kind of instance available in the IP catalog, for example, `altera_avalon_uart`.

instance_name (optional) A unique local name that you can use to manipulate the instance. If not specified, Platform Designer uses a default name.

version (optional) The required version of the specified instance type. If not specified, Platform Designer uses the latest version.

Example

```
create_ip altera_avalon_uart altera_avalon_uart_inst 17.0
```

Related Information

- add_component on page 492
- load_system on page 470
- save_system on page 471
- set_instance_parameter_value on page 518

7.14.4.4. add_component

Description

Adds a new IP Variation component to the system.

Usage

`add_component` <*instance_name*> <*file_name*> [<*component_type*> <*component_instance_name*> <*component_version*>]

Returns

No return value.

Arguments

instance_name A unique local name that you can use to manipulate the instance.

file_name The IP variation file name. If a path is not specified, Platform Designer saves the file in the `./ip/system/` sub-folder of your system.

component_type (optional) The kind of instance available in the IP catalog, for example `altera_avalon_uart`.

component_instance_name (optional) The instance name of the component in the IP variation file. If not specified, Platform Designer uses a default name.

component_version (optional) The required version of the specified instance type. If not specified, Platform Designer uses the latest version.

Example

```
add_component myuart_0 myuart.ip altera_avalon_uart altera_avalon_uart_inst 17.0
```

Related Information

save_system on page 471

7.14.4.5. duplicate_instance

Description

Creates a duplicate instance of the specified instance.

Usage

`duplicate_instance` <*instance*> [<*name*>]

Returns

String The new instance name.

Arguments

instance Specifies the instance name to duplicate.

name (*optional*) Specifies the name of the duplicate instance.

Example

```
duplicate_instance cpu cpu_0
```

Related Information

- add_instance on page 489
- remove_instance on page 517

7.14.4.6. enable_instance_parameter_update_callback

Description

Enables the update callback for instance parameters.

Usage

`enable_instance_parameter_update_callback [<value>]`

Returns

No return value.

Arguments

value (*optional*)	Specifies whether to enable/disable the instance parameters callback. Default option is "1".

Example

```
enabled_instance_parameter_update_callback
```

Related Information

- is_instance_parameter_update_callback_enabled on page 516
- set_instance_parameter_value on page 518

7.14.4.7. get_instance_assignment

Description

Returns the assignment value of a child instance. Platform Designer uses assignments to transfer information about hardware to embedded software tools and applications.

Usage

`get_instance_assignment` <*instance*> <*assignment*>

Returns

String The value of the specified assignment.

Arguments

instance The instance name.

assignment The assignment key to query.

Example

```
get_instance_assignment video_0 embeddedsw.CMacro.colorSpace
```

Related Information

get_instance_assignments on page 496

7.14.4.8. get_instance_assignments

Description

Returns the list of assignment keys for any defined assignments for the instance.

Usage

`get_instance_assignments <instance>`

Returns

String[] The list of assignment keys.

Arguments

instance The instance name.

Example

```
get_instance_assignments sdram
```

Related Information

get_instance_assignment on page 495

7.14.4.9. get_instance_documentation_links

Description

Returns the list of all documentation links provided by an instance.

Usage

`get_instance_documentation_links` <*instance*>

Returns

String[] The list of documentation links.

Arguments

instance The instance name.

Example

```
get_instance_documentation_links cpu_0
```

Notes

The list of documentation links includes titles and URLs for the links. For instance, a component with a single data sheet link may return:

```
{Data Sheet} {http://url/to/data/sheet}
```

7.14.4.10. get_instance_interface_assignment

Description

Returns the assignment value for an interface of a child instance. Platform Designer uses assignments to transfer information about hardware to embedded software tools and applications.

Usage

`get_instance_interface_assignment` <*instance*> <*interface*> <*assignment*>

Returns

String The value of the specified assignment.

Arguments

instance The child instance name.

interface The interface name.

assignment The assignment key to query.

Example

```
get_instance_interface_assignment sdram s1 embeddedsw.configuration.isFlash
```

Related Information

get_instance_interface_assignments on page 499

7.14.4.11. get_instance_interface_assignments

Description

Returns the list of assignment keys for any assignments defined for an interface of a child instance.

Usage

`get_instance_interface_assignments` <*instance*> <*interface*>

Returns

String[] The list of assignment keys.

Arguments

instance The child instance name.

interface The interface name.

Example

```
get_instance_interface_assignments sdram s1
```

Related Information

get_instance_interface_assignment on page 498

7.14.4.12. get_instance_interface_parameter_property

Description

Returns the property value for a parameter in an interface of an instance. Parameter properties are metadata about how Platform Designer uses the parameter.

Usage

`get_instance_interface_parameter_property` <*instance*> <*interface*> <*parameter*> <*property*>

Returns

various The parameter property value.

Arguments

instance The child instance name.

interface The interface name.

parameter The parameter name for the interface.

property The property name for the parameter. Refer to *Parameter Properties*.

Example

```
get_instance_interface_parameter_property uart_0 s0 setupTime ENABLED
```

Related Information

- get_instance_interfaces on page 502
- get_instance_interfaces on page 507
- get_parameter_properties on page 627
- Parameter Properties on page 646

7.14.4.13. get_instance_interface_parameter_value

Description

Returns the parameter value of an interface in an instance.

Usage

`get_instance_interface_parameter_value` <*instance*> <*interface*> <*parameter*>

Returns

various The parameter value.

Arguments

instance The child instance name.

interface The interface name.

parameter The parameter name for the interface.

Example

```
get_instance_interface_parameter_value uart_0 s0 setupTime
```

Related Information

- get_instance_interface_parameters on page 502
- get_instance_interfaces on page 507

7.14.4.14. get_instance_interface_parameters

Description

Returns the list of parameters for an interface in an instance.

Usage

`get_instance_interface_parameters` <*instance*> <*interface*>

Returns

String[] The list of parameter names for parameters in the interface.

Arguments

instance The child instance name.

interface The interface name.

Example

```
get_instance_interface_parameters uart_0 s0
```

Related Information

- get_instance_interface_parameter_value on page 501
- get_instance_interfaces on page 507

7.14.4.15. get_instance_interface_port_property

Description

Returns the property value of a port in the interface of a child instance.

Usage

`get_instance_interface_port_property` <*instance*> <*interface*> <*port*> <*property*>

Returns

various The port property value.

Arguments

instance The child instance name.

interface The interface name.

port The port name.

property The property name of the port. Refer to *Port Properties*.

Example

```
get_instance_interface_port_property uart_0 exports tx WIDTH
```

Related Information

- get_instance_interface_ports on page 504
- get_port_properties on page 607
- Port Properties on page 650

7.14.4.16. get_instance_interface_ports

Description

Returns the list of ports in an interface of an instance.

Usage

`get_instance_interface_ports` <*instance*> <*interface*>

Returns

String[] The list of port names in the interface.

Arguments

instance The instance name.

interface The interface name.

Example

```
get_instance_interface_ports uart_0 s0
```

Related Information

- get_instance_interface_port_property on page 503
- get_instance_interfaces on page 507

7.14.4.17. get_instance_interface_properties

Description

Returns the list of properties that you can query for an interface in an instance.

Usage

```
get_instance_interface_properties
```

Returns

String[] The list of property names.

Arguments

No arguments.

Example

```
get_instance_interface_properties
```

Related Information

- get_instance_interface_property on page 506
- get_instance_interfaces on page 507

7.14.4.18. get_instance_interface_property

Description

Returns the property value for an interface in a child instance.

Usage

`get_instance_interface_property` <*instance*> <*interface*> <*property*>

Returns

String The property value.

Arguments

instance The child instance name.

interface The interface name.

property The property name. Refer to *Element Properties*.

Example

```
get_instance_interface_property uart_0 s0 DESCRIPTION
```

Related Information

- get_instance_interface_properties on page 505
- get_instance_interfaces on page 507
- Element Properties on page 641

7.14.4.19. get_instance_interfaces

Description

Returns the list of interfaces in an instance.

Usage

`get_instance_interfaces <instance>`

Returns

String[] The list of interface names.

Arguments

instance The instance name.

Example

```
get_instance_interfaces uart_0
```

Related Information

- get_instance_interface_ports on page 504
- get_instance_interface_properties on page 505
- get_instance_interface_property on page 506

7.14.4.20. get_instance_parameter_property

Description

Returns the property value of a parameter in an instance. Parameter properties are metadata about how Platform Designer uses the parameter.

Usage

`get_instance_parameter_property` <*instance*> <*parameter*> <*property*>

Returns

various The parameter property value.

Arguments

instance The instance name.

parameter The parameter name.

property The property name of the parameter. Refer to *Parameter Properties*.

Example

```
get_instance_parameter_property uart_0 baudRate ENABLED
```

Related Information

- get_instance_parameters on page 511
- get_parameter_properties on page 627
- Parameter Properties on page 646

7.14.4.21. get_instance_parameter_value

Description

Returns the parameter value in a child instance.

Usage

`get_instance_parameter_value` <*instance*> <*parameter*>

Returns

various The parameter value.

Arguments

instance The instance name.

parameter The parameter name.

Example

```
get_instance_parameter_value pixel_converter input_DPI
```

Related Information

- get_instance_parameters on page 511
- set_instance_parameter_value on page 518

7.14.4.22. get_instance_parameter_values

Description

Returns a list of the parameters' values in a child instance.

Usage

`get_instance_parameter_values` <*instance*> <*parameters*>

Returns

String[] A list of the parameters' value.

Arguments

instance The child instance name.

parameter A list of parameter names in the instance.

Example

```
get_instance_parameter_value uart_0 [list param1 param2]
```

Related Information

- get_instance_parameters on page 511
- set_instance_parameter_value on page 518
- set_instance_parameter_values on page 519

7.14.4.23. get_instance_parameters

Description

Returns the names of all parameters for a child instance that the parent can manipulate. This command omits derived parameters and parameters that have the SYSTEM_INFO parameter property set.

Usage

`get_instance_parameters` <*instance*>

Returns

instance The list of parameters in the instance.

Arguments

instance The instance name.

Example

```
get_instance_parameters uart_0
```

Related Information

- get_instance_parameter_property on page 508
- get_instance_parameter_value on page 509
- set_instance_parameter_value on page 518

7.14.4.24. get_instance_port_property

Description

Returns the property value of a port contained by an interface in a child instance.

Usage

`get_instance_port_property` <*instance*> <*port*> <*property*>

Returns

various The property value for the port.

Arguments

instance The child instance name.

port The port name.

property The property name. Refer to *Port Properties*.

Example

```
get_instance_port_property uart_0 tx WIDTH
```

Related Information

- get_instance_interface_ports on page 504
- get_port_properties on page 607
- Port Properties on page 650

7.14.4.25. get_instance_properties

Description

Returns the list of properties for a child instance.

Usage

```
get_instance_properties
```

Returns

String[] The list of property names for the child instance.

Arguments

No arguments.

Example

```
get_instance_properties
```

Related Information

get_instance_property on page 514

7.14.4.26. get_instance_property

Description

Returns the property value for a child instance.

Usage

`get_instance_property` <*instance*> <*property*>

Returns

String The property value.

Arguments

instance The child instance name.

property The property name. Refer to *Element Properties*.

Example

```
get_instance_property uart_0 ENABLED
```

Related Information

- get_instance_properties on page 513
- Element Properties on page 641

7.14.4.27. get_instances

Description

Returns the list of the instance names for all the instances in the system.

Usage

```
get_instances
```

Returns

String[] The list of child instance names.

Arguments

No arguments.

Example

```
get_instances
```

Related Information

- add_instance on page 489
- remove_instance on page 517

7.14.4.28. is_instance_parameter_update_callback_enabled

Description

Returns true if you enable the update callback for instance parameters.

Usage

```
is_instance_parameter_update_callback_enabled
```

Returns

boolean 1 if you enable the callback; 0 if you disable the callback.

Arguments

No arguments

Example

```
is_instance_parameter_update_callback_enabled
```

Related Information

enable_instance_parameter_update_callback on page 494

7.14.4.29. remove_instance

Description

Removes an instance from the system.

Usage

`remove_instance <instance>`

Returns

No return value.

Arguments

instance The child instance name to remove.

Example

```
remove_instance cpu
```

Related Information

- add_instance on page 489
- get_instances on page 515

7.14.4.30. set_instance_parameter_value

Description

Sets the parameter value for a child instance. You cannot set derived parameters and SYSTEM_INFO parameters for the child instance with this command.

Usage

`set_instance_parameter_value` <*instance*> <*parameter*> <*value*>

Returns

No return value.

Arguments

instance The child instance name.

parameter The parameter name.

value The parameter value.

Example

```
set_instance_parameter_value uart_0 baudRate 9600
```

Related Information

- get_instance_parameter_value on page 509
- get_instance_parameter_property on page 508

7.14.4.31. set_instance_parameter_values

Description

Sets a list of parameter values for a child instance. You cannot set derived parameters and SYSTEM_INFO parameters for the child instance with this command.

Usage

`set_instance_parameter_value` <*instance*> <*parameter_value_pairs*>

Returns

No return value.

Arguments

instance The child instance name.

parameter_value_pairs The pairs of parameter name and value to set.

Example

```
set_instance_parameter_value uart_0 [list baudRate 9600 parity odd]
```

Related Information

- get_instance_parameter_value on page 509
- get_instance_parameter_values on page 510
- get_instance_parameters on page 511

7.14.4.32. set_instance_property

Description

Sets the property value of a child instance. Most instance properties are read-only and can only be set by the instance itself. The primary use for this command is to update the ENABLED parameter, which includes or excludes a child instance when generating Platform Designer interconnect.

Usage

`set_instance_property` <*instance*> <*property*> <*value*>

Returns

No return value.

Arguments

instance The child instance name.

property The property name. Refer to *Instance Properties*.

value The property value.

Example

```
set_instance_property cpu ENABLED false
```

Related Information

- get_instance_parameters on page 511
- get_instance_property on page 514
- Instance Properties on page 642

7.14.5. Instantiations

This section lists the commands that allow you to manipulate the loaded instantiations in a Platform Designer system.

7.14.5.1. add_instantiation_hdl_file

Description

Adds an HDL file to the loaded instantiation.

Usage

`add_instantiation_hdl_file <file> [<kind>]`

Returns

No return value.

Arguments

file Specifies the HDL file name.

kind(optional) Indicates the file set kind to add the file to. If you do not specify this option, the command adds the file to all the file sets. Refer to *File Set Kind*.

Example

```
add_instantiation_hdl_file my_nios2_gen2.vhdl quartus_synth
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- File Set Kind on page 657

7.14.5.2. add_instantiation_interface

Description

Adds an interface to the loaded instantiation.

Usage

`add_instantiation_interface` <*interface*> <*type*> <*direction*>

Returns

No return value.

Arguments

interface Specifies the interface name.

type Specifies the interface type.

direction Specifies the interface direction. Refer to *Interface Direction*.

Example

```
add_instantiation_interface clk_0 clock OUTPUT
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Interface Direction on page 656

7.14.5.3. add_instantiation_interface_port

Description

Adds a port to a loaded instantiation's interface.

Usage

`add_instantiation_interface_port` *<interface> <port> <role> <width> <vhdl_type><direction>*

Returns

No return value.

Arguments

interface Specifies the interface name.

port Specifies the port name.

role Specifies the port role.

width Specifies the port width.

vhdl_type Specifies the VHDL type of the port. Refer to *VHDL Type*.

direction Specifies the port direction. Refer to *Direction Properties*.

Example

```
add_instantiation_interface_port avs_s0 avs_s0_address address 8 {standard logic
vector} input
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- VHDL Type on page 664
- Direction Properties on page 640

7.14.5.4. copy_instance_interface_to_instantiation

Description

Adds an interface to a loaded instantiation by copying the specified interface of another instance.

Usage

`copy_instance_interface_to_instantiation` <*instance*> <*interface*> <*type*>

Returns

String The name of the newly added interface.

Arguments

instance Specifies the name of the instance to copy the interface from.

interface Specifies the name of the interface to copy.

type Specifies the type of copy to make. Refer to *Instantiation Interface Duplicate Type*.

Example

```
copy_instance_interface_to_instantiation cpu_0 data_host CLONE
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Instantiation Interface Duplicate Type on page 660

7.14.5.5. get_instantiation_assignment_value

Description

Gets the assignment value on the loaded instantiation.

Usage

`get_instantiation_assignment_value <name>`

Returns

String The assignment value.

Arguments

name Specifies the name of the assignment to get the value of.

Example

```
get_instantiation_assignment_value embeddedsw.configuration.exceptionOffset
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.6. get_instantiation_assignments

Description

Gets the assignment names in the loaded instantiation.

Usage

```
get_instantiation_assignments
```

Returns

String[] The list of assignment names.

Arguments

No arguments

Example

```
get_instantiation_assignments
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.7. get_instantiation_hdl_file_properties

Description

Returns the list of properties in an HDL file associated with an instantiation.

Usage

```
get_instantiation_hdl_file_properties
```

Returns

String[] The list of property names.

Arguments

No arguments

Example

```
get_instantiation_hdl_file_properties
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.8. get_instantiation_hdl_file_property

Description

Returns the property value of an HDL file associated with the loaded instantiation.

Usage

`get_instantiation_hdl_file_property` <*file*> <*property*>

Returns

various The property value.

Arguments

file Specifies the HDL file name.

property Specifies the property name. Refer to *Instantiation Hdl File Properties*.

Example

```
get_instantiation_hdl_file_property my_nios2_gen2.vhdl OUTPUT_PATH
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Instantiation HDL File Properties on page 659

7.14.5.9. get_instantiation_hdl_files

Description

Returns the list of HDL files of the loaded instantiation.

Usage

`get_instantiation_hdl_files` [<*kind*>]

Returns

String[] The list of HDL file names.

Arguments

kind (*optional*) Specifies the file set kind to get the files of. If you do not specify this option, the command gets the QUARTUS_SYNTH files. Refer to *File Set Kind*.

Example

```
get_instantiation_hdl_files quartus_synth
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- File Set Kind on page 657

7.14.5.10. get_instantiation_interface_assignment_value

Description

Gets the assignment value of the loaded instantiation's interface.

Usage

`get_instantiation_interface_assignment_value` <*interface*> <*name*>

Returns

String The assignment value

Arguments

interface Specifies the interface name.

name Specifies the assignment name to get the value of.

Example

```
get_instantiation_interface_assignment_value avs_s0
embeddedsw.configuration.exceptionOffset
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.11. get_instantiation_interface_assignments

Description

Gets the assignment names of the loaded instantiation's interface.

Usage

`get_instantiation_interface_assignments` <*interface*>

Returns

String[] The list of assignment names.

Arguments

interface Specifies the interface name.

Example

```
get_instantiation_interface_assignments avs_s0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.12. get_instantiation_interface_parameter_value

Description

Returns the parameter value of a loaded instantiation's interface.

Usage

`get_instantiation_interface_parameter_value` <*interface*> <*parameter*>

Returns

String The parameter value.

Arguments

interface Specifies the interface name.

parameter Specifies the parameter name.

Example

```
get_instantiation_interface_parameter_value avs_s0 associatedClock
```

Related Information

- get_instantiation_interface_parameters on page 535
- set_instantiation_interface_parameter_value on page 556
- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.13. get_instantiation_interface_parameters

Description

Returns the list of parameters of an instantiation's interface.

Usage

`get_instantiation_interface_parameters` <*interface*>

Returns

String[] The list of parameter names.

Arguments

interface Specifies the interface name.

Example

```
get_instantiation_interface_parameters avs_s0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- get_instantiation_interface_parameter_value on page 534
- set_instantiation_interface_parameter_value on page 556

7.14.5.14. get_instantiation_interface_port_properties

Description

Returns the list of port properties of an instantiation's interface.

Usage

```
get_instantiation_interface_port_properties
```

Returns

String[] The list of port properties.

Arguments

No arguments

Example

```
get_instantiation_interface_port_properties
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.15. get_instantiation_interface_port_property

Description

Returns the port property value of a loaded instantiation's interface.

Usage

`get_instantiation_interface_port_property` <*interface*> <*port*> <*property*>

Returns

various The property value.

Arguments

interface Specifies the interface name.

port Specifies the port name.

property Specifies the property name. Refer to *Port Properties*.

Example

```
get_instantiation_interface_port_property avs_s0 avs_s0_address WIDTH
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Port Properties on page 663

7.14.5.16. get_instantiation_interface_ports

Description

Returns the list of ports of the loaded instantiation's interface.

Usage

`get_instantiation_interface_ports <interface>`

Returns

String[] The list of port names.

Arguments

interface Specifies the interface name.

Example

```
get_instantiation_interface_ports avs_s0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.17. get_instantiation_interface_property

Description

Returns the value of a single interface property from the specified instantiation interface.

Usage

`get_instantiation_interface_property` <*interface*> <*property*>

Returns

various The property value.

Arguments

interface The interface name on the currently loaded interface.

property The property name. Refer to *Instantiation Interface Properties*.

Example

```
get_instantiation_interface_property in_clk TYPE
```

Related Information

- get_instantiation_interface_properties on page 540
- load_instantiation on page 548
- Instantiation Interface Properties on page 661

7.14.5.18. get_instantiation_interface_properties

Description

Returns the names of all the available instantiation interface properties, common to all interface types.

Usage

```
get_instantiation_interface_properties
```

Returns

String[] A list of instantiation interface properties.

Arguments

No arguments.

Example

```
get_instantiation_interface_properties
```

Related Information

get_instantiation_interface_property on page 539

7.14.5.19. get_instantiation_interface_sysinfo_parameter_value

Description

Gets the system info parameter value for a loaded instantiation's interface.

Usage

`get_instantiation_interface_sysinfo_parameter_value` <*interface*> <*parameter*>

Returns

various The system info property value.

Arguments

interface Specifies the interface name.

parameter Specifies the system info parameter name. Refer to *System Info Type*.

Example

```
get_instantiation_interface_sysinfo_parameter_value debug_mem_agent
max_agent_data_width
```

Related Information

- get_instantiation_interface_sysinfo_parameters on page 542
- set_instantiation_interface_sysinfo_parameter_value on page 558
- System Info Type Properties on page 652

7.14.5.20. get_instantiation_interface_sysinfo_parameters

Description

Returns the list of system info parameters for the loaded instantiation's interface.

Usage

`get_instantiation_interface_sysinfo_parameters` <*interface*> [<*type*>]

Returns

String[] The list of system info parameter names.

Arguments

interface Specifies the interface name.

type (*optional*) Specifies the parameters type to return. If you do not specify this option, the command returns all the parameters. Refer to *Access Type*.

Example

```
get_instantiation_interface_sysinfo_parameters debug_mem_agent
```

Related Information

- get_instantiation_interface_sysinfo_parameter_value on page 541
- set_instantiation_interface_sysinfo_parameter_value on page 558
- Access Type on page 658

7.14.5.21. get_instantiation_interfaces

Description

Returns the list of interfaces for the loaded instantiation.

Usage

```
get_instantiation_interfaces
```

Returns

String[] The list of interface names.

Arguments

No arguments.

Example

```
get_instantiation_interfaces
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.22. get_instantiation_properties

Description

Returns the list of properties for the loaded instantiation.

Usage

```
get_instantiation_properties
```

Returns

String[] The list of property names.

Arguments

No arguments.

Example

```
get_instantiation_properties
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.23. get_instantiation_property

Description

Returns the value of the specified property for the loaded instantiation.

Usage

`get_instantiation_property` <*property*>

Returns

various The value of an instantiation property.

Arguments

property Specifies the property name to get the value of. Refer to *Instantiation Properties*.

Example

```
get_instantiation_property HDL_ENTITY_NAME
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Instantiation Properties on page 662

7.14.5.24. get_loaded_instantiation

Description

Returns the instance name of the loaded instantiation.

Usage

```
get_loaded_instantiation
```

Returns

String The instance name.

Arguments

No arguments

Example

```
get_loaded_instantiation
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.25. import_instantiation_interfaces

Description

Sets the interfaces of a loaded instantiation by importing the interfaces from the specified file.

Usage

`import_instantiation_interfaces <file>`

Returns

No return value

Arguments

file Specifies the IP or IP-XACT file to import the interfaces from.

Example

```
import_instantiation_interfaces ip/my_system/my_system_nios2_gen2_0.ip
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.26. load_instantiation

Description

Loads the instantiation of an instance, so that you can modify the instantiation if necessary.

Usage

`load_instantiation` <*instance*>

Returns

boolean 1 if successful; 0 if unsuccessful.

Arguments

instance Specifies the instance name.

Example

```
load_instantiation cpu
```

Related Information

save_instantiation on page 552

7.14.5.27. remove_instantiation_hdl_file

Description

Removes an HDL file from the loaded instantiation.

Usage

`remove_instantiation_hdl_file` <*file*> [<*kind*>]

Returns

No return value.

Arguments

file Specifies the HDL file name.

kind (*optional*) Specifies the kind of file set to remove the file from. If you do not specify this option, the command removes the file from all the file sets. Refer to *File Set Kind*.

Example

```
remove_instantiation_hdl_file my_counter.vhdl quartus_synth
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- File Set Kind on page 657

7.14.5.28. remove_instantiation_interface

Description

Removes an interface from a loaded instantiation.

Usage

`remove_instantiation_interface` <*interface*>

Returns

No return value

Arguments

interface Specifies the interface name.

Example

```
remove_instantiation_interface avs_s0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.29. remove_instantiation_interface_port

Description

Removes a port from a loaded instantiation's interface.

Usage

`remove_instantiation_interface_port` <*interface*> <*port*>

Returns

No return value

Arguments

interface Specifies the interface name.

port Specifies the port name.

Example

```
remove_instantiation_interface_port avs_s0 avs_s0_address
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.5.30. save_instantiation

Description

Saves the loaded instantiation.

Usage

```
save_instantiation
```

Returns

No return value

Arguments

No arguments

Example

```
save_instantiation
```

Related Information

load_instantiation on page 548

7.14.5.31. set_instantiation_assignment_value

Description

Sets the assignment value for the loaded instantiation.

Usage

`set_instantiation_assignment_value` <*name*> [<*value*>]

Returns

No return value

Arguments

instance Specifies the assignment name to set value for.

value (*optional*) Specifies the assignment value. If you do not specify this option, the command removes the assignment.

Example

```
set_instantiation_assignment_value embeddedsw.configuration.exceptionOffset 32
```

Related Information

get_instantiation_assignment_value on page 527

7.14.5.32. set_instantiation_hdl_file_property

Description

Sets the property value for an HDL file associated with a loaded instantiation.

Usage

`set_instantiation_hdl_file_property<file> <property> <value>`

Returns

No return value

Arguments

file Specifies the HDL file name.

property Specifies the property name. Refer to *Instantiation Hdl File Properties*.

value Specifies the property value.

Example

```
set_instantiation_hdl_file_property my_nios2_gen2.vhdl OUTPUT_PATH
my_nios2_gen2.vhdl
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Instantiation HDL File Properties on page 659

7.14.5.33. set_instantiation_interface_assignment_value

Description

Sets the assignment value for the loaded instantiation's interface.

Usage

`set_instantiation_interface_assignment_value` <*interface*> <*name*> [<*value*>]

Returns

No return value

Arguments

interface Specifies the interface name.

name Specifies the assignment name to set the value of.

value (*optional*) Specifies the new assignment value. If you do not specify this value, the command removes the assignment.

Example

```
set_instantiation_interface_assignment_value
embeddedsw.configuration.exceptionOffset 32
```

Related Information

get_instantiation_assignment_value on page 527

7.14.5.34. set_instantiation_interface_parameter_value

Description

Sets the parameter value for the loaded instantiation's interface.

Usage

`set_instantiation_interface_parameter_value` <*interface*> <*parameter*> <*value*>

Returns

No return value

Arguments

instance Specifies the interface name.

parameter Specifies the parameter name.

value Specifies the parameter value.

Example

```
set_instantiation_interface_parameter avs_s0 associatedClock clk
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- get_instantiation_interface_parameter_value on page 534
- get_instantiation_interface_parameters on page 535

7.14.5.35. set_instantiation_interface_port_property

Description

Sets the port property value on a loaded instantiation's interface.

Usage

`set_instantiation_interface_port_property` <*interface*> <*port*> <*property*> <*value*>

Returns

No return value

Arguments

interface Specifies the interface name.

port Specifies the port name.

property Specifies the property name. Refer to *Port Properties*.

value Specifies the property value.

Example

```
set_instantiation_interface_port_property avs_s0 avs_s0_address WIDTH 1
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Port Properties on page 663

7.14.5.36. set_instantiation_interface_sysinfo_parameter_value

Description

Sets the system info parameter value for the loaded instantiation's interface.

Usage

`set_instantiation_interface_sysinfo_parameter_value` <*interface*> <*parameter*> <*value*>

Returns

No return value

Arguments

interface Specifies the interface name.

parameter Specifies the system info parameter name. Refer to *System Info Type*.

value Specifies the system info parameter value.

Example

```
set_instantiation_interface_sysinfo_parameter_value debug_mem_agent
max_agent_data_width 64
```

Related Information

- get_instantiation_interface_sysinfo_parameter_value on page 541
- get_instantiation_interface_sysinfo_parameters on page 542
- System Info Type Properties on page 652

7.14.5.37. set_instantiation_property

Description

Sets the property value for the loaded instantiation.

Usage

`set_instantiation_property` <*property*> <*value*>

Returns

No return value

Arguments

property Specifies the property name. Refer to *Instantiation Properties*.

value Specifies the value to set.

Example

```
set_instantiation_property HDL_ENTITY_NAME my_system_nios2_gen2_0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- Instantiation Properties on page 662

7.14.6. Components

This section lists the commands that allow you to manipulate the IP components loaded in a Platform Designer system.

7.14.6.1. apply_component_preset

Description

Applies the settings in a preset to the loaded component.

Usage

`apply_component_preset<`*preset_name*`>`

Returns

No return value

Arguments

preset_name Specifies the preset name.

Example

```
apply_component_preset "Custom Debug Settings"
```

Related Information

- load_component on page 581
- set_component_parameter_value on page 584

7.14.6.2. get_component_assignment

Description

Returns the assignment value for the loaded component.

Usage

`get_component_assignment <assignment>`

Returns

String The specified assignment value.

Arguments

assignment Specifies the assignment key value to query.

Example

```
get_component_assignment embeddedsw.CMacro.colorSpace
```

Related Information

- load_component on page 581
- get_component_assignments on page 563

7.14.6.3. get_component_assignments

Description

Returns the list of assignment keys for the loaded component.

Usage

```
get_component_assignments
```

Returns

String[] The list of assignment keys.

Arguments

No arguments

Example

```
get_component_assignments
```

Related Information

- get_instance_assignment on page 495
- load_component on page 581

7.14.6.4. get_component_documentation_links

Description

Returns the list of all documentation links that the loaded component provides.

Usage

```
get_component_documentation_links
```

Returns

String[] The list of documentation links.

Arguments

No arguments

Example

```
get_component_documentation_links
```

Related Information

load_component on page 581

7.14.6.5. get_component_interface_assignment

Description

Returns the assignment value of an interface of the loaded component.

Usage

`get_component_interface_assignment` <*interface*> <*assignment*>

Returns

String The specified assignment value.

Arguments

interface Specifies the interface name.

assignment Specifies the assignment key to the query.

Example

```
get_component_interface_assignment s1 embeddedsw.configuration.isFlash
```

Related Information

- get_component_interface_assignments on page 566
- load_component on page 581

7.14.6.6. get_component_interface_assignments

Description

Returns the list of assignment keys for any assignments that you define for an interface on the loaded component.

Usage

`get_component_interface_assignments` <*interface*>

Returns

String[] The list of assignment keys.

Arguments

interface Specifies the interface name.

Example

```
get_component_interface_assignments s1
```

Related Information

- get_component_interface_assignment on page 565
- load_component on page 581

7.14.6.7. get_component_interface_parameter_property

Description

Returns the property value of a parameter in a loaded component's interface. Parameter properties are metadata about how the Quartus Prime uses the parameters.

Usage

`get_component_interface_parameter_property` <*interface*> <*parameter*> <*property*>

Returns

various The parameter property value.

Arguments

interface Specifies the interface name.

parameter Specifies the parameter name.

property Specifies the parameter property. Refer to *Parameter Properties*.

Example

```
get_component_interface_parameter_property s0 setupTime ENABLED
```

Related Information

- get_component_interface_parameters on page 569
- get_component_interfaces on page 573
- load_component on page 581
- Parameter Properties on page 646
- get_parameter_properties on page 627

7.14.6.8. get_component_interface_parameter_value

Description

Returns the parameter value of an interface of the loaded component.

Usage

`get_component_interface_parameter_value` <*interface*> <*parameter*>

Returns

various The parameter value.

Arguments

interface Specifies the interface name.

parameter Specifies the parameter name.

Example

```
get_component_interface_parameter_value s0 setupTime
```

Related Information

- get_component_interface_parameters on page 569
- get_component_interfaces on page 573
- load_component on page 581

7.14.6.9. get_component_interface_parameters

Description

Returns the list of parameters for an interface of the loaded component.

Usage

`get_component_interface_parameters` <*interface*>

Returns

String[] The list of parameter names.

Arguments

interface Specifies the interface name.

Example

```
get_component_interface_parameters s0
```

Related Information

- get_component_interface_parameter_value on page 568
- get_component_interfaces on page 573
- load_component on page 581

7.14.6.10. get_component_interface_port_property

Description

Returns the property value of a port in the interface of the loaded component.

Usage

`get_component_interface_port_property` <*interface*> <*port*> <*property*>

Returns

various The port property value

Arguments

interface Specifies the interface name.

port Specifies the port name of the interface.

property Specifies the property name of the port. Refer to *Port Properties*.

Example

```
get_component_interface_port_property exports tx WIDTH
```

Related Information

- get_component_interface_ports on page 571
- load_component on page 581
- Port Properties on page 663
- get_port_properties on page 607

7.14.6.11. get_component_interface_ports

Description

Returns the list of interface ports of the loaded component.

Usage

`get_component_interface_ports` <*interface*>

Returns

String[] The list of port names

Arguments

interface Specifies the interface name.

Example

```
get_component_interface_ports s0
```

Related Information

- get_component_interface_port_property on page 570
- get_component_interfaces on page 573
- load_component on page 581

7.14.6.12. get_component_interface_property

Description

Returns the value of a single property from the specified interface for the loaded component.

Usage

`get_component_interface_property` <*interface*> <*property*>

Returns

String The property value.

Arguments

interface Specifies the interface name.

property Specifies the property name. Refer to *Element Properties*.

Example

```
get_interface_property clk_in DISPLAY_NAME
```

Related Information

- load_component on page 581
- Element Properties on page 641
- get_interface_properties on page 604

7.14.6.13. get_component_interfaces

Description

Returns the list of interfaces in the loaded component.

Usage

```
get_component_interfaces
```

Returns

String[] The list of interface names.

Arguments

No arguments

Example

```
get_component_interfaces
```

Related Information

- get_component_interface_ports on page 571
- get_component_interface_property on page 572
- load_component on page 581

7.14.6.14. get_component_parameter_property

Description

Returns the property value of a parameter in the loaded component.

Usage

`get_component_parameter_property` <*parameter*> <*property*>

Returns

Various The parameter property value.

Arguments

parameter Specifies the parameter name in the component.

property Specifies the property name of the parameter. Refer to *Parameter Properties*.

Example

```
get_component_parameter_property baudRate ENABLED
```

Related Information

- get_component_parameters on page 576
- get_parameter_properties on page 627
- load_component on page 581
- Parameter Properties on page 646

7.14.6.15. get_component_parameter_value

Description

Returns the parameter value in the loaded component.

Usage

`get_component_parameter_value <parameter>`

Returns

various The parameter value

Arguments

parameter Specifies the parameter name in the component.

Example

```
get_component_parameter_value baudRate
```

Related Information

- get_component_parameters on page 576
- load_component on page 581
- set_component_parameter_value on page 584

7.14.6.16. get_component_parameters

Description

Returns the list of parameters in the loaded component.

Usage

```
get_component_parameters
```

Returns

String[] The list of parameters in the component.

Arguments

No arguments

Example

```
get_instance_parameters
```

Related Information

- get_component_parameter_property on page 574
- get_component_parameter_value on page 575
- load_component on page 581
- set_component_parameter_value on page 584

7.14.6.17. get_component_project_properties

Description

Returns the list of properties that you query about the loaded component's Quartus Prime project.

Usage

```
get_component_project_properties
```

Returns

String[] The list of project properties.

Arguments

No arguments

Example

```
get_component_project_properties
```

Related Information

- get_component_project_property on page 578
- load_component on page 581
- set_component_project_property on page 585

7.14.6.18. get_component_project_property

Description

Returns the project property value of the loaded component. Only select project properties are available.

Usage

`get_component_project_property` <*property*>

Returns

String The property value.

Arguments

property Specifies the project property name. Refer to *Project Properties*.

Example

```
get_component_project_property HIDE_FROM_IP_CATALOG
```

Related Information

- get_component_project_properties on page 577
- load_component on page 581
- set_component_project_property on page 585
- Project Properties on page 651

7.14.6.19. get_component_property

Description

Returns the property value of the loaded component.

Usage

`get_component_property <property>`

Returns

String The property value.

Arguments

property The property name on the loaded component. Refer to *Element Properties*.

Example

```
get_component_property CLASS_NAME
```

Related Information

- load_component on page 581
- get_instance_properties on page 513
- Element Properties on page 641

7.14.6.20. get_loaded_component

Description

Returns the instance name associated with the loaded component.

Usage

```
get_loaded_component
```

Returns

String The instance name.

Arguments

No arguments

Example

```
get_loaded_component
```

Related Information

- load_component on page 581
- save_component on page 583

7.14.6.21. load_component

Description

Loads the actual component inside of a generic component, so that you can modify the component parameters.

Usage

`load_component <instance>`

Returns

boolean 1 if successful; 0 if unsuccessful.

Arguments

instance Specifies the instance name.

Example

```
load_component cpu
```

Related Information

- get_loaded_component on page 580
- save_component on page 583

7.14.6.22. reload_component_footprint

Description

Validates the footprint of a specified child instance, and updates the footprint of the instance in case of issues.

Usage

`reload_component_footprint [<instance>]`

Returns

String[] A list of validation messages.

Arguments

instance (*optional*)	Specifies the child instance name to validate. If you do not specify this option, the command validates all the generic components in the system.

Example

```
reload_component_footprint cpu_0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- validate_component_footprint on page 621

7.14.6.23. save_component

Description

Saves the loaded component.

Usage

```
save_component
```

Returns

No return value

Arguments

No arguments

Example

```
save_component
```

Related Information

- get_loaded_component on page 580
- load_component on page 581

7.14.6.24. set_component_parameter_value

Description

Sets the parameter value for the loaded component.

Usage

`set_component_parameter_value` <*parameter*> <*value*>

Returns

No return value

Arguments

parameter Specifies the parameter name.

parameter Specifies the new parameter value.

Example

```
set_component_parameter_value baudRate 9600
```

Related Information

- get_component_parameter_value on page 575
- get_component_parameters on page 576
- load_component on page 581

7.14.6.25. set_component_project_property

Description

Sets the project property value of the loaded component, such as hiding from the IP catalog.

Usage

`set_component_project_property` <*property*> <*value*>

Returns

No return value

Arguments

property Specifies the property name. Refer to *Project Properties*.

value Specifies the new property value.

Example

```
set_component_project_property HIDE_FROM_IP_CATALOG false
```

Related Information

- get_component_project_properties on page 577
- get_component_project_property on page 578
- load_component on page 581
- Project Properties on page 651

7.14.7. Connections

This section lists the commands that allow you to manipulate the interface connections in your Platform Designer system.

7.14.7.1. add_connection

Description

Connects the named interfaces using an appropriate connection type. Both interface names consist of an instance name, followed by the interface name that the module provides.

Usage

`add_connection <start> [<end>]`

Returns

No return value.

Arguments

start The start interface that you connect, in `<instance_name>.<interface_name>` format. If you do not specify the end argument, the connection must be of the form `<instance1>.<interface>/<instance2>.<interface>`.

end (optional) The end interface that you connect, in `<instance_name>.<interface_name>` format.

Example

```
add_connection dma.read_host sdram.s1
```

Related Information

- get_connection_parameter_value on page 590
- get_connection_property on page 593
- get_connections on page 594
- remove_connection on page 595
- set_connection_parameter_value on page 597

7.14.7.2. auto_connect

Description

Creates connections from an instance or instance interface to matching interfaces of other instances in the system. For example, Avalon memory mapped agents connect to Avalon memory mapped hosts.

Usage

`auto_connect <element>`

Returns

No return value.

Arguments

element The instance interface name, or the instance name.

Example

```
auto_connect sdram
auto_connect uart_0.s1
```

Related Information

add_connection on page 587

7.14.7.3. get_connection_parameter_property

Description

Returns the property value of a parameter in a connection. Parameter properties are metadata about how Platform Designer uses the parameter.

Usage

`get_connection_parameter_property` <*connection*> <*parameter*> <*property*>

Returns

various The parameter property value.

Arguments

connection The connection to query.

parameter The parameter name.

property The property of the connection. Refer to *Parameter Properties*.

Example

```
get_connection_parameter_property cpu.data_host/dma0.csr baseAddress UNITS
```

Related Information

- get_connection_parameter_value on page 590
- get_connection_property on page 593
- get_connections on page 594
- get_parameter_properties on page 627
- Parameter Properties on page 646

7.14.7.4. get_connection_parameter_value

Description

Returns the parameter value of the connection. Parameters represent aspects of the connection that you can modify, such as the base address for an Avalon memory mapped connection.

Usage

`get_connection_parameter_value` <*connection*> <*parameter*>

Returns

various The parameter value.

Arguments

connection The connection to query.

parameter The parameter name.

Example

```
get_connection_parameter_value cpu.data_host/dma0.csr baseAddress
```

Related Information

- get_connection_parameters on page 591
- get_connections on page 594
- set_connection_parameter_value on page 597

7.14.7.5. get_connection_parameters

Description

Returns the list of parameters of a connection.

Usage

`get_connection_parameters` <*connection*>

Returns

String[] The list of parameter names.

Arguments

connection The connection to query.

Example

```
get_connection_parameters cpu.data_host/dma0.csr
```

Related Information

- get_connection_parameter_property on page 589
- get_connection_parameter_value on page 590
- get_connection_property on page 593

7.14.7.6. get_connection_properties

Description

Returns the properties list of a connection.

Usage

```
get_connection_properties
```

Returns

String[] The list of connection properties.

Arguments

No arguments.

Example

```
get_connection_properties
```

Related Information

- get_connection_property on page 593
- get_connections on page 594

7.14.7.7. get_connection_property

Description

Returns the property value of a connection. Properties represent aspects of the connection that you can modify, such as the connection type.

Usage

`get_connection_property` <*connection*> <*property*>

Returns

String The connection property value.

Arguments

connection The connection to query.

property The connection property name. Refer to *Connection Properties*.

Example

```
get_connection_property cpu.data_host/dma0.csr TYPE
```

Related Information

- get_connection_properties on page 592
- Connection Properties on page 638

7.14.7.8. get_connections

Description

Returns the list of all connections in the system if you do not specify any element. If you specify a child instance, for example `cpu`, Platform Designer returns all connections to any interface on the instance. If you specify an interface of a child instance, for example `cpu.instruction_host`, Platform Designer returns all connections to that interface.

Usage

`get_connections` [<*element*>]

Returns

String[] The list of connections.

Arguments

element (optional) The child instance name, or the qualified interface name on a child instance.

Example

```
get_connections
get_connections cpu
get_connections cpu.instruction_host
```

Related Information

- add_connection on page 587
- remove_connection on page 595

7.14.7.9. remove_connection

Description

Removes a connection from the system.

Usage

`remove_connection` <*connection*>

Returns

No return value.

Arguments

connection The connection name to remove.

Example

```
remove_connection cpu.data_host/sdram.s0
```

Related Information

- add_connection on page 587
- get_connections on page 594

7.14.7.10. remove_dangling_connections

Description

Removes connections where both end points of the connection no longer exist in the system.

Usage

```
remove_dangling_connections
```

Returns

No return value.

Arguments

No arguments.

Example

```
remove_dangling_connections
```

Related Information

- add_connection on page 587
- get_connections on page 594
- remove_connection on page 595

7.14.7.11. set_connection_parameter_value

Description

Sets the parameter value for a connection.

Usage

`set_connection_parameter_value` <*connection*> <*parameter*> <*value*>

Returns

No return value.

Arguments

connection The connection name.

parameter The parameter name.

value The new parameter value.

Example

```
set_connection_parameter_value cpu.data_host/dma0.csr baseAddress "0x000a0000"
```

Related Information

- get_connection_parameter_value on page 590
- get_connection_parameters on page 591

7.14.8. Top-level Exports

This section lists the commands that allow you to manipulate the exported interfaces in your Platform Designer system.

7.14.8.1. add_interface

Description

Adds an interface to your system, which Platform Designer uses to export an interface from within the system. You specify the exported internal interface with `set_interface_property <interface> EXPORT_OF instance.interface`.

Usage

`add_interface <name> <type> <direction>`.

Returns

No return value.

Arguments

name The name of the interface that Platform Designer exports from the system.

type The type of interface.

direction The interface direction.

Example

```
add_interface my_export conduit end
set_interface_property my_export EXPORT_OF uart_0.external_connection
```

Related Information

- get_interface_ports on page 603
- get_interface_properties on page 604
- get_interface_property on page 605
- set_interface_property on page 611

7.14.8.2. get_exported_interface_sysinfo_parameter_value

Description

Gets the value of a system info parameter for an exported interface.

Usage

`get_exported_interface_sysinfo_parameter_value` <*interface*> <*parameter*>

Returns

various The system info parameter value.

Arguments

interface Specifies the name of the exported interface.

parameter Specifies the name of the system info parameter. Refer to *System Info Type*.

Example

```
get_exported_interface_sysinfo_parameter_value clk clock_rate
```

Related Information

- get_exported_interface_sysinfo_parameters on page 601
- set_exported_interface_sysinfo_parameter_value on page 609
- System Info Type Properties on page 652

7.14.8.3. get_exported_interface_sysinfo_parameters

Description

Returns the list of system info parameters for an exported interface.

Usage

`get_exported_interface_sysinfo_parameters` <*interface*> [<*type*>]

Returns

String[] The list of system info parameter names.

Arguments

interface Specifies the name of the exported interface.

type (*optional*) Specifies the parameters type to return. If you do not specify this option, the command returns all the parameters. Refer to *Access Type*.

Example

```
get_exported_interface_sysinfo_parameters clk
```

Related Information

- get_exported_interface_sysinfo_parameter_value on page 600
- set_exported_interface_sysinfo_parameter_value on page 609
- Access Type on page 658

7.14.8.4. get_interface_port_property

Description

Returns the value of a property of a port contained by one of the top-level exported interfaces.

Usage

`get_interface_port_property` <*interface*> <*port*> <*property*>

Returns

various The property value.

Arguments

interface The name of a top-level interface of the system.

port The port name in the interface.

property The property name on the port. Refer to *Port Properties*.

Example

```
get_interface_port_property uart_exports tx DIRECTION
```

Related Information

- get_interface_ports on page 603
- get_port_properties on page 607
- Port Properties on page 650

7.14.8.5. get_interface_ports

Description

Returns the names of all the added ports to a given interface.

Usage

`get_interface_ports` <*interface*>

Returns

String[] The list of port names.

Arguments

interface The top-level interface name of the system.

Example

```
get_interface_ports export_clk_out
```

Related Information

- get_interface_port_property on page 602
- get_interfaces on page 606

7.14.8.6. get_interface_properties

Description

Returns the names of all the available interface properties common to all interface types.

Usage

```
get_interface_properties
```

Returns

String[] The list of interface properties.

Arguments

No arguments.

Example

```
get_interface_properties
```

Related Information

- get_interface_property on page 605
- set_interface_property on page 611

7.14.8.7. get_interface_property

Description

Returns the value of a single interface property from the specified interface.

Usage

`get_interface_property` <*interface*> <*property*>

Returns

various The property value.

Arguments

interface The name of a top-level interface of the system.

property The name of the property. Refer to *Interface Properties*.

Example

```
get_interface_property export_clk_out EXPORT_OF
```

Related Information

- get_interface_properties on page 604
- set_interface_property on page 611
- Interface Properties on page 643

7.14.8.8. get_interfaces

Description

Returns the list of top-level interfaces in the system.

Usage

```
get_interfaces
```

Returns

String[] The list of the top-level interfaces exported from the system.

Arguments

No arguments.

Example

```
get_interfaces
```

Related Information

- add_interface on page 599
- get_interface_ports on page 603
- get_interface_property on page 605
- remove_interface on page 608
- set_interface_property on page 611

7.14.8.9. get_port_properties

Description

Returns the list of properties that you can query for ports.

Usage

```
get_port_properties
```

Returns

String[] The list of port properties.

Arguments

No arguments.

Example

```
get_port_properties
```

Related Information

- get_instance_interface_port_property on page 503
- get_instance_interface_ports on page 504
- get_instance_port_property on page 512
- get_interface_port_property on page 602
- get_interface_ports on page 603

7.14.8.10. remove_interface

Description

Removes an exported top-level interface from the system.

Usage

`remove_interface` <*interface*>

Returns

No return value.

Arguments

interface The name of the exported top-level interface.

Example

```
remove_interface clk_out
```

Related Information

- add_interface on page 599
- get_interfaces on page 606

7.14.8.11. set_exported_interface_sysinfo_parameter_value

Description

Sets the system info parameter value for an exported interface.

Usage

`set_exported_interface_sysinfo_parameter_value` <*interface*> <*parameter*> <*value*>

Returns

No return value

Arguments

interface Specifies the name of the exported interface.

parameter Specifies the name of the system info parameter. Refer to *System Info Type*.

value Specifies the system info parameter value.

Example

```
set_exported_interface_sysinfo_parameter_value clk clock_rate 5000000
```

Related Information

- get_exported_interface_sysinfo_parameter_value on page 600
- get_exported_interface_sysinfo_parameters on page 601
- System Info Type Properties on page 652

7.14.8.12. set_interface_port_property

Description

Sets the port property in a top-level interface of the system.

Usage

`set_interface_port_property` <*interface*> <*port*> <*property*> <*value*>

Returns

No return value

Arguments

interface Specifies the top-level interface name of the system.

port Specifies the port name in a top-level interface of the system.

property Specifies the property name of the port. Refer to *Port Properties*.

value Specifies the property value.

Example

```
set_interface_port_property clk clk_clk NAME my_clk
```

Related Information

- Port Properties on page 663
- get_interface_ports on page 603
- get_interfaces on page 606
- get_port_properties on page 607

7.14.8.13. set_interface_property

Description

Sets the value of a property on an exported top-level interface. You use this command to set the EXPORT_OF property to specify which interface of a child instance is exported via this top-level interface.

Usage

`set_interface_property` <*interface*> <*property*> <*value*>

Returns

No return value.

Arguments

interface The name of an exported top-level interface.

property The name of the property. Refer to *Interface Properties*.

value The property value.

Example

```
set_interface_property clk_out EXPORT_OF clk.clk_out
```

Related Information

- add_interface on page 599
- get_interface_properties on page 604
- get_interface_property on page 605
- Interface Properties on page 643

7.14.9. Validation

This section lists the commands that allow you to validate the components, instances, interfaces and connections in a Platform Designer system.

7.14.9.1. set_validation_property

Description

Sets a property that affects how and when validation is run. To disable system validation after each scripting command, set `AUTOMATIC_VALIDATION` to `False`.

Usage

`set_validation_property` <*property*> <*value*>

Returns

No return value.

Arguments

property The name of the property. Refer to *Validation Properties*.

value The new property value.

Example

```
set_validation_property AUTOMATIC_VALIDATION false
```

Related Information

- validate_system on page 620
- Validation Properties on page 655

7.14.9.2. sync_sysinfo_parameters

Description

Updates the system info parameters of the specified generic component.

Usage

`sync_sysinfo_parameters [<instance> ]`

Returns

String[] A list of update messages.

Arguments

instance (*optional*)	Specifies the name of the instance to sync. If you do not specify this option, the command synchronizes all the generic components in the system.

Example

```
sync_sysinfo_parameters cpu_0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.9.3. validate_component

Description

Validates the loaded component.

Usage

```
validate_component
```

Returns

String[] A list of validation messages.

Arguments

No arguments

Example

```
validate_component
```

Related Information

- validate_component_interface on page 616
- load_component on page 581

7.14.9.4. validate_component_interface

Description

Validates an interface of the loaded component.

Usage

`validate_component_interface <interface>`

Returns

String[] List of validation messages

Arguments

instance Specifies the name of the instance for the loaded component.

Example

```
validate_instance_interface data_host
```

Related Information

- load_component on page 581
- validate_component on page 615

7.14.9.5. validate_connection

Description

Validates the specified connection and returns validation messages.

Usage

`validate_connection <connection>`

Returns

A list of validation messages.

Arguments

connection The connection name to validate.

Example

```
validate_connection cpu.data_host/sdram.s1
```

Related Information

- validate_instance on page 618
- validate_instance_interface on page 619
- validate_system on page 620

7.14.9.6. validate_instance

Description

Validates the specified child instance and returns validation messages.

Usage

`validate_instance` <*instance*>

Returns

A list of validation messages.

Arguments

instance The child instance name to validate.

Example

```
validate_instance cpu
```

Related Information

- validate_connection on page 617
- validate_instance_interface on page 619
- validate_system on page 620

7.14.9.7. validate_instance_interface

Description

Validates an interface of an instance and returns validation messages.

Usage

`validate_instance_interface` <*instance*> <*interface*>

Returns

A list of validation messages.

Arguments

instance The child instance name.

interface The interface to validate.

Example

```
validate_instance_interface cpu data_host
```

Related Information

- validate_connection on page 617
- validate_instance on page 618
- validate_system on page 620

7.14.9.8. validate_system

Description

Validates the system and returns validation messages.

Usage

```
validate_system
```

Returns

A list of validation messages.

Arguments

No arguments.

Example

```
validate_system
```

Related Information

- validate_connection on page 617
- validate_instance on page 618
- validate_instance_interface on page 619

7.14.9.9. validate_component_footprint

Description

Validates the footprint of the specified child instance.

Usage

`validate_component_footprint` <*instance*>

Returns

String[] List of validation messages.

Arguments

instance (*optional*)	Specifies the child instance name. If you omit this option, the command validates all generic components in the system.

Example

```
validate_component_footprint cpu_0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552

7.14.9.10. reload_component_footprint

Description

Validates the footprint of a specified child instance, and updates the footprint of the instance in case of issues.

Usage

`reload_component_footprint [<instance>]`

Returns

String[] A list of validation messages.

Arguments

instance (*optional*)	Specifies the child instance name to validate. If you do not specify this option, the command validates all the generic components in the system.

Example

```
reload_component_footprint cpu_0
```

Related Information

- load_instantiation on page 548
- save_instantiation on page 552
- validate_component_footprint on page 621

7.14.10. Miscellaneous

This section lists the miscellaneous commands that you can use for your Platform Designer systems.

7.14.10.1. auto_assign_base_addresses

Description

Assigns base addresses to all memory-mapped interfaces of an instance in the system. Instance interfaces that are locked with `lock_avalon_base_address` keep their addresses during address auto-assignment.

Usage

`auto_assign_base_addresses` <*instance*>

Returns

No return value.

Arguments

instance The name of the instance with memory-mapped interfaces.

Example

```
auto_assign_base_addresses sdram
```

Related Information

- auto_assign_system_base_addresses on page 626
- lock_avalon_base_address on page 628
- unlock_avalon_base_address on page 631

7.14.10.2. auto_assign_irqs

Description

Assigns interrupt numbers to all connected interrupt senders of an instance in the system.

Usage

`auto_assign_irqs <`*instance*`>`

Returns

No return value.

Arguments

instance The name of the instance with an interrupt sender.

Example

```
auto_assign_irqs uart_0
```

7.14.10.3. auto_assign_system_base_addresses

Description

Assigns legal base addresses to all memory-mapped interfaces of all instances in the system. Instance interfaces that are locked with `lock_avalon_base_address` keep their addresses during address auto-assignment.

Usage

`auto_assign_system_base_addresses`

Returns

No return value.

Arguments

No arguments.

Example

```
auto_assign_system_base_addresses
```

Related Information

- auto_assign_base_addresses on page 624
- lock_avalon_base_address on page 628
- unlock_avalon_base_address on page 631

7.14.10.4. get_parameter_properties

Description

Returns the list of properties that you can query for any parameters, for example parameters of instances, interfaces, instance interfaces, and connections.

Usage

```
get_parameter_properties
```

Returns

String[] The list of parameter properties.

Arguments

No arguments.

Example

```
get_parameter_properties
```

Related Information

- get_connection_parameter_property on page 589
- get_instance_interface_parameter_property on page 500
- get_instance_parameter_property on page 508

7.14.10.5. lock_avalon_base_address

Description

Prevents the memory-mapped base address from being changed for connections to the specified interface of an instance when Platform Designer runs the `auto_assign_base_addresses` or `auto_assign_system_base_addresses` commands.

Usage

`lock_avalon_base_address` <*instance.interface*>

Returns

No return value.

Arguments

instance.interface	The qualified name of the interface of an instance, in <*instance*>.<*interface*> format.

Example

```
lock_avalon_base_address sdram.s1
```

Related Information

- auto_assign_base_addresses on page 624

7.14.10.6. send_message

Description

Sends a message to the user of the component. The message text is normally HTML. You can use the <*b*> element to provide emphasis. If you do not want the message text to be HTML, then pass a list like `{ Info Text }` as the message level,

Usage

`send_message` <*level*> <*message*>

Returns

No return value.

Arguments

level Quartus Prime supports the following message levels:

- `ERROR`—provides an error message.
- `WARNING`—provides a warning message.
- `INFO`—provides an informational message.
- `PROGRESS`—provides a progress message.
- `DEBUG`—provides a debug message when debug mode is enabled.

message The text of the message.

Example

```
send_message ERROR "The system is down!"
send_message { Info Text } "The system is up!"
```

7.14.10.7. set_use_testbench_naming_pattern

Description

Use this command to create testbench systems so that the generated file names for the test system match the system's original generated file names. Without setting this command, the generated file names for the test system receive the top-level testbench system name.

Usage

`set_use_testbench_naming_pattern` <*value*>

Returns

No return value.

Arguments

value True or false.

Example

```
set_use_testbench_naming_pattern true
```

Notes

Use this command only to create testbench systems.

7.14.10.8. unlock_avalon_base_address

Description

Allows the memory-mapped base address to change for connections to the specified interface of an instance when Platform Designer runs the `auto_assign_base_addresses` or `auto_assign_system_base_addresses` commands.

Usage

`unlock_avalon_base_address` <*instance.interface*>

Returns

No return value.

Arguments

instance.interface	The qualified name of the interface of an instance, in <*instance*>.<*interface*> format.

Example

```
unlock_avalon_base_address sdram.s1
```

Related Information

- auto_assign_base_addresses on page 624
- auto_assign_system_base_addresses on page 626
- lock_avalon_base_address on page 628

7.14.10.9. get_testbench_dutname

Description

Returns the currently set dutname for the test-bench systems. Use this command only when creating test-bench systems.

Usage

```
get_testbench_dutname
```

Returns

String The currently set dutname. Returns NULL if empty.

Arguments

No arguments.

Example

```
get_testbench_dutname
```

Related Information

- get_use_testbench_naming_pattern on page 633
- set_use_testbench_naming_pattern on page 630

7.14.10.10. get_use_testbench_naming_pattern

Description

Verifies if the test-bench naming pattern is set to be used. Use this command only when creating test-bench systems.

Usage

```
get_use_testbench_naming_pattern
```

Returns

boolean True, if the test-bench naming pattern is set to be used.

Arguments

No arguments.

Example

```
get_use_testbench_naming_pattern
```

Related Information

- get_testbench_dutname on page 632
- set_use_testbench_naming_pattern on page 630

7.14.11. Wire-Level Connection Commands

Wire-level commands accept optional input ports and wire-level expressions as arguments for the `qsys-script` utility and in `_hw.tcl` files.

You can use wire-level commands to:

- Apply a wire-level expression to a port with `set_wirelevel_expression`.
- Retrieve a list of expressions from a port, instance, or all expressions in the current level of system hierarchy with `get_wirelevel_expression`.
- Remove a list of expressions from a port, instance, or all expressions in the current level of system hierarchy with `remove_wirelevel_expression`.

Note: The following restrictions apply when using wire-level commands `_hw.tcl` files:

- Wire-level commands are only valid in a composition callback.
- Wire-level expressions can only be applied to instances created by `add_instance`.

Related Information

- Scripting Wire-Level Expressions on page 71
- Create a Composed Component or Subsystem on page 196

7.14.11.1. set_wirelevel_expression

Description

Applies a wire-level expression to an optional input port or instance in the system.

Usage

`set_wirelevel_expression` <*instance_or_port_bitselection*> <*expression*>

Returns

No return value.

Arguments

instance_or_port_bitselection	Specify the instance or port to which the wire-level expression using the <*instance_name*>.<*port_name*>[<*bit_selection*>] format. The *bit selection* can be a bit-select, for example `[0]`, or a partial range defined in descending order, for example `[7:0]`. If no *bit selection* is specified, the full range of the port is selected.
expression	The expression to be applied to an optional input port.

Examples

```
set_wirelevel_expression {module0.portA[7:0]} "8'b0"
set_wirelevel_expression module0.portA "8'b0"
set_wirelevel_expression {module0.portA[0]} "1'b0"
```

Related Information

Scripting Wire-Level Expressions on page 71

7.14.11.2. get_wirelevel_expressions

Description

Retrieve a list of wire-level expressions from an optional input port, instance, or all expressions in the current level of system hierarchy. If the port *bit selection* is specified as an argument, the range must be identical to what was used in the `set_wirelevel_expression` statement.

Usage

`get_wirelevel_expressions` <*instance_or_port_bitselection*>

Returns

String[]	A flattened list of wire-level expressions. Every item in the list consists of right- and left-hand clauses of a wire-level expression. You can loop over the returned list using `foreach{port expr} $return_list{}`.

Arguments

instance_or_port_bitselection	Specifies which instance or port from which a list of wire-level expressions are retrieved using the <*instance_name*>.<*port_name*>[<*bit_selection*>] format. • If no <*port_name*>[<*bit_selection*>] is specified, the command causes the return of all expressions from the specified instance. • If no argument is present, the command causes the return of all expressions from the current level of system hierarchy. The *bit selection* can be a bit-select, for example `[0]`, or a partial range defined in descending order, for example `[7:0]`. If no *bit selection* is specified, the full range of the port is selected.

Example

```
get_wirelevel_expressions
get_wirelevel_expressions module0
get_wirelevel_expressions {module0.portA[7:0]}
```

Related Information

Scripting Wire-Level Expressions on page 71

7.14.11.3. remove_wirelevel_expressions

Description

Remove a list of wire-level expressions from an optional input port, instance, or all expressions in the current level of system hierarchy. If the port *bit selection* is specified as an argument, the range must be identical to what was used in the `set_wirelevel_expressions` statement.

Usage

`remove_wirelevel_expressions` <*instance_or_port_bitselection*>

Returns

No return value.

Arguments

instance_or_port_bitselection	Specifies which instance or port from which a list of wire-level expressions are removed using the <*instance_name*>.<*port_name*>[<*bit_selection*>] format.

- If no *<port_name>[<bit_selection>]* is specified, the command causes the removal of all expressions from the specified instance.
- If no argument is present, the command causes the return of all expressions from the current level of system hierarchy.

The *bit selection* can be a bit-select, for example `[0]`, or a partial range defined in descending order, for example `[7:0]`. If no *bit selection* is specified, the full range of the port is selected.

Examples

```
remove_wirelevel_expressions
remove_wirelevel_expressions module0
remove_wirelevel_expressions {module0.portA[7:0]}
```

Related Information

Scripting Wire-Level Expressions on page 71

7.15. Platform Designer Scripting Property Reference

Interface properties work differently for **_hw.tcl** scripting than with Platform Designer scripting. In **_hw.tcl**, interfaces do not distinguish between properties and parameters. In Platform Designer scripting, the properties and parameters are unique.

The following are the Platform Designer scripting properties:

7.15.1. Connection Properties

Type	Name	Description
string	END	Indicates the end interface of the connection.
string	NAME	Indicates the name of the connection.
string	START	Indicates the start interface of the connection.
String	TYPE	The type of the connection.

7.15.2. Design Environment Type Properties

Description

IP cores use the design environment to identify the most appropriate interfaces to connect to the parent system.

Name	Description
NATIVE	Supports native IP interfaces.
QSYS	Supports standard Platform Designer interfaces.

7.15.3. Direction Properties

Name	Description
BIDIR	Indicates the direction for a bidirectional signal.
INOUT	Indicates the direction for an input signal.
OUTPUT	Indicates the direction for an output signal.

7.15.4. Element Properties

Description

Element properties are, with the exception of ENABLED and NAME, read-only properties of the types of instances, interfaces, and connections. These read-only properties represent metadata that does not vary between copies of the same type. ENABLED and NAME properties are specific to particular instances, interfaces, or connections.

Type	Name	Description
String	AUTHOR	The author of the component or interface.
Boolean	AUTO_EXPORT	Indicates whether unconnected interfaces on the instance are automatically exported.
String	CLASS_NAME	The type of the instance, interface or connection, for example, altera_nios2.
String	DESCRIPTION	The description of the instance, interface or connection type.
String	DISPLAY_NAME	The display name for referencing the type of instance, interface or connection.
Boolean	EDITABLE	Indicates whether you can edit the component in the Platform Designer Component Editor.
Boolean	ENABLED	Indicates whether the instance is enabled.
String	GROUP	The IP Catalog category.
Boolean	INTERNAL	Hides internal IP components or sub-components from the IP Catalog..
String	NAME	The name of the instance, interface or connection.
String	VERSION	The version number of the instance, interface or connection, for example, 16.1.

7.15.5. Instance Properties

Type	Name	Description
String	AUTO_EXPORT	Indicates whether Platform Designer automatically exports the unconnected interfaces on the instance.
Boolean	ENABLED	If true, Platform Designer includes this instance in the generated system.
String	NAME	The name of the system, which Platform Designer uses as the name of the top-level module in the generated HDL.

7.15.6. Interface Properties

Type	Name	Description
String	EXPORT_OF	Indicates which interface of a child instance to export through the top-level interface. Before using this command, you must create the top-level interface using the `add_interface` command. You must use the format: <*instanceName.interfaceName*>. For example: `set_interface_property CSC_input EXPORT_OF my_colorSpaceConverter.input_port`

7.15.7. Message Levels Properties

Name	Description
COMPONENT_INFO	Reports an informational message only during component editing.
DEBUG	Provides messages when debug mode is enabled.
ERROR	Provides an error message.
INFO	Provides an informational message.
PROGRESS	Reports progress during generation.
TODOERROR	Provides an error message that indicates the system is incomplete.
WARNING	Provides a warning message.

7.15.8. Module Properties

Type	Name	Description
String	GENERATION_ID	The generation ID for the system.
String	NAME	The name of the instance.

7.15.9. Parameter Properties

Type	Name	Description
Boolean	AFFECTS_ELABORATION	Set AFFECTS_ELABORATION to false for parameters that do not affect the external interface of the module. An example of a parameter that does not affect the external interface is isNonVolatileStorage. An example of a parameter that does affect the external interface is width. When the value of a parameter changes and AFFECTS_ELABORATION is false, the elaboration phase does not repeat and improves performance. When AFFECTS_ELABORATION is set to true, the default value, Platform Designer reanalyzes the HDL file to determine the port widths and configuration each time a parameter changes.
Boolean	AFFECTS_GENERATION	The default value of AFFECTS_GENERATION is false if you provide a top-level HDL module. The default value is true if you provide a fileset callback. Set AFFECTS_GENERATION to false if the value of a parameter does not change the results of fileset generation.
Boolean	AFFECTS_VALIDATION	The AFFECTS_VALIDATION property determines whether a parameter's value sets derived parameters, and whether the value affects validation messages. Setting this property to false may improve response time in the parameter editor when the value changes.
String[]	ALLOWED_RANGES	Indicates the range or ranges of the parameter. For integers, each range is a single value, or a range of values defined by a start and end value, and delimited by a colon, for example, 11:15. This property also specifies the legal values and description strings for integers, for example, {0:None 1:Monophonic 2:Stereo 4:Quadrophonic}, where 0, 1, 2, and 4 are the legal values. You can assign description strings in the parameter editor for string variables. For example, `ALLOWED_RANGES {"dev1:Cyclone IV GX""dev2:Stratix V GT"}`
String	DEFAULT_VALUE	The default value.
Boolean	DERIVED	When True, indicates that the parameter value is set by the component and cannot be set by the user. Derived parameters are not saved as part of an instance's parameter values. The default value is False.
String	DESCRIPTION	A short user-visible description of the parameter, suitable for a tooltip description in the parameter editor.
String[]	DISPLAY_HINT	Provides a hint about how to display a property. • boolean--For integer parameters whose value are 0 or 1. The parameter displays as an option that you can turn on or off. • radio—displays a parameter with a list of values as radio buttons. • hexadecimal—for integer parameters, displays and interprets the value as a hexadecimal number, for example: 0x00000010 instead of 16. • fixed_size—for string_list and integer_list parameters, the fixed_size DISPLAY_HINT eliminates the **Add** and **Remove** buttons from tables. • file--displays a file selection button that allows the user to enter a path to a file for the parameter.
String	DISPLAY_NAME	The GUI label that appears to the left of this parameter.
String	DISPLAY_UNITS	The GUI label that appears to the right of the parameter.

Type	Name	Description
Boolean	ENABLED	When False, the parameter is disabled. The parameter displays in the parameter editor but is grayed out, indicating that you cannot edit this parameter.
String	GROUP	Controls the layout of parameters in the GUI.
Boolean	HDL_PARAMETER	When True, Platform Designer passes the parameter to the HDL component description. The default value is False.
String	LONG_DESCRIPTION	A user-visible description of the parameter. Similar to DESCRIPTION, but allows a more detailed explanation.
String	NEW_INSTANCE_VALUE	Changes the default value of a parameter without affecting older components that do not explicitly set a parameter value, and use the DEFAULT_VALUE property. Oder instances continue to use DEFAULT_VALUE for the parameter and new instances use the value assigned by NEW_INSTANCE_VALUE.
String[]	SYSTEM_INFO	Allows you to assign information about the instantiating system to a parameter that you define. SYSTEM_INFO requires an argument specifying the type of information. For example: `SYSTEM_INFO <info-type>`
String	SYSTEM_INFO_ARG	Defines an argument to pass to SYSTEM_INFO. For example, the name of a reset interface.
(various)	SYSTEM_INFO_TYPE	Specifies the types of system information that you can query. Refer to *System Info Type Properties*.
(various)	TYPE	Specifies the type of the parameter. Refer to *Parameter Type Properties*.
(various)	UNITS	Sets the units of the parameter. Refer to *Units Properties*.
Boolean	VISIBLE	Indicates whether or not to display the parameter in the parameter editor.
String	WIDTH	Indicates the width of the logic vector for the STD_LOGIC_VECTOR parameter.

Related Information

- System Info Type Properties on page 652
- Parameter Type Properties on page 649
- Units Properties on page 654

7.15.10. Parameter Status Properties

Type	Name	Description
Boolean	ACTIVE	Indicates that this parameter is an active parameter.
Boolean	DEPRECATED	Indicates that this parameter exists only for backwards compatibility, and may not have any effect.
Boolean	EXPERIMENTAL	Indicates that this parameter is experimental and not exposed in the design flow.

7.15.11. Parameter Type Properties

Name	Description
BOOLEAN	A boolean parameter set to `true` or `false`.
FLOAT	A signed 32-bit floating point parameter. (Not supported for HDL parameters.)
INTEGER	A signed 32-bit integer parameter.
INTEGER_LIST	A parameter that contains a list of 32-bit integers. (Not supported for HDL parameters.)
LONG	A signed 64-bit integer parameter. (Not supported for HDL parameters.)
NATURAL	A 32-bit number that contains values `0` to `2147483647` (`0x7fffffff`).
POSITIVE	A 32-bit number that contains values `1` to `2147483647` (`0x7fffffff`).
STD_LOGIC	A single bit parameter set to `0` or `1`.
STD_LOGIC_VECTOR	An arbitrary-width number. The parameter property `WIDTH` determines the size of the logic vector.
STRING	A string parameter.
STRING_LIST	A parameter that contains a list of strings. (Not supported for HDL parameters.)

7.15.12. Port Properties

Type	Name	Description
(various)	DIRECTION	The direction of the signal. Refer to *Direction Properties*.
String	ROLE	The type of the signal. Each interface type defines a set of interface types for its ports.
Integer	WIDTH	The width of the signal in bits.

Related Information

Direction Properties on page 640

7.15.13. Project Properties

Type	Name	Description
String	DEVICE	The device part number in the Quartus Prime project that contains the Platform Designer system.
String	DEVICE_FAMILY	The device family name in the Quartus Prime project that contains the Platform Designer system.

7.15.14. System Info Type Properties

Type	Name	Description
String	ADDRESS_MAP	An XML-formatted string that describes the address map for the interface specified in the SYSTEM_INFO parameter property.
Integer	ADDRESS_WIDTH	The number of address bits that Platform Designer requires to address memory-mapped agents connected to the specified memory-mapped host in this instance.
String	AVALON_SPEC	The version of the Platform Designer interconnect. Refer to *Avalon Interface Specifications*.
Integer	CLOCK_DOMAIN	An integer that represents the clock domain for the interface specified in the SYSTEM_INFO parameter property. If this instance has interfaces on multiple clock domains, you can use this property to determine which interfaces are on each clock domain. The absolute value of the integer is arbitrary.
Long, Integer	CLOCK_RATE	The rate of the clock connected to the clock input specified in the SYSTEM_INFO parameter property. If zero, the clock rate is currently unknown.
String	CLOCK_RESET_INFO	The name of this instance's primary clock or reset sink interface. You use this property to determine the reset sink for global reset when you use Platform Designer interconnect that conforms to *Avalon Interface Specifications*.
String	CUSTOM_INSTRUCTION_SLAVES	Provides agent information, including the name, base address, address span, and clock cycle type.
String	DESIGN_ENVIRONMENT	A string that identifies the current design environment. Refer to *Design Environment Type Properties*.
String	DEVICE	The device part number of the selected device.
String	DEVICE_FAMILY	The family name of the selected device.
String	DEVICE_FEATURES	A list of key/value pairs delimited by spaces that indicate whether a device feature is available in the selected device family. The format of the list is suitable for passing to the `array` command. The keys are device features. The values are 1 if the feature is present, and 0 if the feature is absent.
String	DEVICE_SPEEDGRADE	The speed grade of the selected device.
Integer	GENERATION_ID	An integer that stores a hash of the generation time that Platform Designer uses as a unique ID for a generation run.
BigInteger, Long	INTERRUPTS_USED	A mask indicating which bits of an interrupt receiver are connected to interrupt senders. The interrupt receiver is specified in the system info argument.
Integer	MAX_SLAVE_DATA_WIDTH	The data width of the widest agent connected to the specified memory-mapped host.
String, Boolean, Integer	QUARTUS_INI	The value of the `quartus.ini` setting specified in the system info argument.
Integer	RESET_DOMAIN	An integer representing the reset domain for the interface specified in the SYSTEM_INFO parameter property If this instance has interfaces on multiple reset

Type	Name	Description
		domains, you can use this property to determine which interfaces are on each reset domain. The absolute value of the integer is arbitrary.
String	TRISTATECONDUIT_INFO	An XML description of the tri-state conduit hosts connected to a tri-state conduit agent. The agent is specified as the SYSTEM_INFO parameter property. The value contains information about the agent, connected host instance and interface names, and signal names, directions, and widths.
String	TRISTATECONDUIT_MASTERS	The names of the instance's interfaces that are tri-state conduit agents.
String	UNIQUE_ID	A string guaranteed to be unique to this instance.

Related Information

- Design Environment Type Properties on page 639
- Avalon Interface Specifications
- Platform Designer Interconnect on page 251

7.15.15. Units Properties

Name	Description
ADDRESS	A memory-mapped address.
BITS	Memory size in bits.
BITSPERSECOND	Rate in bits per second.
BYTES	Memory size in bytes.
CYCLES	A latency or count in clock cycles.
GIGABITSPERSECOND	Rate in gigabits per second.
GIGABYTES	Memory size in gigabytes.
GIGAHERTZ	Frequency in GHz.
HERTZ	Frequency in Hz.
KILOBITSPERSECOND	Rate in kilobits per second.
KILOBYTES	Memory size in kilobytes.
KILOHERTZ	Frequency in kHz.
MEGABITSPERSECOND	Rate, in megabits per second.
MEGABYTES	Memory size in megabytes.
MEGAHERTZ	Frequency in MHz.
MICROSECONDS	Time in microseconds.
MILLISECONDS	Time in milliseconds.
NANOSECONDS	Time in nanoseconds.
NONE	Unspecified units.
PERCENT	A percentage.
PICOSECONDS	Time in picoseconds.
SECONDS	Time in seconds.

7.15.16. Validation Properties

Type	Name	Description
Boolean	AUTOMATIC_VALIDATION	When `true`, Platform Designer runs system validation and elaboration after each scripting command. When `false`, Platform Designer runs system validation with validation scripting commands. Some queries affected by system elaboration may be incorrect if automatic validation is disabled. You can disable validation to make a system script run faster.

7.15.17. Interface Direction

Type	Name	Description
String	INPUT	Indicates that the interface is an agent (input, transmitter, sink, or end).
String	OUTPUT	Indicates that the interface is a host (output, receiver, source, or start).

7.15.18. File Set Kind

Name	Description
EXAMPLE_DESIGN	This file-set contains example design files.
QUARTUS_SYNTH	This file-set contains files that Platform Designer uses for Quartus Prime Synthesis
SIM_VERILOG	This file-set contains files that Platform Designer uses for Verilog HDL Simulation.
SIM_VHDL	This file-set contains files that Platform Designer uses for VHDL Simulation.

7.15.19. Access Type

Name	Type	Description
String	READ_ONLY	Indicates that the parameter can be only read-only.
String	WRITABLE	Indicates that the parameter has read/write properties.

7.15.20. Instantiation HDL File Properties

Name	Type	Description
Boolean	CONTAINS_INLINE_CONFIGURATION	Returns *True* if the HDL file contains inline configuration.
Boolean	IS_CONFIGURATION_PACKAGE	Returns *True* if the HDL file is a configuration package.
Boolean	IS_TOP_LEVEL	Returns *True* if the HDL file is the top-level HDL file.
String	OUTPUT_PATH	Specifies the output path of the HDL file.
String	TYPE	Specifies the HDL file type of the HDL file.

7.15.21. Instantiation Interface Duplicate Type

Type	Name	Description
String	CLONE	Creates a copy of an interface and all the interface ports.
String	MIRROR	Creates a copy of an interface with all the port roles and directions reversed.

7.15.22. Instantiation Interface Properties

Name	Type	Description
String	`DIRECTION`	The direction of the interface.
String	`TYPE`	The type of the interface.

7.15.23. Instantiation Properties

Name	Type	Description
String	HDL_COMPILATION_LIBRARY	Indicates the HDL compilation library name of the generic component.
String	HDL_ENTITY_NAME	Indicates the HDL entity name of the Generic Component.
String	IP_FILE	Indicates the .ip file path that implements the generic component.

7.15.24. Port Properties

Name	Type	Description
String	`DIRECTION`	Specifies the direction of the signal
String	`NAME`	Renames a top-level port. Only use with `set_interface_port_property`
String	`ROLE`	Specifies the type of the signal. Each interface type defines a set of interface types for its ports.
String	`VHDL_TYPE`	Specifies the VHDL type of the signal. Can be either *STANDARD_LOGIC*, or *STANDARD_LOGIC_VECTOR*.
Integer	`WIDTH`	Specifies the width of the signal in bits.

Related Information

Direction Properties on page 640

7.15.25. VHDL Type

Name	Description
STD_LOGIC	Represents the value of a digital signal in a wire.
STD_LOGIC_VECTOR	Represents an array of digital signals and variables.

7.16. Platform Designer Command-Line Utilities Revision History

The following revision history applies to this chapter:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout. • Added new *Apply Presets to a New Board* topic. • Added missing file option to *Parameter Properties* topic.
2023.12.20	23.4	• Updated *Run the Platform Designer Editor with qsys-edit* topic for new metrics logging switches. • Updated *qsys-generate Command-Line Options* topic for new metrics logging switches. • Updated *Generate a Platform Designer System with qsys-script* topic for new metrics logging switches.
2023.04.03	23.1	• Updated *Board-Aware Flow Scripting Support* topic for new get_quartus_instance_path_for_entity Tcl API. • The product family name is updated to "Intel Agilex 7" to reflect the different family members.
2022.12.12	22.4	• Added new *Board-Aware Flow Scripting Support* topic.
2022.06.20	22.2	• Revised `add_instance` topic to indicate that the `version` argument is required.
2021.03.29	21.1	• Revised *Archive and Extract Platform Designer Systems with qsys-archive* title and link to GUI topic. • Converted to "host" and "agent" inclusive terminology for Avalon memory mapped interface descriptions and related GUI elements throughout.
2020.06.22	20.1	• Added set_design_id command.
2019.11.11	19.1	• Added statement to `qsys-generate` topic indicating that `graybox` option is only for individual Intel FPGA IP cores, and not for complete Platform Designer systems. • Added statement to `qsys-generate` topic indicating that `upgrade-ip-cores` has no impact on subsystems.
2019.04.01	19.1	• Added new Domains command-line reference and deprecated `get_interconnect_requirement`, `get_interconnect_requirements`, and `set_interconnect_requirement assignments`.
2018.12.15	18.1	First release as separate chapter.
2016.10.31	16.1	• Added command-line options for qsys-archive. • Added command-line options for quartus_ipgenerate. • Updated the Qsys Pro scripting commands.

continued...

Document Version	Quartus Prime Version	Changes
2016.05.03	16.0	• Qsys Command-Line Utilities updated with latest supported command-line options.
June 2012	12.0	• Added command-line utilities, and scripts.
December 2010	10.1	Initial release of content.

8. Component Interface Tcl Reference

Tcl commands allow you to perform a wide range of functions in Platform Designer. Command descriptions contain the Platform Designer phases where you can use the command, for example, main program, elaboration, composition, or fileset callback. This reference denotes optional command arguments in brackets [ ].

Note: Intel now refers to Qsys Pro as Platform Designer.

Platform Designer supports Avalon, AMBA 3 AXI (version 1.0), AMBA 4 AXI (version 2.0), AMBA 4 AXI-Lite (version 2.0), AMBA 4 AXI-Stream (version 1.0), and AMBA 3 APB (version 1.0) interface specifications.

For more information about procedures for creating IP component `_hw.tcl` files in the Platform Designer Component Editor, and supported interface standards, refer to *Creating Platform Designer Components* and *Platform Designer Interconnect*.

If you are developing an IP component to work with the Nios II processor, refer to *Publishing Component Information to Embedded Software* in section 3 of the *Nios II Software Developer's Handbook*, which describes how to publish hardware IP component information for embedded software tools, such as a C compiler and a Board Support Package (BSP) generator.

Related Information

- Avalon Interface Specifications
- Creating Platform Designer Components on page 153
- Platform Designer Interconnect on page 251

8.1. Platform Designer _hw.tcl Command Reference

8.1.1. Interfaces and Ports

Related Information

8.1.1.1. add_interface

Description

Adds an interface to your module. An interface represents a collection of related signals that are managed together in the parent system. These signals are implemented in the IP component's HDL, or exported from an interface from a child instance. As the IP component author, you choose the name of the interface.

Availability

Discovery, Main Program, Elaboration, Composition

Usage

`add_interface` <*name*> <*type*> <*direction*> [<*associated_clock*>]

Returns

No returns value.

Arguments

name A name you choose to identify an interface.

type The type of interface.

direction The interface direction.

associated_clock (optional) (deprecated) For interfaces requiring associated clocks, use: `set_interface_property` <*interface*> `associatedClock` <*clockInterface*> For interfaces requiring associated resets, use: `set_interface_property` <*interface*> `associatedReset` <*resetInterface*>

Example

```
add_interface mm_agent avalon agent

add_interface my_export conduit end
set_interface_property my_export EXPORT_OF uart_0.external_connection
```

Notes

By default, interfaces are enabled. You can set the interface property ENABLED to `false` to disable an interface. If an interface is disabled, it is hidden and its ports are automatically terminated to their default values. Active high signals are terminated to 0. Active low signals are terminated to 1.

If the IP component is composed of child instances, the top-level interface is associated with a child instance's interface with `set_interface_property` *`interface`* `EXPORT_OF` *`child_instance.interface`*.

The following direction rules apply to Platform Designer-supported interfaces.

Interface Type	Direction
avalon	host, agent
axi	manager, subordinate
tristate_conduit	host, agent
avalon_streaming	source, sink
interrupt	sender, receiver
conduit	end
clock	source, sink
reset	source, sink
nios_custom_instruction	slave

- get_interface_properties on page 676
- get_interfaces on page 672

8.1.1.2. add_interface_port

Description

Adds a port to an interface on your module. The name must match the name of a signal on the top-level module in the HDL of your IP component. The port width and direction must be set before the end of the elaboration phase. You can set the port width as follows:

- In the Main program, you can set the port width to a fixed value or a width expression.
- If the port width is set to a fixed value in the Main program, you can update the width in the elaboration callback.

Availability

Main Program, Elaboration

Usage

`add_interface_port` *<interface>* *<port>* [*<signal_type>* *<direction>* *<width_expression>*]

Returns

Arguments

interface The name of the interface to which this port belongs.

port The name of the port. This name must match a signal in your top-level HDL for this IP component.

signal_type (optional) The type of signal for this port, which must be unique. Refer to the *Avalon Interface Specifications* for the signal types available for each interface type.

direction (optional) The direction of the signal. Refer to *Direction Properties*.

width_expression (optional) The width of the port, in bits. The width may be a fixed value, or a simple arithmetic expression of parameter values.

Example

```
fixed width:
add_interface_port mm_agent s0_rdata readdata output 32

width expression:
add_parameter DATA_WIDTH INTEGER 32
add_interface_port s0 rdata readdata output "DATA_WIDTH/2"
```

Related Information

- get_port_property on page 679
- get_port_property on page 679
- Direction Properties on page 774
- Avalon Interface Specifications

8.1.1.3. get_interfaces

Description

Returns a list of top-level interfaces.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_interfaces
```

Returns

A list of the top-level interfaces exported from the system.

Arguments

No arguments.

Example

```
get_interfaces
```

Related Information

add_interface on page 668

8.1.1.4. get_interface_assignment

Description

Returns the value of the specified assignment for the specified interface

Availability

Main Program, Elaboration, Validation, Composition

Usage

`get_interface_assignment` <*interface*> <*assignment*>

Returns

The value of the assignment.

Arguments

interface The name of a top-level interface.

assignment The name of an assignment.

Example

```
get_interface_assignment s1 embeddedsw.configuration.isFlash
```

Related Information

- add_interface on page 668
- get_interface_assignments on page 674
- get_interfaces on page 672

8.1.1.5. get_interface_assignments

Description

Returns the value of all interface assignments for the specified interface.

Availability

Main Program, Elaboration, Validation, Composition

Usage

`get_interface_assignments` <*interface*>

Returns

A list of assignment keys.

Arguments

interface The name of the top-level interface whose assignment is being retrieved.

Example

```
get_interface_assignments s1
```

Related Information

- add_interface on page 668
- get_interface_assignment on page 673
- get_interfaces on page 672

8.1.1.6. get_interface_ports

Description

Returns the names of all of the ports that have been added to a given interface. If the interface name is omitted, all ports for all interfaces are returned.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_interface_ports` [<*interface*>]

Returns

A list of port names.

Arguments

interface (optional) The name of a top-level interface.

Example

```
get_interface_ports mm_agent
```

Related Information

- add_interface_port on page 670
- get_port_property on page 679
- set_port_property on page 683

8.1.1.7. get_interface_properties

Description

Returns the names of all the interface properties for the specified interface as a space separated list

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_interface_properties` <*interface*>

Returns

A list of properties for the interface.

Arguments

interface The name of an interface.

Example

```
get_interface_properties interface
```

Notes

The properties for each interface type are different. Refer to the *Avalon Interface Specifications* for more information about interface properties.

Related Information

- get_interface_property on page 677
- set_interface_property on page 682
- Avalon Interface Specifications

8.1.1.8. get_interface_property

Description

Returns the value of a single interface property from the specified interface.

Availability

Discovery, Main Program, Elaboration, Composition, Fileset Generation

Usage

`get_interface_property` <*interface*> <*property*>

Returns

Arguments

interface The name of an interface.

property The name of the property whose value you want to retrieve. Refer to *Interface Properties*.

Example

```
get_interface_property mm_agent linewrapBursts
```

Notes

The properties for each interface type are different. Refer to the *Avalon Interface Specifications* for more information about interface properties.

Related Information

- get_interface_properties on page 676
- set_interface_property on page 682
- Avalon Interface Specifications

8.1.1.9. get_port_properties

Description

Returns a list of port properties.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_port_properties
```

Returns

A list of port properties. Refer to *Port Properties*.

Arguments

No arguments.

Example

```
get_port_properties
```

Related Information

- add_interface_port on page 670
- get_port_property on page 679
- set_port_property on page 683
- Port Properties on page 772

8.1.1.10. get_port_property

Description

Returns the value of a property for the specified port.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_port_property` <*port*> <*property*>

Returns

The value of the property.

Arguments

port The name of the port.

property The name of a port property. Refer to *Port Properties*.

Example

```
get_port_property rdata WIDTH_VALUE
```

Related Information

- add_interface_port on page 670
- get_port_properties on page 678
- set_port_property on page 683
- Port Properties on page 772

8.1.1.11. set_interface_assignment

Description

Sets the value of the specified assignment for the specified interface.

Availability

Main Program, Elaboration, Validation, Composition

Usage

`set_interface_assignment` <*interface*> <*assignment*> [<*value*>]

Returns

No return value.

Arguments

interface The name of the top-level interface whose assignment is being set.

assignment The assignment whose value is being set.

value (optional) The new assignment value.

Example

```
set_interface_assignment s1 embeddedsw.configuration.isFlash 1
```

Notes

Assignments for Nios II Software Build Tools

Interface assignments provide extra data for the Nios II Software Build Tools working with the generated system.

Assignments for Platform Designer Tools

There are several assignments that guide behavior in the Platform Designer tools.

qsys.ui.export_name:	If present, this interface should always be exported when an instance is added to a Platform Designer system. The value is the requested name of the exported interface in the parent system.
qsys.ui.connect:	If present, this interface should be auto-connected when an instance is added to a Platform Designer system. The value is a comma-separated list of other interfaces on the same instance that should be connected with this interface.

ui.blockdiagram.direction:	If present, the direction of this interface in the block diagram is set by the user. The value is either "output" or "input".

Related Information

- add_interface on page 668
- get_interface_assignment on page 673
- get_interface_assignments on page 674

8.1.1.12. set_interface_property

Description

Sets the value of a property on an exported top-level interface. You can use this command to set the EXPORT_OF property to specify which interface of a child instance is exported via this top-level interface.

Availability

Main Program, Elaboration, Composition

Usage

`set_interface_property` <*interface*> <*property*> <*value*>

Returns

No return value.

Arguments

interface The name of an exported top-level interface.

property The name of the property Refer to *Interface Properties*.

value The new property value.

Example

```
set_interface_property clk_out EXPORT_OF clk.clk_out
set_interface_property mm_agent linewrapBursts false
```

Notes

The properties for each interface type are different. Refer to the *Avalon Interface Specifications* for more information about interface properties.

Related Information

- get_interface_properties on page 676
- get_interface_property on page 677
- Avalon Interface Specifications

8.1.1.13. set_port_property

Description

Sets a port property.

Availability

Elaboration

Usage

`set_port_property` <*port*> <*property*> [<*value*>]

Returns

The new value.

Arguments

port The name of the port.

property One of the supported properties. Refer to *Port Properties*.

value (optional) The value to set.

Example

```
set_port_property rdata WIDTH 32
```

Related Information

- add_interface_port on page 670
- get_port_properties on page 678
- set_port_property on page 683

8.1.1.14. set_interface_upgrade_map

Description

Maps the interface name of an older version of an IP core to the interface name of the current IP core. The interface type must be the same between the older and newer versions of the IP cores. This allows system connections and properties to maintain proper functionality. By default, if the older and newer versions of IP core have the same name and type, then Platform Designer maintains all properties and connections automatically.

Availability

Parameter Upgrade

Usage

```
set_interface_upgrade_map { <old_interface_name> <new_interface_name>
<old_interface_name_2> <new_interface_name_2> … }
```

Returns

No return value.

Arguments

{ <old_interface_name> <new_interface_name>}	List of mappings between names of older and newer interfaces.

Example

```
set_interface_upgrade_map { avalon_host_interface new_avalon_host_interface }
```

8.1.2. Parameters

8.1.2.1. add_parameter

Description

Adds a parameter to your IP component.

Availability

Main Program

Usage

`add_parameter <name> <type> [<default_value> <description>]`

Returns

Arguments

name The name of the parameter.

type The data type of the parameter Refer to *Parameter Type Properties*.

default_value (optional) The initial value of the parameter in a new instance of the IP component.

description (optional) Explains the use of the parameter.

Example

```
add_parameter seed INTEGER 17 "The seed to use for data generation."
```

Notes

Most parameter types have a single GUI element for editing the parameter value. `string_list` and `integer_list` parameters are different, because they are edited as tables. A multi-column table can be created by grouping multiple into a single table. To edit multiple list parameters in a single table, the display items for the parameters must be added to a group with a TABLE hint:

```
add_parameter coefficients INTEGER_LIST add_parameter positions
INTEGER_LIST add_display_item "" "Table Group" GROUP TABLE
add_display_item "Table Group" coefficients PARAMETER
add_display_item "Table Group" positions PARAMETER
```

Related Information

- get_parameter_properties on page 688
- get_parameter_property on page 689
- get_parameter_value on page 690
- set_parameter_property on page 693
- set_parameter_value on page 694
- Parameter Type Properties on page 770

8.1.2.2. get_parameters

Description

Returns the names of all the parameters in the IP component.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_parameters
```

Returns

A list of parameter names

Arguments

No arguments.

Example

```
get_parameters
```

Related Information

- add_parameter on page 686
- get_parameter_property on page 689
- get_parameter_value on page 690
- get_parameters on page 687
- set_parameter_property on page 693

8.1.2.3. get_parameter_properties

Description

Returns a list of all the parameter properties as a list of strings. The `get_parameter_property` and `set_parameter_property` commands are used to get and set the values of these properties, respectively.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_parameter_properties
```

Returns

A list of parameter property names. Refer to *Parameter Properties*.

Arguments

No arguments.

Example

```
set property_summary [ get_parameter_properties ]
```

Related Information

- add_parameter on page 686
- get_parameter_property on page 689
- get_parameter_value on page 690
- get_parameters on page 687
- set_parameter_property on page 693
- Parameter Properties on page 768

8.1.2.4. get_parameter_property

Description

Returns the value of a property of a parameter.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_parameter_property` <*parameter*> <*property*>

Returns

The value of the property.

Arguments

parameter The name of the parameter whose property value is being retrieved.

property The name of the property. Refer to *Parameter Properties*.

Example

```
set enabled [ get_parameter_property parameter1 ENABLED ]
```

Related Information

- add_parameter on page 686
- get_parameter_properties on page 688
- get_parameter_value on page 690
- get_parameters on page 687
- set_parameter_property on page 693
- set_parameter_value on page 694
- Parameter Properties on page 768

8.1.2.5. get_parameter_value

Description

Returns the current value of a parameter defined previously with the `add_parameter` command.

Availability

Discovery, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_parameter_value` <*parameter*>

Returns

The value of the parameter.

Arguments

parameter The name of the parameter whose value is being retrieved.

Example

```
set width [ get_parameter_value fifo_width ]
```

Notes

If `AFFECTS_ELABORATION` is `false` for a given parameter, `get_parameter_value` is not available for that parameter from the elaboration callback. If `AFFECTS_GENERATION` is `false` then it is not available from the generation callback.

Related Information

- add_parameter on page 686
- get_parameter_property on page 689
- get_parameters on page 687
- set_parameter_property on page 693
- set_parameter_value on page 694

8.1.2.6. get_string

Description

Returns the value of an externalized string previously loaded by the `load_strings` command.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_string` <*identifier*>

Returns

The externalized string.

Arguments

identifier The string identifier.

Example

```
hw.tcl:
load_strings test.properties
set_module_property NAME test
set_module_property VERSION [get_string VERSION]
set_module_property DISPLAY_NAME [get_string DISPLAY_NAME]
add_parameter firepower INTEGER 0 ""
set_parameter_property firepower DISPLAY_NAME [get_string PARAM_DISPLAY_NAME]
set_parameter_property firepower TYPE INTEGER
set_parameter_property firepower DESCRIPTION [get_string PARAM_DESCRIPTION]

test.properties:
DISPLAY_NAME = Trogdor!
VERSION = 1.0
PARAM_DISPLAY_NAME = Firepower
PARAM_DESCRIPTION = The amount of force to use when breathing fire.
```

Notes

Use uppercase words separated with underscores to name string identifiers. If you are externalizing module properties, use the module property name for the string identifier:

```
set_module_property DISPLAY_NAME [get_string DISPLAY_NAME]
```

If you are externalizing a parameter property, qualify the parameter property with the parameter name, with uppercase format, if needed:

```
set_parameter_property my_param DISPLAY_NAME [get_string MY_PARAM_DISPLAY_NAME]
```

If you use a string to describe a string format, end the identifier with _FORMAT.

```
set formatted_string [ format  [ get_string TWO_ARGUMENT_MESSAGE_FORMAT ] "arg1"
"arg2" ]
```

Related Information

load_strings on page 692

8.1.2.7. load_strings

Description

Loads strings from an external `.properties` file.

Availability

Discovery, Main Program

Usage

`load_strings` <*path*>

Returns

No return value.

Arguments

path The path to the properties file.

Example

```
hw.tcl:
load_strings test.properties
set_module_property NAME test
set_module_property VERSION [get_string VERSION]
set_module_property DISPLAY_NAME [get_string DISPLAY_NAME]
add_parameter firepower INTEGER 0 ""
set_parameter_property firepower DISPLAY_NAME [get_string PARAM_DISPLAY_NAME]
set_parameter_property firepower TYPE INTEGER
set_parameter_property firepower DESCRIPTION [get_string PARAM_DESCRIPTION]

test.properties:
DISPLAY_NAME = Trogdor!
VERSION = 1.0
PARAM_DISPLAY_NAME = Firepower
PARAM_DESCRIPTION = The amount of force to use when breathing fire.
```

Notes

Refer to the *Java Properties File* for properties file format. A `.properties` file is a text file with *KEY*=*value* pairs. For externalized strings, the *KEY* is a string identifier and the *value* is the externalized string.
For example:

```
TROGDOR = A dragon with a big beefy arm
```

Related Information

- get_string on page 691
- Java Properties File

8.1.2.8. set_parameter_property

Description

Sets a single parameter property.

Availability

Main Program, Edit, Elaboration, Validation, Composition

Usage

`set_parameter_property` <*parameter*> <*property*> <*value*>

Returns

Arguments

parameter The name of the parameter that is being set.

property The name of the property. Refer to *Parameter Properties*.

value The new value for the property.

Example

```
set_parameter_property BAUD_RATE ALLOWED_RANGES {9600 19200 38400}
```

Related Information

- add_parameter on page 686
- get_parameter_properties on page 688
- set_parameter_property on page 693
- Parameter Properties on page 768

8.1.2.9. set_parameter_value

Description

Sets a parameter value. The value of a derived parameter can be updated by the IP component in the elaboration callback or the edit callback. Any changes to the value of a derived parameter in the edit callback is not preserved.

Availability

Edit, Elaboration, Validation, Composition, Parameter Upgrade

Usage

`set_parameter_value` <*parameter*> <*value*>

Returns

No return value.

Arguments

parameter The name of the parameter that is being set.

value Specifies the new parameter value.

Example

```
set_parameter_value half_clock_rate [ expr { [ get_parameter_value
clock_rate ] / 2 } ]
```

8.1.3. Interconnect Parameters

8.1.3.1. set_domain_assignment

Description

Sets the assignment value to all connections on the given domain.

Availability

Composition

Usage

```
set_domain_assignment <element> <assignment> <value>
```

Arguments

element Connection or interface in the domain to which you want to set the assignment. If the element name is `$system`, the assignment applies to all the domains in the system.

assignment The name of the assignment.

value The value of the assignment.

8.1.3.2. get_domain_assignment

Description

Returns the value for the specified assignment in the given domain.

Availability

Composition

Usage

```
get_domain_assignment <element> <assignment>
```

Arguments

element Connection or interface in the domain for which you want to get the assignment value.

assignment The name of the assignment.

8.1.3.3. get_domain_assignments

Description

Returns all domain assignments for the given domain as a list of strings. Each "group" of three elements in the list contains the element name, assignment name, and value, in that order. Element name in the output is the input element name. If the input element is `$system`, then the output element name is the connection point in the domain. The Returns section shows a typical list.

Returns

```
[element0 name0 value0 element1 name1 value1 ... ]
```

In TCL, you'd loop over the list by writing a foreach loop:

```
foreach {element name value } \
    $requirement_list { puts " $element $name $value" }
```

Availability

Composition

Usage

```
get_domain_assignments <element>
```

Arguments

element Connection or interface in the domains for which you want to get the assignments value. If you specify $system as the element, the command returns values of all the domains in the system.

8.1.3.4. set_postadaptation_assignment

Description

Adds an post adaptation interconnect assignment.

Availability

Composition

Usage

```
set_postadaptation_assignment <element> <assignment> <value>
```

Arguments

element Connection or interface in the domain to which you want to set the assignment.

assignment The name of the assignment.

value The value of the assignment.

8.1.3.5. get_postadaptation_assignment

Description

Returns the value of the named post adaptation interconnect assignment on the specified element.

Availability

Composition

Usage

```
get_postadaptation_assignment <element> <assignment>
```

Arguments

element Connection or interface in the domain for which you want to get the assignment value.

assignment The name of the assignment.

8.1.3.6. get_postadaptation_assignments

Description

Returns all post adaptation interconnect assignments for the given domain as a list of strings. Each "group" of three elements in the list contains the element name, assignment name and value in that order. The Returns section shows a typical list.

Returns

```
[element0 name0 value0 element1 name1 value1 ... ]
```

In Tcl, you loop over the list by writing a foreach loop:

```
foreach {element name value } $requirement_list \
     { puts " $element $name $value" }
```

Availability

Composition

Usage

```
get_postadaptation_assignments <element>
```

Arguments

element Connection or interface in the domain to which you want to set the assignment.

8.1.4. Display Items

8.1.4.1. add_display_item

Description

Specifies the following aspects of the IP component display:

- Creates logical groups for an IP component's parameters. For example, to create separate groups for the IP component's timing, size, and simulation parameters. An IP component displays the groups and parameters in the order that you specify the display items in the `_hw.tcl` file.
- Groups a list of parameters to create multi-column tables.
- Specifies an image to provide representation of a parameter or parameter group.
- Creates a button by adding a display item of type `action`. The display item includes the name of the callback to run.

Availability

Main Program

Usage

`add_display_item` <*parent_group*> <*id*> <*type*> [<*args*>]

Returns

Arguments

parent_group Specifies the group to which a display item belongs

id The identifier for the display item. If the item being added is a parameter, this is the parameter name. If the item is a group, this is the group name.

type The type of the display item. Refer to *Display Item Kind Properties*.

args (optional) Provides extra information required for display items.

Example

```
add_display_item "Timing" read_latency PARAMETER
add_display_item "Sounds" speaker_image_id ICON speaker.jpg
```

Notes

The following examples illustrate further illustrate the use of arguments:

- `add_display_item groupName id icon` *`path-to-image-file`*
- `add_display_item groupName parameterName parameter`
- `add_display_item groupName id text "your-text"`

  The your-text argument is a block of text that is displayed in the GUI. Some simple HTML formatting is allowed, such as <b> and <i>, if the text starts with `<html>`.
- `add_display_item parentGroupName childGroupName group [tab]`

  The tab is an optional parameter. If present, the group appears in separate tab in the GUI for the instance.
- `add_display_item parentGroupName actionName action buttonClickCallbackProc`

Related Information

- get_display_item_properties on page 702
- get_display_item_property on page 703
- get_display_items on page 701
- set_display_item_property on page 704
- Display Item Kind Properties on page 776

8.1.4.2. get_display_items

Description

Returns a list of all items to be displayed as part of the parameterization GUI.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_display_items
```

Returns

List of display item IDs.

Arguments

No arguments.

Example

```
get_display_items
```

Related Information

- add_display_item on page 699
- get_display_item_properties on page 702
- get_display_item_property on page 703
- set_display_item_property on page 704

8.1.4.3. get_display_item_properties

Description

Returns a list of names of the properties of display items that are part of the parameterization GUI.

Availability

Main Program

Usage

```
get_display_item_properties
```

Returns

A list of display item property names. Refer to *Display Item Properties*.

Arguments

No arguments.

Example

```
get_display_item_properties
```

Related Information

- add_display_item on page 699
- get_display_item_property on page 703
- set_display_item_property on page 704
- Display Item Properties on page 775

8.1.4.4. get_display_item_property

Description

Returns the value of a specific property of a display item that is part of the parameterization GUI.

Availability

Main Program, Elaboration, Validation, Composition

Usage

`get_display_item_property` <*display_item*> <*property*>

Returns

The value of a display item property.

Arguments

display_item The id of the display item.

property The name of the property. Refer to *Display Item Properties*.

Example

```
set my_label [get_display_item_property my_action DISPLAY_NAME]
```

Related Information

- add_display_item on page 699
- get_display_item_properties on page 702
- get_display_items on page 701
- set_display_item_property on page 704
- Display Item Properties on page 775

8.1.4.5. set_display_item_property

Description

Sets the value of specific property of a display item that is part of the parameterization GUI.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Composition

Usage

`set_display_item_property` <*display_item*> <*property*> <*value*>

Returns

No return value.

Arguments

display_item The name of the display item whose property value is being set.

property The property that is being set. Refer to *Display Item Properties*.

value The value to set.

Example

```
set_display_item_property my_action DISPLAY_NAME "Click Me"
set_display_item_property my_action DESCRIPTION "clicking this button runs the
click_me_callback proc in the hw.tcl file"
```

Related Information

- add_display_item on page 699
- get_display_item_properties on page 702
- get_display_item_property on page 703
- Display Item Properties on page 775

8.1.5. Module Definition

8.1.5.1. add_documentation_link

Description

Allows you to link to documentation for your IP component.

Availability

Discovery, Main Program

Usage

`add_documentation_link` <*title*> <*path*>

Returns

No return value.

Arguments

title The title of the document for use on menus and buttons.

path A path to the IP component documentation, using a syntax that provides the entire URL, not a relative path. For example: `http://www.mydomain.com/my_memory_controller.html` or `file:///datasheet.txt`

Example

```
add_documentation_link "Avalon Verification IP Suite User Guide" http://

```

8.1.5.2. get_module_assignment

Description

This command returns the value of an assignment. You can use the `get_module_assignment` and `set_module_assignment` and the `get_interface_assignment` and `set_interface_assignment` commands to provide information about the IP component to embedded software tools and applications.

Availability

Main Program, Elaboration, Validation, Composition

Usage

`get_module_assignment` <*assignment*>

Returns

The value of the assignment

Arguments

assignment The name of the assignment whose value is being retrieved

Example

```
get_module_assignment embeddedsw.CMacro.colorSpace
```

Related Information

- get_module_assignments on page 708
- set_module_assignment on page 713

8.1.5.3. get_module_assignments

Description

Returns the names of the module assignments.

Availability

Main Program, Elaboration, Validation, Composition

Usage

```
get_module_assignments
```

Returns

A list of assignment names.

Arguments

No arguments.

Example

```
get_module_assignments
```

Related Information

- get_module_assignment on page 707
- set_module_assignment on page 713

8.1.5.4. get_module_ports

Description

Returns a list of the names of all the ports which are currently defined.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_module_ports
```

Returns

A list of port names.

Arguments

No arguments.

Example

```
get_module_ports
```

Related Information

- add_interface on page 668
- add_interface_port on page 670

8.1.5.5. get_module_properties

Description

Returns the names of all the module properties as a list of strings. You can use the `get_module_property` and `set_module_property` commands to get and set values of individual properties. The value returned by this command is always the same for a particular version of Platform Designer

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_module_properties
```

Returns

List of strings. Refer to *Module Properties*.

Arguments

No arguments.

Example

```
get_module_properties
```

Related Information

- get_module_property on page 711
- set_module_property on page 714
- Module Properties on page 778

8.1.5.6. get_module_property

Description

Returns the value of a single module property.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_module_property` <*property*>

Returns

Various.

Arguments

property The name of the property, Refer to *Module Properties*.

Example

```
set my_name [ get_module_property NAME ]
```

Related Information

- get_module_properties on page 710
- set_module_property on page 714
- Module Properties on page 778

8.1.5.7. send_message

Description

Sends a message to the user of the IP component. The message text is normally interpreted as HTML. You can use the <b> element to provide emphasis. If you do not want the message text to be interpreted as HTML, then pass a list as the message level, for example, `{ Info Text }`.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

`send_message` <*level*> <*message*>

Returns

No return value .

Arguments

level The following message levels are supported:

- **ERROR**--Provides an error message. The Platform Designer system cannot be generated with existing error messages.
- **WARNING**--Provides a warning message.
- **INFO**--Provides an informational message. The **INFO** level is not available in the Main Program.
- **PROGRESS**--Reports progress during generation.
- **DEBUG**--Provides a debug message when debug mode is enabled.

message The text of the message.

Example

```
send_message ERROR "The system is down!"
send_message { Info Text } "The system is up!"
```

8.1.5.8. set_module_assignment

Description

Sets the value of the specified assignment.

Availability

Main Program, Elaboration, Validation, Composition

Usage

`set_module_assignment` <*assignment*> [<*value*>]

Returns

No return value.

Arguments

assignment The assignment whose value is being set

value (optional) The value of the assignment

Example

```
set_module_assignment embeddedsw.CMacro.colorSpace CMYK
```

Related Information

- get_module_assignment on page 707
- get_module_assignments on page 708

8.1.5.9. set_module_property

Description

Allows you to set the values for module properties.

Availability

Discovery, Main Program

Usage

`set_module_property` <*property*> <*value*>

Returns

No return value.

Arguments

property The name of the property. Refer to *Module Properties*.

value The new value of the property.

Example

```
set_module_property VERSION 10.0
```

Related Information

- get_module_properties on page 710
- get_module_property on page 711
- Module Properties on page 778

8.1.5.10. add_hdl_instance

Description

Adds an instance of a predefined module, referred to as a *child* or *child instance*. The HDL entity generated from this instance can be instantiated and connected within this IP component's HDL.

Availability

Main Program, Elaboration, Composition

Usage

`add_hdl_instance` <*entity_name*> <*ip_type*> [<*version*>]

Returns

The entity name of the added instance.

Arguments

entity_name Specifies a unique local name that you can use to manipulate the instance. This name is used in the generated HDL to identify the instance.

ip_type The type refers to a kind of instance available in the IP Catalog, for example `altera_avalon_uart`.

version (optional) The required version of the specified instance type. If no version is specified, the latest version is used.

Example

```
add_hdl_instance my_uart altera_avalon_uart
```

Related Information

- get_instance_parameter_value on page 733
- get_instance_parameters on page 731
- get_instances on page 723
- set_instance_parameter_value on page 736

8.1.5.11. package

Description

Allows you to specify a particular version of the Platform Designer software to avoid software compatibility issues, and to determine which version of the **_hw.tcl** API to use for the IP component. You must use the package command at the beginning of your **_hw.tcl** file.

Availability

Main Program

Usage

```
package require -exact qsys <version>
```

Returns

No return value

Arguments

version The version of Platform Designer that you require, such as 14.1.

Example

```
package require -exact qsys 14.1
```

8.1.6. Composition

8.1.6.1. add_instance

Description

Adds an instance of an IP component, referred to as a child or child instance to the subsystem. You can use this command to create IP components that are composed of other IP component instances. The HDL for this subsystem generates; There is no need to write custom HDL for the IP component.

Availability

Main Program, Composition

Usage

`add_instance` <*name*> <*type*> [<*version*>]

Returns

No return value.

Arguments

name Specifies a unique local name that you can use to manipulate the instance. This name is used in the generated HDL to identify the instance.

type The type refers to a type available in the IP Catalog, for example `altera_avalon_uart`.

version The required version of the specified instance type. This argument is required in Package version 19.1 and later. Before package version 19.1, when not specified the latest IP version is used.

Example

```
add_instance my_uart altera_avalon_uart
add_instance my_uart altera_avalon_uart 22.1
```

Related Information

- add_connection on page 719
- get_instance_interface_property on page 730
- get_instance_parameter_value on page 733
- get_instance_parameters on page 731
- get_instance_property on page 727
- get_instances on page 723
- set_instance_parameter_value on page 736

8.1.6.2. add_connection

Description

Connects the named interfaces on child instances together using an appropriate connection type. Both interface names consist of a child instance name, followed by the name of an interface provided by that module. For example, `mux0.out` is the interface named `out` on the instance named `mux0`. Be careful to connect the start to the end, and not the other way around.

Availability

Main Program, Composition

Usage

`add_connection` <*start*> [<*end*> <*kind*> <*name*>]

Returns

The name of the newly added connection in `start.point/end.point` format.

Arguments

start The start interface to be connected, in `<instance_name>.<interface_name>` format.

end (optional) The end interface to be connected, `<instance_name>.<interface_name>`.

kind (optional) The type of connection, such as `avalon` or `clock`.

name (optional) A custom name for the connection. If unspecified, the name will be `<start_instance>.<interface>.<end_instance><interface>`

Example

```
add_connection dma.read_host sdram.s1 avalon
```

Related Information

- add_instance on page 718
- get_instance_interfaces on page 724

8.1.6.3. get_connections

Description

Returns a list of all connections in the composed subsystem.

Availability

Main Program, Composition

Usage

```
get_connections
```

Returns

A list of connections.

Arguments

No arguments.

Example

```
set all_connections [ get_connections ]
```

Related Information

add_connection on page 719

8.1.6.4. get_connection_parameters

Description

Returns a list of parameters found on a connection.

Availability

Main Program, Composition

Usage

`get_connection_parameters` <*connection*>

Returns

A list of parameter names

Arguments

connection The connection to query.

Example

```
get_connection_parameters cpu.data_host/dma0.csr
```

Related Information

- add_connection on page 719
- get_connection_parameter_value on page 722

8.1.6.5. get_connection_parameter_value

Description

Returns the value of a parameter on the connection. Parameters represent aspects of the connection that can be modified once the connection is created, such as the base address for an Avalon Memory Mapped connection.

Availability

Composition

Usage

`get_connection_parameter_value` <*connection*> <*parameter*>

Returns

The value of the parameter.

Arguments

connection The connection to query.

parameter The name of the parameter.

Example

```
get_connection_parameter_value cpu.data_host/dma0.csr baseAddress
```

Related Information

- add_connection on page 719
- get_connection_parameters on page 721

8.1.6.6. get_instances

Description

Returns a list of the instance names for all child instances in the system.

Availability

Main Program, Elaboration, Validation, Composition

Usage

```
get_instances
```

Returns

A list of child instance names.

Arguments

No arguments.

Example

```
get_instances
```

Notes

This command can be used with instances created by either `add_instance` or `add_hdl_instance`.

Related Information

- add_hdl_instance on page 715
- add_instance on page 718
- get_instance_parameter_value on page 733
- get_instance_parameters on page 731
- set_instance_parameter_value on page 736

8.1.6.7. get_instance_interfaces

Description

Returns a list of interfaces found in a child instance. The list of interfaces can change if the parameterization of the instance changes.

Availability

Validation, Composition

Usage

`get_instance_interfaces` <*instance*>

Returns

A list of interface names.

Arguments

instance The name of the child instance.

Example

```
get_instance_interfaces pixel_converter
```

Related Information

- add_instance on page 718
- get_instance_interface_ports on page 725
- get_instance_interfaces on page 724

8.1.6.8. get_instance_interface_ports

Description

Returns a list of ports found in an interface of a child instance.

Availability

Validation, Composition, Fileset Generation

Usage

`get_instance_interface_ports` <*instance*> <*interface*>

Returns

A list of port names found in the interface.

Arguments

instance The name of the child instance.

interface The name of an interface on the child instance.

Example

```
set port_names [ get_instance_interface_ports cpu data_host ]
```

Related Information

- add_instance on page 718
- get_instance_interfaces on page 724
- get_instance_port_property on page 734

8.1.6.9. get_instance_interface_properties

Description

Returns the names of all of the properties of the specified interface

Availability

Validation, Composition

Usage

`get_instance_interface_properties` <*instance*> <*interface*>

Returns

List of property names.

Arguments

instance The name of the child instance.

interface The name of an interface on the instance.

Example

```
set properties [ get_instance_interface_properties cpu data_host ]
```

Related Information

- add_instance on page 718
- get_instance_interface_property on page 730
- get_instance_interfaces on page 724

8.1.6.10. get_instance_property

Description

Returns the value of a single instance property.

Availability

Main Program, Elaboration, Validation, Composition, Fileset Generation

Usage

`get_instance_property` <*instance*> <*property*>

Returns

Various.

Arguments

instance The name of the instance.

property The name of the property. Refer to *Instance Properties*.

Example

```
set my_name [ get_instance_property myinstance NAME ]
```

Related Information

- add_instance on page 718
- get_instance_properties on page 729
- set_instance_property on page 728
- Instance Properties on page 767

8.1.6.11. set_instance_property

Description

Allows a user to set the properties of a child instance.

Availability

Main Program, Elaboration, Validation, Composition

Usage

`set_instance_property` <*instance*> <*property*> <*value*>

Returns

Arguments

instance The name of the instance.

property The name of the property to set. Refer to *Instance Properties*.

value The new property value.

Example

```
set_instance_property myinstance SUPRESS_ALL_WARNINGS true
```

Related Information

- add_instance on page 718
- get_instance_properties on page 729
- get_instance_property on page 727
- Instance Properties on page 767

8.1.6.12. get_instance_properties

Description

Returns the names of all the instance properties as a list of strings. You can use the `get_instance_property` and `set_instance_property` commands to get and set values of individual properties. The value returned by this command is always the same for a particular version of Platform Designer

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_instance_properties
```

Returns

List of strings. Refer to *Instance Properties*.

Arguments

No arguments.

Example

```
get_instance_properties
```

Related Information

- add_instance on page 718
- get_instance_property on page 727
- set_instance_property on page 728
- Instance Properties on page 767

8.1.6.13. get_instance_interface_property

Description

Returns the value of a property for an interface in a child instance.

Availability

Validation, Composition

Usage

`get_instance_interface_property` <*instance*> <*interface*> <*property*>

Returns

The value of the property.

Arguments

instance The name of the child instance.

interface The name of an interface on the child instance.

property The name of the property of the interface.

Example

```
set value [ get_instance_interface_property cpu data_host setupTime ]
```

Related Information

- add_instance on page 718
- get_instance_interfaces on page 724

8.1.6.14. get_instance_parameters

Description

Returns a list of names of the parameters on a child instance that can be set using `set_instance_parameter_value`. It omits parameters that are derived and those that have the `SYSTEM_INFO` parameter property set.

Availability

Main Program, Elaboration, Validation, Composition

Usage

`get_instance_parameters` <*instance*>

Returns

A list of parameters in the instance.

Arguments

instance The name of the child instance.

Example

```
set parameters [ get_instance_parameters instance ]
```

Notes

You can use this command with instances created by either `add_instance` or `add_hdl_instance`.

Related Information

- add_hdl_instance on page 715
- add_instance on page 718
- get_instance_parameter_value on page 733
- get_instances on page 723
- set_instance_parameter_value on page 736

8.1.6.15. get_instance_parameter_property

Description

Returns the value of a property on a parameter in a child instance. Parameter properties are metadata that describe how the Platform Designer tools use the parameter.

Availability

Validation, Composition

Usage

`get_instance_parameter_property` <*instance*> <*parameter*> <*property*>

Returns

The value of the parameter property.

Arguments

instance The name of the child instance.

parameter The name of the parameter in the instance.

property The name of the property of the parameter. Refer to *Parameter Properties*.

Example

```
get_instance_parameter_property instance parameter property
```

Related Information

- add_instance on page 718
- Parameter Properties on page 768

8.1.6.16. get_instance_parameter_value

Description

Returns the value of a parameter in a child instance. You cannot use this command to get the value of parameters whose values are derived or those that are defined using the SYSTEM_INFO parameter property.

Availability

Elaboration, Validation, Composition

Usage

`get_instance_parameter_value` <*instance*> <*parameter*>

Returns

The value of the parameter.

Arguments

instance The name of the child instance.

parameter Specifies the parameter whose value is being retrieved.

Example

```
set dpi [ get_instance_parameter_value pixel_converter input_DPI ]
```

Notes

You can use this command with instances created by either `add_instance` or `add_hdl_instance`.

Related Information

- add_hdl_instance on page 715
- add_instance on page 718
- get_instance_parameters on page 731
- get_instances on page 723
- set_instance_parameter_value on page 736

8.1.6.17. get_instance_port_property

Description

Returns the value of a property of a port contained by an interface in a child instance.

Availability

Validation, Composition, Fileset Generation

Usage

`get_instance_port_property` <*instance*> <*port*> <*property*>

Returns

The value of the property for the port.

Arguments

instance The name of the child instance.

port The name of a port in one of the interfaces on the child instance.

property The property whose value is being retrieved. Only the following port properties can be queried on ports of child instances: `ROLE`, `DIRECTION`, `WIDTH`, `WIDTH_EXPR` and `VHDL_TYPE`. Refer to *Port Properties*.

Example

```
get_instance_port_property instance port property
```

Related Information

- add_instance on page 718
- get_instance_interface_ports on page 725
- Port Properties on page 772

8.1.6.18. set_connection_parameter_value

Description

Sets the value of a parameter of the connection. The start and end are each interface names of the format `<instance>.<interface>`. Connection parameters depend on the type of connection, for Avalon memory mapped they include base addresses and arbitration priorities.

Availability

Main Program, Composition

Usage

`set_connection_parameter_value` <*connection*> <*parameter*> <*value*>

Returns

No return value.

Arguments

connection Specifies the name of the connection as returned by the `add_conection` command. It is of the form `start.point/end.point`.

parameter The name of the parameter.

value The new parameter value.

Example

```
set_connection_parameter_value cpu.data_host/dma0.csr baseAddress "0x000a0000"
```

Related Information

- add_connection on page 719
- get_connection_parameter_value on page 722

8.1.6.19. set_instance_parameter_value

Description

Sets the value of a parameter for a child instance. Derived parameters and SYSTEM_INFO parameters for the child instance cannot be set with this command.

Availability

Main Program, Elaboration, Composition

Usage

`set_instance_parameter_value` <*instance*> <*parameter*> <*value*>

Returns

Vo return value.

Arguments

instance Specifies the name of the child instance.

parameter Specifies the parameter that is being set.

value Specifies the new parameter value.

Example

```
set_instance_parameter_value uart_0 baudRate 9600
```

Notes

You can use this command with instances created by either `add_instance` or `add_hdl_instance`.

Related Information

- add_hdl_instance on page 715
- add_instance on page 718
- get_instance_parameter_value on page 733
- get_instances on page 723

8.1.7. Fileset Generation

8.1.7.1. add_fileset

Description

Adds a generation fileset for a particular target as specified by the `kind`. Platform Designer calls the target (`SIM_VHDL`, `SIM_VERILOG`, `QUARTUS_SYNTH`, or `EXAMPLE_DESIGN`) when the specified generation target is requested. You can define multiple filesets for each kind of fileset. Platform Designer passes a single argument to the specified callback procedure. The value of the argument is a generated name, which you must use in the top-level module or entity declaration of your IP component. To override this generated name, you can set the fileset property `TOP_LEVEL`.

Availability

Main Program

Usage

`add_fileset` <*name*> <*kind*> [<*callback_proc*> <*display_name*>]

Returns

No return value.

Arguments

name The name of the fileset.

kind The kind of fileset. Refer to *Fileset Properties*.

callback_proc (optional) A string identifying the name of the callback procedure. If you add files in the global section, you can then specify a blank callback procedure.

display_name (optional) A display string to identify the fileset.

Example

```
add_fileset my_synthesis_fileset QUARTUS_SYNTH mySynthCallbackProc "My Synthesis"
proc mySynthCallbackProc { topLevelName } { ... }
```

Notes

If using the `TOP_LEVEL` fileset property, all parameterizations of the component must use identical HDL.

Related Information

- add_fileset_file on page 739
- get_fileset_property on page 744
- Fileset Properties on page 780

8.1.7.2. add_fileset_file

Description

Adds a file to the generation directory. You can specify source file locations with either an absolute path, or a path relative to the IP component's `_hw.tcl` file. When you use the `add_fileset_file` command in a fileset callback, the Quartus Prime software compiles the files in the order that they are added.

Availability

Main Program, Fileset Generation

Usage

`add_fileset_file` <*output_file*> <*file_type*> <*file_source*> <*path_or_contents*> [<*attributes*>]

Returns

No return value.

Arguments

output_file Specifies the location to store the file after Platform Designer generation

file_type The kind of file. Refer to *File Kind Properties*.

file_source Specifies whether the file is being added by path, or by file contents. Refer to *File Source Properties*.

path_or_contents When the `file_source` is PATH, specifies the file to be copied to `output_file`. When the `file_source` is TEXT, specifies the text contents to be stored in the file.

attributes (optional) An optional list of file attributes. Typically used to specify that a file is intended for use only in a particular simulator. Refer to *File Attribute Properties*.

Example

```
add_fileset_file "./implementation/rx_pma.sv" SYSTEM_VERILOG PATH synth_rx_pma.sv
add_fileset_file gui.sv SYSTEM_VERILOG TEXT "Customize your IP core"
```

Related Information

- add_fileset on page 738
- get_fileset_file_attribute on page 741
- File Kind Properties on page 784
- File Source Properties on page 785
- File Attribute Properties on page 783

8.1.7.3. set_fileset_property

Description

Allows you to set the properties of a fileset.

Availability

Main Program, Elaboration, Fileset Generation

Usage

`set_fileset_property` <*fileset*> <*property*> <*value*>

Returns

No return value.

Arguments

fileset The name of the fileset.

property The name of the property to set. Refer to *Fileset Properties*.

value The new property value.

Example

```
set_fileset_property mySynthFileset TOP_LEVEL simple_uart
```

Notes

When a fileset callback is called, the callback procedure is passed a single argument. The value of this argument is a generated name which must be used in the top-level module or entity declaration of your IP component. If set, the TOP_LEVEL specifies a fixed name for the top-level name of your IP component.

The TOP_LEVEL property must be set in the global section. It cannot be set in a fileset callback.

If using the TOP_LEVEL fileset property, all parameterizations of the IP component must use identical HDL.

Related Information

- add_fileset on page 738
- Fileset Properties on page 780

8.1.7.4. get_fileset_file_attribute

Description

Returns the attribute of a fileset file.

Availability

Main Program, Fileset Generation

Usage

`get_fileset_file_attribute` <*output_file*> <*attribute*>

Returns

Value of the fileset File attribute.

Arguments

output_file Location of the output file.

attribute Specifies the name of the attribute Refer to *File Attribute Properties*.

Example

```
get_fileset_file_attribute my_file.sv ALDEC_SPECIFIC
```

Related Information

- add_fileset on page 738
- add_fileset_file on page 739
- get_fileset_file_attribute on page 741
- File Attribute Properties on page 783
- add_fileset on page 738
- add_fileset_file on page 739
- get_fileset_file_attribute on page 741
- File Attribute Properties on page 783

8.1.7.5. set_fileset_file_attribute

Description

Sets the attribute of a fileset file.

Availability

Main Program, Fileset Generation

Usage

`set_fileset_file_attribute` <*output_file*> <*attribute*> <*value*>

Returns

The attribute value if it was set.

Arguments

output_file Location of the output file.

attribute Specifies the name of the attribute Refer to *File Attribute Properties*.

value Value to set the attribute to.

Example

```
set_fileset_file_attribute my_file_pkg.sv COMMON_SYSTEMVERILOG_PACKAGE
my_file_package
```

8.1.7.6. get_fileset_properties

Description

Returns a list of properties that can be set on a fileset.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Generation, Composition, Fileset Generation, Parameter Upgrade

Usage

```
get_fileset_properties
```

Returns

A list of property names. Refer to *Fileset Properties*.

Arguments

No arguments.

Example

```
get_fileset_properties
```

Related Information

- add_fileset on page 738
- get_fileset_properties on page 743
- set_fileset_property on page 740
- Fileset Properties on page 780

8.1.7.7. get_fileset_property

Description

Returns the value of a fileset property for a fileset.

Availability

Main Program, Elaboration, Fileset Generation

Usage

`get_fileset_property` <*fileset*> <*property*>

Returns

The value of the property.

Arguments

fileset The name of the fileset.

property The name of the property to query. Refer to *Fileset Properties*.

Example

```
get_fileset_property fileset property
```

Related Information

Fileset Properties on page 780

8.1.7.8. get_fileset_sim_properties

Description

Returns simulator properties for a fileset.

Availability

Main Program, Fileset Generation

Usage

`get_fileset_sim_properties` <*fileset*> <*platform*> <*property*>

Returns

The fileset simulator properties.

Arguments

fileset The name of the fileset.

platform The operating system that applies to the property. Refer to *Operating System Properties*.

property Specifies the name of the property to set. Refer to *Simulator Properties*.

Example

```
get_fileset_sim_properties my_fileset LINUX64 OPT_CADENCE_64BIT
```

Related Information

- add_fileset on page 738
- set_fileset_sim_properties on page 746
- Operating System Properties on page 792
- Simulator Properties on page 786

8.1.7.9. set_fileset_sim_properties

Description

Sets simulator properties for a given fileset

Availability

Main Program, Fileset Generation

Usage

`set_fileset_sim_properties` <*fileset*> <*platform*> <*property*> <*value*>

Returns

The fileset simulator properties if they were set.

Arguments

fileset The name of the fileset.

platform The operating system that applies to the property. Refer to *Operating System Properties*.

property Specifies the name of the property to set. Refer to *Simulator Properties*.

value Specifies the value of the property.

Example

```
set_fileset_sim_properties my_fileset LINUX64 OPT_MENTOR_PLI "{libA} {libB}"
```

Related Information

- get_fileset_sim_properties on page 745
- Operating System Properties on page 792
- Simulator Properties on page 786

8.1.7.10. create_temp_file

Description

Creates a temporary file, which you can use inside the fileset callbacks of a `_hw.tcl` file. This temporary file is included in the generation output if it is added using the `add_fileset_file` command.

Availability

Fileset Generation

Usage

`create_temp_file` <*path*>

Returns

The path to the temporary file.

Arguments

path The name of the temporary file.

Example

```
set filelocation [create_temp_file "./hdl/compute_frequency.v" ]
add_fileset_file compute_frequency.v VERILOG PATH ${filelocation}
```

Related Information

- add_fileset on page 738
- add_fileset_file on page 739

8.1.8. Miscellaneous

8.1.8.1. check_device_family_equivalence

Description

Returns 1 if the device family is equivalent to one of the families in the device families list. Returns 0 if the device family is not equivalent to any families. This command ignores differences in capitalization and spaces.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Composition, Fileset Generation, Parameter Upgrade

Usage

`check_device_family_equivalence` <*device_family*> <*device_family_list*>

Returns

1 if equivalent, 0 if not equivalent.

Arguments

device_family The device family name that is being checked.

device_family_list The list of device family names to check against.

Example

```
check_device_family_equivalence "CYLCONE III LS" { "stratixv" "Cyclone IV"
"cycloneiiils" }
```

Related Information

get_device_family_displayname on page 750

8.1.8.2. get_device_family_displayname

Description

Returns the display name of a given device family.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Composition, Fileset Generation, Parameter Upgrade

Usage

`get_device_family_displayname <device_family>`

Returns

The preferred display name for the device family.

Arguments

device_family A device family name.

Example

```
get_device_family_displayname cycloneiiils ( returns: "Cyclone IV LS" )
```

Related Information

check_device_family_equivalence on page 749

8.1.8.3. get_qip_strings

Description

Returns a Tcl list of QIP strings for the IP component.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Composition, Parameter Upgrade

Usage

```
get_qip_strings
```

Returns

A Tcl list of qip strings set by this IP component.

Arguments

No arguments.

Example

```
set strings [ get_qip_strings ]
```

Related Information

set_qip_strings on page 752

8.1.8.4. set_qip_strings

Description

Places strings in the Quartus Prime IP File (**.qip**) file, which Platform Designer passes to the command as a Tcl list. You add the **.qip** file to your Quartus Prime project on the **Files** page, in the **Settings** dialog box. Successive calls to `set_qip_strings` are not additive and replace the previously declared value.

Availability

Discovery, Main Program, Edit, Elaboration, Validation, Composition, Parameter Upgrade

Usage

`set_qip_strings` <*qip_strings*>

Returns

The Tcl list which was set.

Arguments

qip_strings A space-delimited Tcl list.

Example

```
set_qip_strings {"QIP Entry 1" "QIP Entry 2"}
```

Notes

You can use the following macros in your QIP strings entry:

%entityName%	The generated name of the entity replaces this macro when the string is written to the **.qip** file.
%libraryName%	The compilation library this IP component was compiled into is inserted in place of this macro inside the **.qip** file.
%instanceName%	The name of the instance is inserted in place of this macro inside the `.qip` file.

Related Information

get_qip_strings on page 751

8.1.9. SystemVerilog Interface Commands

8.1.9.1. add_sv_interface

Description

Adds a SystemVerilog interface to the IP component.

Availability

Elaboration, Global

Usage

`add_sv_interface` <*sv_interface_name*> <*sv_interface_type*>

Returns

No return value.

Arguments

sv_interface_name	The name of the SystemVerilog interface in the IP component.
sv_interface_type	The type of the SystemVerilog interface used by the IP component.

Example

```
add_sv_interface my_sv_interface my_sv_interface_type
```

8.1.9.2. get_sv_interfaces

Description

Returns the list of SystemVerilog interfaces in the IP component.

Availability

Elaboration, Global

Usage

```
get_sv_interfaces
```

Returns

String[] Returns the list of SystemVerilog interfaces defined in the IP component.

Arguments

No arguments.

Example

```
get_sv_interfaces
```

8.1.9.3. get_sv_interface_property

Description

Returns the value of a single SystemVerilog interface property from the specified interface.

Availability

Elaboration, Global

Usage

`get_sv_interface_property` <*sv_interface_name*> <*sv_interface_property*>

Returns

various The property value.

Arguments

sv_interface_name The name of a SystemVerilog interface of the system.

sv_interface_property The name of the property. Refer to *System Verilog Interface Properties*.

Example

```
get_sv_interface_property my_sv_interface USE_ALL_PORTS
```

8.1.9.4. get_sv_interface_properties

Description

Returns the names of all the available SystemVerilog interface properties common to all interface types.

Availability

Elaboration, Global

Usage

```
get_sv_interface_properties
```

Returns

String[] The list of SystemVerilog interface properties.

Arguments

No arguments.

Example

```
get_sv_interface_properties
```

8.1.9.5. set_sv_interface_property

Description

Sets the value of a property on a SystemVerilog interface.

Availability

Elaboration, Global

Usage

`set_sv_interface_property` <*sv_interface_name*> <*sv_interface_property*> <*value*>

Returns

No return value.

Arguments

interface The name of a SystemVerilog interface.

sv_interface_property The name of the property. Refer to *SystemVerilog Interface Properties*.

value The property value.

Example

```
set_sv_interface_property my_sv_interface USE_ALL_PORTS True
```

8.1.10. Wire-Level Expression Commands

8.1.10.1. set_wirelevel_expression

Description

Applies a wire-level expression to an optional input port or instance in the system.

Usage

`set_wirelevel_expression` <*instance_or_port_bitselection*> <*expression*>

Returns

No return value.

Arguments

instance_or_port_bitselection	Specify the instance or port to which the wire-level expression using the <*instance_name*>.<*port_name*>[<*bit_selection*>] format. The *bit selection* can be a bit-select, for example `[0]`, or a partial range defined in descending order, for example `[7:0]`. If no *bit selection* is specified, the full range of the port is selected.
expression	The expression to be applied to an optional input port.

Examples

```
set_wirelevel_expression {module0.portA[7:0]} "8'b0"
set_wirelevel_expression module0.portA "8'b0"
set_wirelevel_expression {module0.portA[0]} "1'b0"
```

Related Information

Scripting Wire-Level Expressions on page 71

8.1.10.2. get_wirelevel_expressions

Description

Retrieve a list of wire-level expressions from an optional input port, instance, or all expressions in the current level of system hierarchy. If the port *bit selection* is specified as an argument, the range must be identical to what was used in the `set_wirelevel_expression` statement.

Usage

`get_wirelevel_expressions` <*instance_or_port_bitselection*>

Returns

String[] A flattened list of wire-level expressions. Every item in the list consists of right- and left-hand clauses of a wire-level expression. You can loop over the returned list using `foreach{port expr} $return_list{}`.

Arguments

instance_or_port_bitselection Specifies which instance or port from which a list of wire-level expressions are retrieved using the <*instance_name*>.<*port_name*>[<*bit_selection*>] format.

- If no <*port_name*>*[<bit_selection>]* is specified, the command causes the return of all expressions from the specified instance.
- If no argument is present, the command causes the return of all expressions from the current level of system hierarchy.

The *bit selection* can be a bit-select, for example `[0]`, or a partial range defined in descending order, for example `[7:0]`. If no *bit selection* is specified, the full range of the port is selected.

Example

```
get_wirelevel_expressions
get_wirelevel_expressions module0
get_wirelevel_expressions {module0.portA[7:0]}
```

Related Information

Scripting Wire-Level Expressions on page 71

8.1.10.3. remove_wirelevel_expressions

Description

Remove a list of wire-level expressions from an optional input port, instance, or all expressions in the current level of system hierarchy. If the port *bit selection* is specified as an argument, the range must be identical to what was used in the `set_wirelevel_expressions` statement.

Usage

`remove_wirelevel_expressions` <*instance_or_port_bitselection*>

Returns

No return value.

Arguments

instance_or_port_bitselection	Specifies which instance or port from which a list of wire-level expressions are removed using the <*instance_name*>.<*port_name*>[<*bit_selection*>] format. • If no <*port_name*>*[<bit_selection>]* is specified, the command causes the removal of all expressions from the specified instance. • If no argument is present, the command causes the return of all expressions from the current level of system hierarchy. The *bit selection* can be a bit-select, for example `[0]`, or a partial range defined in descending order, for example `[7:0]`. If no *bit selection* is specified, the full range of the port is selected.

Examples

```
remove_wirelevel_expressions
remove_wirelevel_expressions module0
remove_wirelevel_expressions {module0.portA[7:0]}
```

Related Information

Scripting Wire-Level Expressions on page 71

8.2. Platform Designer _hw.tcl Property Reference

8.2.1. Script Language Properties

Name	Description
TCL	Implements the script in Tcl.

8.2.2. Interface Properties

Name	Description
CMSIS_SVD_FILE	Specifies the connection point's associated CMSIS file.
CMSIS_SVD_VARIABLES	Defines the variables inside a .svd file.
ENABLED	Specifies whether or not interface is enabled.
EXPORT_OF	For composed `_hwl.tcl` files, the EXPORT_OF property indicates which interface of a child instance is to be exported through this interface. Before using this command, you must have created the border interface using `add_interface`. The interface to be exported is of the form <*instanceName.interfaceName*>. Example: `set_interface_property CSC_input EXPORT_OF my_colorSpaceConverter.input_port`
PORT_NAME_MAP	A map of external port names to internal port names, formatted as a Tcl list. Example: `set_interface_property <interface name> PORT_NAME_MAP "<new port name> <old port name> <new port name 2> <old port name 2>"`
SVD_ADDRESS_GROUP	Generates a CMSIS SVD file. Hosts in the same SVD address group write register data of their connected agents into the same SVD file
SVD_ADDRESS_OFFSET	Generates a CMSIS SVD file. Agents connected to this host have their base address offset by this amount in the SVD file.
SV_INTERFACE	When SV_INTERFACE is set, all the ports in the given interface are part of the SystemVerilog interface. Example: `set_interface_property my_qsys_interface SV_INTERFACE my_sv_interface`
IPXACT_REGISTER_MAP	Specifies the connection point's associated IP-XACT register map file. Platform Designer supports register map files in IP-XACT 2009 or 2014 format. Example: `set_interface_property my_qsys_interface IPXACT_REGISTER_MAP <path_to_ipxact_reg_file>`
IPXACT_REGISTER_MAP_VARIABLES	For macro substitution inside the IP-XACT register map file. Specifies a list of key value pairs, where key is the macro name and value is the replacement text that substitutes the macros in the IP-XACT register map.

Related Information

Interfaces and Ports on page 667

8.2.3. SystemVerilog Interface Properties

Name	Description
SV_INTERFACE_TYPE	Set the interface type of the SystemVerilog interface.

Name	Description
USE_ALL_PORTS	When USE_ALL_PORTS is set to true, all the ports defined in the Module, are declared in this SystemVerilog interface. USE_ALL_PORTS must be set to true only if the module has one SystemVerilog interface and the SystemVerilog interface signal names match with the port names declared for Platform Designer interface. When USE_ALL_PORTS is true, SV_INTERFACE_PORT or SV_INTERFACE_SIGNAL port properties should not be set.

8.2.4. Instance Properties

Name	Description
HDLINSTANCE_GET_GENERATED_NAME	Platform Designer uses this property to get the auto-generated fixed name when the instance property HDLINSTANCE_USE_GENERATED_NAME is set to true, and only applies to fileSet callbacks.
HDLINSTANCE_USE_GENERATED_NAME	If true, instances added with the `add_hdl_instance` command are instructed to use unique auto-generated fixed names based on the parameterization.
SUPPRESS_ALL_INFO_MESSAGES	If true, allows you to suppress all Info messages that originate from a child instance.
SUPPRESS_ALL_WARNINGS	If true, allows you to suppress all warnings that originate from a child instance

8.2.5. Parameter Properties

Type	Name	Description
Boolean	AFFECTS_ELABORATION	Set AFFECTS_ELABORATION to false for parameters that do not affect the external interface of the module. An example of a parameter that does not affect the external interface is isNonVolatileStorage. An example of a parameter that does affect the external interface is width. When the value of a parameter changes, if that parameter has set AFFECTS_ELABORATION=false, the elaboration phase (calling the callback or hardware analysis) is not repeated, improving performance. Because the default value of AFFECTS_ELABORATION is true, the provided HDL file is normally re-analyzed to determine the new port widths and configuration every time a parameter changes.
Boolean	AFFECTS_GENERATION	The default value of AFFECTS_GENERATION is false if you provide a top-level HDL module; it is true if you provide a fileset callback. Set AFFECTS_GENERATION to false if the value of a parameter does not change the results of fileset generation.
Boolean	AFFECTS_VALIDATION	The AFFECTS_VALIDATION property marks whether a parameter's value is used to set derived parameters, and whether the value affects validation messages. When set to false, this may improve response time in the parameter editor UI when the value is changed.
String[]	ALLOWED_RANGES	Indicates the range or ranges that the parameter value can have. For integers, The ALLOWED_RANGES property is a list of ranges that the parameter can take on, where each range is a single value, or a range of values defined by a start and end value separated by a colon, such as 11:15. This property can also specify legal values and display strings for integers, such as {0:None 1:Monophonic 2:Stereo 4:Quadrophonic} meaning 0, 1, 2, and 4 are the legal values. You can also assign display strings to be displayed in the parameter editor for string variables. For example, ALLOWED_RANGES {"dev1:Cyclone IV GX""dev2:Stratix V GT"}.
String	DEFAULT_VALUE	The default value.
Boolean	DERIVED	When true, indicates that the parameter value can only be set by the IP component, and cannot be set by the user. Derived parameters are not saved as part of an instance's parameter values. The default value is false.
String	DESCRIPTION	A short user-visible description of the parameter, suitable for a tooltip description in the parameter editor.
String[]	DISPLAY_HINT	Provides a hint about how to display a property. The following values are possible: • boolean--for integer parameters whose value can be 0 or 1. The parameter displays as an option that you can turn on or off. • radio--displays a parameter with a list of values as radio buttons instead of a drop-down list. • hexadecimal--for integer parameters, display and interpret the value as a hexadecimal number, for example: 0x00000010 instead of 16. • fixed_size--for string_list and integer_list parameters, the fixed_size DISPLAY_HINT eliminates the **add** and **remove** buttons from tables.
String	DISPLAY_NAME	This is the GUI label that appears to the left of this parameter.
String	DISPLAY_UNITS	This is the GUI label that appears to the right of the parameter.

Type	Name	Description
Boolean	ENABLED	When `false`, the parameter is disabled, meaning that it is displayed, but greyed out, indicating that it is not editable on the parameter editor.
String	GROUP	Controls the layout of parameters in GUI
Boolean	HDL_PARAMETER	When true, the parameter must be passed to the HDL IP component description. The default value is `false`.
String	LONG_DESCRIPTION	A user-visible description of the parameter. Similar to DESCRIPTION, but allows for a more detailed explanation.
String	NEW_INSTANCE_VALUE	This property allows you to change the default value of a parameter without affecting older IP components that have did not explicitly set a parameter value, and use the DEFAULT_VALUE property. The practical result is that older instances continue to use DEFAULT_VALUE for the parameter and new instances use the value that NEW_INSTANCE_VALUE assigns.
String	SV_INTERFACE_PARAMETER	This parameter is used in the SystemVerilog interface instantiation. Example: `set_parameter_property my_parameter SV_INTERFACE_PARAMETER my_sv_interface`
String[]	SYSTEM_INFO	Allows you to assign information about the instantiating system to a parameter that you define. SYSTEM_INFO requires an argument specifying the type of information requested, *<info-type>*.
String	SYSTEM_INFO_ARG	Defines an argument to be passed to a particular SYSTEM_INFO function, such as the name of a reset interface.
(various)	SYSTEM_INFO_TYPE	Specifies one of the types of system information that can be queried. Refer to *System Info Type Properties*.
(various)	TYPE	Specifies the type of the parameter. Refer to *Parameter Type Properties*.
(various)	UNITS	Sets the units of the parameter. Refer to *Units Properties*.
Boolean	VISIBLE	Indicates whether or not to display the parameter in the parameterization GUI.
String	WIDTH	For a STD_LOGIC_VECTOR parameter, this indicates the width of the logic vector.

Related Information

- System Info Type Properties on page 788
- Parameter Type Properties on page 770
- Units Properties on page 791

8.2.6. Parameter Type Properties

Name	Description
BOOLEAN	A boolean parameter whose value is `true` or `false`.
FLOAT	A signed 32-bit floating point parameter. Not supported for HDL parameters.
INTEGER	A signed 32-bit integer parameter.
INTEGER_LIST	A parameter that contains a list of 32-bit integers. Not supported for HDL parameters.
LONG	A signed 64-bit integer parameter. Not supported for HDL parameters.
NATURAL	A 32-bit number that contain values `0` to `2147483647` (`0x7fffffff`).
POSITIVE	A 32-bit number that contains values `1` to `2147483647` (`0x7fffffff`).
STD_LOGIC	A single bit parameter whose value can be `1` or `0`;
STD_LOGIC_VECTOR	An arbitrary-width number. The parameter property `WIDTH` determines the size of the logic vector.
STRING	A string parameter.
STRING_LIST	A parameter that contains a list of strings. Not supported for HDL parameters.

8.2.7. Parameter Status Properties

Type	Name	Description
Boolean	ACTIVE	Indicates the parameter is a regular parameter.
Boolean	DEPRECATED	Indicates the parameter exists only for backwards compatibility, and may not have any effect.
Boolean	EXPERIMENTAL	Indicates the parameter is experimental, and not exposed in the design flow.

8.2.8. Port Properties

Type	Name	Description
(various)	DIRECTION	The direction of the port from the IP component's perspective. Refer to *Direction Properties*.
String	DRIVEN_BY	Indicates that this output port is always driven to a constant value or by an input port. If all outputs on an IP component specify a driven_by property, the HDL for the IP component is generated automatically.
String[]	FRAGMENT_LIST	This property can be used in 2 ways: First you can take a single RTL signal and split it into multiple Platform Designer signals add_interface_port <interface> alpha <role> <direction> <width> add_interface_port <interface> bar <role> <direction> <width> set_port_property alpha fragment_list "my_rtl_signal(3:0)" set_port_property bar fragment_list "my_rtl_signal(6:4)" Second you can take multiple RTL signals and combine them into a single Platform Designer signal add_interface_port <interface> baz <role> <direction> <width> set_port_property baz fragment_list "rtl_signal_1(3:0) rtl_signal_2(3:0)" Note: The listed bits in a port fragment must match the declared width of the Platform Designer signal.
String	ROLE	Specifies an Avalon signal type such as waitrequest, readdata, or read. For a complete list of signal types, refer to the *Avalon Interface Specifications*.
String	SV_INTERFACE_PORT	This port from the module is used as I/O in the SystemVerilog interface instantiation. The top-level wrapper of the module which contains this port is from the SystemVerilog interface. Example: `set_port_property port_x SV_INTERFACE_PORT my_sv_interface`
String	SV_INTERFACE_PORT_NAME	This property is used only when the Platform Designer port name defined for the module is different from the port name in the SystemVerilog interface. Example: `set_port_property port_x SV_INTERFACE_PORT_NAME port_a` When writing the RTL, the Platform Designer port name port_x is mapped to RTL name port_a in the SystemVerilog interface
String	SV_INTERFACE_SIGNAL	This port from the module is assumed to be inside the SystemVerilog interface or the modport used by the module. The top-level wrapper of the module containing this port is unwrapped from SystemVerilog interface. Example: `set_port_property port_y SV_INTERFACE_SIGNAL my_sv_interface`
String	SV_INTERFACE_SIGNAL_NAME	This property is only used when the Platform Designer port name defined for the module is different from the port name in the SystemVerilog interface. Example: `set_port_property port_y SV_INTERFACE_SIGNAL_NAME port_b`
Boolean	TERMINATION	When true, instead of connecting the port to the Platform Designer system, it is left unconnected for output and bidir or set to a fixed value for input.

Type	Name	Description
BigInteger	TERMINATION_VALUE	The constant value to drive an input port.
(various)	VHDL_TYPE	Indicates the type of a VHDL port. The default value, auto, selects std_logic if the width is fixed at 1, and std_logic_vector otherwise. Refer to *Port VHDL Type Properties*.
String	WIDTH	The width of the port in bits. Cannot be set directly. Any changes must be set through the WIDTH_EXPR property.
String	WIDTH_EXPR	The width expression of a port. The width_value_expr property can be set directly to a numeric value if desired. When get_port_property is used width always returns the current integer width of the port while width_expr always returns the unevaluated width expression.
Integer	WIDTH_VALUE	The width of the port in bits. Cannot be set directly. Any changes must be set through the WIDTH_EXPR property.

Related Information

- Direction Properties on page 774
- Port VHDL Type Properties on page 787
- Avalon Interface Specifications

8.2.9. Direction Properties

Name	Description
`Bidir`	Direction for a bidirectional signal.
`Input`	Direction for an input signal.
`Output`	Direction for an output signal.

8.2.10. Display Item Properties

Type	Name	Description
String	DESCRIPTION	A description of the display item, which you can use as a tooltip.
String[]	DISPLAY_HINT	A hint that affects how the display item displays in the parameter editor.
String	DISPLAY_NAME	The label for the display item in a the parameter editor.
Boolean	ENABLED	Indicates whether the display item is enabled or disabled.
String	PATH	The path to a file. Only applies to display items of type ICON.
String	TEXT	Text associated with a display item. Only applies to display items of type TEXT.
Boolean	VISIBLE	Indicates whether this display item is visible or not.

8.2.11. Display Item Kind Properties

Name	Description
ACTION	An action displays as a button in the GUI. When the button is clicked, it calls the callback procedure. The button label is the display item `id`.
GROUP	A group that is a child of the `parent_group` group. If the `parent_group` is an empty string, this is a top-level group.
ICON	A `.gif`, `.jpg`, or `.png` file.
PARAMETER	A parameter in the instance.
TEXT	A block of text.

8.2.12. Display Hint Properties

Name	Description
BIT_WIDTH	Bit width of a number
BOOLEAN	Integer value either 0 or 1.
COLLAPSED	Indicates whether a group is collapsed when initially displayed.
COLUMNS	Number of columns in text field, for example, "columns:N".
EDITABLE	Indicates whether a list of strings allows free-form text entry (editable combo box).
FILE	Indicates that the string is an optional file path, for example, "file:jpg,png,gif".
FIXED_SIZE	Indicates a fixed size for a table or list.
GROW	if set, the widget can grow when the IP component is resized.
HEXADECIMAL	Indicates that the long integer is hexadecimal.
RADIO	Indicates that the range displays as radio buttons.
ROWS	Number of rows in text field, or visible rows in a table, for example, "rows:N".
SLIDER	Range displays as slider.
TAB	if present for a group, the group displays in a tab
TABLE	if present for a group, the group must contain all list-type parameters, which display collectively in a single table.
TEXT	String is a text field with a limited character set, for example, "text:A-Za-z0-9_".
WIDTH	width of a table column

8.2.13. Module Properties

Name	Description
ANALYZE_HDL	When set to false, prevents a call to the Quartus Prime mapper to verify port widths and directions, speeding up generation time at the expense of fewer validation checks. If this property is set to false, invalid port widths and directions are discovered during the Quartus Prime software compilation. This does not affect IP components using filesets to manage synthesis files.
AUTHOR	The IP component author.
COMPOSITION_CALLBACK	The name of the composition callback. If you define a composition callback, you cannot not define the generation or elaboration callbacks.
DATASHEET_URL	Deprecated. Use `add_documentation_link` to provide documentation links.
DESCRIPTION	The description of the IP component, such as "This IP component implements a half-rate bridge."
DISPLAY_NAME	The name to display when referencing the IP component, such as "My Platform Designer IP Component".
EDITABLE	Indicates whether you can edit the IP component in the Component Editor.
ELABORATION_CALLBACK	The name of the elaboration callback. When set, the IP component's elaboration callback is called to validate and elaborate interfaces for instances of the IP component.
GROUP	The group in the IP Catalog that includes this IP component.
ICON_PATH	A path to an icon to display in the IP component's parameter editor.
INSTANTIATE_IN_SYSTEM_MODULE	If true, this IP component is implemented by HDL provided by the IP component. If false, the IP component creates exported interfaces allowing the implementation to be connected in the parent.
INTERNAL	An IP component which is marked as internal does not appear in the IP Catalog. This feature allows you to hide the sub-IP-components of a larger composed IP component.
MODULE_DIRECTORY	The directory in which the hw.tcl file exists.
MODULE_TCL_FILE	The path to the hw.tcl file.
NAME	The name of the IP component, such as `my_qsys_component`.
OPAQUE_ADDRESS_MAP	For composed IP components created using a _hw.tcl file that include children that are memory-mapped agents, specifies whether the children's addresses are visible to downstream software tools. When `true`, the children's address are not visible. When `false`, the children's addresses are visible.
PREFERRED_SIMULATION_LANGUAGE	The preferred language to use for selecting the fileset for simulation model generation.
REPORT_HIERARCHY	null
STATIC_TOP_LEVEL_MODULE_NAME	Deprecated.
STRUCTURAL_COMPOSITION_CALLBACK	The name of the structural composition callback. This callback is used to represent the structural hierarchical model of the IP component and the RTL can be generated either with module property COMPOSITION_CALLBACK or by ADD_FILESET with target QUARTUS_SYNTH

Name	Description
SUPPORTED_DEVICE_FAMILIES	A list of device family supported by this IP component.
TOP_LEVEL_HDL_FILE	Deprecated.
TOP_LEVEL_HDL_MODULE	Deprecated.
UPGRADEABLE_FROM	null
VALIDATION_CALLBACK	The name of the validation callback procedure.
VERSION	The IP component's version, such as 10.0.

8.2.14. Fileset Properties

Name	Description
ENABLE_FILE_OVERWRITE_MODE	null
ENABLE_RELATIVE_INCLUDE_PATHS	If true, HDL files can include other files using relative paths in the fileset.
TOP_LEVEL	The name of the top-level HDL module that the fileset generates. If set, the HDL top level must match the TOP_LEVEL name, and the HDL must not be parameterized. Platform Designer runs the generate callback one time, regardless of the number of instances in the system.

8.2.15. Fileset Kind Properties

Name	Description
EXAMPLE_DESIGN	Contains example design files.
QUARTUS_SYNTH	Contains files that Platform Designer uses for the Quartus Prime software synthesis.
SIM_VERILOG	Contains files that Platform Designer uses for Verilog HDL simulation.
SIM_VHDL	Contains files that Platform Designer uses for VHDL simulation.
SYSTEMVERILOG_INTERFACE	This file is treated as SystemVerilog interface file by the Platform Designer. Example: `add_fileset_file mem_ifc.sv SYTEM_VERILOG PATH “.ifc/mem_ifc.sv” SYSTEMVERILOG_INTERFACE`

8.2.16. Callback Properties

Description

This list describes each type of callback. Each command may only be available in some callback contexts.

Name	Description
ACTION	Called when an ACTION display item's action is performed.
COMPOSITION	Called during instance elaboration when the IP component contains a subsystem.
EDITOR	Called when the IP component is controlling the parameterization editor.
ELABORATION	Called to elaborate interfaces and signals after a parameter change. In API 9.1 and later, validation is called before elaboration. In API 9.0 and earlier, elaboration is called before validation.
GENERATE_VERILOG_SIMULATION	Called when the IP component uses a custom generator to generates the Verilog simulation model for an instance.
GENERATE_VHDL_SIMULATION	Called when the IP component uses a custom generator to generates the VHDL simulation model for an instance.
GENERATION	Called when the IP component uses a custom generator to generates the synthesis HDL for an instance.
PARAMETER_UPGRADE	Called when attempting to instantiate an IP component with a newer version than the saved version. This allows the IP component to upgrade parameters between released versions of the component.
STRUCTURAL_COMPOSITION	Called during instance elaboration when an IP component is represented by a structural hierarchical model which may be different from the generated RTL.
VALIDATION	Called to validate parameter ranges and report problems with the parameter values. In API 9.1 and later, validation is called before elaboration. In API 9.0 and earlier, elaboration is called before validation.

8.2.17. File Attribute Properties

Name	Description
ALDEC_SPECIFIC	Applies to Aldec simulation tools and for simulation filesets only.
CADENCE_SPECIFIC	Applies to Cadence simulation tools and for simulation filesets only.
COMMON_SYSTEMVERILOG_PACKAGE	The name of the common SystemVerilog package. Applies to simulation filesets only.
MENTOR_SPECIFIC	Applies to Mentor simulation tools and for simulation filesets only.
SYNOPSYS_SPECIFIC	Applies to Synopsys simulation tools and for simulation filesets only.
TOP_LEVEL_FILE	Contains the top-level module for the fileset and applies to synthesis filesets only.

8.2.18. File Kind Properties

Name	Description
DAT	DAT Data
FLI_LIBRARY	FLI Library
HEX	HEX Data
MIF	MIF Data
OTHER	Other
PLI_LIBRARY	PLI Library
SDC	Timing Constraints
SYSTEM_VERILOG	SystemVerilog HDL
SYSTEM_VERILOG_ENCRYPT	Encrypted SystemVerilog HDL
SYSTEM_VERILOG_INCLUDE	SystemVerilog Include
VERILOG	Verilog HDL
VERILOG_ENCRYPT	Encrypted Verilog HDL
VERILOG_INCLUDE	Verilog Include
VHDL	VHDL
VHDL_ENCRYPT	Encrypted VHDL
VPI_LIBRARY	VPI Library

8.2.19. File Source Properties

Name	Description
PATH	Specifies the original source file and copies to `output_file`.
TEXT	Specifies an arbitrary text string for the contents of `output_file`.

8.2.20. Simulator Properties

Name	Description
ENV_ALDEC_LD_LIBRARY_PATH	LD_LIBRARY_PATH when running riviera-pro
ENV_CADENCE_LD_LIBRARY_PATH	LD_LIBRARY_PATH when running ncsim
ENV_MENTOR_LD_LIBRARY_PATH	LD_LIBRARY_PATH when running modelsim
ENV_SYNOPSYS_LD_LIBRARY_PATH	LD_LIBRARY_PATH when running vcs
OPT_ALDEC_PLI	-pli option for riviera-pro
OPT_CADENCE_64BIT	-64bit option for ncsim
OPT_CADENCE_PLI	-loadpli1 option for ncsim
OPT_CADENCE_SVLIB	-sv_lib option for ncsim
OPT_CADENCE_SVROOT	-sv_root option for ncsim
OPT_MENTOR_64	-64 option for modelsim
OPT_MENTOR_CPPPATH	-cpppath option for modelsim
OPT_MENTOR_LDFLAGS	-ldflags option for modelsim
OPT_MENTOR_PLI	-pli option for modelsim
OPT_SYNOPSYS_ACC	+acc option for vcs
OPT_SYNOPSYS_CPP	-cpp option for vcs
OPT_SYNOPSYS_FULL64	-full64 option for vcs
OPT_SYNOPSYS_LDFLAGS	-LDFLAGS option for vcs
OPT_SYNOPSYS_LLIB	-l option for vcs
OPT_SYNOPSYS_VPI	+vpi option for vcs

8.2.21. Port VHDL Type Properties

Name	Description
AUTO	The VHDL type of this signal is automatically determined. Single-bit signals are STD_LOGIC; signals wider than one bit are STD_LOGIC_VECTOR.
STD_LOGIC	Indicates that the signal is not rendered in VHDL as a STD_LOGIC signal.
STD_LOGIC_VECTOR	Indicates that the signal is rendered in VHDL as a STD_LOGIC_VECTOR signal.

8.2.22. System Info Type Properties

Type	Name	Description
String	ADDRESS_MAP	An XML-formatted string describing the address map for the interface specified in the system info argument.
Integer	ADDRESS_WIDTH	The number of address bits required to address all memory-mapped agents connected to the specified memory-mapped host in this instance, using byte addresses.
String	AVALON_SPEC	The version of the interconnect. SOPC Builder interconnect uses Avalon Specification 1.0. Platform Designer interconnect uses Avalon Specification 2.0.
Integer	CLOCK_DOMAIN	An integer that represents the clock domain for the interface specified in the system info argument. If this instance has interfaces on multiple clock domains, this can be used to determine which interfaces are on each clock domain. The absolute value of the integer is arbitrary.
Long, Integer	CLOCK_RATE	The rate of the clock connected to the clock input specified in the system info argument. If 0, the clock rate is currently unknown.
String	CLOCK_RESET_INFO	The name of this instance's primary clock or reset sink interface. This is used to determine the reset sink to use for global reset when using SOPC interconnect.
String	CUSTOM_INSTRUCTION_SLAVES	Provides custom instruction agent information, including the name, base address, address span, and clock cycle type.
(various)	DESIGN_ENVIRONMENT	A string that identifies the current design environment. Refer to *Design Environment Type Properties*.
String	DEVICE	The device part number of the currently selected device.
String	DEVICE_FAMILY	The family name of the currently selected device.
String	DEVICE_FEATURES	A list of key/value pairs delineated by spaces indicating whether a particular device feature is available in the currently selected device family. The format of the list is suitable for passing to the Tcl `array` set command. The keys are device features; the values are 1 if the feature is present, and 0 if the feature is absent.
String	DEVICE_SPEEDGRADE	The speed grade of the currently selected device.
Integer	GENERATION_ID	A integer that stores a hash of the generation time to be used as a unique ID for a generation run.
BigInteger, Long	INTERRUPTS_USED	A mask indicating which bits of an interrupt receiver are connected to interrupt senders. The interrupt receiver is specified in the system info argument.
Integer	MAX_SLAVE_DATA_WIDTH	The data width of the widest agent connected to the specified memory-mapped host.
String, Boolean, Integer	QUARTUS_INI	The value of the quartus.ini setting specified in the system info argument.
Integer	RESET_DOMAIN	An integer that represents the reset domain for the interface specified in the system info argument. If this instance has interfaces on multiple reset domains, this can be used to determine which interfaces are on each reset domain. The absolute value of the integer is arbitrary.

Type	Name	Description
String	TRISTATECONDUIT_INFO	An XML description of the Avalon Tri-state Conduit hosts connected to an Avalon Tri-state Conduit agent. The agent is specified as the system info argument. The value contains information about the agent, the connected host instance and interface names, and signal names, directions and widths.
String	TRISTATECONDUIT_MASTERS	The names of the instance's interfaces that are tri-state conduit agents.
String	UNIQUE_ID	A string guaranteed to be unique to this instance.

Related Information

Design Environment Type Properties on page 790

8.2.23. Design Environment Type Properties

Description

A design environment is used by IP to tell what sort of interfaces are most appropriate to connect in the parent system.

Name	Description
NATIVE	Design environment prefers native IP interfaces.
QSYS	Design environment prefers standard Platform Designer interfaces.

8.2.24. Units Properties

Name	Description
`Address`	A memory-mapped address.
`Bits`	Memory size, in bits.
`BitsPerSecond`	Rate, in bits per second.
`Bytes`	Memory size, in bytes.
`Cycles`	A latency or count, in clock cycles.
`GigabitsPerSecond`	Rate, in gigabits per second.
`Gigabytes`	Memory size, in gigabytes.
`Gigahertz`	Frequency, in GHz.
`Hertz`	Frequency, in Hz.
`KilobitsPerSecond`	Rate, in kilobits per second.
`Kilobytes`	Memory size, in kilobytes.
`Kilohertz`	Frequency, in kHz.
`MegabitsPerSecond`	Rate, in megabits per second.
`Megabytes`	Memory size, in megabytes.
`Megahertz`	Frequency, in MHz.
`Microseconds`	Time, in micros.
`Milliseconds`	Time, in ms.
`Nanoseconds`	Time, in ns.
`None`	Unspecified units.
`Percent`	A percentage.
`Picoseconds`	Time, in ps.
`Seconds`	Time, in s.

8.2.25. Operating System Properties

Name	Description
ALL	All operating systems
LINUX32	Linux 32-bit
LINUX64	Linux 64-bit
WINDOWS32	Windows 32-bit
WINDOWS64	Windows 64-bit

8.2.26. Quartus.ini Type Properties

Name	Description
ENABLED	Returns `1` if the setting is turned on, otherwise returns `0`.
STRING	Returns the string value of the `.ini` setting.

8.3. Component Interface Tcl Reference Revision History

The table below indicates edits made to the *Component Interface Tcl Reference* content since its creation:

Document Version	Quartus Prime Version	Changes
2024.04.01	24.1	• Applied initial Altera rebranding throughout. • Added missing file option to *Parameter Properties* topic.
2023.04.03	23.1	• The product family name is updated to "Intel Agilex 7" to reflect the different family members.
2022.09.26	22.3	• Updated *Port Properties* and *Module Properties* topics to remove instances of obsolete `GENERATION_CALLBACK` port and module properties.
2022.06.20	22.2	• Revised `add_instance` topic to indicate that the `version` argument is required.
2021.03.29	21.1	• Converted to "host" and "agent" inclusive terminology for Avalon memory mapped interface descriptions and related GUI elements throughout.
2019.04.01	19.1.0	• Described new domain and post adaptation assignments in "Interconnect Parameters" topic.
2018.09.24	18.1.0	• Added new _hw.tcl interface properties that allow importing and exporting register maps in IP-XACT format.
2018.05.07	18.0.0	• Added wire-level expression commands to support wire-level interfaces. • Updated `send_message` level availability for `INFO` messages. • Updated `set_port_property` availability.
2017.11.06	17.1.0	• Changed instances of *Qsys Pro* to *Platform Designer* • Added statement clarifying use of brackets. • Added properties and interface commands to support SystemVerilog.
2016.10.31	16.1.0	• Implemented Intel rebranding. • Implemented *Qsys* rebranding.
2015.11.02	15.1.0	Changed instances of *Quartus II* to *Quartus Prime*.
2015.05.04	15.0.0	Edit to `add_fileset_file` command.
December 2014	14.1.0	• set_interface_upgrade_map • Moved **Port Roles (Interface Signal Types)** section to *Qsys Interconnect*.
November 2013	13.1.0	• add_hdl_instance
May 2013	13.0.0	• Consolidated content from other Qsys chapters. • Added AMBA APB support.
November 2012	12.1.0	• Added the **demo_axi_memory** example with screen shots and example **_hw.tcl** code.
June 2012	12.0.0	• Added AXI 3 support. • Added: `set_display_item_property`, `set_parameter_property`,`LONG_DESCRIPTION`, and static filesets.

continued...

Document Version	Quartus Prime Version	Changes
November 2011	11.1.0	• Template update. • Added: `set_qip_strings`, `get_qip_strings`, `get_device_family_displayname`, `check_device_family_equivalence`.
May 2011	11.0.0	• Revised section describing HDL and composed component implementations. • Separated reset and clock interfaces in example. • Added: `TRISTATECONDUIT_INFO`, `GENERATION_ID`, `UNIQUE_ID` `SYSTEM_INFO`. • Added: `WIDTH` and `SYSTEM_INFO_ARG` parameter properties. • Removed the `doc_type` argument from the `add_documentation_link` command. • Removed: `get_instance_parameter_properties` • Added: `add_fileset`, `add_fileset_file`, `create_temp_file`. • Updated Tcl examples to show separate clock and reset interfaces.
December 2010	10.1.0	• Initial release.

9. Quartus Prime Pro Edition User Guide: Platform Designer Document Archives

For the latest and previous versions of this user guide, refer to Quartus Prime Pro Edition User Guide: Platform Designer. If an IP or software version is not listed, the user guide for the previous IP or software version applies.

A. Quartus Prime Pro Edition User Guides

Refer to the following user guides for comprehensive information on all phases of the Quartus Prime Pro Edition FPGA design flow.

Related Information

- Quartus Prime Pro Edition User Guide: Getting Started
  Introduces the basic features, files, and design flow of the Quartus Prime Pro Edition software, including managing Quartus Prime Pro Edition projects and IP, initial design planning considerations, and project migration from previous software versions.
- Quartus Prime Pro Edition User Guide: Platform Designer
  Describes creating and optimizing systems using Platform Designer, a system integration tool that simplifies integrating customized IP cores in your project. Platform Designer automatically generates interconnect logic to connect intellectual property (IP) functions and subsystems.
- Quartus Prime Pro Edition User Guide: Design Recommendations
  Describes best design practices for designing FPGAs with the Quartus Prime Pro Edition software. HDL coding styles and synchronous design practices can significantly impact design performance. Following recommended HDL coding styles ensures that Quartus Prime Pro Edition synthesis optimally implements your design in hardware.
- Quartus Prime Pro Edition User Guide: Design Compilation
  Describes set up, running, and optimization for all stages of the Quartus Prime Pro Edition Compiler. The Compiler synthesizes, places, and routes your design before generating a device programming file.
- Quartus Prime Pro Edition User Guide: Design Optimization
  Describes Quartus Prime Pro Edition settings, tools, and techniques that you can use to achieve the highest design performance in Intel FPGAs. Techniques include optimizing the design netlist, addressing critical chains that limit retiming and timing closure, optimizing device resource usage, device floorplanning, and implementing engineering change orders (ECOs).
- Quartus Prime Pro Edition User Guide: Programmer
  Describes operation of the Quartus Prime Pro Edition Programmer, which allows you to configure Intel FPGA devices, and program CPLD and configuration devices, via connection with an Intel FPGA download cable.
- Quartus Prime Pro Edition User Guide: Block-Based Design
  Describes block-based design flows, also known as modular or hierarchical design flows. These advanced flows enable preservation of design blocks (or logic that comprises a hierarchical design instance) within a project, and reuse of design blocks in other projects.

- Quartus Prime Pro Edition User Guide: Partial Reconfiguration
  Describes Partial Reconfiguration, an advanced design flow that allows you to reconfigure a portion of the FPGA dynamically, while the remaining FPGA design continues to function. Define multiple personas for a particular design region, without impacting operation in other areas.
- Quartus Prime Pro Edition User Guide: Third-party Simulation
  Describes RTL- and gate-level design simulation support for third-party simulation tools by Aldec*, Cadence*, Siemens EDA, and Synopsys that allow you to verify design behavior before device programming. Includes simulator support, simulation flows, and simulating Intel FPGA IP.
- Quartus Prime Pro Edition User Guide: Third-party Synthesis
  Describes support for optional synthesis of your design in third-party synthesis tools by Siemens EDA, and Synopsys. Includes design flow steps, generated file descriptions, and synthesis guidelines.
- Quartus Prime Pro Edition User Guide: Third-party Logic Equivalence Checking Tools
  Describes support for optional logic equivalence checking (LEC) of your design in third-party LEC tools by OneSpin*.
- Quartus Prime Pro Edition User Guide: Debug Tools
  Describes a portfolio of Quartus Prime Pro Edition in-system design debugging tools for real-time verification of your design. These tools provide visibility by routing (or "tapping") signals in your design to debugging logic. These tools include System Console, Signal Tap logic analyzer, system debugging toolkits, In-System Memory Content Editor, and In-System Sources and Probes Editor.
- Quartus Prime Pro Edition User Guide: Timing Analyzer
  Explains basic static timing analysis principals and use of the Quartus Prime Pro Edition Timing Analyzer, a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology.
- Quartus Prime Pro Edition User Guide: Power Analysis and Optimization
  Describes the Quartus Prime Pro Edition Power Analysis tools that allow accurate estimation of device power consumption. Estimate the power consumption of a device to develop power budgets and design power supplies, voltage regulators, heat sink, and cooling systems.
- Quartus Prime Pro Edition User Guide: Design Constraints
  Describes timing and logic constraints that influence how the Compiler implements your design, such as pin assignments, device options, logic options, and timing constraints. Use the Interface Planner to prototype interface implementations, plan clocks, and quickly define a legal device floorplan. Use the Pin Planner to visualize, modify, and validate all I/O assignments in a graphical representation of the target device.
- Quartus Prime Pro Edition User Guide: PCB Design Tools
  Describes support for optional third-party PCB design tools by Siemens EDA and Cadence*. Also includes information about signal integrity analysis and simulations with HSPICE and IBIS Models.
- Quartus Prime Pro Edition User Guide: Scripting
  Describes use of Tcl and command line scripts to control the Quartus Prime Pro Edition software and to perform a wide range of functions, such as managing projects, specifying constraints, running compilation or timing analysis, or generating reports.

Contents

1. Recommended HDL Coding Styles

This chapter provides Hardware Description Language (HDL) coding style recommendations to ensure optimal synthesis results when targeting Intel FPGA devices.

HDL coding styles have a significant effect on the quality of results for programmable logic designs. Synthesis tools optimize HDL code for both logic utilization and performance; however, synthesis tools cannot interpret the intent of your design. Therefore, the most effective optimizations require conformance to recommended coding styles.

Note: For style recommendations, options, or HDL attributes specific to your synthesis tool, refer to the synthesis tool vendor's documentation.

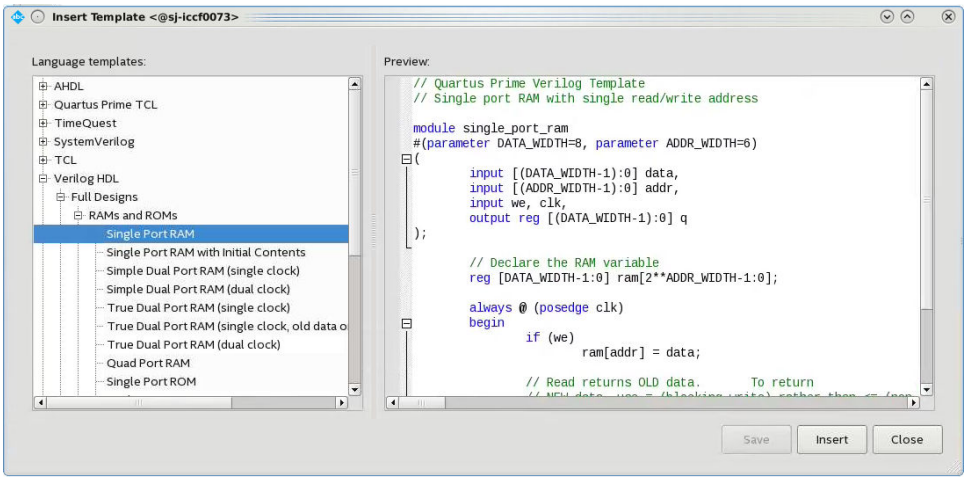
1.1. Using Provided HDL Templates

The Intel® Quartus® Prime software provides templates for Verilog HDL, SystemVerilog, and VHDL templates to start your HDL designs. Many of the HDL examples in this document correspond with the **Full Designs** examples in the **Intel Quartus Prime Templates**. You can insert HDL code into your own design using the templates or examples.

1.1.1. Inserting HDL Code from a Provided Template

1. Click **File ➤ New**.
2. In the **New** dialog box, select the HDL language for the design files: **SystemVerilog HDL File**, **VHDL File**, or **Verilog HDL File**; and click **OK**. A text editor tab with a blank file opens.
3. Right-click the blank file and click **Insert Template**.
4. In the **Insert Template** dialog box, expand the section corresponding to the appropriate HDL, then expand the **Full Designs** section.
5. Select a template. The template now appears in the **Preview** pane.
6. To paste the HDL design into the blank Verilog or VHDL file you created, click **Insert**.
7. Click **Close** to close the **Insert Template** dialog box.

Figure 1. Inserting a RAM Template



Note: Use the Intel Quartus Prime Text Editor to modify the HDL design or save the template as an HDL file to edit in your preferred text editor.

1.2. Instantiating IP Cores in HDL

Intel provides parameterizable IP cores that are optimized for Intel FPGA device architectures. Using IP cores instead of coding your own logic saves valuable design time.

Additionally, the Intel-provided IP cores offer more efficient logic synthesis and device implementation. Scale the IP core's size and specify various options by setting parameters. To instantiate the IP core directly in your HDL file code, invoke the IP core name and define its parameters as you would do for any other module, component, or sub design. Alternatively, you can use the IP Catalog (**Tools ➤ IP Catalog**) and parameter editor GUI to simplify customization of your IP core variation. You can infer or instantiate IP cores that optimize device architecture features, for example:

- Transceivers
- LVDS drivers
- Memory and DSP blocks
- Phase-locked loops (PLLs)
- Double-data rate input/output (DDIO) circuitry

For some types of logic functions, such as memories and DSP functions, you can infer device-specific dedicated architecture blocks instead of instantiating an IP core. Intel Quartus Prime synthesis recognizes certain HDL code structures and automatically infers the appropriate IP core or map directly to device atoms.

1.3. Inferring Multipliers and DSP Functions

The following sections describe how to infer multiplier and DSP functions from generic HDL code, and, if applicable, how to target the dedicated DSP block architecture in Intel FPGA devices.

Related Information

Intel FPGA Digital Signal Processing

1.3.1. Inferring Multipliers

To infer multiplier functions, synthesis tools detect multiplier logic and implement this in Intel FPGA IP cores, or map the logic directly to device atoms.

For devices with DSP blocks, Intel Quartus Prime synthesis can implement the function in a DSP block instead of logic, depending on device utilization. The Intel Quartus Prime fitter can also place input and output registers in DSP blocks (that is, perform register packing) to improve performance and area utilization.

The following Verilog HDL and VHDL code examples show that synthesis tools can infer signed and unsigned multipliers as IP cores or DSP block atoms. Each example fits into one DSP block element. In addition, when register packing occurs, no extra logic cells for registers are required.

Example 1. Verilog HDL Unsigned Multiplier

```
module unsigned_mult (out, a, b);
    output [15:0] out;
    input [7:0] a;
    input [7:0] b;
    assign out = a * b;
endmodule
```

Note: The `signed` declaration in Verilog HDL is a feature of the Verilog 2001 Standard.

Example 2. Verilog HDL Signed Multiplier with Input and Output Registers (Pipelining = 2)

```
module signed_mult (out, clk, a, b);
   output [15:0] out;
   input clk;
   input signed [7:0] a;
   input signed [7:0] b;

   reg signed [7:0] a_reg;
   reg signed [7:0] b_reg;
   reg signed [15:0] out;
   wire signed [15:0] mult_out;

   assign mult_out = a_reg * b_reg;

   always @ (posedge clk)
   begin
      a_reg <= a;
      b_reg <= b;
      out <= mult_out;
   end
endmodule
```

Example 3. VHDL Unsigned Multiplier with Input and Output Registers (Pipelining = 2)

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;

ENTITY unsigned_mult IS
   PORT (
      a: IN UNSIGNED (7 DOWNTO 0);
```

```
      b: IN UNSIGNED (7 DOWNTO 0);
      clk: IN STD_LOGIC;
      aclr: IN STD_LOGIC;
      result: OUT UNSIGNED (15 DOWNTO 0)
   );
END unsigned_mult;

ARCHITECTURE rtl OF unsigned_mult IS
   SIGNAL a_reg, b_reg: UNSIGNED (7 DOWNTO 0);
BEGIN
   PROCESS (clk, aclr)
   BEGIN
      IF (aclr ='1') THEN
         a_reg <= (OTHERS => '0');
         b_reg <= (OTHERS => '0');
         result <= (OTHERS => '0');
      ELSIF (rising_edge(clk)) THEN
         a_reg <= a;
         b_reg <= b;
         result <= a_reg * b_reg;
      END IF;
   END PROCESS;
END rtl;
```

Example 4. VHDL Signed Multiplier

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;

ENTITY signed_mult IS
   PORT (
      a: IN SIGNED (7 DOWNTO 0);
      b: IN SIGNED (7 DOWNTO 0);
      result: OUT SIGNED (15 DOWNTO 0)
   );
END signed_mult;

ARCHITECTURE rtl OF signed_mult IS
BEGIN
   result <= a * b;
END rtl;
```

1.3.2. Inferring Multiply-Accumulator and Multiply-Adder Functions

Synthesis tools detect multiply-accumulator or multiply-adder functions, and either implement them as Intel FPGA IP cores or map them directly to device atoms. During placement and routing, the Intel Quartus Prime software places multiply-accumulator and multiply-adder functions in DSP blocks.

Note: Synthesis tools infer multiply-accumulator and multiply-adder functions only if the Intel device family has dedicated DSP blocks that support these functions.

A simple multiply-accumulator consists of a multiplier feeding an addition operator. The addition operator feeds a set of registers that then feeds the second input to the addition operator. A simple multiply-adder consists of two to four multipliers feeding one or two levels of addition, subtraction, or addition/subtraction operators. Addition is always the second-level operator, if it is used. In addition to the multiply-accumulator and multiply-adder, the Intel Quartus Prime Fitter also places input and output registers into the DSP blocks to pack registers and improve performance and area utilization.

Some device families offer additional advanced multiply-adder and accumulator functions, such as complex multiplication, input shift register, or larger multiplications.

The Verilog HDL and VHDL code samples infer multiply-accumulator and multiply-adder functions with input, output, and pipeline registers, as well as an optional asynchronous `clear` signal. Using the three sets of registers provides the best performance through the function, with a latency of three. To reduce latency, remove the registers in your design.

Note: To obtain high performance in DSP designs, use register pipelining and avoid unregistered DSP functions.

Example 5. Verilog HDL Multiply-Accumulator

```
module sum_of_four_multiply_accumulate
   #(parameter INPUT_WIDTH=18, parameter OUTPUT_WIDTH=44)
   (
      input clk, ena,
      input [INPUT_WIDTH-1:0] dataa, datab, datac, datad,
      input [INPUT_WIDTH-1:0] datae, dataf, datag, datah,
      output reg [OUTPUT_WIDTH-1:0] dataout
   );
   // Each product can be up to 2*INPUT_WIDTH bits wide.
   // The sum of four of these products can be up to 2 bits wider.
   wire [2*INPUT_WIDTH+1:0] mult_sum;

   // Store the results of the operations on the current inputs
   assign mult_sum = (dataa * datab + datac * datad) +
                     (datae * dataf + datag * datah);

   // Store the value of the accumulation
   always @ (posedge clk)
   begin
      if (ena == 1)
         begin
            dataout <= dataout + mult_sum;
         end
   end
endmodule
```

1.4. Inferring Memory Functions from HDL Code

The following coding recommendations provide portable examples of generic HDL code targeting dedicated Intel FPGA memory IP cores. However, if you want to use some of the advanced memory features in Intel FPGA devices, consider using the IP core directly so that you can customize the ports and parameters easily.

You can also use the Intel Quartus Prime templates provided in the Intel Quartus Prime software as a starting point.

Table 1. Intel Memory HDL Language Templates

Language	Full Design Name
VHDL	Single-Port RAM Single-Port RAM with Initial Contents Simple Dual-Port RAM (single clock) Simple Dual-Port RAM (dual clock) True Dual-Port RAM (single clock) True Dual-Port RAM (dual clock)

continued...

Language	Full Design Name
	Mixed-Width RAM Mixed-Width True Dual-Port RAM Byte-Enabled Simple Dual-Port RAM Byte-Enabled True Dual-Port RAM Single-Port ROM Dual-Port ROM
Verilog HDL	Single-Port RAM Single-Port RAM with Initial Contents Simple Dual-Port RAM (single clock) Simple Dual-Port RAM (dual clock) True Dual-Port RAM (single clock) True Dual-Port RAM (dual clock) Single-Port ROM Dual-Port ROM

1.4.1. Inferring RAM functions from HDL Code

To infer RAM functions, synthesis tools recognize certain types of HDL code and map the detected code to technology-specific implementations. For device families that have dedicated RAM blocks, the Intel Quartus Prime software uses an Intel FPGA IP core to target the device memory architecture.

Synthesis tools typically consider all signals and variables that have a multi-dimensional array type and then create a RAM block, if applicable. This is based on the way the signals or variables are assigned or referenced in the HDL source description.

Standard synthesis tools recognize single-port and simple dual-port (one read port and one write port) RAM blocks. Some synthesis tools (such as the Intel Quartus Prime software) also recognize true dual-port (two read ports and two write ports) RAM blocks that map to the memory blocks in certain Intel FPGA devices.

Some tools (such as the Intel Quartus Prime software) also infer memory blocks for array variables and signals that are referenced (read/written) by two indexes, to recognize mixed-width and byte-enabled RAMs for certain coding styles.

Note: If your design contains a RAM block that your synthesis tool does not recognize and infer, the design might require a large amount of system memory that can potentially cause compilation problems.

1.4.1.1. Use Synchronous Memory Blocks

Memory blocks in Intel FPGA are synchronous. Therefore, RAM designs must be synchronous to map directly into dedicated memory blocks. For these devices, Intel Quartus Prime synthesis implements asynchronous memory logic in regular logic cells.

Synchronous memory offers several advantages over asynchronous memory, including higher frequencies and thus higher memory bandwidth, increased reliability, and less standby power. To convert asynchronous memory, move registers from the datapath into the memory block.

A memory block is synchronous if it has one of the following read behaviors:

- Memory read occurs in a Verilog HDL `always` block with a `clock` signal or a VHDL clocked process. The recommended coding style for synchronous memories is to create your design with a registered read output.
- Memory read occurs outside a clocked block, but there is a synchronous read address (that is, the address used in the read statement is registered). Synthesis does not always infer this logic as a memory block, or may require external bypass logic, depending on the target device architecture. Avoid this coding style for synchronous memories.

Note: The synchronous memory structures in Intel FPGA devices can differ from the structures in other vendors' devices. For best results, match your design to the target device architecture.

This chapter provides coding recommendations for various memory types. All the examples in this document are synchronous to ensure that they can be directly mapped into the dedicated memory architecture available in Intel FPGAs.

1.4.1.2. Avoid Unsupported Reset and Control Conditions

To ensure correct implementation of HDL code in the target device architecture, avoid unsupported reset conditions or other control logic that does not exist in the device architecture.

The RAM contents of Intel FPGA memory blocks cannot be cleared with a `reset` signal during device operation. If your HDL code describes a RAM with a `reset` signal for the RAM contents, the logic is implemented in regular logic cells instead of a memory block. Do not place RAM read or write operations in an `always` block or `process` block with a `reset` signal. To specify memory contents, initialize the memory or write the data to the RAM during device operation.

In addition to reset signals, other control logic can prevent synthesis from inferring memory logic as a memory block. For example, if you use a clock enable on the read address registers, you can alter the output latch of the RAM, resulting in the synthesized RAM result not matching the HDL description. Use the address stall feature as a read address clock enable to avoid this limitation. Check the documentation for your FPGA device to ensure that your code matches the hardware available in the device.

Example 6. Verilog RAM with Reset Signal that Clears RAM Contents: Not Supported in Device Architecture

```
module clear_ram
(
    input clock, reset, we,
    input [7:0] data_in,
    input [4:0] address,
    output reg [7:0] data_out
);

    reg [7:0] mem [0:31];
    integer i;

    always @ (posedge clock or posedge reset)
    begin
        if (reset == 1'b1)
            mem[address] <= 0;
        else if (we == 1'b1)
            mem[address] <= data_in;

        data_out <= mem[address];
    end
endmodule
```

1.4.1.3. Check Read-During-Write Behavior

Ensure the read-during-write behavior of the memory block described in your HDL design is consistent with your target device architecture.

Your HDL source code specifies the memory behavior when you read and write from the same memory address in the same clock cycle. The read returns either the old data at the address, or the new data written to the address. This is referred to as the read-during-write behavior of the memory block. Intel FPGA memory blocks have different read-during-write behavior depending on the target device family, memory mode, and block type.

Synthesis tools preserve the functionality described in your source code. Therefore, if your source code specifies unsupported read-during-write behavior for the RAM blocks, the Intel Quartus Prime software implements the logic in regular logic cells as opposed to the dedicated RAM hardware.

Example 7. Continuous read in HDL code

One common problem occurs when there is a continuous read in the HDL code, as in the following examples. Avoid using these coding styles:

```
//Verilog HDL concurrent signal assignment
assign q = ram[raddr_reg];
```

```
-- VHDL concurrent signal assignment
q <= ram(raddr_reg);
```

This type of HDL implies that when a write operation takes place, the read immediately reflects the new data at the address independent of the read clock, which is the behavior of asynchronous memory blocks. Synthesis cannot directly map this behavior to a synchronous memory block. If the write clock and read clock are the

same, synthesis can infer memory blocks and add extra bypass logic so that the device behavior matches the HDL behavior. If the write and read clocks are different, synthesis cannot reliably add bypass logic, so it implements the logic in regular logic cells instead of dedicated RAM blocks. The examples in the following sections discuss some of these differences for read-during-write conditions.

In addition, the MLAB memories in certain device logic array blocks (LABs) does not easily support old data or new data behavior for a read-during-write in the dedicated device architecture. Implementing the extra logic to support this behavior significantly reduces timing performance through the memory.

Note: For best performance in MLAB memories, ensure that your design does not depend on the read data during a write operation.

In many synthesis tools, you can declare that the read-during-write behavior is not important to your design (for example, if you never read from the same address to which you write in the same clock cycle). In Intel Quartus Prime Pro Edition synthesis, set the synthesis attribute `ramstyle` to `no_rw_check` to allow Intel Quartus Prime software to define the read-during-write behavior of a RAM, rather than use the behavior specified by your HDL code. This attribute can prevent the synthesis tool from using extra logic to implement the memory block, or can allow memory inference when it would otherwise be impossible.

1.4.1.4. Controlling RAM Inference and Implementation

Intel Quartus Prime synthesis provides options to control RAM inference and implementation for Intel FPGA devices with synchronous memory blocks. Synthesis tools usually do not infer small RAM blocks because implementing small RAM blocks is more efficient if using the registers in regular logic.

To direct the Intel Quartus Prime software to infer RAM blocks globally for all sizes, enable the **Allow Any RAM Size for Recognition** option in the **Advanced Analysis & Synthesis Settings** dialog box (**Assignments ➤ Settings ➤ Compiler Settings ➤ Synthesis Settings (Advanced)**).

Alternatively, use the `ramstyle` RTL attribute to specify how an inferred RAM is implemented, including the type of memory block or the use of regular logic instead of a dedicated memory block. Intel Quartus Prime synthesis does not map inferred memory into MLABs unless the HDL code specifies the appropriate `ramstyle` attribute, although the Fitter may map some memories to MLABs.

Set the `ramstyle` attribute in the RTL or in the `.qsf` file.

```
(* ramstyle = "mlab" *) my_shift_reg
```

```
set_instance_assignment -name RAMSTYLE_ATTRIBUTE LOGIC -to ram
```

. This attribute controls the implementation of an inferred memory. Apply the attribute to a variable declaration that infers a RAM, ROM, or shift-register. Legal values are: `"M9K"`, `"M10K"`, `"M20K"`, `"M144K"`, `"MLAB`, `"no_rw_check"`, `"logic"`

You can also specify the maximum depth of memory blocks for RAM or ROM inference in RTL. Specify the `max_depth` synthesis attribute to the declaration of a variable that represents a RAM or ROM in your design file. For example:

```
// Limit the depth of the memory blocks implement "ram" to 512
// This forces the Intel Quartus Prime software to use two M512 blocks instead
of one M4K block to implement this RAM
(* max_depth = 512 *) reg [7:0] ram[0:1023];
```

In addition, you can specify the `no_ram` synthesis attribute to prevent RAM inference on a specific array. For example:

```
 (* no_ram *) logic [11:0] my_array [0:12];
```

1.4.1.5. Single-Clock Synchronous RAM with Old Data Read-During-Write Behavior

The code examples in this section show Verilog HDL and VHDL code that infers simple dual-port, single-clock synchronous RAM. Single-port RAM blocks use a similar coding style.

The read-during-write behavior in these examples is to read the old data at the memory address. For best performance in MLAB memories, use the appropriate attribute so that your design does not depend on the read data during a write operation. The simple dual-port RAM code samples map directly into Intel synchronous memory.

Single-port versions of memory blocks (that is, using the same read address and write address signals) allow better RAM utilization than dual-port memory blocks, depending on the device family. Refer to the appropriate device handbook for recommendations on your target device.

Example 8. Verilog HDL Single-Clock, Simple Dual-Port Synchronous RAM with Old Data Read-During-Write Behavior

```
module single_clk_ram(
    output reg [7:0] q,
    input [7:0] d,
    input [4:0] write_address, read_address,
    input we, clk
);
    reg [7:0] mem [31:0];

    always @ (posedge clk) begin
        if (we)
            mem[write_address] <= d;
        q <= mem[read_address]; // q doesn't get d in this clock cycle
    end
endmodule
```

Example 9. VHDL Single-Clock, Simple Dual-Port Synchronous RAM with Old Data Read-During-Write Behavior

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY single_clock_ram IS
    PORT (
        clock: IN STD_LOGIC;
        data: IN STD_LOGIC_VECTOR (7 DOWNTO 0);
        write_address: IN INTEGER RANGE 0 to 31;
        read_address: IN INTEGER RANGE 0 to 31;
```

```
        we: IN STD_LOGIC;
        q: OUT STD_LOGIC_VECTOR (7 DOWNTO 0)
    );
END single_clock_ram;

ARCHITECTURE rtl OF single_clock_ram IS
    TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(7 DOWNTO 0);
    SIGNAL ram_block: MEM;
BEGIN
    PROCESS (clock)
    BEGIN
        IF (rising_edge(clock)) THEN
            IF (we = '1') THEN
                ram_block(write_address) <= data;
            END IF;
            q <= ram_block(read_address);
            -- VHDL semantics imply that q doesn't get data
            -- in this clock cycle
        END IF;
    END PROCESS;
END rtl;
```

Note: The small size of this `single_clock_ram` causes the Compiler to infer the memory as MLAB memory blocks, rather than M20K memory blocks. If `single_clock_ram` specifies a larger width, the Compiler infers the memory as M20K memory blocks.

1.4.1.6. Single-Clock Synchronous RAM with New Data Read-During-Write Behavior

The examples in this section describe RAM blocks in which the read-during-write behavior returns the new value being written at the memory address.

To implement this behavior in the target device, synthesis tools add bypass logic around the RAM block. This bypass logic increases the area utilization of the design, and decreases the performance if the RAM block is part of the design's critical path. If the device memory supports new data read-during-write behavior when in single-port mode (same clock, same read address, and same write address), the Verilog memory block doesn't require any bypass logic. Refer to the appropriate device handbook for specifications on your target device.

The following examples use a blocking assignment for the write so that the data is assigned intermediately.

Example 10. Verilog HDL Single-Clock, Simple Dual-Port Synchronous RAM with New Data Read-During-Write Behavior

```
module single_clock_wr_ram(
    output reg [7:0] q,
    input [7:0] d,
    input [6:0] write_address, read_address,
    input we, clk
);
    reg [7:0] mem [127:0];

    always @ (posedge clk) begin
        if (we)
            mem[write_address] = d;
        q = mem[read_address]; // q does get d in this clock
                               // cycle if we is high
    end
endmodule
```

Example 11. VHDL Single-Clock, Simple Dual-Port Synchronous RAM with New Data Read-During-Write Behavior:

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
ENTITY single_clock_ram IS
    PORT (
        clock: IN STD_LOGIC;
        data: IN STD_LOGIC_VECTOR (2 DOWNTO 0);
        write_address: IN INTEGER RANGE 0 to 31;
        read_address: IN INTEGER RANGE 0 to 31;
        we: IN STD_LOGIC;
        q: OUT STD_LOGIC_VECTOR (2 DOWNTO 0)
    );
END single_clock_ram;

ARCHITECTURE rtl OF single_clock_ram IS
    TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(2 DOWNTO 0);

BEGIN
    PROCESS (clock)
    VARIABLE ram_block: MEM;
    BEGIN
        IF (rising_edge(clock)) THEN
            IF (we = '1') THEN
                ram_block(write_address) := data;
            END IF;
            q <= ram_block(read_address);
            -- VHDL semantics imply that q doesn't get data
            -- in this clock cycle
        END IF;
    END PROCESS;
END rtl;
```

It is possible to create a single-clock RAM by using an `assign` statement to read the address of `mem` and create the output `q`. By itself, the RTL describes new data read-during-write behavior. However, if the RAM output feeds a register in another hierarchy, a read-during-write results in the old data. Synthesis tools may not infer a RAM block if the tool cannot determine which behavior is described, such as when the memory feeds a hard hierarchical partition boundary. Avoid this type of RTL.

Example 12. Avoid Verilog Coding Style with Vague read-during-write Behavior

```
reg [7:0] mem [127:0];
reg [6:0] read_address_reg;

always @ (posedge clk) begin
    if (we)
        mem[write_address] <= d;
    read_address_reg <= read_address;
end
assign q = mem[read_address_reg];
```

Example 13. Avoid VHDL Coding Style with Vague read-during-write Behavior

The following example uses a concurrent signal assignment to read from the RAM, and presents a similar behavior.

```
ARCHITECTURE rtl OF single_clock_rw_ram IS
    TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(2 DOWNTO 0);
    SIGNAL ram_block: MEM;
    SIGNAL read_address_reg: INTEGER RANGE 0 to 31;
BEGIN
    PROCESS (clock)
    BEGIN
```

```
        IF (rising_edge(clock)) THEN
            IF (we = '1') THEN
                ram_block(write_address) <= data;
            END IF;
            read_address_reg <= read_address;
        END IF;
    END PROCESS;
    q <= ram_block(read_address_reg);
END rtl;
```

1.4.1.7. Simple Dual-Port, Dual-Clock Synchronous RAM

With dual-clock designs, synthesis tools cannot accurately infer the read-during-write behavior because it depends on the timing of the two clocks within the target device. Therefore, the read-during-write behavior of the synthesized design is undefined and may differ from your original HDL code.

Example 14. Verilog HDL Simple Dual-Port, Dual-Clock Synchronous RAM

```
module simple_dual_port_ram_dual_clock
#(parameter DATA_WIDTH=8, parameter ADDR_WIDTH=6)
(
    input [(DATA_WIDTH-1):0] data,
    input [(ADDR_WIDTH-1):0] read_addr, write_addr,
    input we, read_clock, write_clock,
    output reg [(DATA_WIDTH-1):0] q
);

    // Declare the RAM variable
    reg [DATA_WIDTH-1:0] ram[2**ADDR_WIDTH-1:0];

    always @ (posedge write_clock)
    begin
        // Write
        if (we)
            ram[write_addr] <= data;
    end

    always @ (posedge read_clock)
    begin
        // Read
        q <= ram[read_addr];
    end

endmodule
```

Example 15. VHDL Simple Dual-Port, Dual-Clock Synchronous RAM

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
ENTITY dual_clock_ram IS
    PORT (
        clock1, clock2: IN STD_LOGIC;
        data: IN STD_LOGIC_VECTOR (3 DOWNTO 0);
        write_address: IN INTEGER RANGE 0 to 31;
        read_address: IN INTEGER RANGE 0 to 31;
        we: IN STD_LOGIC;
        q: OUT STD_LOGIC_VECTOR (3 DOWNTO 0)
    );
END dual_clock_ram;
ARCHITECTURE rtl OF dual_clock_ram IS
    TYPE MEM IS ARRAY(0 TO 31) OF STD_LOGIC_VECTOR(3 DOWNTO 0);
    SIGNAL ram_block: MEM;
    SIGNAL read_address_reg : INTEGER RANGE 0 to 31;
BEGIN
```

```
    PROCESS (clock1)
    BEGIN
        IF (rising_edge(clock1)) THEN
            IF (we = '1') THEN
                ram_block(write_address) <= data;
            END IF;
        END IF;
    END PROCESS;
    PROCESS (clock2)
    BEGIN
        IF (rising_edge(clock2)) THEN
            q <= ram_block(read_address_reg);
            read_address_reg <= read_address;
        END IF;
    END PROCESS;
END rtl;
```

Check Read-During-Write Behavior on page 11

1.4.1.8. True Dual-Port Synchronous RAM

The code examples in this section show Verilog HDL and VHDL code that infers true dual-port synchronous RAM. Different synthesis tools may differ in their support for these types of memories.

Intel FPGA synchronous memory blocks have two independent address ports, allowing for operations on two unique addresses simultaneously. A read operation and a write operation can share the same port if they share the same address.

The Intel Quartus Prime software infers true dual-port RAMs in Verilog HDL and VHDL, with the following characteristics:

- Any combination of independent read or write operations in the same clock cycle.
- At most two unique port addresses.
- In one clock cycle, with one or two unique addresses, they can perform:
  - Two reads and one write
  - Two writes and one read
  - Two writes and two reads

In the synchronous RAM block architecture, there is no priority between the two ports. Therefore, if you write to the same location on both ports at the same time, the result is indeterminate in the device architecture. You must ensure your HDL code does not imply priority for writes to the memory block, if you want the design to be implemented in a dedicated hardware memory block. For example, if both ports are defined in the same process block, the code is synthesized and simulated sequentially so that there is a priority between the two ports. If your code does imply a priority, the logic cannot be implemented in the device RAM blocks and is implemented in regular logic cells. You must also consider the read-during-write behavior of the RAM block to ensure that it can be mapped directly to the device RAM architecture.

When a read and write operation occurs on the same port for the same address, the read operation may behave as follows:

- **Read new data**—Intel Arria® 10 and Intel Stratix® 10 devices support this behavior.
- **Read old data**—Not supported.

When a read and write operation occurs on different ports for the same address (also known as mixed port), the read operation may behave as follows:

- **Read new data**—Intel Quartus Prime Pro Edition synthesis supports this mode by creating bypass logic around the synchronous memory block.
- **Read old data**—Intel Arria 10 and Intel Cyclone® 10 devices support this behavior.
- **Read don't care**—Synchronous memory blocks support this behavior in simple dual-port mode.

The Verilog HDL single-clock code sample maps directly into synchronous Intel Arria 10 memory blocks. When a read and write operation occurs on the same port for the same address, the new data being written to the memory is read. When a read and write operation occurs on different ports for the same address, the old data in the memory is read. Simultaneous writes to the same location on both ports results in indeterminate behavior.

If you generate a dual-clock version of this design describing the same behavior, the inferred memory in the target device presents undefined mixed port read-during-write behavior, because it depends on the relationship between the clocks.

Example 16. Verilog HDL True Dual-Port RAM with Single Clock

```
/ Quartus Prime Verilog Template
// True Dual Port RAM with single clock
//
// Read-during-write behavior is undefined for mixed ports
// and "new data" on the same port

module true_dual_port_ram_single_clock
#(parameter DATA_WIDTH=8, parameter ADDR_WIDTH=6)
(
    input [(DATA_WIDTH-1):0] data_a, data_b,
    input [(ADDR_WIDTH-1):0] addr_a, addr_b,
    input we_a, we_b, clk,
    output reg [(DATA_WIDTH-1):0] q_a, q_b
);

    // Declare the RAM variable
    reg [DATA_WIDTH-1:0] ram[2**ADDR_WIDTH-1:0];

    // Port A
    always @ (posedge clk)
    begin
        if (we_a)
        begin
            ram[addr_a] = data_a;
        end
        q_a <= ram[addr_a];
    end

    // Port B
    always @ (posedge clk)
    begin
        if (we_b)
        begin
            ram[addr_b] = data_b;
        end
        q_b <= ram[addr_b];
    end

endmodule
```

Example 17. VHDL Read Statement Example

```
-- Port A
process(clk)
    begin
    if(rising_edge(clk)) then
        if(we_a = '1') then
            ram(addr_a) := data_a;
        end if;
        q_a <= ram(addr_a);
    end if;
end process;

-- Port B
process(clk)
    begin
    if(rising_edge(clk)) then
        if(we_b = '1') then
            ram(addr_b) := data_b;
        end if;
        q_b <= ram(addr_b);
    end if;
end process;
```

The VHDL single-clock code sample maps directly into Intel FPGA synchronous memory. When a read and write operation occurs on the same port for the same address, the new data writing to the memory is read. When a read and write operation occurs on different ports for the same address, the behavior results in old data for Intel Arria 10 and Intel Cyclone 10 devices, and is undefined for Intel Stratix 10 devices. Simultaneous write operations to the same location on both ports results in indeterminate behavior.

If you generate a dual-clock version of this design describing the same behavior, the memory in the target device presents undefined mixed port read-during-write behavior because it depends on the relationship between the clocks.

Example 18. VHDL True Dual-Port RAM with Single Clock

```
-- Quartus Prime VHDL Template
-- True Dual-Port RAM with single clock
--
-- Read-during-write behavior is undefined for mixed ports
-- and "new data" on the same port

library ieee;

1.4.1.9. Mixed-Width Dual-Port RAM

The RAM code examples in this section show SystemVerilog and VHDL code that infers RAM with data ports with different widths.

Verilog-1995 doesn't support mixed-width RAMs because the standard lacks a multi-dimensional array to model the different read width, write width, or both. Verilog-2001 doesn't support mixed-width RAMs because this type of logic requires multiple packed dimensions. Different synthesis tools may differ in their support for these memories. This section describes the inference rules for Intel Quartus Prime Pro Edition synthesis.

The first dimension of the multi-dimensional packed array represents the ratio of the wider port to the narrower port. The second dimension represents the narrower port width. The read and write port widths must specify a read or write ratio supported by the memory blocks in the target device. Otherwise, the synthesis tool does not infer a RAM.

Refer to the Intel Quartus Prime HDL templates for parameterized examples with supported combinations of read and write widths. You can also find examples of true dual port RAMs with two mixed-width read ports and two mixed-width write ports.

Example 19. SystemVerilog Mixed-Width RAM with Read Width Smaller than Write Width

```
module mixed_width_ram    // 256x32 write and 1024x8 read
(
        input [7:0] waddr,
        input [31:0] wdata,
        input we, clk,
        input [9:0] raddr,
        output logic [7:0] q
);
    logic [3:0][7:0] ram[0:255];
    always_ff@(posedge clk)
        begin
            if(we) ram[waddr] <= wdata;
            q <= ram[raddr / 4][raddr % 4];
        end
endmodule : mixed_width_ram
```

Example 20. SystemVerilog Mixed-Width RAM with Read Width Larger than Write Width

```
module mixed_width_ram     // 1024x8 write and 256x32 read
(
        input [9:0] waddr,
        input [31:0] wdata,
        input we, clk,
        input [7:0] raddr,
        output logic [9:0] q
);
    logic [3:0][7:0] ram[0:255];
    always_ff@(posedge clk)
         begin
            if(we) ram[waddr / 4][waddr % 4] <= wdata;
            q <= ram[raddr];
         end
endmodule : mixed_width_ram
```

Example 21. VHDL Mixed-Width RAM with Read Width Smaller than Write Width

```
library ieee;
use ieee.std_logic_1164.all;

package ram_types is
    type word_t is array (0 to 3) of std_logic_vector(7 downto 0);
    type ram_t is array (0 to 255) of word_t;
end ram_types;

library ieee;
use ieee.std_logic_1164.all;
library work;
use work.ram_types.all;

entity mixed_width_ram is
    port (
        we, clk : in  std_logic;
        waddr   : in  integer range 0 to 255;
        wdata   : in  word_t;
        raddr   : in  integer range 0 to 1023;
        q       : out std_logic_vector(7 downto 0));
end mixed_width_ram;

architecture rtl of mixed_width_ram is
    signal ram : ram_t;
begin  -- rtl
    process(clk, we)
    begin
        if(rising_edge(clk)) then
            if(we = '1') then
```

```
                ram(waddr) <= wdata;
            end if;
            q <= ram(raddr / 4 )(raddr mod 4);
        end if;
    end process;
end rtl;
```

Example 22. VHDL Mixed-Width RAM with Read Width Larger than Write Width

```
library ieee;
use ieee.std_logic_1164.all;

package ram_types is
    type word_t is array (0 to 3) of std_logic_vector(7 downto 0);
    type ram_t is array (0 to 255) of word_t;
end ram_types;

library ieee;
use ieee.std_logic_1164.all;
library work;
use work.ram_types.all;

entity mixed_width_ram is
    port (
        we, clk : in  std_logic;
        waddr   : in  integer range 0 to 1023;
        wdata   : in  std_logic_vector(7 downto 0);
        raddr   : in  integer range 0 to 255;
        q       : out word_t);
end mixed_width_ram;

architecture rtl of mixed_width_ram is
    signal ram : ram_t;
begin  -- rtl
    process(clk, we)
    begin
        if(rising_edge(clk)) then
            if(we = '1') then
                ram(waddr / 4)(waddr mod 4) <= wdata;
            end if;
            q <= ram(raddr);
        end if;
    end process;
end rtl;
```

1.4.1.10. RAM with Byte-Enable Signals

The RAM code examples in this section show SystemVerilog and VHDL code that infers RAM with controls for writing single bytes into the memory word, or byte-enable signals.

Synthesis models byte-enable signals by creating write expressions with two indexes, and writing part of a RAM "word." With these implementations, you can also write more than one byte at once by enabling the appropriate byte enables.

Verilog-1995 doesn't support mixed-width RAMs because the standard lacks a multi-dimensional array to model the different read width, write width, or both. Verilog-2001 doesn't support mixed-width RAMs because this type of logic requires multiple packed dimensions. Different synthesis tools may differ in their support for these memories. This section describes the inference rules for Intel Quartus Prime Pro Edition synthesis.

Refer to the Intel Quartus Prime HDL templates for parameterized examples that you can use for different address widths, and true dual port RAM examples with two read ports and two write ports.

Example 23. SystemVerilog Simple Dual-Port Synchronous RAM with Byte Enable

```
module byte_enabled_simple_dual_port_ram
(
    input we, clk,
    input [ADDRESS_WIDTH-1:0] waddr, raddr,// address width = 6
    input [NUM_BYTES-1:0] be, // 4 bytes per word
    input [(BYTE_WIDTH * NUM_BYTES -1):0] wdata, // byte width = 8, 4 bytes per
word
    output reg [(BYTE_WIDTH * NUM_BYTES -1):0] q // byte width = 8, 4 bytes per
word
);

   parameter ADDRESS_WIDTH = 6;
   parameter DEPTH = 2**ADDRESS_WIDTH;
   parameter BYTE_WIDTH = 8;
   parameter NUM_BYTES = 4;

   // use a multi-dimensional packed array
   //to model individual bytes within the word
   logic [NUM_BYTES-1:0][BYTE_WIDTH-1:0] ram[0:DEPTH-1];
     // # words = 1 << address width

    // port A
   always@(posedge clk)
   begin
       if(we) begin
          for (int i = 0; i < NUM_BYTES; i = i + 1) begin
            if(be[i]) ram[waddr][i] <= wdata[i*BYTE_WIDTH +: BYTE_WIDTH];
          end
      end
      q <= ram[raddr];
   end
endmodule
```

Example 24. VHDL Simple Dual-Port Synchronous RAM with Byte Enable

```
library ieee;
use ieee.std_logic_1164.all;
library work;

entity byte_enabled_simple_dual_port_ram is
generic (DEPTH      : integer := 64;
         NUM_BYTES  : integer :=  4;
         BYTE_WIDTH : integer :=  8
);
port (
    we, clk : in  std_logic;
    waddr, raddr : in  integer range 0 to DEPTH -1 ;     -- address width = 6
    be   : in  std_logic_vector (NUM_BYTES-1 downto 0);   -- 4 bytes per word
    wdata: in  std_logic_vector((NUM_BYTES * BYTE_WIDTH -1) downto 0);   --
width = 32
    q    : out std_logic_vector((NUM_BYTES * BYTE_WIDTH -1) downto 0) ); --
width = 32
end byte_enabled_simple_dual_port_ram;

architecture rtl of byte_enabled_simple_dual_port_ram is

    --  build up 2D array to hold the memory
    type word_t is array (0 to NUM_BYTES-1) of std_logic_vector(BYTE_WIDTH-1
downto 0);
    type ram_t is array (0 to DEPTH-1) of word_t;

    signal ram : ram_t;
    signal q_local : word_t;
```

```
    begin  -- Re-organize the read data from the RAM to match the output
        unpack: for i in 0 to NUM_BYTES-1 generate
            q(BYTE_WIDTH*(i+1) - 1 downto BYTE_WIDTH*i) <= q_local(i);
    end generate unpack;

    -- port A
    process(clk)
    begin
        if(rising_edge(clk)) then
            if(we = '1') then
                for I in (NUM_BYTES-1) downto 0 loop
                    if(be(I) = '1') then
                        ram(waddr)(I) <= wdata(((I+1)*BYTE_WIDTH-1) downto
I*BYTE_WIDTH);
                    end if;
                 end loop;
            end if;
            q_local <= ram(raddr);
        end if;
    end process;
end rtl;
```

1.4.1.11. Specifying Initial Memory Contents at Power-Up

Your synthesis tool may offer various ways to specify the initial contents of an inferred memory. There are slight power-up and initialization differences between dedicated RAM blocks and the MLAB memory, due to the continuous read of the MLAB.

Intel FPGA dedicated RAM block outputs always power-up to zero, and are set to the initial value on the first read. For example, if address `0` is pre-initialized to FF, the RAM block powers up with the output at `0`. A subsequent read after power-up from address `0` outputs the pre-initialized value of FF. Therefore, if a RAM powers up and an enable (read enable or clock enable) is held low, the power-up output of `0` maintains until the first valid read cycle. The synthesis tool implements MLAB using registers that power-up to `0`, but initialize to their initial value immediately at power-up or reset. Therefore, the initial value is seen, regardless of the enable status. The Intel Quartus Prime software maps inferred memory to MLABs when the HDL code specifies an appropriate `ramstyle` attribute.

In Verilog HDL, you can use an initial block to initialize the contents of an inferred memory. Intel Quartus Prime Pro Edition synthesis automatically converts the initial block into a Memory Initialization File (`.mif`) for the inferred RAM.

Example 25. Verilog HDL RAM with Initialized Contents

```
module ram_with_init(
   output reg [7:0] q,
   input [7:0] d,
   input [4:0] write_address, read_address,
   input we, clk
);
   reg [7:0] mem [0:31];
   integer i;

   initial begin
      for (i = 0; i < 32; i = i + 1)
         mem[i] = i[7:0];
   end

   always @ (posedge clk) begin
      if (we)
         mem[write_address] <= d;
```

```
      q <= mem[read_address];
   end
endmodule
```

Intel Quartus Prime Pro Edition synthesis and other synthesis tools also support the `$readmemb` and `$readmemh` attributes. These attributes allow RAM initialization and ROM initialization work identically in synthesis and simulation.

Example 26. Verilog HDL RAM Initialized with the readmemb Command

```
reg [7:0] ram[0:15];
initial
begin
    $readmemb("ram.txt", ram);
end
```

In VHDL, you can initialize the contents of an inferred memory by specifying a default value for the corresponding signal. Intel Quartus Prime Pro Edition synthesis automatically converts the default value into a `.mif` file for the inferred RAM.

Example 27. VHDL RAM with Initialized Contents

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
use ieee.numeric_std.all;

ENTITY ram_with_init IS
    PORT(
            clock: IN STD_LOGIC;
            data: IN UNSIGNED (7 DOWNTO 0);
            write_address: IN integer RANGE 0 to 31;
            read_address: IN integer RANGE 0 to 31;
            we: IN std_logic;
            q: OUT UNSIGNED (7 DOWNTO 0));
END;

ARCHITECTURE rtl OF ram_with_init IS

    TYPE MEM IS ARRAY(31 DOWNTO 0) OF unsigned(7 DOWNTO 0);
    FUNCTION initialize_ram
        return MEM is
        variable result : MEM;
    BEGIN
        FOR i IN 31 DOWNTO 0 LOOP
            result(i) := to_unsigned(natural(i), natural'(8));
        END LOOP;
        RETURN result;
    END initialize_ram;

    SIGNAL ram_block : MEM := initialize_ram;
BEGIN
    PROCESS (clock)
    BEGIN
        IF (rising_edge(clock)) THEN
            IF (we = '1') THEN
            ram_block(write_address) <= data;
            END IF;
            q <= ram_block(read_address);
        END IF;
    END PROCESS;
END rtl;
```

1.4.2. Inferring ROM Functions from HDL Code

Synthesis tools infer ROMs when a CASE statement exists in which a value is set to a constant for every choice in the CASE statement.

Because small ROMs typically achieve the best performance when they are implemented using the registers in regular logic, each ROM function must meet a minimum size requirement for inference and placement in memory.

For device architectures with synchronous RAM blocks, to infer a ROM block, synthesis must use registers for either the address or the output. When your design uses output registers, synthesis implements registers from the input registers of the RAM block without affecting the functionality of the ROM. If you register the address, the power-up state of the inferred ROM can be different from the HDL design. In this scenario, Intel Quartus Prime synthesis issues a warning.

The following ROM examples map directly to the Intel FPGA memory architecture.

Example 28. Verilog HDL Synchronous ROM

```
module sync_rom (clock, address, data_out);
    input clock;
    input [7:0] address;
    output reg [5:0] data_out;
    reg [5:0] data_out;

    always @ (posedge clock)
    begin
        case (address)
            8'b00000000: data_out = 6'b101111;
            8'b00000001: data_out = 6'b110110;
            ...
            8'b11111110: data_out = 6'b000001;
            8'b11111111: data_out = 6'b101010;
        endcase
    end
endmodule
```

Example 29. VHDL Synchronous ROM

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;

ENTITY sync_rom IS
    PORT (
        clock: IN STD_LOGIC;
        address: IN STD_LOGIC_VECTOR(7 downto 0);
        data_out: OUT STD_LOGIC_VECTOR(5 downto 0)
    );
END sync_rom;

ARCHITECTURE rtl OF sync_rom IS
BEGIN
PROCESS (clock)
    BEGIN
    IF rising_edge (clock) THEN
        CASE address IS
            WHEN "00000000" => data_out <= "101111";
            WHEN "00000001" => data_out <= "110110";
            ...
            WHEN "11111110" => data_out <= "000001";
            WHEN "11111111" => data_out <= "101010";
            WHEN OTHERS     => data_out <= "101111";
        END CASE;
```

```
    END IF;
    END PROCESS;
END rtl;
```

Example 30. Verilog HDL Dual-Port Synchronous ROM Using readmemb

```
module dual_port_rom
#(parameter data_width=8, parameter addr_width=8)
(
    input [(addr_width-1):0] addr_a, addr_b,
    input clk,
    output reg [(data_width-1):0] q_a, q_b
);
    reg [data_width-1:0] rom[2**addr_width-1:0];

    initial // Read the memory contents in the file
             //dual_port_rom_init.txt.
    begin
        $readmemb("dual_port_rom_init.txt", rom);
    end

    always @ (posedge clk)
    begin
        q_a <= rom[addr_a];
        q_b <= rom[addr_b];
    end
endmodule
```

Example 31. VHDL Dual-Port Synchronous ROM Using Initialization Function

```
library ieee;
use ieee.std_logic_1164.all;
use ieee.numeric_std.all;

entity dual_port_rom is
    generic (
        DATA_WIDTH : natural := 8;
        ADDR_WIDTH : natural := 8
    );
    port (
        clk     : in std_logic;
        addr_a  : in natural range 0 to 2**ADDR_WIDTH - 1;
        addr_b  : in natural range 0 to 2**ADDR_WIDTH - 1;
        q_a     : out std_logic_vector((DATA_WIDTH -1) downto 0);
        q_b     : out std_logic_vector((DATA_WIDTH -1) downto 0)
    );
end entity;

architecture rtl of dual_port_rom is
    -- Build a 2-D array type for the ROM
    subtype word_t is std_logic_vector((DATA_WIDTH-1) downto 0);
    type memory_t is array(2**ADDR_WIDTH - 1 downto 0) of word_t;

    function init_rom
        return memory_t is
        variable tmp : memory_t := (others => (others => '0'));
    begin
        for addr_pos in 0 to 2**ADDR_WIDTH - 1 loop
            -- Initialize each address with the address itself
            tmp(addr_pos) := std_logic_vector(to_unsigned(addr_pos, DATA_WIDTH));
        end loop;
        return tmp;
    end init_rom;

    -- Declare the ROM signal and specify a default initialization value.
    signal rom : memory_t := init_rom;
begin
    process(clk)
```

```
    begin
    if (rising_edge(clk)) then
        q_a <= rom(addr_a);
        q_b <= rom(addr_b);
    end if;
    end process;
end rtl;
```

1.4.3. Inferring Shift Registers in HDL Code

The Intel Quartus Prime software Analysis & Synthesis stage of the Compiler automatically detects and infers shift registers in your HDL code according to the following guidelines:

- Shift Register Inference for Intel Stratix 10 and Intel Agilex™ 7 Devices on page 29
- Shift Register Inference for Intel Arria 10 and Intel Cyclone 10 GX Devices on page 30

Shift Register Inference for Intel Stratix 10 and Intel Agilex™ 7 Devices

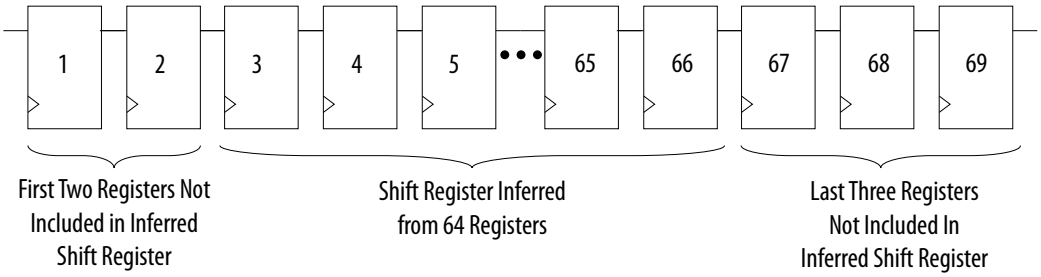
Because of the high prevalence of registers in routing segments of the Intel Hyperflex™ architecture, the Compiler's threshold for shift register inference is increased for Intel Stratix 10 and Intel Agilex™ 7 devices. This increase in the threshold means that some logic that the Compiler infers as a shift register in a previous generation FPGA, may not be inferred as a shift register when targeting Intel Stratix 10 or Intel Agilex 7 devices. This threshold increase allows more register retiming, thus improving overall design performance.

The following criteria apply to shift register detection and inference for Intel Stratix 10 and Intel Agilex 7 devices.

Default shift register inference requirements for Intel Stratix 10 and Intel Agilex 7 Devices:

1. The minimum number of registers inferred in the shift register is 64. When the width of a chain of registers is 1, the chain must contain at least 69 registers for synthesis to infer a shift register. From these 69 registers, synthesis does not include the first and second registers in the chain in the inferred shift register. Synthesis places these first and second shift registers in ALMs. Synthesis infers a 64 bit long shift register with the third through sixty sixth registers. Synthesis does not include the last three registers in the chain in the inferred shift register. Rather, synthesis places the last three registers in ALMs.
2. The minimum depth of registers inferred in the shift register is 32. When the width of a chain of registers is two or more, the chain must contain at least 37 register levels for synthesis to infer a shift register. As in the first requirement, synthesis does not include the first and second registers levels in each chain in the inferred shift register, nor are the last three register levels.

Figure 2. Shift Register Inference for Intel Stratix 10 and Intel Agilex 7 Devices



- With the following assignment, the total number of required registers (depth * width) drops to 37:

```
set_global_assignment -name ALLOW_ANY_SHIFT_REGISTER_SIZE_FOR_RECOGNITION ON
```

  Note: An additional stage of inference takes place during the early retiming stage as physical synthesis optimization recovers area for registers that have not been retimed.

- With both of the following assignments, the total number of required registers (`depth * width`) drops to 13:

```
set_global_assignment -name ALLOW_ANY_SHIFT_REGISTER_SIZE_FOR_RECOGNITION ON
set_global_assignment -name PHYSICAL_SHIFT_REGISTER_INFERENCE=OFF
```

Note: Reducing the shift register inference threshold can negatively impact design performance, as the technique reduces the number of registers available for retiming.

Shift Register Inference for Intel Arria 10 and Intel Cyclone 10 GX Devices

For Intel Arria 10 devices, Analysis & Synthesis detects a group of shift registers of the same length, and implements the registers using the Shift Register Intel FPGA IP.

For automatic detection, all of the shift registers must have the following characteristics:

- Use the same clock and clock enable
- Have no other secondary signals
- Have equally spaced taps that are at least three registers apart

Synthesis recognizes shift registers only for device families with dedicated RAM blocks. Intel Quartus Prime Pro Edition synthesis uses the following guidelines:

- The Intel Quartus Prime software determines whether to infer the Shift Register Intel FPGA IP based on the width of the registered bus (W), the length between each tap (L), or the number of taps (N).
- If the **Auto Shift Register Recognition** option is set to **Auto**, Intel Quartus Prime Pro Edition synthesis determines which shift registers are implemented in RAM blocks for logic by using the following methods:
  - The **Optimization Technique** setting
  - Logic and RAM utilization information about the design
  - Timing information from **Timing-Driven Synthesis**
- If the registered bus width is one ($W = 1$), Intel Quartus Prime synthesis infers the shift register IP if the number of taps, times the length between each tap, is greater than or equal to 64 ($N \times L > 64$).
- If the registered bus width is greater than one ($W > 1$), and the registered bus width times the number of taps times the length between each tap is greater than or equal to 32 ($W \times N \times L > 32$), then Intel Quartus Prime synthesis the Shift Register Intel FPGA IP.
- If the length between each tap (L) is not a power of two, Intel Quartus Prime synthesis needs external logic (LEs or ALMs) to decode the read and write counters, because of different sizes of shift registers. This extra decode logic eliminates the performance and utilization advantages of implementing shift registers in memory.

The registers that Intel Quartus Prime synthesis maps to the Shift Register Intel FPGA IP, and places in RAM are not available in a Verilog HDL or VHDL output file for simulation tools, because their node names do not exist after synthesis.

Note: The Compiler cannot implement a shift register that uses a `shift enable` signal into MLAB memory; instead, the Compiler uses dedicated RAM blocks. To control the type of memory structure that implements the shift register, use the `ramstyle` attribute. For example:

```
(* ramstyle = "mlab" *) my_shift_reg
```

1.4.3.1. Simple Shift Register

The examples in this section show a simple, single-bit wide, 69-bit long shift register.

Intel Quartus Prime synthesis implements the register (`W = 1` and `M = 69`) by using the Shift Register Intel FPGA IP, and maps it to RAM in the device, which may be placed in dedicated RAM blocks or MLAB memory. If the length of the register is less than 69 bits, Intel Quartus Prime synthesis implements the shift register in logic.

Example 32. Verilog HDL Single-Bit Wide, 69-Bit Long Shift Register

```
module shift_1x69 (clk, shift, sr_in, sr_out);
    input clk, shift;
    input sr_in;
    output sr_out;

    reg [68:0] sr;

    always @ (posedge clk)
    begin
        if (shift == 1'b1)
        begin
            sr[68:1] <= sr[67:0];
            sr[0] <= sr_in;
        end
    end
    assign sr_out = sr[68];
endmodule
```

Example 33. VHDL Single-Bit Wide, 69-Bit Long Shift Register

```
LIBRARY IEEE;
USE IEEE.STD_LOGIC_1164.all;
ENTITY shift_1x69 IS
    PORT (
        clk: IN STD_LOGIC;
        shift: IN STD_LOGIC;
        sr_in: IN STD_LOGIC;
        sr_out: OUT STD_LOGIC
    );
END shift_1x69;

ARCHITECTURE arch OF shift_1x69 IS
    TYPE sr_length IS ARRAY (68 DOWNTO 0) OF STD_LOGIC;
    SIGNAL sr: sr_length;
BEGIN
    PROCESS (clk)
        BEGIN
        IF (rising_edge(clk)) THEN
            IF (shift = '1') THEN
            sr(68 DOWNTO 1) <= sr(67 DOWNTO 0);
            sr(0) <= sr_in;
            END IF;
```

```
        END IF;
    END PROCESS;
    sr_out <= sr(68);
END arch;
```

1.4.3.2. Shift Register with Evenly Spaced Taps

The following examples show a Verilog HDL and VHDL 8-bit wide, 255-bit long shift register (`W > 1` and `M = 255`) with evenly spaced taps at 64, 128, 192, and 254.

The synthesis software implements this function in a single ALTSHIFT_TAPS IP core and maps it to RAM in supported devices, which is allowed placement in dedicated RAM blocks or MLAB memory.

Example 34. Verilog HDL 8-Bit Wide, 255-Bit Long Shift Register with Evenly Spaced Taps

```
module top (clk, shift, sr_in, sr_out, sr_tap_one, sr_tap_two,
                sr_tap_three );
    input clk, shift;
    input [7:0] sr_in;
    output [7:0] sr_tap_one, sr_tap_two, sr_tap_three, sr_out;
    reg [7:0] sr [254:0];
    integer n;
    always @ (posedge clk)
        begin
        if (shift == 1'b1)
            begin

1.4.4. Inferring FIFOs in HDL Code

There are various methods of implementing dual clock FIFOs, depending on the features needed in your design. The following dual clock FIFO example shows the basic FIFO functionality, with a design goal of high speed (f_{MAX}) and small area.

The FIFO supports parameterization up to 32 words deep, and targets memory LABs (MLABs) for its memory block. Synthesis infers the MLABs from behavioral RTL in the `generic_mlab_dc` module.

Note: If you don't want to code your own FIFO, you can parameterize the dual clock FIFO IP with the IP parameter editor in the Intel Quartus Prime software. Refer to the *FIFO Intel FPGA IP User Guide*.

1.4.4.2. Dual Clock FIFO Timing Constraints

If you choose to code your own dual clock FIFO, you must also create appropriate timing constraints in Synopsis Design Constraints format (`.sdc`).

Typically, you set the read and write clock domains asynchronous to each other by using the `set_clock_groups` SDC command. You typically specify the `set_clock_groups` command in a top-level `.sdc` file.

Constrain the read and write pointer clock domain crossings with skew and net delay constraints.

A skew constraint ensures the gray-coded pointer values transfer correctly between the clock domains. A net delay constraint bounds the wire delay between the two clock domains, to help reduce latency through the FIFO.

In the RTL example above, the pointers cross clock domains at the `ff_launch` to `ff_meta` register path, in two instances of the `synchronizer_ff_r2` entity.

The following example constraints are appropriate for the RTL above. You can customize the `-from` and `-to` names as necessary for your implementation.

```
# Skew from read to write domain
set_max_skew -from rd2wr|ff_launch[*] -to rd2wr|ff_meta[*] \
     -get_skew_value_from_clock_period
src_clock_period -skew_value_multiplier 0.8
# Skew from write to read domain
set_max_skew -from wr2rd|ff_launch[*] -to wr2rd|ff_meta[*] \
     -get_skew_value_from_clock_period
src_clock_period -skew_value_multiplier 0.8
# Net delay from read to write domain
set_net_delay -from rd2wr|ff_launch[*] -to rd2wr|ff_meta[*] \
     -get_value_from_clock_period
dst_clock_period -value_multiplier 0.8 -max
# Net delay from write to read domain
set_net_delay -from wr2rd|ff_launch[*] -to wr2rd|ff_meta[*] \
     -get_value_from_clock_period
dst_clock_period -value_multiplier 0.8 -max
```

After writing the skew and net delay constraints in the `.sdc` file, specify an entity-bound `.sdc` file `.qsf` assignment to apply the constraints to the synchronizer register paths in all instances of your FIFO.

Use the name of the `.sdc` file containing these constraints in the entity-bound `.sdc` file assignment in your `.qsf`. Also provide the name of the FIFO entity to which the constraints apply.

The following `.qsf` assignment example assumes that you save the constraints in `fifo_synchronizer.sdc` in your project directory, and that the constraints therein apply to the `dcfifo_example` entity:

```
set_global_assignment -name SDC_ENTITY_FILE fifo_synchronizer.sdc \
     -entity dcfifo_example
```

1.5. Register and Latch Coding Guidelines

This section provides device-specific coding recommendations for Intel registers and latches. Understanding the architecture of the target Intel device helps ensure that your RTL produces the expected results and achieves the optimal quality of results.

1.5.1. Register Power-Up Values

Registers in the device core power-up to a low (0) logic level on all Intel FPGA devices. However, for designs that specify a power-up level other than 0, synthesis tools can implement logic that directs registers to behave as if they were powering up to a high (1) logic level.

For designs that use `preset` signals, but the target device does not support presets in the register architecture, synthesis may convert the `preset` signal to a `clear` signal, which requires to perform a NOT gate push-back optimization. NOT gate push-back adds an inverter to the input and the output of the register, so that the reset and power-up conditions appear high, and the device operates as expected. In this case, the synthesis tool may issue a message about the power-up condition. The register itself powers up low, but since the register output inverts, the signal that arrives at all destinations is high.

Due to these effects, if you specify a non-zero reset value, the synthesis tool may use the asynchronous clear (`aclr`) signals available on the registers to implement the high bits with NOT gate push-back. In that case, the registers look as though they power-up to the specified reset value.

When an asynchronous load (`aload`) signal is available in the device registers, the synthesis tools can implement a reset of `1` or `0` value by using an asynchronous load of `1` or `0`. When the synthesis tool uses a `load` signal, it is not performing NOT gate push-back, so the registers power-up to a `0` logic level. For additional details, refer to the appropriate device family handbook.

Optionally you can force all registers into their appropriate values after reset through an explicit reset signal. This technique allows to reset the device after power-up to restore the proper state.

Synchronizing the device architecture's external or combinational logic before driving the register's asynchronous control ports allows for more stable designs and avoids potential glitches.

Related Information

Recommended Design Practices on page 69

1.5.1.1. Specifying a Power-Up Value

Options available in synthesis tools allow you to specify power-up conditions for the design. Intel Quartus Prime Pro Edition synthesis provides the **Power-Up Level** logic option.

You can also specify the power-up level with an `altera_attribute` assignment in the source code. This attribute forces synthesis to perform NOT gate push-back, because synthesis tools cannot change the power-up states of core registers.

You can apply the **Power-Up Level** logic option to a specific register, or to a design entity, module, or sub design. When you assign this option, every register in that block receives the value. Registers power up to `0` by default. Therefore, you can use this assignment to force all registers to power-up to `1` using NOT gate push-back.

Setting the **Power-Up Level** to a logic level of **high** for a large design entity could degrade the quality of results due to the number of inverters that requires. In some situations, this design style causes issues due to `enable` signal inference or secondary control logic inference. It may also be more difficult to migrate this type of designs.

Some synthesis tools can also read the default or initial values for registered signals and implement this behavior in the device. For example, Intel Quartus Prime Pro Edition synthesis converts default values for registered signals into **Power-Up Level** settings. When the Intel Quartus Prime software reads the default values, the synthesized behavior matches the power-up state of the HDL code during a functional simulation.

Example 35. Verilog Register with High Power-Up Value

```
reg q = 1'b1; //q has a default value of '1'

always @ (posedge clk)
begin
    q <= d;
end
```

Example 36. VHDL Register with High Power-Up Level

```
SIGNAL q : STD_LOGIC := '1'; -- q has a default value of '1'

PROCESS (clk, reset)
BEGIN
    IF (rising_edge(clk)) THEN
        q <= d;
    END IF;
END PROCESS;
```

Your design may contain undeclared default power-up conditions based on signal type. If you declare a VHDL register signal as an integer, Intel Quartus Prime synthesis uses the left end of the integer range as the power-up value. For the default signed integer type, the default power-up value is the highest magnitude negative integer (`100…001`). For an unsigned integer type, the default power-up value is `0`.

Note: If the target device architecture does not support two asynchronous control signals, such as `aclr` and `aload`, you cannot set a different power-up state and reset state. If the NOT gate push-back algorithm creates logic to set a register to `1`, that register powers-up high. If you set a different power-up condition through a synthesis attribute or initial value, synthesis ignores the power-up level.

1.5.2. Secondary Register Control Signals Such as Clear and Clock Enable

The registers in Intel FPGAs provide a number of secondary control signals. Use these signals to implement control logic for each register without using extra logic cells. Intel FPGA device families vary in their support for secondary signals, so consult the device family data sheet to verify which signals are available in your target device.

To make the most efficient use of the signals in the device, ensure that HDL code matches the device architecture as closely as possible. The control signals have a certain priority due to the nature of the architecture. Your HDL code must follow that priority where possible.

Your synthesis tool can emulate any control signals using regular logic, so achieving functionally correct results is always possible. However, if your design requirements allow flexibility in controlling use and priority of control signals, match your design to the target device architecture to achieve the most efficient results. If the priority of the signals in your design is not the same as that of the target architecture, you may require extra logic to implement the control signals. This extra logic uses additional device resources, and can cause additional delays for the control signals.

In certain cases, using logic other than the dedicated control logic in the device architecture can have a larger impact. For example, the `clock enable` signal has priority over the synchronous `reset` or `clear` signal in the device architecture. The `clock enable` turns off the clock line in the LAB, and the `clear` signal is synchronous. Therefore, in the device architecture, the synchronous clear takes effect only when a clock edge occurs.

If you define a register with a synchronous `clear` signal that has priority over the `clock enable` signal, Intel Quartus Prime synthesis emulates the clock enable functionality using data inputs to the registers. You cannot apply a Clock Enable Multicycle constraint, because the emulated functionality does not use the `clock enable` port of the register. In this case, using a different priority causes unexpected results with an assignment to the `clock enable` signal.

The signal order is the same for all Intel FPGA device families. However, not all device families provide every signal. The priority order is:

1. Asynchronous Clear (`clrn`)—highest priority
2. Enable (`ena`)
3. Synchronous Clear (`sclr`)
4. Synchronous Load (`sload`)
5. Data In (`data`)—lowest priority

The priority order for secondary control signals in Intel FPGA devices differs from the order for other vendors' FPGA devices. If your design requirements are flexible regarding priority, verify that the secondary control signals meet design performance requirements when migrating designs between FPGA vendors. To achieve the best results. try to match your target device architecture.

Example 37. Verilog D-type Flipflop bus with Secondary Signals

This module uses all Intel Arria 10 DFF secondary signals: `clrn`, `ena`, `sclr`, and `sload`. Note that it instantiates 8-bit bus of DFFs rather than a single DFF, because synthesis infers some secondary signals only if there are multiple DFFs with the same secondary signal.

```
module top(clk, clrn, sclr, sload, ena, data, sdata, q);
    input clk, clrn, sclr, sload, ena;
    input [7:0] data, sdata;
    output [7:0] q;
    reg [7:0] q;
    always @ (posedge clk or posedge clrn)
        begin
        if (clrn)
            q <= 8'b0;
        else if (ena)
            begin
            if (sclr)
                q <= 8'b0;
```

```
            else if (!sload)
                q <= data;
            else
                q <= sdata;
            end
        end
endmodule
```

1.5.3. Latches

A latch is a small combinational loop that holds the value of a signal until a new value is assigned. Synthesis tools can infer latches from HDL code when you did not intend to use a latch. If you do intend to infer a latch, it is important to infer it correctly to guarantee correct device operation.

Note: Design without the use of latches whenever possible.

Related Information

Avoid Unintended Latch Inference on page 72

1.5.3.1. Avoid Unintentional Latch Generation

When you design combinational logic, certain coding styles can create an unintentional latch. For example, when CASE or IF statements do not cover all possible input conditions, synthesis tools can infer latches to hold the output if a new output value is not assigned. Check your synthesis tool messages for references to inferred latches.

If your code unintentionally creates a latch, modify your RTL to remove the latch:

- Synthesis infers a latch when HDL code assigns a value to a signal outside of a clock edge (for example, with an asynchronous `reset`), but the code does not assign a value in an edge-triggered design block.
- Unintentional latches also occur when HDL code assigns a value to a signal in an edge-triggered design block, but synthesis optimizations remove that logic. For example, when a CASE or IF statement tests a condition that only evaluates to FALSE, synthesis removes any logic or signal assignment in that statement during optimization. This optimization may result in the inference of a latch for the signal.
- Omitting the final ELSE or WHEN OTHERS clause in an IF or CASE statement can also generate a latch. Don't care (X) assignments on the default conditions are useful in preventing latch generation. For the best logic optimization, assign the default CASE or final ELSE value to don't care (X) instead of a logic value.

In Verilog HDL designs, use the `full_case` attribute to treat unspecified cases as don't care values (X). However, since the `full_case` attribute is synthesis-only, it can cause simulation mismatches, because simulation tools still treat the unspecified cases as latches.

Example 38. VHDL Code Preventing Unintentional Latch Creation

Without the final ELSE clause, the following code creates unintentional latches to cover the remaining combinations of the SEL inputs. When you are targeting a Stratix series device with this code, omitting the final ELSE condition can cause synthesis

tools to use up to six LEs, instead of the three it uses with the ELSE statement. Additionally, assigning the final ELSE clause to 1 instead of X can result in slightly more LEs, because synthesis tools cannot perform as much optimization when you specify a constant value as opposed to a don't care value.

```
LIBRARY ieee;
USE IEEE.std_logic_1164.all;

ENTITY nolatch IS
    PORT (a,b,c: IN STD_LOGIC;
        sel: IN STD_LOGIC_VECTOR (4 DOWNTO 0);
        oput: OUT STD_LOGIC);
END nolatch;

ARCHITECTURE rtl OF nolatch IS
BEGIN
    PROCESS (a,b,c,sel) BEGIN
        IF sel = "00000" THEN
            oput <= a;
        ELSIF sel = "00001" THEN
            oput <= b;
        ELSIF sel = "00010" THEN
            oput <= c;
        ELSE                    --- Prevents latch inference
            oput <= 'X'; --/
        END IF;
    END PROCESS;
END rtl;
```

1.5.3.2. Inferring Latches Correctly

Synthesis tools can infer a latch that does not exhibit the glitch and timing hazard problems typically associated with combinational loops. Intel Quartus Prime Pro Edition software reports latches that synthesis inferred in the **User-Specified and Inferred Latches** section of the Compilation Report. This report indicates whether the latch presents a timing hazard, and the total number of user-specified and inferred latches.

Note: In some cases, timing analysis does not completely model latch timing. As a best practice, avoid latches unless required by the design and you fully understand the impact.

If latches or combinational loops in the design do not appear in the **User Specified and Inferred Latches** section, then Intel Quartus Prime synthesis did not infer the latch as a safe latch, so the latch is not considered glitch-free.

All combinational loops listed in the **Analysis & Synthesis Logic Cells Representing Combinational Loops** table in the Compilation Report are at risk of timing hazards. These entries indicate possible problems with the design that require further investigation. However, correct designs can include combinational loops. For example, it is possible that the combinational loop cannot be sensitized. This occurs when there is an electrical path in the hardware, but either:

- The designer knows that the circuit never encounters data that causes that path to be activated, or
- The surrounding logic is set up in a mutually exclusive manner that prevents that path from ever being sensitized, independent of the data input.

For 6-input LUT-based devices, Intel Quartus Prime synthesis implements all latch inputs with a single adaptive look-up table (ALUT) in the combinational loop. Therefore, all latches in the **User-Specified and Inferred Latches** table are free of timing hazards when a single input changes.

If Intel Quartus Prime synthesis report lists a latch as a safe latch, other optimizations, such as physical synthesis netlist optimizations in the Fitter, maintain the hazard-free performance. To ensure hazard-free behavior, only one control input can change at a time. Changing two inputs simultaneously, such as deasserting `set` and `reset` at the same time, or changing data and enable at the same time, can produce incorrect behavior in any latch.

Intel Quartus Prime synthesis infers latches from `always` blocks in Verilog HDL and `process` statements in VHDL. However, Intel Quartus Prime synthesis does not infer latches from continuous assignments in Verilog HDL, or concurrent signal assignments in VHDL. These rules are the same as for register inference. The Intel Quartus Prime synthesis infers registers or flipflops only from `always` blocks and `process` statements.

Example 39. Verilog HDL Set-Reset Latch

```
module simple_latch (
   input SetTerm,
   input ResetTerm,
   output reg LatchOut
   );
   always @ (SetTerm or ResetTerm) begin
      if (SetTerm)
         LatchOut = 1'b1;
      else if (ResetTerm)
         LatchOut = 1'b0;
   end
endmodule
```

Example 40. VHDL Data Type Latch

```
LIBRARY IEEE;
USE IEEE.std_logic_1164.all;
ENTITY simple_latch IS
    PORT (
        enable, data    : IN STD_LOGIC;
        q               : OUT STD_LOGIC
    );
END simple_latch;
ARCHITECTURE rtl OF simple_latch IS
BEGIN
    latch : PROCESS (enable, data)
        BEGIN
        IF (enable = '1') THEN
            q <= data;
        END IF;
    END PROCESS latch;
END rtl;
```

The following example shows a Verilog HDL continuous assignment that does not infer a latch in the Intel Quartus Prime software:

Example 41. Verilog Continuous Assignment Does Not Infer Latch

```
assign latch_out = (~en & latch_out) | (en & data);
```

The behavior of the assignment is similar to a latch, but it may not function correctly as a latch, and its timing is not analyzed as a latch. Intel Quartus Prime Pro Edition synthesis also creates safe latches when possible for instantiations of an Intel FPGA latch IP core. Intel FPGA latch IPs allow you to define a latch with any combination of data, enable, set, and `reset` inputs. The same limitations apply for creating safe latches as for inferring latches from HDL code.

Inferring the Intel FPGA latch IP core in another synthesis tool ensures that Intel Quartus Prime synthesis also recognizes the implementation as a latch. If a third-party synthesis tool implements a latch using the Intel FPGA latch IP core, Intel Quartus Prime Pro Edition synthesis reports the latch in the **User-Specified and Inferred Latches** table, in the same manner as it lists latches you define in HDL source code. The coding style necessary to produce an Intel FPGA latch IP core implementation depends on the synthesis tool. Some third-party synthesis tools list the number of Intel FPGA latch IP cores that are inferred.

The Fitter uses global routing for control signals, including signals that synthesis identifies as latch enables. In some cases, the global insertion delay decreases timing performance. If necessary, you can turn off the **Intel Quartus Prime Global Signal** logic option to manually prevent the use of global signals. The **Global & Other Fast Signals** table in the Compilation Report reports Global latch enables.

1.6. General Coding Guidelines

This section describes how coding styles impact synthesis of HDL code into the target Intel FPGA devices. You can improve your design efficiency and performance by following these recommended coding styles, and designing logic structures to match the appropriate device architecture.

1.6.1. Tri-State Signals

Use tri-state signals only when they are attached to top-level bidirectional or output pins.

Avoid lower-level bidirectional pins. Also avoid using the Z logic value unless it is driving an output or bidirectional pin. Even though some synthesis tools implement designs with internal tri-state signals correctly in Intel FPGA devices using multiplexer logic, do not use this coding style for Intel FPGA designs.

Note: In hierarchical block-based design flows, a hierarchical boundary cannot contain any bidirectional ports, unless the lower-level bidirectional port is connected directly through the hierarchy to a top-level output pin without connecting to any other design logic. If you use boundary tri-states in a lower-level block, synthesis software must push the tri-states through the hierarchy to the top level to make use of the tri-state drivers on output pins of Intel FPGA devices. Because pushing tri-states requires optimizing through hierarchies, lower-level tri-states are restricted with block-based design methodologies.

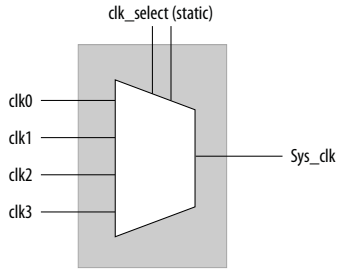
1.6.2. Clock Multiplexing

Clock multiplexing is sometimes used to operate the same logic function with different clock sources. This type of logic can introduce glitches that create functional problems. The delay inherent in the combinational logic can also lead to timing problems. Clock multiplexers trigger warnings from a wide range of design rule check and timing analysis tools.

Use dedicated hardware to perform clock multiplexing when it is available, instead of using multiplexing logic. For example, you can use the Clock Switchover feature or the Clock Control Block available in certain Intel FPGA devices. These dedicated hardware blocks avoid glitches, ensure that you use global low-skew routing lines, and avoid any possible hold time problems on the device due to logic delay on the clock line. Intel FPGA devices also support dynamic PLL reconfiguration, which is the safest and most robust method of changing clock rates during device operation.

If your design has too many clocks to use the clock control block, or if dynamic reconfiguration is too complex for your design, you can implement a clock multiplexer in logic cells. However, if you use this implementation, consider simultaneous toggling inputs and ensure glitch-free transitions.

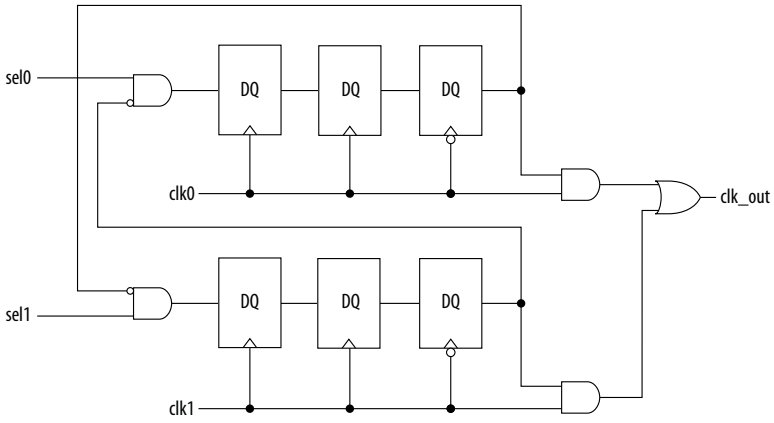
Figure 3. Simple Clock Multiplexer in a 6-Input LUT



Each device datasheet describes how LUT outputs can glitch during a simultaneous toggle of input signals, independent of the LUT function. Even though the 4:1 MUX function does not generate detectable glitches during simultaneous data input toggles, some cell implementations of multiplexing logic exhibit significant glitches, so this clock mux structure is not recommended. An additional problem with this implementation is that the output behaves erratically during a change in the `clk_select` signals. This behavior could create timing violations on all registers fed by the system clock and result in possible metastability.

A more sophisticated clock select structure can eliminate the simultaneous toggle and switching problems.

Figure 4. Glitch-Free Clock Multiplexer Structure



You can generalize this structure for any number of clock channels. The design ensures that no clock activates until all others are inactive for at least a few cycles, and that activation occurs while the clock is low. The design applies a `synthesis_keep` directive to the AND gates on the right side, which ensures there are no simultaneous toggles on the input of the `clk_out` OR gate.

Note: Switching from clock A to clock B requires that clock A continue to operate for at least a few cycles. If clock A stops immediately, the design sticks. The select signals are implemented as a "one-hot" control in this example, but you can use other encoding if you prefer. The input side logic is asynchronous and is not critical. This design can tolerate extreme glitching during the switch process.

Example 42. Verilog HDL Clock Multiplexing Design to Avoid Glitches

This example works with Verilog-2001.

```
module clock_mux (clk,clk_select,clk_out);

    parameter num_clocks = 4;

    input [num_clocks-1:0] clk;
    input [num_clocks-1:0] clk_select; // one hot
    output clk_out;

    genvar i;

    reg [num_clocks-1:0] ena_r0;
    reg [num_clocks-1:0] ena_r1;
    reg [num_clocks-1:0] ena_r2;
    wire [num_clocks-1:0] qualified_sel;

    // A look-up-table (LUT) can glitch when multiple inputs
    // change simultaneously. Use the keep attribute to
    // insert a hard logic cell buffer and prevent
    // the unrelated clocks from appearing on the same LUT.

    wire [num_clocks-1:0] gated_clks /* synthesis keep */;

    initial begin
        ena_r0 = 0;
        ena_r1 = 0;
        ena_r2 = 0;
    end

    generate
        for (i=0; i<num_clocks; i=i+1)
        begin : lp0
            wire [num_clocks-1:0] tmp_mask;
            assign tmp_mask = {num_clocks{1'b1}} ^ (1 << i);

            assign qualified_sel[i] = clk_select[i] & (~|(ena_r2 & tmp_mask));

            always @(posedge clk[i]) begin
                ena_r0[i] <= qualified_sel[i];
                ena_r1[i] <= ena_r0[i];
            end

            always @(negedge clk[i]) begin
                ena_r2[i] <= ena_r1[i];
            end

            assign gated_clks[i] = clk[i] & ena_r2[i];
        end
    endgenerate

    // These will not exhibit simultaneous toggle by construction
```

```
    assign clk_out = |gated_clks;

endmodule
```

1.6.3. Adder Trees

Structuring adder trees appropriately to match your targeted Intel FPGA device architecture can provide significant improvements in your design's efficiency and performance.

A good example of an application using a large adder tree is a finite impulse response (FIR) correlator. Using a pipelined binary or ternary adder tree appropriately can greatly improve the quality of your results.

1.6.3.1. Architectures with 6-Input LUTs in Adaptive Logic Modules

In Intel FPGA device families with 6-input LUT in their basic logic structure, ALMs can simultaneously add three bits. Take advantage of this feature by restructuring your code for better performance.

Although code targeting 4-input LUT architectures compiles successfully for 6-input LUT devices, the implementation can be inefficient. For example, to take advantage of the 6-input adaptive ALUT, you must rewrite large pipelined binary adder trees designed for 4-input LUT architectures. By restructuring the tree as a ternary tree, the design becomes much more efficient, significantly improving density utilization.

Example 43. Verilog HDL Pipelined Ternary Tree

The example shows a pipelined adder, but partitioning your addition operations can help you achieve better results in non-pipelined adders as well. If your design is not pipelined, a ternary tree provides much better performance than a binary tree. For example, depending on your synthesis tool, the HDL code `sum = (A + B + C) + (D + E)` is more likely to create the optimal implementation of a 3-input adder for `A + B + C` followed by a 3-input adder for `sum1 + D + E` than the code without the parentheses. If you do not add the parentheses, the synthesis tool may partition the addition in a way that is not optimal for the architecture.

```
module ternary_adder_tree (a, b, c, d, e, clk, out);
    parameter width = 16;
    input [width-1:0] a, b, c, d, e;
    input    clk;
    output [width-1:0] out;

    wire [width-1:0] sum1, sum2;
    reg [width-1:0] sumreg1, sumreg2;
    // registers

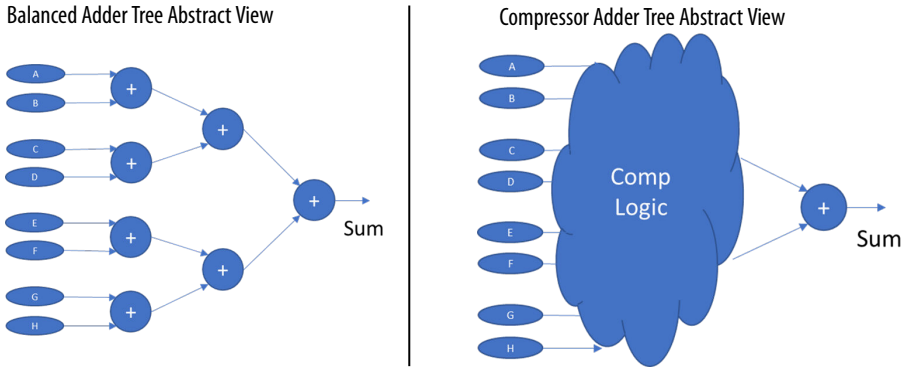
    always @ (posedge clk)
        begin
            sumreg1 <= sum1;
            sumreg2 <= sum2;
        end

    // 3-bit additions
    assign sum1 = a + b + c;
    assign sum2 = sumreg1 + d + e;
    assign out = sumreg2;
endmodule
```

1.6.3.2. Change Adder Tree Styles

Because ALMs can implement functions of up to six inputs, you can improve the performance of certain designs by using a compressor implementation for adder trees, rather than the default balanced binary tree implementation. The expected downside tradeoff of the compressor implementation is the use of more ALM logic resources. However the overall logic depth is lower, and the final timing characteristics improve.

Figure 5. Balanced Binary Versus Compressor Style Adder Trees



For designs that may benefit, you can apply the **Use Compressor Implementation** (`USE_COMPRESSOR_IMPLEMENTATION`) global, entity, or instance assignment to specify whether the Compiler synthesizes adder trees as balanced binary trees, or as compressor style trees.

You can specify this assignment in the Assignment Editor, or with the following assignment in the `.qsf`.

```
set_instance_assignment -name USE_COMPRESSOR_IMPLEMENTATION ALWAYS -to <foo>
```

The following options are available for this assignment:

Table 2. Use Compressor Implementation Assignment Options

Option	Description
Always	The Compiler always synthesizes all adder trees with this assignment as compressor style trees. There is a limit of at least 2 non-constant operands before this triggers (otherwise synthesis implements a binary add or a pure-LUT implementation depending on size).
Never	The Compiler never synthesizes the assigned adder tree as a compressor. The Compiler synthesizes the adder as either a balanced binary tree, or if sufficiently small, in pure LUTs.
Auto	This setting currently behaves the same as the **Never** setting. The Compiler synthesizes the adder as either a balanced binary tree, or if sufficiently small, in pure LUTs. This setting never uses compressor style adder trees.

1.6.4. State Machine HDL Guidelines

Synthesis tools can recognize and encode Verilog HDL and VHDL state machines during synthesis. This section presents guidelines to secure the best results when you use state machines.

Synthesis tools that can recognize a piece of code as a state machine can perform optimizations that improve the design area and performance. For example, the tool can recode the state variables to improve the quality of results, or optimize other parts of the design through known properties of state machines.

To achieve the best results, synthesis tools often use one-hot encoding for FPGA devices and minimal-bit encoding for CPLD devices, although the choice of implementation can vary for different state machines and different devices. Refer to the synthesis tool documentation for techniques to control the encoding of state machines.

To ensure proper recognition and inference of state machines and to improve the quality of results, observe the following guidelines for both Verilog HDL and VHDL:

- Assign default values to outputs derived from the state machine so that synthesis does not generate unwanted latches.
- Separate state machine logic from all arithmetic functions and datapaths, including assigning output values.
- For designs in which more than one state perform the same operation, define the operation outside the state machine, and direct the output logic of the state machine to use this value.
- Ensure a defined power-up state with a simple asynchronous or synchronous `reset`. In designs where the state machine contains more elaborate `reset` logic, such as both an asynchronous `reset` and an asynchronous load, the Intel Quartus Prime software infers regular logic rather than a state machine.

If a state machine enters an illegal state due to a problem with the device, the design likely ceases to function correctly until the next `reset` of the state machine. Synthesis tools do not provide for this situation by default. The same issue applies to any other registers if there is some fault in the system. A `default` or `when others` clause does not affect this operation, assuming that the design never deliberately enters this state. Synthesis tools remove any logic generated by a default state if it is not reachable by normal state machine operation.

Many synthesis tools (including Intel Quartus Prime synthesis) have an option to implement a safe state machine. The Intel Quartus Prime software inserts extra logic to detect illegal states and force the state machine's transition to the `reset` state. Safe state machines are useful when the state machine can enter an illegal state, for example, when a state machine has control inputs that originate in another clock domain, such as the control logic for a dual-clock FIFO.

This option protects state machines by forcing them into the `reset` state. All other registers in the design are not protected this way. As a best practice for designs with asynchronous inputs, use a synchronization register chain instead of relying on the safe state machine option.

1.6.4.1. State Machine Power-Up

In Intel Stratix 10 devices, registers do not necessarily power-up in the same clock cycle if they are not in the same sector. This fact can cause issues with state machines if the state machine enters an undefined state.

One-hot encoded state machines are especially susceptible to this issue, as the number of undefined states is large compared to the number of legal states. Retiming also increases the risk of this issue because when state registers retime across logic or routing, it becomes more likely that the different state registers of one state machine are in different sectors.

To mitigate this risk, the Compiler automatically uses **Safe State Machine** for any state machine of 6 or less states for Intel Stratix 10 designs. This **Safe State Machine** setting forces the state machines back into the reset state if they enter an undefined state. The Compiler does not automatically use **Safe State Machine** for state machines of more than 6 states, or for Intel Arria 10 or Intel Cyclone 10 GX devices, because the effect on the quality of results can be significant.

1.6.4.2. Verilog HDL State Machines

To ensure proper recognition and inference of Verilog HDL state machines, observe the following additional Verilog HDL guidelines.

Refer to your synthesis tool documentation for specific coding recommendations. If the synthesis tool doesn't recognize and infer the state machine, the tool implements the state machine as regular logic gates and registers, and the state machine doesn't appear as a state machine in the **Analysis & Synthesis** section of the Intel Quartus Prime Compilation Report. In this case, Intel Quartus Prime synthesis does not perform any optimizations specific to state machines.

- If you are using the SystemVerilog standard, use enumerated types to describe state machines.
- Represent the states in a state machine with the parameter data types in Verilog-1995 and Verilog-2001, and use the parameters to make state assignments. This parameter implementation makes the state machine easier to read and reduces the risk of errors during coding.
- Do not directly use integer values for state variables, such as `next_state <= 0`. However, using an integer does not prevent inference in the Intel Quartus Prime software.
- Intel Quartus Prime software doesn't infer a state machine if the state transition logic uses arithmetic similar to the following example:

```
case (state)
    0: begin
        if (ena) next_state <= state + 2;
        else next_state <= state + 1;
        end
    1: begin
    ...
endcase
```

- Intel Quartus Prime software doesn't infer a state machine if the state variable is an output.
- Intel Quartus Prime software doesn't infer a state machine for signed variables.

1.6.4.2.1. Verilog-2001 State Machine Coding Example

The following module `verilog_fsm` is an example of a typical Verilog HDL state machine implementation. This state machine has five states.

The asynchronous reset sets the variable `state` to `state_0`. The sum of `in_1` and `in_2` is an output of the state machine in `state_1` and `state_2`. The difference (`in_1` – `in_2`) is also used in `state_1` and `state_2`. The temporary variables `tmp_out_0` and `tmp_out_1` store the sum and the difference of `in_1` and `in_2`. Using these temporary variables in the various states of the state machine ensures proper resource sharing between the mutually exclusive states.

Example 44. Verilog-2001 State Machine

```
module verilog_fsm (clk, reset, in_1, in_2, out);
    input clk, reset;
    input [3:0] in_1, in_2;
    output [4:0] out;
    parameter state_0 = 3'b000;
    parameter state_1 = 3'b001;
    parameter state_2 = 3'b010;
    parameter state_3 = 3'b011;
    parameter state_4 = 3'b100;

    reg [4:0] tmp_out_0, tmp_out_1, tmp_out_2;
    reg [2:0] state, next_state;

    always @ (posedge clk or posedge reset)
    begin
        if (reset)
            state <= state_0;
        else
            state <= next_state;
    end
    always @ (*)
    begin
        tmp_out_0 = in_1 + in_2;
        tmp_out_1 = in_1 - in_2;
        case (state)
            state_0: begin
               tmp_out_2 = in_1 + 5'b00001;
               next_state = state_1;
            end
            state_1: begin
                if (in_1 < in_2) begin
                    next_state = state_2;
                    tmp_out_2 = tmp_out_0;
                end
                else begin
                    next_state = state_3;
                    tmp_out_2 = tmp_out_1;
                end
            end
            state_2: begin
                tmp_out_2 = tmp_out_0 - 5'b00001;
                next_state = state_3;
            end
            state_3: begin
                tmp_out_2 = tmp_out_1 + 5'b00001;
                next_state = state_0;
            end
            state_4:begin
                tmp_out_2 = in_2 + 5'b00001;
                next_state = state_0;
            end
            default:begin
                tmp_out_2 = 5'b00000;
                next_state = state_0;
            end
        endcase
```

```
    end
    assign out = tmp_out_2;
endmodule
```

You can achieve an equivalent implementation of this state machine by using `‘define` instead of the `parameter` data type, as follows:

```
‘define state_0 3'b000
‘define state_1 3'b001
‘define state_2 3'b010
‘define state_3 3'b011
‘define state_4 3'b100
```

In this case, you assign `` `state_x `` instead of `state_x` to `state` and `next_state`, for example:

```
next_state <= ‘state_3;
```

Note: Although Intel supports the `‘define` construct, use the `parameter` data type, because it preserves the state names throughout synthesis.

1.6.4.2.2. SystemVerilog State Machine Coding Example

Use the following coding style to describe state machines in SystemVerilog.

Example 45. SystemVerilog State Machine Using Enumerated Types

The module `enum_fsm` is an example of a SystemVerilog state machine implementation that uses enumerated types.

In Intel Quartus Prime Pro Edition synthesis, the enumerated type that defines the states for the state machine must be of an unsigned integer type. If you do not specify the enumerated type as `int unsigned`, synthesis uses a signed `int` type by default. In this case, the Intel Quartus Prime software synthesizes the design, but does not infer or optimize the logic as a state machine.

```
module enum_fsm (input clk, reset, input int data[3:0], output int o);
enum int unsigned { S0 = 0, S1 = 2, S2 = 4, S3 = 8 } state, next_state;
always_comb begin : next_state_logic
      next_state = S0;
      case(state)
        S0: next_state = S1;
        S1: next_state = S2;
        S2: next_state = S3;
        S3: next_state = S3;
      endcase
end
always_comb begin
      case(state)
         S0: o = data[3];
         S1: o = data[2];
         S2: o = data[1];
         S3: o = data[0];
      endcase
end
always_ff@(posedge clk or negedge reset) begin
      if(~reset)
         state <= S0;
      else
         state <= next_state;
end
endmodule
```

1.6.4.3. VHDL State Machines

To ensure proper recognition and inference of VHDL state machines, represent the different states with enumerated types, and use the corresponding types to make state assignments.

This implementation makes the state machine easier to read, and reduces the risk of errors during coding. If your RTL does not represent states with an enumerated type, Intel Quartus Prime synthesis (and other synthesis tools) do not recognize the state machine. Instead, synthesis implements the state machine as regular logic gates and registers. Consequently, and the state machine does not appear in the state machine list of the Intel Quartus Prime Compilation Report, **Analysis & Synthesis** section. Moreover, Intel Quartus Prime synthesis does not perform any of the optimizations that are specific to state machines.

1.6.4.3.1. VHDL State Machine Coding Example

The following state machine has five states. The asynchronous reset sets the variable `state` to `state_0`.

The sum of `in1` and `in2` is an output of the state machine in `state_1` and `state_2`. The difference (`in1 - in2`) is also used in `state_1` and `state_2`. The temporary variables `tmp_out_0` and `tmp_out_1` store the sum and the difference of `in1` and `in2`. Using these temporary variables in the various states of the state machine ensures proper resource sharing between the mutually exclusive states.

Example 46. VHDL State Machine

```
LIBRARY ieee;
USE ieee.std_logic_1164.all;
USE ieee.numeric_std.all;
ENTITY vhdl_fsm IS
   PORT(
      clk: IN STD_LOGIC;
      reset: IN STD_LOGIC;
      in1: IN UNSIGNED(4 downto 0);
      in2: IN UNSIGNED(4 downto 0);
      out_1: OUT UNSIGNED(4 downto 0)
      );
END vhdl_fsm;
ARCHITECTURE rtl OF vhdl_fsm IS
   TYPE Tstate IS (state_0, state_1, state_2, state_3, state_4);
   SIGNAL state: Tstate;
   SIGNAL next_state: Tstate;
BEGIN
   PROCESS(clk, reset)
   BEGIN
      IF reset = '1' THEN
            state <=state_0;
      ELSIF rising_edge(clk) THEN
            state <= next_state;
      END IF;
   END PROCESS;
PROCESS (state, in1, in2)
      VARIABLE tmp_out_0: UNSIGNED (4 downto 0);
      VARIABLE tmp_out_1: UNSIGNED (4 downto 0);
   BEGIN
      tmp_out_0 := in1 + in2;
      tmp_out_1 := in1 - in2;
      CASE state IS
         WHEN state_0 =>
            out_1 <= in1;
```

```
            next_state <= state_1;
         WHEN state_1 =>
            IF (in1 < in2) then
               next_state <= state_2;
               out_1 <= tmp_out_0;
            ELSE
               next_state <= state_3;
               out_1 <= tmp_out_1;
            END IF;
         WHEN state_2 =>
            IF (in1 < "0100") then
               out_1 <= tmp_out_0;
            ELSE
               out_1 <= tmp_out_1;
            END IF;
               next_state <= state_3;
         WHEN state_3 =>
               out_1 <= "11111";
               next_state <= state_4;
         WHEN state_4 =>
               out_1 <= in2;
               next_state <= state_0;
         WHEN OTHERS =>
               out_1 <= "00000";
               next_state <= state_0;
      END CASE;
   END PROCESS;
END rtl;
```

1.6.5. Multiplexer HDL Guidelines

Multiplexers form a large portion of the logic utilization in many FPGA designs. By optimizing your multiplexer logic, you ensure the most efficient implementation.

This section addresses common problems and provides design guidelines to achieve optimal resource utilization for multiplexer designs. The section also describes various types of multiplexers, and how they are implemented.

For more information, refer to the *Advanced Synthesis Cookbook*.

1.6.5.1. Intel Quartus Prime Software Option for Multiplexer Restructuring

Intel Quartus Prime Pro Edition synthesis provides the **Restructure Multiplexers** logic option that extracts and optimizes buses of multiplexers during synthesis. The default **Auto** for this option setting uses the optimization whenever beneficial for your design. You can turn the option on or off specifically to have more control over use.

Even with this Intel Quartus Prime-specific option turned on, it is beneficial to understand how your coding style can be interpreted by your synthesis tool, and avoid the situations that can cause problems in your design.

1.6.5.2. Multiplexer Types

This section addresses how Intel Quartus Prime synthesis creates multiplexers from various types of HDL code.

State machines, CASE statements, and IF statements are all common sources of multiplexer logic in designs. These HDL structures create different types of multiplexers, including binary multiplexers, selector multiplexers, and priority multiplexers.

The first step toward optimizing multiplexer structures for best results is to understand how Intel Quartus Prime infers and implements multiplexers from HDL code.

1.6.5.2.1. Binary Multiplexers

Binary multiplexers select inputs based on binary-encoded selection bits.

Device families featuring 6-input look up tables (LUTs) are perfectly suited for 4:1 multiplexer building blocks (4 data and 2 select inputs). The extended input mode facilitates implementing 8:1 blocks, and the fractured mode handles residual 2:1 multiplexer pairs.

Example 47. Verilog HDL Binary-Encoded Multiplexers

```
case (sel)
   2'b00: z = a;
   2'b01: z = b;
   2'b10: z = c;
   2'b11: z = d;
endcase
```

1.6.5.2.2. Selector Multiplexers

Selector multiplexers have a separate select line for each data input. The select lines for the multiplexer are one-hot encoded. Intel Quartus Prime commonly builds selector multiplexers as a tree of AND and OR gates.

Even though the implementation of a tree-shaped, N-input selector multiplexer is slightly less efficient than a binary multiplexer, in many cases the select signal is the output of a decoder. Intel Quartus Prime synthesis combines the selector and decoder into a binary multiplexer.

Example 48. Verilog HDL One-Hot-Encoded CASE Statement

```
case (sel)
   4'b0001: z = a;
   4'b0010: z = b;
   4'b0100: z = c;
   4'b1000: z = d;
   default: z = 1'bx;
endcase
```

1.6.5.2.3. Priority Multiplexers

In priority multiplexers, the select logic implies a priority. The options to select the correct item must be checked in a specific order based on signal priority.

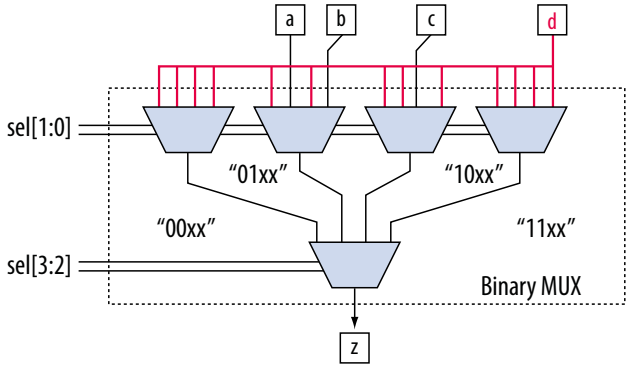
Synthesis tools commonly infer these structures from `IF`, `ELSE`, `WHEN`, `SELECT`, and `?:` statements in VHDL or Verilog HDL.

Example 49. VHDL IF Statement Implying Priority

The multiplexers form a chain, evaluating each condition or select bit sequentially.

```
IF cond1 THEN z <= a;
ELSIF cond2 THEN z <= b;
ELSIF cond3 THEN z <= c;
ELSE z <= d;
END IF;
```

Figure 6. Priority Multiplexer Implementation of an IF Statement



Depending on the number of multiplexers in the chain, the timing delay through this chain can become large, especially for device families with 4-input LUTs.

To improve the timing delay through the multiplexer, avoid priority multiplexers if priority is not required. If the order of the choices is not important to the design, use a CASE statement to implement a binary or selector multiplexer instead of a priority multiplexer. If delay through the structure is important in a multiplexed design requiring priority, consider recoding the design to reduce the number of logic levels to minimize delay, especially along your critical paths.

1.6.5.3. Implicit Defaults in IF Statements

IF statements in Verilog HDL and VHDL can simplify expressing conditions that do not easily lend themselves to a CASE-type approach. However, IF statements can result in complex multiplexer trees that are not easy for synthesis tools to optimize. In particular, all IF statements have an ELSE condition, even when not specified in the code. These implicit defaults can cause additional complexity in multiplexed designs.

You can simplify multiplexed logic and remove unneeded defaults with multiple methods. The optimal method is recoding the design, so the logic takes the structure of a 4:1 CASE statement. Alternatively, if priority is important, you can restructure the code to reduce default cases and flatten the multiplexer. Examine whether the default "ELSE IF" conditions are don't care cases. You can add a default ELSE statement to make the behavior explicit. Avoid unnecessary default conditions in the multiplexer logic to reduce the complexity and logic utilization that the design implementation requires.

1.6.5.4. default or OTHERS CASE Assignment

To fully specify the cases in a CASE statement, include a default (Verilog HDL) or OTHERS (VHDL) assignment.

This assignment is especially important in one-hot encoding schemes where many combinations of the select lines are unused. Specifying a case for the unused select line combinations gives the synthesis tool information about how to synthesize these cases, and is required by the Verilog HDL and VHDL language specifications.

For some designs you do not need to consider the outcome in the unused cases, because these cases are unreachable. For these types of designs, you can specify any value for the `default` or OTHERS assignment. However, the assignment value you choose can have a large effect on the logic utilization required to implement the design.

To obtain best results, explicitly define invalid CASE selections with a separate `default` or OTHERS statement, instead of combining the invalid cases with one of the defined cases.

If the value in the invalid cases is not important, specify those cases explicitly by assigning the X (don't care) logic value instead of choosing another value. This assignment allows your synthesis tool to perform the best area optimizations.

1.6.6. Cyclic Redundancy Check Functions

CRC computations are used heavily by communications protocols and storage devices to detect any corruption of data. These functions are highly effective; there is a very low probability that corrupted data can pass a 32-bit CRC check

CRC functions typically use wide XOR gates to compare the data. The way synthesis tools flatten and factor these XOR gates to implement the logic in FPGA LUTs can greatly impact the area and performance results for the design. XOR gates have a cancellation property that creates an exceptionally large number of reasonable factoring combinations, so synthesis tools cannot always choose the best result by default.

The 6-input ALUT has a significant advantage over 4-input LUTs for these designs. When properly synthesized, CRC processing designs can run at high speeds in devices with 6-input ALUTs.

The following guidelines help you improve the quality of results for CRC designs in Intel FPGA devices.

1.6.6.1. If Performance is Important, Optimize for Speed

To minimize area and depth of levels of logic, synthesis tools flatten XOR gates.

By default, Intel Quartus Prime Pro Edition synthesis targets area optimization for XOR gates. Therefore, for more focus on depth reduction, set the synthesis optimization technique to speed.

Note: Flattening for depth sometimes causes a significant increase in area.

1.6.6.2. Use Separate CRC Blocks Instead of Cascaded Stages

Some designs optimize CRC to use cascaded stages (for example, four stages of 8 bits). In such designs, Intel Quartus Prime synthesis uses intermediate calculations (such as the calculations after 8, 24, or 32 bits) depending on the data width.

This design is not optimal for FPGA devices. The XOR cancellations that Intel Quartus Prime synthesis performs in CRC designs mean that the function does not require all the intermediate calculations to determine the final result. Therefore, forcing the use of intermediate calculations increases the area required to implement the function, as

well as increasing the logic depth because of the cascading. It is typically better to create full separate CRC blocks for each data width that you require in the design, and then multiplex them together to choose the appropriate mode at a given time

1.6.6.3. Use Separate CRC Blocks Instead of Allowing Blocks to Merge

Synthesis tools often attempt to optimize CRC designs by sharing resources and extracting duplicates in two different CRC blocks because of the factoring options in the XOR logic.

CRC logic allows significant reductions, but this works best when the Compiler optimizes CRC function separately. Check for duplicate extraction behavior if for designs with different CRC functions that are driven by common data signals or that feed the same destination signals.

For designs with poor quality results that have two CRC functions sharing logic you can ensure that the blocks are synthesized independently with one of the following methods:

- Define each CRC block as a separate design partition in a hierarchical compilation design flow.
- Synthesize each CRC block as a separate project in a third-party synthesis tool and then write a separate Verilog Quartus Mapping (`.vqm`) or EDIF netlist file for each.

1.6.6.4. Take Advantage of Latency if Available

If your design can use more than one cycle to implement the CRC functionality, adding registers and retiming the design can help reduce area, improve performance, and reduce power utilization.

If your synthesis tool offers a retiming feature (such as the Intel Quartus Prime software **Perform gate-level register retiming** option), you can insert an extra bank of registers at the input and allow the retiming feature to move the registers for better results. You can also build the CRC unit half as wide and alternate between halves of the data in each clock cycle.

1.6.6.5. Save Power by Disabling CRC Blocks When Not in Use

CRC designs are heavy consumers of dynamic power because the logic toggles whenever there is a change in the design.

To save power, use clock enables to disable the CRC function for every clock cycle that the logic is not required. Some designs don't check the CRC results for a few clock cycles while other logic is performing. It is valuable to disable the CRC function even for this short amount of time.

1.6.6.6. Initialize the Device with the Synchronous Load (sload) Signal

CRC designs often require the data to be initialized to 1's before operation. In devices that support the `sload` signal, you can use this signal to set all registers in the design to 1's before operation.

To enable the `sload` signal, follow the coding guidelines in this chapter. After compilation you can check the register equations in the Chip Planner to ensure that the signal behaves as expected.

If you must force a register implementation using an `sload` signal, refer to *Designing with Low-Level Primitives User Guide* to see how you can use low-level device primitives.

Related Information

Secondary Register Control Signals Such as Clear and Clock Enable on page 40

1.6.7. Comparator HDL Guidelines

This section provides information about the different types of implementations available for comparators (<, >, or ==), and provides suggestions on how you can code the design to encourage a specific implementation. Synthesis tools, including Intel Quartus Prime Pro Edition synthesis, use device and context-specific implementation rules, and select the best one for the design.

Synthesis tools implement the == comparator in general logic cells and the < comparison in either the carry chain or general logic cells. In devices with 6-input ALUTs, the carry chain can compare up to three bits per cell. Carry chain implementation tends to be faster than general logic on standalone benchmark test cases, but can result in lower performance on larger designs due to increased restrictions on the Fitter. The area requirement is similar for most input patterns. The synthesis tools select an appropriate implementation based on the input pattern.

You can guide the Intel Quartus Prime Synthesis engine by choosing specific coding styles. To select a carry chain implementation explicitly, rephrase the comparison in terms of addition.

For example, the following coding style allows the synthesis tool to select the implementation, which is most likely using general logic cells in modern device families:

```
wire [6:0] a,b;
wire alb = a<b;
```

In the following coding style, the synthesis tool uses a carry chain (except for a few cases, such as when the chain is very short, or the signals a and b minimize to the same signal):

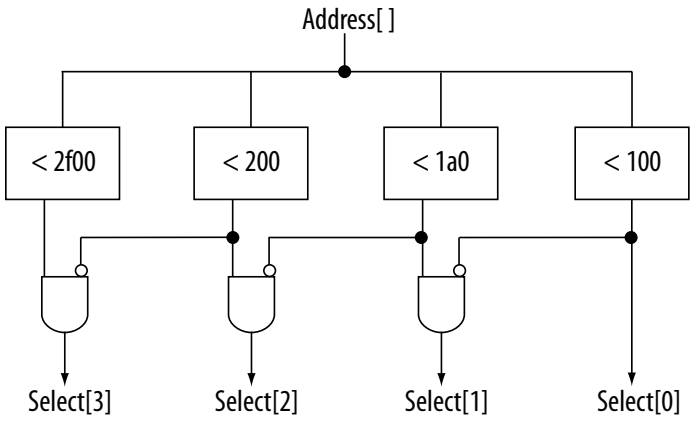
```
wire [6:0] a,b;
wire [7:0] tmp = a - b;
wire alb = tmp[7]
```

This second coding style uses the top bit of the `tmp` signal, which is 1 in two's complement logic if *a* is less than *b*, because the subtraction *a* - *b* results in a negative number.

If you have any information about the range of the input, you can use “don’t care” values to optimize the design. This information is not available to the synthesis tool, so specific hand implementation of the logic can reduce the device area required to implement the comparator.

The following logic structure, which occurs frequently in address decoders, allows you to check whether a bus value is within a constant range with a small amount of logic area:

Figure 7. Example Logic Structure for Using Comparators to Check a Bus Value Range



1.6.8. Counter HDL Guidelines

The Intel Quartus Prime synthesis engine implements counters in HDL code as an adder followed by registers, and makes available register control signals such as enable (`ena`), synchronous clear (`sclr`), and synchronous load (`sload`). For best area utilization, ensure that the up and down control or controls are expressed in terms of one addition operator, instead of two separate addition operators.

If you use the following coding style, your synthesis engine may implement two separate carry chains for addition:

```
out <= count_up ? out + 1 : out - 1;
```

For simple designs, the synthesis engine identifies this coding style and optimizes the logic. However, in complex designs, or designs with preserve pragmas, the Compiler cannot optimize all logic, so more careful coding becomes necessary.

The following coding style requires only one adder along with some other logic:

```
out <= out + (count_up ? 1 : -1);
```

This style makes more efficient use of resources and area, since it uses only one carry chain adder, and the –1 constant logic is implemented in the LUT before the adder.

1.7. Designing with Low-Level Primitives

Low-level HDL design is the practice of using low-level primitives and assignments to dictate a particular hardware implementation for a piece of logic. Low-level primitives are small architectural building blocks that assist you in creating your design.

With the Intel Quartus Prime software, you can use low-level HDL design techniques to force a specific hardware implementation that can help you achieve better resource utilization or faster timing results.

Note: Using low-level primitives is an optional advanced technique to help with specific design challenges. For many designs, synthesizing generic HDL source code and Intel FPGA IP cores give you the best results.

Low-level primitives allow you to use the following types of coding techniques:

- Instantiate the logic cell or LCELL primitive to prevent Intel Quartus Prime Pro Edition synthesis from performing optimizations across a logic cell
- Instantiate registers with specific control signals using DFF primitives
- Specify the creation of LUT functions by identifying the LUT boundaries
- Use I/O buffers to specify I/O standards, current strengths, and other I/O assignments
- Use I/O buffers to specify differential pin names in your HDL code, instead of using the automatically-generated negative pin name for each pair

For details about and examples of using these types of assignments, refer to the *Designing with Low-Level Primitives User Guide*.

1.8. Cross-Module Referencing (XMR) in HDL Code

Cross Module Referencing (XMR), also known as hierarchical reference, is enabled by default. It is a mechanism built into Verilog, SystemVerilog, and VHDL to globally reference nets in any hierarchy across modules, which means you can refer to any net of a particular module in a different module (irrespective of the hierarchy) directly without going through the ports. Hence, XMR can be a downward reference or an upward reference.

Note: XMR also works in mixed language designs.

You can use XMR to read from nets or write to a net in different hierarchies. XMR is helpful in debugging and verification, for example:

- Override or force any signal. For more information, refer to Using force Statements in HDL Code on page 64.
- Write cover points for functional coverage.
- Tap into any signal from anywhere in the entire design.

Consider the following hierarchy within the instance `top` of module `a`:

```
module a
  net x
  instance p of module b
    net x
    instance m of module d
      net x
  instance q of module c
    net x
    instance n of module e
      net x
  instance r of module b
     net x
     instance m of module d
       net x
```

In the above scenario, all modules consist of a net named x. By using full-path-based XMR, you can globally reference each net x anywhere within the hierarchy, as follows:

- top.x
- top.p.x
- top.p.m.x
- top.q.x
- top.q.n.x
- top.r.x
- top.r.m

XMR starts with searching within the current module. Then, it hierarchically searches downwards through child instances. If XMR is unresolved, it searches one step above in the hierarchy (parent module) and hierarchically downwards. It keeps going further in the hierarchy until it gets resolved. To avoid unexpected behavior, Intel recommends always using the hierarchy path where possible.

XMR Use Case Examples

Example 50. XMR of Signals in Higher Modules from Lower Modules

In the following example, the signal d in the sub module is assigned to the value a from the top module:

```
module top (input a, input b, output c, output d);
  sub inst1 (.a(a), .b(b), .c(c), .d(d));
endmodule

module sub (input a, input b, output c, output d);
  assign c = a & b;
  assign d = top.a;
endmodule
```

Example 51. XMR of Signals in Lower Modules from Higher Modules

In the following example, the sub module's value a assigns the output value d, given the complete path in the top module:

```
module top (input a, input b, output c, output d);
  sub inst1 (.a(a), .b(b), .c(c));
  assign d = inst1.a;
endmodule
module sub (input a, input b, output c);
  assign c = a & b;
endmodule
```

Example 52. XMR of Signals in generate Block

Consider the following example with a generate block where you write the value to temp at the top module and read the out2 value from the top module:

```
module top (input [3:0] in1, in2, input clk, output [3:0] out1, out2);
  generate
    begin:blk1 sub inst (in1, clk, out1, temp);
  end:blk1
  endgenerate
```

```
//XMR read
assign out2 = top.blk1.inst.temp;
endmodule
```

Example 53. XMR From Inside an `always` Block

Consider the following example of XMR of signals within the `always_comb` construct, where the output value `d` in the `top` module is assigned from the `sub` module value `a`:

```
module top (input logic a, input logic b, output logic c, output logic d);
  sub inst1 (.a(a), .b(b), .c(c));
  always_comb d = inst1.a;

endmodule

module sub (input logic a, input logic b, output logic c);
  assign c = b & a;
endmodule
```

Limitations of XMR

The following are some limitations of XMR in the Intel Quartus Prime software:

- XMR must be within the same design partition. For example, if there are partitions A and B, then in partition B, there cannot be any XMR to anything in partition A and vice versa.

  Note: The same partition requirement applies for global signals that are specified in a package and can be used in any module.
- Multiple-driven nets are not supported. So, you cannot use XMR to drive a net already driven by another signal.
- You can use XMR only in Verilog, SystemVerilog, and VHDL. It does not work for Text Design File (TDF) or Block Design File (BDF).

  Note: Intel does not recommend using XMR on SystemVerilog interfaces since they are prone to errors.
- You cannot use XMR to refer to signals inside an Intel FPGA IP core or a Signal Tap partition that is automatically created during synthesis.

Synplify Pro for Microsemi Edition Language Support Reference Manual

1.9. Using `force` Statements in HDL Code

`force` statement in SystemVerilog is a continuous procedural assignment on a net or a variable. Applying a `force` statement to a net or variable overrides all other drivers to that net or variable. In simulation, you can use a `force` statement in conjunction with a `release` statement. However, Intel Quartus Prime software synthesis supports using only the `force` statement to override the drivers of a net (gate outputs, module outputs, and continuous assignments) and previous assignments made on a particular net or a net bus.

Note: Synthesis supports using a `force` statement only inside an initial block.

Examples of force Statements in Synthesis

The following are some examples of force statements that the Intel Quartus Prime software synthesis supports:

Example 54. Using a force Statement to Set Counter enable to 0

The following is an example of how you can use a force statement to tie the en port of the counter instance u1 to logic 0:

```
module top(clk, rst, enable, dout);
  input clk, rst, enable;
  output [3:0] dout;
  counter u1(.clk(clk), .reset(rst), .en(enable), .q(dout));

  initial  begin
    force u1.en = 1'b0
  end
endmodule
```

You can observe that the force statement overrides the other driver of the en port, which is the enable port of the top module.

Example 55. Using a force Statement to Change Connections

The following example shows how you can use a force statement to change the connections in the design:

```
module top(input [3:0] din, din1, output logic [3:0] dout, dout1, input clk,
rst);
  dff i0(.din(din), .dout(dout), .clk(clk), .rst(rst) );
  dff i1(.din(din1), .dout(dout1), .clk(clk), .rst(rst) );
endmodule

module top_modified(input [3:0] din, din1, output logic [3:0] dout, dout1, input
clk, rst);
  top i_top(.*);
  initial
  begin
    force i_top.i1.din = i_top.din;
  end
endmodule
```

In this example, the design's top module instantiates two instances of the dff module. din and din1 ports of the top module drive the din port of i0 and i1 instances.

Suppose you want to change the connections in the top module without changing the RTL inside the top module. In this situation, you can use a force statement within a wrapper module (top_modified), which becomes the new top module. In the new top module, use the force statement to modify the connections in the top module such that the din port of both i0 and i1 instances is driven by the same din port of the top module. The force statement uses a cross-module reference (XMR) to access signals in a hierarchy below it. For more information about XMR, refer to Cross-Module Referencing (XMR) in HDL Code on page 62.

Note: For this example, instead of creating a wrapper `top_modified` that instantiates the `top` module, you can also create a secondary top-level entity and make the `force` assignment in it, as shown in the following:

```
module secondary_top(input [3:0] din, din1, output logic [3:0] dout, dout1,
input clk, rst);
initial begin
  force top.i1.din = top.din;
end
endmodule
```

1.10. Recommended HDL Coding Styles Revision History

The following revisions history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.10.02	23.1	• Made minor updates to code snippets in *Using force Statements in HDL Code* and *Cross-Module Referencing (XMR) in HDL Code*.
2023.04.03	23.1	• Updated product family name to "Intel Agilex 7."
2022.09.26	22.3	• Added *Using force Statements in HDL Code*. • Added *Cross-Module Referencing (XMR) in HDL Code*.
2021.10.04	21.3	• Added new *Inferring FIFOs in HDL Code* topic and linked to *FIFO Intel FPGA IP User Guide*. • Added new *Dual Clock FIFO Example in Verilog HDL* topic. • Added new *Dual Clock FIFO Timing Constraints* topic.
2021.06.21	21.2	• Updated *Inferring Shift Registers in HDL Code* for Intel Stratix 10 and Intel Agilex 7 devices. • Updated wording of *Controlling RAM Inference and Implementation* for clarity.
2019.09.30	19.3	• Updated Simple Dual-Port Synchronous RAM with Byte Enable examples. • Updated True Dual-Port Synchronous RAM examples. • Updated Verilog HDL Single-Bit Wide Shift Register example from 64 to 69 bits. • Updated VHDL Single-Bit Wide Shift Register example from 67 to 69 bits. • Updated Verilog HDL 8-Bit Wide Shift Register with Evenly Spaced Taps from 64 to 254 bits.
2018.09.24	18.1	• Added "State Machine Power-Up" topic. • Updated "Designing with Low-Level Primitives" to remove support for carry and cascade chains using CARRY, CARRY_SUM, and CASCADE primitives. • Renamed topic: "Use the Device Synchronous Load (sload) Signal to Initialize" to "Initialize the Device with the Synchronous Load (sload) Signal"
2017.11.06	17.1	• Described new no_ram synthesis attribute.
2017.05.08	17.0	• Updated example: Verilog HDL Multiply-Accumulator • Updated information about use of safe state machine. • Revised Check Read-During-Write Behavior. • Revised Controlling RAM Inference and Implementation. • Revised Single-Clock Synchronous RAM with Old Data Read-During-Write Behavior. • Revised Single-Clock Synchronous RAM with New Data Read-During-Write Behavior.

continued...

Document Version	Intel Quartus Prime Version	Changes
		• Updated and moved template for VHDL Single-Clock Simple Dual Port Synchronous RAM with New Data Read-During-Write Behavior. • Revised Inferring ROM Functions from HDL Code. • Removed example: VHDL 8-Bit Wide, 64-Bit Long Shift Register with Evenly Spaced Taps. • Removed example: Verilog HDL D-Type Flipflop (Register) With ena, aclr, and aload Control Signals • Removed example: VHDL D-Type Flipflop (Register) With ena, aclr, and aload Control Signals • Added example: Verilog D-type Flipflop bus with Secondary Signals • Removed references to 4-input LUT-based devices. • Removed references to Integrated Synthesis. • Created example: Avoid this VHDL Coding Style.
2016.10.31	16.1	• Provided corrected Verilog HDL Pipelined Binary Tree and Ternary Tree examples. • Implemented Intel rebranding.
2016.05.03	16.0	• Added information about use of safe state machine. • Updated example code templates with latest coding styles.
2015.11.02	15.1	• Changed instances of *Quartus II* to *Intel Quartus Prime*.
2015.05.04	15.0	Added information and reference about ramstyle attribute for sift register inference.
2014.12.15	14.1	Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Optimization Settings to Compiler Settings.
2014.08.18	14.0.a10	• Added recommendation to use register pipelining to obtain high performance in DSP designs.
2014.06.30	14.0	Removed obsolete MegaWizard Plug-In Manager support.
November 2013	13.1	Removed HardCopy device support.
June 2012	12.0	• Revised section on inserting Altera templates. • Code update for Example 11-51. • Minor corrections and updates.
November 2011	11.1	• Updated document template. • Minor updates and corrections.
December 2010	10.1	• Changed to new document template. • Updated Unintentional Latch Generation content. • Code update for Example 11-18.
July 2010	10.0	• Added support for mixed-width RAM • Updated support for no_rw_check for inferring RAM blocks • Added support for byte-enable
November 2009	9.1	• Updated support for Controlling Inference and Implementation in Device RAM Blocks • Updated support for Shift Registers

Document Version	Intel Quartus Prime Version	Changes
March 2009	9.0	• Corrected and updated several examples • Added support for Arria II GX devices • Other minor changes to chapter
November 2008	8.1	Changed to 8-1/2 x 11 page size. No change to content.
May 2008	8.0	Updates for the Intel Quartus Prime software version 8.0 release, including: • Added information to "RAM • Functions—Inferring ALTSYNCRAM and ALTDPRAM Megafunctions from HDL Code" on page 6–13 • Added information to "Avoid Unsupported Reset and Control Conditions" on page 6–14 • Added information to "Check Read-During-Write Behavior" on page 6–16 • Added two new examples to "ROM Functions—Inferring ALTSYNCRAM and LPM_ROM Megafunctions from HDL Code" on page 6–28: Example 6–24 and Example 6–25 • Added new section: "Clock Multiplexing" on page 6–46 • Added hyperlinks to references within the chapter • Minor editorial updates

2. Recommended Design Practices

This chapter provides design recommendations for Intel FPGA devices.

Current FPGA applications have reached the complexity and performance requirements of ASICs. In the development of complex system designs, design practices have an enormous impact on the timing performance, logic utilization, and system reliability of a device. Well-coded designs behave in a predictable and reliable manner even when retargeted to different families or speed grades. Good design practices also aid in successful design migration between FPGA and ASIC implementations for prototyping and production.

For optimal performance, reliability, and faster time-to-market when designing with Intel FPGA devices, you should adhere to the following guidelines:

- Understand the impact of synchronous design practices
- Follow recommended design techniques, including hierarchical design partitioning, and timing closure guidelines
- Take advantage of the architectural features in the targeted device

2.1. Following Synchronous FPGA Design Practices

The first step in good design methodology is to understand the implications of your design practices and techniques. This section outlines the benefits of optimal synchronous design practices and the hazards involved in other approaches.

Good synchronous design practices can help you meet your design goals consistently. Problems with other design techniques can include reliance on propagation delays in a device, which can lead to race conditions, incomplete timing analysis, and possible glitches.

In a synchronous design, a clock signal triggers every event. If you ensure that all the timing requirements of the registers are met, a synchronous design behaves in a predictable and reliable manner for all process, voltage, and temperature (PVT) conditions. You can easily migrate synchronous designs to different device families or speed grades.

2.1.1. Implementing Synchronous Designs

In a synchronous design, the clock signal controls the activities of all inputs and outputs.

On every active edge of the clock (usually the rising edge), the data inputs of registers are sampled and transferred to outputs. Following an active clock edge, the outputs of combinational logic feeding the data inputs of registers change values. This change triggers a period of instability due to propagation delays through the logic as the

signals go through several transitions and finally settle to new values. Changes that occur on data inputs of registers do not affect the values of their outputs until after the next active clock edge.

Because the internal circuitry of registers isolates data outputs from inputs, instability in the combinational logic does not affect the operation of the design if you meet the following timing requirements:

- Before an active clock edge, you must ensure that the data input has been stable for at least the setup time of the register.
- After an active clock edge, you must ensure that the data input remains stable for at least the hold time of the register.

  When you specify all your clock frequencies and other timing requirements, the Intel Quartus Prime Timing Analyzer reports actual hardware requirements for the setup times (t_{SU}) and hold times (t_H) for every pin in your design. By meeting these external pin requirements and following synchronous design techniques, you ensure that you satisfy the setup and hold times for all registers in your device.

  Tip: To meet setup and hold time requirements on all input pins, any inputs to combinational logic that feed a register should have a synchronous relationship with the clock of the register. If signals are asynchronous, you can register the signals at the inputs of the device to help prevent a violation of the required setup and hold times.

  When you violate the setup or hold time of a register, you might oscillate the output, or set the output to an intermediate voltage level between the high and low levels called a metastable state. In this unstable state, small perturbations such as noise in power rails can cause the register to assume either the high or low voltage level, resulting in an unpredictable valid state. Various undesirable effects can occur, including increased propagation delays and incorrect output states. In some cases, the output can even oscillate between the two valid states for a relatively long period of time.

2.1.2. Asynchronous Design Hazards

Asynchronous design techniques, such as ripple counters or pulse generators, can work as "short cuts" to save device resources. However, asynchronous techniques have inherent problems. For example, relying on propagation delays can result in incomplete timing constraints and possible glitches and spikes, because propagation delay varies with temperature and voltage fluctuations.

Asynchronous design structures that depend on the relative propagation delays can present race conditions. Race conditions arise when the order of signal changes affect the output of the logic. The same logic design can have varying timing delays with each compilation, depending on placement and routing. The number of possible variations make it impossible to determine the timing delay associated with a particular block of logic. As devices become faster due to process improvements, delays in asynchronous designs may decrease, resulting in designs that do not function as expected. Relying on a particular delay also makes asynchronous designs difficult to migrate to other architectures, devices, or speed grades.

The timing of asynchronous design structures is often difficult or impossible to model with timing assignments and constraints. If you do not have complete or accurate timing constraints, the timing-driven algorithms that synthesis and place-and-route tools use may not be able to perform the best optimizations, and the reported results may be incomplete.

Additionally, asynchronous design structures can generate glitches, which are pulses that are very short compared to clock periods. Combinational logic is the main cause of glitches. When the inputs to the combinational logic change, the outputs exhibit several glitches before settling to their new values. Glitches can propagate through combinational logic, leading to incorrect values on the outputs in asynchronous designs. In synchronous designs, glitches on register's data inputs have no negative consequences, because data processing waits until the next clock edge.

2.2. HDL Design Guidelines

When designing with HDL code, consider how synthesis tools interpret different HDL design techniques and what results to expect.

Design style can affect logic utilization and timing performance, as well as the design's reliability. This section describes basic design techniques that ensure optimal synthesis results for designs that target Intel FPGA devices while avoiding common causes of unreliability and instability. As a best practice, consider potential problems when designing combinational logic, and pay attention to clocking schemes so that the design maintains synchronous functionality and avoids timing issues.

2.2.1. Considerations for the Intel Hyperflex FPGA Architecture

The Intel Hyperflex FPGA architecture and the Hyper-Retimer require a review of the best design practices to achieve the highest clock rates possible.

While most common techniques of high-speed design apply to designing for the Intel Hyperflex architecture, you must use some new approaches to achieve the highest performance. Follow these general RTL design guidelines to enable the Hyper-Retimer to optimize design performance:

- Design in a way that facilitates register retiming by the Hyper-Retimer.
- Use a latency-insensitive design that supports the addition of pipeline stages at clock domain boundaries, top-level I/Os, and at the boundaries of functional blocks.
- Restructure RTL to avoid performance-limiting loops.

For more information about best design practices targeting Intel Stratix 10 devices, refer to the *Intel Stratix 10 High-Performance Design Handbook*.

Related Information

Intel® Hyperflex™ Architecture High-Performance Design Handbook

2.2.2. Optimizing Combinational Logic

Combinational logic structures consist of logic functions that depend only on the current state of the inputs. In Intel FPGAs, these functions are implemented in the look-up tables (LUTs) with either logic elements (LEs) or adaptive logic modules (ALMs).

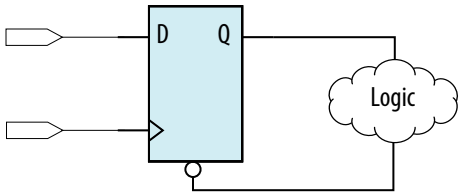
For cases where combinational logic feeds registers, the register control signals can implement part of the logic function to save LUT resources. By following the recommendations in this section, you can improve the reliability of your combinational design.

2.2.2.1. Avoid Combinational Loops

Combinational loops are among the most common causes of instability and unreliability in digital designs. Combinational loops generally violate synchronous design principles by establishing a direct feedback loop that contains no registers.

Avoid combinational loops whenever possible. In a synchronous design, feedback loops should include registers. For example, a combinational loop occurs when the left-hand side of an arithmetic expression also appears on the right-hand side in HDL code. A combinational loop also occurs when you feed back the output of a register to an asynchronous pin of the same register through combinational logic.

Figure 8. Combinational Loop Through Asynchronous Control Pin



Tip: Use recovery and removal analysis to perform timing analysis on asynchronous ports, such as `clear` or `reset` in the Intel Quartus Prime software.

Combinational loops are inherently high-risk design structures for the following reasons:

- Combinational loop behavior generally depends on relative propagation delays through the logic involved in the loop. As discussed, propagation delays can change, which means the behavior of the loop is unpredictable.
- In many design tools, combinational loops can cause endless computation loops . Most tools break open combinational loops to process the design. The various tools used in the design flow may open a given loop differently, and process it in a way inconsistent with the original design intent.

2.2.2.2. Avoid Unintended Latch Inference

Avoid using latches to ensure that you can completely analyze the timing performance and reliability of your design. A latch is a small circuit with combinational feedback that holds a value until a new value is assigned. You can implement latches with the Intel Quartus Prime Text Editor or Block Editor.

A common mistake in HDL code is unintended latch inference; Intel Quartus Prime Synthesis issues a warning message if this occurs. Unlike other technologies, a latch in FPGA architecture is not significantly smaller than a register. However, the architecture is not optimized for latch implementation and latches generally have slower timing performance compared to equivalent registered circuitry.

Latches have a transparent mode in which data flows continuously from input to output. A positive latch is in transparent mode when the enable signal is high (low for a negative latch). In transparent mode, glitches on the input can pass through to the output because of the direct path created. This presents significant complexity for timing analysis. Typical latch schemes use multiple enable phases to prevent long transparent paths from occurring. However, timing analysis cannot identify these safe applications.

The Timing Analyzer analyzes latches as synchronous elements clocked on the falling edge of the positive latch signal by default. It allows you to treat latches as having nontransparent start and end points. Be aware that even an instantaneous transition through transparent mode can lead to glitch propagation. The Timing Analyzer cannot perform cycle-borrowing analysis.

Due to various timing complexities, latches have limited support in formal verification tools. Therefore, you should not rely on formal verification for a design that includes latches.

Related Information

Avoid Unintentional Latch Generation on page 42

2.2.2.3. Avoid Delay Chains in Clock Paths

Delays in PLD designs can change with each placement and routing cycle. Effects such as rise and fall time differences and on-chip variation mean that delay chains, especially those placed on clock paths, can cause significant problems in your design. Avoid using delay chains to prevent these kinds of problems.

You require delay chains when you use two or more consecutive nodes with a single fan-in and a single fan-out to cause delay. Inverters are often chained together to add delay. Delay chains are sometimes used to resolve race conditions created by other asynchronous design practices.

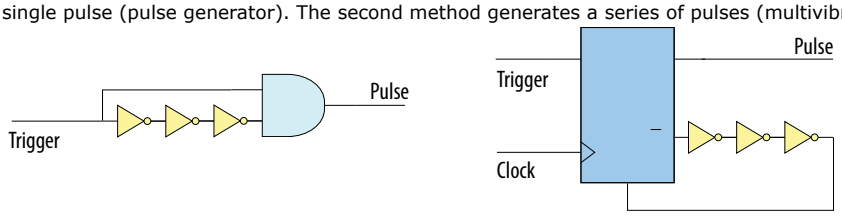
In some ASIC designs, delays are used for buffering signals as they are routed around the device. This functionality is not required in FPGA devices because the routing structure provides buffers throughout the device.

2.2.2.4. Use Synchronous Pulse Generators

Use synchronous techniques to design pulse generators.

Figure 9. Asynchronous Pulse Generators

The figure shows two methods for asynchronous pulse generation. The first method uses a delay chain to generate a single pulse (pulse generator). The second method generates a series of pulses (multivibrators).



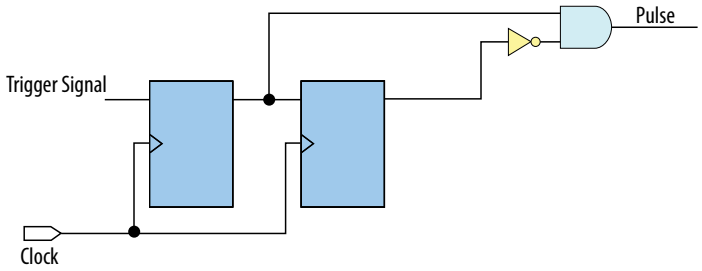
In the first method, a trigger signal feeds both inputs of a 2-input AND gate, and the design adds inverters to one of the inputs to create a delay chain. The width of the pulse depends on the time differences between the path that feeds the gate directly and the path that goes through the delay chain. This is the same mechanism responsible for the generation of glitches in combinational logic following a change of input values. This technique artificially increases the width of the glitch.

In the second method, a register's output drives its asynchronous reset signal through a delay chain. The register resets itself asynchronously after a certain delay. The Compiler can determine the pulse width only after placement and routing, when routing and propagation delays are known. You cannot reliably create a specific pulse

width when creating HDL code, and it cannot be set by EDA tools. The pulse may not be wide enough for the application under all PVT conditions. Also, the pulse width changes if you change to a different device. Additionally, verification is difficult because static timing analysis cannot verify the pulse width.

Multivibrators use a glitch generator to create pulses, together with a combinational loop that turns the circuit into an oscillator. This method creates additional problems because of the number of pulses involved. Additionally, when the structures generate multiple pulses, they also create a new artificial clock in the design that must be analyzed by design tools.

Figure 10. Recommended Synchronous Pulse-Generation Technique



The pulse width is always equal to the clock period. This pulse generator is predictable, can be verified with timing analysis, and is easily moved to other architectures, devices, or speed grades.

2.2.3. Optimizing Clocking Schemes

Like combinational logic, clocking schemes have a large effect on the performance and reliability of a design.

Intel recommends avoiding the use of internally generated clocks (other than PLLs) wherever possible because they can cause functional and timing problems in the design. If not carefully designed, clocks generated with or passing through combinational logic can introduce glitches that create functional problems, and the delay inherent in combinational logic can lead to timing problems. Refer to the sections listed below for information on some common scenarios of using combinational logic in a clock path (for example, clock mux) and design considerations to prevent unexpected failures.

Tip: Specify all clock relationships in the Intel Quartus Prime software to allow for the best timing-driven optimizations during fitting and to allow correct timing analysis. Use clock setting assignments on any derived or internal clocks to specify their relationship to the base clock.

Use global device-wide, low-skew dedicated routing for all internally-generated clocks, instead of routing clocks on regular routing lines.

Avoid data transfers between different clocks wherever possible. If you require a data transfer between different clocks, use FIFO circuitry. You can use the clock uncertainty features in the Intel Quartus Prime software to compensate for the variable delays between clock domains. Consider setting a clock setup uncertainty and clock hold uncertainty value of 10% to 15% of the clock delay.

The following sections provide specific examples and recommendations for avoiding clocking scheme problems:

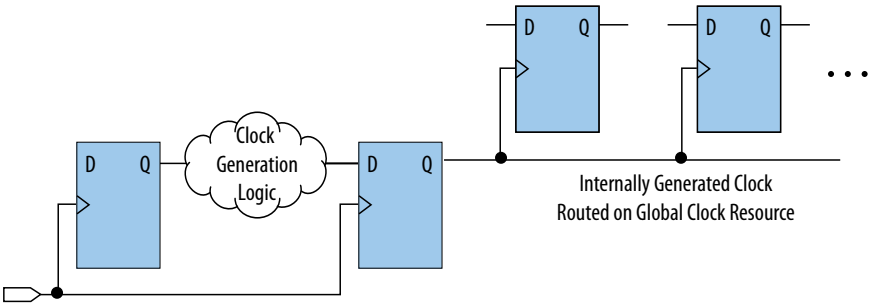
2.2.3.1. Register Combinational Logic Outputs

If you use the output from combinational logic as a clock signal or as an asynchronous reset signal, you can expect to see glitches in your design. In a synchronous design, glitches on data inputs of registers are normal events that have no consequences. However, a glitch or a spike on the clock input (or an asynchronous input) to a register can have significant consequences.

Narrow glitches can violate the register's minimum pulse width requirements. Setup and hold requirements might also be violated if the data input of the register changes when a glitch reaches the clock input. Even if the design does not violate timing requirements, the register output can change value unexpectedly and cause functional hazards elsewhere in the design.

To avoid these problems, you should always register the output of combinational logic before you use it as a clock signal.

Figure 11. Recommended Clock-Generation Technique



Registering the output of combinational logic ensures that glitches generated by the combinational logic are blocked at the data input of the register.

2.2.3.2. Avoid Asynchronous Clock Division

Designs often require clocks that you create by dividing a master clock. Most Intel FPGAs provide dedicated phase-locked loop (PLL) circuitry for clock division. Using dedicated PLL circuitry can help you avoid many of the problems that can be introduced by asynchronous clock division logic.

When you must use logic to divide a master clock, always use synchronous counters or state machines. Additionally, create your design so that registers always directly generate divided clock signals, and route the clock on global clock resources. To avoid glitches, do not decode the outputs of a counter or a state machine to generate clock signals.

2.2.3.3. Avoid Ripple Counters

To simplify verification, avoid ripple counters in your design. In the past, FPGA designers implemented ripple counters to divide clocks by a power of two because the counters are easy to design and may use fewer gates than their synchronous counterparts.

Ripple counters use cascaded registers, in which the output pin of one register feeds the clock pin of the register in the next stage. This cascading can cause problems because the counter creates a ripple clock at each stage. These ripple clocks must be handled properly during timing analysis, which can be difficult and may require you to make complicated timing assignments in your synthesis and placement and routing tools.

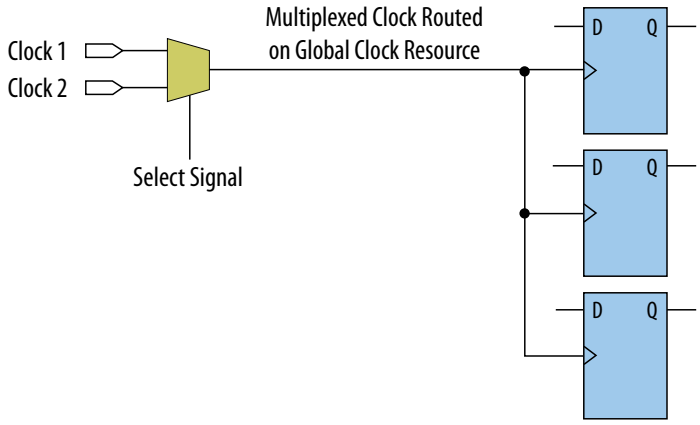
You can often use ripple clock structures to make ripple counters out of the smallest amount of logic possible. However, in all Intel devices supported by the Intel Quartus Prime software, using a ripple clock structure to reduce the amount of logic used for a counter is unnecessary because the device allows you to construct a counter using one logic element per counter bit. You should avoid using ripple counters completely.

2.2.3.4. Use Multiplexed Clocks

Use clock multiplexing to operate the same logic function with different clock sources. In these designs, multiplexing selects a clock source.

For example, telecommunications applications that deal with multiple frequency standards often use multiplexed clocks.

Figure 12. Multiplexing Logic and Clock Sources



Adding multiplexing logic to the clock signal can create the problems addressed in the previous sections, but requirements for multiplexed clocks vary widely, depending on the application. Clock multiplexing is acceptable when the clock signal uses global clock routing resources and if the following criteria are met:

- The clock multiplexing logic does not change after initial configuration
- The design uses multiplexing logic to select a clock for testing purposes
- Registers are always reset when the clock switches
- A temporarily incorrect response following clock switching has no negative consequences

If the design switches clocks in real time with no reset signal, and your design cannot tolerate a temporarily incorrect response, you must use a synchronous design so that there are no timing violations on the registers, no glitches on clock signals, and no race conditions or other logical problems. By default, the Intel Quartus Prime software optimizes and analyzes all possible paths through the multiplexer and between both internal clocks that may come from the multiplexer. This may lead to more restrictive

analysis than required if the multiplexer is always selecting one particular clock. If you do not require the more complete analysis, you can assign the output of the multiplexer as a base clock in the Intel Quartus Prime software, so that all register-to-register paths are analyzed using that clock.

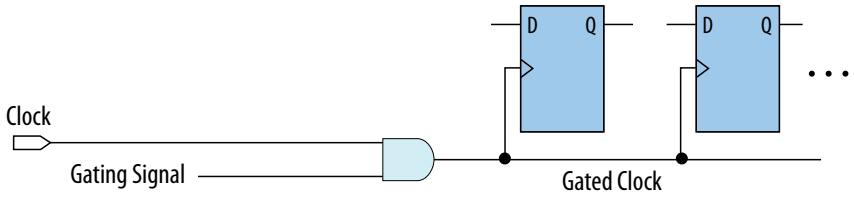
Tip: Use dedicated hardware to perform clock multiplexing when it is available, instead of using multiplexing logic. For example, you can use the clock-switchover feature or clock control block available in certain Intel FPGA devices. These dedicated hardware blocks ensure that you use global low-skew routing lines and avoid any possible hold time problems on the device due to logic delay on the clock line.

Note: For device-specific information about clocking structures, refer to the appropriate device data sheet or handbook.

2.2.3.5. Use Gated Clocks

Gated clocks turn a clock signal on and off using an enable signal that controls gating circuitry. When a clock is turned off, the corresponding clock domain is shut down and becomes functionally inactive.

Figure 13. Gated Clock



You can use gated clocks to reduce power consumption in some device architectures by effectively shutting down portions of a digital circuit when they are not in use. When a clock is gated, both the clock network and the registers driven by it stop toggling, thereby eliminating their contributions to power consumption. However, gated clocks are not part of a synchronous scheme and therefore can significantly increase the effort required for design implementation and verification. Gated clocks contribute to clock skew and make device migration difficult. These clocks are also sensitive to glitches, which can cause design failure.

Use dedicated hardware to perform clock gating rather than an AND or OR gate. For example, you can use the clock control block in newer Intel FPGA devices to shut down an entire clock network. Dedicated hardware blocks ensure that you use global routing with low skew, and avoid any possible hold time problems on the device due to logic delay on the clock line.

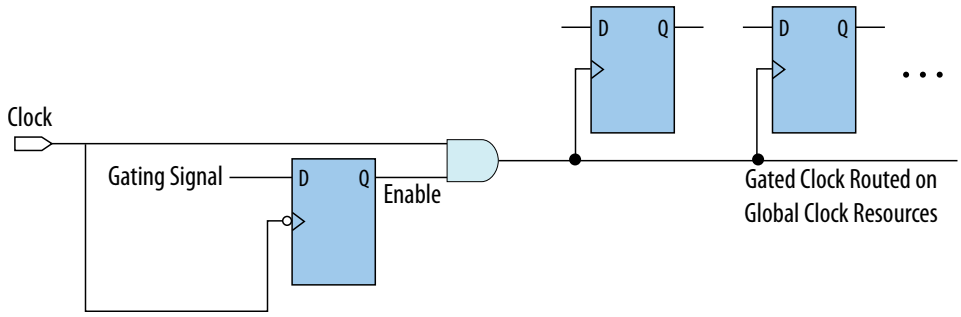
From a functional point of view, you can shut down a clock domain in a purely synchronous manner using a synchronous clock enable signal. However, when using a synchronous clock enable scheme, the clock network continues toggling. This practice does not reduce power consumption as much as gating the clock at the source does. In most cases, use a synchronous scheme.

2.2.3.5.1. Recommended Clock-Gating Methods

Use gated clocks only when your target application requires power reduction and gated clocks provide the required reduction in your device architecture. If you must use clocks gated by logic, follow a robust clock-gating methodology and ensure the gated clock signal uses dedicated global clock routing.

You can gate a clock signal at the source of the clock network, at each register, or somewhere in between. Since the clock network contributes to switching power consumption, gate the clock at the source whenever possible to shut down the entire clock network instead of further along.

Figure 14. Recommended Clock-Gating Technique for Clock Active on Rising Edge



To generate a gated clock with the recommended technique, use a register that triggers on the inactive edge of the clock. With this configuration, only one input of the gate changes at a time, preventing glitches or spikes on the output. If the clock is active on the rising edge, use an AND gate. Conversely, for a clock that is active on the falling edge, use an OR gate to gate the clock and register

Pay attention to the delay through the logic generating the enable signal, because the enable command must be ready in less than one-half the clock cycle. This might cause problems if the logic that generates the enable command is particularly complex, or if the duty cycle of the clock is severely unbalanced. However, careful management of the duty cycle and logic delay may be an acceptable solution when compared with problems created by other methods of gating clocks.

In the Timing Analyzer, ensure to apply a clock setting to the output of the AND gate. Otherwise, the timing analyzer might analyze the circuit using the clock path through the register as the longest clock path and the path that skips the register as the shortest clock path, resulting in artificial clock skew.

In certain cases, converting the gated clocks to clock enable pins may help reduce glitch and clock skew, and eventually produce a more accurate timing analysis. You can set the Intel Quartus Prime software to automatically convert gated clocks to clock enable pins by turning on the **Auto Gated Clock Conversion** option. The conversion applies to two types of gated clocking schemes: single-gated clock and cascaded-gated clock.

Related Information

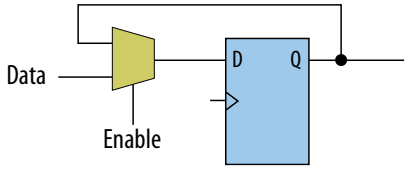
Auto Gated Clock Conversion logic option
In *Intel Quartus Prime Help*

2.2.3.6. Use Synchronous Clock Enables

To turn off a clock domain in a synchronous manner, use a synchronous clock enable signal. FPGAs efficiently support clock enable signals because there is a dedicated clock enable signal available on all device registers.

This scheme does not reduce power consumption as much as gating the clock at the source because the clock network keeps toggling, and performs the same function as a gated clock by disabling a set of registers. Insert a multiplexer in front of the data input of every register to either load new data, or copy the output of the register.

Figure 15. Synchronous Clock Enable



When designing for Intel Stratix 10 devices, consider that high fan-out clock enable signals can limit the performance achievable by the Hyper- Retimer. For specific recommendations, refer to the *Intel Stratix 10 High-Performance Design Handbook*.

Intel® Hyperflex™ Architecture High-Performance Design Handbook

2.2.4. Optimizing Physical Implementation and Timing Closure

This section provides design and timing closure techniques for high speed or complex core logic designs with challenging timing requirements. These techniques may also be helpful for low or medium speed designs.

2.2.4.1. Planning Physical Implementation

When planning a design, consider the following elements of physical implementation:

- The number of unique clock domains and their relationships
- The amount of logic in each functional block
- The location and direction of data flow between blocks
- How data routes to the functional blocks between I/O interfaces

Interface-wide control or status signals may have competing or opposing constraints. For example, when a functional block's control or status signals interface with physical channels from both sides of the device. In such cases you must provide enough pipeline register stages to allow these signals to traverse the width of the device. In addition, you can structure the hierarchy of the design into separate logic modules for each side of the device. The side modules can generate and use registered control signals per side. This simplifies floorplanning, particularly in designs with transceivers, by placing per-side logic near the transceivers.

When adding register stages to pipeline control signals, turn off **Auto Shift Register Replacement** in the **Assignment Editor** (**Assignments ➤ Assignment Editor**) for each register as needed. By default, chains of registers can be converted to a RAM-based implementation based on performance and resource estimates. Since pipelining helps meet timing requirements over long distance, this assignment ensures that control signals are not converted.

2.2.4.2. Planning FPGA Resources

Your design requirements impact the use of FPGA resources. Plan functional blocks with appropriate global, regional, and dual-regional network signals in mind.

In general, after allocating the clocks in a design, use global networks for the highest fan-out control signals. When a global network signal distributes a high fan-out control signal, the global signal can drive logic anywhere in the device. Similarly, when using a regional network signal, the driven logic must be in one quadrant of the device, or half the device for a dual-regional network signal. Depending on data flow and physical locations of the data entry and exit between the I/Os and the device, restricting a functional block to a quadrant or half the device may not be practical for performance or resource requirements.

When floorplanning a design, consider the balance of different types of device resources, such as memory, logic, and DSP blocks in the main functional blocks. For example, if a design is memory intensive with a small amount of logic, it may be difficult to develop an effective floorplan. Logic that interfaces with the memory would have to spread across the chip to access the memory. In this case, it is important to use enough register stages in the data and control paths to allow signals to traverse the chip to access the physically disparate resources needed.

2.2.4.3. Optimizing for Timing Closure

To achieve timing closure for your design, you can enable compilation settings in the Intel Quartus Prime software, or you can directly modify your timing constraints.

Compilation Settings for Timing Closure

Note: Changes in project settings can significantly increase compilation time. You can view the performance gain versus runtime cost by reviewing the Fitter messages after design processing.

Table 3. Compilation Settings that Impact Timing Closure

Setting	Location	Effect on Timing Closure
Allow Register Duplication	**Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**	This technique is most useful where registers have high fan-out, or where the fan-out is in physically distant areas of the device. Review the netlist optimizations report and consider manually duplicating registers automatically added by physical synthesis. You can also locate the original and duplicate registers in the Chip Planner. Compare their locations, and if the fan-out is improved, modify the code and turn off register duplication to save compile time.
Prevent Register Retiming	**Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**	Useful if some combinatorial paths between registers exceed the timing goal while other paths fall short. If a design is already heavily pipelined, register retiming is less likely to provide significant performance gains, since there should not be significantly unbalanced levels of logic across pipeline stages.

Guidelines for Optimizing Timing Closure using Timing Constraints

Appropriate timing constraints are essential to achieving timing closure. Use the following general guidelines in applying timing constraints:

- Apply multicycle constraints in your design wherever single-cycle timing analysis is not necessary.
- Apply False Path constraints to all asynchronous clock domain crossings or resets in the design. This technique prevents overconstraining and the Fitter focuses only on critical paths to reduce compile time. However, overconstraining timing critical clock domains can sometimes provide better timing results and lower compile times than physical synthesis.
- Overconstrain rather than using physical synthesis when the slack improvement from physical synthesis is near zero. Overconstrain the frequency requirement on timing critical clock domains by using setup uncertainty.
- When evaluating the effect of constraint changes on performance and runtime, compile the design with at least three different seeds to determine the average performance and runtime effects. Different constraint combinations produce various results. Three samples or more establish a performance trend. Modify your constraints based on performance improvement or decline.
- Leave settings at the default value whenever possible. Increasing performance constraints can increase the compile time significantly. While those increases may be necessary to close timing on a design, using the default settings whenever possible minimizes compile time.

Related Information

Intel Quartus Prime Pro Edition User Guide: Design Optimization

2.2.4.4. Optimizing Critical Timing Paths

To close timing in high speed designs, review paths with the largest timing failures. Correcting a single, large timing failure can result in a very significant timing improvement.

Review the register placement and routing paths by clicking **Tools ➤ Chip Planner**. Large timing failures on high fan-out control signals can be caused by any of the following conditions:

- Sub-optimal use of global networks
- Signals that traverse the chip on local routing without pipelining
- Failure to correct high fan-out by register duplication

For high-speed and high-bandwidth designs, optimize speed by reducing bus width and wire usage. To reduce wire usage, move the data as little as possible. For example, if a block of logic functions on a few bits of a word, store inactive bits in a FIFO or memory. Memory is cheaper and denser than registers, and reduces wire usage.

Related Information

Intel Quartus Prime Pro Edition User Guide: Design Optimization

2.2.5. Optimizing Power Consumption

The total FPGA power consumption is comprised of I/O power, core static power, and core dynamic power. Knowledge of the relationship between these components is fundamental in calculating the overall total power consumption.

You can use various optimization techniques and tools to minimize power consumption when applied during FPGA design implementation. The Intel Quartus Prime software offers power-driven compilation features to fully optimize device power consumption. Power-driven compilation focuses on reducing your design's total power consumption using power-driven synthesis and power-driven placement and routing.

2.2.6. Managing Design Metastability

In FPGA designs, synchronization of asynchronous signals can cause metastability. You can use the Intel Quartus Prime software to analyze the mean time between failures (MTBF) due to metastability. A high metastability MTBF indicates a more robust design.

Related Information

2.3. Use Clock and Register-Control Architectural Features

In addition to following general design guidelines, you must code your design with the device architecture in mind. FPGAs provide device-wide clocks and register control signals that can improve performance.

2.3.1. Use Global Reset Resources

ASIC designs may use local resets to avoid long routing delays. Take advantage of the device-wide asynchronous reset pin available on most FPGAs to eliminate these problems. This reset signal provides low-skew routing across the device.

The following are three types of resets used in synchronous circuits:

- Synchronous Reset
- Asynchronous Reset
- Synchronized Asynchronous Reset—preferred when designing an FPGA circuit

2.3.1.1. Use Synchronous Resets

The synchronous reset ensures that the circuit is fully synchronous. You can easily time the circuit with the Intel Quartus Prime Timing Analyzer.

Because clocks that are synchronous to each other launch and latch the reset signal, the data arrival and data required times are easily determined for proper slack analysis. The synchronous reset is easier to use with cycle-based simulators.

There are two methods by which a reset signal can reach a register; either by being gated in with the data input, or by using an LAB-wide control signal (`synclr`). If you use the first method, you risk adding an additional gate delay to the circuit to accommodate the reset signal, which causes increased data arrival times and negatively impacts setup slack. The second method relies on dedicated routing in the LAB to each register, but this is slower than an asynchronous reset to the same register.

Figure 16. Synchronous Reset

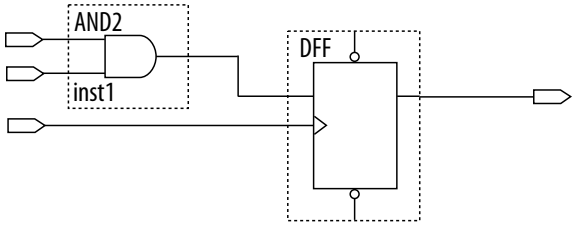

Figure 17. LAB-Wide Control Signals

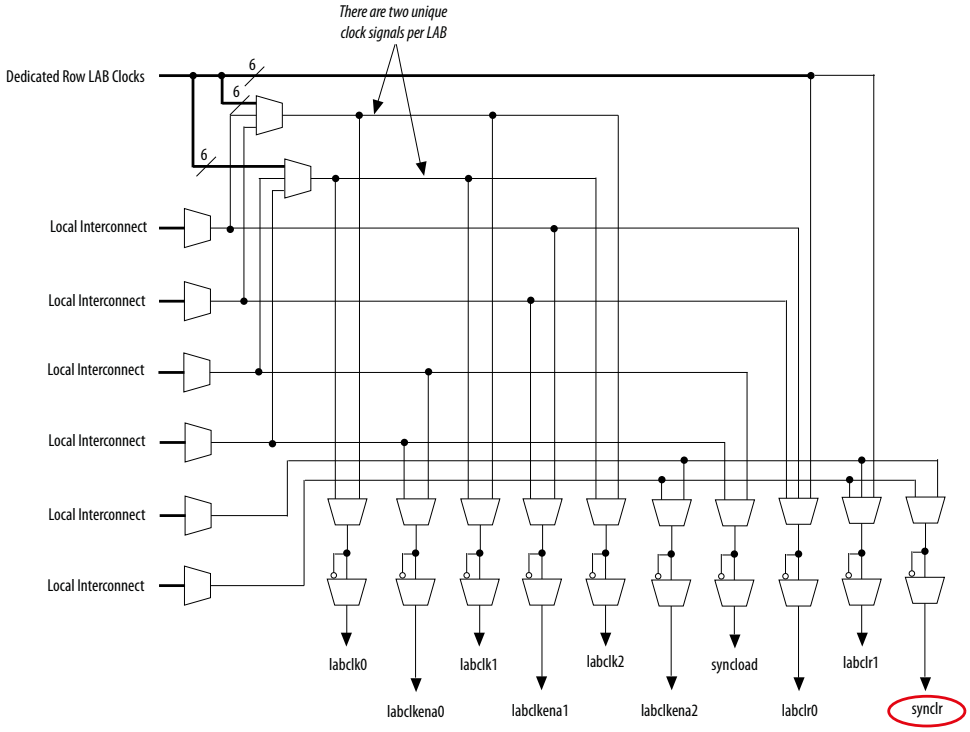
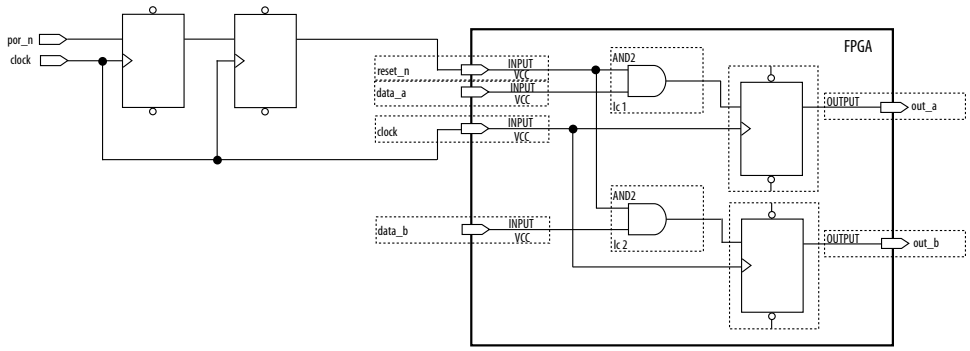


Consider two types of synchronous resets when you examine the timing analysis of synchronous resets—externally synchronized resets and internally synchronized resets. Externally synchronized resets are synchronized to the clock domain outside the FPGA, and are not very common. A power-on asynchronous reset is dual-rank synchronized externally to the system clock and then brought into the FPGA. Inside the FPGA, gate this reset with the data input to the registers to implement a synchronous reset.

Figure 18. Externally Synchronized Reset



The following example shows the Verilog HDL equivalent of the schematic. When you use synchronous resets, the reset signal is not put in the sensitivity list.

The following example shows the necessary modifications that you should make to the internally synchronized reset.

Example 56. Verilog HDL Code for Externally Synchronized Reset

```
module sync_reset_ext (
         input   clock,
         input   reset_n,
         input   data_a,
         input   data_b,
         output  out_a,
         output  out_b
         );
reg      reg1, reg2
assign   out_a  = reg1;
assign   out_b  = reg2;
always @ (posedge clock)
begin
     if (!reset_n)
     begin
         reg1     <= 1'b0;
         reg2     <= 1'b0;
    end
    else
    begin
         reg1     <= data_a;
         reg2     <= data_b;
    end
end
endmodule     //  sync_reset_ext
```

The following example shows the constraints for the externally synchronous reset. Because the external reset is synchronous, you only need to constrain the `reset_n` signal as a normal input signal with `set_input_delay` constraint for `-max` and `-min`.

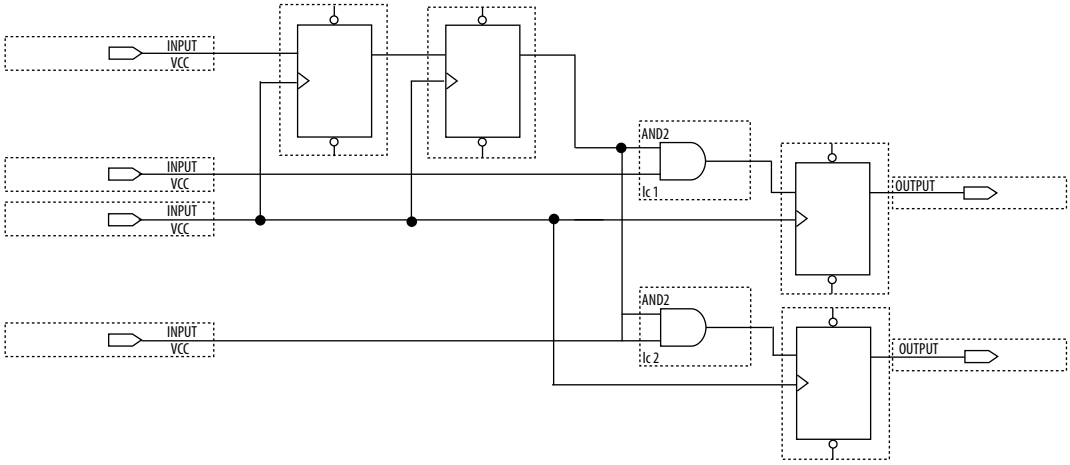
Example 57. SDC Constraints for Externally Synchronized Reset

```
# Input clock - 100 MHz
create_clock [get_ports {clock}] \
        -name {clock} \
        -period 10.0 \
```

```
        -waveform {0.0 5.0}
# Input constraints on low-active reset
# and data
set_input_delay 7.0 \
        -max \
        -clock [get_clocks {clock}] \
        [get_ports {reset_n data_a data_b}]
set_input_delay 1.0 \
        -min \
        -clock [get_clocks {clock}] \
        [get_ports {reset_n data_a data_b}]
```

More often, resets coming into the device are asynchronous, and must be synchronized internally before being sent to the registers.

Figure 19. Internally Synchronized Reset



The following example shows the Verilog HDL equivalent of the schematic. Only the clock edge is in the sensitivity list for a synchronous reset.

Example 58. Verilog HDL Code for Internally Synchronized Reset

```
module sync_reset (
        input clock,
        input reset_n,
        input data_a,
        input data_b,
        output out_a,
        output out_b
        );
reg     reg1, reg2
reg     reg3, reg4

assign     out_a = reg1;
assign     out_b = reg2;
assign     rst_n = reg4;

always @ (posedge clock)
begin
    if (!rst_n)
    begin
        reg1 <= 1'bo;
        reg2 <= 1'b0;
    end
    else
    begin
```

```
        reg1 <= data_a;
        reg2 <= data_b;
    end
end

always @ (posedge clock)
begin
    reg3 <= reset_n;
    reg4 <= reg3;
end
endmodule // sync_reset
```

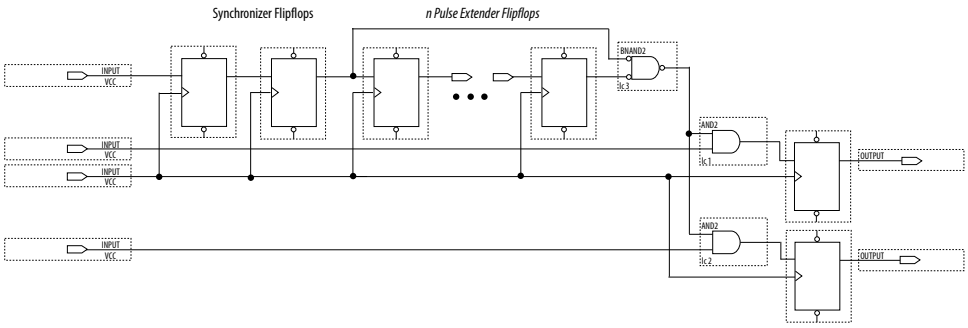
The SDC constraints are similar to the external synchronous reset, except that the input reset cannot be constrained because it is asynchronous. Cut the input path with a `set_false_path` statement to avoid these being considered as unconstrained paths.

Example 59. SDC Constraints for Internally Synchronized Reset

```
# Input clock - 100 MHz
create_clock [get_ports {clock}] \
        -name {clock} \
        -period 10.0 \
        -waveform {0.0 5.0}
# Input constraints on data
set_input_delay 7.0 \
        -max \
        -clock [get_clocks {clock}] \
        [get_ports {data_a data_b}]
set_input_delay 1.0 \
        -min \
        -clock [get_clocks {clock}] \
        [get_ports {data_a data_b}]
# Cut the asynchronous reset input
set_false_path \
        -from [get_ports {reset_n}] \
        -to [all_registers]
```

An issue with synchronous resets is their behavior with respect to short pulses (less than a period) on the asynchronous input to the synchronizer flipflops. This can be a disadvantage because the asynchronous reset requires a pulse width of at least one period wide to guarantee that it is captured by the first flipflop. However, this can also be viewed as an advantage in that this circuit increases noise immunity. Spurious pulses on the asynchronous input have a lower chance of being captured by the first flipflop, so the pulses do not trigger a synchronous reset. In some cases, you might want to increase the noise immunity further and reject any asynchronous input reset that is less than n periods wide to debounce an asynchronous input reset.

Figure 20. Internally Synchronized Reset with Pulse Extender



Junction dots indicate the number of stages. You can have more flipflops to get a wider pulse that spans more clock cycles.

Many designs have more than one clock signal. In these cases, use a separate reset synchronization circuit for each clock domain in the design. When you create synchronizers for PLL output clocks, these clock domains are not reset until you lock the PLL and the PLL output clocks are stable. If you use the reset to the PLL, this reset does not have to be synchronous with the input clock of the PLL. You can use an asynchronous reset for this. Using a reset to the PLL further delays the assertion of a synchronous reset to the PLL output clock domains when using internally synchronized resets.

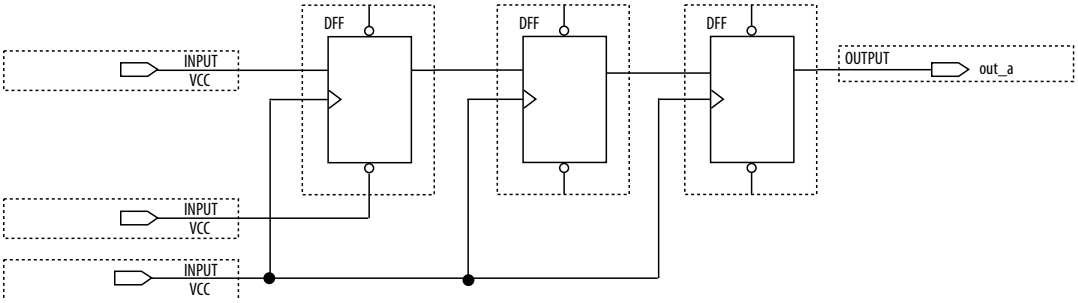
2.3.1.2. Using Asynchronous Resets

Asynchronous resets are the most common form of reset in circuit designs, as well as the easiest to implement. Typically, you can insert the asynchronous reset into the device, turn on the global buffer, and connect to the asynchronous reset pin of every register in the device.

This method is only advantageous under certain circumstances—you do not need to always reset the register. Unlike the synchronous reset, the asynchronous reset is not inserted in the datapath, and does not negatively impact the data arrival times between registers. Reset takes effect immediately, and as soon as the registers receive the reset pulse, the registers are reset. The asynchronous reset is not dependent on the clock.

However, when the reset is deasserted and does not pass the recovery (μt_{SU}) or removal (μt_H) time check (the Timing Analyzer recovery and removal analysis checks both times), the edge is said to have fallen into the metastability zone. Additional time is required to determine the correct state, and the delay can cause the setup time to fail to register downstream, leading to system failure. To avoid this, add a few follower registers after the register with the asynchronous reset and use the output of these registers in the design. Use the follower registers to synchronize the data to the clock to remove the metastability issues. You should place these registers close to each other in the device to keep the routing delays to a minimum, which decreases data arrival times and increases MTBF. Ensure that these follower registers themselves are not reset, but are initialized over a period of several clock cycles by “flushing out” their current or initial state.

Figure 21. Asynchronous Reset with Follower Registers



The following example shows the equivalent Verilog HDL code. The active edge of the reset is now in the sensitivity list for the procedural block, which infers a clock enable on the follower registers with the inverse of the reset signal tied to the clock enable. The follower registers should be in a separate procedural block as shown using non-blocking assignments.

Example 60. Verilog HDL Code of Asynchronous Reset with Follower Registers

```
module async_reset (
        input   clock,
        input   reset_n,
        input   data_a,
        output   out_a,
        );
reg     reg1, reg2, reg3;
assign  out_a  = reg3;
always @ (posedge clock, negedge reset_n)
begin
    if (!reset_n)
        reg1    <= 1'b0;
    else
        reg1    <= data_a;
end
always @ (posedge clock)
begin
    reg2    <= reg1;
    reg3    <= reg2;
end
endmodule  //  async_reset
```

You can easily constrain an asynchronous reset. By definition, asynchronous resets have a non-deterministic relationship to the clock domains of the registers they are resetting. Therefore, static timing analysis of these resets is not possible and you can use the `set_false_path` command to exclude the path from timing analysis. Because the relationship of the reset to the clock at the register is not known, you cannot run recovery and removal analysis in the Timing Analyzer for this path. Attempting to do so even without the false path statement results in no paths reported for recovery and removal.

Example 61. SDC Constraints for Asynchronous Reset

```
# Input clock - 100 MHz
create_clock [get_ports {clock}] \
        -name {clock} \
        -period 10.0 \
        -waveform {0.0 5.0}
```

```
# Input constraints on data
set_input_delay 7.0 \
        -max \
        -clock [get_clocks {clock}]\
        [get_ports {data_a}]
set_input_delay 1.0 \
        -min \
        -clock [get_clocks {clock}] \
        [get_ports {data_a}]
# Cut the asynchronous reset input
set_false_path \
        -from [get_ports {reset_n}] \
        -to [all_registers]
```

The asynchronous reset is susceptible to noise, and a noisy asynchronous reset can cause a spurious reset. You must ensure that the asynchronous reset is debounced and filtered. You can easily enter into a reset asynchronously, but releasing a reset asynchronously can lead to potential problems (also referred to as "reset removal") with metastability, including the hazards of unwanted situations with synchronous circuits involving feedback.

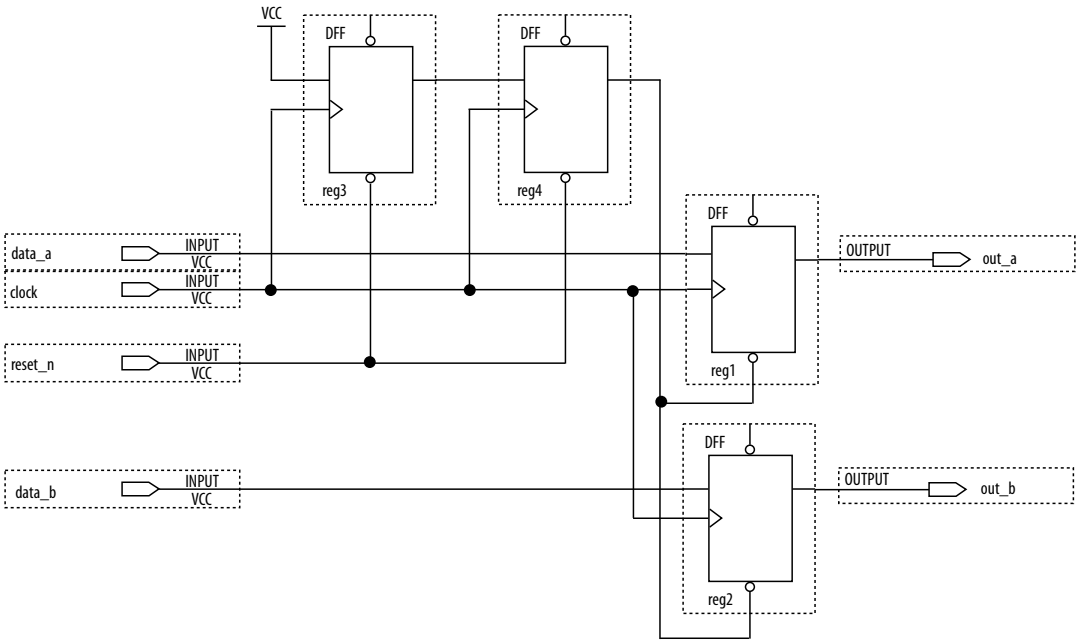
2.3.1.3. Use Synchronized Asynchronous Reset

To avoid potential problems associated with purely synchronous resets and purely asynchronous resets, you can use synchronized asynchronous resets. Synchronized asynchronous resets combine the advantages of synchronous and asynchronous resets.

These resets are asynchronously asserted and synchronously deasserted. This takes effect almost instantaneously, and ensures that no datapath for speed is involved. Also, the circuit is synchronous for timing analysis and is resistant to noise.

The following example shows a method for implementing the synchronized asynchronous reset. You should use synchronizer registers in a similar manner as synchronous resets. However, the asynchronous reset input is gated directly to the CLRN pin of the synchronizer registers and immediately asserts the resulting reset. When the reset is deasserted, logic "1" is clocked through the synchronizers to synchronously deassert the resulting reset.

Figure 22. Schematic of Synchronized Asynchronous Reset



The following example shows the equivalent Verilog HDL code. Use the active edge of the reset in the sensitivity list for the blocks.

Example 62. Verilog HDL Code for Synchronized Asynchronous Reset

```
module sync_async_reset (
        input    clock,
        input    reset_n,
        input    data_a,
        input    data_b,
        output   out_a,
        output   out_b
        );
reg     reg1, reg2;
reg     reg3, reg4;
assign  out_a    = reg1;
assign  out_b    = reg2;
assign  rst_n    = reg4;
always @ (posedge clock, negedge reset_n)
begin
    if (!reset_n)
    begin
       reg3     <= 1'b0;
       reg4     <= 1'b0;
    end
    else
    begin
       reg3     <= 1'b1;
       reg4     <= reg3;
    end
end
always @ (posedge clock, negedge rst_n)
begin
    if (!rst_n)
    begin
       reg1     <= 1'b0;
       reg2     <= 1;b0;
```

```
    end
    else
    begin
       reg1     <= data_a;
       reg2     <= data_b;
    end
end
endmodule  // sync_async_reset
```

To minimize the metastability effect between the two synchronization registers, and to increase the MTBF, the registers should be located as close as possible in the device to minimize routing delay. If possible, locate the registers in the same logic array block (LAB). The input reset signal (`reset_n`) must be excluded with a `set_false_path` command:

```
set_false_path -from [get_ports {reset_n}] -to [all_registers]
```

The `set_false_path` command used with the specified constraint excludes unnecessary input timing reports that would otherwise result from specifying an input delay on the reset pin.

The instantaneous assertion of synchronized asynchronous resets is susceptible to noise and runt pulses. If possible, you should debounce the asynchronous reset and filter the reset before it enters the device. The circuit ensures that the synchronized asynchronous reset is at least one full clock period in length. To extend this time to *n* clock periods, you must increase the number of synchronizer registers to *n* + 1. You must connect the asynchronous input reset (`reset_n`) to the CLRN pin of all the synchronizer registers to maintain the asynchronous assertion of the synchronized asynchronous reset.

2.3.2. Use Global Clock Network Resources

Intel FPGAs provide device-wide global clock routing resources and dedicated inputs. Use the FPGA's low-skew, high fan-out dedicated routing where available.

By assigning a clock input to one of these dedicated clock pins or with an Intel Quartus Prime assignment to assign global routing, you can take advantage of the dedicated routing available for clock signals.

In an ASIC design, you must balance the clock delay distributed across the device. Because Intel FPGAs provide device-wide global clock routing resources and dedicated inputs, there is no need to manually balance delays on the clock network.

Limit the number of clocks in the design to the number of dedicated global clock resources available in the FPGA. Clocks feeding multiple locations that do not use global routing may exhibit clock skew across the device leading to timing problems. In addition, generating internal clocks with combinational logic adds delays on the clock path. Delay on a clock line can result in a clock skew greater than the data path length between two registers. If the clock skew is greater than the data delay, you violate the timing parameters of the register (such as hold time requirements) and the design does not function correctly.

FPGAs offer low-skew global routing resources to distribute high fan-out signals. These resources help with the implementation of large designs with multiple clock domains. Many large FPGA devices provide dedicated global clock networks, regional clock networks, and dedicated fast regional clock networks. These clocks are organized into a hierarchical clock structure that allows multiple clocks in each device region with low

skew and delay. There are typically several dedicated clock pins to drive either global or regional clock networks, and both PLL outputs and internal clocks can drive various clock networks.

Intel Stratix 10 devices have a newer architecture. You can configure Intel Stratix 10 clocking resources to create efficiently balanced clock trees of various sizes, ranging from a single clock sector to the entire device. By default, the Intel Quartus Prime Software automatically determines the size and location of the clock tree. Alternatively, you can directly constrain the clock tree size and location either with a Clock Region assignment or by Logic Lock Regions.

To reduce clock skew in a given clock domain and ensure that hold times are met in that clock domain, assign each clock signal to one of the global high fan-out, low-skew clock networks in the FPGA device. The Intel Quartus Prime software automatically assigns global routing resources for high fan-out control signals, PLL outputs, and signals feeding the global clock pins on the device. To direct the software to assign global routing for a signal, turn on the **Global Signal** option in the Assignment Editor.

Note: Global Signal assignments only controls whether a signal is promoted using the specified dedicated resources or not, but does not control which or how many resources are used.

To take full advantage of the routing resources in a design, make sure that the sources of clock signals (input clock pins or internally-generated clocks) drive only the clock input ports of registers. In older Intel device families, if a clock signal feeds the data ports of a register, the signal may not be able to use dedicated routing, which can lead to decreased performance and clock skew problems. In general, allowing clock signals to drive the data ports of registers is not considered synchronous design and can complicate timing closure.

2.3.3. Use Clock Region Assignments to Optimize Clock Constraints

The Intel Quartus Prime software determines how clock regions are assigned. You can override these assignments with Clock Region assignments to specify that a signal routed with global routing paths must use the specified clock region.

Clock Region assignments allow you to control the placement of the clock region for floorplanning reasons. For example, use a Clock Region assignment to ensure that a certain area of the device has access to a global signal, throughout your design iterations. A Clock Region assignment can also be used in cases of congestion involving global signal resources. By specifying a smaller clock region size, the assignment prevents a signal using spine clock resources in the excluded sectors that may be encountering clock-related congestion.

You can specify Clock Region assignments in the assignment editor.

2.3.3.1. Clock Region Assignments in Intel Stratix 10 Devices

In Intel Stratix 10 devices, clock networks are constructed using programmable clock routing. As with other Intel device families, you can use Clock Region assignments for floorplanning, controlling the size and location of each clock tree.

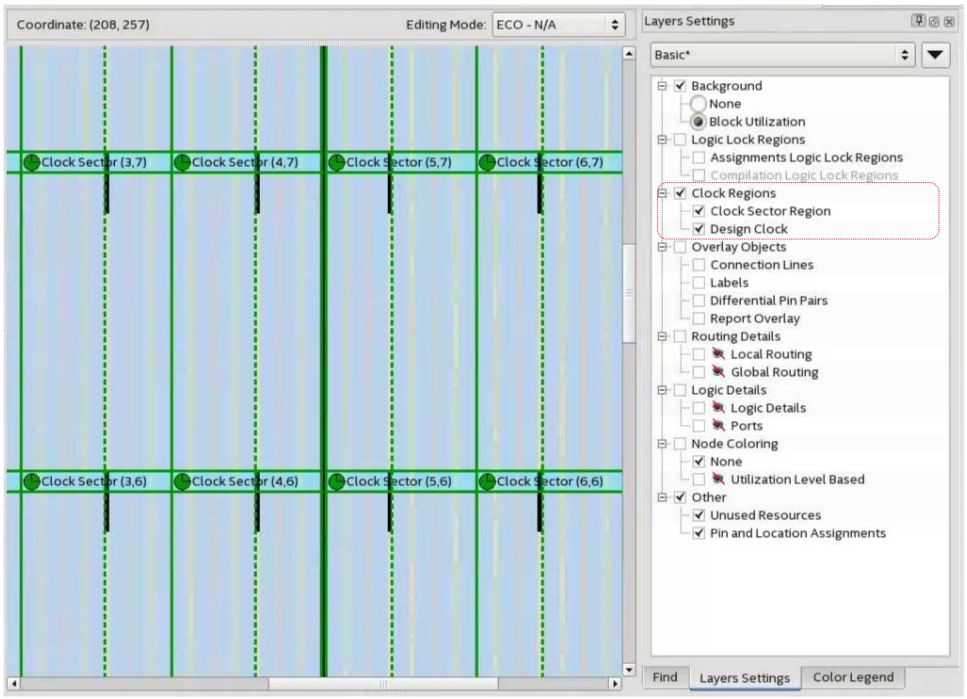
Although the Intel Quartus Prime Pro Edition software generates balanced clock trees, there are sources of timing variation, such as process variation and jitter, which prevents clock trees from being perfectly skew balanced. Longer paths, with higher insertion delay, have more timing variation. However, the Timing Analyzer can account

for and eliminate some sources of variation in timing along common clock paths. In practice, this means that the size of the clock region has a significant impact on the worst-case skew of the clock tree; a larger clock tree experiences higher insertion delay and worst-case clock skew when compared to a smaller clock region. The distance between the clock region and the clock source also increases insertion delay, but the impact of distance on worst-case clock skew is much smaller than the impact of the size of the clock region.

One case to consider is when a design contains high-speed clock domains that are expected to grow during the design process. Specifying a clock region constraint to create a larger clock region than the compiler generates automatically helps ensure that timing closure is robust with higher clock insertion delays and clock skews.

An additional design consideration is the minimum pulse width constraint on clock signals. For a clock signal to propagate correctly on the Intel Stratix 10 clock network, a minimum delay must be met between the rising edge and falling edge of the clock pulse. If the Timing Analyzer cannot guarantee that this constraint is met, the clock signal may not propagate as expected under all operating conditions. This can happen when the delay variation on a clock path becomes too great. This situation does not normally occur, but may arise if clock signals are routed through core logic elements or core routing resources.

In designs that target Intel Stratix 10 devices, clock regions can be constrained to a rectangle whose dimensions are defined by the sector grid, as seen in the Clock Sector Region layer of the Chip Planner.



This assignment specifies the bottom left and top right coordinates of the rectangle in the format "SX# SY# SX# SY#". For example, "SX0 SY0 SX1 SY1" constrains the clock to a 2x2 region, from the bottom left of sector (0,0) to the top right of sector (1,1). For a constraint spanning only one sector, it is sufficient to specify the location of that sector, for example "SX1 SY1". The bounding rectangle can also be specified

by the bottom left and top right corners in chip coordinates, for example, "X37 Y181 X273 Y324". However, such a constraint should be sector aligned (using sector coordinates guarantees this) or the Fitter automatically snaps to the smallest sector aligned rectangle that still encompasses the original assignment. The "SX# SY# SX# SY#"|"X# Y# X# Y#" strings are case-insensitive.

2.3.3.2. Clock Region Assignments in Intel Arria 10 and Older Device Families

In device families with dedicated clock network resources and predefined clock regions, this assignment takes as its value the names of those Global, Regional, Periphery or Spine Clock regions. These region names are visible in Chip Planner by enabling the appropriate Clock Region layer in the **Layers Settings** dialog box. Examples of valid values include `Regional Clock Region 1` or `Periphery Clock Region 1`.

When constraining a global signal to a smaller than normal region, for example, to avoid clock congestion, you may specify a clock region of a different type than the global resources being used. For example, a signal with a Global Signal assignment of `Global Clock`, but a Clock Region assignment of `Regional Clock Region 0`, constrains the clock to use global network routing resources, but only to the region covered by `Regional Clock Region 0`. To provide a finer level of control, you can also list multiple smaller clock regions, separated by commas. For example: `Periphery Clock Region 0, Periphery Clock Region 1` constrains a signal to only the area reachable by those two periphery clock networks.

2.3.4. Avoid Asynchronous Register Control Signals

Avoid using an asynchronous load signal if the design target device architecture does not include registers with dedicated circuitry for asynchronous loads. Also, avoid using both asynchronous clear and preset if the architecture provides only one of these control signals.

Some Intel devices directly support an asynchronous clear function, but not a preset or load function. When the target device does not directly support the signals, the synthesis or placement and routing software must use combinational logic to implement the same functionality. In addition, if you use signals in a priority other than the inherent priority in the device architecture, combinational logic may be required to implement the necessary control signals. Combinational logic is less efficient and can cause glitches and other problems; it is best to avoid these implementations.

2.4. Implementing Embedded RAM

Intel's dedicated memory architecture offers many advanced features that you can enable with Intel-provided IP cores. Use synchronous memory blocks for your design, so that the blocks can be mapped directly into the device dedicated memory blocks.

You can use single-port, dual-port, or three-port RAM with a single- or dual-clocking method. You should not infer the asynchronous memory logic as a memory block or place the asynchronous memory logic in the dedicated memory block, but implement the asynchronous memory logic in regular logic cells.

Intel memory blocks have different read-during-write behaviors, depending on the targeted device family, memory mode, and block type. Read-during-write behavior refers to read and write from the same memory address in the same clock cycle; for example, you read from the same address to which you write in the same clock cycle.

You should check how you specify the memory in your HDL code when you use read-during-write behavior. The HDL code that describes the read returns either the old data stored at the memory location, or the new data being written to the memory location.

In some cases, when the device architecture cannot implement the memory behavior described in your HDL code, the memory block is not mapped to the dedicated RAM blocks, or the memory block is implemented using extra logic in addition to the dedicated RAM block. Implement the read-during-write behavior using single-port RAM in Arria GX devices and the Cyclone and Stratix series of devices to avoid this extra logic implementation.

In many synthesis tools, you can specify that the read-during-write behavior is not important to your design; if, for example, you never read and write from the same address in the same clock cycle.

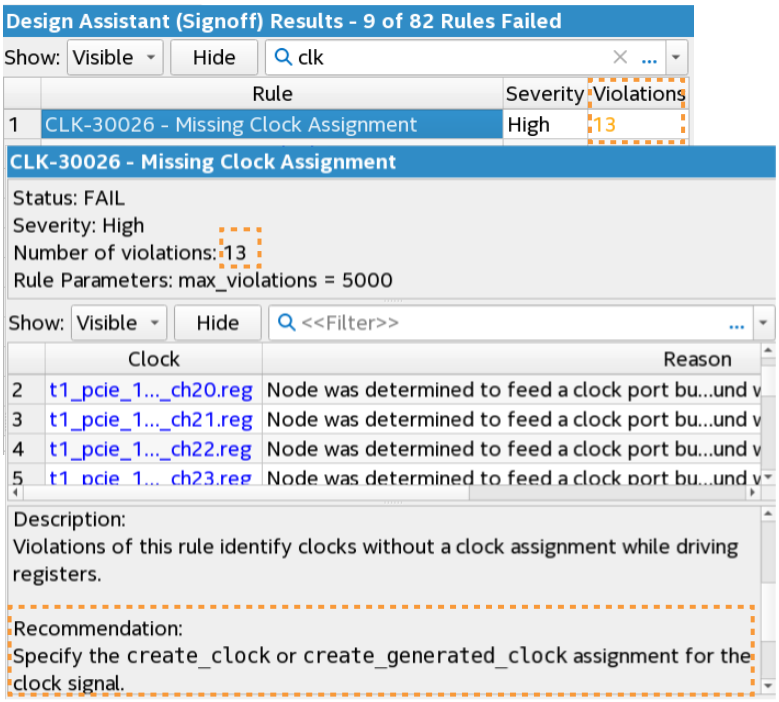
2.5. Design Assistant Design Rule Checking

The Intel Quartus Prime Design Assistant increases productivity by reducing the total number of design iterations for design closure, and by minimizing the time in each iteration with targeted rule checks and guidance at each stage of compilation.

The Design Assistant detects and helps you to resolve design rule violations by providing recommendations for correction and pathways to the violation source. Avoiding design rule violations improves the reliability, timing performance, and logic utilization of your design.

When enabled, Design Assistant automatically reports any violations against a standard set of Intel FPGA-recommended design guidelines [(1)]. You can run Design Assistant automatically during compilation, and report violations detected throughout the compilation process.

Figure 23. Design Assistant Recommends Corrections for Design Rule Violations



Alternatively, you can run Design Assistant in analysis mode, which allows you to launch Design Assistant checks from other Intel Quartus Prime tools, such as Chip Planner. For some rules, Design Assistant supports cross-probing to the Timing Analyzer and Intel Quartus Prime design visualization tools for root cause analysis and correction.

You can specify which rules Design Assistant checks, thus eliminating the rule checks that are unimportant for your design.

(1) A set of default rules ensures design health without significant runtime increase.

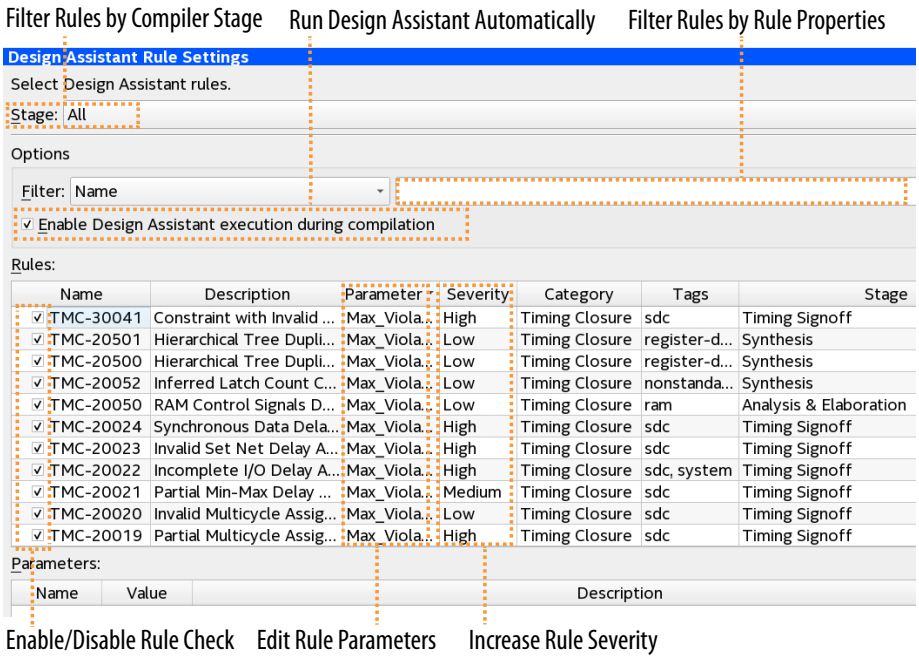
2.5.1. Setting Up Design Assistant

Customize the Design Assistant for individual design characteristics and reporting requirements. For example, you can disable rules for specific stages of compilation, change the threshold for violation reporting, and other options. Follow these steps to specify initial options for running Design Assistant:

1. Open an Intel Quartus Prime project.
2. Click **Assignments ➤ Settings ➤ Design Assistant Rule Settings**.

Figure 24. Design Assistant Rule Settings



3. Use the default settings or specify any of the following options:

Table 4. Design Assistant Rule Settings

Option	Description
Stage filter	Filters the **Rules** list by **All**, **Analysis & Elaboration**, **Synthesis**, **Plan**, **Place**, **Finalize** or **Timing Signoff** Compiler stages.
Text **Filter**	Filters the **Rules** list by matching text and the **Name**, **Description**, **Parameter**, **Severity**, **Category**, or **Tags** of the rule.
Enable Design Assistant execution during compilation	Runs Design Assistant automatically during compilation. Alternatively, enable this setting with `FLOW_ENABLE_DESIGN_ASSISTANT` in the `.qsf`. The settings in this dialog have no impact when this setting is disabled.
Rules	Lists all available Design Assistant rules and properties. Enable or disable analysis for the rule by enabling or disabling the rule **checkbox**.

continued...

Option	Description
Name Column	Specifies the alphanumeric rule ID. Rules that apply to more than one Compiler stage have sub-rules for each stage.
Description Column	Summary rule description.
Parameter Column	Lists rule parameters or "Multiple Values" for rules that support multiple Compiler stages. Select any rule to edit parameter values. Specify parameters on a per-stage basis by specifying parameters for the stage subrule.
Severity Column	Specifies **Low**, **Medium**, **High**, **Critical**, or **Fatal** as the rule **Severity** for reporting. You can increase the **Severity** level of rules.
Category Column	Specifies the rule class, such as **Timing Closure**, **Reset**, and others.
Tags	Specifies one or more additional facet of the rule for search and filtering purposes. For example, **global-signal** tag for design rule checks related to global signals. *Design Assistant Tags* defines the meaning of each tag.
Stage Column	Specifies the Compiler stages to which the rule applies. Rules for **Analysis & Elaboration**, **Synthesis**, **Plan**, **Place**, **Finalize**, and **Timing Signoff** stages are available. Enable or disable the rule on a per-stage basis by enabling or disabling the **checkbox** option for the stage subrule.
Parameters for rule Column	Allows you to specify parameters for rules that support parameters. Specify parameters on a per-stage basis by specifying parameters for the stage subrule.

- Design Assistant Tags on page 115

2.5.1.1. Design Assistant Rule Severity Levels

Design Assistant designates each rule violation with a severity level. You can increase the severity level for any rule to match your particular design requirements.

Table 5. Design Assistant Rule Severity Levels

Severity	Description	Severity Level Color
Fatal	Failure condition that stops the Compiler flow after violation.	Red
Critical	A critical issue that requires correction for sign-off.	Red
High	Potentially causes functional failure. May indicate missing or incorrect design data.	Yellow
Medium	Potentially impacts quality of results for f_{MAX} or resource utilization.	Brown
Low	Optional suggestions that can reflect FPGA design best practices and may have small impact on device performance and utilization in typical designs.	Blue

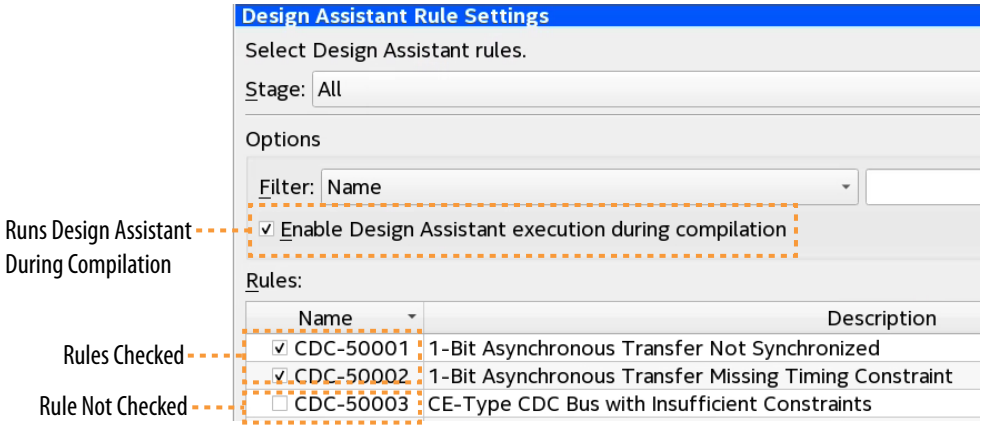
2.5.2. Running Design Assistant During Compilation

When enabled, Design Assistant runs automatically during compilation and reports design rule violations in the Compilation Report.

When you enable or specify parameters for a rule check in compilation mode, those specifications apply by default to running Design Assistant in compilation mode. If you change the rule settings for analysis mode, those settings are independent from the rule settings in compilation mode.

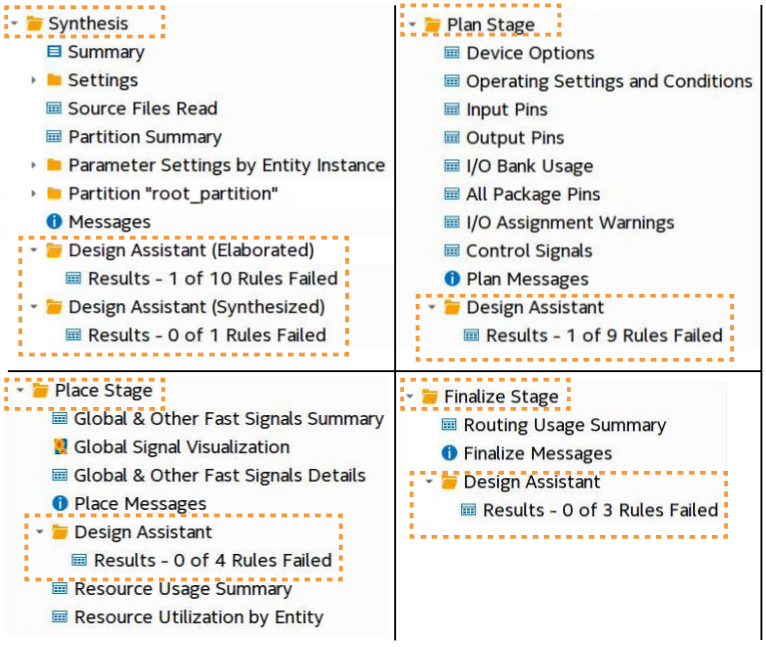
1. To run Design Assistant checking during compilation flows, ensure that **Enable Design Assistant execution during compilation** is on.
2. To enable or disable specific design rule checks, turn on or off the checkbox for that rule in the **Name** column. If the rule is unchecked, Design Assistant does not report violations for the rule.
3. In the **Parameters** field, consider changing default values for rules you enable.

Figure 25. Design Assistant Rule Settings



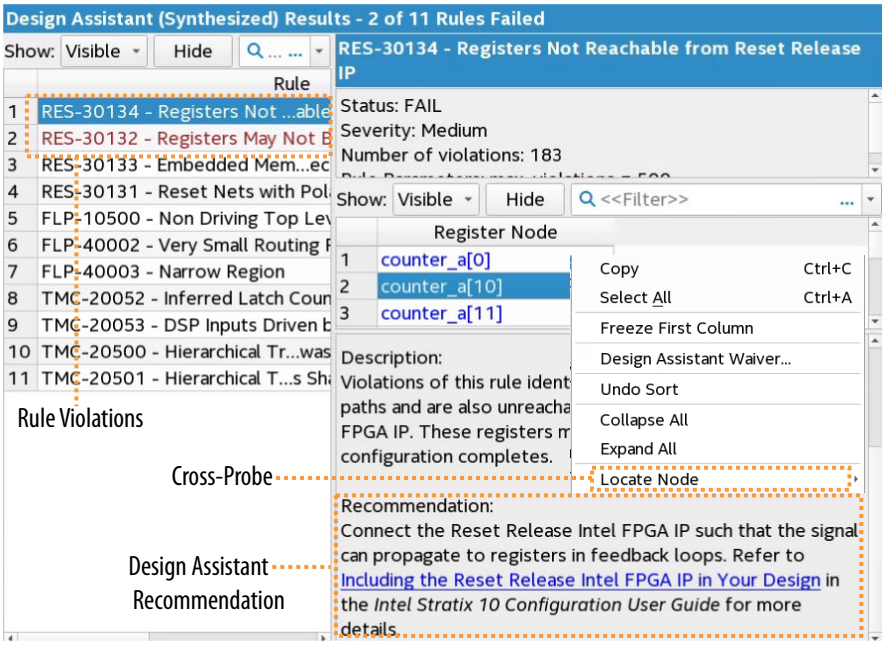
4. To run Design Assistant during compilation, run one or more stages of the Compiler from the Processing menu or Compilation Dashboard.

Figure 26. Example Design Assistant Results in Compilation Reports



5. To view the results for each rule, click the rule in the **Rules** list. A description of the rule and design recommendations for correction appear.

Figure 27. Design Assistant Rule Violation Recommendation

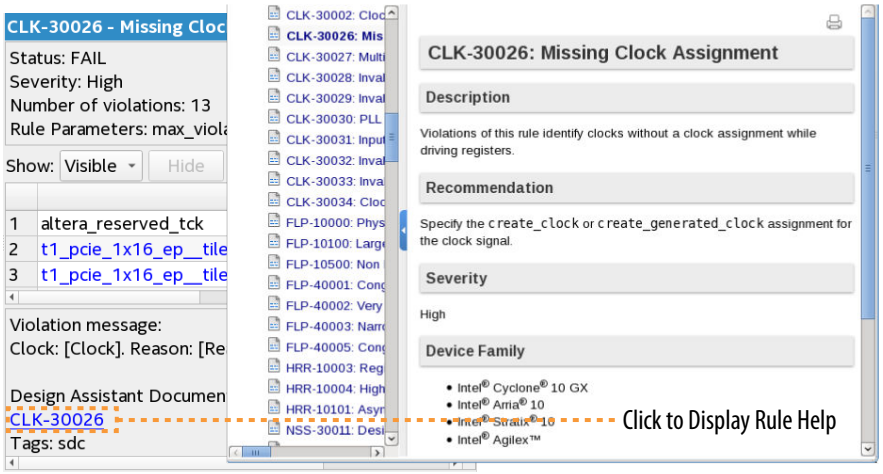


2.5.2.1. Opening Design Assistant Rule Help

Each rule report contains a link to the rule's Intel Quartus Prime Help topic. Help includes full rule descriptions and diagrams. To link to the Design Assistant rule Help:

1. In the Design Assistant report, click any rule in the **Rule** list. The right pane shows the rule description.

Figure 28. Linking in Design Assistant Reports to Rule Help



2. Click the rule ID link under **Design Assistant Document**. The rule displays in Help.

2.5.3. Running Design Assistant in Analysis Mode

You can launch Design Assistant in analysis mode directly from the Timing Analyzer or Chip Planner to rapidly run the specific rule checks that relate to those tools. For example, when you launch Design Assistant from the Chip Planner, Design Assistant is preset to check only a subset of the FLP (floorplanning) Design Assistant rules.

Similarly, when you launch Design Assistant from the Timing Analyzer, Design Assistant is preset to check only a subset of rules that are helpful during timing analysis. You can cross-probe to the Timing Analyzer and design visualization tools to determine the root cause of violations.

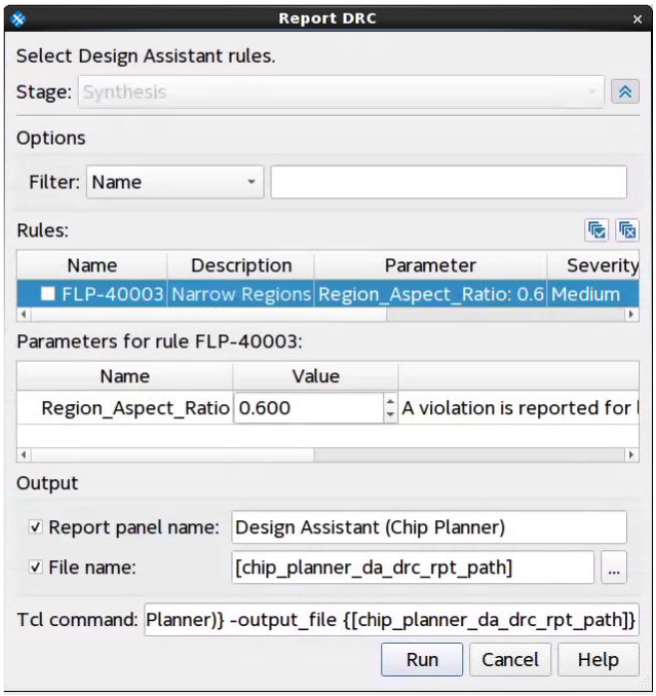
When you enable or specify parameters for a rule check in analysis mode, those specifications do not apply to running Design Assistant in compilation mode. The rule settings for analysis mode are independent from the rule settings in compilation mode.

2.5.3.1. Launching Design Assistant from Chip Planner

You can run Design Assistant directly from Chip Planner to assist when optimizing the floorplan in the tool. When you launch Design Assistant from the Chip Planner, Design Assistant is preset to check only the FLP (floorplanning) Design Assistant rules. Follow these steps to run the Design Assistant from the Chip Planner:

1. Run any stage of the Compiler. You must run at least the Analysis & Elaboration stage before running Design Assistant from Chip Planner.
2. Click **Tools ➤ Chip Planner**.

Figure 29. Report DRC Dialog Box in Chip Planner



3. In Chip Planner **Tasks** pane, click **Report DRC** under **Design Assistant**. The **Report DRC** (design rule check) dialog box appears.

4. Under **Rules**, disable any rules that are not important to your analysis by removing the check mark.
5. Consider whether to adjust rule parameter values in the **Parameters** field.
6. Under **Output**, confirm the **Report panel name** and optionally specify an output **File name**.
7. Click **Run**. The Results reports generate and appear in the **Report** pane and in the Compilation Report.

Figure 30. Rule Violations in Chip Planner Reports Pane

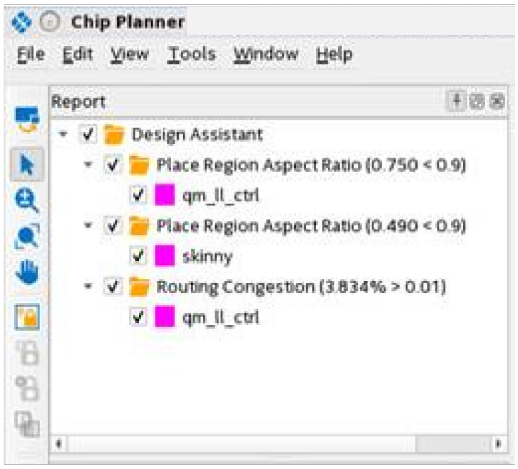


Figure 31. Chip Planner Rule Violations in Main Compilation Report

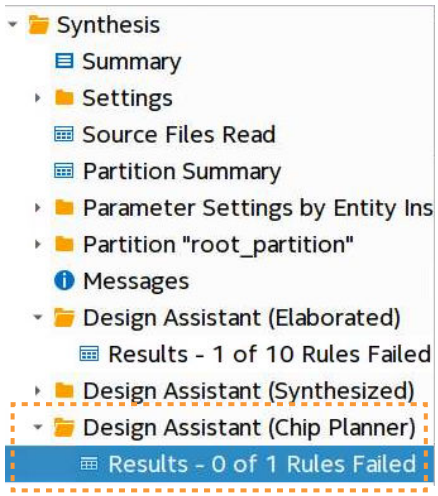


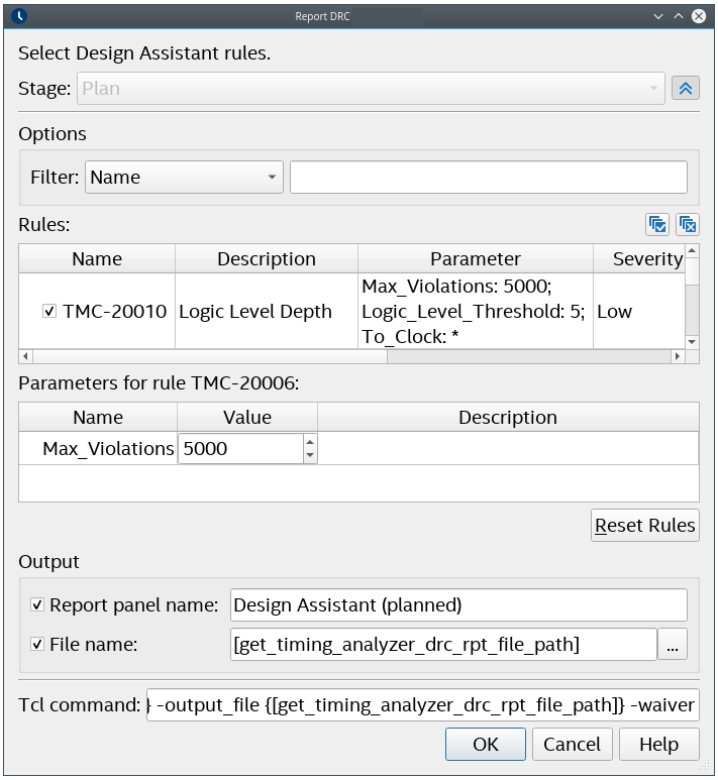
2.5.3.2. Launching Design Assistant from Timing Analyzer

You can run Design Assistant directly from the Timing Analyzer to assist when optimizing timing paths and other timing conditions. When you launch Design Assistant from the Timing Analyzer, Design Assistant is preset to check only rules that relate to timing analysis.

Follow these steps to run the Design Assistant from the Timing Analyzer:

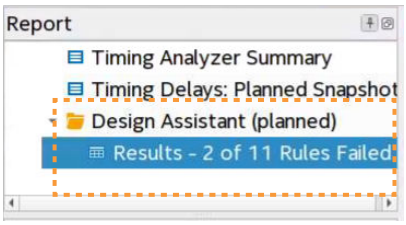
1. Compile the design through at least the Compiler's Plan stage.
2. Open the Timing Analyzer for the Compiler stage from the Compilation Dashboard.
3. In the Timing Analyzer, click **Reports ➤ Design Assistant ➤ Report DRC...**. The **Report DRC** (design rule check) dialog box opens.
4. Under **Rules**, disable any rules that are not important to your analysis by removing the check mark.
5. Consider whether to adjust rule parameter values in the **Parameters** field.

Figure 32. Report DRC (Design Rule Check) Dialog Box



6. Confirm the **Report panel name** and optionally specify an output **File name**.
7. Click **Run**. The Results reports generate and appear in the **Report** pane, as well as the main Compilation Report.

Figure 33. Design Assistant Reports in Timing Analyzer Report Pane



2.5.4. Cross-Probing from Design Assistant

In addition to the Locate Node command, Design Assistant allows you to cross-probe individual design objects relevant to the violation. For select high-value rules, Design Assistant provides full violation cross-probing ability into the Intel Quartus Prime Timing Analyzer and other design visualization tools.

For example, for rule TMC-20210 - Paths Failing Setup Analysis with High Routing Delay Added for Hold, you can right-click the violation, and then click **Report Timing (Extra Info)** to locate the path in the Timing Analyzer GUI.

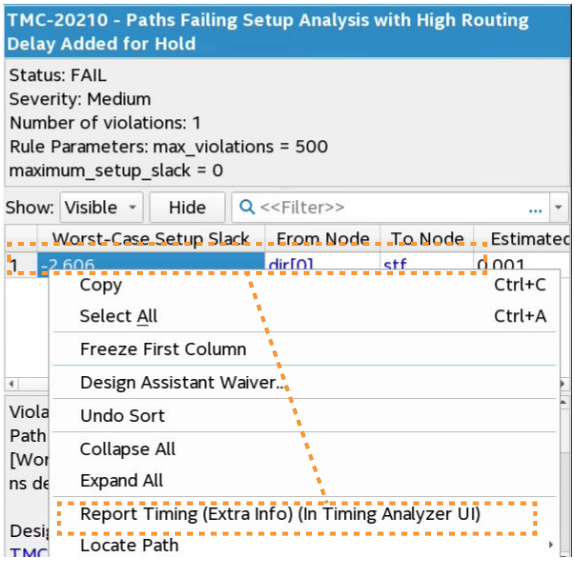
You can also locate from a rule violation instance to the source of the violation in Intel Quartus Prime design visualization tools, such as RTL Viewer, Resource Property Viewer, Technology Map Viewer, and Chip Planner. You can also locate to the violation source in the design file.

Cross-probing with Design Assistant can help you to more rapidly identify the root cause and resolve any rule violations negatively impacting your design.

2.5.4.1. Cross-Probing from Design Assistant to Timing Analyzer

Some Design Assistant rule violations allow cross-probing into Timing Analyzer. For example, for a path that Design Assistant flags with a setup analysis violation due to delay added for hold, you can cross-probe into the Timing Analyzer to view more information on the affected path and edge.

Figure 34. Cross Probing from Design Assistant Rule TMC-20210 Violations to Timing Analyzer



Follow these steps to cross-probe from such Design Assistant rule violations to the Timing Analyzer:

1. Compile the design through at least the Compiler's Plan stage.
2. Locate a rule violation in the Design Assistant folder of the Compilation Report.
3. Right-click the rule violation to display any **Report Timing** commands available for the violation.
4. Click the **Report Timing** command. The Timing Analyzer opens and reports the timing data for the violation path. **Report Timing (Extra Info)** includes Estimated Delay Added for Hold and Route Stage Congestion Impact extra data.

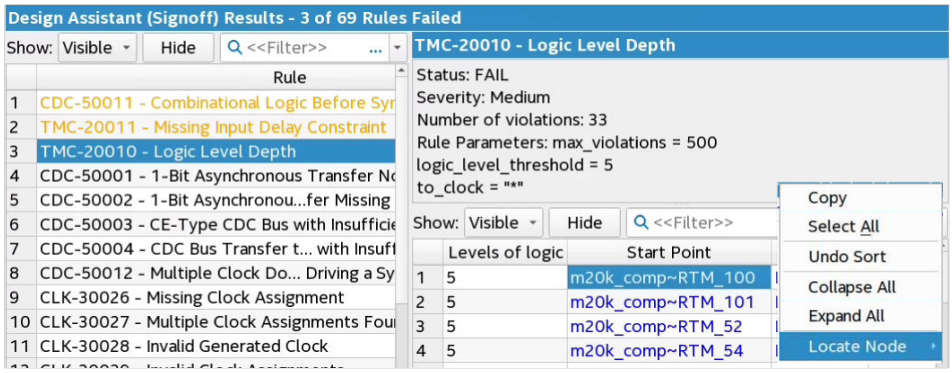
2.5.4.2. Cross-Probing from Design Assistant to Visualization Tools

Design Assistant can cross-probe from rule violations to the source in various Intel Quartus Prime design visualization tools. The following example demonstrates expanding from the cross-probing location for violation analysis.

The following example illustrates cross probing for the TMC-20010 Logic Level Depth rule violation to the RTL Viewer:

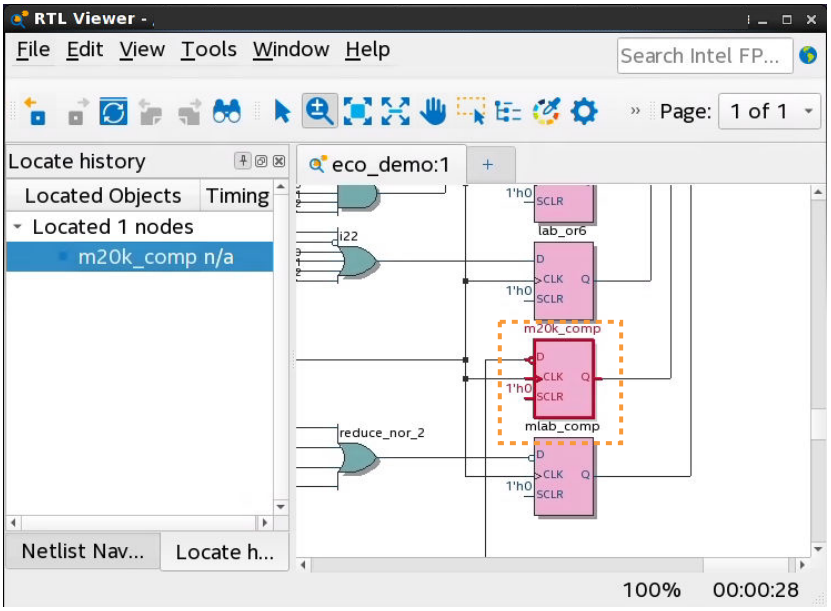
1. When Design Assistant reports FAIL status for rule TMC-20010, you can right-click any of the rule violations in the Design Assistant report, and then click **Locate Node ➤ Locate in RTL Viewer**.

Figure 35. Locate in RTL Viewer



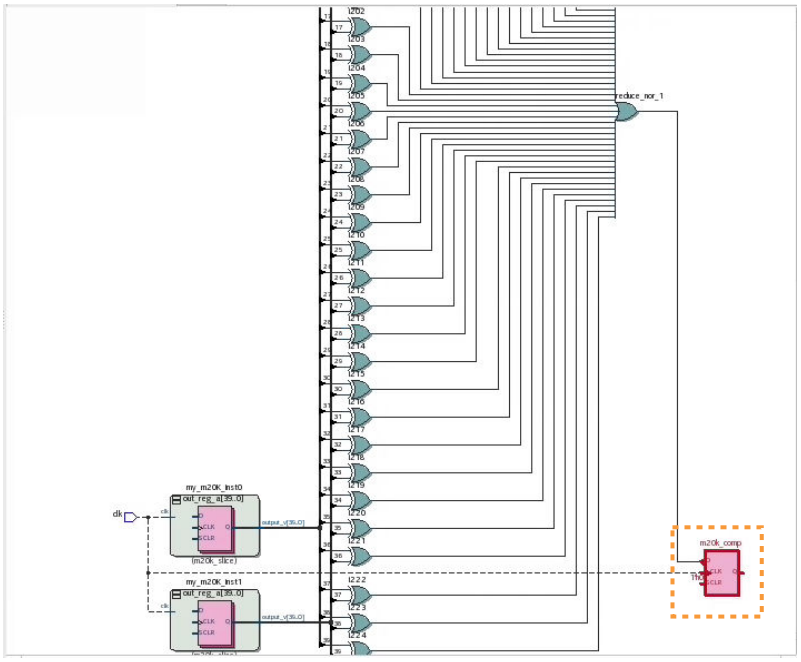
Cross-probing allows you to locate the driver register in the RTL Viewer.

Figure 36. Driver Register in RTL Viewer



2. To then fully visualize the logic level depth, right-click the register and click **Filter** to display **Sources and Destinations** of the register.

Figure 37. Expanded Connections



2.5.5. Managing Design Assistant Rules

The Design Assistant provides functions to help you manage the rules that are important for your design characteristics. You can use these features to help ensure that you are only checking rules that are important for your design at the relevant stage of compilation.

Design Assistant provides the following functionality to help you manage rule checking and reporting:

- Waiving Design Assistant Rules on page 109
- Enabling Rules for Specific Compiler Stages on page 107
- Specifying Rule Parameters for a Specific Compiler Stage on page 108
- Modifying Rule Severity Levels on page 108
- Changing the Default Number of Violations per Rule on page 107

2.5.5.1. Changing the Default Number of Violations per Rule

The default number of violations per rule is set to 5000 to limit runtime that rule processing incurs. The default limit is set to 5000 to help ensure that every violation is presented in all but the most exceptional cases. In typical designs, most rule violations do not approach this limit.

You can change the default number of violations that Design Assistant reports per rule, to show more or less violations per rule. Specify the following assignment in the project `.qsf` to change the default number of violations per rule:

```
set_global_assignment -name DESIGN_ASSISTANT_MAX_VIOLATIONS_PER_RULE <number>
```

To specify no limit on the number of violations per rule, at the possible expense of increased runtimes, enter `-1` for the `<number>` of the `DESIGN_ASSISTANT_MAX_VIOLATIONS_PER_RULE` assignment.

Change the default number of violations for individual rules in the **Design Assistant Settings** page, as Setting Up Design Assistant on page 97 describes.

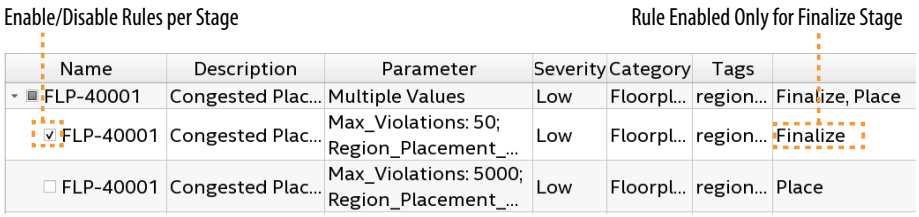
2.5.5.2. Enabling Rules for Specific Compiler Stages

You can enable or disable checking of Design Assistant rules on a per stage basis. This feature allows you to disable rule checks that are not important during one or more stage of compilation, while leaving the rule enabled for other stages.

To enable or disable rules for specific Compiler stages, follow these steps:

1. Specify initial Design Assistant Settings, as Setting Up Design Assistant on page 97 describes.
2. In the **Design Assistant Rule Settings** page, click the arrow next to a rule that supports multiple Compiler stages to expand the subrules for each stage.
3. For the subrule, enable or disable the **checkbox** to enable or disable checking for that rule during that Compiler stage.

Figure 38. Enable or Disable Rules per Stage



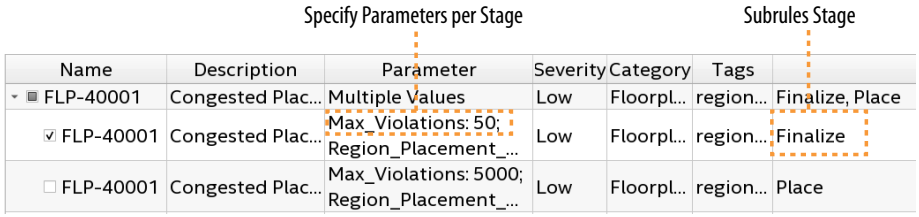
2.5.5.3. Specifying Rule Parameters for a Specific Compiler Stage

You can specify different parameters for Design Assistant rules for each Compiler stages. This feature allows you apply a set of rule parameters to a specific stage of compilation, and have a different set of rule parameters for another stage.

To enable or disable parameters for specific Compiler stages, follow these steps:

1. Specify initial Design Assistant Settings, as Setting Up Design Assistant on page 97 describes.
2. In the **Design Assistant Rule Settings** page, click the arrow next to a rule that supports multiple Compiler stages to expand the subrules for each stage.
3. Select the subrule and then specify the parameters in **Parameters for rule**.

Figure 39. Specifying Parameters Per Stage



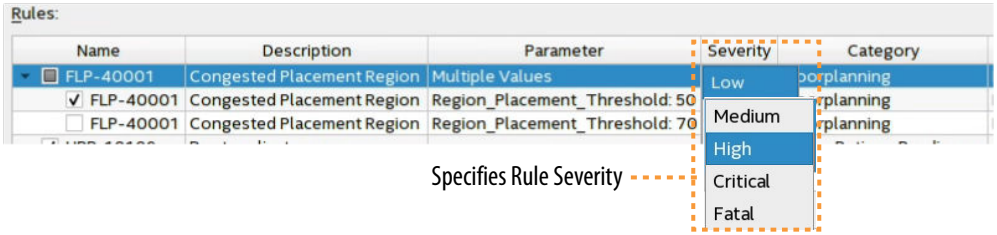
2.5.5.4. Modifying Rule Severity Levels

You can increase the severity level of a Design Assistant rule to match the importance of the rule for your design. You cannot decrease the severity level below the default. Design Assistant messages and reports reflect the rule severity level. You can filter and hide rule messages based on the severity level that you specify.

To customize rule severity level, follow these steps:

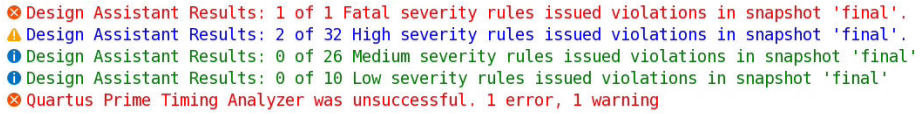
1. Specify initial Design Assistant Settings, as Setting Up Design Assistant on page 97 describes.
2. In the **Design Assistant Rule Settings** page, select the rule with a **Severity** that you want to change. You can only change the severity level of parent rules. Subrules for each stage must reflect the parent rule **Severity** level.
3. Click the **Severity** cell and select **Low**, **Medium**, **High**, **Critical**, or **Fatal**. Design Assistant reports the severity level you specify for the rule violations. Fatal violations cause failure of the Compiler stage.

Figure 40. Modifying Rule Severity Level



Note: Fatal violations indicate conditions that cause design failure and therefore cause the Compiler stage to be unsuccessful. You must correct the fatal condition, reduce the rule **Severity**, or create a rule waiver before proceeding to the next Compiler stage.

Figure 41. Messages Report Fatal Rule Violation Causes Compiler Failure



2.5.5.5. Waiving Design Assistant Rules

After running an initial design rule check, you can waive (ignore) design rule violations that you determine are unimportant for one or more iterations of design rule checking. When you create a waiver, Design Assistant does not check for compliance with the rules that match the violation conditions you specify, nor report results for the rule. For teams or individual designers, rule waivers also provide an audit trail that tracks the user, description, and reason for the design rule waiver.

You can create rule waivers to ignore violations for which you already have identified the root cause and correction, for violations that occur in a block that another developed owns, or to waive specific rules that you determine are not an issue for your design.

Initially, run Design Assistant checks without rule waivers to evaluate the complete list of violations. As you begin root cause analysis and violation correction, you can consider creating waivers to eliminate one or more rule violations from obscuring the rule violations that are still relevant.

After creating a design rule waiver, you can modify the rule parameters to fine tune rule checks, or you can delete waivers. For example, if a first pass rule check reports 800 violations with the **Max_Violations** per rule parameter set to default of 500, Design Assistant reports only the first 500 of the 800 total violations. You could then create rule waivers to omit the first 100 rule violations that you correct, thereby reporting rule violations number 501 and higher the next time you run Design Assistant.

When a Design Assistant waiver becomes completely unneeded, you can delete the waiver in the **Design Assistant Manage Waivers** dialog box or directly from the Design Assistant Waivers (`.dawf`) file.

Creating Design Assistant Waivers on page 110

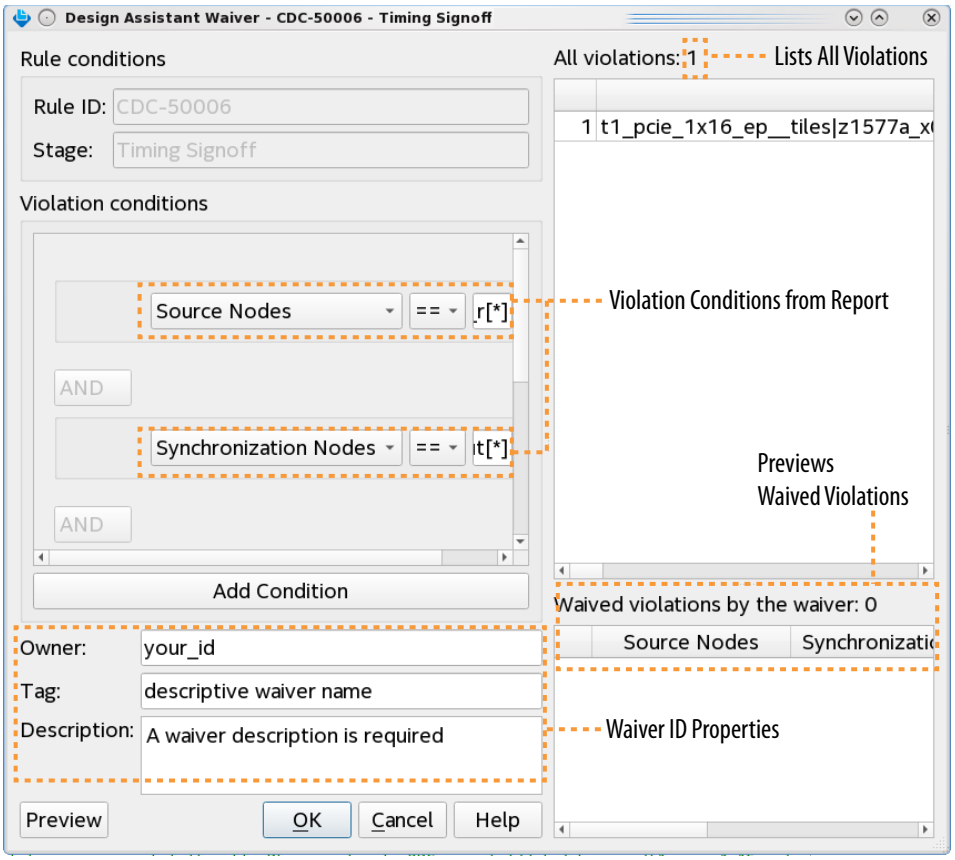
Design Assistant Waiver Dialog Box on page 111

2.5.5.5.1. Creating Design Assistant Waivers

To create a design rule waiver, follow these steps:

1. Run one or more stages of the Compiler to generate Design Assistant reports for the rules that you enable for your design.
2. In the Design Assistant report, right-click one or more rule violations, or right-click an entire rule category in the rule summary list, and then click **Design Assistant Waiver**. The **Design Assistant Waiver** dialog box opens preset with values from your violation selection.

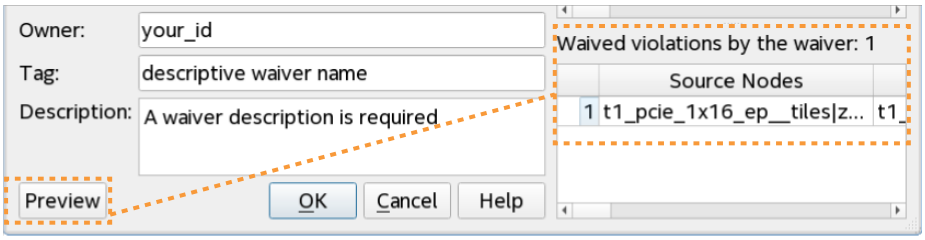
Figure 42. Right-Click Rule Violation in Report to Create Waiver for Violation



3. Modify any of the default **Violation conditions** that define when the waiver applies. The default settings are the most descriptive, using all applicable fields. The comparison operator is always **==** (equal to) by default for all conditions. Refer to Design Assistant Waiver Dialog Box on page 111 for all available options.

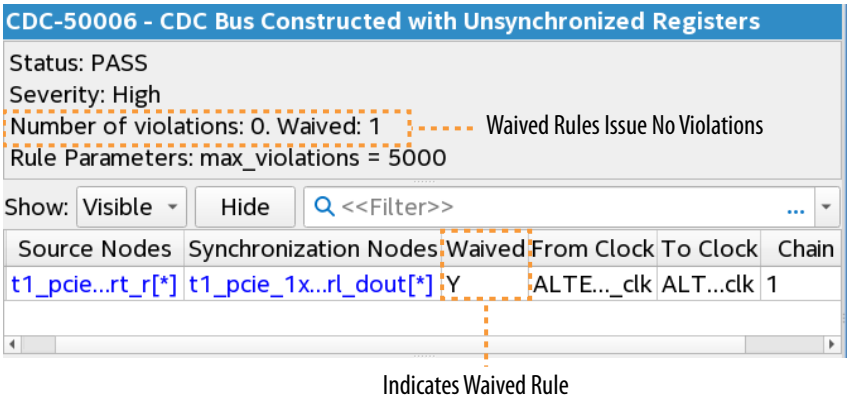
4. Click the **X** button to delete a sub-condition and simplify the query. Click **Add Condition** to add a violation sub-condition.
5. For waiver identification and audit tracking, optionally specify the waiver **Owner** name, a descriptive **Tag**, and a text **Description**.

Figure 43. Design Assistant Waiver Dialog Box



6. To preview the waived violations, click the **Preview** button. The **Waived violations by the waiver** list shows the waived rule violations during the next Design Assistant run. When you create a waiver after running Design Assistant, the newly added waiver specifies **To be Waived** in the **Waived** column. For any waivers that you delete, the **Waiver** column specifies **Y + To be unwaived**.
7. When waiver definition is complete, click **OK** to apply the waiver the next time you run Design Assistant. Design Assistant does not check for compliance with the rules that match waiver conditions, nor report results for the rules you waive. The Design Assistant reports indicate waived violations following compilation.

Figure 44. Applied Waiver Reported in Compilation Report



The report's **Waived** column specifies **Y** (for yes) for waived violations.

Design Assistant saves the rule waiver to a `da_drc.dawf` file in the project directory.

2.5.5.5.2. Design Assistant Waiver Dialog Box

You can define and apply waivers to Design Assistant rule violations that are not of concern in the **Design Assistant Waiver** dialog box.

The following table shows the **Design Assistant Waiver** dialog box options:

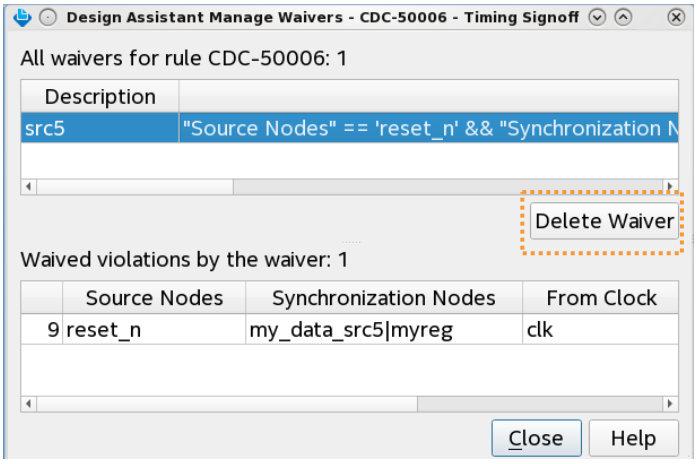
Table 6. Design Assistant Waiver Dialog Box Options

Setting	Description
Rule conditions	Automatically specifies the alphanumeric **Rule ID** and Compiler **Stage** of the rule violation.
Violation conditions	Specifies the conditions that define a rule violation waiver. The default **Violation conditions** automatically reflect the currently selected rule violation from the report. The available condition attributes are context-sensitive: • **==**is equal to • **!=** is not equal to • **<** is less than • **>** is greater than • **<=** is less than or equal to • **>=** is greater than or equal to • **!** is a negative unary operator for boolean expressions • **=~**—string contains • **!~**—string does not contain The join operators between conditions are always **AND**.
Add Condition	Click the **Add Condition** button to add more conditions to the rule waiver definition. Clicking the button adds a condition of default type.
Owner	Specifies the waiver owner's ID.
Tag	Specifies an identifying tag for the rule waiver.
Description	Required value that specifies a text description of the waiver for tracking and identifying.
Preview button	Previews the rule violations waived during the next Design Assistant run in the **Waived by the waiver** field.
Waived violations by the waiver	Upon clicking the **Preview** button, lists the rule violations that are waived during the next Design Assistant run.
All violations	Lists all violations of the currently selected Design Assistant rule.

2.5.5.5.3. Deleting Design Assistant Waivers

To fully remove (delete) any Design Assistant waivers that are no longer useful, delete the waiver in the **Design Assistant Manage Waivers** dialog box.

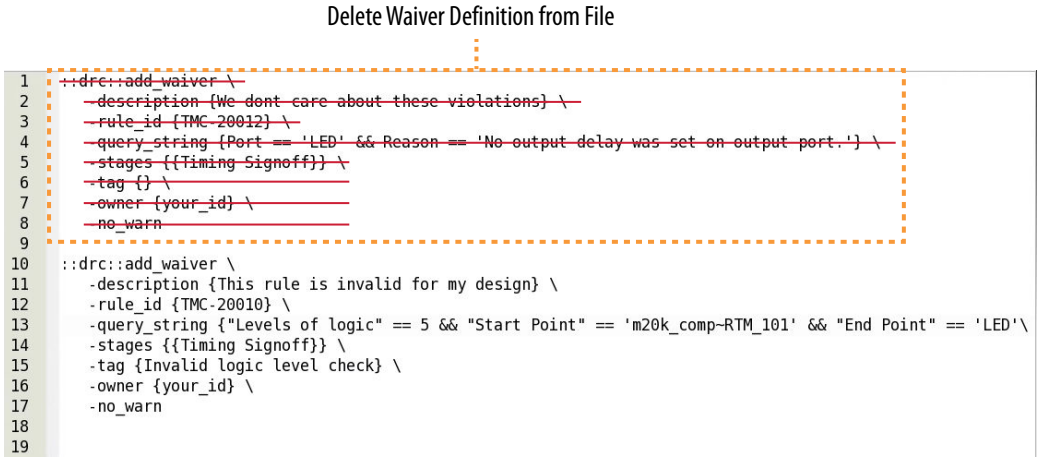
Figure 45. Design Assistant Manage Waivers Dialog Box



1. Right-click a rule violation with a waiver, and click **Waivers ➤ Manage Waivers**.
2. In the **Design Assistant Manager Waivers** dialog box, select the waiver you want to delete under **All waivers for rule**.
3. Click the **Delete Waiver** button to delete the waiver.

As an alternative to the GUI, you can also create and modify Design Assistant waivers by editing the Design Assistant Waivers File (`da_drc.dawf`), or by using Tcl commands within an interactive Tcl shell. The `da_drc.dawf` stores the waiver definitions you specify in the GUI. To avoid unintended results, do not edit the `da_drc.dawf` file while Compiler processes are running.

Figure 46. Deleting Waiver from Design Waivers File



2.5.5.5.4. Design Assistant Waiver Tcl Commands

As an alternative to the Design Assistant GUI, you can create, query, and report Design Assistant waivers by specifying the following Tcl commands within an interactive Tcl shell:

2.5.5.5.5. drc::add_waiver Command

Description

Creates a new Design Assistant waiver for the rule, Compiler stages, and query string that you specify. Optionally maintain audit tracking with the `timestamp` and `owner` arguments. Specify wildcard characters with the `stages` argument to create generic waivers across multiple rules. Specify any subset of violation arguments, comparison operators, and join operators to build any generic query string.

Syntax

```
drc::add_waiver
-description <description text>
-owner <userid>
-rule <rule_id>
query_string
-stages <compiler stages>
[-tag <string>]
```

Arguments

description Text description explaining the reason for the waiver.

owner User ID of waiver creator for audit trail.

rule Alpha-numeric rule ID.

query_string Query string specifying violation column arguments to define the violation patterns the waiver ignores. You can specify all or a subset of all violation column arguments, depending on the scope of the waiver.

stages Subset of Compiler stage(s) to which the rule waiver applies.

tag Short text description for tracking different types of violations across the entire project.

2.5.5.5.6. drc::get_waivers Command

Description

Returns a Design Assistant waiver for the rule, Compiler stages, owner, and query string that you specify. If you specify no option, `drc::get_waivers` returns all existing waivers.

Syntax

```
drc::get_waivers
-owner <userid>
-rule <rule_id>
query_string
-stages <compiler stages>
[-tag <string>]
```

Arguments

owner User ID of waiver creator for audit trail.

rule Alpha-numeric rule ID.

query_string Query string specifying violation column arguments to define the violation patterns the waiver ignores. The query string must exactly match the `query_string` you specify during waiver creation with the `add_waiver` command.

stages Subset of Compiler stage(s) to which the rule waiver applies.

tag Short text description for tracking different types of violations across the entire project.

2.5.5.5.7. drc::report_waivers Command

Description

Returns a collection of Design Assistant waivers for the rule, Compiler stages, and owner that you specify, or adds those waivers to a waiver file that you specify.

Syntax

```
drc::report_waivers
-file <waiver_file>
-owner <userid>
-rule <rule_id>
-stages <compiler stages>
[-tag <string>]
```

Arguments

file A waiver output file that design assistant creates and appends the returned waivers.

owner User ID of waiver creator for audit trail.

rule Alpha-numeric rule ID.

stages Subset of Compiler stage(s) to which the rule waiver applies.

tag Short text description for tracking different types of violations across the entire project.

2.5.5.6. Design Assistant Tags

Different Design Assistant **Tags** apply to each rule to extend search or filter capabilities based on the following facets of the rule. Refer to the **Design Assistant Rule Settings** to view which tags apply to each rule.

Table 7. Design Assistant Tags

Tag	Description
cdc-bus	Design rule checks related to topologies that use a bus to transfer multiple bits of data between clock domains at once.
clock-skew	Design rule checks related to clock skew.
design-partition	Design rule checks which check design partitions.
dsp	Design rule checks related to DSP blocks inside the FPGA fabric.
false-positive-synchronizer	Design rule checks related to automatically-detected synchronizer chains that may have been over-zealously detected.
global-signal	Design rule checks related to global signals.
impossible-requirements	Design rule checks which check the requirements on failing timing paths and flag those which fail by construction.

continued...

Tag	Description
ip-parameterization	Design rule checks which look for parameterizable IP modules which may need to be adjusted to meet performance specifications.
intrinsic-margin	Design rule checks which use the Intrinsic Margin metric (slack ignoring cell delay, IC delay and clock skew) to diagnose potential timing issues on failing paths.
latch	Design rule checks related to latches.
logic-levels	Design rule checks which flag potentially problematic amounts of logic on a timing path.
minimum-pulse-width	Design rule checks related to minimum pulse width.
nonstandard-timing	Design rule checks related to topologies which have unique timing analysis methodologies and may prove problematic.
partial-reconfiguration	Design rule checks which check Partial Reconfiguration designs.
place	Design rule checks which pertain to the Compiler's Place stage.
project-settings	Design rule checks related to validating the project settings.
ram	Design rule checks related to M20k blocks inside the FPGA fabric.
region-constraints	Design rule checks related to region constraints in the design (both placement and routing).
register-duplication	Design rule checks related to duplication of registers in the design, either manually or automatically.
register-spread	Design rule checks related to measuring the spread of a register's sinks, as found in the "Report Register Spread" command.
reset-usage	Design rule checks related to safe resets or appropriate use of reset modes.
reset-reachability	Design rule checks related to reachability analysis of reset signals, including convergence of multiple reset signals.
resource-usage	Design rule checks related to managing the resource usage of the design.
retime	Design rule checks which pertain to the Compiler's Retime stage.
route	Design rule checks which pertain to the Compiler's Route stage.
sdc	Design rule checks related to SDC validity checking.
synchronizer	Design rule checks related to synchronizer chains.
synthesis	Design rule checks which pertain to the Compiler's Analysis & Synthesis stage.
system	Design rule checks which validate full-system design.

2.5.6. Design Assistant Rule Categories

Each Design Assistant rule has a unique alphanumeric ID that reflects the rule category. You can enable or disable Design Assistant rules for specific stages of compilation. The following lists all categories of Design Assistant rules, and provides a link to rule documentation in Intel Quartus Prime Help. Some categories are device-specific.

Table 8. Design Assistant Rule Categories

Rule Category and Help Link	Acronym	Description
Clock Domain Crossing Rules	CDC	Rule checks for clock domain crossings
Clock Rules	CLK	Rule checks for clocks

continued...

Rule Category and Help Link	Acronym	Description
Floorplanning Rules	FLP	Rule checks for floorplanning, such as Logic Lock regions and congestion
Linting Rules	LNT	Rules checks of source code for programmatic and stylistic errors
Project Rules	PRJ	Rule checks related to Intel Quartus Prime projects
Reset Domain Crossing	RDC	Rule checks for reset domain crossings
Reset Rules	RES	Rule checks for resets
Timing Closure Rules	TMC	Rule checks for timing closure

2.6. Recommended Design Practices Revision History

The following revision history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2023.04.14	23.1	• Updated the recommendation in *Optimizing Clocking Schemes*.
2022.06.20	22.2	• Removed obsolete Block Based Design rule category from *Design Assistant Design Rule Checking* topic.
2021.10.04	21.3	• Updated *Design Assistant Design Rule Checking* topic for latest rule categories.
2021.03.29	21.1	• Updated *Design Assistant Design Rule Checking* topic with screenshot, minor wording changes, and link to *AN 919: Improving Quality of Results with Design Assistant*. • Updated *Setting Up Design Assistant* topic for rule tags. • Updated *Running Design Assistant During Compilation* step 4 wording. • Updated *Opening Design Assistant Rule Help* topic to show rule included in this release. • Updated screenshots in *Cross-Probing from Design Assistant to Timing Analyzer* topic. • Removed *Filtering and Hiding Rule Violations* section as waivers are most effective method in current version. • Updated *Changing the Default Number of Violations per Rule* for minor wording changes. • Created new *Design Assistant Tags* topic to define all tags. • Created new *Design Assistant Waiver Dialog Box* topic to define all settings in this dialog box. including new waiver features. • Updated *Creating Design Assistant Waivers* topic for waiver preview and reporting. • Updated *Deleting Design Assistant Waivers* topic for new GUI method. • Updated *Design Assistant Rule Categories* topic for latest rule categories. • Revised *Design Assistant Rule Severity Levels* descriptions.
2020.09.28	20.3	• Added new "Waiving Design Assistant Rules" section. • Added new "Cross-Probing with Design Assistant" section. • Added description of new Fatal severity level Design Assistant rule to "Modifying Rule Severity Levels" topic. • Updated "Setting Up Design Assistant" for new Fatal severity level and RDC rule category.

continued...

Document Version	Intel Quartus Prime Version	Changes
		• Updated "Running Design Assistant in Analysis Mode" with screenshots and detailed steps. • Added RDC to "Design Assistant Rule Categories" topic. • Removed individual Design Assistant rule descriptions from document and linked to updated rule description in Help. • Replaced obsolete rule screenshots throughout.
2020.04.13	20.1	• Added support for Design Assistant during Timing Signoff to "Setting Up Design Assistant" and "Running Design Assistant During Compilation" topics. • Added new Design Assistant rules. • Revised Design Assistant rules HRR-10201, HRR-10201, and RES-30131. • Removed various obsolete Design Assistant rules.
2019.11.01	19.3.0	• Revised "Changing Design Assistant Rule Scope or Number of Violations" topic for clarity. • Created separate "Clock Domain Crossing (CDC) Rules" category and topic. • Added "CLK-30026: Missing Clock Assignment" Design Assistant rule. • Added "CLK-30027: Multiple Clock Assignment" Design Assistant rule. • Added "CLK-30028: Invalid Generated Clock" Design Assistant rule. • Added "CLK-30029: Invalid Clock Assignment" Design Assistant rule. • Added "CLK-30030: PLL Setting Violation" Design Assistant rule. • Added "CLK-30031: Input Delay Assigned to Clock" Design Assistant rule.
2019.09.30	19.3.0	• Added new "Setting Up Design Assistant" topic. • Added new "Managing Design Assistant Rules" topic. • Added new "Enabling Rules for Specific Compiler Stages" topic. • Added new "Specifying Rule Parameters for Specific Compiler Stages" topic. • Added new "Modifying Rule Severity Levels" topic. • Added new "Filtering and Hiding Rule Violations" topic. • Added new "Filter Options Dialog Box" topic. • Added new "Linking to Design Assistant Rule Documentation" topic.

continued...

Document Version	Intel Quartus Prime Version	Changes
		• Updated screenshots for latest GUI elements. • Added the following new Design Assistant rules: — CDC-50001: Missing 1-Bit Synchronizer — CDC-50002: 1-Bit Synchronized Missing Constraint — CDC-50003: CE-Type CDC No Constraints — HRR-10015: High Fan-out Signal — HRR-10201: Registers Cannot Power Up with Don't Care Logic Level — HRR-10204: Reset Release Instance Count Check — RES-30132: Registers May Not Be Properly Reset — TMC-20500: Hierarchical Tree Duplication was Shallower than Possible — TMC-20501: Hierarchical Tree Duplication was Shallower than Requested — TMC-20550: Duplication Candidate Rejected for Placement Constraint — TMC-20551: Automatically-Discovered Duplication Candidate Likely Requires More Duplication — TMC-20552: User-Directed Duplication Candidate was Rejected — TMC-20601: Registers with High Immediate Fan-Out Tension — TMC-20602: Registers with High Timing Path Endpoint Tension — TMC-20603: Registers with High Immediate Fan-Out Span — TMC-20604: Registers with High Timing Path Endpoint Span • Removed obsolete Design Assistant rules: — HRR-10014: High Fan-out Nets Driving Clock-Enable Pins — HRR-10016: Registers Cannot Power-Up With Dont Care Logic Level
2019.04.01	19.1.0	• Described new Design Assistant design rule checking tool. • Added new topics describing each of the Design Assistant rules, under the *Recommended Design Practices > Checking for Design Rule Violations* section.
2018.09.24	18.1.0	• Created subtopics: *Clock Region Assignments in Intel Arria 10 and Older Device Families* and *Clock Region Assignments in Intel Stratix 10 Devices* from content in topic: *Use Clock Region Assignments to Optimize Clock Constraints*.
2017.11.06	17.1.0	• Updated topic: *Optimizing Timing Closure*. • Updated topic *Use Global Clock Network Resources* and added topic *Use Clock Region Assignments to Optimize Clock Constraints* for Intel Stratix 10 support.
2017.05.08	17.0.0	• Removed information about Integrated Synthesis. • Removed information about quartus_drc.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2016.05.03	16.0.0	• Replaced Internally Synchronized Reset code sample with corrected version. • Removed information about deprecated physical synthesis options. • Removed information about unsupported Design Assistant.
2015.11.02	15.1.0	• Changed instances of *Quartus II* to *Quartus Prime*.
2014.12.15	14.1.0	Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Optimization Settings to Compiler Settings.
June 2014	14.0.0	Removed references to obsolete MegaWizard Plug-In Manager.
November 2013	13.1.0	Removed HardCopy device information.
May 2013	13.0.0	Removed PrimeTime support.

continued...

Document Version	Intel Quartus Prime Version	Changes
June 2012	12.0.0	Removed survey link.
November 2011	11.0.1	Template update.
May 2011	11.0.0	Added information to Reset Resources .
December 2010	10.1.0	• Title changed from Design Recommendations for Altera Devices and the Quartus II Design Assistant. • Updated to new template. • Added references to Quartus II Help for "Metastability" on page 9–13 and "Incremental Compilation" on page 9–13. • Removed duplicated content and added references to Help for "Custom Rules" on page 9–15.
July 2010	10.0.0	• Removed duplicated content and added references to Quartus II Help for Design Assistant settings, Design Assistant rules, Enabling and Disabling Design Assistant Rules, and Viewing Design Assistant reports. • Removed information from "Combinational Logic Structures" on page 5–4 • Changed heading from "Design Techniques to Save Power" to "Power Optimization" on page 5–12 • Added new "Metastability" section • Added new "Incremental Compilation" section • Added information to "Reset Resources" on page 5–23 • Removed "Referenced Documents" section
November 2009	9.1.0	• Removed documentation of obsolete rules.
March 2009	9.0.0	• No change to content.
November 2008	8.1.0	• Changed to 8-1/2 x 11 page size • Added new section "Custom Rules Coding Examples" on page 5–18 • Added paragraph to "Recommended Clock-Gating Methods" on page 5–11 • Added new section: "Design Techniques to Save Power" on page 5–12
May 2008	8.0.0	• Updated Figure 5–9 on page 5–13; added custom rules file to the flow • Added notes to Figure 5–9 on page 5–13 • Added new section: "Custom Rules Report" on page 5–34 • Added new section: "Custom Rules" on page 5–34 • Added new section: "Targeting Embedded RAM Architectural Features" on page 5–38 • Minor editorial updates throughout the chapter • Added hyperlinks to referenced documents throughout the chapter

3. Managing Metastability with the Intel Quartus Prime Software

You can use the Intel Quartus Prime software to analyze the average mean time between failures (MTBF) due to metastability caused by synchronization of asynchronous signals, and optimize the design to improve the metastability MTBF.

All registers in digital devices, such as FPGAs, have defined signal-timing requirements that allow each register to correctly capture data at its input ports and produce an output signal. To ensure reliable operation, the input to a register must be stable for a minimum amount of time before the clock edge (register setup time or t_{SU}) and a minimum amount of time after the clock edge (register hold time or t_H). The register output is available after a specified clock-to-output delay (t_{CO}).

If the data violates the setup or hold time requirements, the output of the register might go into a metastable state. In a metastable state, the voltage at the register output hovers at a value between the high and low states, which means the output transition to a defined high or low state is delayed beyond the specified t_{CO}. Different destination registers might capture different values for the metastable signal, which can cause the system to fail.

In synchronous systems, the input signals must always meet the register timing requirements, so that metastability does not occur. Metastability problems commonly occur when a signal is transferred between circuitry in unrelated or asynchronous clock domains, because the signal can arrive at any time relative to the destination clock.

The MTBF due to metastability is an estimate of the average time between instances when metastability could cause a design failure. A high MTBF (such as hundreds or thousands of years between metastability failures) indicates a more robust design. You should determine an acceptable target MTBF in the context of your entire system and taking in account that MTBF calculations are statistical estimates.

The metastability MTBF for a specific signal transfer, or all the transfers in a design, can be calculated using information about the design and the device characteristics. Improving the metastability MTBF for your design reduces the chance that signal transfers could cause metastability problems in your device.

The Intel Quartus Prime software provides analysis, optimization, and reporting features to help manage metastability in Intel designs. These metastability features are supported only for designs constrained with the Intel Quartus Prime Timing Analyzer. Both typical and worst-case MBTF values are generated for select device families.

3.1. Metastability Analysis in the Intel Quartus Prime Software

When a signal transfers between circuitry in unrelated or asynchronous clock domains, the first register in the new clock domain acts as a synchronization register.

To minimize the failures due to metastability in asynchronous signal transfers, circuit designers typically use a sequence of registers (a synchronization register chain or synchronizer) in the destination clock domain to resynchronize the signal to the new clock domain and allow additional time for a potentially metastable signal to resolve to a known value. Designers commonly use two registers to synchronize a new signal, but a standard of three registers provides better metastability protection.

The timing analyzer can analyze and report the MTBF for each identified synchronizer that meets its timing requirements, and can generate an estimate of the overall design MTBF. The software uses this information to optimize the design MTBF, and you can use this information to determine whether your design requires longer synchronizer chains.

- MTBF Optimization on page 127

3.1.1. Data Synchronization Register Chains

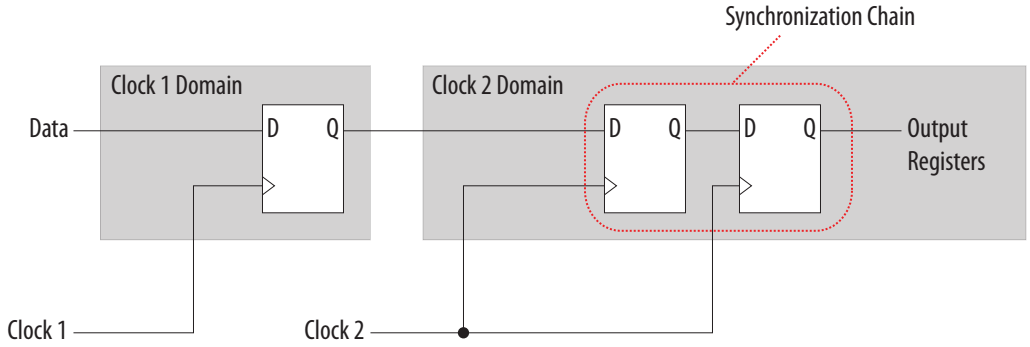
A synchronization register chain, or synchronizer, is defined as a sequence of registers that meets the following requirements:

- The registers in the chain are all clocked by the same clock or phase-related clocks.
- The first register in the chain is driven asynchronously or from an unrelated clock domain.
- Each register fans out to only one register, except the last register in the chain.

For Intel Quartus Prime software to identify a synchronization register chain, the registers in the chain must not include any resets.

The length of the synchronization register chain is the number of registers in the synchronizing clock domain that meet the requirements listed earlier. The following figure shows a sample two-register synchronization chain.

Figure 47. Sample Synchronization Register Chain



The timing slack available in the register-to-register paths of the synchronizer allows a metastable signal to settle, and is referred to as the available settling time. The available settling time in the MTBF calculation for a synchronizer is the sum of the output timing slacks for each register in the chain. Adding available settling time with additional synchronization registers improves the metastability MTBF.

Related Information

- How Timing Constraints Affect Synchronizer Identification and Metastability Analysis on page 123

- Identify Synchronizers for Metastability Analysis on page 123

3.1.2. Identify Synchronizers for Metastability Analysis

The first step in enabling metastability MTBF analysis and optimization in the Intel Quartus Prime software is to identify which registers are part of a synchronization register chain. You can apply synchronizer identification settings globally to automatically list possible synchronizers with the **Synchronizer identification** option on the **Timing Analyzer** page in the **Settings** dialog box.

Synchronization chains are already identified within most Intel FPGA intellectual property (IP) cores.

Related Information

Force the Identification of Synchronization Registers on page 129

3.1.3. How Timing Constraints Affect Synchronizer Identification and Metastability Analysis

The timing analyzer can analyze metastability MTBF only if a synchronization chain meets its timing requirements. The metastability failure rate depends on the timing slack available in the synchronizer's register-to-register connections, because that slack is the available settling time for a potential metastable signal. Therefore, you must ensure that your design is correctly constrained with the real application frequency requirements to get an accurate MTBF report.

In addition, the **Auto** and **Forced If Asynchronous** synchronizer identification options use timing constraints to automatically detect the synchronizer chains in the design. These options check for signal transfers between circuitry in unrelated or asynchronous clock domains, so clock domains must be related correctly with timing constraints.

The timing analyzer views input ports as asynchronous signals unless they are associated correctly with a clock domain. If an input port fans out to registers that are not acting as synchronization registers, apply a `set_input_delay` constraint to the input port; otherwise, the input register might be reported as a synchronization register. Constraining a synchronous input port with a `set_max_delay` constraint for a setup (t_{SU}) requirement does not prevent synchronizer identification because the constraint does not associate the input port with a clock domain.

Instead, use the following command to specify an input setup requirement associated with a clock:

`set_input_delay -max -clock` *<clock name> <latch – launch – tsu requirement> <input port name>*

Registers that are at the end of false paths are also considered synchronization registers because false paths are not timing-analyzed. Because there are no timing requirements for these paths, the signal may change at any point, which may violate the t_{SU} and t_H of the register. Therefore, these registers are identified as

synchronization registers. If these registers are not used for synchronization, you can turn off synchronizer identification and analysis. To do so, set **Synchronizer Identification** to **Off** for the first synchronization register in these register chains.

3.2. Metastability and MTBF Reporting

The Intel Quartus Prime software reports the metastability analysis results in the Compilation Report and Timing Analyzer reports.

The MTBF calculation uses timing and structural information about the design, silicon characteristics, and operating conditions, along with the data toggle rate.

If you change the **Synchronizer Identification** settings, you can generate new metastability reports by rerunning the timing analyzer. However, you should rerun the Fitter first so that the registers identified with the new setting can be optimized for metastability MTBF.

Related Information

- Metastability Reports on page 124
- MTBF Optimization on page 127
- Synchronizer Data Toggle Rate in MTBF Calculation on page 126

3.2.1. Metastability Reports

Metastability reports summarize the results of the metastability analysis. In addition to the MTBF Summary and Synchronizer Summary reports, the Timing Analyzer tool reports additional statistics for each synchronizer chain.

If the design uses only the **Auto Synchronizer Identification** setting, the reports list likely synchronizers but do not report MTBF. To obtain an MTBF for each register chain you must force identification of synchronization registers.

If the synchronizer chain does not meet its timing requirements, the reports list identified synchronizers but do not report MTBF. To obtain MTBF calculations, ensure that the design is constrained correctly, and that the synchronizer meets its timing requirements.

Related Information

- Identify Synchronizers for Metastability Analysis on page 123
- How Timing Constraints Affect Synchronizer Identification and Metastability Analysis on page 123

3.2.1.1. MTBF Summary Report

The MTBF Summary reports an estimate of the overall robustness of cross-clock domain and asynchronous transfers in the design. This estimate uses the MTBF results of all synchronization chains in the design to calculate an MTBF for the entire design.

3.2.1.1.1. Typical and Worst-Case MTBF of Design

The MTBF Summary Report shows the **Typical MTBF of Design** and the **Worst-Case MTBF of Design** for supported fully-characterized devices. The typical MTBF result assumes typical conditions, defined as nominal silicon characteristics for the selected device speed grade, as well as nominal operating conditions. The worst-case MTBF result uses the worst case silicon characteristics for the selected device speed grade.

When you analyze multiple timing corners in the timing analyzer, the MTBF calculation may vary because of changes in the operating conditions, and the timing slack or available metastability settling time. Intel recommends running multi-corner timing analysis to ensure that you analyze the worst MTBF results, because the worst timing corner for MTBF does not necessarily match the worst corner for timing performance.

Related Information

Timing Analyzer
In *Intel Quartus Prime Help*

3.2.1.1.2. Synchronizer Chains

The MTBF Summary report also lists the **Number of Synchronizer Chains Found** and the length of the **Shortest Synchronizer Chain**, which can help you identify whether the report is based on accurate information.

If the number of synchronizer chains found is different from what you expect, or if the length of the shortest synchronizer chain is less than you expect, you might have to add or change **Synchronizer Identification** settings for the design. The report also provides the **Worst Case Available Settling Time**, defined as the available settling time for the synchronizer with the worst MTBF.

You can use the reported **Fraction of Chains for which MTBFs Could Not be Calculated** to determine whether a high proportion of chains are missing in the metastability analysis. A fraction of 1, for example, means that MTBF could not be calculated for any chains in the design. MTBF is not calculated if you have not identified the chain with the appropriate **Synchronizer identification** option, or if paths are not timing-analyzed and therefore have no valid slack for metastability analysis. You might have to correct your timing constraints to enable complete analysis of the applicable register chains.

3.2.1.1.3. Increasing Available Settling Time

The MTBF Summary report specifies how an increase of 100ps in available settling time increases the MTBF values. If your MTBF is not satisfactory, this metric can help you determine how much extra slack would be required in your synchronizer chain to allow you to reach the desired design MTBF.

3.2.1.2. Synchronizer Summary Report

The **Synchronizer Summary** lists the synchronization register chains detected in the design depending on the Synchronizer Identification setting.

The **Source Node** is the register or input port that is the source of the asynchronous transfer. The **Synchronization Node** is the first register of the synchronization chain. The **Source Clock** is the clock domain of the source node, and the **Synchronization Clock** is the clock domain of the synchronizer chain.

This summary reports the calculated **Worst-Case MTBF**, if available, and the **Typical MTBF**, for each appropriately identified synchronization register chain that meets its timing requirement.

Related Information

Synchronizer Chain Statistics Report in the Timing Analyzer on page 126

3.2.1.3. Synchronizer Chain Statistics Report in the Timing Analyzer

The timing analyzer provides an additional report for each synchronizer chain.

The **Chain Summary** tab matches the Synchronizer Summary information described in the Synchronizer Summary Report, while the **Statistics** tab adds more details. These details include whether the **Method of Synchronizer Identification** was **User Specified** (with the **Forced if Asynchronous** or **Forced** settings for the **Synchronizer Identification** setting), or **Automatic** (with the **Auto** setting). The **Number of Synchronization Registers in Chain** report provides information about the parameters that affect the MTBF calculation, including the **Available Settling Time** for the chain and the **Data Toggle Rate Used in MTBF Calculation**.

The following information is also included to help you locate the chain in your design:

- **Source Clock** and **Asynchronous Source** node of the signal.
- **Synchronization Clock** in the destination clock domain.
- Node names of the **Synchronization Registers** in the chain.

Related Information

Synchronizer Data Toggle Rate in MTBF Calculation on page 126

3.2.2. Synchronizer Data Toggle Rate in MTBF Calculation

The MTBF calculations assume the data being synchronized is switching at a toggle rate of 12.5% of the source clock frequency. That is, the arriving data is assumed to switch once every eight source clock cycles.

If multiple clocks apply, the highest frequency is used. If no source clocks can be determined, the data rate is taken as 12.5% of the synchronization clock frequency.

If you know an approximate rate at which the data changes, specify it with the **Synchronizer Toggle Rate** assignment in the Assignment Editor. You can also apply this assignment to an entity or the entire design. Set the data toggle rate, in number of transitions per second, on the first register of a synchronization chain. The timing analyzer takes the specified rate into account when computing the MTBF of that register chain. If a data signal never toggles and does not affect the reliability of the design, you can set the **Synchronizer Toggle Rate** to **0** for the synchronization chain so the MTBF is not reported. To apply the assignment with Tcl, use the following command:

```
set_instance_assignment -name SYNCHRONIZER_TOGGLE_RATE <toggle rate in
transitions/second> -to <register name>
```

In addition to **Synchronizer Toggle Rate,** there are two other assignments associated with toggle rates, which are not used for metastability MTBF calculations. The I/O Maximum Toggle Rate is only used for pins, and specifies the worst-case

toggle rates used for signal integrity purposes. The Power Toggle Rate assignment is used to specify the expected time-averaged toggle rate, and is used by the Power Analyzer to estimate time-averaged power consumption.

3.3. MTBF Optimization

In addition to reporting synchronization register chains and MTBF values found in the design, the Intel Quartus Prime software can also protect these registers from optimizations that might negatively impact MTBF and can optimize the register placement and routing if the MTBF is too low.

Synchronization register chains must first be explicitly identified as synchronizers. Intel recommends that you set **Synchronizer Identification** to **Forced If Asynchronous** for all registers that are part of a synchronizer chain.

Optimization algorithms, such as register duplication and logic retiming in physical synthesis, are not performed on identified synchronization registers. The Fitter protects the number of synchronization registers specified by the **Synchronizer Register Chain Length** option.

In addition, the Fitter optimizes identified synchronizers for improved MTBF by placing and routing the registers to increase their output setup slack values. Adding slack in the synchronizer chain increases the available settling time for a potentially metastable signal, which improves the chance that the signal resolves to a known value, and exponentially increases the design MTBF. The Fitter optimizes the number of synchronization registers specified by the **Synchronizer Register Chain Length** option.

Metastability optimization is **on** by default. To view or change the **Optimize Design for Metastability** option, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**. To turn the optimization on or off with Tcl, use the following command:

```
set_global_assignment -name OPTIMIZE_FOR_METASTABILITY <ON|OFF>
```

Related Information

Identify Synchronizers for Metastability Analysis on page 123

3.3.1. Synchronization Register Chain Length

The **Synchronization Register Chain Length** option specifies how many registers should be protected from optimizations that might reduce MTBF for each register chain, and controls how many registers should be optimized to increase MTBF with the **Optimize Design for Metastability** option.

For example, if the **Synchronization Register Chain Length** option is set to **2**, optimizations such as register duplication or logic retiming are prevented from being performed on the first two registers in all identified synchronization chains. The first two registers are also optimized to improve MTBF when the **Optimize Design for Metastability** option is turned on.

The default setting for the **Synchronization Register Chain Length** option is **3**. The first register of a synchronization chain is always protected from operations that might reduce MTBF, but you should set the protection length to protect more of the

synchronizer chain. Intel recommends that you set this option to the maximum length of synchronization chains you have in your design so that all synchronization registers are preserved and optimized for MTBF.

Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)** to change the global **Synchronization Register Chain Length** option.

You can also set the **Synchronization Register Chain Length** on a node or an entity in the Assignment Editor. You can set this value on the first register in a synchronization chain to specify how many registers to protect and optimize in this chain. This individual setting is useful if you want to protect and optimize extra registers that you have created in a specific synchronization chain that has low MTBF, or optimize less registers for MTBF in a specific chain where the maximum frequency or timing performance is not being met. To make the global setting with Tcl, use the following command:

```
set_global_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH <number of registers>
```

To apply the assignment to a design instance or the first register in a specific chain with Tcl, use the following command:

```
set_instance_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH <number of registers> -to <register or instance name>
```

3.4. Reducing Metastability Effects

You can check your design's metastability MTBF in the Metastability Summary report, and determine an acceptable target MTBF given the context of your entire system and the fact that MTBF calculations are statistical estimates. A high metastability MTBF (such as hundreds or thousands of years between metastability failures) indicates a more robust design.

This section provides guidelines to ensure complete and accurate metastability analysis, and some suggestions to follow if the Intel Quartus Prime metastability reports calculate an unacceptable MTBF value.

Related Information

Metastability Reports on page 124

3.4.1. Apply Complete System-Centric Timing Constraints for the Timing Analyzer

To enable the Intel Quartus Prime metastability features, make sure that the timing analyzer is used for timing analysis.

Ensure that the design is fully timing constrained and that it meets its timing requirements. If the synchronization chain does not meet its timing requirements, MTBF cannot be calculated. If the clock domain constraints are set up incorrectly, the signal transfers between circuitry in unrelated or asynchronous clock domains might be identified incorrectly.

Use industry-standard system-centric I/O timing constraints instead of using FPGA-centric timing constraints.

You should use `set_input_delay` constraints in place of `set_max_delay` constraints to associate each input port with a clock domain to help eliminate false positives during synchronization register identification.

Related Information

How Timing Constraints Affect Synchronizer Identification and Metastability Analysis on page 123

3.4.2. Force the Identification of Synchronization Registers

Use the guidelines in *Identifying Synchronizers for Metastability Analysis* to ensure the software reports and optimizes the appropriate register chains.

Identify synchronization registers by setting **Synchronizer Identification** to **Forced If Asynchronous** in the Assignment Editor. If there are any registers that the software detects as synchronous, but you want to analyze for metastability, apply the **Forced** setting to the first synchronizing register. Set **Synchronizer Identification** to **Off** for registers that are not synchronizers for asynchronous signals or unrelated clock domains.

To help you find the synchronizers in your design, you can set the global **Synchronizer Identification** setting on the **Timing Analyzer** page of the **Settings** dialog box to **Auto** to generate a list of all the possible synchronization chains in your design.

Related Information

Identify Synchronizers for Metastability Analysis on page 123

3.4.3. Set the Synchronizer Data Toggle Rate

The MTBF calculations assume the data being synchronized is switching at a toggle rate of 12.5% of the source clock frequency.

To obtain a more accurate MTBF for a specific chain or all chains in your design, set the **Synchronizer Toggle Rate**.

Related Information

Synchronizer Data Toggle Rate in MTBF Calculation on page 126

3.4.4. Optimize Metastability During Fitting

Ensure that the **Optimize Design for Metastability** setting is turned on.

Related Information

MTBF Optimization on page 127

3.4.5. Increase the Length of Synchronizers to Protect and Optimize

Increase the Synchronizer Chain Length parameter to the maximum length of synchronization chains in your design. If you have synchronization chains longer than 2 identified in your design, you can protect the entire synchronization chain from operations that might reduce MTBF and allow metastability optimizations to improve the MTBF.

Related Information

Synchronization Register Chain Length on page 127

3.4.6. Increase the Number of Stages Used in Synchronizers

Designers commonly use two registers in a synchronization chain to minimize the occurrence of metastable events, and a standard of three registers provides better metastability protection. However, synchronization chains with two or even three registers may not be enough to produce a high enough MTBF when the design runs at high clock and data frequencies.

If a synchronization chain is reported to have a low MTBF, consider adding an additional register stage to your synchronization chain. This additional stage increases the settling time of the synchronization chain, allowing more opportunity for the signal to resolve to a known state during a metastable event. Additional settling time increases the MTBF of the chain and improves the robustness of your design. However, adding a synchronization stage introduces an additional stage of latency on the signal.

If you use the Intel FPGA IP core with separate read and write clocks to cross clock domains, increase the metastability protection (and latency) for better MTBF. In the DCFIFO parameter editor, choose the **Best metastability protection, best fmax, unsynchronized clocks** option to add three or more synchronization stages. You can increase the number of stages to more than three using the **How many sync stages?** setting.

3.4.7. Select a Faster Speed Grade Device

The design MTBF depends on process parameters of the device used. Faster devices are less susceptible to metastability issues. If the design MTBF falls significantly below the target MTBF, switching to a faster speed grade can improve the MTBF substantially.

3.5. Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run procedures at a command prompt.

For detailed information about scripting command options, refer to the Intel Quartus Prime Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt and then press Enter:

```
quartus_sh --qhelp
```

3.5.1. Identifying Synchronizers for Metastability Analysis

To apply the global Synchronizer Identification assignment, use the following command:

```
set_global_assignment -name SYNCHRONIZER_IDENTIFICATION <OFF|AUTO|"FORCED IF
ASYNCHRONOUS">
```

To apply the **Synchronizer Identification** assignment to a specific register or instance, use the following command:

```
set_instance_assignment -name SYNCHRONIZER_IDENTIFICATION <AUTO|"FORCED IF
ASYNCHRONOUS"|FORCED|OFF> -to <register or instance name>
```

3.5.2. Synchronizer Data Toggle Rate in MTBF Calculation

To specify a toggle rate for MTBF calculations as described on page "R**Synchronizer Data Toggle Rate in MTBF Calculation", use the following command:

```
set_instance_assignment -name SYNCHRONIZER_TOGGLE_RATE <toggle rate in
transitions/second> -to <register name>
```

Related Information

Synchronizer Data Toggle Rate in MTBF Calculation on page 126

3.5.3. report_metastability and Tcl Command

If you use a command-line or scripting flow, you can generate the metastability analysis reports described in "C**Metastability Reports" outside of the Intel Quartus Prime and user interfaces.

The table describes the options for the `report_metastability` and Tcl command.

Table 9. report_metastabilty Command Options

Option	Description
`-append`	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
`-file <name>`	Sends the results to an ASCII or HTML file. The extension specified in the file name determines the file type — either **`*.txt`** or **`*.html`**.
`-panel_name <name>`	Sends the results to the panel and specifies the name of the new panel.
`-stdout`	Indicates the report be sent to the standard output, via messages. This option is required only if you have selected another output format, such as a file, and would also like to receive messages.

Related Information

Metastability Reports on page 124

3.5.4. MTBF Optimization

To ensure that metastability optimization described on page "C**MTBF Optimization" is turned on (or to turn it off), use the following command:

```
set_global_assignment -name OPTIMIZE_FOR_METASTABILITY <ON|OFF>
```

Related Information

MTBF Optimization on page 127

3.5.5. Synchronization Register Chain Length

To globally set the number of registers in a synchronization chain to be protected and optimized as described on page "C**Synchronization Register Chain Length", use the following command:

```
set_global_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH <number of registers>
```

To apply the assignment to a design instance or the first register in a specific chain, use the following command:

```
set_instance_assignment -name SYNCHRONIZATION_REGISTER_CHAIN_LENGTH <number of registers> -to <register or instance name>
```

Related Information

Synchronization Register Chain Length on page 127

3.6. Managing Metastability

Intel's Intel Quartus Prime software provides industry-leading analysis and optimization features to help you manage metastability in your FPGA designs. Set up your Intel Quartus Prime project with the appropriate constraints and settings to enable the software to analyze, report, and optimize the design MTBF. Take advantage of these features in the Intel Quartus Prime software to make your design more robust with respect to metastability.

3.7. Managing Metastability with the Intel Quartus Prime Software Revision History

The following revisions history applies to this chapter:

Document Version	Intel Quartus Prime Version	Changes
2022.03.28	22.1	• Renamed "Synchronization Register Chains" to "Data Synchronization Register Chains" and revised the topic. • Removed references to obsolete Advisors.
2018.05.07	18.0.0	• First release as part of the stand-alone *Design Recommendations User Guide*
2017.11.06	17.1.0	• Corrected broken links to other documents.
2016.10.31	16.1.0	• Implemented Intel rebranding.
2015.11.02	15.1.0	• Changed instances of *Quartus II* to *Intel Quartus Prime*.
2014.12.15	14.1.0	Updated location of Fitter Settings, Analysis & Synthesis Settings, and Physical Optimization Settings to Compiler Settings.
June 2014	14.0.0	Updated formatting.
June 2012	12.0.0	Removed survey link.
November 2011	10.0.2	Template update.
December 2010	10.0.1	Changed to new document template.

continued...

Document Version	Intel Quartus Prime Version	Changes
July 2010	10.0.0	Technical edit.
November 2009	9.1.0	Clarified description of synchronizer identification settings. Minor changes to text and figures throughout document.
March 2009	9.0.0	Initial release.

Design Compilation

Updated for Quartus® Prime Design Suite: **24.1**

This document is part of a collection - Quartus® Prime Pro Edition User Guides - Combined PDF link

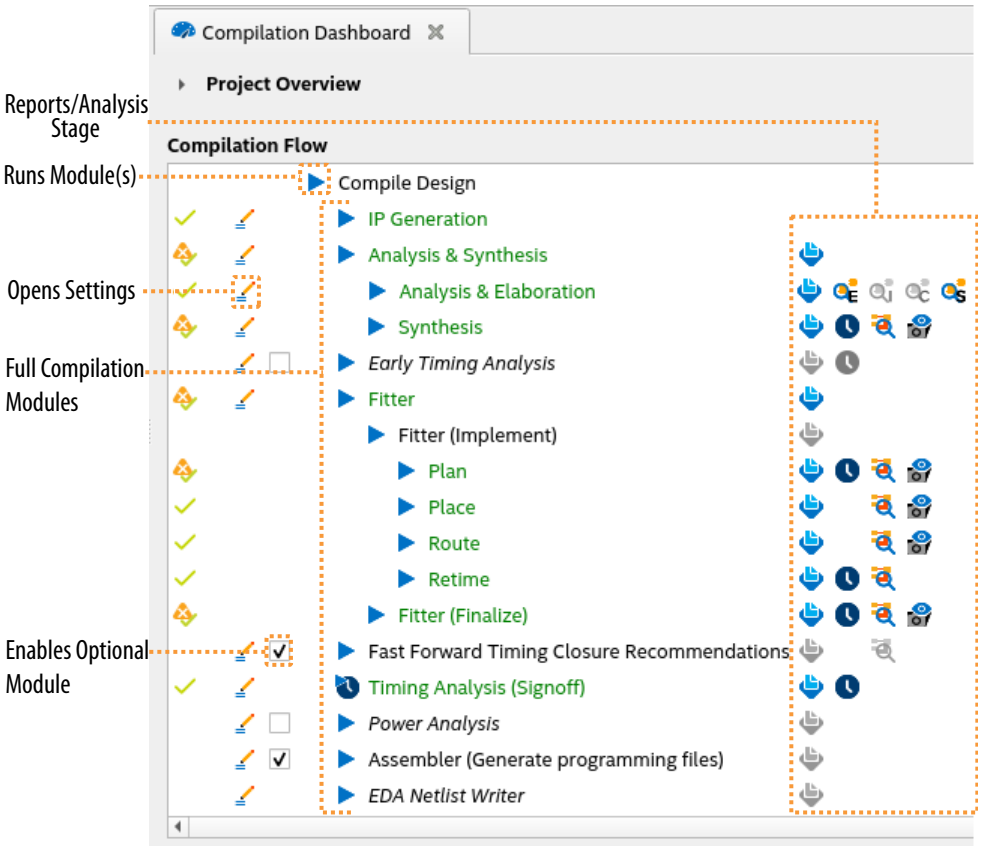
Answers to Top FAQs:

Contents

1. Design Compilation

The Quartus® Prime Compiler synthesizes, places, and routes your design before generating device programming files. The Compiler supports a variety of high-level, HDL, and schematic design entry methods. The modules of the Compiler include IP Generation, Analysis & Synthesis, Fitter, Timing Analyzer, and Assembler.

Figure 1. Compilation Dashboard



The Quartus Prime Pro Edition version of the Compiler supports these advanced features:

- Supports Arria® 10, Cyclone® 10 GX, Stratix® 10, and Agilex™ 7 devices.
- Incremental Fitter optimization—analyze and optimize after each Fitter stage to maximize performance and shorten total compilation time.
- Hyper-Aware Design Flow—use Hyper-Retiming and Fast Forward compilation for the highest performance in Stratix 10 and Agilex 7 devices.
- Partial Reconfiguration—dynamic reconfiguration of a portion of the FPGA, while the remaining FPGA continues to function.
- Block-Based Design Flows—preservation and reuse of design blocks.

1.1. Compilation Overview

The Compiler is modular, allowing you to run only the process that you need. Each Compiler module performs a specific function in the full compilation process. When you run any module, the Compiler runs any prerequisite modules automatically and generates detailed reports at each stage. The Compiler can preserve a "snapshot" of the compilation results after each stage.

Table 1. Compilation Modules

Compilation Process	Description
IP Generation	Identifies the status and version of IP components in the project, reports outdated IP that require upgrade, and generates Intel FPGA IPs in the project.
Analysis & Synthesis	• Analysis & Elaboration—a stage of Analysis & Synthesis that checks for design file and projects errors. It provides different checkpoints or previews (elaborated, instrumented, constrained, and swept) of your design early in the compilation flow and serves as a platform to better analyze your design and improve it. • Synthesis—Synthesizes, optimizes, minimizes, and maps design logic to device resources. The "synthesized" snapshot preserves the results of this stage.
Early Timing Analysis	Combines Synopsys* Design Constraint (SDC) on RTL and post-synthesis static timing analysis. The SDC-on-RTL allows you to integrate SDC constraints that target nodes using the same names as in your RTL design early in the compilation flow and uses them in the later stages of the Quartus Prime compilation. However, you can run the module even without RTL SDCs where you can view the synthesized timing netlist.
Fitter (Place & Route)	Assigns the placement and routing of the design to specific device resources, while honoring timing and placement constraints. The Fitter includes the following stages: • Plan—places all periphery elements (such as I/Os and PLLs) and determines a legal clock plan, without core placement or routing. The "planned" snapshot preserves the stage results. • Place—places all core elements in a legal location. The "placed" snapshot preserves the stage results. • Route—creates all routing between the elements in the design. The "routed" snapshot preserves the stage results. • Retime—moves (retimes) existing registers into Hyper-Registers for fine-grained performance improvement. The "retimed" snapshot preserves the stage results. (1) • Fitter (Finalize)—for Arria 10 and Cyclone 10 GX devices, converts unnecessary tiles to High-Speed or Low-Power. For Stratix 10 and Agilex 7 devices, performs post-Route fix-up. The "final" snapshot preserves the stage results.
Fast Forward Timing Closure Recommendations	Generates detailed reports that estimate performance gains achievable by making specific RTL modifications.

continued...

(1) Retiming and Fast Forward compilation available only for Stratix 10 and Agilex 7 devices.

Compilation Process	Description
Timing Analysis	Analyzes and validates the timing performance of all design logic with the Timing Analyzer.
Power Analysis	Optional module that estimates device power consumption. Specify the electrical standard on each I/O cell and the board trace model on each I/O standard in your design.
Assembler	Converts the Fitter's placement and routing assignments into a programming image for the FPGA device.
EDA Netlist Writer	Generates output files for use in other EDA tools, as Integrating Other EDA Tools on page 147 describes.

Note: Each successive release of the Quartus Prime software typically includes:

- Added support for new features in supported FPGA devices.
- Added support for new devices.
- Efficiency and performance improvements.
- Improvements to compilation time and resource use of the design software.

Due to these improvements, different versions of the Quartus Prime Pro Edition, Quartus Prime Standard Edition, and Quartus Prime Lite Edition software can produce different programming files from release to release.

1.1.1. Compilation Flows

The Quartus Prime Pro Edition Compiler supports a variety of flows to help you maximize performance and minimize compilation processing time. The modular Compiler is flexible and efficient, allowing you to run all modules in sequence with a single command, or to run and optimize each stage of compilation separately.

As you develop and optimize your design, run only the Compiler stages that you need, rather than waiting for full compilation. Run full compilation only when your design is complete and you are ready to run all Compiler modules and generate a device programming image.

Table 2. Compilation Flows

Compiler Flow	Function
Full Compilation Flow	Launches all Compiler modules in sequence to synthesize, fit, analyze final timing, and generate a device programming file. By default, the Compiler generates and preserves only the synthesized and final snapshots during a full compilation. You can optionally **Enable Intermediate Fitter Snapshots** to preserve the planned, placed, routed, and retimed snapshots.
Block-Based Design Flows	Supports preservation and reuse of design blocks in one or more projects. You can reuse synthesized or final design blocks in other projects. Reusable design blocks can include device core or periphery resources.
Incremental Optimization Flow	Incremental optimization allows you to stop processing after each Fitter stage, analyze the results, and adjust settings or RTL before proceeding to the next compilation stage. This iterative flow optimizes at each stage, without waiting for full compilation results.

continued...

Compiler Flow	Function
Hyper-Aware Design Flow	Combines automated register retiming (Hyper-Retiming), with implementation of targeted timing closure recommendations (Fast Forward Compilation), to maximize use of Hyper-Registers and drive the highest performance in Stratix 10 and Agilex 7 devices.
Partial Reconfiguration	Reconfigures a portion of the FPGA dynamically, while the remaining FPGA design continues to function.
ECO Compilation Flow	The Quartus Prime Pro Edition software supports last-minute, targeted design changes (also known as engineering change orders (ECOs)), even after you fully compile the design. ECOs typically occur during the design verification stage. Refer to the *Quartus Prime Pro Edition User Guide: Design Optimization*.

1.1.2. Compilation Hierarchy

The Quartus Prime Pro Edition Compiler generates a hierarchical project structure that isolates results of each compilation stage, for each design entity.

For example, the `dni` database directory contains checkpoint directories pertaining to each of the Analysis and Elaboration stages, such as elaborated, instrumented, swept, and constrained. Similarly, the `synthesized` directory contains a snapshot of the Synthesis stage of the compilation.

If you use design partitions, such as in a block-based design, the Compiler also isolates the results for each design partition. The Compiler fully preserves routing and placement within a partition. Changes to other portions of the design hierarchy do not impact the partition.

This hierarchical structure allows you to optimize specific design elements without impacting placement and routing in other partitions. The hierarchical project structure also supports distributed work groups and compilation processing across multiple machines.

Figure 2. Hierarchical Project Structure

1.1.3. Compilation on a Compute Farm

If you want to run Quartus Prime Pro Edition compiles on a compute farm, use the Design Space Explorer II or manually submit jobs with your regular job submission commands.

For Design Space Explorer II, refer to the following topics:

- Design Space Explorer II Tool
  - Setup Page
  - Project Page
  - Exploration Page
  - Status Page
  - Report Page
- Using Design Space Explorer
- Optimize Settings with Design Space Explorer II
- Optimize Settings with Project Revisions
- Design Space Explorer II Computing Resources
- Design Space Explorer II Optimization Parameters
- Design Space Explorer II Result Management
- Running Design Space Explorer II
- How to Set Up a Remote Farm Machine in the Design Space Explorer II

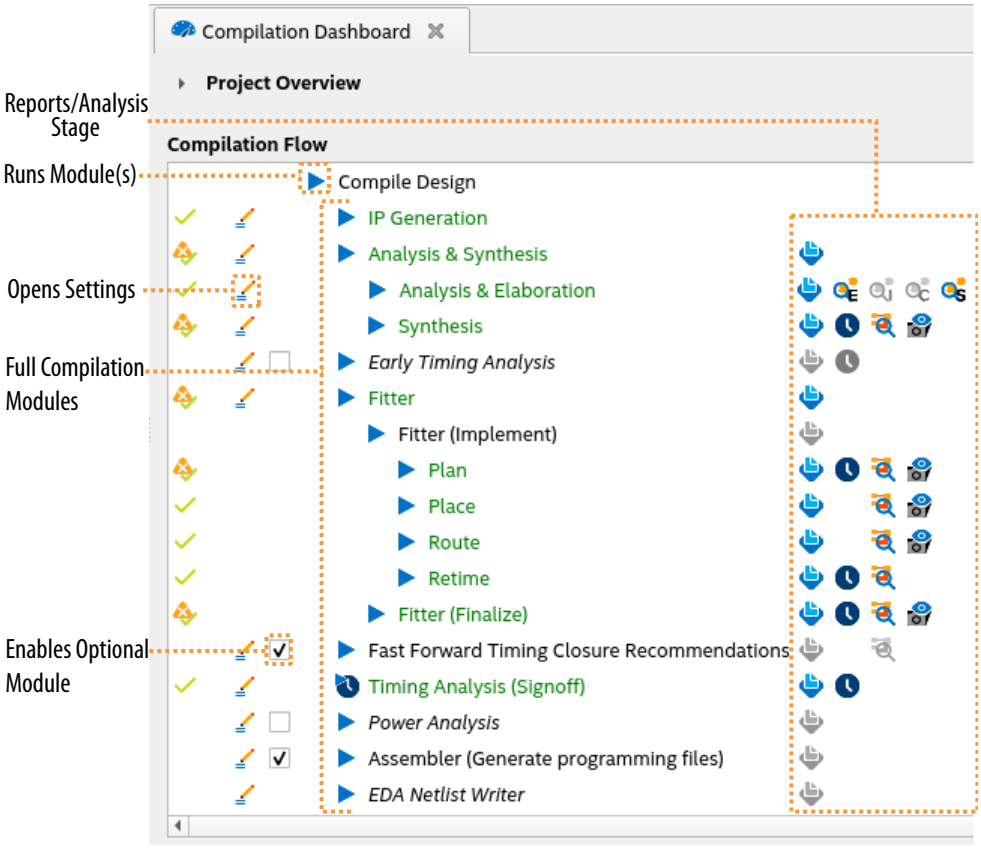
Refer to the command-line commands in the *Quartus Prime Pro Edition User Guide: Scripting* to run a Quartus compilation.

1.2. Using the Compilation Dashboard

The Compilation Dashboard provides immediate access to settings, controls, and reporting for each stage of the compilation flow.

The Compilation Dashboard appears by default when you open a project, or you can click **Compilation Dashboard** in the Tasks window to re-open it.

Figure 3. Compilation Dashboard



- Click the **Pencil** icon to edit settings for that stage of the compilation flow.
- Click any Compiler stage to run one or more Compiler stage.

  You can click a Compiler stage to resume an interrupted compilation flow provided no compilation settings have changed from the initial start of the compilation flow.
- Click the **Report**, **RTL Viewer**, **Technology Map Viewer**, **Timing Analyzer**, or **Snapshot Viewer** icons for analysis of stage results.

As the Compiler progresses through the flow, the dashboard updates the status of each module, and enables icons that you can click for reports and analysis. The dashboard is also updated if you run your compilation flow from a command line with the `quartus_sh --flow` command.

Related Information

1.3. Design Netlist Infrastructure

Design Netlist Infrastructure (DNI) is a major foundational evolution of the Quartus Prime software. It enables new features for faster design convergence and a better user experience.

As a first step, applications and flow for Early Design Analysis have been enabled that unlock the following significant benefits:

- Comprehensive and interactive schematic visualization of an unaltered view of your design (RTL).
- Deeper and advanced design analysis with an intuitive and rich Tcl scripting interface.
- Faster design interactions with granular synthesis.
- Simplified and user-friendly constraint authoring by allowing SDC-on-RTL targets.
- Faster design iterations by SDC cleanup and early timing analysis with post-synthesis timing.

Starting from the 23.3 release, DNI compilation flow is available by default and it is compatible with all components of the design flow. It supports the Assembler to generate and download bit stream to the hardware. It is compatible with Signal Tap, various design flows (Partial Reconfiguration, black box incremental compile, and import/export flows), and simulation model generation.

1.3.1. DNI Netlist Five-Box Data Model

DNI introduces a conventional netlist five-box data model used in most Electronic Design Automation (EDA) tools and uses Tcl commands to traverse the netlist. Consider the following two instances example:

```
module top (input PI_1,
            input PI_2,
            input PI_3,
            output PO_4);

    wire net_2;
    wire net_3;

    AND_OR inst_1(PI_1, PI_2, PI_3, net_2);
    AND_OR inst_2(PI_3, PI_2, PI_1, net_3);
    assign PO_4 = net_2 | net_3;
endmodule

module AND_OR (input in_1,
               input in_2,
               input in_3,
               output out_1);

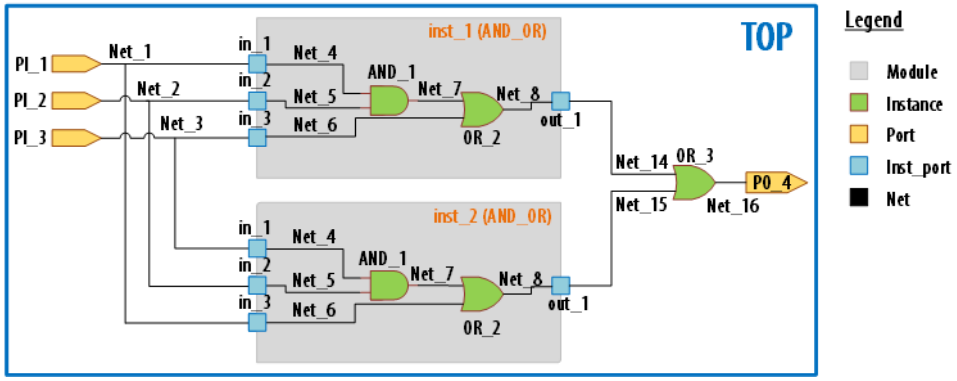
    wire net_1;

    assign net_1 = in_1 & in_2;
    assign out_1 = net_1 | in_3;

endmodule
```

A DNI netlist consists of modules, instances, ports, instance ports, and nets, as shown in the following color-coded diagram:

Figure 4. DNI Netlist Five-box Data Model



The following table describes the core elements of this netlist data model:

Table 3. Core Elements of the Netlist Data Model

Data Model Elements	Description	Tcl Command
Module	A collection of connected netlist objects, such as instances, ports, nets, and instance ports. It is similar to the Verilog module or VHDL entity. Each design has only a single top module containing a group of instances of other modules or library cells. *Note:* A library cell instance is also referred to as a leaf instance.	–
Port	An I/O interface of a module. A design can have input ports, output ports, or bidirectional ports. In the DNI Data Model, `PI_1`, `PI_2`, `PI_3`, and `PO_4` are ports.	`dni::get_ports`
Instance	An instantiation of a module or primitive. A module instance is also referred to as a hierarchical instance, submodule, or a child of the top-level module. A module instance (submodule) may also contain a group of instances of other modules or library cells. These nested module-children instances are referred to as design hierarchies. You can build a hierarchy tree for the entire design with the root as the top module. In the DNI Data Model, `inst_1`, `inst_2`, `AND_1`, `OR_2`, and `OR_3` are instances. *Note:* Multiple unique objects can reference an instance if it exists in a netlist instantiated more than once.	`dni::get_cells`
Instance port (inst_port)	A terminal of an instance. The hierarchical I/O interfaces or leaf instances are referred to as instance ports. Their directions can be input or output. *Note:* FPGA hardware does not support bidirectional signals. Hence, your design must not include any bidirectional instance ports.	`dni::get_pins`

continued...

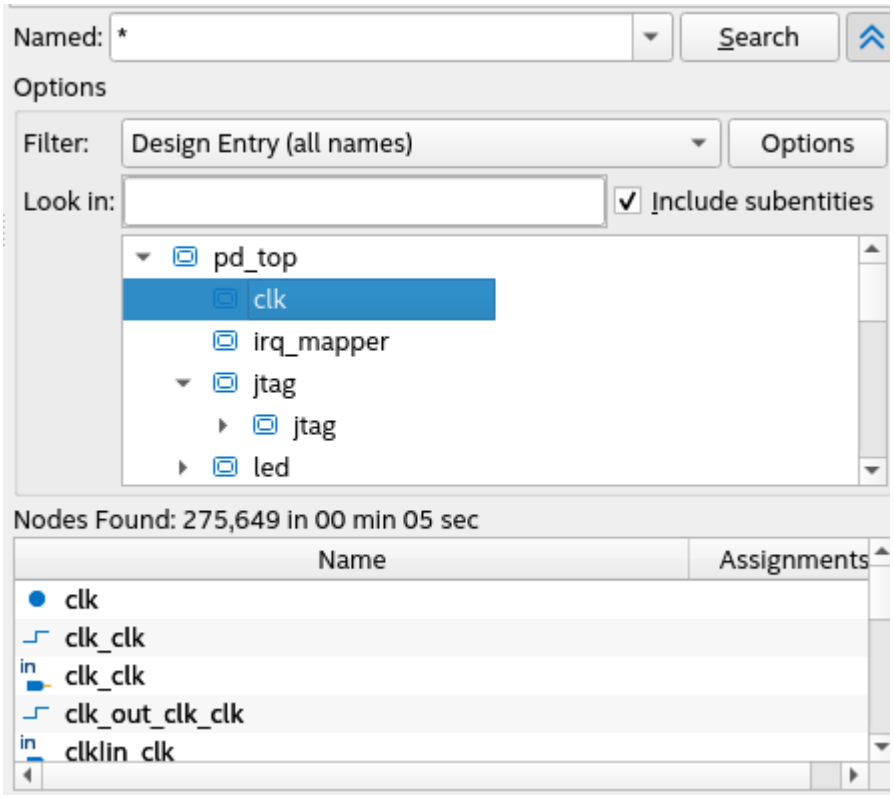
Data Model Elements	Description	Tcl Command
	In the DNI Data Model, `inst_1|in_1`, `inst_2|AND_1|in_1` are few examples of instance ports.	
Net	A wire that connects terminals of instantiations or a netlist. A local net or a hierarchical net is an object within a submodule or top module to hold the connection between instance ports of child instances, instance ports of the submodule boundary, or primary ports of the top module. Hierarchical nets in the submodule and outside the top module of a hierarchical instance port have the same corresponding global or flat net. A global net or a flat net represents the connection of leaf instances or primary ports. In the DNI Data Model, `Net_1`, `Net_2`, `Net_3`, `Net_4` and so on are nets.	`dni::get_nets`

1.4. Using the Node Finder

The Node Finder allows you to search objects in the design netlist based on your search criteria. It returns a list of matching nodes. From the nodes list, you can also locate a node using the RTL Analyzer and other Quartus Prime software tools. In terms of the functionality, it is similar to the Object Finder in the RTL Analyzer. You must complete the Analysis & Elaboration compilation stage to perform a search.

Note: This version of the Node Finder is available only in Quartus Prime Pro Edition software versions 23.3 and later.

To launch the Node Finder, on the Quartus Prime software menu, click **View ➤ Node Finder**. In the following example, the Node Finder has found all user-entered names in your design files:



The **Named** field accepts partial or full-text characters and standard wildcard characters. When you click **Search**, the Node Finder searches all node names matching the specified text. Your search strings are saved, so you can access previously searched strings using the drop-down. The Node Finder provides additional search options (described in the section below) to refine your search.

Node Finder Search Options

Use the **Show More Search Options** button in the Node Finder to apply filters and refine your search. The following search options are available:

Important: Search options available in the Node Finder vary based on the filter you select in the **Filter** drop-down list.

Table 4. Node Finder Search Options

Node Finder Search Options	Description
Filter	Provides a set of default filters. For more information about each filter, refer to the Node Finder Search Filters table. Depending on the filter selected, when you click the **Options** button, some options are enabled, disabled, or grayed out by default.

continued...

Node Finder Search Options	Description
	To refine your search, you can either use one of the default filters or create a custom filter based on one of the default filters using the **Customize** button.
Options	• **Case-insensitivity**: Allows searching case-insensitive node names. By default, the search is case-sensitive. With this option enabled, the search returns the same result irrespective of whether you use lowercase or uppercase search strings. • **Object Type**: Specifies the object type to search for. You can choose between **instance**, **instance_bus**, **instance_port**, **port**, **port_bus**, **net**, and **net_bus**. • **Properties**: Allows adding or removing object properties, such as object name, name of an object's parent, number of ports, source file or line number in the source, and so on. You can type the property values (integer or string) manually.
Look in	Allows you to refine your search hierarchy path. Use the browse button to select the search hierarchy level. It displays the **Select Hierarchy Level** dialog box, allowing you to navigate and select the desired hierarchy level.
Include subentities	Includes node names below the current search hierarchy level in the **Nodes Found** list.
Hierarchy view	Allows you to view nodes in the **Nodes Found** list in hierarchy levels.

Node Finder Search Filters

The following search filters are available in the Node Finder:

Table 5. Node Finder Filters and Search Mode

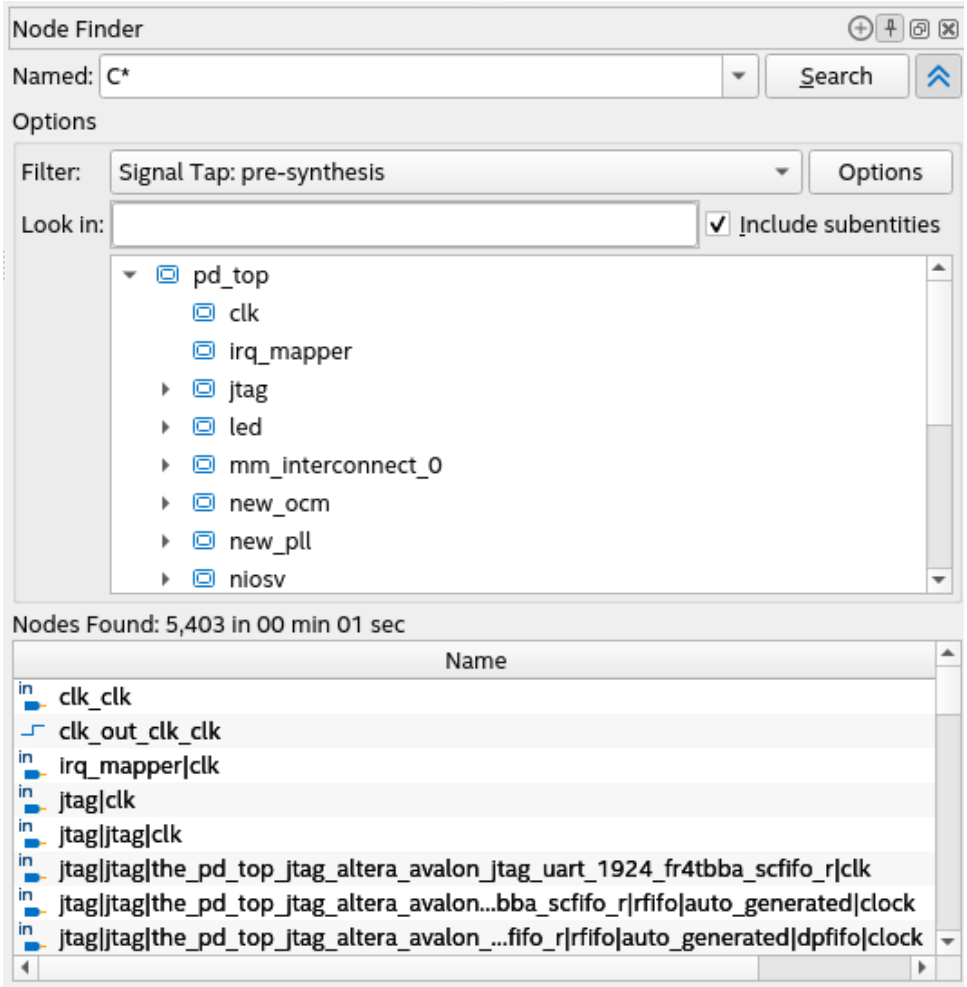
Filter Name	Description
Design Entry (all names)	Finds all user-entered names in the search hierarchy path.
Pins: assigned	Finds all assigned pins in the search hierarchy path.
Pins: unassigned	Finds all unassigned pins in the search hierarchy path.
Pins: input	Finds all input pins in the search hierarchy path.
Pins: output	Finds all output pins in the search hierarchy path.
Pins: bidirectional	Finds all bidirectional pins in the search hierarchy path.
Pins: virtual	Finds all I/O elements mapped to logic elements with a virtual pin logic option assignment.
Pins: all	Finds all pins in the search hierarchy path.
Pins: all & Registers: post-fitting	Finds all pins and registers that persist after physical synthesis and fitting within the search hierarchy path. *Note:* This filter is a combination of the **Pins: all** and **Registers: post-fitting** filters.
Ports: partition	Finds all user-entered and compiler-generated partition ports within the post-fit netlist and search hierarchy path.
Entity instance: pre-synthesis	Finds all entity instances within the pre-synthesis netlist and search hierarchy path.
Registers: pre-synthesis	Finds all user-entered register names contained in the design after Analysis & Elaboration, but before physical synthesis performs any synthesis optimizations.
Registers: post-fitting	Finds all user-entered registers in the search hierarchy path that survived physical synthesis and fitting.
Post-synthesis	Finds all user-entered and synthesis-generated nodes contained in the design after design elaboration and physical synthesis.
Post-synthesis: preserved for debug	Finds all internal device nodes that you have designated with preserve for debug in the post-synthesis netlist.

continued...

Filter Name	Description
Post-Compilation	Finds all user-centered and compiler-generated names that persist post-fit and do not have location assignments.
Signal Tap: pre-synthesis	Finds all internal device nodes in the pre-synthesis netlist that are preserved for analysis by the Signal Tap Logic Analyzer. *Note:* **Signal Tap: pre-synthesis user defined** filter option is unsupported in the DNI mode because functionally, it is same as the **Signal Tap: pre-synthesis**.
Signal Tap: post-fitting	Finds all internal device nodes in the post-fit netlist that are preserved for analysis by the Signal Tap Logic Analyzer.
Signal Tap: post-fitting user defined	Finds all user defined internal device nodes in the post-fit netlist that are preserved for analysis by the Signal Tap Logic Analyzer.
Signal Tap: pre-synthesis preserved for debug	Finds all internal device nodes in the pre-synthesis netlist that are preserved for analysis by the Signal Tap Logic Analyzer.
Signal Tap: post-fitting preserved for debug	Finds all internal device nodes in the post-fit netlist that are preserved for analysis by the Signal Tap Logic Analyzer.

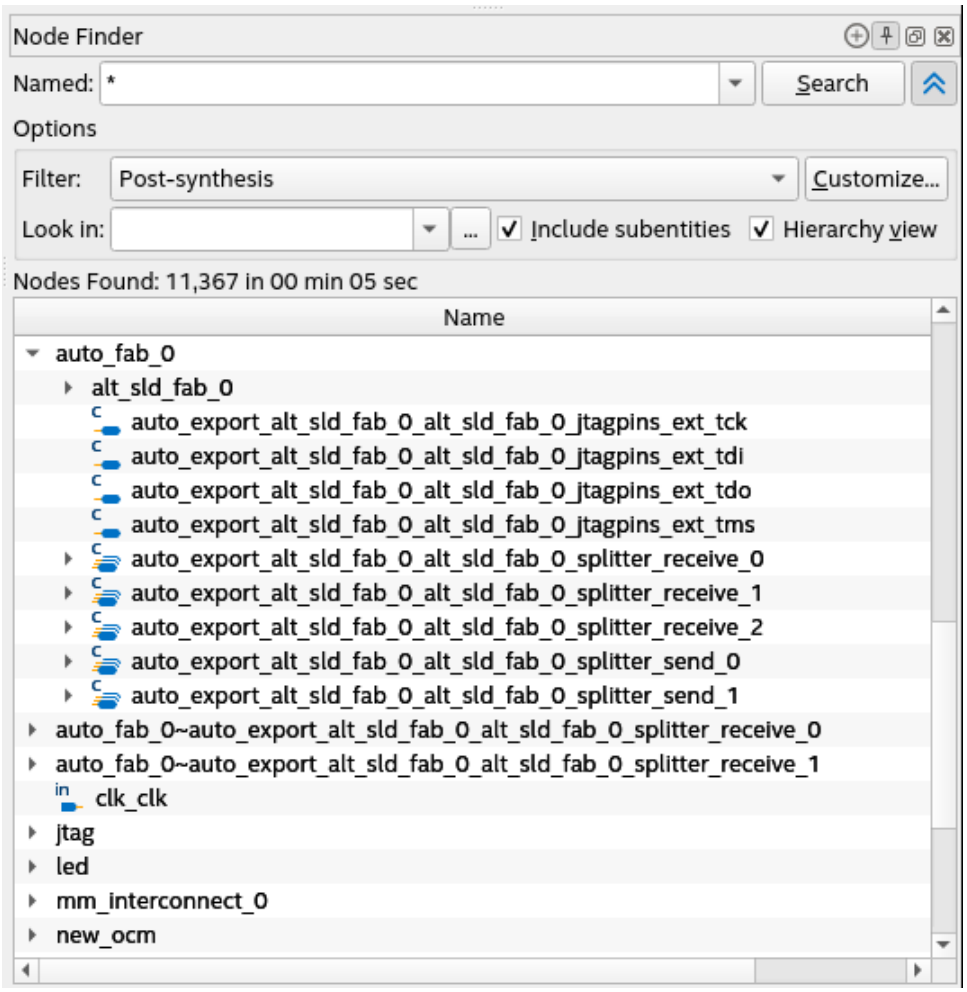
The following image illustrates an example of the Node Finder finding case-insensitive internal device nodes in the pre-synthesis netlist:

Figure 5. Example of Finding Case-insensitive Internal Device Nodes



The following image illustrates an example of the Node Finder using the Post-synthesis filter to find user-entered synthesis-generated nodes in the design:

Figure 6. Example of Finding User-entered Synthesis-generated Nodes



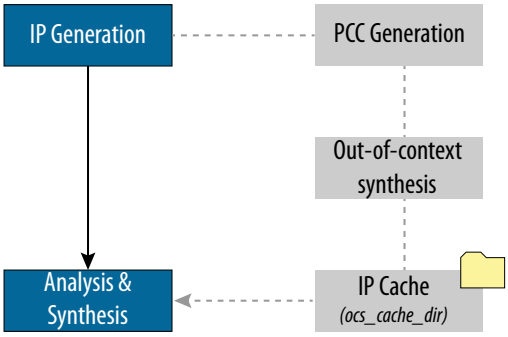
1.5. Precompiled Component (PCC) Generation Flow

Precompiled Components (PCC) generation flow is a compilation stage that runs between IP Generation and Analysis & Synthesis stages on the compilation dashboard. It synthesizes and caches the results of the Intel® FPGA IP components in your design.

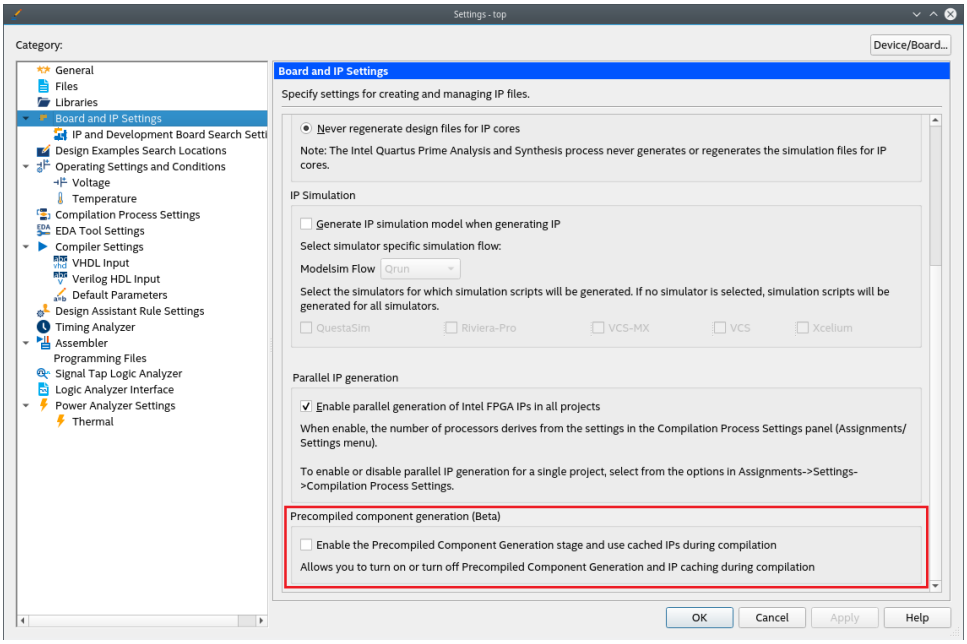
PCC generation reduces Synthesis compile time through the following steps and allows you to iterate and go to post-synthesis timing analysis stages faster and reduce the development cycle time:

1. Synthesizes Intel FPGA IP components in your design.
2. Generates and caches IP compilation results in your project's `ocs_cache_dir` (IP cache) directory.
3. Reuses the IP cache in subsequent Synthesis runs.

Figure 7. PCC Generation



By default, the PCC generation flow is disabled. You can enable it from **Assignments ➤ Settings ➤ Board and IP Settings** dialog as shown in the following:



If the PCC generation flow compiles successfully, you can view the **Precompiled Components** compilation report for each IP that participates in the flow under the **Compilation Reports** dialog.

Advantages of PCC Generation Flow

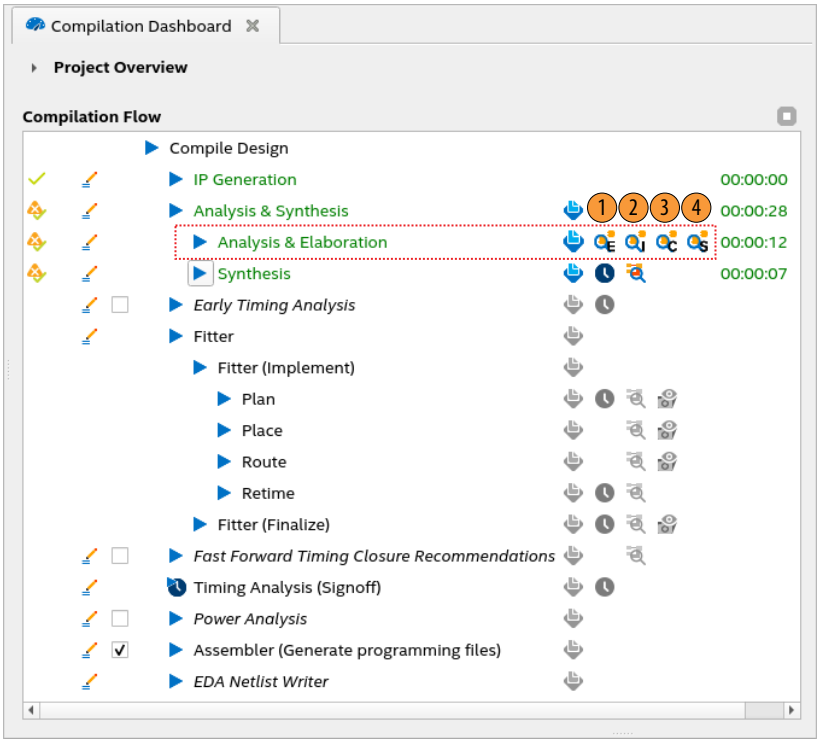
- Each unique IP is generated only once and cached, so the subsequent Synthesis run does not perform PCC generation if you have not modified any IP in your design.
- If you modify any IP, the PCC generation flow synthesizes only that IP and skips synthesizing the remaining IPs.
- The PCC generation process occurs in parallel for each IP.
- Synthesis compile time savings scales with the proportion of the design that is IP.

1.6. Analysis & Elaboration Flow

The Analysis & Elaboration compilation flow provides a complete and unmodified view of your design early in the compilation flow. It serves as a platform to better analyze your design and improve it. With this feature, the monolithic Analysis & Synthesis stage splits into Analysis & Elaboration and Synthesis stages.

This flow allows you to access the preview modes of the Analysis & Elaboration stage, as shown in the following image:

Figure 8. Analysis & Elaboration Checkpoints

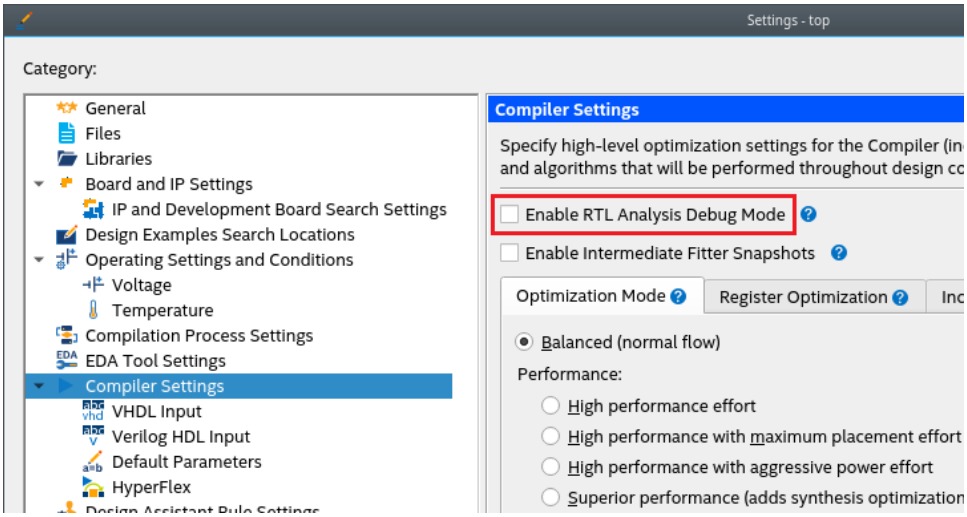


The Analysis & Elaboration stage is composed of a series of checkpoints and you can preview your design at each checkpoint as shown in Analysis & Elaboration Checkpoints, where:

1. **Elaborated**: Provides an unmodified preview of your design captured directly from RTL.
2. **Instrumented**: Provides an instrumented preview with system-level debugging (debug fabric and Signal Tap logic analyzer inserted in your design). This checkpoint is disabled by default (**Hint**: See Note below to enable it).
3. **Constrained**: Provides a design preview with SDC-on-RTL constraints shown on the target nodes. This checkpoint is disabled by default (**Hint**: See Note below to enable it).
4. **Swept**: Provides a design preview with unnecessary logic removed from your design.

Note: You can control the number of checkpoints generated using the **RTL Analysis Debug Mode** option under **Project ➤ Settings**. This mode is off by default, which means only Elaborated and Swept checkpoints are available, and Instrumented and Constrained checkpoints are unavailable. When you enable this mode, all four checkpoints become available.

When the mode is off, you can obtain information about the **Hierarchies Optimized Away** and **Top Causes for Logic Optimized Away During Sweep**, under **Synthesis Compilation Reports ➤ Synthesis ➤ Analysis & Elaboration**.



For information about the Synthesis stage, refer to Design Synthesis on page 58.

Caution: **Incompatibility with older software versions**

A design compiled with the DNI-based compilation flow is not compatible with the Quartus Prime software versions older than 23.3 due to the new DNI database. Ensure the following:

- If you compile your design with the software version 23.3 and launch the project in the Quartus Prime software GUI, a message displays indicating that you compiled your design with a different compilation engine. If you continue to launch the project, then you must recompile the design. This also applies for designs compiled with the Quartus Prime software versions older than 23.3.
- For any partition-based design (for example, Partial Reconfiguration), mixing 23.3 version with 23.2 or older version compilation flow among the user-defined partitions is not supported. You must compile all partitions with the same compilation flow.
- For version-compatible design export or import feature, a design compiled with and exported from an older Quartus Prime version requires the Quartus Prime 23.2 or older version. Similarly, the Quartus Prime 23.3 version is necessary for version-compatible databases compiled with the DNI flow, and this feature is not supported yet.

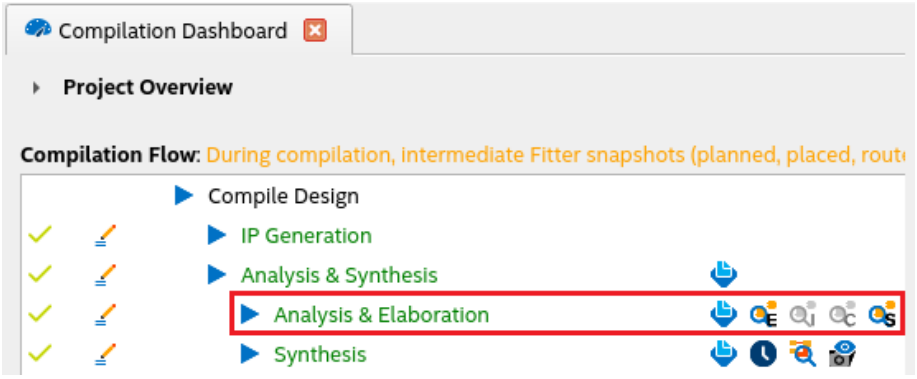
Executing Tcl Commands

The Quartus Prime software GUI (`quartus`) and Synthesis tool (`quartus_syn`) support Tcl commands.

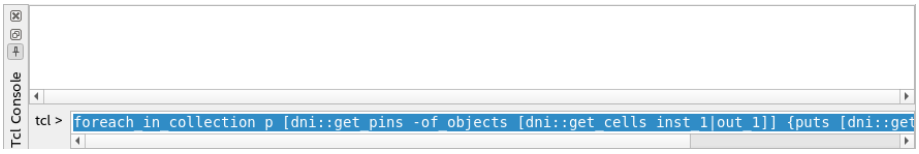
Use one of the following suitable methods to execute your Tcl commands:
Quartus Prime Software GUI (`quartus`)

Perform the following steps in the GUI:

1. On the **Compilation Dashboard**, run **Analysis & Synthesis ➤ Analysis & Elaboration** task to generate the netlist.



2. Click the magnifier icon to Invoke the RTL Analyzer.
3. Execute your Tcl command in the **Tcl Console**.



Synthesis Tool (`quartus_syn`)

1. Enable the flow for your project with the following command:

```
quartus_syn --analysis_and_elaboration <project_name>
```

2. Load your design.

```
> quartus_syn -s
<... Quartus Info Message...>
tcl> project_open top
tcl> dni::load_design -checkpoint elaborated
dms_path::sandboxes::sandbox_1239_0::design
```

3. Execute your Tcl commands:

```
tcl> foreach_in_collection p [dni::get_pins -of_objects [dni::get_cells
inst_1|out_1]] {puts [dni::get_property -name name -object $p]}
a[0]
a[1]
o
tcl> foreach_in_collection p [dni::get_pins -of_objects [dni::get_cells
inst_1|out_1]] {puts [dni::get_property -name direction -object $p]}
input
input
output
tcl>
```

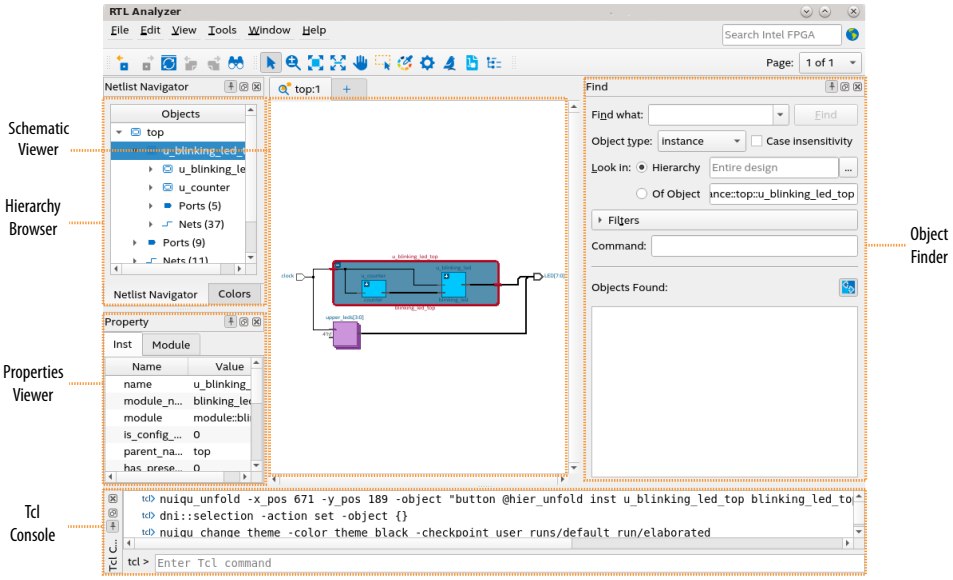
1.6.1. Exploring the RTL Analyzer

You can invoke the RTL Analyzer from the Elaborated checkpoint of the Analysis & Elaboration stage by clicking on the first magnifier icon in the compilation dashboard. For details about checkpoints, refer to the Analysis & Elaboration Flow on page 20.

The RTL Analyzer GUI has the following major components:

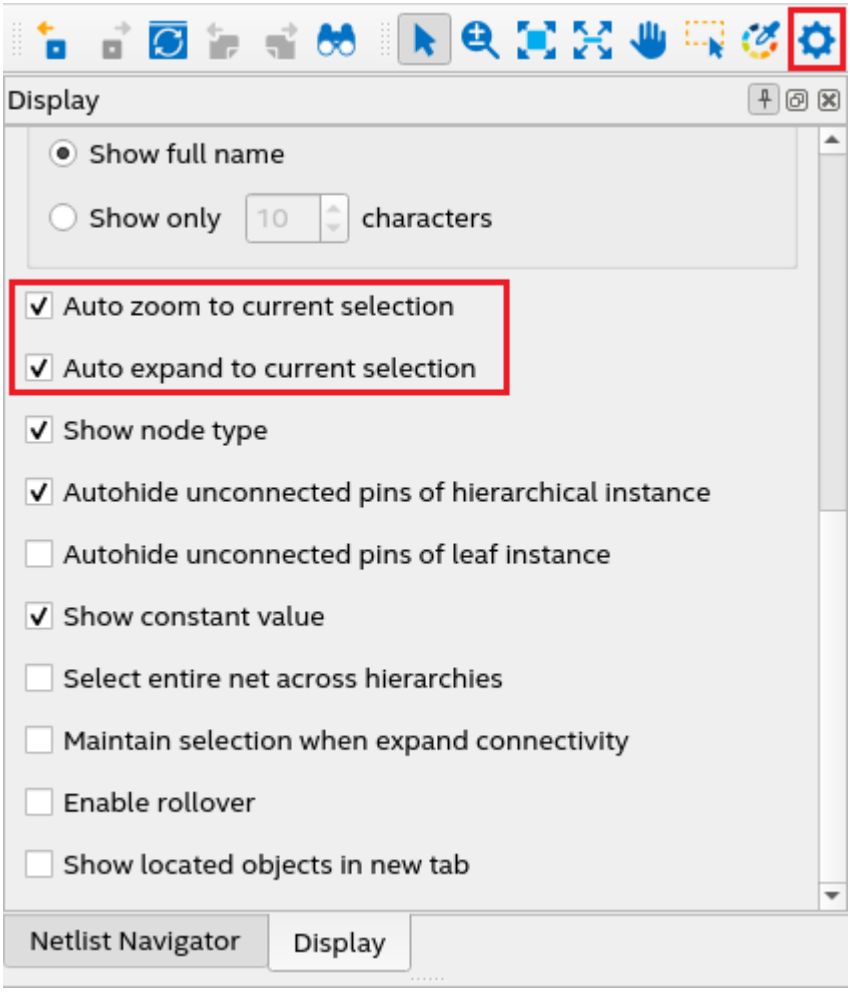
- Design Hierarchy Browser
- Schematic Viewer
- Object Property Viewer
- Tcl Console
- Object Finder

Figure 10. RTL Analyzer GUI



Note: Before exploring your design in the RTL Analyzer, select your desired viewing modes in the **Display** settings by navigating to **View ➤ Display Settings** menu. The **Auto zoom to current selection** and **Auto expand to current selection** modes are enabled by default in the **Display** settings. You can disable one or both of these modes. In the enabled mode, the object you select in the hierarchy browser gets automatically highlighted in the schematic viewer. The schematic viewer and hierarchy browser expands the current selected object's hierarchy and adjusts the view to ensure the object is visible. Disable both modes if you do not want your current view to change in the hierarchy browser and schematic viewer.

Figure 11. Display Settings



Note: RTL Analyzer automatically saves the last view of your design when you close it. So, when you relaunch the RTL Analyzer, the last view is restored, including the highlighted objects and nodes, and you can continue your work from where you left it previously. However, in the event you change your RTL design and recompile the project after exiting the RTL Analyzer, the saved view is invalidated and not restored.

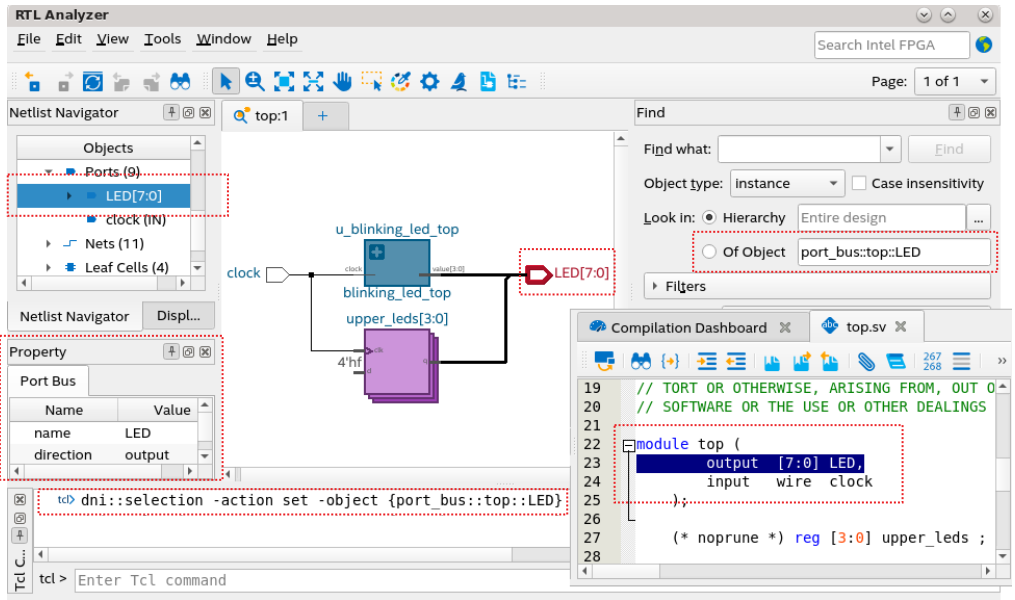
Design Hierarchy Browser

The design hierarchy browser renders the design netlist five-box data model. The core elements of this data model are modules, instances, ports, instance ports, and nets. For more information about this data model, refer to DNI Netlist Five-Box Data Model on page 11.

All objects in the hierarchy are organized by the object type. For example, I/Os are grouped based on the direction.

Various GUI elements of the RTL analyzer are synchronized and respond to the objects within the **Objects** pane. For example, for the currently selected object in the hierarchy browser, the schematic viewer brings the object into focus with a highlight, the **Tcl Console** emits an equivalent Tcl command, and the **Properties** viewer provides relevant information about the object. You can cross-probe from selected objects in the netlist to the source where they were defined by right-clicking on an object and selecting **Locate Node ➤ Locate in Design File** option in the context-sensitive menu. The source file displays in the Quartus main window showing the line that instantiates the object.

Figure 12. Cross-probing Selected Objects in the Netlist



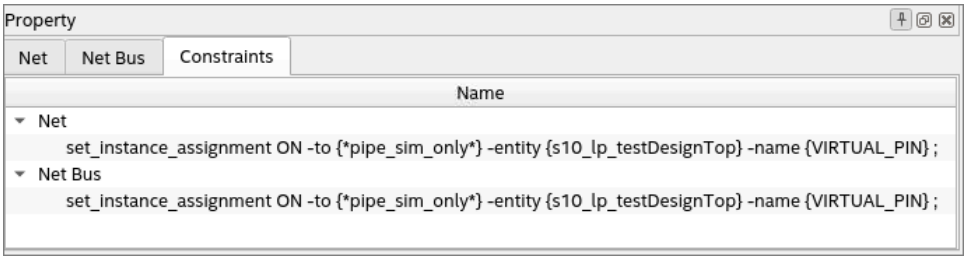
Schematic Viewer

The schematic viewer represents the design elements, such as modules, instances, ports, instance ports, and nets, schematically within the viewer. The viewer reacts and updates to bring different objects into focus as you navigate through the netlist.

Properties Viewer

The **Property** pane provides information about assignments and SDC constraints attached to the selected object in the hierarchy browser. You can cross-probe to the definition of the assignment in the source file.

Figure 13. Property Viewer Showing Constraints



Tcl Console

The Tcl Console provides a robust scripting interface that reports issues and displays relevant Tcl commands for GUI actions. It allows you to traverse and analyze your design. As you type the Tcl commands, notice how the schematic viewer and the hierarchy browser respond accordingly.

Object Finder

The object finder helps in locating an object in the design netlist. You can refine your search based on the object type (instance, instance bus, inst_port, port, port_bus, net, and net_bus) and modules. For complicated designs, you can further use filters to refine your search.

The RTL Analyzer provides the following tools and functionality:

Sweep Hints Viewer on page 26
Object Set Console on page 33
Module Interfaces on page 37
Bundled Instances on page 40
Auto-hide Unconnected Pins on page 45
Filtering Ports and Nets on page 46
Expand Connections on page 49

Related Information

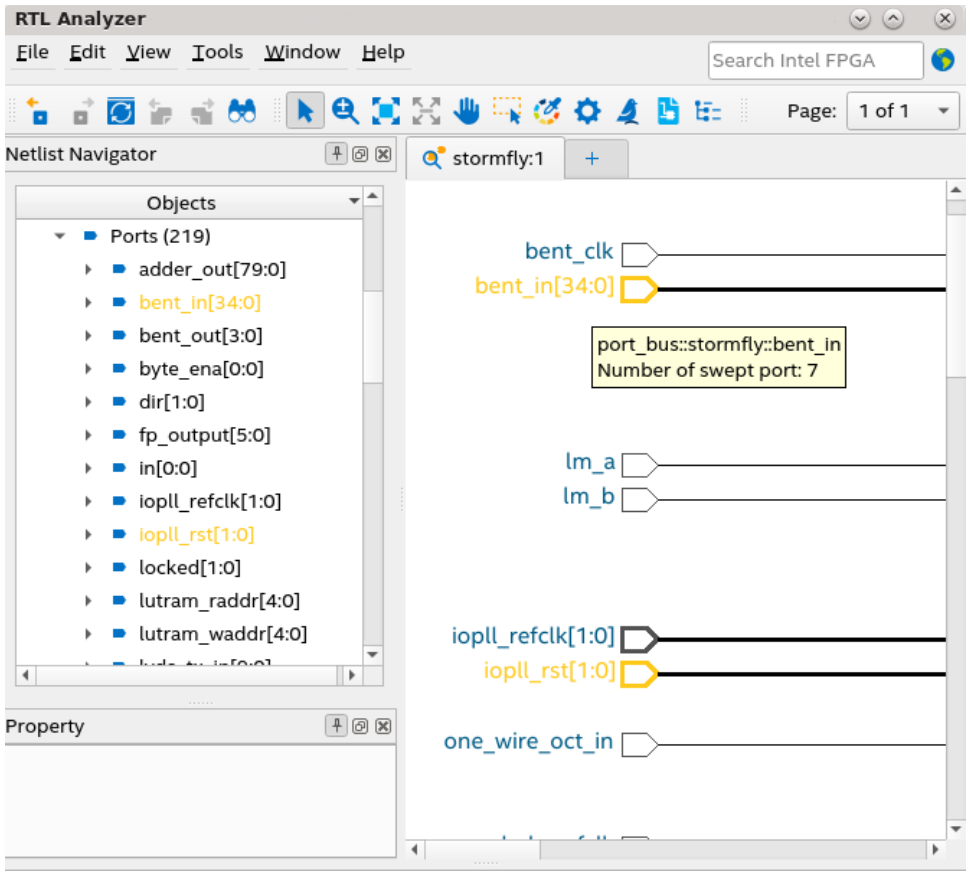
Overview Video: RTL Analyzer for Quartus Prime Software

1.6.1.1. Sweep Hints Viewer

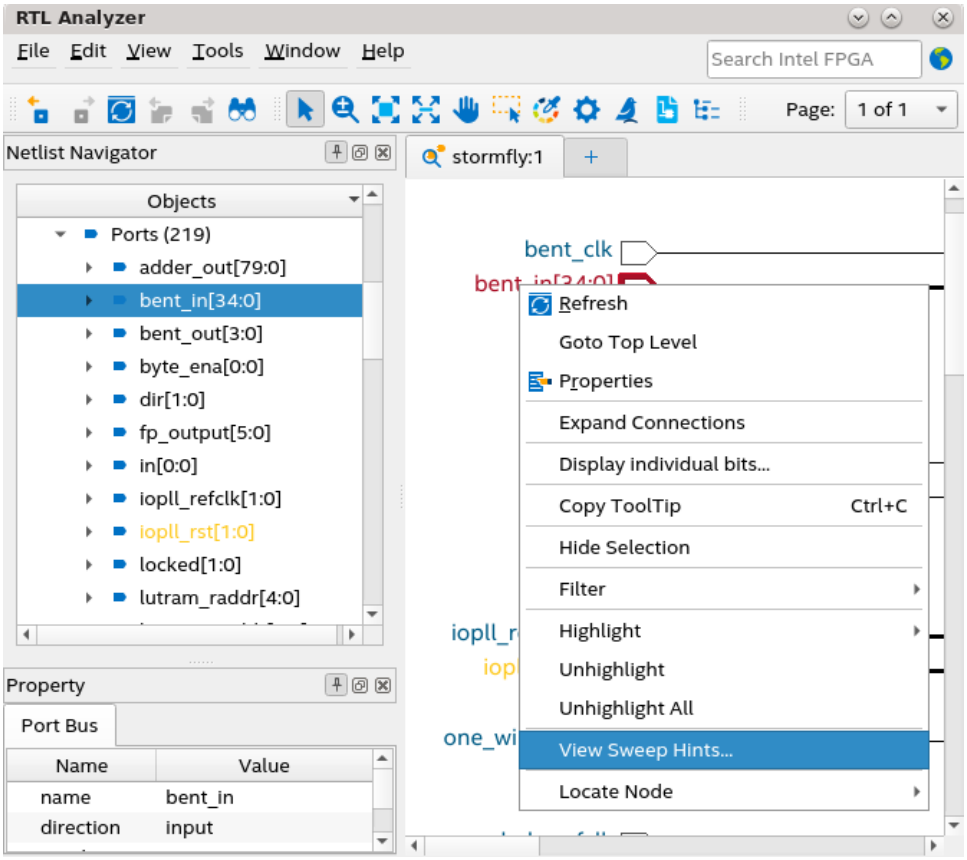
Sweep Hints Viewer allows you to visualize and identify why Synthesis removed logic in your design. It is one of the RTL Analyzer tools you can access from the menu by selecting **Tools ➤ View Sweep Hints**. You can also launch it from the context-sensitive menu of the swept instance.

The RTL Analyzer highlights the top-level module port and leaf instance with associated sweep hints in orange color. When you hover over the swept port or instance, the tooltip displays the number of swept ports, sweep hint type, and sweep hint reason. These highlights and tooltips are available in both the schematic view and the Netlist Navigator, as shown in the following image:

Figure 14. Sweep Hints View in the RTL Analyzer

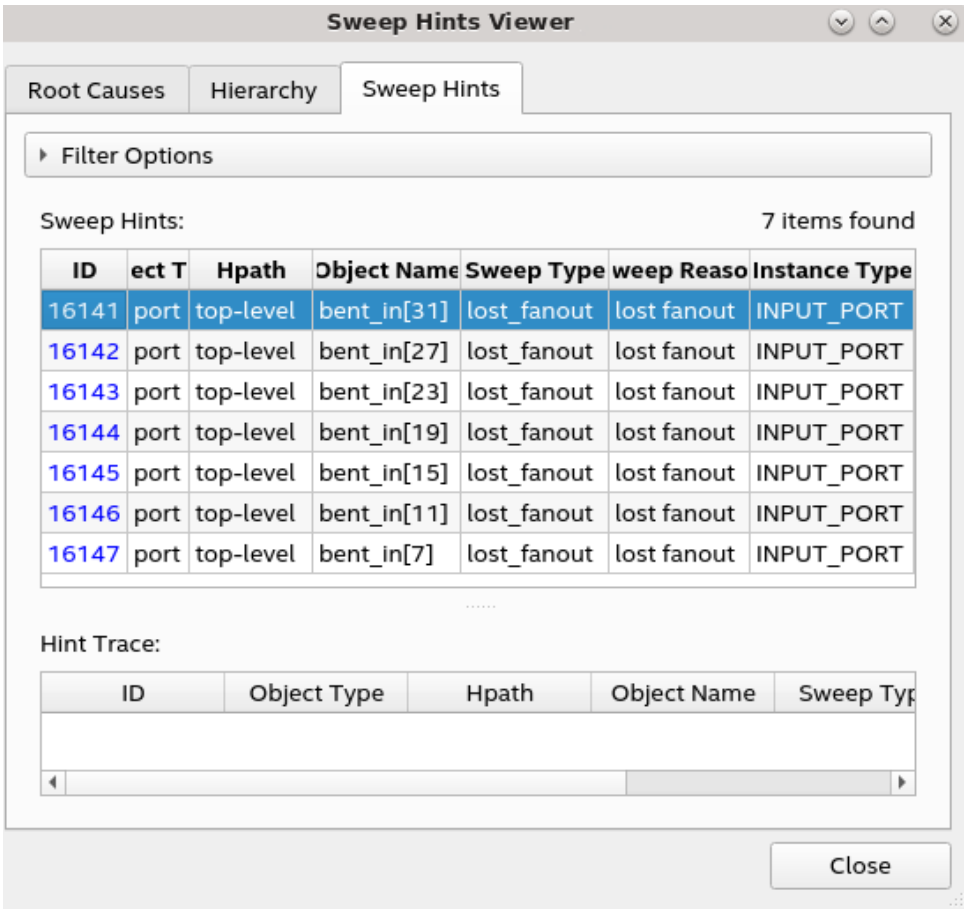


From the RTL Analyzer, you can launch Sweep Hints Viewer by selecting **View Sweep Hints** from the context-sensitive menu of the swept instance or the top-level module port in the netlist navigator or schematic view, as shown in the following image:



Upon selecting the **View Sweep Hints** option from the context-sensitive menu, the Sweep Hints Viewer auto-populates with sweep hints of the selected instance or port, as shown in the following image:

Figure 15. Auto-populated List of Sweep Hints for the Selected instance



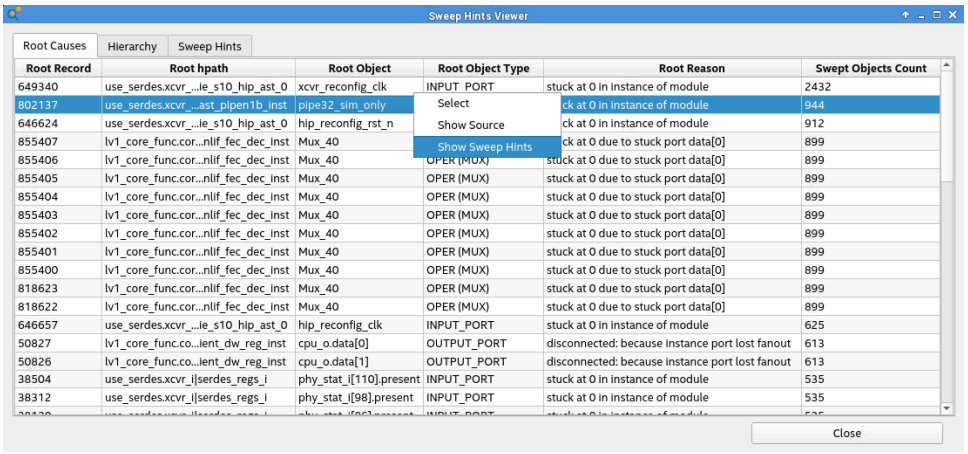
Root Causes View of the Sweep Hints Viewer

To identify the root cause for a particular node in the design being swept away, you must understand various reasons behind why a single node was marked during the sweep, as listed in the following:

- A node stuck at constant 0 or 1. For example, an input port of an AND gate stuck at 0 triggers a sweep of the AND gate since the output of the AND gate is also stuck at 0.
- A node behaved as a wire and was deleted. For example, a multiplexer whose select line is connected to constant acts as a wire.
- A node was modified during the sweep but it was not deleted.
- A node lost all fan-outs and it was deleted.
- A port or instance port got disconnected because the parent or child did not have a fan-out.

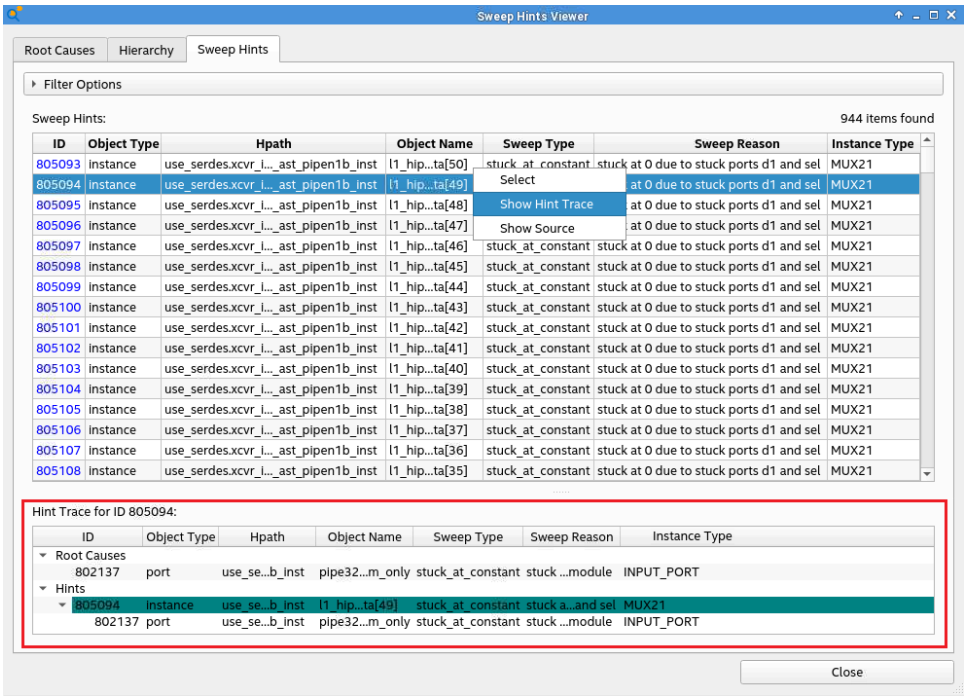
The **Root Causes** tab of the Sweep Hints Viewer provides a list of sweep records and their root cause for being swept away, as shown in the following example:

Figure 16. Root Causes Tab of the Sweep Hints Viewer



The Root Causes view shows the root reason and total number of swept objects of a root object in the **Swept Objects Count** column, which you can trace to a sweep record in the **Root Record** column (for instance, 802137 in the above image). Selecting the **Show Sweep Hints** option in the context-sensitive menu switches the interface to the **Sweep Hints** view to show all sweep records that identify the root record as the root cause, as shown in the following image:

Figure 17. Tracing Sweep Records of a Root Record



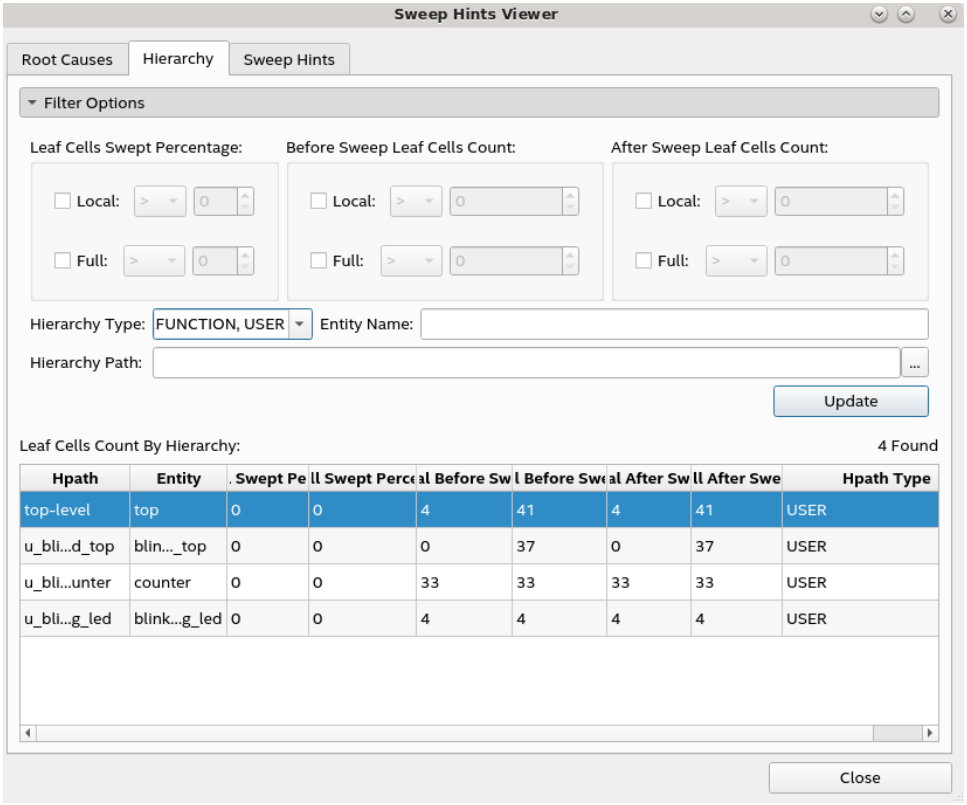
Note: For more information about the **Show Hint Trace**, refer to the Sweep Hints View of the Sweep Hints Viewer on page 32 section.

Hierarchy View of the Sweep Hints Viewer

Recall from the Analysis & Elaboration Flow on page 20 how to sweep optimization (Swept checkpoint) happens as part of the Analysis & Elaboration stage. The sweep optimization phase leaves behind a database of objects that are swept away along with the reason for their removal. The database also tracks relationships between the removed objects. For example, if an output of a gate is dangling, it is swept away. Few cells in the fan-in cone can also be swept away because their output does not drive anything useful. The Sweep Hints Viewer allows you to view the sweep hints database with a list of marked objects in the pre-swept design that are removed later.

Note: For large and complex designs, the total number of swept objects can be significant (in millions). Hence, the swept objects are hierarchically arranged so that you can quickly query, filter, and find regions of your interest.

Figure 18. Hierarchy Tab in the Sweep Hints Viewer



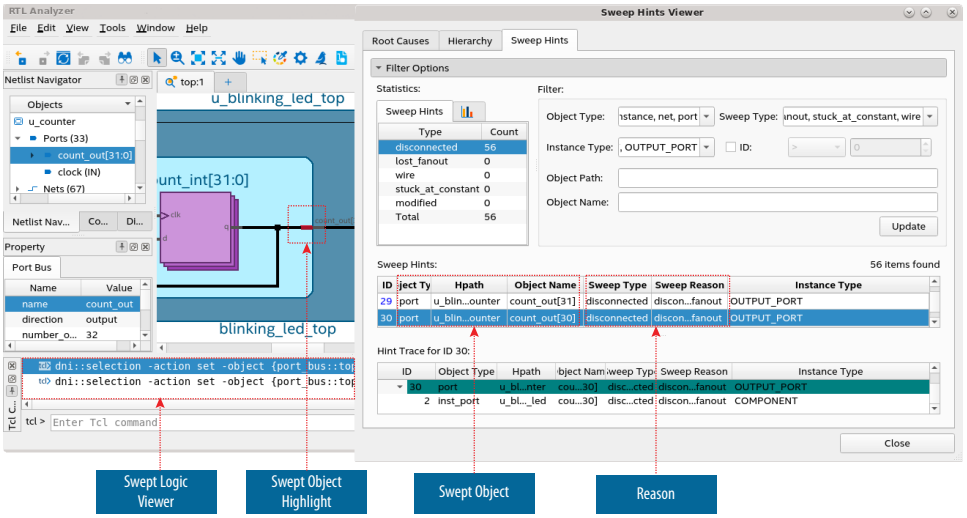
Within the **Hierarchy** tab of the Sweep Hints Viewer, you can observe various hierarchy levels and their sweep statistics. The logic unit here is a leaf cell, which refers to logical primitives, such as AND/OR gate or registers. A hierarchical cell is a composite of leaf cells and other hierarchical cells.

The **Leaf Cells Count by Hierarchy** table in the above image provides information about the percentage of the logic swept either locally or in the full hierarchy of a given hierarchical path. The table columns for the number of leaf cells indicate before and after a sweep and the type of hierarchical path, which can be USER (RTL you designed), Intel IP, or MEGAFUNCTION (Intel-provided library modules). If the hierarchy table is large, use the filter options to refine the regions of your design.

Note: Intel IP and MEGAFUNCTION types are hidden by default since you cannot modify them. However, you can view them in specific circumstances by selecting the desired option in the **Hierarchy Type** drop-down list. Encrypted modules are always hidden from this view.

Sweep Hints View of the Sweep Hints Viewer

Figure 19. Example of Swept Objects in the Sweep Hints Viewer



Notice the swept object highlighted with the teal color in the schematic view. If you hover over this object tooltip or view the sweep reason in the Sweep Hints Viewer, you can see that this instance was swept away because the instance port lost fanout. Similarly, you can select other swept objects to identify their root cause and view them in the schematic viewer and hierarchy view. All these objects are eventually swept away from the design when you proceed with the compilation flow.

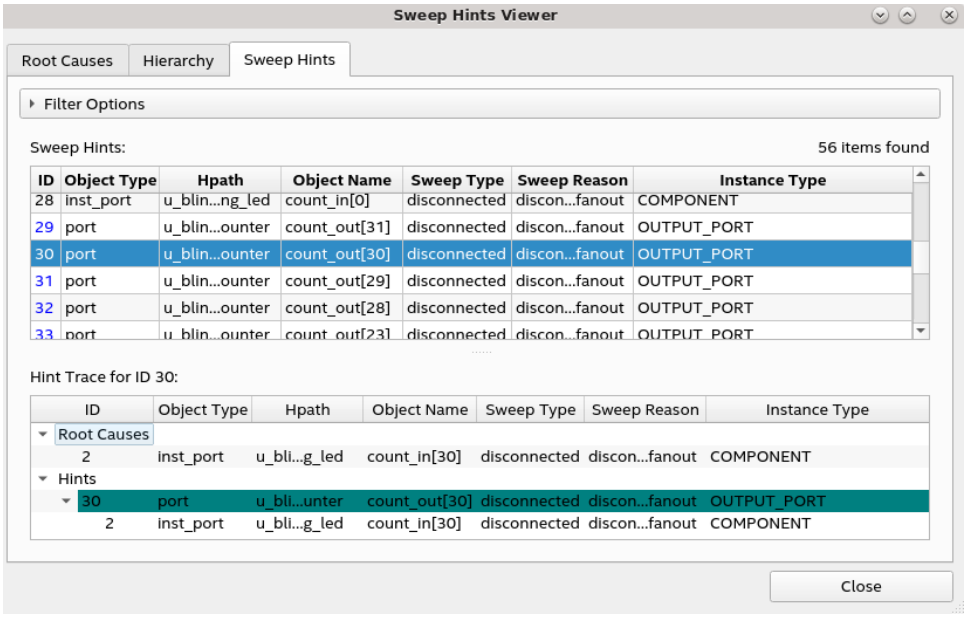
While the **Hierarchy** tab helps filter by the sweep statistics of an instance, the **Sweep Hints** tab allows you to filter and query the leaf objects swept away in a given hierarchy level. Various columns in the table describe the object involved in the sweep and provide ways to query data. For instance, you can look for specific instance types or limit the results to specific sweep reasons, types, and so on.

Viewing Related Swept Objects

You can also view related swept objects by right-clicking on a select object under **Sweep Hints** and selecting **Show Hint Trace** in the context-sensitive menu. **Hint Trace for ID <*number*>** section displays a hierarchical listing of swept objects that caused a particular object to be swept away and objects swept away as a result of one object. The ability to highlight and select various objects in the chain allows you to narrow down the desired sweep information.

In the following figure, when you trace the sweep hints for a port with object ID 30, under **Hint Trace for ID *30***, you notice an instance port with object ID 2 being related to the swept port 30. The sweep reason for both objects is disconnected fanout.

Figure 20. Related Swept Objects



1.6.1.2. Object Set Console

The Object Set Console helps you conveniently navigate and manipulate the currently selected, highlighted, or colored node object sets when you have multiple lists to manage in the console. To launch the Object Set Console dialog box, select **View ➤ Object Set Console Window** on the RTL Analyzer menu.

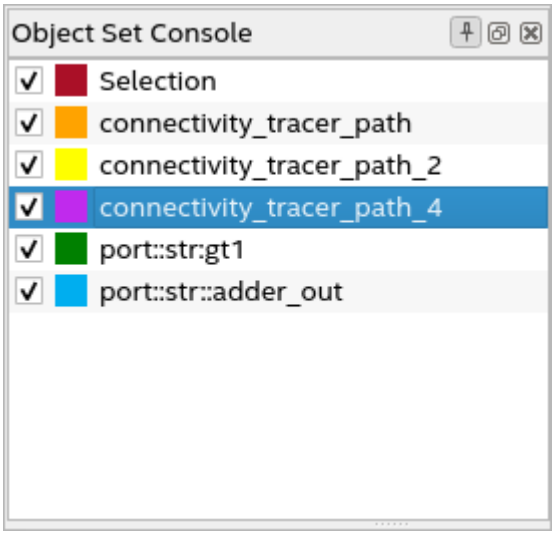
The Object Set Console is split into a top pane and a bottom pane, which are explained in the following sections:

Top Pane of the Object Set Console Window

The top pane displays the design's currently selected, highlighted, or colored nodes.

Consider an example where you traced fan-in or fan-out connectivity of your design. When you view a specific traced path, it gets highlighted in the schematic viewer. When you click **Show Path** for one or more traced paths, the top pane lists all paths in different color codes, as shown in the following image:

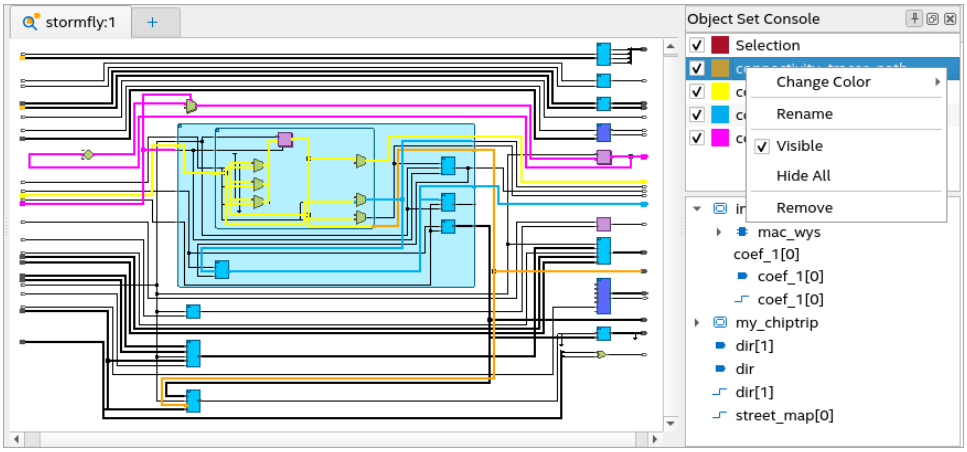
Figure 21. Top Pane of the Object Set Console



Note: You can save all highlighted paths and restore them anytime using the **Save** and **Restore** options, respectively, from the context-sensitive menu.

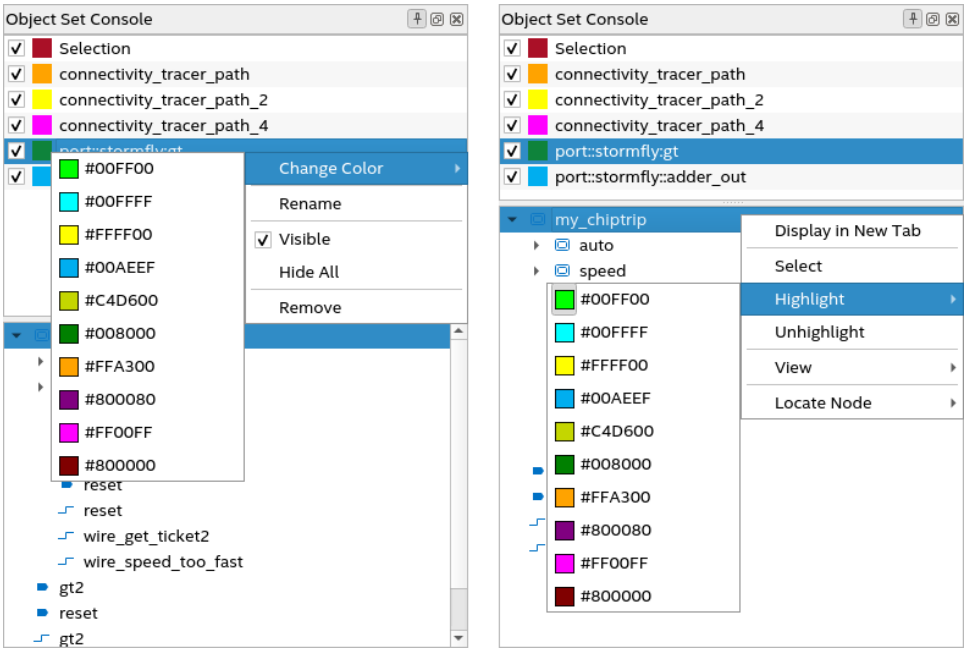
Use the context-sensitive menu to change node color, rename the traced path identifier, toggle a node's visibility, hide one or more traced paths. or delete a node from the list, as shown in the following image:

Figure 22. Object Set Console Window



To change the node color, use the **Change Color** option. Alternatively, you can directly use the **Highlight** option in the bottom pane to select a color and highlight the traced path in the desired color.

Figure 23. Changing Node Color from the Context-sensitive Menu



Bottom Pane of the Object Set Console Window

When you select one of the nodes in the top pane, the bottom pane displays a tree or list view of all netlist objects (ports, instances, instance ports, and nets) that are part of that node. Using the context-sensitive menu, you can select and view the desired node in a new tab within the schematic viewer and highlight/unhighlight the path with a different color.

With the **View** sub-options (List, Hierarchy, and Type), you can change the view of the traced paths. By default, the objects are organized hierarchically in the bottom pane.

- **List** lists out all the netlist objects.
- **Hierarchy** arranges the netlist objects in the traced path hierarchically. This is the default view.
- **Type** categorizes and lists netlist objects by type (for example, Ports and Nets).

Figure 24. Bottom Pane Context-sensitive Menu

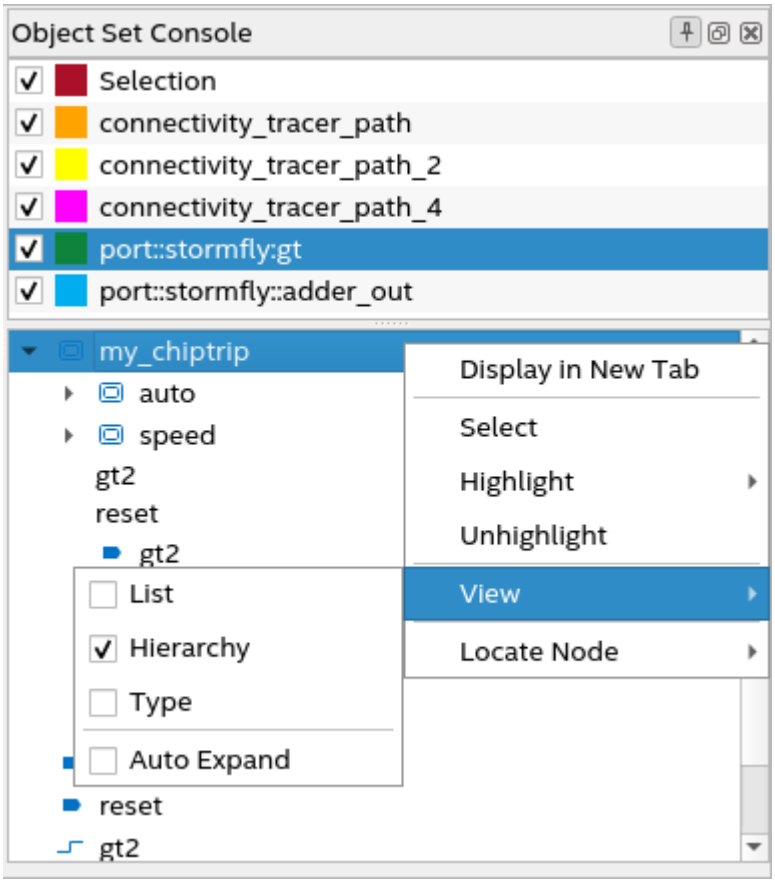


Figure 25. Example of Displaying a Node in a New Tab in the Schematic Viewer

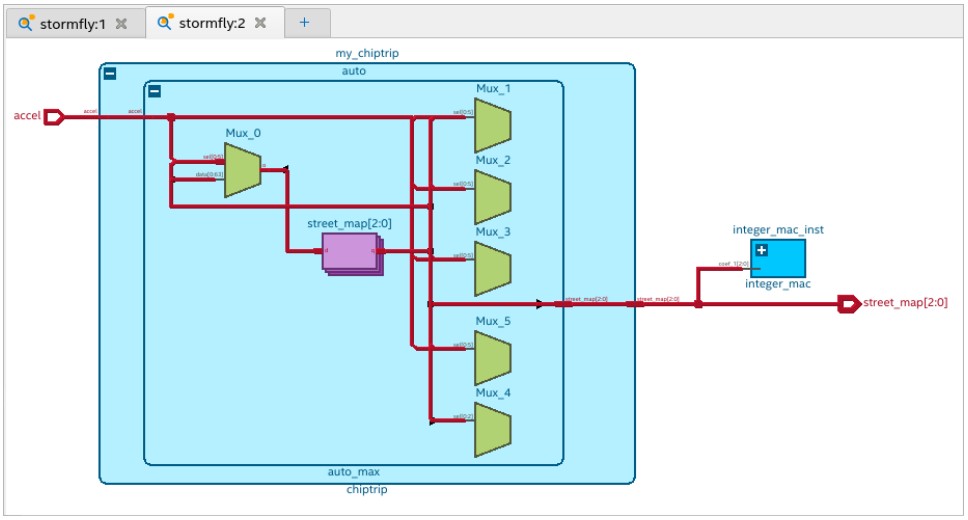


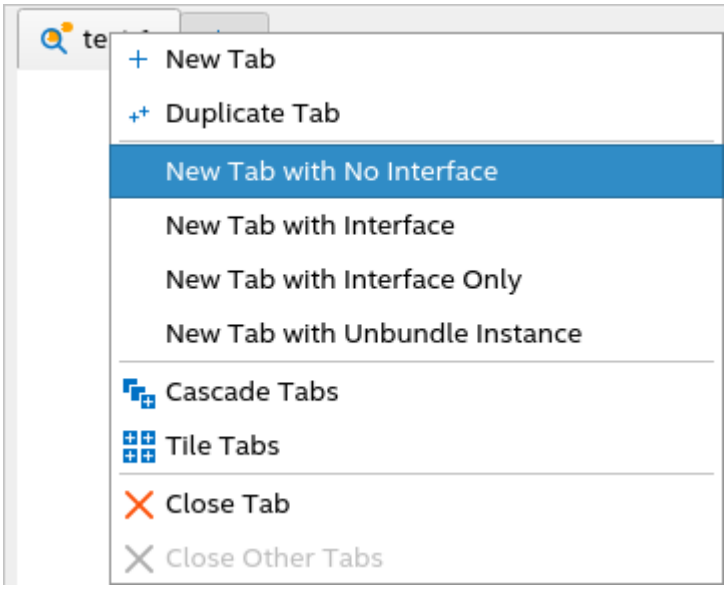
Bottom Pane

The bottom pane lists all netlist objects, such as ports, instances, instance ports, and nets, currently selected in the schematic viewer. Using the context-sensitive menu, you can view the object in a new tab or locate the node in the design file.

1.6.1.3. Module Interfaces

The schematic viewer in the RTL Analyzer supports viewing module interface for designs containing interfaces in the SystemVerilog. You can access the interface modes by launching your design in the schematic viewer and selecting one of the interface modes from the tab's context-sensitive menu. The RTL Analyzer supports three interface modes, as shown in the following image:

Figure 27. Interface Modes



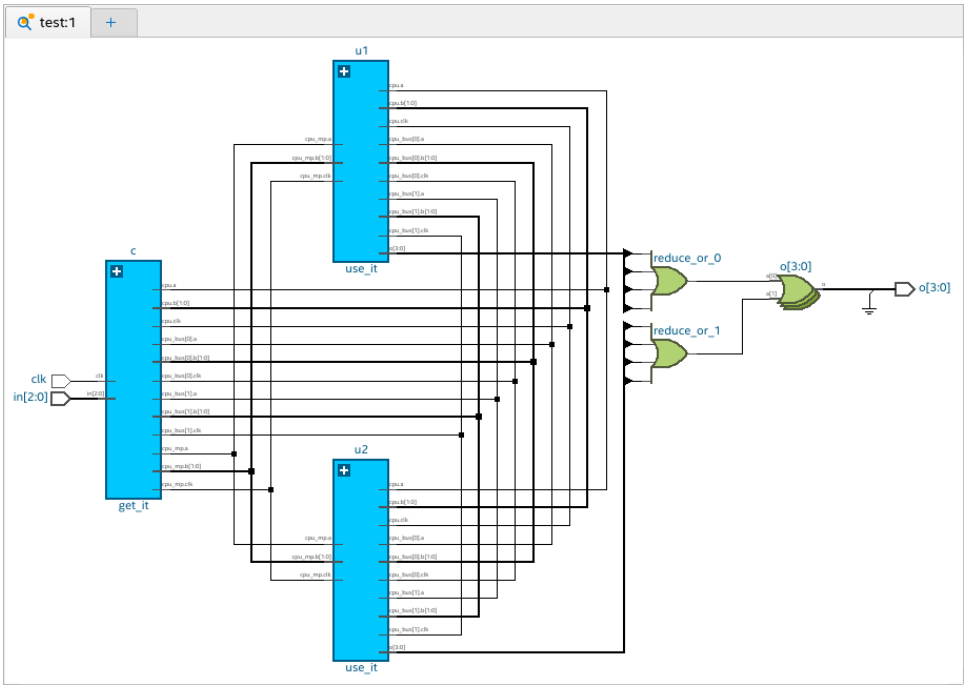
Note: For details about the unbundle instance mode, refer to Bundled Instances on page 40.

No Interface Mode (Default)

This is the default mode where all ports display individually, even if they are part of an interface.

In the following example, you can observe that all ports for c, u1, and u2 modules are listed without any grouping of ports.

Figure 28. No Interface Mode

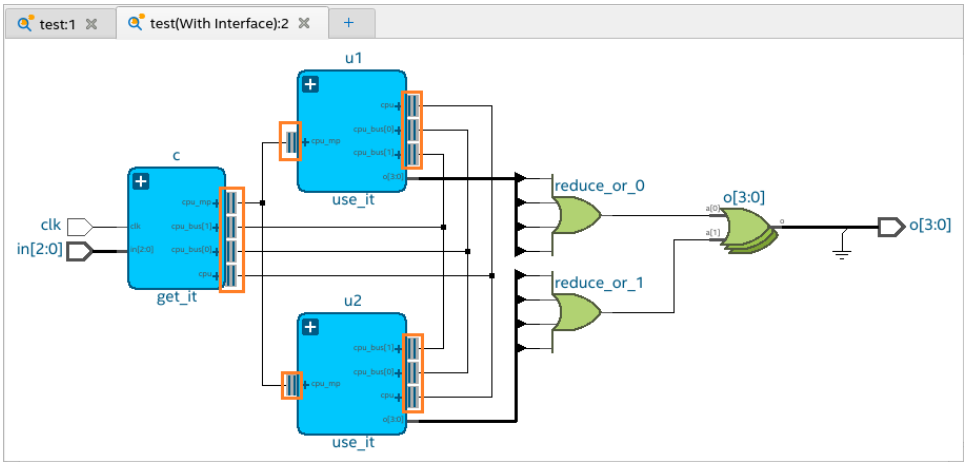


With Interface Mode

In this mode, all ports of an interface are grouped to show a compact and simplified view of the schematic. Interfaces have an expand button "+" and double vertical lines beside the port. You can expand each interface to view all ports under the interface.

In the following example, you can observe that in the u1 module, all ports that are part of cpu, cpu_bus[0], cpu_bus[1], and cpu_mp interfaces are grouped (indicated by the '+' symbol). Each interface has two dark gray lines marked beside them.

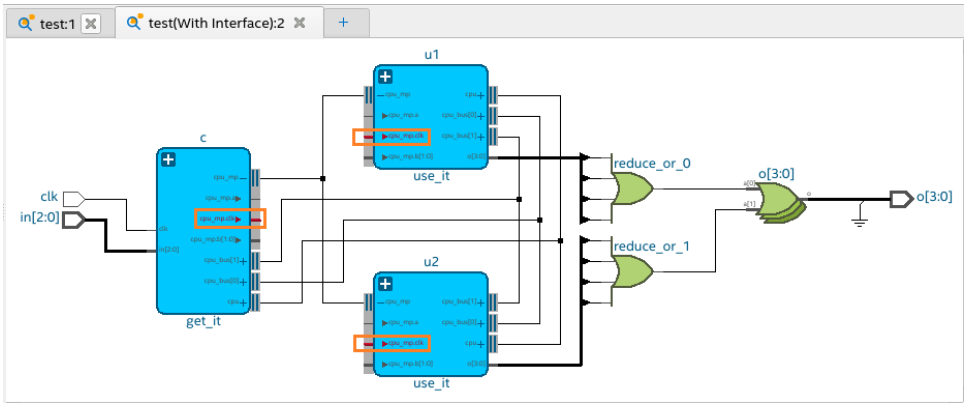
Figure 29. With Interface Mode



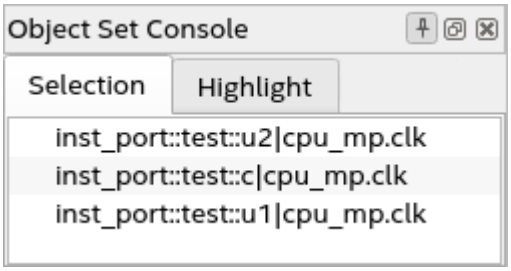
In this mode, all related ports (input/output) are automatically highlighted when you expand an interface and select any port under the interface.

In the following example, you can see that when you expand the `cpu_mp` interface in `c`, `u1`, and `u2` modules and select the `cpu_mp.clk` port in one of the modules, all related ports (highlighted in red) are automatically highlighted, as shown in the following image:

Figure 30. With an Interface Expanded



Note: You can also view these related ports in the Object Set Console Window.

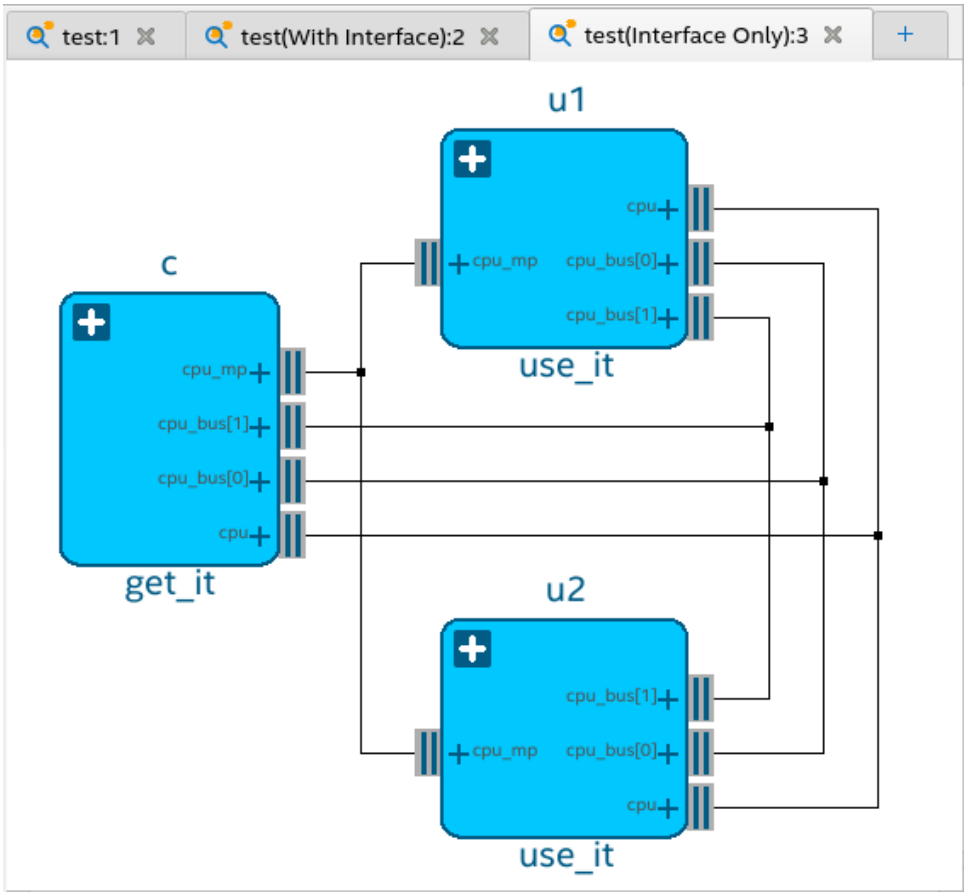


Interface Only Mode

In this mode, only modules with interfaces are shown in the schematic viewer. All non-interface ports and objects are removed. This mode is helpful in viewing the relationship between modules that are connected by an interface. You can expand each interface to view all ports under the interface.

In the following example, you can observe that the non-interface port `o[3:0]` is removed in `c` and `u1` modules, and all other objects are no longer visible in the schematic viewer.

Figure 31. Interface Only Mode



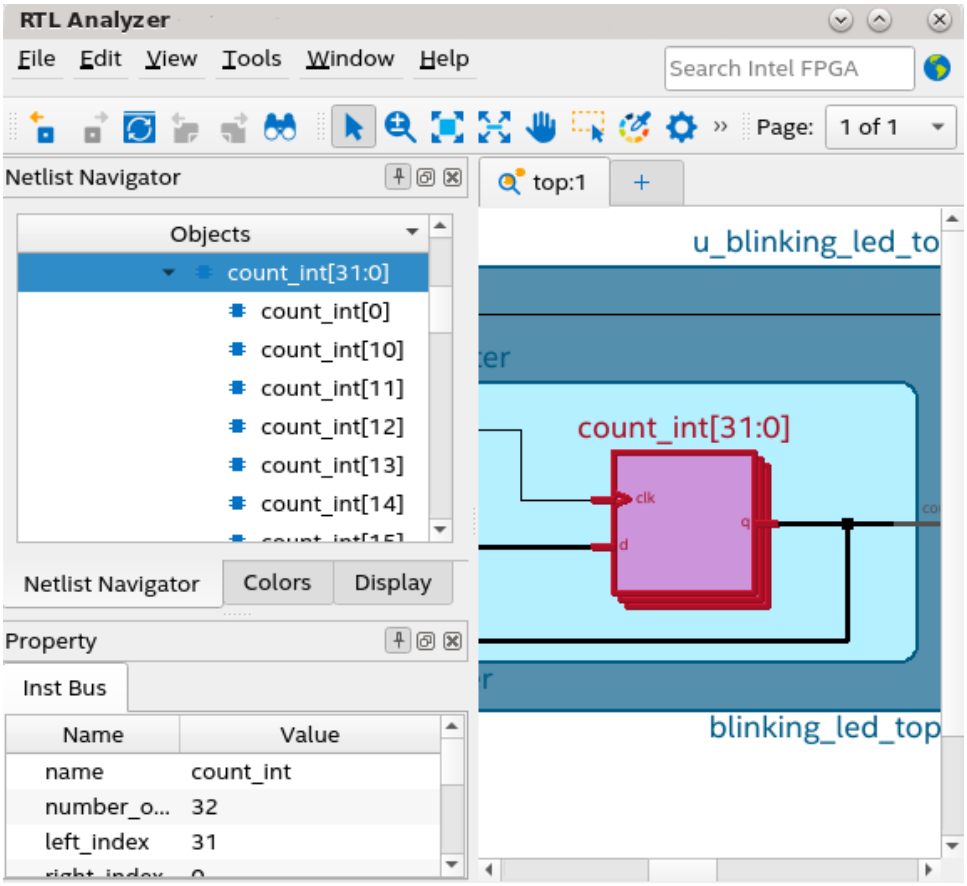
1.6.1.4. Bundled Instances

To improve schematic readability, the RTL Analyzer bundles single-bit instances into a collection known as a bundled instance and hides unconnected pins of instances by default.

Bundled instances appear stacked, and the indexes of the bits appear in the instance name as left and right indexes. You can expand bundled instances to view single-bit instance members in the hierarchy browser. You can view more information about a bundled instance, such as the number of instances, left and right index, and instance members from the Property viewer.

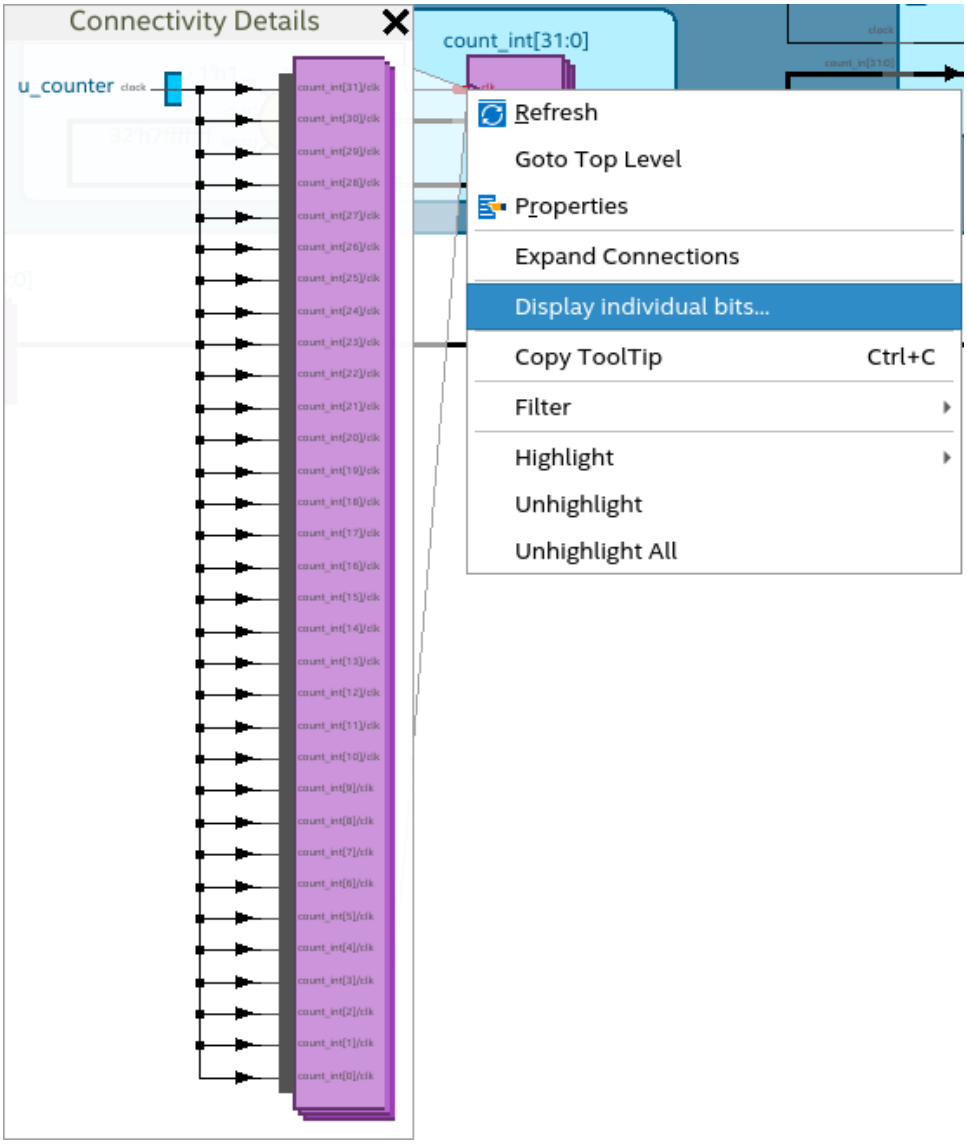
In the following figure, `count_int[31:0]` is a bundled instance, where 31 is the left index and 0 is the right index. Under the **Objects** pane (hierarchy browser), `count_int[0]`, `count_int[10]`, `count_int[11]`, and so on are single-bit instance members.

Figure 32. Bundled Instance



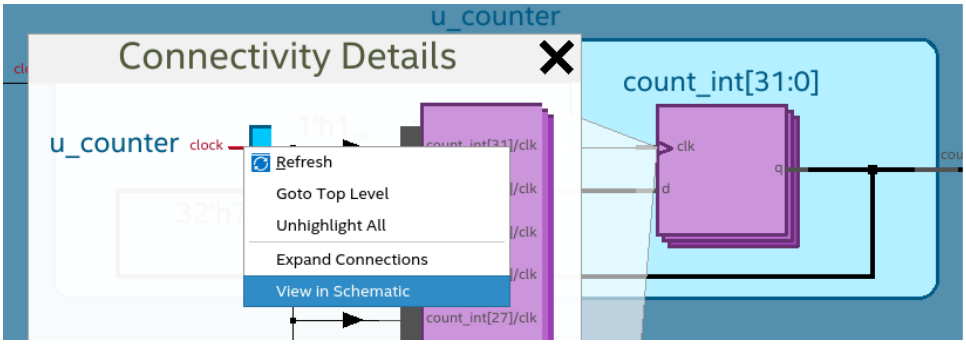
If you want to view individual bits of a bundled instance within the schematic viewer, select the pin bus, right-click to display the context-sensitive menu, and click **Display Individual Bits**. The **Connectivity Details** dialog displays connectivity details of the single-bit instances.

Figure 33. Connectivity Details of Single-bit Instances



Within the **Connectivity Details** dialog box, you can select the first individual instance, right-click to display the context-sensitive menu, and select **View in Schematic**. The first object in the hierarchy gets highlighted automatically.

Figure 34. View Connectivity Details in the Schematic Viewer

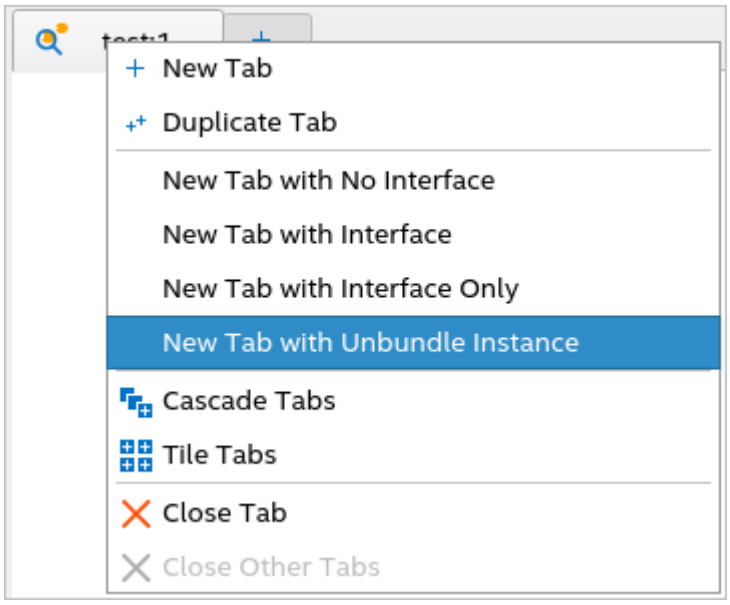


Viewing Unbundled Instances

To view unbundled instances, launch your design in the schematic viewer and use one of the following options:

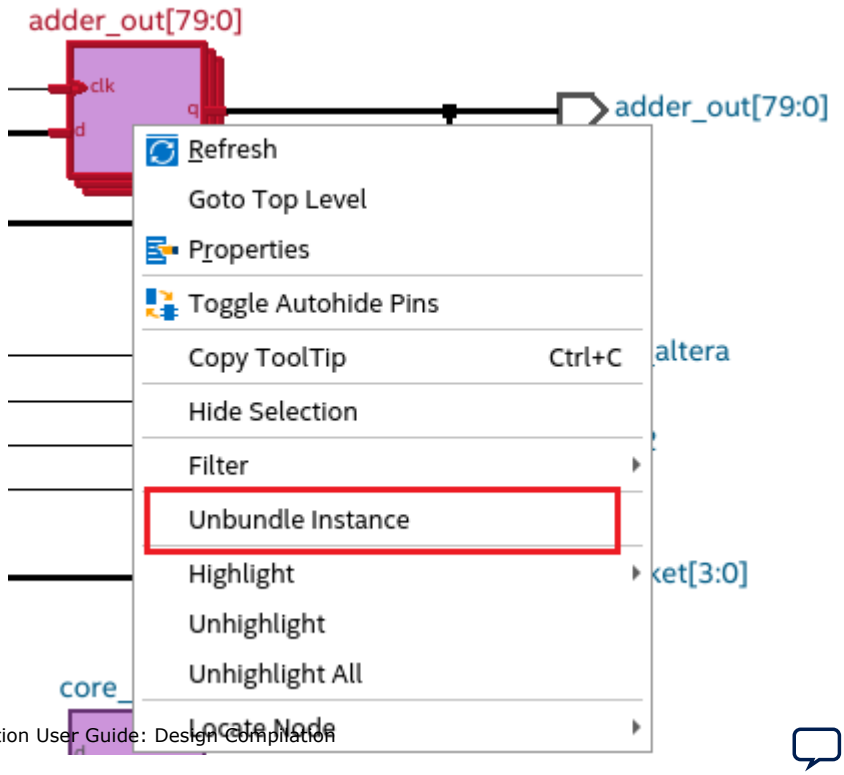
- Select **New Tab with Unbundle Instance** from the tab's context-sensitive menu.

Figure 35. Opening a New Tab with Unbundled Instances



- Select **Unbundle Instance** option from the context-sensitive menu.

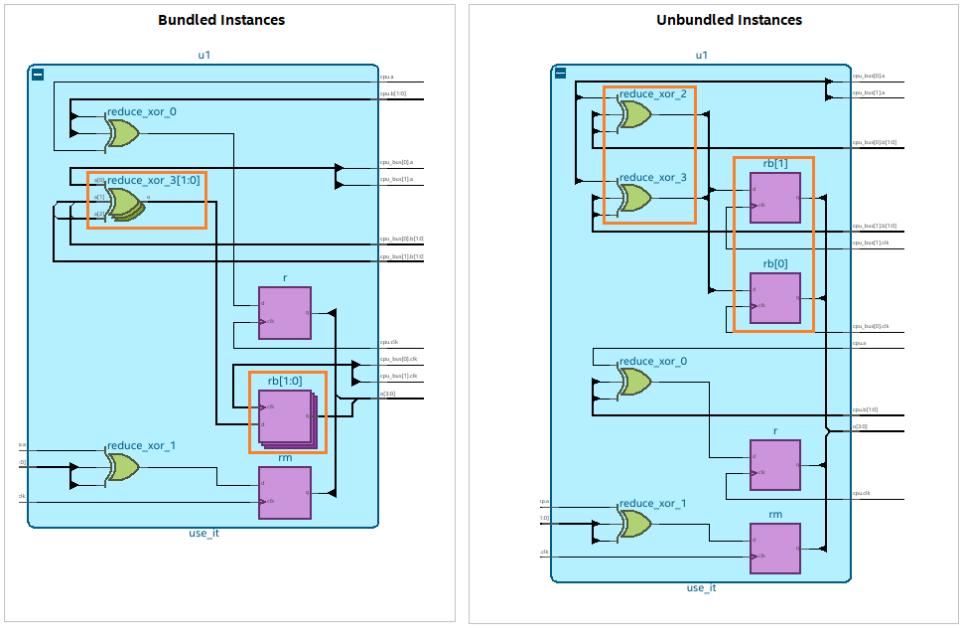
Figure 36. Viewing Unbundled Instances



Using either option, you get an unbundled view of the bundled instances in a new tab of the schematic viewer. This mode is helpful when you want to view single-bit instances of a bundled object.

In the following example, when you view the design in the default no interface mode (left), you observe that the instances `reduce_xor_3[1:0]` and `rb[1:0]` are bundled. However, within the unbundle instance mode (right), you can view single-bit instances `reduce_xor_3`, `reduce_xor_2`, `rb[1]`, and `rb[0]`.

Figure 37. Example of Bundled and Unbundled Instances



Related Information

Module Interfaces on page 37

1.6.1.5. Auto-hide Unconnected Pins

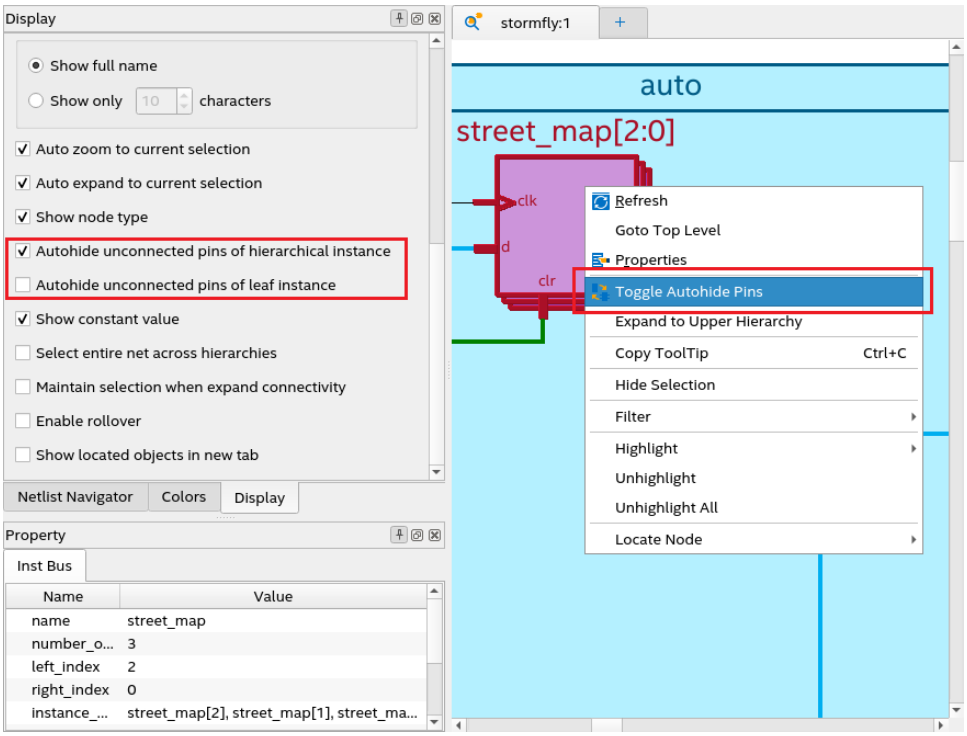
The **Autohide unconnected pins of hierarchical instance** option is enabled by default. However, **Autohide unconnected pins of leaf instance** is disabled by default, which means that the schematic viewer displays all instance ports even when the connected net is not displayed on the same schematic. This allows you to further expand the connectivity of the hanging instance port without requiring you to toggle autohide pins option first.

Note: Instance ports that are configured with default connection are hidden in the schematic viewer to improve schematic readability. For example, RAM block.

Auto-hiding unconnected pins makes the instance symbol less cluttered by hiding pins that are not connected to any net. You can disable both auto-hide unconnected pins options when you want to view all pins or obtain properties of unconnected pins.

You can disable auto-hide unconnected pins options either for all instances in the **Display** setting or for a particular instance using the context-sensitive menu, as shown in the following image:

Figure 38. Auto-hiding Unconnected Pins

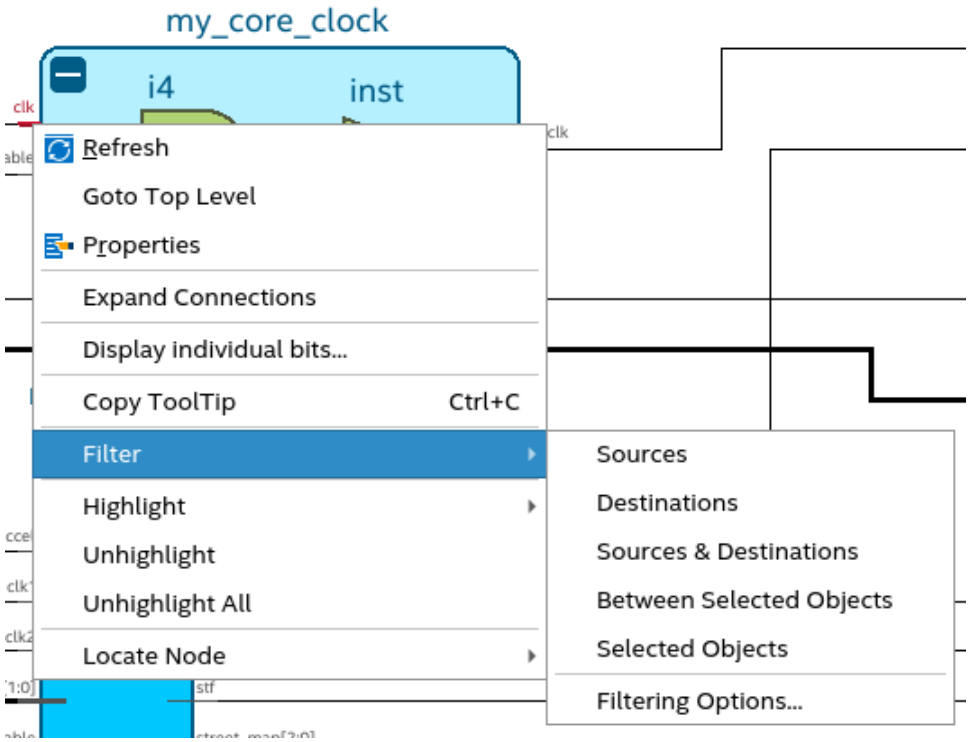


1.6.1.6. Filtering Ports and Nets

Filtering allows you to filter your netlist and view only a desired logic path. To filter the netlist, select ports, nodes, or node ports in the desired path.

You access the **Filter** feature either from the netlist hierarchy browser or the schematic viewer of the RTL Analyzer GUI. Select and right-click on the desired design object (port or node), point to **Filter**, and select the desired filter command in the context-sensitive menu, as shown in the following image. The RTL Analyzer generates a new page in the schematic view displaying the netlist that remains after filtering.

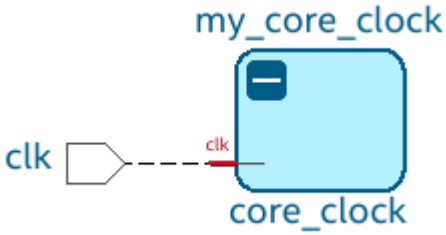
Figure 39. Filtering the Design Objects



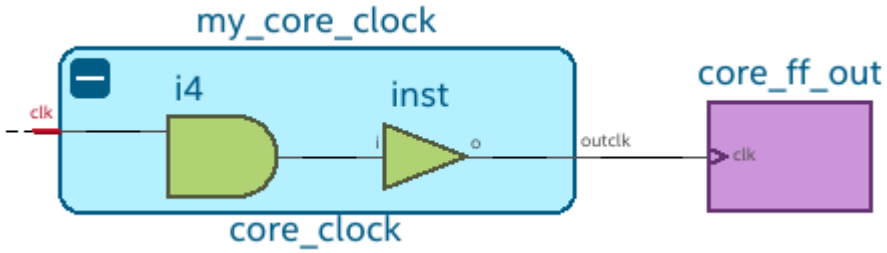
The following filtering commands are available:

Note: **Sources**, **Destinations**, **Sources & Destinations**, and **Between Selected Objects** are visible only for ports.

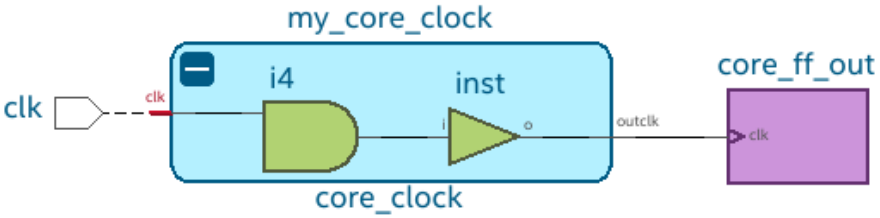
- **Sources**: Displays only the input source nodes that feed the selected port. In the following example image, when you use the **Sources** filter for the selected instance port `clk`, the source port `clk` displays:



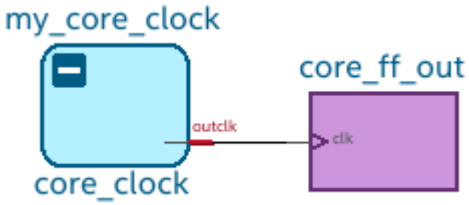
- **Destinations**: Displays only the fan-out destination nodes fed by the selected port. In the following example image, when you use the **Destinations** filter for the selected instance port `clk`, the destination instance port `outclk` displays:



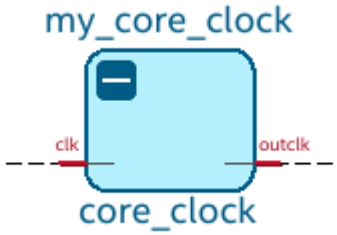
- **Sources & Destinations**: This option is a combination of source and destination filtering commands. The filtered view displays both sources and destinations of the selected port. In the following example image, when you use the **Sources & Destinations** filter for the selected instance port `clk`, you can view the source and destination nodes:



- **Between Selected Objects**: Displays nodes and connections in the path between the selected ports. In the following image, when you use the **Between Selected Objects** filter for the selected instance port `clk`, all objects between the input and output instance ports displays:



- **Selected Objects**: Displays only the selected objects. In the following image, when you use the **Selected Objects** filter, only the selected instance ports `clk` and `outclk` displays:



For all the filtering commands, the RTL Analyzer stops tracing through the netlist to obtain the filtered netlist when it reaches the port or instances. You can further control the filtering result by selecting **Filter ➤ Filtering Options** in the context-sensitive menu. The **Filtering Options** dialog box provides the following filtering options:

- **Stop filtering at register** (optional): The filtering stops when a register is encountered. This option is turned on by default.
- **Stop filtering at design partition** (optional): The filtering stops at the design partition. This option is turned on by default.
- **A specified number of logic levels**: The logic levels are counted from the selected port. The default value is 5 to ensure optimal processing time when performing filtering. However, you can specify a value between 1 and 15.

Note: A progress bar is shown while filtering is in progress. Click **Stop trace** to halt if the process takes too long to complete.

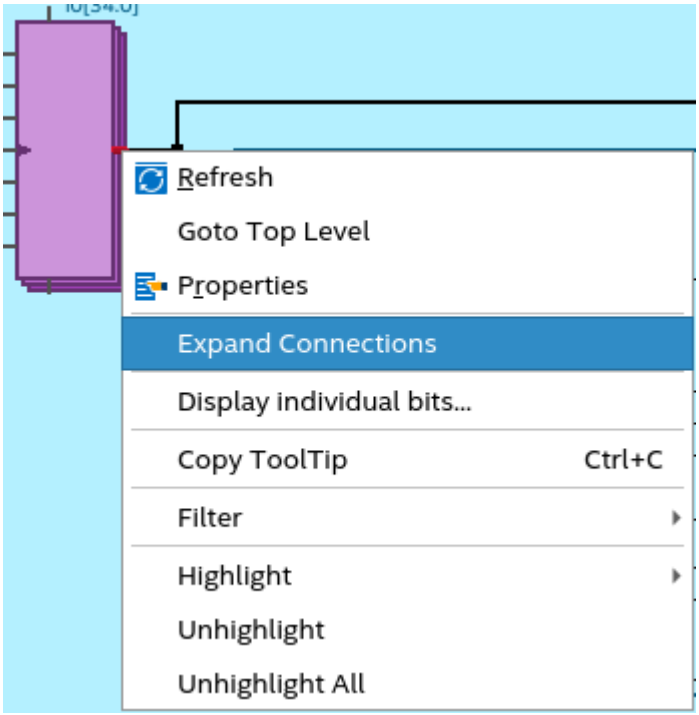
1.6.1.7. Expand Connections

Expand connections, which was previously supported in the Netlist Viewer, is also supported in the RTL Analyzer and useful when performing filtering. Expand Connections allow you to expand a selected pin and reveal the next connected node.

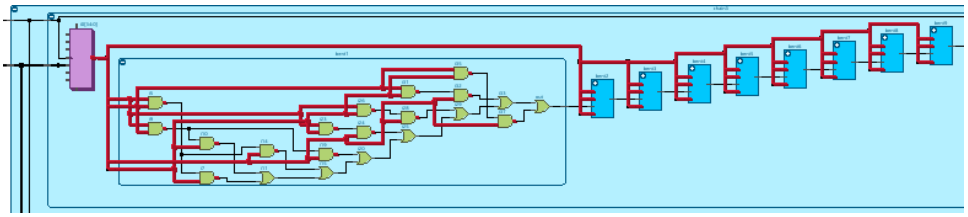
Note: Before using the **Expand Connections** feature, disable the Auto-hide Unconnected Pins in the Display settings.

To use this feature, select a pin, right-click and select **Expand Connections** in the context-sensitive menu, as shown in the following image:

Figure 40. Expand Connections



The logical path from the selected pin to the next connected node is highlighted, as shown in the following image:



1.6.2. Use Case Examples

In this section, you can explore the following examples:

Scripting Routine Tasks Using Tcl Commands on page 50

Traversing the Design Netlist Using Tcl Commands on page 52

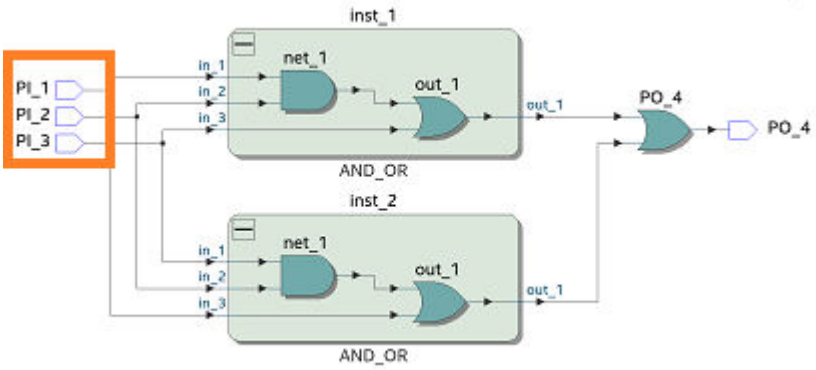
1.6.2.1. Scripting Routine Tasks Using Tcl Commands

The following examples enumerate how you can easily script a few routine tasks, such as attribute-based object filtering, name-based searching, or traversing object relationships, using different features of the `get` command:

Example 1. Retrieving Top-level Input Ports (highlighted in the schematic)

In some scenarios, you may need a list of top-level ports. For example, to ensure all input ports are constrained with `set_input_delay`, you must retrieve all ports in the design and filter based on `direction` using the `dni::get_ports` tcl command, as shown in the following:

```
dni::get_ports -filter direction==input
```



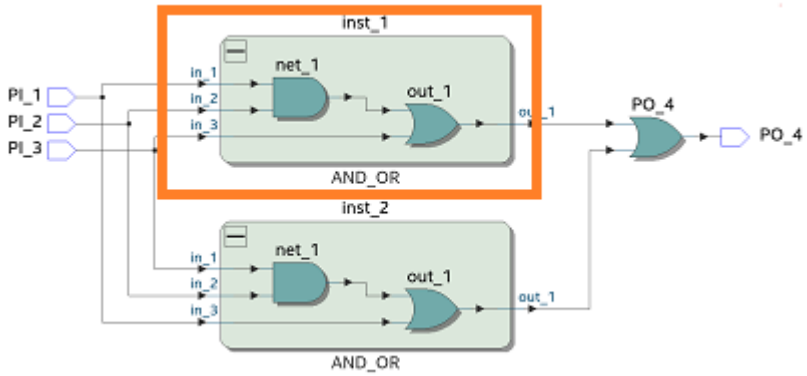
The tcl command returns a collection of input ports in the design, such as `PI_1`, `PI_2`, and `PI_3`. You can use the returned collection to pass or chain into other `get_object` commands. To access members of the collection, use collection iterators, such as `foreach_in_collection`. For example:

```
foreach_in_collection p [dni::get_ports -filter direction=input] { puts $p }
port::top::PI_1
port::top::PI_2
port::top::PI_3
```

Example 2. Retrieving the `inst_1` Instance

Within your design, you can search for a specific object (for example, instance) by name. To find an instance, use the `dni::get_cells` tcl command, as shown in the following:

```
dni::get_cells inst_1
```



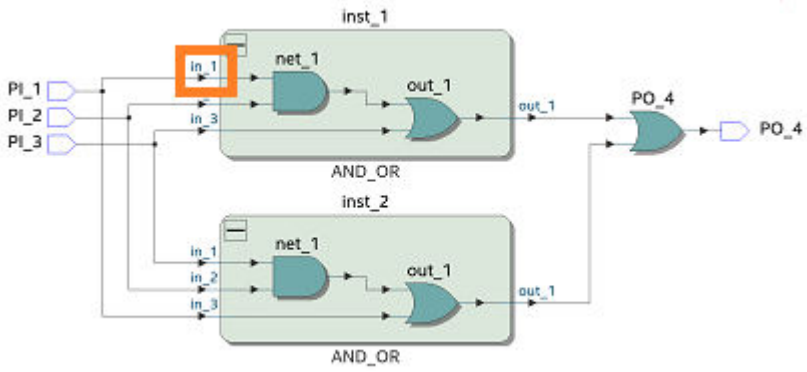
The tcl command returns the `inst_1` instance in the design. You can use the returned instance to pass or chain into other `get_object` commands. For example:

```
foreach_in_collection p [dni::get_cells inst_1] { puts [dni::get_property -name
name -object $p] }
inst_1
```

Example 3. Retrieving the `in_1` Instance Port of the `inst_1` Instance

During connectivity traversal, you may want to find a specific instance pin of an instance. In such scenarios, use the `-of_object` interface of the `dni::get_pins` command to traverse instance-to-instance pin relationship as shown in the following:

```
dni::get_pins -of_objects [dni::get_cells inst_1] -filter name==in_1
```



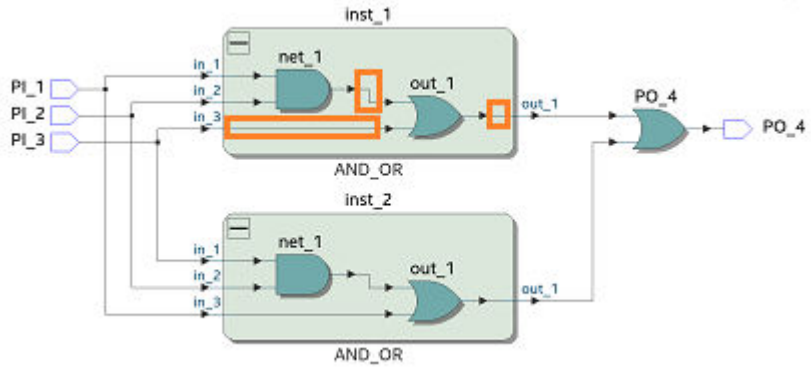
The tcl command returns `in_1` instance port of the `inst_1` instance in the design. You can use the returned instance port to pass or chain into other `get_object` commands. For example:

```
foreach_in_collection p [dni::get_pins -of_objects [dni::get_cells inst_1] -
filter name==in_1] { puts $p }
inst_port::top::inst_1|in_1
```

Example 4. Retrieving Nets of the `inst_1|out1` Instance

During connectivity trace, you may want to traverse all nets connected to an instance. In such a scenario, use the `-of_objects` interface of the `dni::get_nets` command to traverse nets connected to an instance. For example:

```
dni::get_nets -of_objects [dni::get_cells inst_1|out_1]
```



The tcl command returns nets of the `inst_1|out1` instance in the design. You can use the returned collection to pass or chain into other commands. For example:

```
foreach_in_collection p [dni::get_nets -of_objects [dni::get_cells inst_1|
out_1] ] { puts $p }
inst_port::top::inst_1|out_1|Net_7
inst_port::top::inst_1|out_1|Net_6
inst_port::top::inst_1|out_1|Net_8
```

Example 5. Listing the Properties Available on the `net` Object Type

The tcl interface allows you to access object schema via the `dni::list_properties` tcl command. You can use this command to list accessible properties of any object type as follows:

```
dni::list_properties -type net
name parent_name number_of_ports ports net_bus_name source_file source_line
is_user_declared
```

1.6.2.2. Traversing the Design Netlist Using Tcl Commands

In this topic, you can see examples of Tcl commands that you can use to extract basic netlist objects or selective objects of your design using filters, pattern, and other techniques.

Traversing Basic Design Objects

The following table lists Tcl command examples for extracting hierarchical instances, instance ports, nets, and ports from your design netlist:

Note: When using `dni::` Tcl commands in an SDC file, you can skip adding `dni::` as `read_sdc` adds the namespace correctly.

Table 6. Tcl Commands for Traversing Design Objects

Task	Tcl Command Example
Get all instances directly under the top module.	`foreach_in_collection obj [dni::get_cells] { puts $obj; }`
Get all design instances at all hierarchies.	`foreach_in_collection obj [dni::get_cells -hierarchical] { puts $obj; }`
Get all instances directly under a hierarchical instance using a pattern with the hierarchy separator (|).	`foreach_in_collection obj [dni::get_cells auto|*] { puts $obj; }`
Get all direct child instances of a specific hierarchical instance (for example, the instance `auto`).	# Use `dni::current_instance` to move the browsing scope to the `auto` hierarchical instance. `dni::current_instance auto` # Get all direct child instances of the hierarchical instance `auto`. `foreach_in_collection obj [dni::get_cells] { puts $obj; }` # Set the scope back to top design `dni::current_instance`
Get all nets directly under the top module.	`foreach_in_collection obj [dni::get_nets] { puts $obj; }`
Get all nets of the design at all hierarchies.	`foreach_in_collection obj [dni::get_nets -hierarchical] { puts $obj; }`
Get all nets directly under a hierarchical instance using a pattern with the hierarchy separator (|).	`foreach_in_collection obj [dni::get_nets tick|*] { puts $obj; }`
Get all nets directly under a specific hierarchical instance (for example, the instance `tick`).	# Use `dni::current_instance` to move the browsing scope to the `tick`hierarchical instance. `dni::current_instance tick` # Get all nets directly under `tick` `foreach_in_collection obj [dni::get_nets] { puts $obj; }` # Set the scope back to top design `dni::current_instance`
Get all ports of the design.	`foreach_in_collection obj [dni::get_ports] { puts $obj; }`
Get all instance ports of direct child instances under the design top module.	`foreach_in_collection obj [dni::get_pins] { puts $obj; }`
Get all instance ports of all child instances under a specific hierarchical instance (for example, `tick`).	# Use `dni::current_instance` to move the browsing scope to the `tick` hierarchical instance. `dni::current_instance tick` # Get all instance ports under `tick` `foreach_in_collection obj [dni::get_pins] { puts $obj; }` # Set the scope back to the top design `dni::current_instance`

continued...

Task	Tcl Command Example
Get all instance ports on all child instances using the object ID format to specify a hierarchical instance.	`set inst [get_cells tick]` `foreach_in_collection obj [dni::get_pins -of_objects $inst] { puts $obj; }`
	`foreach_in_collection obj [dni::get_pins -of_objects tick|ticket[1]] { puts $obj; }`
	`foreach_in_collection obj [dni::get_pins -of_objects instance::chiptrip::tick|ticket[1]] { puts $obj; }`

Getting Selective Design Objects

You can use the following techniques to refine your search criteria and extract select design objects from your netlist:

- **<patterns>**: It extracts objects by matching patterns in `dni::get_cells`, `dni::get_nets`, and `dni::get_pins` commands. Patterns can include wildcard characters * or ?. Wildcard characters do not match with the hierarchical separator.

  For objects in the design hierarchy:

  — The hierarchical path name of the object is matched against the pattern.

  — The hierarchical separator | splits the pattern into individual subpatterns, each of which is matched against one level of hierarchy. This means that a * does not match the hierarchy.

  — The name being matched is relative to the current search root (design top module). You can change the current search root using the `dni::current_instance` command.

Table 7. Getting Selective Design Objects Using <pattern>

Tasks Using <pattern>	Tcl Command Example
Get all first-level hierarchical and leaf instances.	`foreach_in_collection obj [dni::get_cells *] { puts $obj; }`
Get all second-level hierarchical and leaf instances.	`foreach_in_collection obj [dni::get_cells *|*] { puts $obj; }`
Get all instances under the hierarchical instance, for example, `auto`.	`foreach_in_collection obj [dni::get_cells auto|*] { puts $obj; }`
Get all nets under the top module.	`foreach_in_collection obj [dni::get_nets *] { puts $obj; }`
Get all nets under the first level hierarchical and leaf instances.	`foreach_in_collection obj [dni::get_nets *|*] { puts $obj; }`
Get all nets under the first-level hierarchical instance, for example, `auto`.	`foreach_in_collection obj [dni::get_nets auto|*] { puts $obj; }`
Get all instance ports on first-level hierarchical and leaf instances.	`foreach_in_collection obj [dni::get_pins *|*] { puts $obj; }`
Get all instance ports on the hierarchical instance, for example, `auto`.	`foreach_in_collection obj [dni::get_pins auto|*] { puts $obj; }`
Get all instance ports on all the child instances of the hierarchical instance, for example, `auto`.	`foreach_in_collection obj [dni::get_pins auto|*|*] { puts $obj; }`

- **<-of_objects>**: It extracts related design objects of the input object collection for `dni::get_cells`, `dni::get_nets`, `dni::get_pins`, and `dni::get_ports`. The following object relationships are considered:
  - `dni::get_cells -of_objects <inst_port|net>`
  - `dni::get_nets -of_objects <inst_port|port|instance>`
  - `dni::get_pins -of_objects <instance|net>`
  - `dni::get_ports -of_objects <net>`

Table 8. Getting Selective Design Objects Using <-of_objects>

Tasks Using <-of_objects>	Tcl Command Example
Get the hierarchical or leaf instance on which the input instance port is.	`foreach_in_collection obj [dni::get_cells -of_objects inst_port::chiptrip::auto|dir[0]] { puts $obj; }` `foreach_in_collection obj [dni::get_cells -of_objects inst_port::chiptrip::auto|street_map[2]|q] { puts $obj; }`
Get the hierarchical or leaf instances to which the input net is connected.	`foreach_in_collection obj [dni::get_cells -of_objects net::chiptrip::wire_get_ticket1] { puts $obj; }` `foreach_in_collection obj [dni::get_cells -of_objects net::chiptrip::auto|n5] { puts $obj; }` `foreach_in_collection obj [dni::get_cells -of_objects [dni::get_nets *]] { puts $obj; }` `foreach_in_collection obj [dni::get_cells -of_objects [dni::get_nets auto|*]] { puts $obj; }`
Get the net connecting a leaf instance port.	`foreach_in_collection obj [dni::get_nets -of_objects inst_port::chiptrip::auto|street_map[0]|q] { puts $obj; }`
Get the net connecting a hierarchical instance port.	`foreach_in_collection obj [dni::get_nets -of_objects inst_port::chiptrip::auto|get_ticket] { puts $obj; }`
Get the nets connecting to all the instance ports of a leaf instance.	`foreach_in_collection obj [dni::get_nets -of_objects instance::chiptrip::auto|street_map[0]] { puts $obj; }`
Get the nets connecting to all the instance ports of a hierarchical instance.	`foreach_in_collection obj [dni::get_nets -of_objects instance::chiptrip::auto] { puts $obj; }`
Get the net connecting to a primary port of the design.	`foreach_in_collection obj [dni::get_nets -of_objects port::chiptrip::gt1] { puts $obj; }`
Get instance ports on a leaf instance.	`foreach_in_collection obj [dni::get_pins -of_objects instance::chiptrip::tick|add_0] { puts $obj; }`
Get instance ports on a hierarchical instance.	`foreach_in_collection obj [dni::get_pins -of_objects instance::chiptrip::tick] { puts $obj; }`
Get the instance ports on the hierarchical instance, for example, `instance::chiptrip::auto`.	`foreach_in_collection obj [dni::get_pins -of_objects [dni::get_cells auto]] { puts $obj; }`
Get instance ports connected by a hierarchical net.	`foreach_in_collection obj [dni::get_pins -of_objects net::chiptrip::wire_get_ticket1] { puts $obj; }`
Get primary ports connected by a hierarchical net on the top level.	`foreach_in_collection obj [dni::get_ports -of_objects net::chiptrip::wire_get_ticket1] { puts $obj; }`

- **<-filter>**: It extracts objects by filtering objects returned from `dni::get_cells`, `dni::get_nets`, `dni::get_pins`, and `dni::get_ports` based on the filter expression. The filter expression verifies every object that satisfies the other search criteria. If the object does not satisfy the filter, it is not returned in the result.

  A filter expression comprises predicates combined using logical operators, such as `&&`, `and`/`AND`, `||`, `or`/`OR`, and `!`. Parentheses `( )` in the expression override precedence. Each predicate has the following form:

  ```
  prop_name relop value
  ```

  where,

  — *`prop_name`* is the name of the object property being evaluated.

  — *`value`* is a number or a string. You can provide simple strings without the surrounding double-quotes.

  — *`relop`* is one of the following comparison operators:

    - == (equal)
    - != (not equal)
    - =~ (matches, value is then a pattern)
    - !~ (does not match, value is then a pattern)
    - > (greater than)
    - < (less than)
    - >= (greater than or equal to)
    - <= (less than or equal to)

  For example: `-filter {name=~"out[*]" && ! (master_name==mod_1 || parent_name != block_1)}`

Table 9. Getting Selective Design Objects Using <-filter>

Tasks Using <-filter>	Tcl Command Example
Get all child instances under the top-level.	`foreach_in_collection obj [dni::get_cells *] { puts $obj; }`
Get properties of the instance object type.	`dni::list_properties -type instance`
Get objects that are not a leaf instance	`foreach_in_collection obj [dni::get_cells * -filter {is_leaf==1}] { puts $obj; }`
Get all objects that are hierarchical instances.	`foreach_in_collection obj [dni::get_cells * -filter {is_leaf==0}] { puts $obj; }`
Return hierarchical instances matching the name pattern (for example, `t*`) under the design top-level module.	`foreach_in_collection obj [dni::get_cells * -filter {is_leaf==0 && name=~"t*"}] { puts $obj; }`
Get all instances under the hierarchical instance, for example, `auto` that matches the module name in the filter.	`foreach_in_collection obj [dni::get_cells auto|*] { puts $obj; }` `dni::get_property -name module_name -object instance::chiptrip::auto|Mux_0`

continued...

Tasks Using <-filter>	Tcl Command Example
	foreach_in_collection obj [dni::get_cells auto|* -filter {module_name=="primitive_lib_WORKING_LIBRARY_INTERNAL/OPER_(MUX)"}] { puts $obj; }
Get properties that you can use to filter net objects. Then, get nets with three connected instance ports and primary ports under the top-level design.	dni::list_properties -type net foreach_in_collection obj [dni::get_nets -filter {number_of_ports==3}] { puts $obj; }
Get all nets in the full design hierarchies that are under the parent module, for example, auto_max.	foreach_in_collection obj [dni::get_nets -hierarchical -filter {parent_name=="auto_max"}] { puts $obj; }
Get all nets in the full design hierarchies that are associated with the net_bus, for example, street_map.	foreach_in_collection obj [dni::get_nets -hierarchical -filter {net_bus_name=="street_map"}] { puts $obj; }
Get properties that you can use to filter instance port objects and get the value of the direction property. Then, get all output inst_ports under the top-level design.	dni::list_properties -type inst_port dni::get_property -name direction -object inst_port::chiptrip::auto|get_ticket foreach_in_collection obj [dni::get_pins -filter {direction==output}] { puts $obj; }
Get all primary input ports in the design.	foreach_in_collection obj [dni::get_ports -filter {direction==input}] { puts $obj; }

- **Combined use of <pattern>, -of_objects <obj_col>, -hierarchical, and -filter <filter_expr>**:

Table 10. Combined Search Criteria

Tasks Using Combined Search Criteria	
Get all instance ports under the design top-module that match the combined search criteria of -of_objects and -filter.	foreach_in_collection obj [dni::get_pins -of_objects [dni::get_cells *] -filter {direction==input}] { puts $obj; }
Get all nets under the design top module that match the pattern and -hierarchical.	foreach_in_collection obj [dni::get_nets time* -hierarchical] { puts $obj; }

The following example shows the limitation of the combined search criteria:

```
tcl> foreach_in_collection obj [dni::get_pins clk -hierarchical]  { puts $obj; }
inst_port::chiptrip::auto|clk
inst_port::chiptrip::speed|clk
inst_port::chiptrip::tick|clk

tcl> foreach_in_collection obj [dni::get_nets time* -of_objects
instance::chiptrip::time_c] { puts $obj; }
Arguments '-of_objects' and 'patterns' are mutually exclusive

tcl> foreach_in_collection obj [dni::get_pins -hierarchical -of_objects
instance::chiptrip::time_c]  { puts $obj; }

Arguments '-of_objects' and '-hierarchical' are mutually exclusive
```

1.7. Design Synthesis

The Quartus Prime compiler's Analysis & Elaboration module analyzes your complete design source files, such as standards-compliant Verilog HDL (`.v`), VHDL (`.vhd`), SystemVerilog (`.sv`), and the Verilog Quartus Mapping (`.vqm`) generated from other EDA tools, and constraint files (`.sdc` or `.rtlsdc`) and provides an unmodified view of your design early in the compilation flow. The SDC-on-RTL constraints are applied to the elaborated netlist.

In the Synthesis stage, the compiler synthesizes and translates your design files into an atom netlist for mapping to device resources. During synthesis, timing constraints that were read during elaboration are propagated to the synthesized atom netlist.

Caution: Starting from the Quartus Prime Pro Edition software version 23.3, the compiler cannot synthesize schematic Block Design File (`.bdf`). You must convert it to an acceptable format, such as Verilog or VHDL using only the Quartus Prime Standard Edition (not possible with the Pro Edition) command `quartus_map` as shown in the following:

- To convert your `.bdf` file to Verilog Design File (`.v`):

```
quartus_map <project_name> --convert_bdf_to_verilog=<bdf_file_name>
```

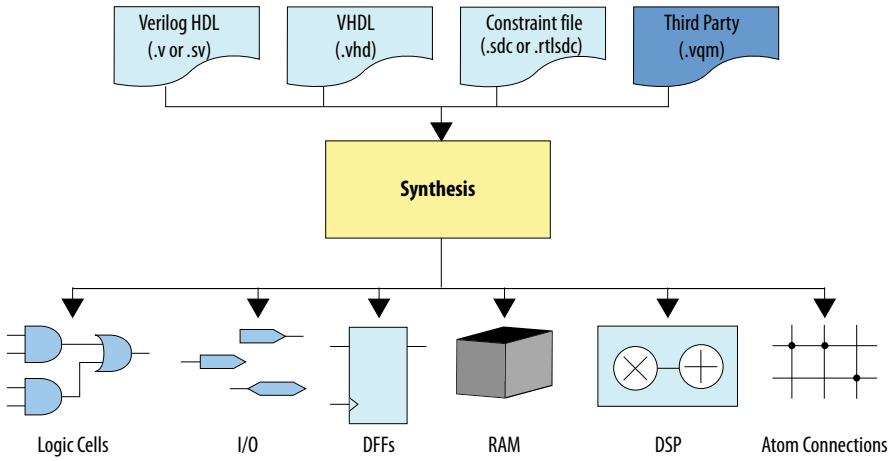
- To convert your `.bdf` file to VHDL Design File (`.vhd`):

```
quartus_map <project_name> --convert_bdf_to_vhdl=<bdf_file_name>
```

Synthesis examines the logical completeness and consistency of the design, and checks for boundary connectivity and syntax errors. Synthesis also minimizes and optimizes design logic. For example, synthesis infers D flip flops, latches, and state machines from "behavioral" languages, such as Verilog HDL, VHDL, and SystemVerilog. Synthesis may replace operators, such as + or –, with modules from the Quartus Prime IP library, when advantageous. During synthesis, the Compiler may change or remove user logic and design nodes. Quartus Prime synthesis minimizes gate count, removes redundant logic, and ensures efficient use of device resources.

At the end of synthesis, the Compiler generates an atom netlist. Atom refers to the most basic hardware resource in the FPGA device. Atoms include logic cells organized into look-up tables, D flip flops, I/O pins, block memory resources, DSP blocks, and the connections between the atoms. The atom netlist is a database of the atom elements that design synthesis requires to implement the design in silicon.

Figure 41. Design Synthesis



1.7.1. Preparing for Design Synthesis

Before running synthesis, apply any of the following settings and constraints that impact synthesis:

- To specify options for the synthesis of Verilog HDL input files, click **Assignments ➤ Settings ➤ Verilog HDL Input**.
- To specify options for the synthesis of VHDL input files, click **Assignments ➤ Settings ➤ VHDL Input**.
- To specify options that affect compilation processing time, click **Assignments ➤ Settings ➤ Compilation Process Settings**.
- To specify the Compiler's high-level optimization strategy and other options, click **Assignments ➤ Settings ➤ Compiler Settings**. Specify the optimization goal, according to Compiler Optimization Modes on page 149.
- On the **Compiler Settings** page enable or disable the **Enable Intermediate Fitter Snapshots** option to preserve snapshots for the Plan, Place, Route, and Retime stages any time you run full compilation. The Compiler does not generate intermediate snapshots by default.
- To specify advanced synthesis settings, click **Assignments ➤ Settings ➤ Compiler Settings**, and then click **Advanced Settings (Synthesis)**.
- Consider enabling fractal synthesis for arithmetic-intensive designs that exhaust all DSP resources, according to the guidelines in Fractal Synthesis Optimization on page 155.
- To register your SDC-on-RTL files and apply them to the elaboration netlist, refer to Registering the SDC-on-RTL SDC File on page 65 and Applying the SDC-on-RTL Constraints on page 66.

1.7.2. Running Synthesis

Run design synthesis as part of a full compilation, or as an independent process. Before running synthesis, specify settings that control synthesis processing. The Messages window dynamically displays processing information, warnings, or errors.

Following Analysis & Elaboration processing, the Synthesis report provides detailed information about the synthesis of your project. To run synthesis, perform the following steps.

1. Review Preparing for Design Synthesis on page 59.
2. Create or open an Quartus Prime project with valid design files for compilation.
3. Click **Synthesis** on the Compilation Dashboard.

Related Information

Synthesis Settings Reference on page 168

1.7.2.1. Preserving Registers During Synthesis

Quartus Prime synthesis minimizes gate count, merges redundant logic, and ensures efficient use of device resources. If you need to preserve specific registers through synthesis processing, you can specify any of the following entity-level assignments.

Assign the **Preserve Registers in Synthesis** or **Preserve Fan-Out Free Register Node** options to allow Fitter optimization of the preserved registers. **Preserve Registers** restricts Fitter optimization of the preserved registers. Specify synthesis preservation assignments by clicking **Assignments ➤ Assignment Editor**, by modifying the `.qsf` file, or by specifying synthesis attributes in your RTL.

Table 11. Synthesis Preserve Options

Assignment	Description	Allows Fitter Optimization?	Assignment Syntax
Preserve Registers in Synthesis	Prevents removal of registers during synthesis without restricting any optimization after synthesis, such as Hyper-Retiming or physical synthesis optimizations.	Yes	• `set_global_assignment -name PRESERVE_REGISTER_SYN_ONLY ON|OFF -entity <entity name>` `set_instance_assignment -name PRESERVE_REGISTER_SYN_ONLY ON|OFF -to <to> -entity <entity name>` • `preserve_syn_only` or `syn_preservesyn_only` (synthesis attributes)
Preserve Fan-Out Free Register Node	Prevents removal of assigned registers without fan-out during synthesis. The PRESERVE_FANOUT_FREE_NODE assignment cannot preserve a fanout-free register that has no fanout inside the Verilog HDL or VHDL module in which you define it. To preserve these fanout-free registers, implement the `noprune` pragma in the source file: `(*noprune*)reg r;` If there are multiple instances of this module, with only some instances requiring preservation of the fanout-free register, set a dummy pragma on the register in the HDL and also set the PRESERVE_FANOUT_FREE_NODE assignment. This dummy pragma	Yes	• `set_instance_assignment -name PRESERVE_FANOUT_FREE_NODE ON|OFF -to <to> -entity <entity name>` • `noprune on` (see Verilog or VHDL synthesis attribute for syntax)

continued...

Assignment	Description	Allows Fitter Optimization?	Assignment Syntax
	allows the register synthesis to implement the assignment. For example, set the following dummy pragma for a register r in Verilog HDL: `(*dummy*)reg r;`		
Preserve Registers	Prevents removal and sequential optimization of assigned registers during synthesis. Sequential netlist optimizations can eliminate redundant registers and registers with constant drivers.	No	• `set_global_assignment -name PRESERVE_REGISTER ON|OFF -entity <entity name>` `set_instance_assignment -name PRESERVE_REGISTER ON|OFF -to <to> -entity <entity name>` • `preserve`, `syn_preserve`, or `keep on` (synthesis attributes)

1.7.2.2. Preserving Signals for Monitoring and Debugging

The Compiler optimizes the RTL signals during synthesis and place-and-route. Unless preserved, the signal names in your RTL might not exist in the post-fit netlist after signal optimizations. For example, the compilation process can merge duplicate registers, or add tildes (~) to net names that fan-out from a node.

Preserving a signal so that it is available for debugging after synthesis and place-and-route involves the following steps:

- Marking the signal for preservation.

  You can mark the signal directly in your RTL code or through a QSF assignment command.
- Enabling signal preservation either for the entire project or for the instance that contains the marked signal.

  You can enable project-wide signal preservation through the Quartus Prime GUI or a QSF assignment command. To preserve signals in an instance, use a QSF assignment command.

By separating marking signals for preservation and enabling signal preservation, you can tag signals of interest as you write your code with no effect on optimization until you enable signal preservation.

When signal preservation is enabled, the nodes marked `preserve_for_debug` inherit the following attributes:

Table 12. Attributes Inherited by Nodes Marked `preserve_for_debug`

Attribute	Result
`preserve`	Prevents Quartus Prime from optimizing away or retiming a register
`keep`	Prevents Quartus Prime from minimizing or removing a signal net during combinational logic optimization
`noprune`	Prevents Quartus Prime from removing or optimizing a fanout free register
`dont_merge`	Prevents Quartus Prime from merging a register with a duplicate register
`dont_replicate`	Prevents Quartus Prime from duplicating a register

Important: Instance-level signal preservation settings always override project-wide level settings. Also, signal preservation settings in your RTL always override QSF settings.

After you synthesize your design, you can locate and review your preserved signals:

- The *Preserve for Debug Assignments* report shows the preservation status and name of all nodes that are marked for preservation.
- The *preserved for debug* filters in Node Finder helps you quickly find preserved nodes.

The overall flow to follow to preserve signals for monitoring and debugging is as follows:

1. Mark the signals that you want to preserve in one of the following ways:
   - Mark the signals directly in your RTL code with the `preserve_for_debug` attribute:

Table 13. Examples of Marking Signals with the `preserve_for_debug` Attribute in RTL

Verilog Example	VHDL Example
`(* preserve_for_debug *) wire [3:0] counter_wire;` `(* preserve_for_debug *) reg [3:0] counter_reg;` `(* preserve_for_debug *) wire [15:0] decode_out_top;` `(* preserve_for_debug *) reg [15:0] decode_out_reg_top;`	`attribute preserve_for_debug : boolean;` `attribute preserve_for_debug of counter_wire : signal is true;` `attribute preserve_for_debug of counter_reg : signal is true;` `attribute preserve_for_debug of decode_out : signal is true;` `attribute preserve_for_debug of decode_out_reg : signal is true;`

     In the Quartus Prime GUI, you can also use the **Insert Template** (**Edit ➤ Insert Template**) dialog box to add the `preserve_for_debug` attribute.
   - Mark the signals with the PRESERVE_FOR_DEBUG assignment in one of the following ways:
     - Specify the PRESERVE_FOR_DEBUG assignment for specific nodes from a command line or in your QSF file:

       ```
       set_instance_assignment -name PRESERVE_FOR_DEBUG ON -to <node hpath>
       ```

     - Specify the **Preserve signal for debug** assignment **To** any node of interest in the Assignment Editor. Select **On** as the assignment value.

     Important: In some rare cases, logic might be optimized away before the signal can be preserved when you use the PRESERVE_FOR_DEBUG assignment. If you encounter this issue, use the `preserve_for_debug` attribute in your HDL code instead.
   - Mark a system module, interface, or port for preservation in Platform Designer.

     For details, refer to "Preserving a System Module, Interface, or Port for Debugging" in *Quartus Prime Pro Edition User Guide: Platform Designer*.
2. Enable preserve for debug either project-wide or for specific instances.
   - To enable preservation and reporting project-wide, do one of the following steps:

- Enable project-wide signal preservation from the Signal Tap Logic Analyzer settings:

  Select **Assignments ➤ Settings ➤ Signal Tap Logic Analyzer ➤ Enable preserve for debug assignments**.

- Specify the global PRESERVE_FOR_DEBUG_ENABLE assignment from a command line or in your QSF file:

  ```
  set_global_assignment -name PRESERVE_FOR_DEBUG_ENABLE ON
  ```

- Specify a global **Enable preserve for debug assignments** assignment in the Assignment Editor. Select **On** as the assignment value.

Tip: When project-wide signal preservation and reporting is enabled, use the instance-level setting to exclude instances from project-wide signal preservation and reporting.

- To enable (or disable) preservation and reporting for only specific instances:
  - Specify the instance PRESERVE_FOR_DEBUG_ENABLE assignment as ON (or OFF) from a command line or in your QSF file:

    ```
    set_instance_assignment -name PRESERVE_FOR_DEBUG_ENABLE ON -to
    <instance hpath>
    ```

  - Specify the **Enable preserve for debug assignments** assignment **To** any instance of interest in the Assignment Editor. Select **On** (or **Off**) as the assignment value.
  - Specify the PRESERVE_FOR_DEBUG_ENABLE attribute with a value of ON (or OFF) on the instance in your RTL.

Table 14. Examples of Setting the PRESERVE_FOR_DEBUG_ENABLE Attribute in RTL

Verilog Example	VHDL Example
... (* altera_attribute = "-name PRESERVE_FOR_DEBUG_ENABLE ON" *) decoder decoder_inst(...	... attribute altera_attribute : string; attribute altera_attribute of my_decoder_inst : LABEL is "-name PRESERVE_FOR_DEBUG_ENABLE ON"; ... begin ... my_decoder_inst : decoder

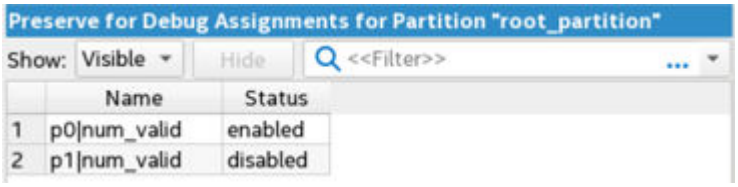
3. Synthesize your design.

   On the Compilation Dashboard, click **Analysis & Synthesis**. The Compilation Report generates when synthesis is complete. You can also now use *preserved for debug* filters in Node Finder to help you quickly find preserved nodes.

4. View the results of signal preservation.

   Open the Preserve for Debug Assignments report located in the **Synthesis ➤ Partition <*name*> ➤ Preserve for Debug** report folder.

Figure 42. Preserve for Debug Assignments Report



5. Run a full compilation to perform place and route of the design and Signal Tap instance by selecting **Processing ➤ Start Compilation**.

   The debug signals that you preserve persist through the Fitter into the finalized compilation database.

After running a full compilation, you can debug your design with any of the Quartus Prime debug tools.

Remember: After you have debugged your design, you might want to disable signal preservation (both globally and at the instance level) and run a full compilation to optimize signals that were preserved.

Table 15. Debug Signal Preservation Assignments

Assignment	Description	Example
`preserve_for_debug` (**Preserve signal for debug** in Assignments Editor)	Marks a signal to be preserved during compilation for post-synthesis or post-fit debugging when preserve-for-debug is enabled.	`set_instance_assignment -name PRESERVE_FOR_DEBUG ON -to <node hpath>`
`preserve_for_debug_enable` (**Enable preserve for debug assignments** in Assignments Editor)	Enables preserve-for-debug at either the project or instance level. When enabled, the Compiler reports the results of signal preservation in the Preserve for Debug Assignments report after compilation. The Compiler reports these nodes in the Preserve for Debug Assignments report following compilation.	`set_global_assignment -name PRESERVE_FOR_DEBUG_ENABLE ON` `set_instance_assignment -name PRESERVE_FOR_DEBUG_ENABLE ON -to <instance hpath>`

1.7.3. Using Synopsys* Design Constraint (SDC) on RTL Files

SDC-on-RTL supports SDC files written using SDC 2.1-compliant SDC commands and can support general Tcl code that the Tcl console can parse. These SDC files target your design netlist, allowing you to target hierarchical ports.

Note:

- Only the Timing Analyzer Tcl console supports the `sdc_ext Tcl` package.
- Quartus Prime software GUI-based constraint authoring is currently disabled for files with `RTL_SDC_FILE` assignments. This means the timing constraint entry dialogs are not available. You must enter timing constraints only by typing them in.
- Issues, such as incorrect options or other syntax errors, found in the SDC-on-RTL SDC files are posted as warnings in the Quartus Prime software GUI and message console.

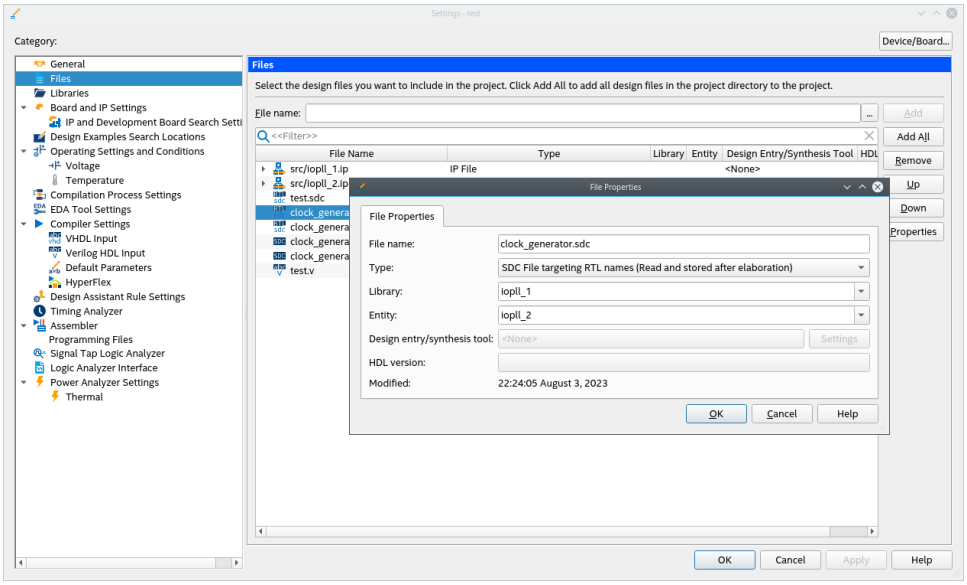
For more information about how to manage SDC-on-RTL SDC files, refer to the following topics:

Registering the SDC-on-RTL SDC File on page 65
Applying the SDC-on-RTL Constraints on page 66
Inspecting SDC-on-RTL Constraints on page 67
Creating Constraints in SDC-on-RTL SDC Files on page 72
Using Entity-Based SDC-on-RTL Constraints on page 75
Types of SDC Files Used in the Quartus Prime Software on page 78
Example: Using SDC-on-RTL Features on page 80

1.7.3.1. Registering the SDC-on-RTL SDC File

For the Post-Synthesis Static Timing Analysis (STA) on page 87, your design must include an associated SDC-on-RTL SDC file. You can use the GUI to register an SDC-on-RTL file with your current project from the **File Properties** dialog by specifying its type as **SDC File Targeting RTL names**, as shown in the following image:

Figure 43. Registering the SDC-on-RTL SDC File



Note: Alternatively, you can also associate an SDC-on-RTL file with your project from the Timing Analyzer's **Constraints ➤ Read SDC File** option.

SDC-on-RTL files are registered with an Quartus Prime software project through the following RTL_SDC_FILE assignment:

```
set_global_assignment -name RTL_SDC_FILE sdc_on_rtl_file.sdc
```

Note: Although you can use any file extension, Intel recommends using an intuitive file extension, for example, `rtlsdc`, to help distinguish SDC-on-RTL SDC files from the conventional Quartus Prime software SDC files if your design uses both.

1.7.3.2. Applying the SDC-on-RTL Constraints

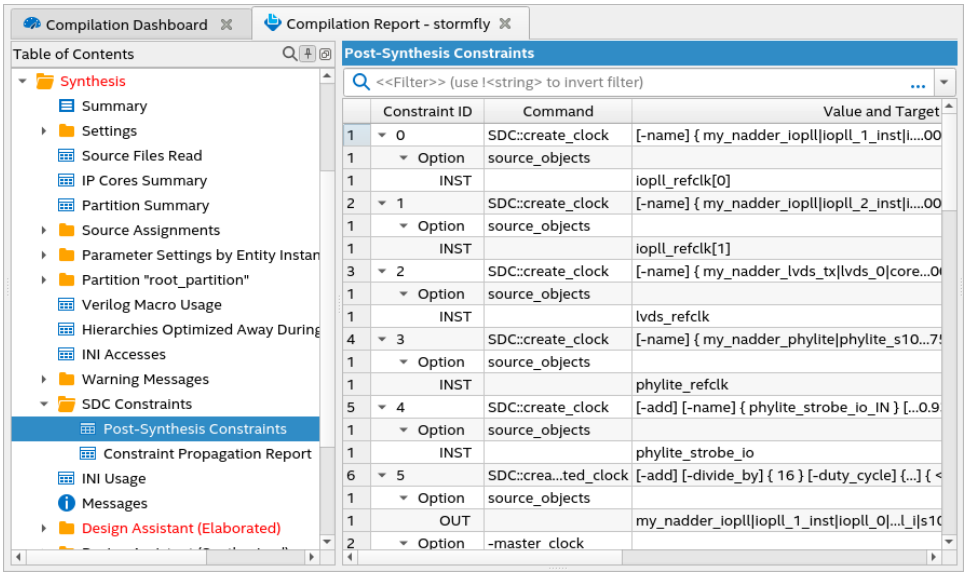
When you perform Analysis & Elaboration on your design, the SDC-on-RTL constraints are read and applied to your elaborated design. If you modify the constraints after Analysis and Elaboration, then you must rerun Analysis and Elaboration.

During the Analysis & Elaboration, `quartus_syn` reads all SDC-on-RTL SDC files and applies constraints to your design netlist. The order in which the files are listed in the QSF defines the reading order. Once this compilation stage completes, you can inspect the constraints in multiple ways. For more information, refer to Inspecting SDC-on-RTL Constraints on page 67 and Types of SDC Files Used in the Quartus Prime Software on page 78.

The constraints are stored in the internal Quartus Prime software netlist. As the compilation flow progresses, various compiler optimizations keep the constraint targets updated. This permits a write once, use anywhere methodology for the constraints.

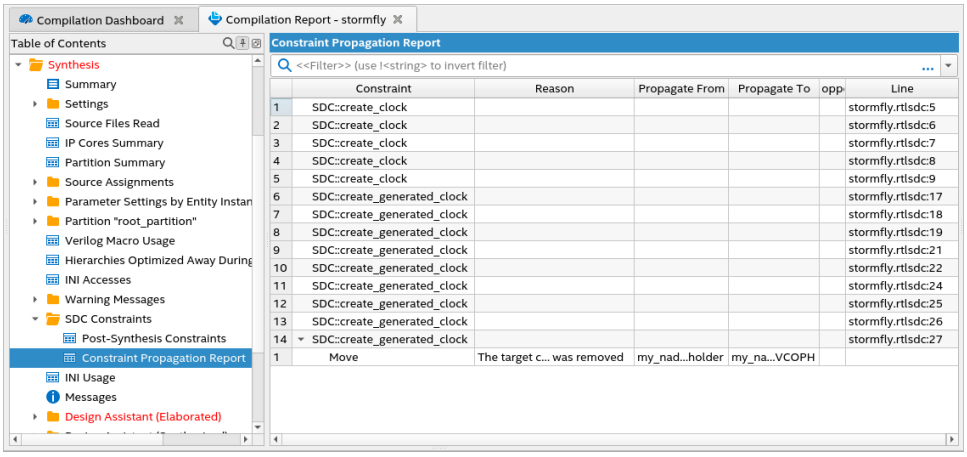
Once you are satisfied with the constraints, you can run Synthesis from the compilation dashboard. Synthesis converts the elaborated netlist into the node netlist for mapping to device resources. When Synthesis runs, the SDC constraints are processed and propagated by the Synthesis tool and you can review this in the **Post-Synthesis Constraints** report and **Constraint Propagation Report**.

Figure 44. Sample Post-Synthesis Constraints Compilation Report



The Constraint Propagation Report shows a chronological history of all changes made to each constraint during the compilation flow. You can observe an entry in the report whenever a constraint is duplicated, moved, or deleted. This report keeps getting updated with entries for modified constraints throughout the compilation flow and includes a reason when a constraint is moved. This report is beneficial for troubleshooting if the constraints changed in a way you did not expect.

Figure 45. Sample Constraint Propagation Report



1.7.3.3. Inspecting SDC-on-RTL Constraints

You can access SDC-on-RTL constraints in multiple ways in the order of the earliest opportunity in the flow, as described in the following sections:

Note: In all of the methods discussed in this section, the SDC-on-RTL constraints are read-only. You cannot modify the constraints in the compilation flow. You can only change the constraints by changing the source RTL SDC file and reloading it during Analysis and Elaboration.

Tcl Console

The Tcl console allows you to experiment conveniently with targeting constraints and the related syntax. The netlist is read-only when accessed from the Tcl console, and constraint commands are not saved into the design database.

Access the Tcl Console through the command-line interface using the following command:

```
quartus_syn -s
```

Once the Analysis & Elaboration compilation stage completes, you can load the project in the console (`project_open` *<project_name>*) and load the appropriate checkpoint using the `dni::load_design -checkpoint "constrained"` command. You can now perform tasks such as:

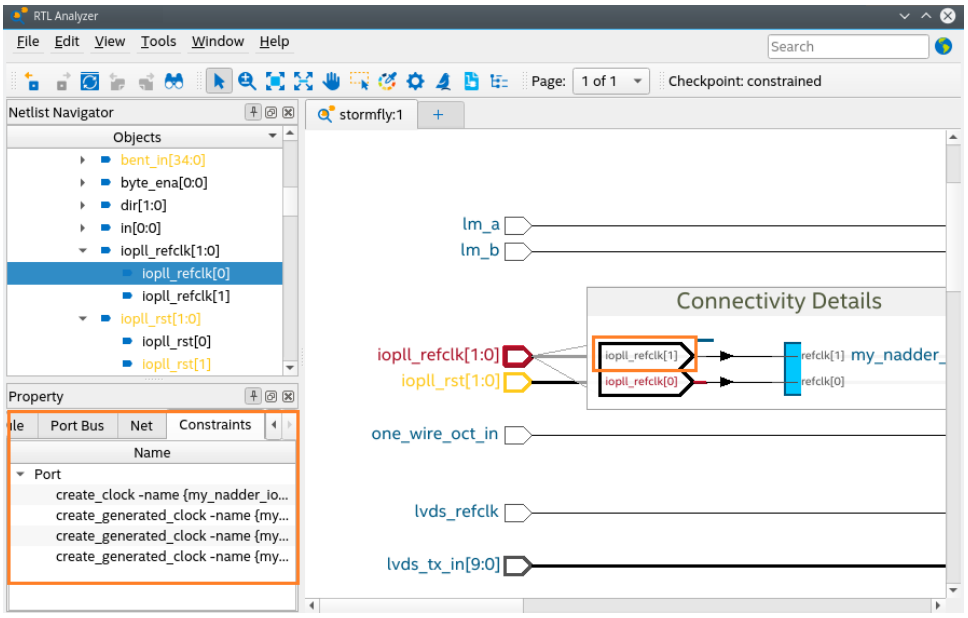
- Read a specific SDC file using the `dni::read_sdc`*<file_name>* command.
- Dump constraints using the `dni::write_sdc` command.
- Run constraint commands that are limited to the local session. For more information, refer to Creating Constraints in SDC-on-RTL SDC Files on page 72.

RTL Analyzer

To invoke the RTL Analyzer (Constrained mode) from the compilation dashboard, enable the **RTL Analysis Debug Mode** option under **Project ➤ Settings** as described in Analysis & Elaboration. The RTL Analyzer GUI allows you to view the constraints on the design netlist. When you select a netlist object in the schematic viewer or Netlist Navigator, you can view constraints targeting that object in the **Property** viewer. This helps ensure the constraints target the intended nodes in your RTL.

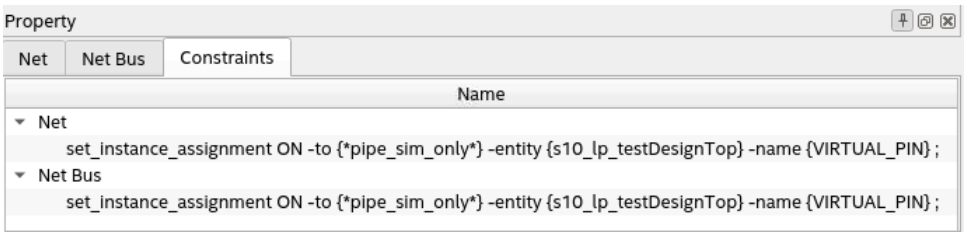
In the following example, when you select `iopll_refclk[1:0]` and right-click and select **Display Individual Bits** from its context-sensitive menu, the **Connectivity Details** pop-up window displays its ports. When you select one of the ports, constraints applied to the port are displayed in a separate **Constraints** tab, as shown in the following image:

Figure 46. Viewing Constraints in the RTL Analyzer



Besides the constraints of the selected object, the **Constraints** tab also includes constraints of the associated object. For example, a net bus' constraints are included along with the net's constraints, an instance bus' constraints with the instance's constraint, and so on.

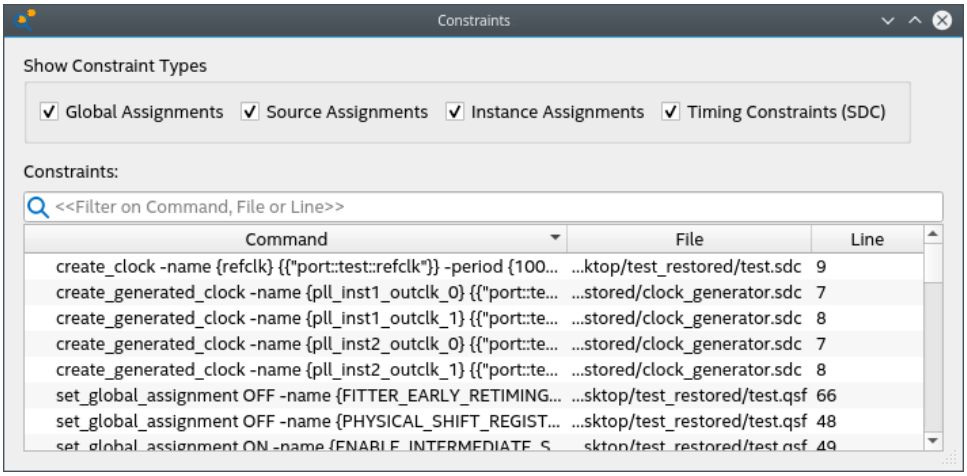
Figure 47. Viewing Constraints of Associated Objects



Note: You can cross-probe the SDC file by right-clicking on a constraint in the **Property** viewer and selecting the **View in Source** option.

You can also launch the **Constraints** dialog box (**Tools ➤ Object Constraints**) from the RTL Analyzer menu to view a list of all constraints (assignments and timing-related SDC). It allows you to select an assignment or a constraint and cross-probe to its source file by right-clicking and selecting **View in Source**. The source file that contains the assignment or constraint launches in the Quartus Prime GUI with the assignment line highlighted.

Figure 48. Object Constraints

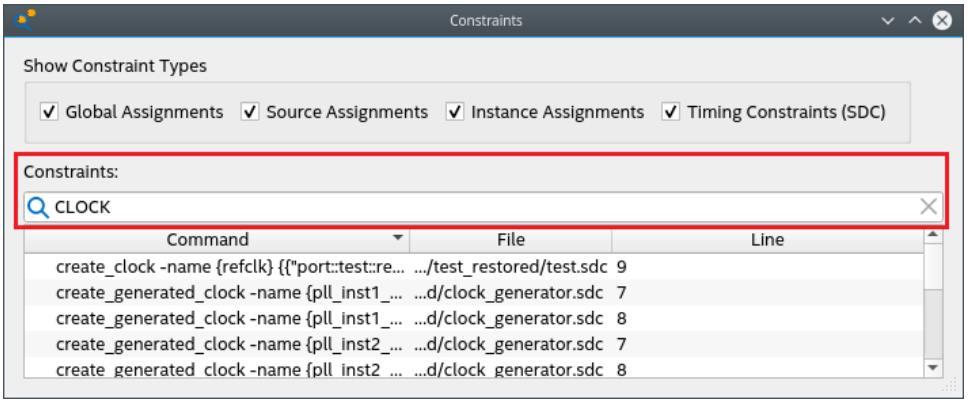


The Constraints GUI allows you to filter four types of constraints:

- **Global Assignments**: Assignments that are created with the `set_global_assignment` command.
- **Source Assignments**: Assignments embedded in source RTLs.
- **Instance Assignments**: Assignments created with the `set_instance_assignment` command.
- **Timing Constraints (SDC)**: Constraints created through SDC-on-RTL. They usually appear in the Constrained view of the Analysis & Synthesis stage. If no SDC is read in, the **Timing Constraints (SDC)** option is disabled. This can happen in views before SDC are read in, for example, in "Elaborated" and "Instrumented" views of the Analysis & Synthesis stage or when no SDC-on-RTL file is read in.

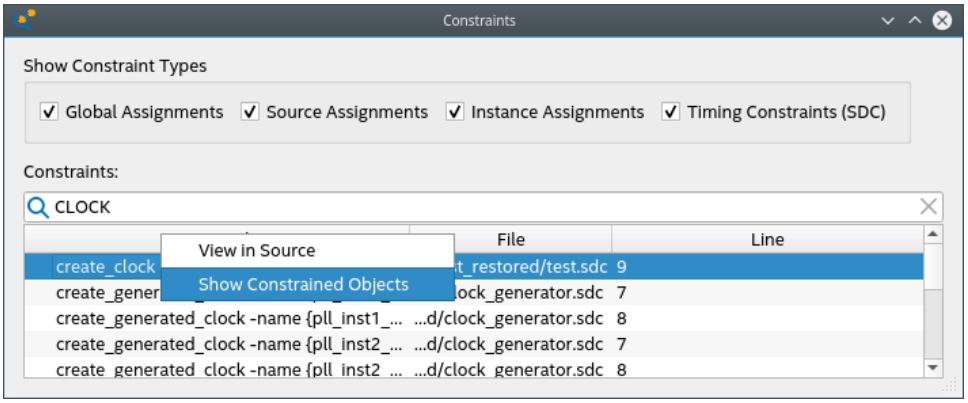
You can filter the constraints further using the filtering field to view constraints matching the string. It supports filtering through command name, file name, and line number. You can also sort the constraints using the **Command**, **File**, and **Line** column header.

Figure 49. Filtering Constraints



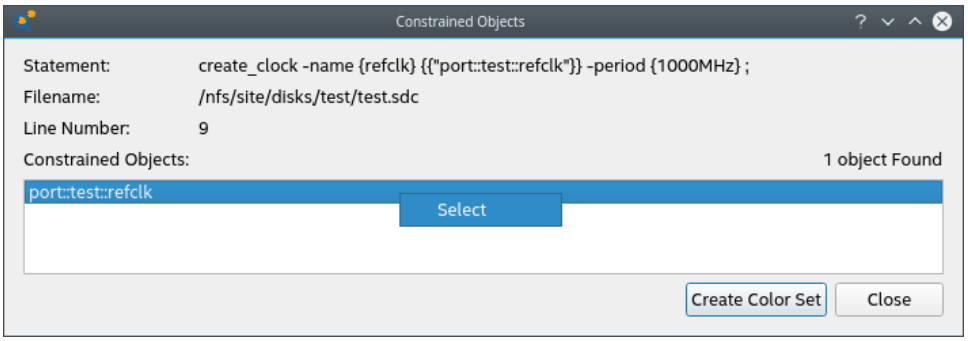
Through the context-sensitive menu of the Constraints GUI, you can view the selected constraints in its source file or the objects that it applies to.

Figure 50. Context-Sensitive Menu of the Constraints GUI



You can view objects that a constraint apply to through the **Show Constrained Objects** option, which displays the **Constrained Objects** dialog. In the **Constrained Objects**, you can select the constrained object through its context-sensitive menu. This allows you to view the object's property in the **Property Viewer**. You can also apply a color to each constrained object by clicking **Create Color Set**.

Figure 51. Constrained Objects



Quartus Prime Timing Analyzer

The Quartus Prime Timing Analyzer uses industry-standard constraint and analysis methodology to report on all data required times, data arrival times, and clock arrival times for all register-to-register, I/O, and asynchronous reset paths in your design. The Timing Analyzer verifies that the required timing relationships are met for your design to function correctly and confirms actual signal arrival times against the constraints you specify. For more information about the Timing Analyzer, refer to the *Quartus Prime Pro Edition User Guide: Timing Analyzer*.

Using the Timing Analyzer GUI or Tcl command console, you can load SDC-on-RTL constraints into the timing analysis session by running the `read_sdc` command. By default, the `read_sdc` command always loads SDC-on-RTL constraints, which happens before loading other conventional Quartus Prime software SDC files (`SDC_FILE`).

During static timing analysis, you can load only the SDC-on-RTL SDC constraints using the `import_sdc` command. This is helpful when debugging issues you suspect are caused by SDC-on-RTL constraints.

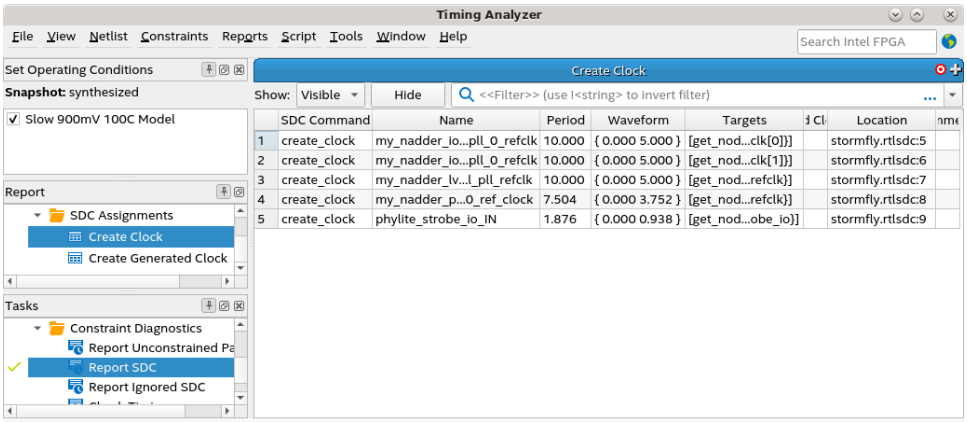
To disable the loading of SDC-on-RTL constraints during the calls to `read_sdc`, use the `read_sdc -no_import` option or set the QSF variable `ENABLE_IMPORT_SDC_DURING_READ_SDC` to `OFF`.

Note: If you change the actual SDC-on-RTL files and import them using `read_sdc` or `import_sdc` command without rerunning Analysis & Elaboration, the Timing Analyzer issues a warning message informing you that changes to the SDC-on-RTL files will not be observed until Analysis & Elaboration is rerun.

Once you import the constraints using the `read_sdc` or `import_sdc` command, they become standard constraints in the Timing Analyzer. Standard constraint diagnostic reports (`report_exceptions`, `report_sdc`, and so on) operate on these constraints, and you can update the constraints for the current Timing Analyzer session using the existing Quartus Prime timing analysis API commands.

Note: You can cross-probe the constraints in the `report_sdc` by right-clicking on the Location column of a constraint and selecting **Locate in Constraint File**.

Figure 52. SDC Report in the Timing Analyzer



1.7.3.4. Creating Constraints in SDC-on-RTL SDC Files

SDC 2.1 Compliance

SDC-on-RTL SDCs is an industry-standard to provide constraints targeting your RTL. Target nodes are from the elaborated netlist and aligned closely with your RTL. You can target hierarchical nodes and propagate constraints into the compilation flow through various compilation stages.

Note: The `read_sdc` command loads SDC-on-RTL SDC files into the Timing Analyzer. Depending on the snapshot you loaded, `read_sdc` attempts to read other SDCs suitable for that snapshot. For additional information about the types of SDC files used for different use cases, refer to Types of SDC Files Used in the Quartus Prime Software.

The Quartus Prime software preserves the order of constraints in SDC-on-RTL SDC files. The order in which you list constraints in the SDC file defines the order in which they are loaded in the Quartus Prime software.

SDC-on-RTL constraints are designed to support only SDC 2.1-compliant commands. Object accessors, such as `get_keepers`, `get_registers`, or `get_nodes`, are notably absent. The following is the list of supported SDC commands, and you can find more information about them in the TCL Commands and Packages Summary section of the *Quartus Prime Pro Edition User Guide: Scripting*:

- `create_clock`
- `create_generated_clock`
- `set_input_delay`
- `set_output_delay`
- `set_false_path`
- `set_max_delay`
- `set_min_delay`
- `set_multicycle_path`
- `set_clock_groups`
- `set_clock_latency`
- `set_clock_uncertainty`
- `set_data_delay`
- `set_net_delay`
- `set_max_skew`

Note: Not all of these commands support the full selection of SDC 2.1 arguments because the Timing Analyzer does not support all arguments. If you specify an unsupported argument, these commands issue a warning message and ignore the argument. If you prefer a Tcl error when you encounter a warning in the Timing Analyzer, use the following:

```
set_global_assignment -name ERROR_ON_WARNINGS_LOADING_SDC_ON_RTL_CONSTRAINTS ON
```

Identifying Timing Paths

For defining timing paths, use SDC standard accessors, such as `get_pins`, instead of the Quartus Prime software-specific commands, such as `get_keepers` or `get_registers`. Intel recommends using explicit `get_<pins|ports|nets>` commands when targeting objects. Using bare names can result in unintended targets, and the database issues a warning.

Quartus Prime Conventional SDC (targets Quartus Prime timing graph):

```
set_false_path -from [get_keepers { reg_A }] -to [get_keepers { reg_B }]
```

SDC-on-RTL SDC (targets your netlist nodes):

```
set_false_path -from [get_pins { reg_A|clk }] -to [get_pins { reg_B|d }]
```

Note: The path must start at the register `clk` pin to identify the timing path. If your design uses `reg_A|d` or `reg_A|q`, the timing path in the Timing Analyzer is invalid, as shown in the Report Exception report:

Status	Exception Command	From Flag	From	To Flag	To	Setup Slack
Complete	set_false_path	-from	[get_pins{tf_sync[0]|ff_src|clk}]	-to	[get_pins{tf_sync[0]|ff_dst|d}]	3.603
Invalid	set_false_path	-from	[get_pins{tf_sync[2]|ff_src|q}]	-to	[get_pins{tf_sync[2]|ff_dst|d}]	Invalid
Invalid	set_false_path	-from	[get_pins{tf_sync[3]|ff_src|d}]	-to	[get_pins{tf_sync[3]|ff_dst|d}]	Invalid

Note: Netlist targets are case-sensitive. Sometimes, the lower-level module ports are capitalized. In this case, using the `-nocase` option with the `get_<pins|ports|nets>` commands ignore the case sensitivity.

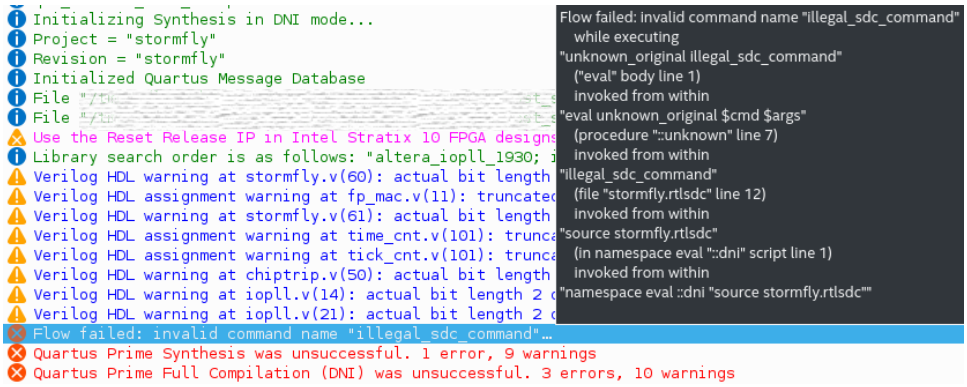
Debugging SDC-on-RTL Constraints

There are several ways to debug SDC-on-RTL constraints. For example, you can isolate the exact locations where constraints are used in your design and analyze them in the flow. You can also use compilation reports that report the constraints (see Elaboration Constraints Compilation Report). However, when debugging the constraints, consider the following:

Explicit Errors When Loading Constraints

Errors with reading SDC-on-RTL constraints issue an error message with a command stack showing the line number of the offending command. For example:

Figure 53. Error Message with a Command Stack



You can debug erroneous constraints directly through the Tcl console. You can iterate on issues with initial target resolution or command syntax at this early stage easily, as this is the stage where Quartus Prime software loads the SDC-on-RTL SDC files.

Note: In general, it is not possible to directly load SDC-on-RTL constraints in the Timing Analyzer because of the following reasons:

- The target netlist is different in the elaborated netlist and not the timing netlist. Although there may be some common nodes between the two netlists, both netlists are different.
- Compliant SDC 2.1 syntax used in SDC-on-RTL can be different from the conventional Quartus SDC commands.

Despite these caveats, if you still want to attempt to load any SDC file in the Timing Analyzer, use `read_sdc <sdc filename>`.

Constraint Behavior and Interpretation Issues

When handling the constraints, ensure the following:

- Targets and basic syntax are correct (node finding or target acquisition). You can use the RTL Analyzer to find the nodes on the elaborated netlist.
- Constraints make sense with respect to the timing graph (constraint behavior). You can review this in the Timing Analyzer.

  Examine the SDC-on-RTL constraints conveyed to the Timing Analyzer (`import_sdc` loads only the SDC-on-RTL commands) from the design netlist. The `import_sdc` command loads a version of the SDC-on-RTL constraints after propagating through various stages of the compile flow. After this step, the experience is the same as a typical Timing Analyzer session.

Note: Although Intel does not recommend loading raw SDC-on-RTL SDC files from the Timing Analyzer, you can issue Timing Analyzer-compatible SDC commands using the Timing Analyzer Tcl console to debug your design. By issuing SDC commands directly, you can override SDC-on-RTL constraints and explore the effect of changing the values. However, the changes are valid only for that timing analysis session. For permanent changes, you must update the source SDC-on-RTL SDC file and rerun Analysis and Elaboration.

1.7.3.5. Using Entity-Based SDC-on-RTL Constraints

A typical design includes a combination of third-party IPs and RTL, so the primary goal of entity-based SDC-on-RTL is to ensure seamless integration of IPs by empowering IP owners to encapsulate their IP's SDC constraints.

Given that timing constraints specified in an SDC file are generally applied globally throughout a design rather than to specific entities, proper encapsulation of IP SDCs becomes crucial. This encapsulation allows utilizing the IPs without encountering unexpected SDC leaks. To achieve this, the entity binding prepends the RTL path name of the IPs, effectively preventing any SDC leaks and averting the potential impact on design paths that might coincidentally match the name.

In addition, the introduction of entity based SDC-on-RTL constraints offer IP authors the ability to define specific constraints at the module boundaries. These constraints are optimized for post-synthesis timing analysis within the context IP instantiation in the design hierarchy. Even when IP authors lack precise knowledge about where their IPs are instantiated in the design hierarchy during its implementation, the constraints remain effective. This approach allows IP authors to implement their SDC constraints without requiring detailed information about the eventual placement of the IP within the hierarchy.

The flow supports reading entity-based SDC-on-RTL in designs and IP cores during the Analysis & Elaboration stage, where the entity-based SDC-on-RTL constraints are read and saved in a low-level entity database. These constraints are eventually processed in the SDC read-in order and applied to the hierarchical netlist objects during compilation.

The Quartus Prime runtime generates IP SDCs along with the IP instantiation and specifies a project assignment to associate IP SDCs with the IP design entity name.

QSF Assignment Syntax

```
set_instance_assignment -name RTL_SDC_FILE <sdc_file_name> -entity <entity_name>
[-no_sdc_promotion]
```

Where:

Argument	Description
`RTL_SDC_FILE`	Specifies the SDC-on-RTL file name.
`-entity`	Indicates that it is an entity-based assignment. The SDC file is applied to each instance of the design entity. The instance hierarchy path is implicitly applied to the `pattern` argument search for `dni::get_*` (`get_cells`, `get_pins`, `get_ports`, and `get_nets`) commands.
`[-no_sdc_promotion]`	An optional argument that works only with the `-entity` flag. For the entity-based constraints, the `[-no_sdc_promotion]` argument removes the default behavior of the instance hierarchy path being the default implicit with the netlist search commands, This

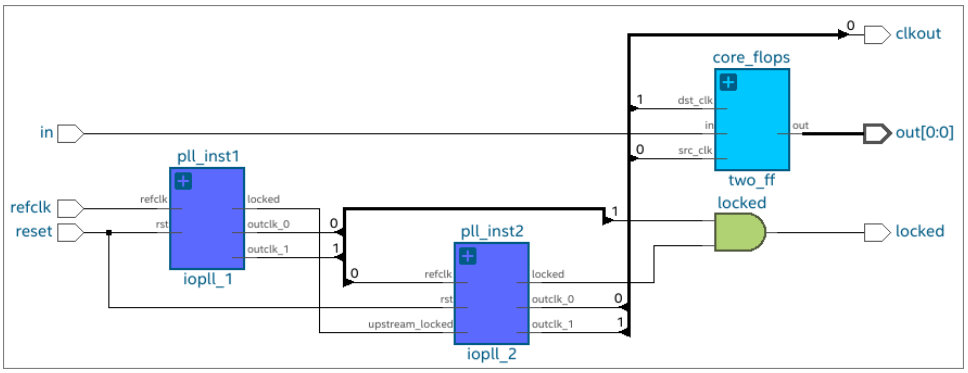
continued...

Argument	Description
	allows you to control which individual command to apply the instance hierarchy path in the netlist object search. Use the `get_entity_current_instance` Tcl command to obtain the current instance hierarchy path of the entity. For example: `set_false_path -from [get_pins [get_entity_current_instance]|ff_src|clk] \` `-to [get_pins [get_entity_current_instance]|ff_dst|d]]`

Example 6. Entity-based SDC-on-RTL Constraints Example

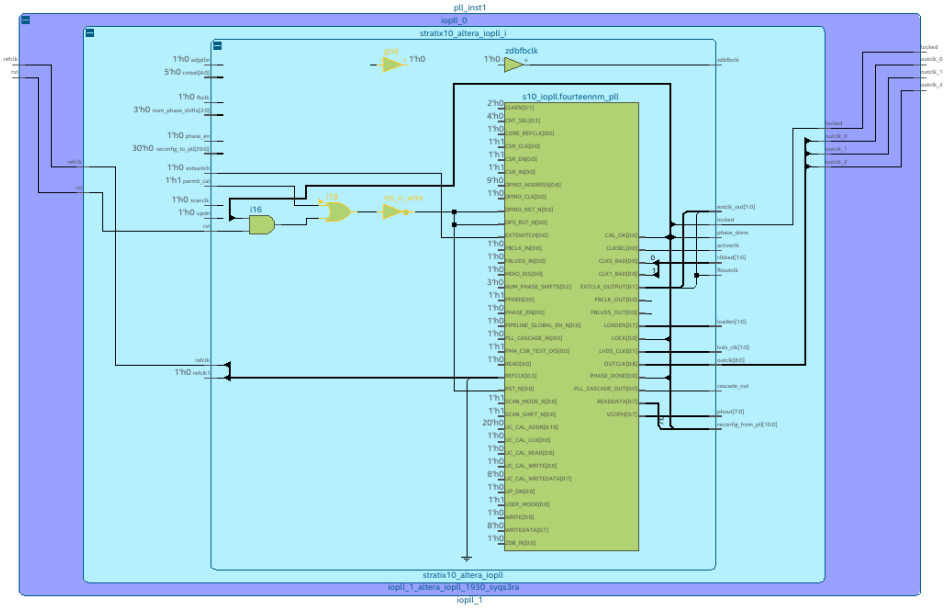
Furthermore, these entity-based SDC-on-RTL constraints provide flexibility. You can enhance or override them by introducing additional SDC constraints during the implementation stages. The following example shows how to establish logical constraints for post-synthesis timing analysis using entity-based SDC constraints on a design that includes two instances of IOPLLs:

Figure 54. Example Design with Two Instances of IOPLLs



In this simple design example, observe `iopll_1` and `iopll_2` entities. There are additional hierarchies inside these entities. The following image depicts the hierarchy for `iopll_1`:

Figure 55. Hierarchy Inside the `iopll_1` Block



1. Apply the initial SDC-on-RTL constraints file to the entire design using the RTL_SDC_FILE argument.

```
set_global_assignment -name RTL_SDC_FILE test.sdc
```

2. Define a specific SDC-on-RTL constraint file using the RTL_SDC_FILE complemented by the arguments `-entity` and `-library` to target each IOPLL entity.

```
set_global_assignment -name RTL_SDC_FILE clock_generator.sdc  -entity
"iopll_1" -library "iopll_1"
set_global_assignment -name RTL_SDC_FILE clock_generator.sdc  -entity
"iopll_2" -library "iopll_2"
```

3. Define the constraints that rule over the IOPLL module.

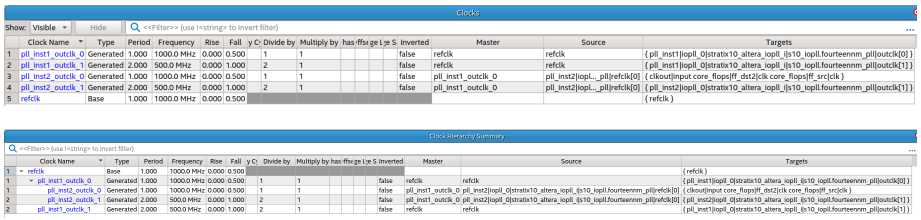
   Note: During the initial stages of designing when the RTL netlist is generated, the internal connections of the PLL might not be fully known. Consequently, apply these constraints at the module boundaries, specifically at the IOPLL ports using the `get_ports` (or `get_pins` *<port_name>*) Tcl command when addressing the module inputs and outputs. Along with other constraints, they facilitate the creation and propagation of output clocks generated from the incoming reference clock. The actual connections in the RTL netlist between the clock source and the target are not required to exist initially to apply early timing constraints. However, the Timing Analyzer will issue a warning about the missing connectivity and continue to operate.

```
# clock_generator.sdc
# get the name of the current instance to generate a name
set current_entity_instance [get_entity_current_instance]
```

```
# Note: Do not specify the -master_clock if you want STA to
#       use the source to determine the master clock name.
create_generated_clock -divide_by 1 -source [get_ports refclk] [get_ports
outclk_0] -name ${current_entity_instance}_outclk_0
create_generated_clock -divide_by 2 -source [get_ports refclk] [get_ports
outclk_1] -name ${current_entity_instance}_outclk_1
```

The clocks are shown here in the Timing Analyzer report, as shown in the following:

Figure 56. Post-Synthesis Clock Reports



It is advantageous to leverage SDC-on-RTL scoping capabilities to generate timing constraints that target RTL nodes, which can be applied during the early stages of timing analysis. Even so, the constraints defined through entity-based SDC-on-RTL files can be adjusted, replaced or supplemented, during the implementation stage, where physical constraints come into play, this allows you to target internal nodes as needed for accurate timing modeling.

Tcl Commands

The SDC commands set model closely relates to the industry-standard SDCs. In particular, the `dni::get_ports` command can query hierarchical ports on an unflattened design netlist. This behavior differs from the existing Timing Analyzer `get_ports` command that can query top-level ports in the post-synthesis design.

When used in the context of entity-based SDC-on-RTL file, the `dni::get_ports` command, for example, `[dni::get_ports refclk]` searches for a port in the context of the current instance of the instantiated RTL. To avoid the implicit prefix of the current instance in the `dni::get_ports` command, use the `-no_sdc_promotion` option along with the `dni::get_entity_current_instance` command in the SDC file where the entity's instance hierarchy path is required.

Related Information

Example: Using SDC-on-RTL Features on page 80

1.7.3.6. Types of SDC Files Used in the Quartus Prime Software

This section provides a high-level summary of the differences between various SDC file types available for use.

The Quartus Prime software uses conventional SDC files to target the timing netlist. These SDCs are not applied until the Fitter plan stage completes. However, for Post-Synthesis Static Timing Analysis (STA) on page 87, you can introduce SDC files to the Quartus Prime software in one of the following ways:

- SDC-on-RTL
- Synthesis SDC

The following table attempts to summarize the differences between the various SDC file types:

Table 16. Types of SDC Files Used in the Quartus Prime Software

	SDC-on-RTL	Synthesis SDC	SDC (Conventional)
Stage where constraints are read	Analysis & Elaboration	Synthesis	Fitter, Signoff
Stage where constraints are processed	Synthesis through Fitter	Synthesis only	Fitter, Signoff
QSF assignment	`RTL_SDC_FILE` (supports entities)	`SDC_FILE SDC_ENTITY_FILE-read_during_post_syn_and_post_fit_timing_analysis` `SDC_FILE SDC_ENTITY_FILE-read_during_post_syn_and_not_post_fit_timing_analysis`	`SDC_FILE`
Syntax supported	Tcl with SDC 2.1 commands	Tcl with Quartus Prime SDC commands	Tcl with Quartus Prime SDC commands
SDC 2.1-compliant	Yes	No	No
Target type	RTL	Quartus Prime timing graph	Quartus Prime timing graph
Hierarchical targets	Yes	No	No
Buried timing nodes (used by IP)	No	Core fabric only. *Note:* Such nodes do not exist for the periphery in post-synthesis STA.	Yes
STA command to load constraints	Executes the `read_sdc` or `import_sdc` command in any snapshot.	Executes the `read_sdc` command only during static timing analysis on the synthesized snapshot.	Executes the `read_sdc` command during static timing analysis on any fitter snapshot (plan, place, route, retime). *Note:* Not loaded during synthesis.

As shown in the table, the assignments allow different SDCs to be used during post-synthesis STA and post-fit STA. It is also possible for an SDC to check the current snapshot through `is_post_syn_sta` to determine the appropriate commands to use, as shown in the following example:

```
if {[is_post_syn_sta]} {
    puts "In post syn sta!"
}
```

1.7.3.7. Example: Using SDC-on-RTL Features

This topic provides some examples of how to use SDC-on-RTL features and set up timing constraints in your design.

You can work with both new and pre-existing designs that incorporate components from diverse sources, including Verilog, VHDL, IPs, and Platform Designer. Suppose your designs contain nodes that require constraint definitions, such as clocks, generated clocks, or asynchronous paths, across various hierarchy levels. In that case, you can efficiently target them using SDC-on-RTL constraints. It is imperative that your chosen design successfully passes the Analysis & Elaboration stages within the compilation flow for seamless and effective testing process.

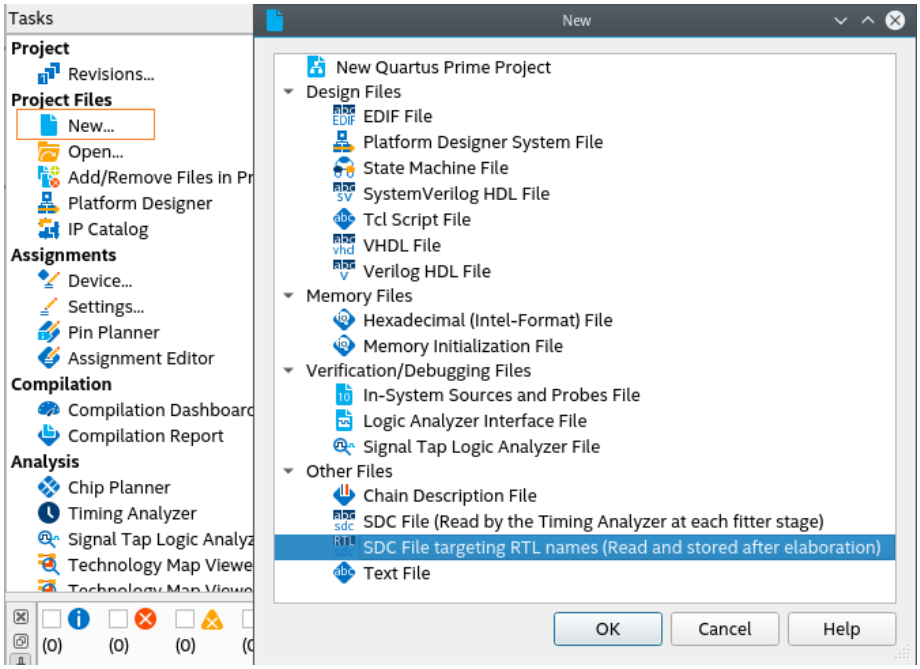
You can control the number of stages generated during the Analysis & Elaboration using the **RTL Analysis Debug Mode** option under **Project ➤ Settings**. This mode is off by default, which means only Elaborated and Swept checkpoints are available, and Instrumented and Constrained checkpoints are unavailable. When you enable this mode, all four checkpoints become available.

Note: Currently, Quartus Prime IPs use conventional SDCs only, which means if you want to create SDC-on-RTL constraints that interact with IP clocks, define them initially with SDC-on-RTL constraints. These clocks can eventually be overwritten by the IP SDCs. Alternatively, if you do not need the clocks defined at Elaboration, use `derive_clocks` during Post-Synthesis Static Timing Analysis (STA) on page 87 to automatically generate clocks temporarily for the Timing Analyzer session.

The following steps demonstrate the process of setting up timing constraints for your designs by targeting RTL node names:

1. Click **New** in the left-hand **Tasks** pane. The New dialog appears.
2. Click **SDC File targeting RTL Names (Read and stored after elaboration)**.

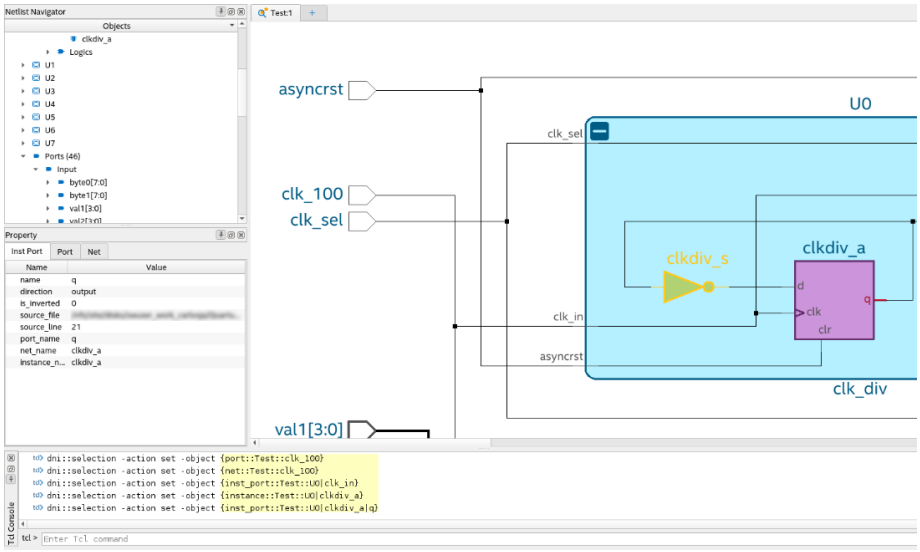
Figure 57. New Dialog Box



3. Click **OK**.
4. Within the new SDC-on-RTL file, formulate a comprehensive set of constraints targeting nodes by their RTL names. For information about how to obtain a list of the supported commands, refer to Creating Constraints in SDC-on-RTL SDC Files on page 72.
5. Ensure the constraint targets are correct and the selected design passes the Analysis & Elaboration compilation stage as the constraints are read during this stage and applied to the elaborated netlist. This step is pivotal as it empowers the software to generate a database of your design. Additionally, it grants access to various checkpoints from where you can access the RTL Analyzer.

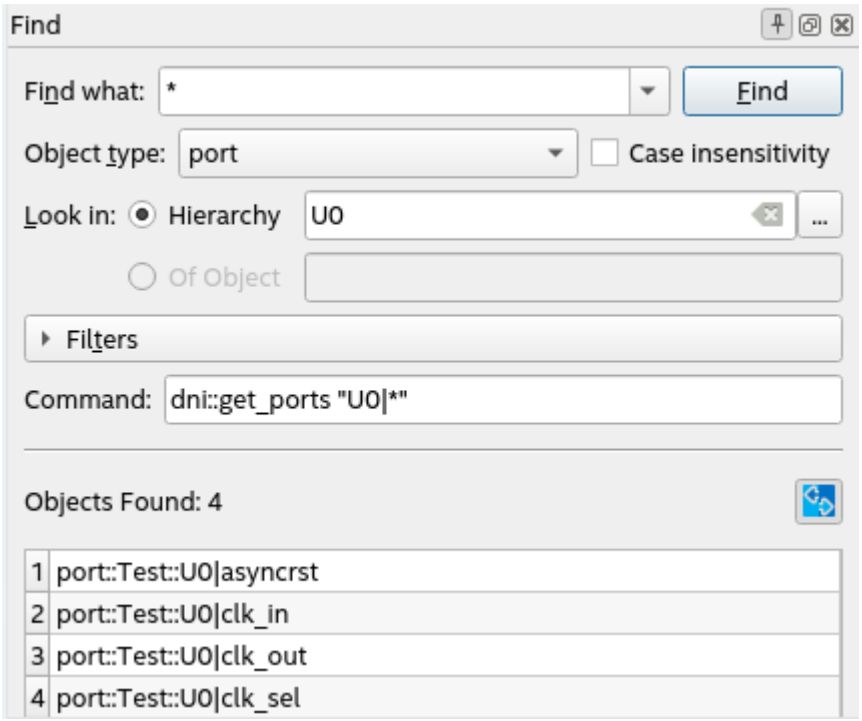
   Note: The RTL Analyzer assists you in locating specific netlist nodes within your design that require constraint application. It allows you to navigate your design and select your desired target nodes. Subsequently, you can use corresponding Tcl commands generated within the Tcl console to extract hierarchical node names from the Tcl commands. This process streamlines the task of implementing constraints on the netlist nodes. For more information about the RTL Analyzer, refer to Exploring the RTL Analyzer on page 23.

Figure 58. Locating Specific Netlist Nodes in the RTL Analyzer



Alternatively, you can locate nodes within your target netlist using the **Find** tool, which is available from the **Edit** menu in the RTL Analyzer. The **Find** tool allows you to search objects within the updated database from the checkpoint accessed.

Figure 59. Find Dialog in the RTL Analyzer



In addition, you can create your collections by focusing on the inputs and outputs of your design through the use of the `get_ports` command. Within your design, you can locate specific nets using the `get_nets` command or target pins using the `get_pins` command.

After establishing your timing constraints in your designs, use the following examples as a guide to set up your constraints, specifically focusing on RTL node names, thereby ensuring precision and efficiency throughout your design process.

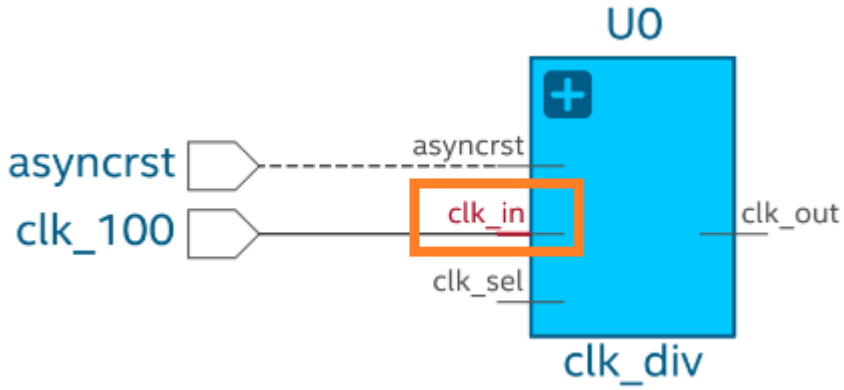
Example 7. Targeting Pins of Top-level Instances

In certain scenarios, it is necessary to constrain pins of top-level instances. For example, when defining clocks and reset inputs, you can utilize the `get_pins` Tcl command followed by the hierarchical pin name to filter each pin as shown in the following:

```
get_pins U0|clk_in
```

This Tcl command returns the input pin `clk_in` in the instance `U0`.

Figure 60. Targeting Pins of Top-level Instances



Similarly, you can target other pins of the same instance and apply necessary constraints as shown in the following:

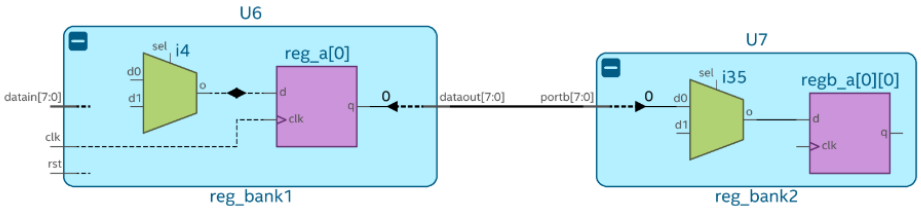
```
create_clock -name clk_input -period 10 [get_pins U0|clk_in]
create_generated_clock -name clk_output -source [get_pins U0|clk_in] -divide_by
2 [get_pins U0|clk_out]
```

Example 8. Targeting Pins in Cells

When constraining your design, you might need to target cell pins to apply constraints. In such scenarios, you can use the `get_pins` Tcl command and RTL names to locate specific cell pins, such as `clk` or `d` inputs and `q` outputs. For example:

```
get_pins U6|reg_a[0]|clk
get_pins U6|reg_a[0]|d
get_pins U6|reg_a[0]|q
```

Figure 61. Targeting Pins in Cells Example



These Tcl commands return specific pins of the `reg_a[0]` register in the U6 instance. You can use the returned collection to constrain paths. For example, from `U6|reg_a[0]` to `U7|regb_a[0][7]` as follows:

```
set_false_path -from [get_pins U6|reg_a[0]|clk] -to [get_pins U7|regb_a[0][0]|d]
```

Example 9. Targeting Pins Using Wildcards

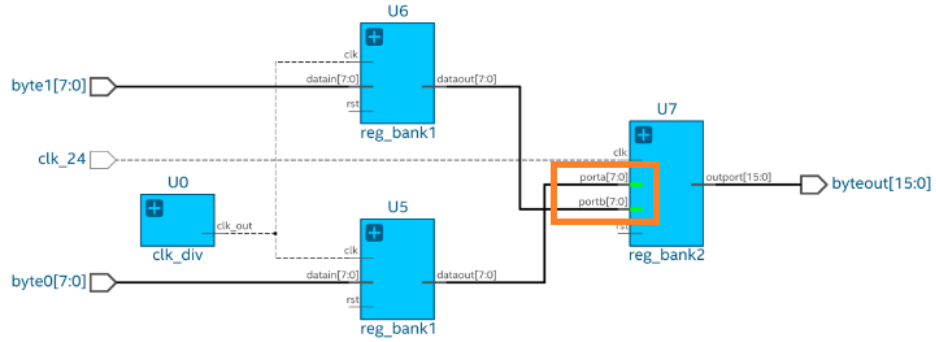
Within your design, you might need to constrain several pins with similar properties and names. In this case, use wildcards to filter the results.

Note: Use the wildcards judiciously and ensure the scope does not include more targets than necessary. Targeting extraneous nodes can limit optimizations and increase compilation runtime and memory.

The `get_pins` command can target buses `porta` or `portb` of `U7`, as shown in the following:

```
get_pins U7|porta[*]
get_pins U7|portb[*]
```

Figure 62. Targeting Pins Using Wildcards Example



The Tcl command returns a collection of pins from `porta[0]` to `porta[7]` and from `portb[0]` to `portb[7]`. You can use the returned collection to constrain all objects simultaneously, as shown in the following:

```
set_false_path -from [get_pins U5|rega*|clk] -to [get_pins U7|porta[*]]
set_false_path -from [get_pins U6|rega*|clk] -to [get_pins U7|portb[*]]
```

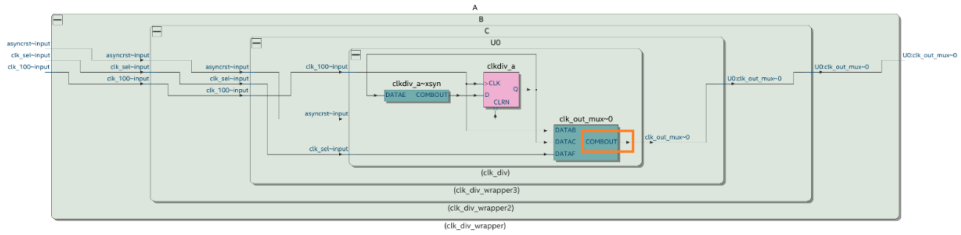
Example 10. Example 4. Applying Constraints at Deeper Hierarchies

Within your design, you can apply constraints at different levels of hierarchy using the pipe character (|) to separate hierarchy levels of instances. Constraints are applied when the hierarchy levels match and the string values, including wildcards, match the pin names. For example:

```
get_pins U3|U0_lv1|U0_lv2|U0_lv3|flag
```

The fundamental timing analysis flow requires executing the fitter to elaborate the timing netlist before applying any constraints. In the following example, suppose you intend to constraint a generated clock buried deep within module A:

Figure 63. Applying Constraints at Deeper Hierarchies Example

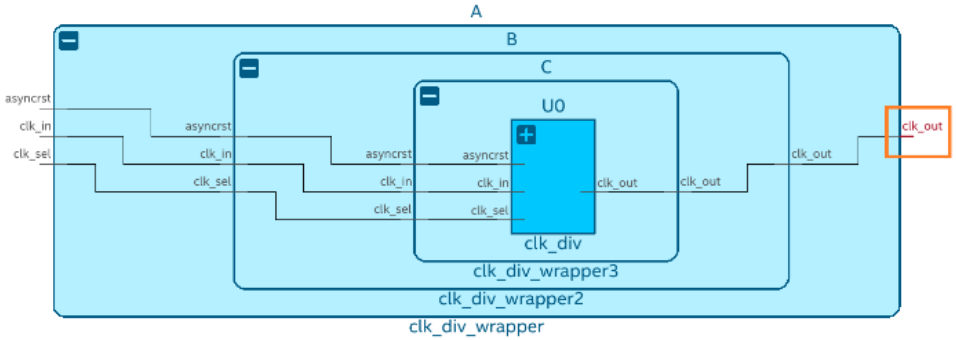


To achieve this, locate the cell `clk_out_mux` where the constraint must be applied and identify the pin name `COMBOUT`. This process often results in a complex path name that can be challenging to decipher, especially when module names are intricate (unlike straightforward names, such as `A|B|C`). Additionally, suppose the hierarchy evolves in the future. In that case, you must rerun the fitter and delve into the design again to derive the updated path, which can lead to inconsistencies between the design and the constraint targets. You can target the `COMBOUT` pin as follows:

```
get_pins A|B|C|U0|clk_out_mux~0|combout
```

SDC-on-RTL also offers an efficient means of constraint propagation, enabling you to apply constraints at module boundaries. It ensures that these constraints seamlessly extend to the corresponding leaf instances during the synthesis stage. For instance, revisit the previous example, in which the clock constraint embedded within module A can be established using SDC-on-RTL constraints at the module A's boundaries, specifically focusing on the `clk_out` pin.

Figure 64. Deeper Design Hierarchies



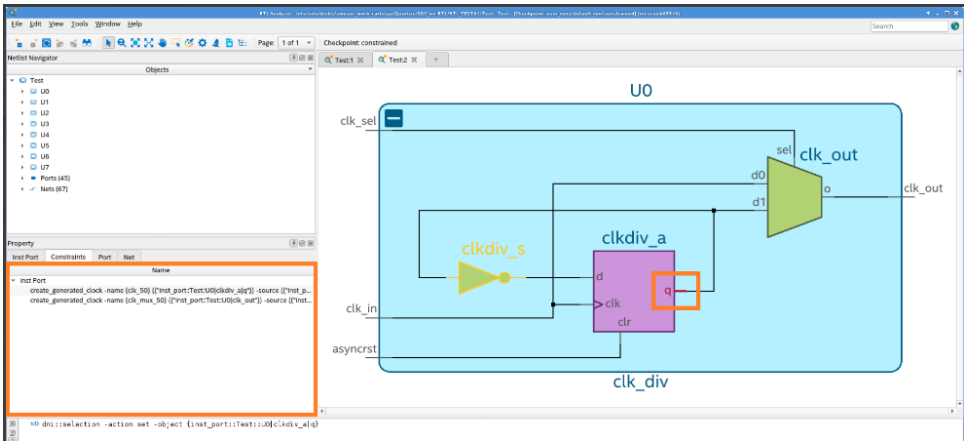
To target the `clk_out` pin of module A, use the following filter:

```
get_pins A|clk_out
```

By directing your attention towards pins located at the boundaries of abstract blocks, you gain the flexibility to modify the internal instance hierarchy as needed. Constraints remain effective even if you decide to rename an internal instance within your module, for instance, changing it from `A|B|C|U0` to `A|X|Y|U0`. Importantly, this can be accomplished without requiring alterations to your existing constraints. This demonstrates the robust capabilities of SDC-on-RTL, allowing you to concentrate on boundary pins rather than navigating complex hierarchies. This approach ensures constraint accuracy and simplifies constraint management.

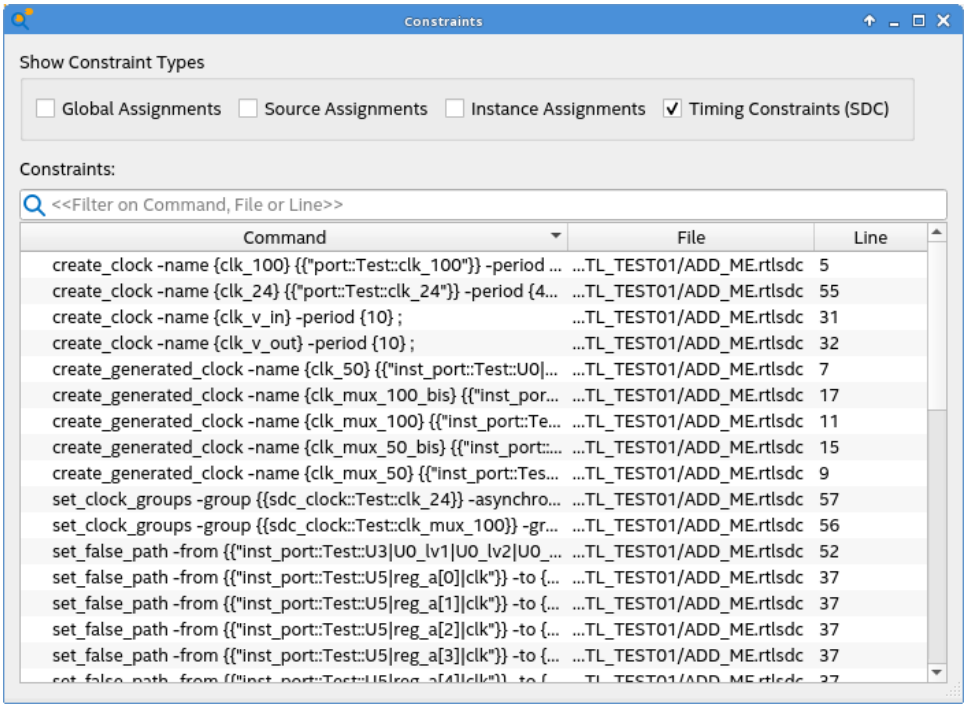
After creating the constraints, rerun the Analysis & Elaboration on the compilation dashboard so that constraints are read and applied to your design. Open the constrained checkpoint of the RTL Analyzer and carefully select the nodes where the constraints were applied. Utilize the Property Viewer to verify the correct application of constraints to these nodes. For additional information, refer to Inspecting SDC-on-RTL Constraints on page 67.

Figure 65. Property Viewer in the RTL Analyzer



Utilize the Quartus Prime software's additional tools to explore and confirm that all SDC constraints were read and successfully applied. Tools like the Constraints viewer launched from the RTL Analyzer can assist you in verifying and cross-probing the constraints with the Schematic Viewer.

Figure 66. Constraints Viewer



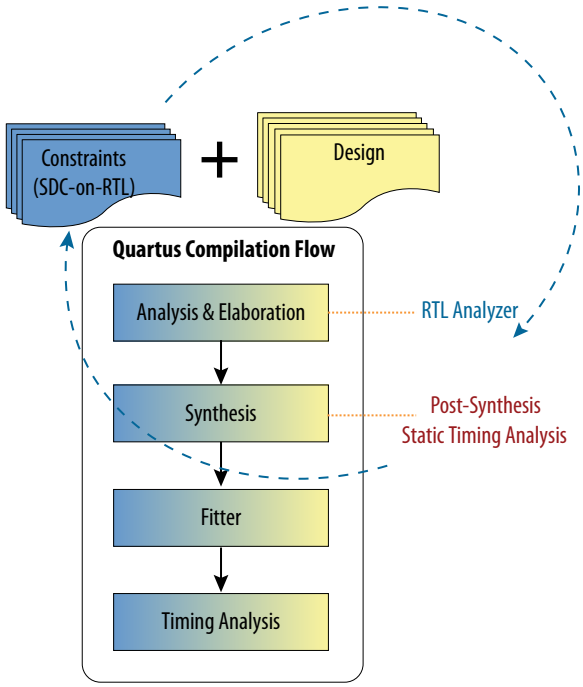
Additionally, the reports under **Compilation Report ➤ SDC Constraints** folder provide a detailed view of the constraints and their locations. Use the Constraint Propagation Report to view how constraints are propagated as the netlist is transformed and inspect where the constraints end up post optimizations.

Important: These tools offer valuable means to verify the accurate application of your constraints. However, if you intend to iterate on the process of defining constraints using the SDC-on-RTL approach, you must rerun the Analysis & Elaboration stage each time. This iterative approach ensures that the constraints are meticulously analyzed during netlist generation, resulting in enhanced performance and seamless integration with your design.

1.7.4. Post-Synthesis Static Timing Analysis (STA)

Post-synthesis static timing analysis (STA) allows you to run the Timing Analyzer directly after synthesis. This flow involves running Analysis & Elaboration and Synthesis stages and iterating on your design's static timing analysis results early in the Quartus Prime software compilation flow without running the Fitter.

Figure 67. Early Timing Analysis Flow



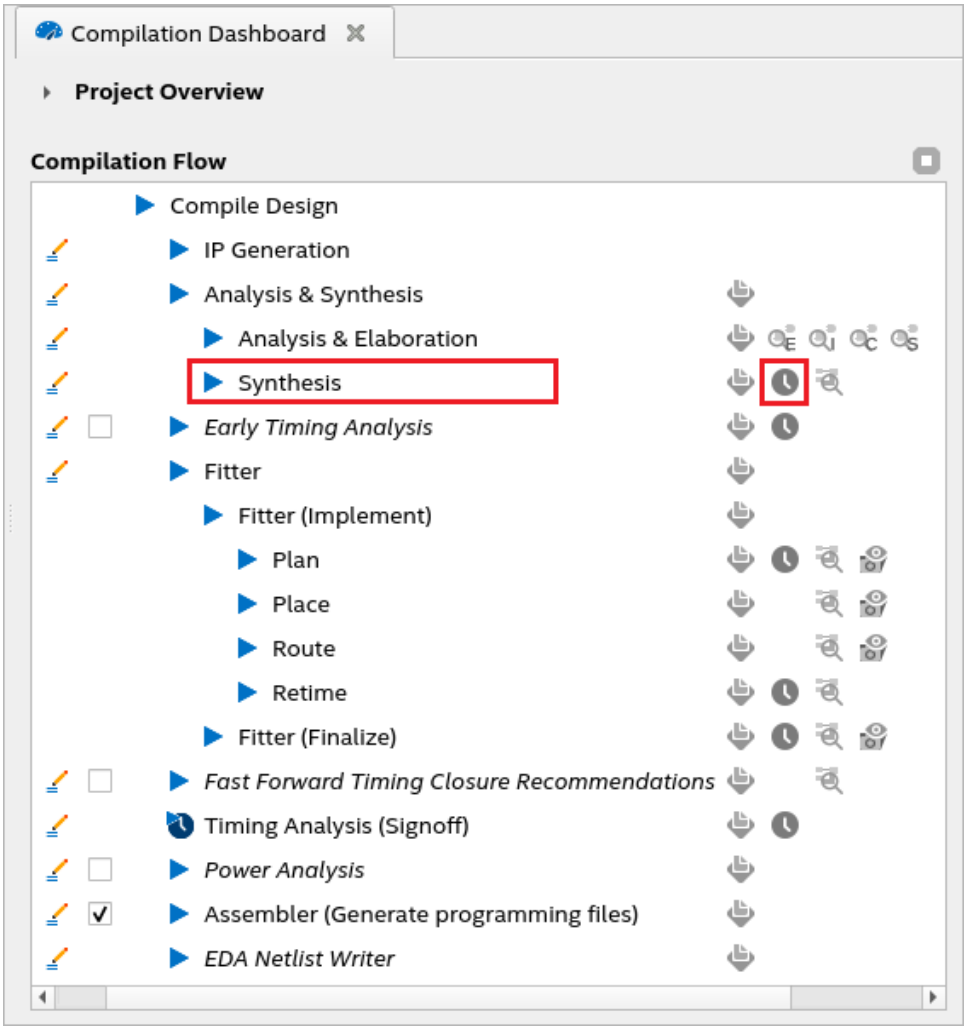
The Synopsys* Design Constraint (SDC) on RTL supports the underlying technology to read the constraints early in the compilation flow and use them in the later stages of the Quartus Prime compilation. However, you can run the flow even without RTL SDCs where you can view the synthesized timing netlist.

Post-synthesis STA defaults to a simple average value delay model based on the types of blocks a net connects. "Average Value" interconnect (IC) delay model to control STA after synthesis. Using the STA_POST_SYN_DELAY_MODEL QSF, you can switch to the "Zero Value" IC delay model to exclude interconnect delays from the timing model.

Note: If you want zero delays, you can also use `create_timing_netlist -zero_ic_delay` argument.

You can now access the Timing Analyzer right after design synthesis in the compilation dashboard, as shown in the following image:

Figure 68. Early Timing Analysis Stage



Post-synthesis static timing analysis (STA) uses a timing netlist representing core blocks and their contents. It also includes periphery blocks (but nothing inside them is modeled) and cell delays of the core blocks. Routing delays between core blocks is represented by IC delays that use the average interconnect model mentioned above.

Post-synthesis STA timing netlist provides you with an early view of your design's core timing. You can run timing analysis reports and constraint diagnostic commands, allowing you to examine SDC-on-RTL constraints.

Perform the following steps to run post-synthesis STA:

1. Create an Quartus Prime software project using your design RTL and associated SDC-on-RTL SDC file.
2. Run **Analysis and Elaboration** compilation stage on your design as follows:

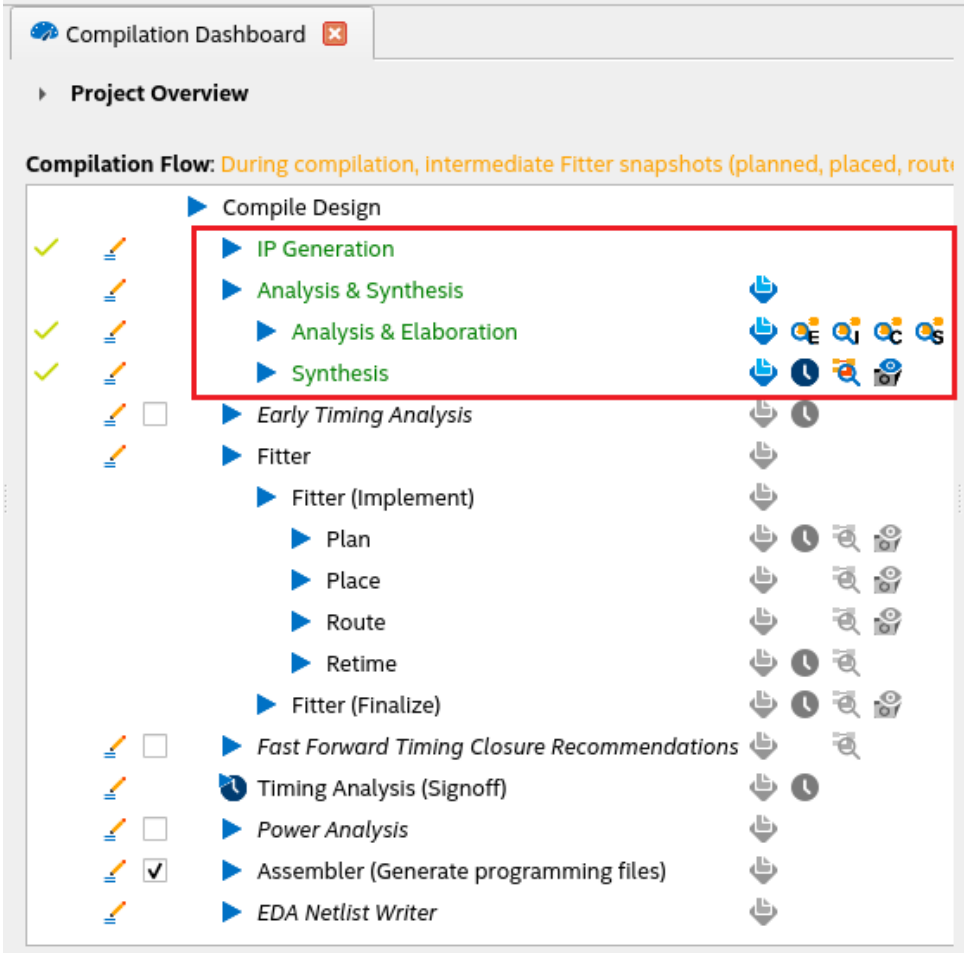
```
quartus_syn --analysis_and_elaboration <design>
```

3. Perform Synthesis on your design as follows:

```
quartus_syn --synthesis <design>
```

You can also perform the above steps using the Quartus Prime software GUI, as shown in the following image:

Figure 69. Performing Post-synthesis STA in the Quartus Prime Software GUI



After running post-synthesis STA on your design, you can use the Timing Analyzer conventionally. However, a fundamental difference in the netlist topography is that the post-synthesis STA timing netlist has no connectivity inside any periphery block.

Note: The post-synthesis STA delay model defaults to a simple average value delay model. Cell delays are computed assuming default configurations.

For post-synthesis constraints, Intel recommends using an SDC-on-RTL file. In cases where this is not possible, post-synthesis STA introduces the `SDC_FILE -read_during_post_syn_and_not_post_fit_timing_analysis` QSF argument, which is used to inform the Timing Analyzer to include a conventional SDC in the list of SDCs to be read during a post-synthesis STA session. This QSF is beneficial for blocks that do not have SDC-on-RTL constraints available. Since the post-synthesis STA netlist differs from the post-plan STA netlist, conventional SDCs written for the post-plan netlist might not function during post-synthesis STA. By creating a new category of SDC files, you can identify scripts you want to load during post-synthesis STA.

1.7.5. Viewing Synthesis Reports

The Compilation Report window opens automatically during compilation processing. The Report window displays detailed synthesis results for each partition in the current project revision.

Figure 70. Synthesis Reports

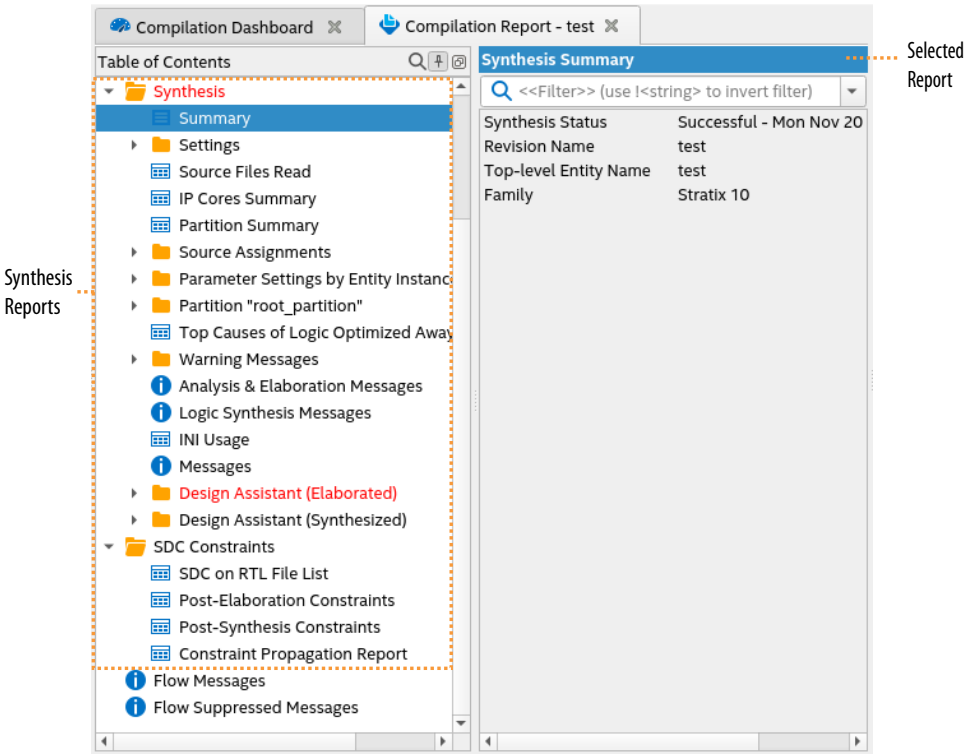


Table 17. Synthesis Reports (Design Dependent)

Generated Report	Description
Summary	Shows summary information about synthesis, such as the status, date, software version, entity name, device family, timing model status, and various types of logic utilization.
Settings	Lists the values of all synthesis settings during design processing.
Source Files Read	Lists details about all source files in design synthesis. Details include file path, file type, and any library information.

continued...

Generated Report	Description
IP Cores Summary	Lists details about each IP core instance in design synthesis. Details include IP core name, vendor, version, license type, entity instance, and IP include file.
Partition Summary	Shows a summary of partitions in the design. Details include partitions names, hierarchy path, partition type, and partition properties.
Source Assignments	A series of reports that list details about source assignments. Details include assignment, value, and source location.
Parameter Settings by Entity Instance	A series of reports that list parameter settings for entities in your design. Details in the reports include parameter name, parameter value, and parameter data type. *Note:* You can view the parameter settings for a module directly from the Project Navigator by locating the module and selecting **View Parameter Settings** in its context-sensitive menu. Compilation Report appears, displaying the parameter settings for the entity.
Partition reports	Each design partition has a series of reports: • Resource Utilization By Entity: Lists the quantity of all types of logic usage for each entity in design synthesis. • Optimization Results: The reports in this folder provide statistics for the following items: — Registers, including registers protected by synthesis and registers removed by synthesis — Multiplexers, including restructuring that synthesis performs and multiplexers implemented. • Post-Synthesis Netlist Statistics • Resource Usage Summary: Lists the quantity of all types of logic usage for the design partition in design synthesis. • RAM Summary: Lists RAM usage details for the design partition in design synthesis. Details include the name, type, mode, and density.
Messages	Lists all information, warning, and error messages that report conditions observed during the Analysis & Synthesis process.
Warning Messages	A series of reports that summarize the warning messages generated during synthesis by providing one entry per message ID, its severity, the count of all its occurrences, and one sample warning message. A separate report is generated for warnings from each source file. General warning messages that are not associated with a source file are put in a separate report.
Design Assistant (Elaborated)	Lists Design Assistant rules that failed during the Analysis & Elaboration stage.
Design Assistant (Synthesized)	Lists Design Assistant rules that failed during the Synthesis stage.
SDC Constraints	Lists all constraints-related reports. Post-Elaboration Constraints, Post-Synthesis Constraints, and Constraint Propagation Reports are available at the end of synthesis. For more information about these reports, refer to Applying the SDC-on-RTL Constraints on page 66.

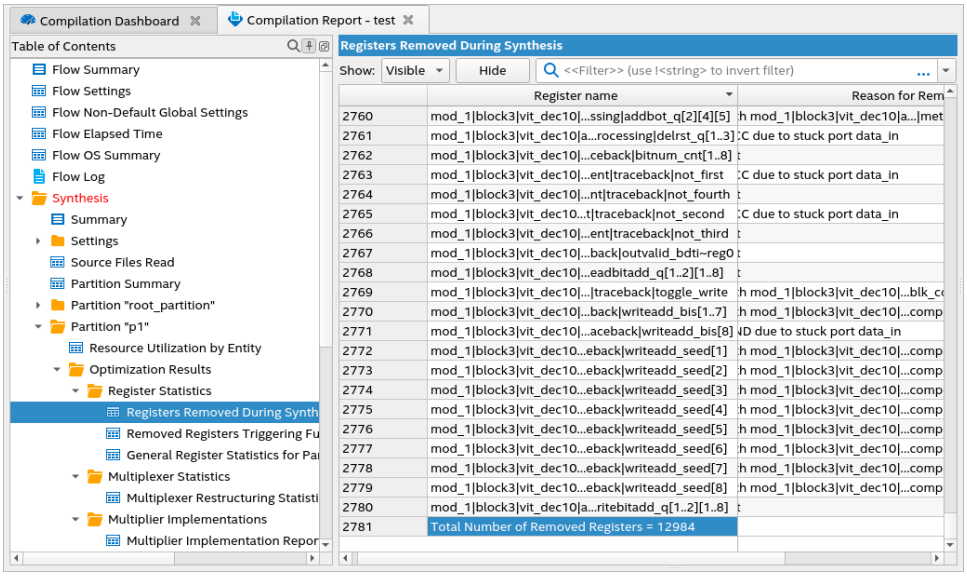
1.7.6. Viewing Synthesis Dynamic Report

The dynamic report feature allows you to interact with a full report that displays only a few items in the GUI. This feature is off by default, and you can enable it through the `synth_rpt_enable_dynamic_report` QSF. Currently, you can view dynamic reports only for the **Registers Removed During Synthesis** report.

In the following report, you can observe that the compiler removed 12984 registers during synthesis. However, after 2780 registers, the remaining registers are truncated from the report due to the GUI threshold. With the dynamic report feature, you can retrieve details of these remaining registers without recompiling your design using the updated GUI threshold.

Note: You can modify the number of removed registers reported through the **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis) ➤ Number of Removed Registers Reported in Synthesis Report** option.

Figure 71. Sample Registers Removed During Synthesis Report



Within one compilation, the compiler stores all items from the report in a dynamic SQLite database under `<project_directory>/dynamic_report/registers_removed.sqlite`. After design synthesis, you can access the SQLite database through Tcl commands to extract a summary of the SQLite database (for example, data column and total size of the items), query from the database using SQL commands (for example, SELECT and WHERE), and retrieve the desired number of truncated lines from the report.

Note:

- If you recompile after generating the SQLite database, contents are rewritten to the same database. If you turn off the QSF during recompilation, the SQLite database retains the information from the previous compile.
- If your design does not contain registers to be removed during synthesis, the compiler does not generate the **Registers Removed During Synthesis** report. Hence, the `dynamic_report` directory and the SQLite database are also not generated.

Executing Tcl Commands

You can execute the `dynamic_report` Tcl commands in one of the following ways:

- Include Tcl commands in a Tcl script and run it using `quartus_syn -t <name>.tcl`.
- Execute a single command directly from your terminal as `quartus_syn --tcl_eval <tcl command>`.
- Execute a single command from the GUI by launching your project in the Quartus Prime software and navigating to **View ➤ Tcl Console** on the menu. In the Tcl Console window, type your Tcl command.

The result is the same irrespective of the method you use to execute your `dynamic_report` Tcl command.

Note: When you execute a `dynamic_report` Tcl command, the Tcl command attempts to open the corresponding SQLite database immediately for further action. The path to open the database is absolute. So, you must ensure that your current directory is where your design is located and not in the `dynamic_report` directory. Otherwise, an error displays indicating the path to the SQLite database is incorrect or an issue with opening the SQLite database.

The following table lists some example `dynamic_report` Tcl commands with various options:

Table 18. `dynamic_report` Tcl Command Examples

`dynamic_report` Command Option	Description	Tcl Command Example
`-help`	Provides detailed help for the `dynamic_report` Tcl command, including currently supported report values, options, and error values.	`dynamic_report -help`
`-long_help`	Provides long help for the `dynamic_report` Tcl command with examples and possible return values.	`dynamic_report -long_help`
`-report <report name>`	Targets the report that `<report name>` specifies. For the **Registers Removed During Synthesis** report, use `"registers removed"`. *Note:* The `-report` option is mandatory as the Tcl command takes further action based on the report name. Absence of the `-report` option or using an unsupported value for `<report name>` results in an error.	`dynamic_report -report "registers removed"`
`-summary`	Generates a summary of the specified report, such as the table name, total size, and column names, which help query from the SQLite database.	`dynamic_report -report "registers removed" -summary`
`-query <sqlite query>`	Accepts an entire SQLite query as an option to retrieve the desired result from the database. For example, `-query "SELECT * FROM <table> WHERE <column> = <...>"`	`dynamic_report -report "registers removed" -query "SELECT * FROM 'Registers Removed During Synthesis' WHERE reason = 'Stuck at VCC due to stuck port data_in'"`

continued...

dynamic_report Command Option	Description	Tcl Command Example
	If the query command is incorrect or incomplete, an error message displays with details. The result of this query is sent to an output file under the <project directory>/dynamic_report directory in ASCII format by default.	
-dump_all	Dumps all items in the report. The result of this query is sent to an output file under the <project directory>/dynamic_report directory in ASCII format by default.	dynamic_report -report "registers removed" -dump_all
-dump_lines <*unsigned integer*>	Dumps first <*unsigned integer*> of lines in the report. An error message displays if the value specified for <*unsigned integer*> is not an unsigned integer or not in the range of 1 and 999999999. The result of this query is sent to an output file under the <project directory>/dynamic_report directory in ASCII format by default.	dynamic_report -report "registers removed" -dump_lines 250
-filename <*file_name*>	Specifies an output file name for the results dumped by -query, -dump_all, and -dump_lines options. -filename is optional. If you do not specify a file name, the compiler names the output file as <*report name*>.ascii. An error message displays if the file name is empty or contains special characters or spaces. *Note:* With the -filename option, you can use the -html or -xml option to generate the output file in HTML or XML format, respectively.	dynamic_report -report "registers removed" -dump_all -filename "my_result"

Attention: The options -summary, -query, -dump_all, and -dump_lines are mandatory but exclusive, which means that the dynamic_report Tcl command requires only one option. If you include multiple options within a single dynamic_report Tcl command, an error message displays requesting you to specify a single option.

Related Information

dynamic_report (::quartus::interactive_synthesis)

1.8. Design Place and Route

The Compiler's Fitter module (quartus_fit) performs design placement and routing. During place and route, the Fitter determines the best placement and routing of logic in the target FPGA device, while respecting any Fitter settings or constraints that you specify.

By default, the Fitter selects appropriate resources, interconnection paths, and pin locations. If you assign logic to specific device resources, the Fitter attempts to match those requirements, and then fits and optimizes any remaining unconstrained design logic. If the Fitter cannot fit the design in the current target device, the Fitter terminates compilation and issues an error message.

The Quartus Prime Pro Edition Fitter introduces a hybrid placement technique that combines analytical and annealing placement techniques. Analytical placement determines an initial mathematical starting placement. The annealing technique then fine-tunes logic block placement in high resource utilization scenarios.

Related Information

- Running the Fitter on page 96
- Viewing Fitter Reports on page 98

1.8.1. Running the Fitter

The Compiler's Fitter module performs all stages of design place and route, including the Plan, Early Place, Place, Route, and Retime stages.

The Quartus Prime Pro Edition Compiler allows control and optimization of each individual Fitter stage, including the Plan, Place, and Route stages. Run all stages of the Fitter as part of a full design compilation, or run any Fitter stage independently after design synthesis. Before running the Fitter, you specify settings that impact Fitter processing.

After running a Fitter stage, view detailed report data and analyze the timing of that stage. The Compiler preserves Fitter results of the final snapshot by default.

1. Specify initial Fitter constraints:
   a. To assign device I/O pins, click **Assignments ➤ Pin Planner**.
   b. To assign device periphery, clocks, and I/O interfaces, click **Tools ➤ Interface Planner**.
   c. To constrain logic placement regions, click **Tools ➤ Chip Planner**.
   d. To specify Fitter optimization goals, click **Assignments ➤ Settings ➤ Compiler Settings**. Compiler Optimization Modes on page 149 describes these options in detail
   e. To fine-tune place and route with advanced Fitter options, click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)**
2. To run one or more stages of the Fitter, click any of the following commands on the Compilation Dashboard:
   - To run all Fitter stages in sequence, click **Fitter**.
   - To run only device periphery placement and routing, click **Plan**.
   - To run only logic placement, click **Place**.
   - To run only logic routing, click **Route**.
   - To run only retiming of ALM registers into Hyper-Registers, click **Retime**.(2)
   - To run the Implement flow (runs Plan, Place, Route, and Retime stages), click **Fitter (Implement)**.
   - To run the Finalize flow (runs Plan, Place, Route, Retime, and Finalize stages), click **Fitter (Finalize)**.

(2) Retime available for Hyperflex® architecture devices only.

1.8.1.1. Fitter Commands

Launch Fitter processes from the Processing menu or Compilation Dashboard with Fitter commands.

Table 19. Start Fitter Commands

Command	Description
Start Fitter (Plan)	Loads synthesized periphery placement data and constraints, and assigns periphery elements to device I/O resources. This command creates the planned snapshot.
Start Fitter (Place)	Places all core elements in a legal location. This command creates the placed snapshot.
Start Fitter (Route)	Creates all routing between the elements in the design. This command creates the routed snapshot.
Start Fitter (Retime)	Performs register retiming and moves existing registers into Hyper-Registers to increase performance by removing retiming restrictions and eliminating critical paths. The Compiler may report hold violations for short paths following the Retime stage. This command creates the retimed snapshot.
Start Fitter (Finalize)	Performs post-routing optimization on the design. The Fitter identifies and corrects the short paths with hold violations during the Fitter (Finalize) stage by adding routing wire along the paths. After correcting the hold violation, the Fitter performs the following physical synthesis optimizations for further setup timing improvement: retiming, LUT and ALM rotation, re-synthesize logic, wire LUT removal, inverter optimization, and skew-optimization for Agilex 7 devices. This stage converts unneeded tiles from High Speed to Low Power. This command creates the final snapshot. For Stratix 10 and Agilex 7 designs, the Fitter also runs post-route fix-up to correct any short path hold violations remaining from retiming.

Note: The Compiler reports violations under the **Compilation Report ➤ Fitter** section. The Fitter identifies and corrects the short paths with hold violations during the Fitter (Finalize) stage by adding routing wire along the paths.

1.8.1.2. Disabling or Enabling Physical Synthesis Optimization

Physical synthesis optimization improves circuit performance by performing combinational and sequential optimization and register duplication.

The Compiler performs physical synthesis optimization by default during place and route. You can disable or enable physical synthesis optimization and related options by following these steps:

To disable or enable physical synthesis optimization:

1. Click **Assignments ➤ Settings ➤ Compiler Settings**.
2. To enable retiming, combinational optimization, and register duplication, click **Advanced Settings (Fitter)**.
3. Enable **Advanced Physical Synthesis**.
4. View physical synthesis results in the **Netlist Optimizations** report under **Compilation Report ➤ Fitter** section.

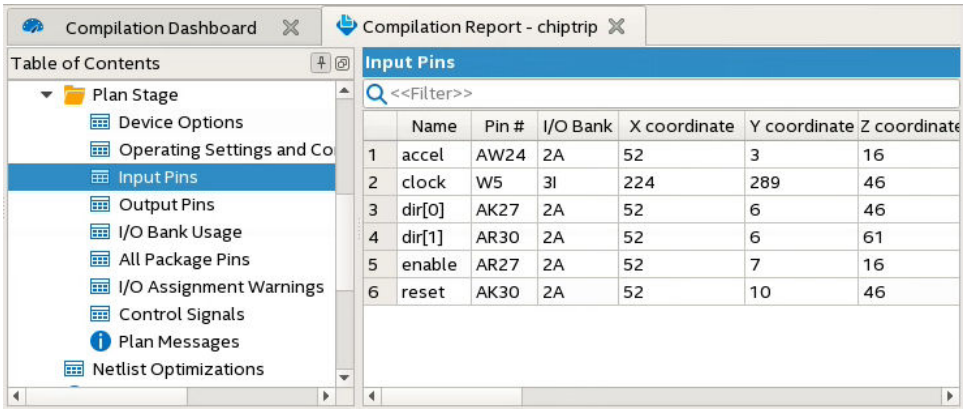
1.8.2. Viewing Fitter Reports

The Fitter generates detailed reports and messages for each stage of place and route. The Fitter Summary reports basic information about the Fitter run, such as date, software version, device family, timing model, and logic utilization.

1.8.2.1. Plan Stage Reports

The Plan stage reports describe the I/O, interface, and control signals discovered during the periphery planning stage of the Fitter.

Figure 72. Plan Stage Reports (Arria 10 and Cyclone 10 GX Designs)



For Arria 10 and Cyclone 10 GX designs, the Plan stage includes the **Global & Other Fast Signals Summary** report that allows you to verify which clocks the Compiler promotes to global clocks. Clock planning occurs after the Plan stage for Stratix 10 and Agilex 7 designs.

NoC Connectivity Report

For Agilex 7 M-Series FPGAs only, the NoC Connectivity Report provides information on connections between NoC initiators and targets in the implemented design, and their associated base addresses. Use this report to verify that the implementation of connection and attribute assignments are correct. The table in this report contains a row for each initiator to target connection. Additional rows may report any unconnected NoC elements. The following columns report data:

- **Group**—displays which NoC group the connection is assigned to.
- **Status**—displays whether the row is for connected or unconnected elements.
- **Initiator**—lists the NoC initiator elements.
- **Target**—lists the NoC target elements.
- **Address**—displays the hexadecimal base address for each connection

NoC Performance Report

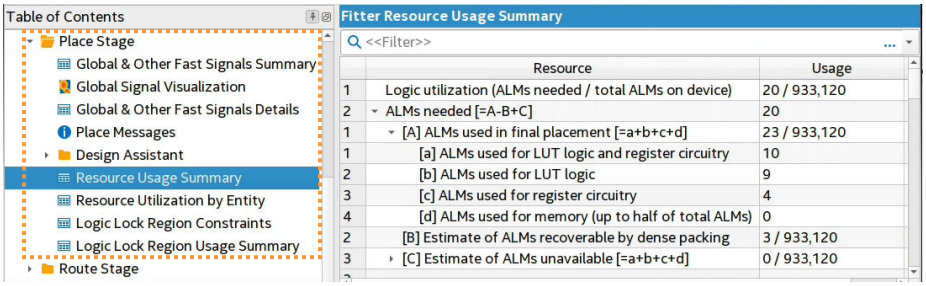
For Agilex 7 M-Series FPGAs only, reports the user-requested read and write bandwidths, as well as the minimum latency of NoC request and response transactions.

The latencies in this report are based on the minimum structural latency with respect to the initiator and target placement. These latencies are for the NoC portion of the path only. These latencies do not include any latency of, for instance, external memory access. Nor do these latencies account for potential delay due to congestion on the NoC. You can achieve lower minimum structural latency by placing the NoC initiators and targets closer together.

1.8.2.2. Place Stage Reports

The Place stage reports describe all device resources the Fitter allocates during logic placement, as well as use of Logic Lock regions and global and other fast signals.

Figure 73. Place Stage Reports



1.8.2.2.1. Global Signal Visualization Report

For Stratix 10 and Agilex 7 designs, you can access the Global Signal Visualization report to view global signal routing and clock sector utilization in an interactive heat-map. This report allows you to track the routing and placement of each individual clock. You can use this data to analyze global signal routing congestion issues, and to debug global signal placement and routing failures.

View global clock tree implementation details and assess capacity to add more global signals to the design. In cases of clock tree synthesis errors, the report can also show targeted regions for failing signals, and competing signals that are contributing to routing congestion.

The interactive heatmap color gradients show clock sector congestion of the clock signals terminating inside the sector. Hover the cursor over a clock signal in the table to highlight the clocks sectors and routing elements. Select a clock signal in the table to dim all irrelevant sectors and routing elements, while highlighting only the clock's sectors and routing elements. The global clock signal routing on different layers displays in the report's stacked layer view.

Figure 74. Global Routing Wire Utilization (Single Layer)

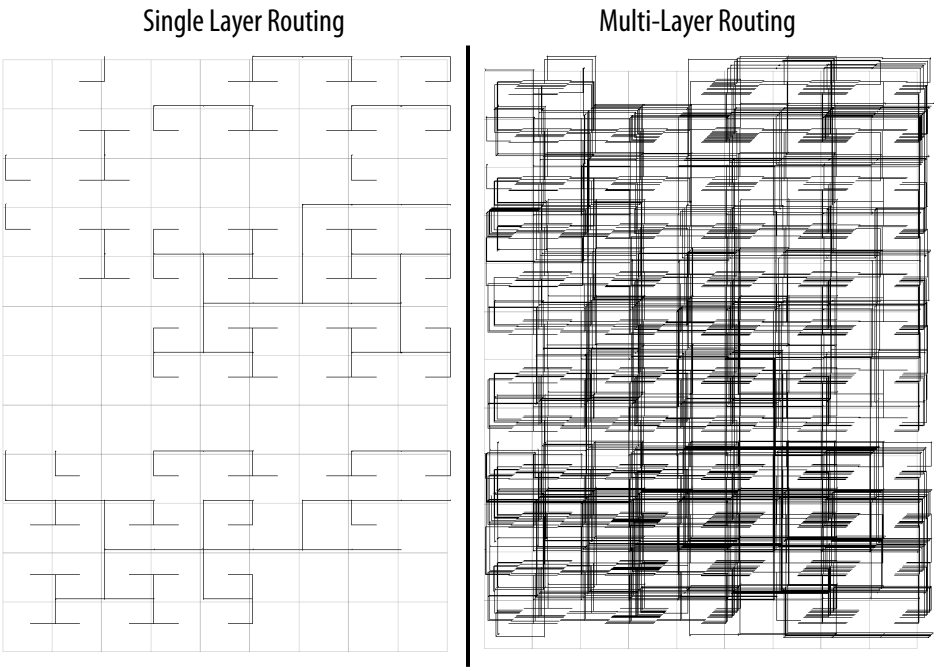


Figure 75. Heat Map Sector and Routing Wire Utilization (All Layers)

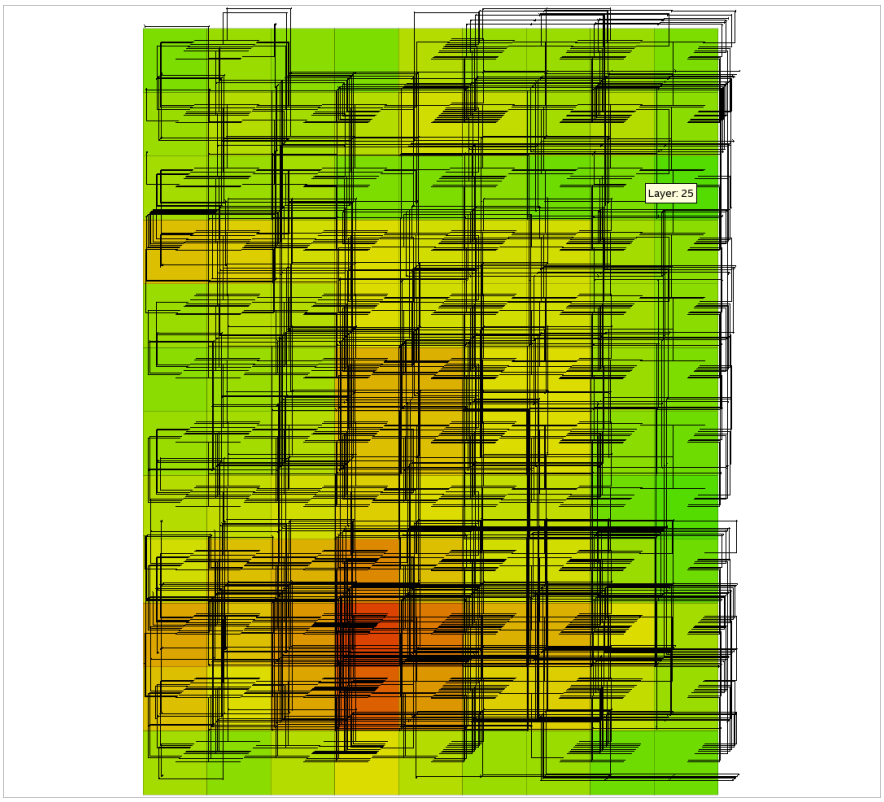
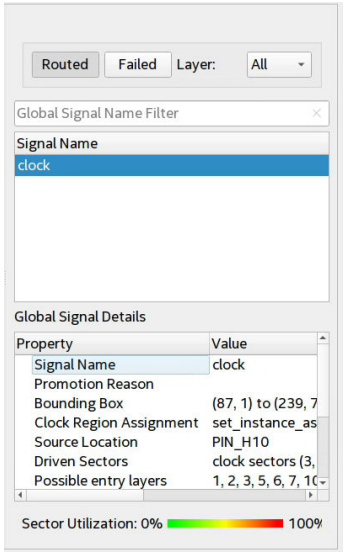


Filter the display to **Show Routing Utilization** and **Show Sector Utilization**. The content of the table changes based on the selections you make in the heatmap. You can search for **Signal Names**, and then select the signal names to display its properties in the lower pane. Select any signal to **Locate** in other tools.

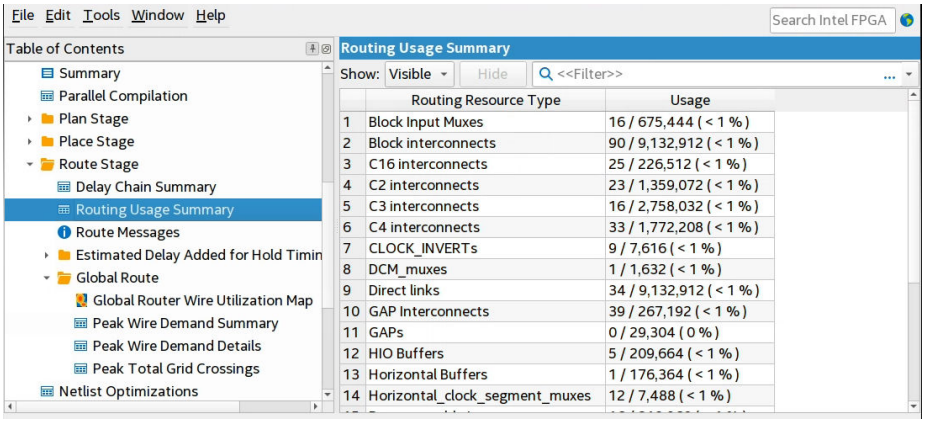
Figure 76. Signals Names and Property Details



1.8.2.3. Route Stage Reports

The Route stage reports describe all device resources that the Fitter allocates during routing. Details include the type, number, and overall percentage of each resource type. The Route stage also reports delay chain summary information.

Figure 77. Route Stage Reports



1.8.2.3.1. Global Router Congestion Hotspot Summary Report

The Global Router Congestion Hotspot Summary report shows congested net hotspots in your design by hierarchical node name.

A global routing congested region is an area of the FPGA where short wire usage in a particular direction exceeds the capacity of that region. A congested net is a net that passes through a congested region.

If the congested area is small, detailed routing can recover by detouring around these overused regions. However, if the congested area is large, you most likely encounter a no route. The exact threshold where that happens varies greatly depending on the design.

Use the Global Router Congestion Hotspot Summary report to identify parts of your RTL code that are associated with routing congestion.

Figure 78. Example of the Global Router Congestion Hotspot Summary Report

Global Router Congestion Hierarchical Summary

<<filter>>

	Hierarchical Node Name	Number of Congested Nets	Full Hierarchy Name
1	▾ |	7583 / 271506 (2.8%)	|
1	|prg[64]~input	1 / 1 (100.0%)	prg[64]~input
2	▾ |u_respe|	7581 / 250835 (3.0%)	u_respe|

15	▾ |g_tmc1.u_tmc1|	28 / 4685 (0.6%)	u_respe|g_impl_on.resp_0|g_tmc1.u_tmc1|
1	|p_inreg_s_dt_tin32_r_15_21_	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|g_tmc1.u_tmc1|p_inreg_s_dt_tin32_r_15_21_
2	|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout101	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|g_tmc1.u_tmc1|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout101
3	|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout103	1 / 1 (100.0%)	u_respe|g_impl_on.resp_0|g_tmc1.u_tmc1|p_inreg_s_dt_tin32_r_28_5_~sr_lutram_dout103

Note: In the **Number of Congested Nets** column, the numerator is the number of nets under the current hierarchical level that overlap with the largest congestion island, and the denominator is the total number of nets under the current hierarchical level (including nets that are not in the congestion island). The largest congestion island is the largest group of adjacent grids whose short wire usage exceeds capacity. You can see a visualization of this report in the Global Router Wire Utilization Map.

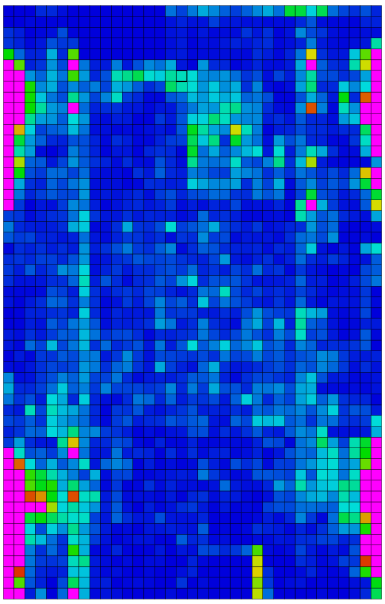
The Global Router Wire Utilization Map provides a visualization of the Global Router Congestion Hotspot Summary Report.

If the size of adjacent congested regions is below a threshold, the report shows the threshold and size of the largest congested region instead of a hierarchical report of congested nets.

1.8.2.3.2. Global Router Wire Utilization Map Report

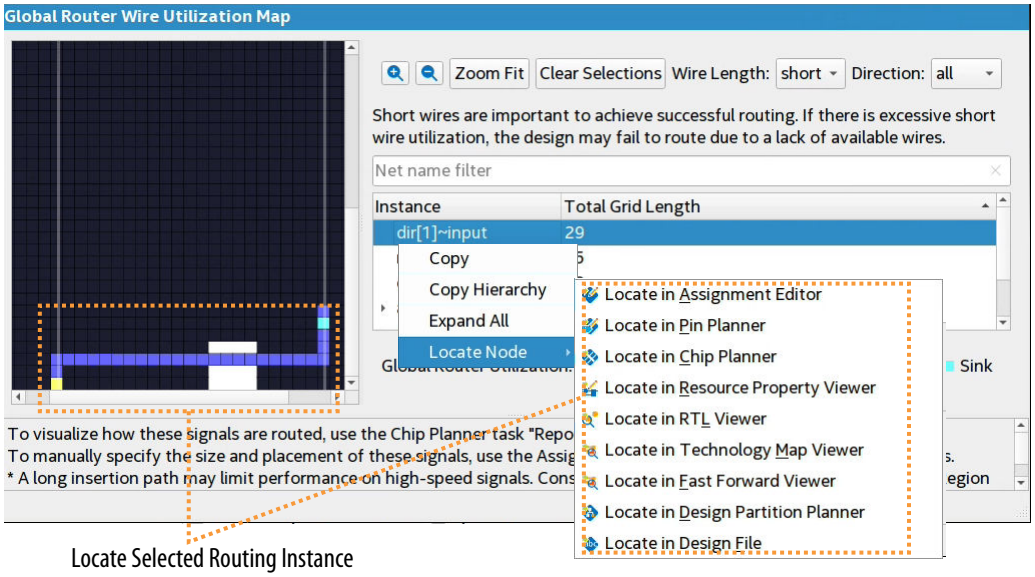
The Global Router Wire Utilization Map report displays global signal routing in an interactive heat-map. This report shows routing utilization rate of long and short routing wires. You can also use this report to obtain a detailed view of all the nets in the design. The report's heatmap grid shows the available device LABs. The color of the grid ranges from blue to red as the utilization rate changes from 0% to 100%. The color becomes pink if the utilization rate is greater than 100%.

Figure 79. Global Router Wire Utilization Heat Map (Multiple Layers)



Filter the Global Router Wire table to show **short** or **long Wirelengths** in all **Directions**. The content of the table changes based on the selections you make in the heatmap. You can search for **Signal Names**, and then single- or multi-select the signal names to display properties in the lower pane. Select one or more nodes in the table to **Locate** in various editors.

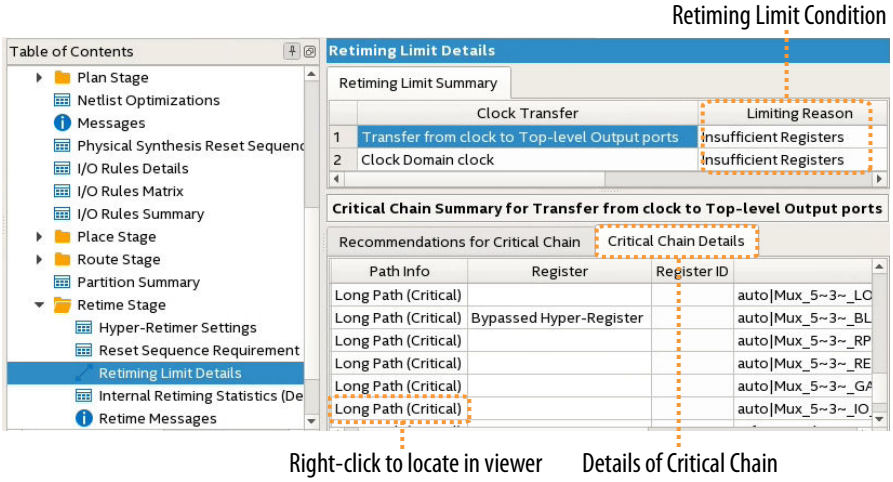
Figure 80. Global Router Wire Utilization Details



1.8.2.4. Retime Stage Reports

For Stratix 10 and Agilex 7 designs, the Fitter generates detailed reports showing the results of the Retime stage, including the Retiming Limit Details report. This report lists the limiting reason, along with the critical chain and recommendations for the critical chain for each clock transfer.

Figure 81. Retiming Limit Details



Related Information

- Viewing Critical Chains
- Report Retiming Restrictions
- Interpreting Critical Chain Reports

1.8.2.5. Finalize Stage Reports

The Finalize stage reports describe final placement and routing operations, including:

- HSLP Summary. For Arria 10 and Cyclone 10 GX designs, the Compiler converts unnecessary tiles to High-Speed or Low-Power (HSLP) tiles.
- Post-route hold fix-up data. For Stratix 10 and Agilex 7 designs, the Compiler reports hold violations for short paths following the Retime stage. The Fitter identifies and corrects the short paths with hold violations during the Fitter (Finalize) stage by adding routing wire along the paths.

Figure 82. Finalize Stage Reports (Stratix 10 Design)

Step 2: Review Retiming Results on page 117
For information on Retiming and Fast Forward compilation reports

1.9. Incremental Optimization Flow

The Quartus Prime Pro Edition software supports incremental optimization at each stage of design compilation. In incremental optimization, you run and optimize each compilation stage independently before running the next compilation module in sequence. The Compiler preserves the results of each stage as a snapshot for analysis. When you make changes to your design or constraints, the Compiler only runs stages impacted by the change. Following synthesis or any Fitter stage, you can view results and perform timing analysis; modify design RTL or Compiler settings as needed; and then re-run synthesis or the Fitter and evaluate the results of these changes. Repeat this process until the module performance meets requirements. This flow maximizes the results at each stage without waiting for full compilation results.

Figure 83. Incremental Optimization Flow

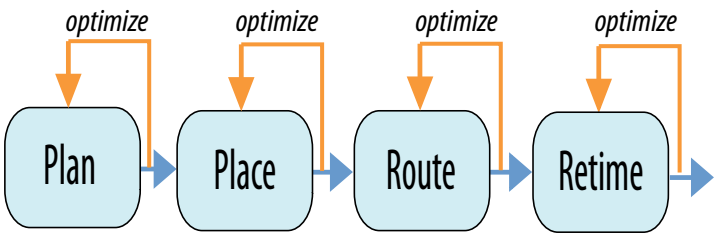

Table 20. Incremental Optimization at Fitter Stages

Fitter Stage	Incremental Optimization
Plan	After this stage, you can run post-Plan timing analysis to verify timing constraints, and validate cross-clock timing windows. View the placement and properties of the periphery (I/O).
Place	After this stage, validate resource and logic utilization in the Compilation Reports, and review placement of design elements in the Chip Planner.
Route	After this stage, perform detailed setup and hold timing closure in the Timing Analyzer, and view routing congestion in the Chip Planner.
Retime	After this stage, review the Retiming results in the Fitter report and correct any restrictions limiting further retiming optimization.

Note: The Compiler saves the planned, placed, routed, and retimed snapshots during full compilation only if you turn on **Enable Intermediate Fitter Snapshots** (**Assignments ➤ Settings ➤ Compiler Settings**). You can also run any intermediate Fitter stage independently to generate the snapshot for that stage.

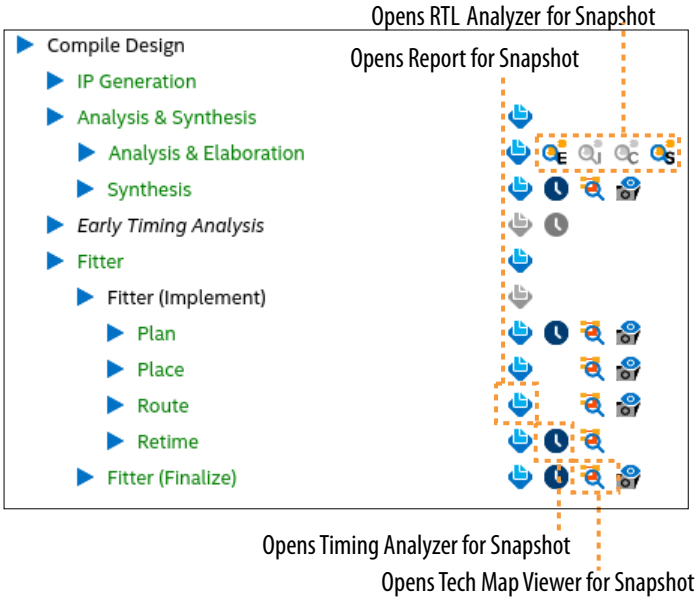
1.9.1. Concurrent Analysis During Synthesis or Fitting

If you run Analysis & Synthesis, or the Fitter, you can access results while downstream Fitter stages are still running. Once the **Concurrent Analysis** icons become active in the dashboard, you can view the analysis without interrupting compilation.

During Analysis & Synthesis, you can click the **Concurrent Analysis** icons on the Dashboard to view reports, the RTL Viewer, or the Technology Map Viewer. While the Fitter is processing, you can analyze timing during the stages displaying the **Timing Analyzer** icon, and view Technology Map Viewer snapshots during Fitter stages.

Caution: Do not attempt to change the SDC-on-RTL constraints during concurrent analysis. SDC-on-RTL constraints are read and loaded in the post-elaboration stage. If you modify the constraints at the Fitter stages, you must restart the compilation from the beginning.

Figure 84. Concurrent Analysis Options



1.9.2. Analyzing Compiler Snapshots

You can analyze the results of a compilation snapshot to evaluate your design before running the next stage, or before running a full compilation. Analyze Compiler snapshots to isolate potential problems and reduce the overall time you spend running design compilation.

1.9.2.1. Running Snapshot Viewer

You can run the Snapshot Viewer to assist with timing closure and design analysis after running the Plan, Place, Route, or Finalize stages of the Fitter. The Snapshot Viewer allows you to run various analysis tasks from the **Flow Navigator** to achieve faster timing closure and maximize design performance.

Figure 85. Snapshot Viewer Flow Navigator

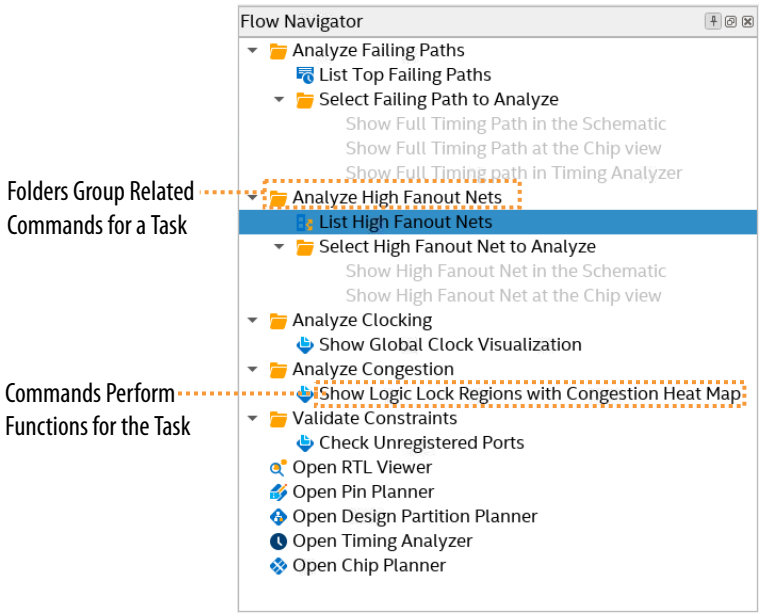


Table 21. Snapshot Viewer Tasks and Commands

Design Task	Available at Snapshot	Snapshot Viewer Commands
Timing Closure—**Analyze Failing Paths**	Planned, Placed, Routed, Finalized	• **List Top Failing Paths**—lists all top failing paths in **Snapshot Selections**. Select a path to locate in RTL Viewer or Chip Planner. • **Show Full Timing Path in the Schematic**—highlights the path in RTL Viewer for further analysis. • **Show Full Timing Path in Timing Analyzer**—The path loads in the Timing Analyzer for further analysis.
	Placed, Routed, Finalized	• **Show Full Timing Path in the Chip View**—highlights the path in Chip Planner for further analysis.
Timing Closure—**Analyze Clocking** This task is available only for Stratix 10 devices.	Placed, Finalized	**Show Global Clock Visualization**—loads the Global Signal Visualization report for the snapshot that allows you to visualize clock sector utilization.
Timing Closure—**Analyze High Fanout Nets**	Placed, Routed, Finalized	• **List High Fanout Nets**—lists high fan-out nets in **Snapshot Selections**. Select a path to locate in RTL Viewer or Chip Planner. • **Show High Fanout Nets in the Schematic**—highlights the paths in RTL Viewer for further analysis. • **Show High Fanout Nets in the Chip View**—highlights the paths in Chip Planner for further analysis.
Timing Closure—**Validate Constraints**	Planned	**Timing Exceptions**—displays the Timing Exceptions Results report that identifies timing paths with hold or removal slack exceeding threshold.
	Planned, Placed, Finalized	**Check Unregistered Ports**—displays the Check Unregistered Ports Results report that identifies unregistered partition inputs and paths.
Timing Closure—**Analyze Congestion**	Placed, Routed, Finalized	**Show Logic Lock Regions with Congestion Heat Map**—the Chip Planner displays the Logic Lock regions in a congestion heat map for further analysis.

The following sections describe each analysis task in detail.

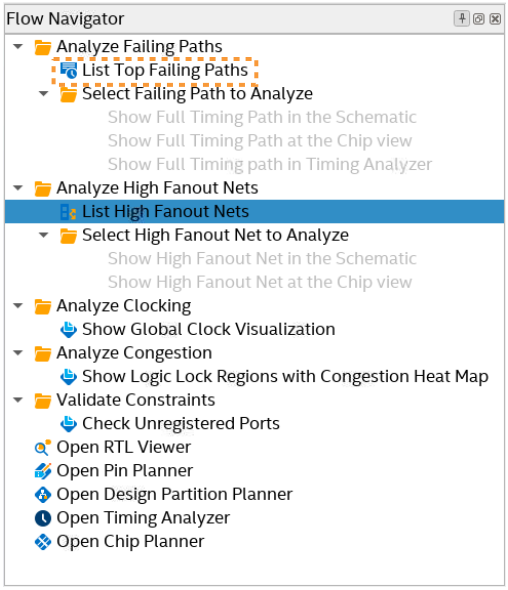
1.9.2.1.1. Analyzing Failing Paths with Snapshot Viewer

1. To run the Plan, Place, or Route stage of the Fitter, double-click the stage in the Compilation Dashboard.
2. After the stage completes, click the **Snapshot Viewer** icon for that stage in the Compilation Dashboard. The Snapshot Viewer opens.

Figure 86. Snapshot Viewer Icon

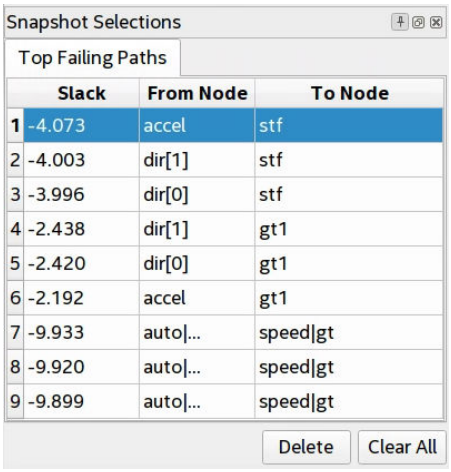
3. Under **Analyze Failing Paths**, click **List Top Failing Paths**.

Figure 87. List Top Failing Paths



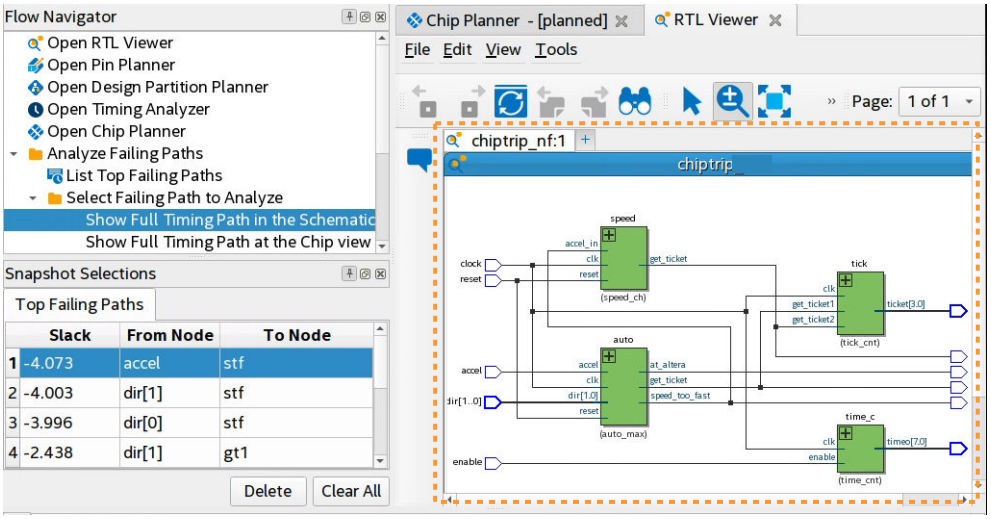
4. In **Snapshot Selections**, select the failing path for analysis.

Figure 88. Snapshot Selections



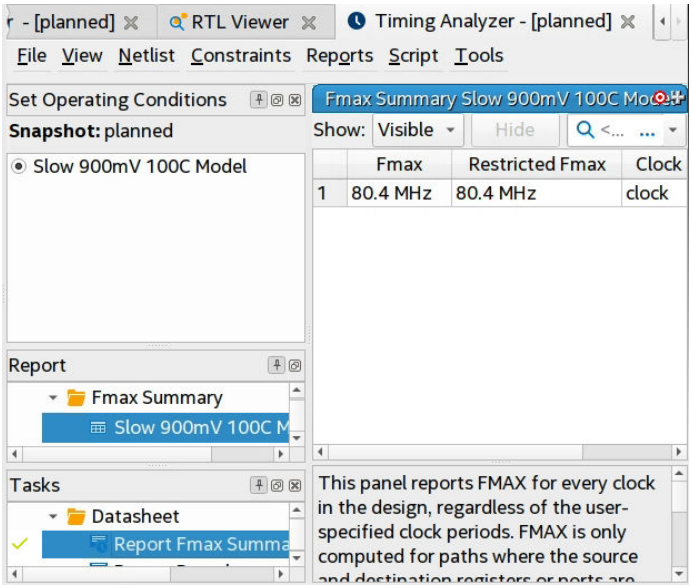
5. Under **Select Failing Path to Analyze**, click **Show Full Timing Path in the Chip View**. The path displays and highlights in the Chip Planner for further analysis.
6. Under **Select Failing Path to Analyze**, click **Show Full Timing Path in Schematic**. The path displays and highlights in RTL Viewer for further analysis.

Figure 89. Show Full Timing Path in Schematic



7. Under **Select Failing Path to Analyze**, click **View Path Characteristics**. The path loads in the Timing Analyzer for further analysis.

Figure 90. View Path Characteristics in Timing Analyzer

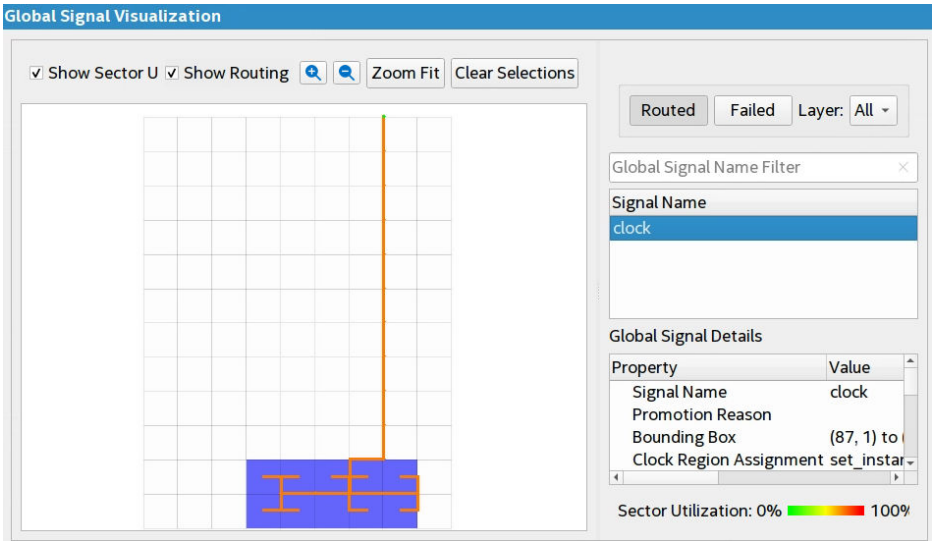


1.9.2.1.2. Analyzing Clocking with Snapshot Viewer

This task is available only for Stratix 10 devices.

1. Run the Place stage, and then click the **Snapshot Viewer** icon for the stage in the Compilation Dashboard. The Snapshot Viewer opens.
2. Under **Analyze Clocking**, double-click **Show Global Clock Visualization**. The Global Signal Visualization report displays in Snapshot Viewer for analysis of clock sector and routing utilization.

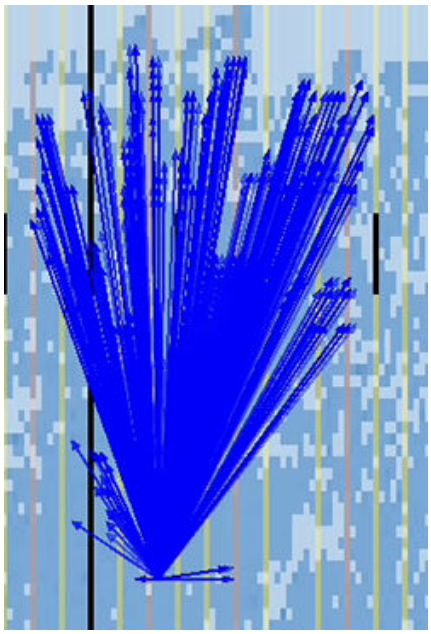
Figure 91. Global Clock Visualization Report



1.9.2.1.3. Analyzing High Fan-out Nets with Snapshot Viewer

1. To run the Place or Route stage of the Fitter, double-click the stage in the Compilation Dashboard.
2. After the stage completes, click the **Snapshot Viewer** icon for that stage in the Compilation Dashboard. The Snapshot Viewer opens.
3. Under **Analyze High Fanout Nets**, click **Show High Fanout Nets in the Schematic**. The path displays and highlights in Tech Map Viewer for further analysis.
4. Under **Analyze High Fanout Nets**, click **Show High Fanout Nets in the Chip View**. The path displays and highlights in the Chip Planner for further analysis.

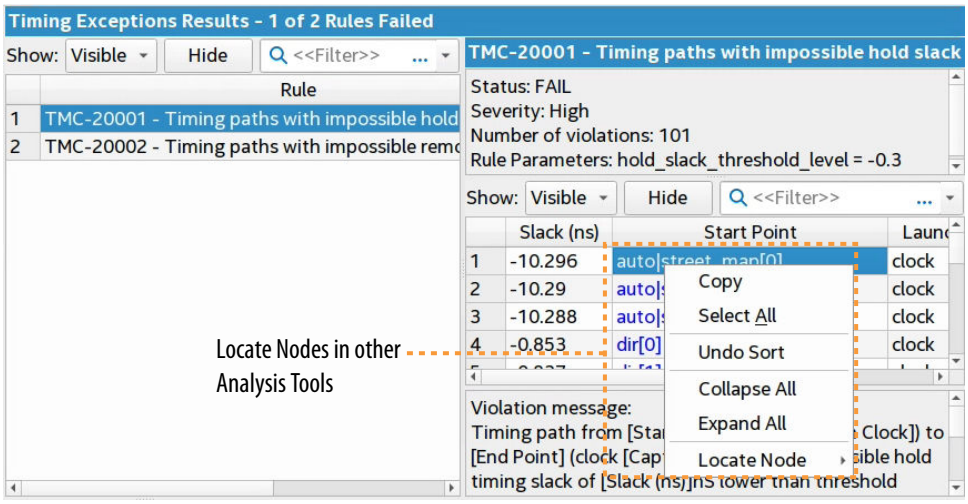
Figure 92. Non-Global High Fan-Out Signal in Chip Planner



1.9.2.1.4. Validating Timing Constraints with Snapshot Viewer

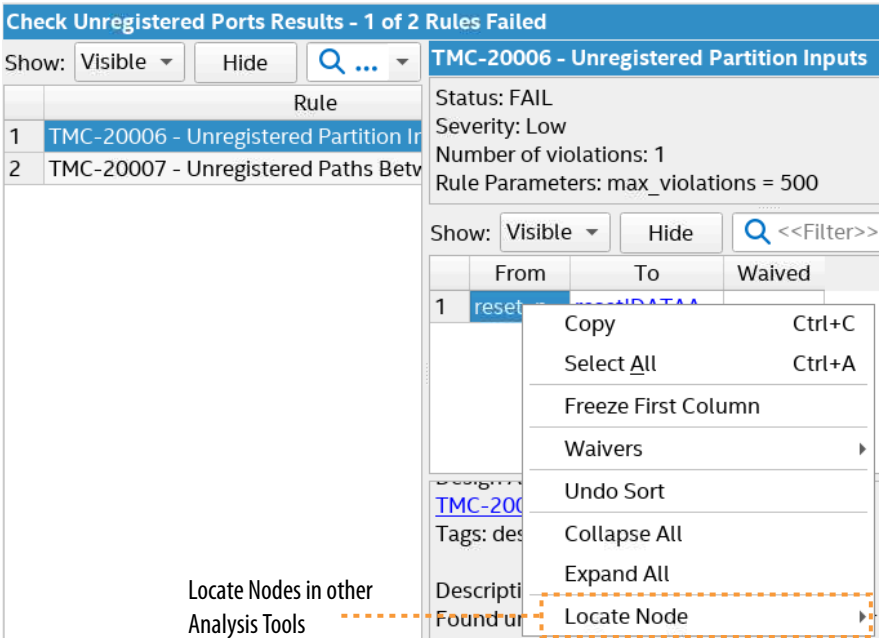
1. To run the Plan or Place stage of the Fitter, double-click the stage in the Compilation Dashboard.
2. After the stage completes, click the Snapshot Viewer icon for that stage in the Compilation Dashboard. The Snapshot Viewer opens.
3. Under **Validate Constraints**, double-click **Timing Exceptions**. The Timing Exception Results report opens, allowing additional analysis and locating to other tools.

Figure 93. Validate Constraints—Timing Exceptions Report



4. Under **Validate Constraints**, double-click **Check Unregistered Ports**.

Figure 94. Validate Constraints—Check Unregistered Ports Report



1.9.2.1.5. Analyzing Congestion with Snapshot Viewer

1. To run the Place or Route stage of the Fitter, double-click the stage in the Compilation Dashboard.
2. After the stage completes, click the **Snapshot Viewer** icon for that stage in the Compilation Dashboard. The Snapshot Viewer opens.
3. Under **Analyze Congestion**, double-click **Show Logic Lock Regions with Congestion Heat Map**. The Chip Planner displays the Logic Lock regions in a congestion heat map for further analysis.

Figure 95. Show Logic Lock Regions with Congestion Heat Map

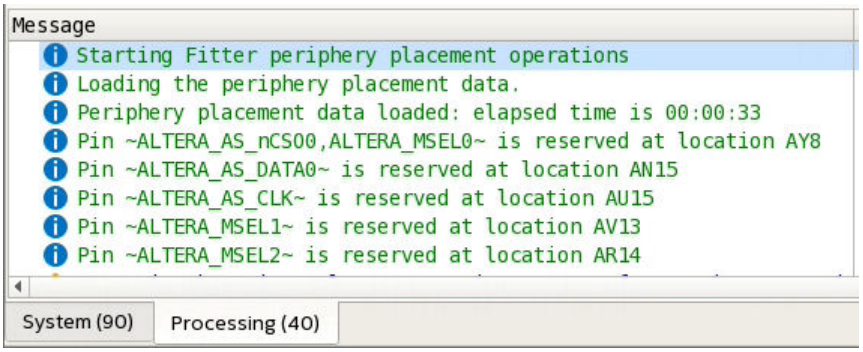
1.9.3. Validating Periphery (I/O) after the Plan Stage

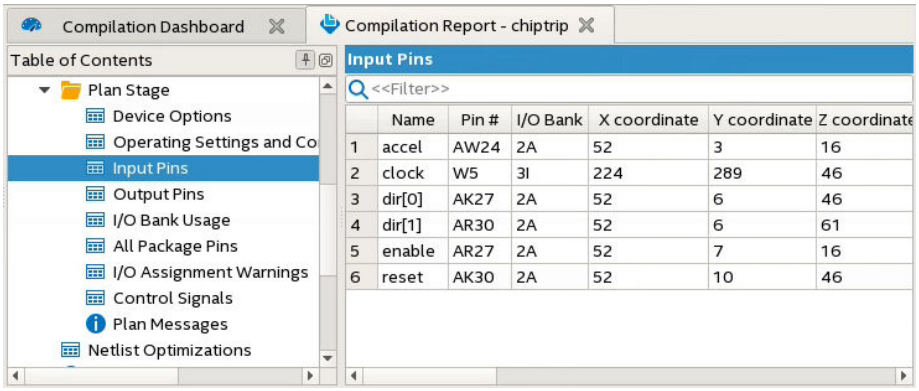
The Compiler begins periphery placement during the Plan stage, and reports data about periphery elements, such as I/O pins and PLLs. After the Plan stage, view the Compilation Report to evaluate the placement of periphery elements before proceeding to the next compilation stage.

Figure 96. Plan Stage Periphery Placement Message



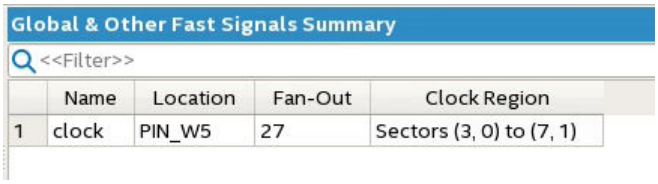
1. In the Compilation Dashboard, click the **Plan** stage.
2. In the Compilation Report, under the **Plan Stage** folder, click the **Input Pins**, **Output Pins**, **I/O Bank Usage**, **PLL Usage Summary**, or other reports. Verify attributes of the I/O pins, such as the physical pin location, I/O standards, and PLL placement.

Figure 97. Input Pins Report



3. For Arria 10 and Cyclone 10 GX designs, click **Global & Other Fast Signals Summary** report to verify which clocks the Compiler promotes to global clocks. Clock planning occurs after the Plan stage for Stratix 10 and Agilex 7 designs.

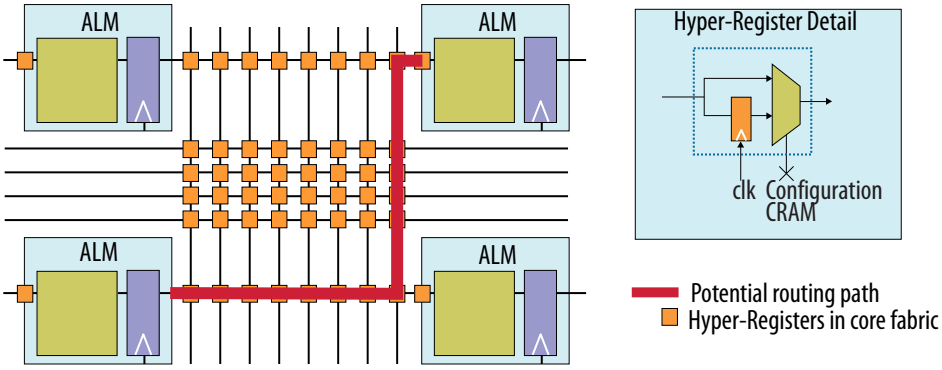
Figure 98. Global & Other Fast Signals Report Shows Clock Promotion (Intel Arria 10 and Intel Cyclone 10 GX FPGAs)



1.10. Fast Forward Compilation Flow

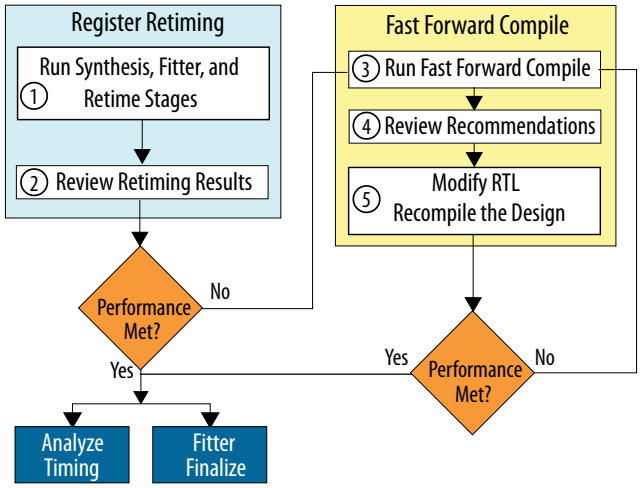
The Hyperflex architecture includes multiple Hyper-Registers in every routing segment and block input. Maximizing the use of Hyper-Registers improves the balance of time delays between registers, and mitigates critical path delays. Fast Forward compilation generates design recommendations to help you to break performance bottlenecks and maximize use of Hyper-Registers to drive the highest performance in Stratix 10 and Agilex 7 designs.

Figure 99. Hyper-Registers in Hyperflex Architecture



The Fast Forward compilation reports show precisely where to make the most impact with RTL changes, and the performance benefits you can expect from each change after removing retiming restrictions. The Fast Forward compilation flow includes the following high-level steps:

Figure 100. Fast Forward Compile Flow



1.10.1. Step 1: Run Register Retiming

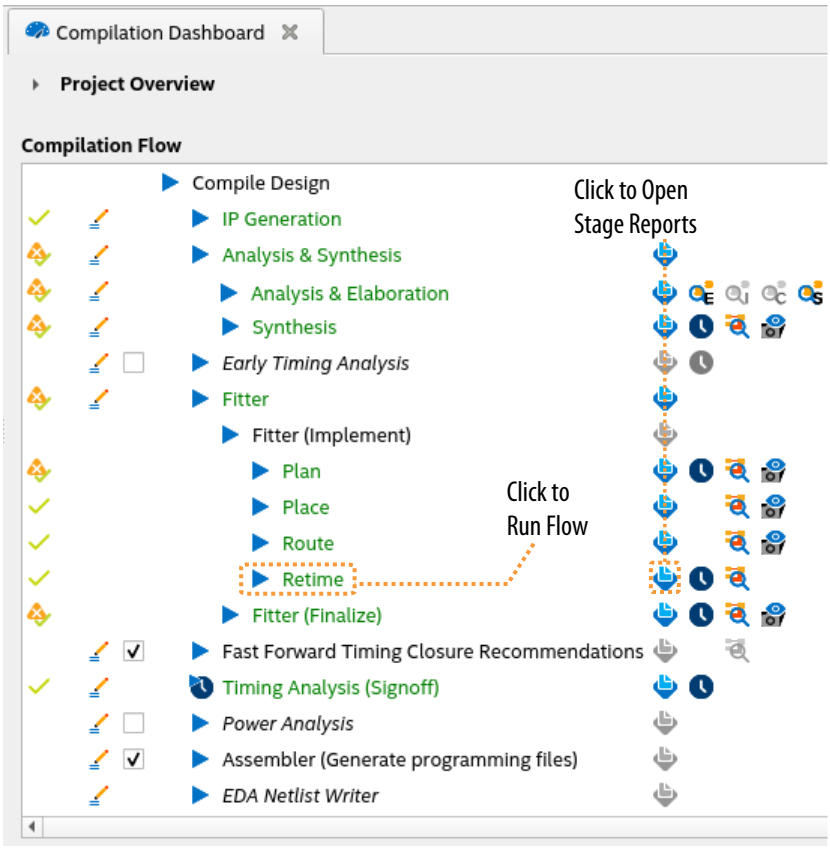
Register retiming improves design performance by moving registers out of ALMs and retimes them into Hyper-Registers in the Stratix 10 and Agilex 7 device interconnect.

The Fitter runs the **Retime** stage automatically following place and route when you target an Stratix 10 or Agilex 7 device. Alternatively, start or stop the individual **Retime** stage in the Compilation Dashboard. After running register retiming, view the Fitter reports to optimize remaining critical paths.

To run register retiming:

1. Click **Retime** on the Compilation Dashboard. The Compiler runs prerequisite stages automatically before running Retime stage.

Figure 101. Retiming Stage in Compilation Dashboard



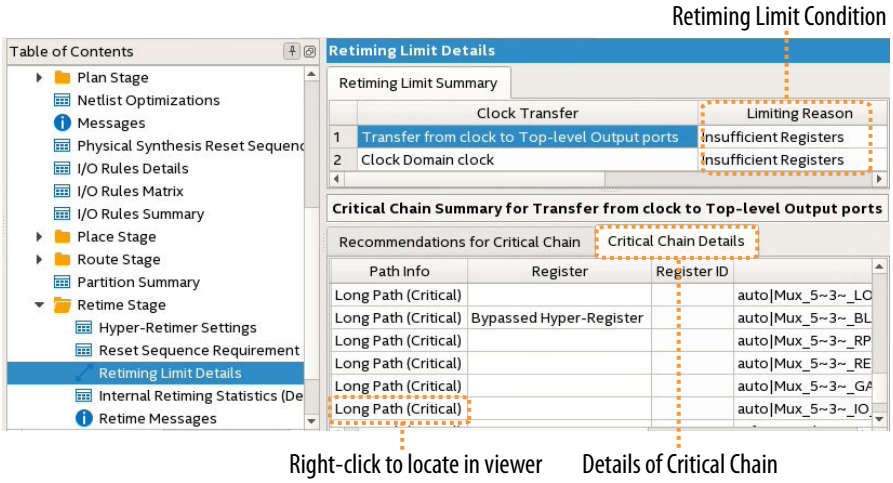
2. Review the results of the register retiming stage, as Step 2: Review Retiming Results on page 117 describes.

1.10.2. Step 2: Review Retiming Results

Follow these steps to review the results of register retiming. Use the results to determine if additional performance improvements are necessary and possible by removing retiming limits.

1. To open the **Retiming Limit Details** report, click the **Report** icon for the **Retime** stage in the Compilation Dashboard. The **Retiming Limit Details** lists the number of registers moved, their paths, and the limiting reason preventing further retiming.

Figure 102. Retiming Limit Details



2. To further optimize, resolve any **Limiting Reason** in your design, and then rerun the **Retime** stage, as necessary.

Table 22. Retiming Limit Details Report Data

Report Data	Description
Clock Transfer	Lists each clock domain in your design. Click the domain to display data about each entry.
Limiting Reason	Specifies any design condition that prevent further register retiming improvement, such as any of the following conditions: • **Insufficient Registers**—indicates insufficient quantity of registers at either end of the chain for retiming. Adding more registers can improve performance. • **Short Path/Long Path**—indicates that the critical chain has dependent paths with conflicting characteristics. For example, one path improves performance with more registers, and another path has no place for additional hyper-registers. • **Path Limit**—indicates that there are no further Hyper-Register locations available on the critical path, or the design reached a performance limit of the current place and route. • **Loops**—indicates a feedback path in a circuit. When the critical chain includes a feedback loop, retiming cannot change the number of registers in the loop without changing functionality. The Compiler can retime around the loop without changing functionality. However, the Compiler cannot place additional registers in the loop.
Critical Chain Details	Lists register timing path associated with the retiming limitations. Right-click any path to **Locate Critical Chain in Technology Map Viewer**.

3. If register retiming achieves all performance goals for your design, proceed to Fitter (Finalize) and Timing Analysis stages of compilation.
4. If your design requires further optimization, run **Fast Forward Timing Closure Recommendations** as Step 3: Run Fast Forward Compile on page 120 describes.

1.10.2.1. Locate Critical Chains

The **Retiming Limit Details** report shows the design paths that limit further register retiming. Right-click any path to locate the path in the Technology Map Viewer - Post-fitting view. This viewer displays a schematic representation of the complete design after place, route, and register retiming. To view the retimed netlist in the Technology Map Viewer, follow these steps:

1. To open the **Retiming Limit Details** report, click the **Report** icon next to the **Retime** stage in the Compilation Dashboard.
2. Right-click any path in the **Retiming Limit Details** report and click **Locate Critical Chain in Technology Map Viewer**. The netlist displays as a schematic in the Technology Map Viewer.

Figure 103. Technology Map Viewer

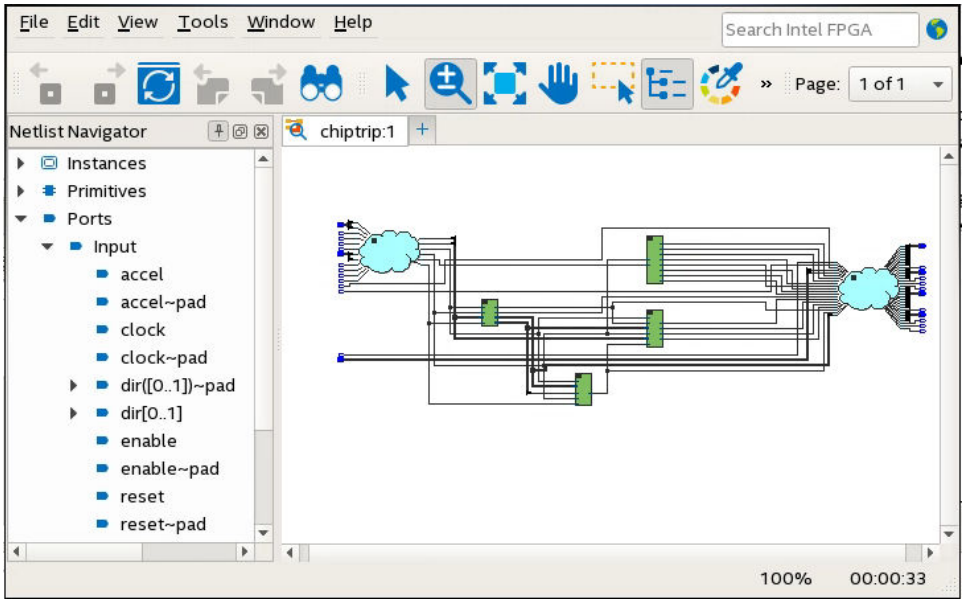


Figure 104. Post-Fit Viewer After Retiming

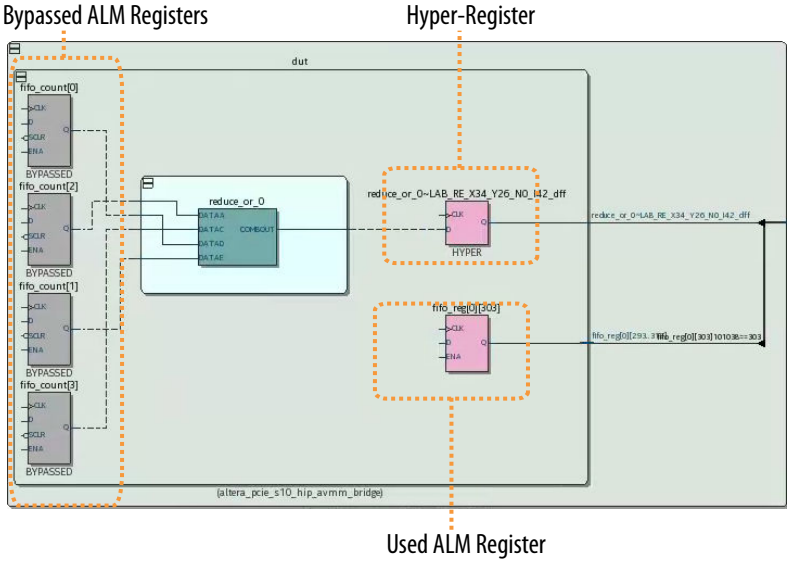
In the post-fit viewer, bypassed ALM registers are gray. Hyper-Registers are pink with the word "HYPER" below them. Used ALMs are pink without the word "HYPER" below them



1.10.3. Step 3: Run Fast Forward Compile

Fast Forward compilation generates design-specific timing closure recommendations, and predicts the maximum performance after the removal of all timing restrictions.

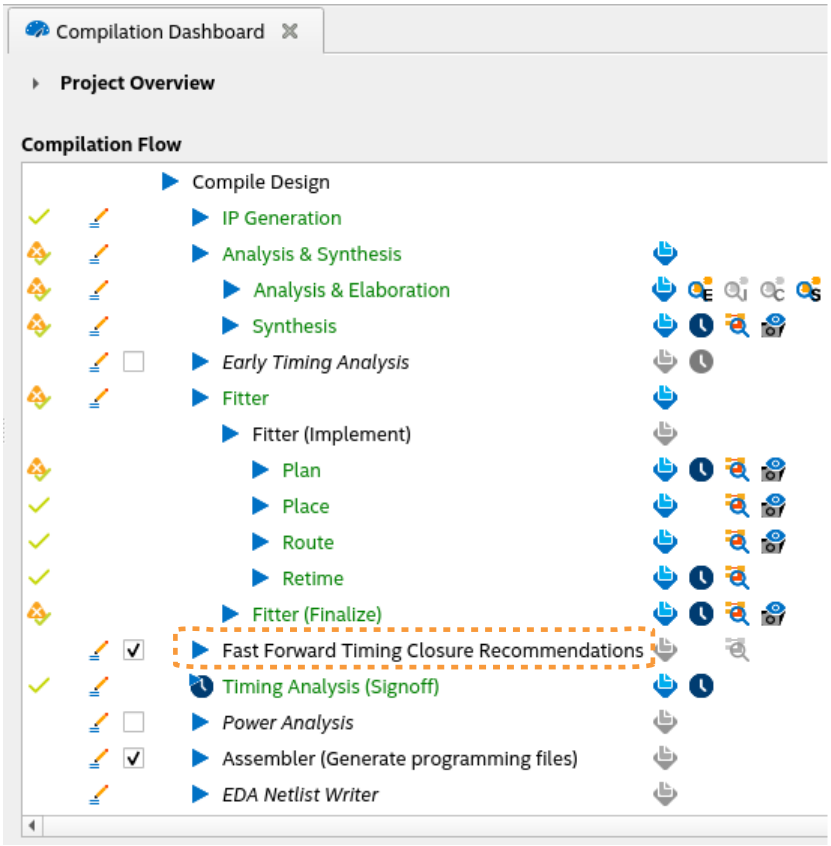
You can review the Fast Forward recommendations and implement the changes in your RTL that remove timing restrictions and enable mobility within the netlist for register Hyper-Retiming.

You can run Fast Forward compilation for the entire design hierarchy, or for only specific instances in the hierarchy, as Fast Forward Compile By Hierarchy on page 121 describes.

To generate Fast Forward timing closure recommendations, follow these steps:

1. Optionally, specify any of the following options if you want to automate or refine Fast Forward analysis:
   - If you want to run Fast Forward compilation during each full compilation, click **Assignments ➤ Settings ➤ Compiler Settings ➤ HyperFlex** and enable **Run Fast Forward Timing Closure Recommendations during compilation.**
   - If you want to modify how Fast Forward compilation interprets specific I/O and block types, click **Assignments ➤ Settings ➤ Compiler Settings ➤ HyperFlex ➤ Advanced Settings**.
2. On the Compilation Dashboard, click **Fast Forward Timing Closure Recommendations**. The Compiler runs prerequisite synthesis or Fitter stages automatically, as needed, and generates timing closure recommendations in the Compilation Report.

Figure 105. Running Fast Forward Compilation



3. View timing closure recommendations in the Compilation Report to evaluate design performance and implement key RTL performance improvements, as Step 4: Review Fast Forward Results on page 124 describes.

1.10.3.1. Fast Forward Compile By Hierarchy

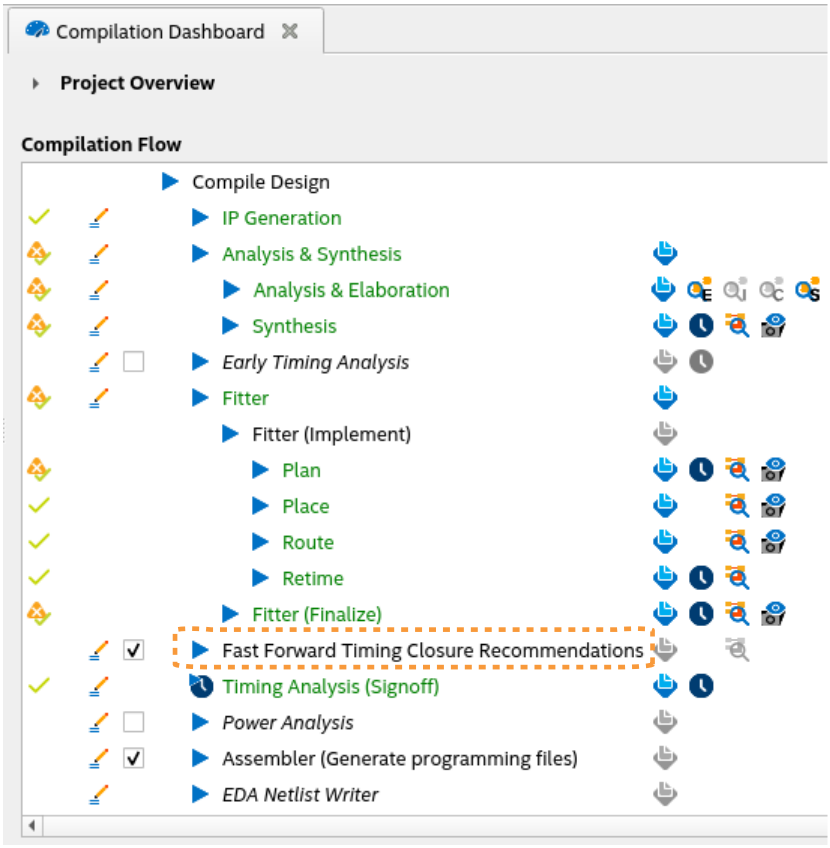
When enabled, Fast Forward compile runs on the entire design hierarchy by default. Optionally, you can specify the **Enable Hyper-Retimer Fast Forward Hierarchy analysis during compilation** assignment to include or exclude specific design subhierarchies and instances during Fast Forward compile. This technique allows you to focus Fast Forward reporting and optimization efforts on only specific areas of the design. Fast Forward compilation by hierarchy generates the same reports as Fast Forward compilation of the entire hierarchy.

Follow these steps to include or exclude specific design subhierarchies and instances during Fast Forward compilation:

1. To enable the optional Fast Forward Compilation stage during full compilation, turn on **Fast Forward Timing Closure Recommendations** on the Compilation Dashboard, or add the following assignment to the project `.qsf`:

```
set_global_assignment -name FLOW_ENABLE_HYPER_RETIMER_FAST_FORWARD ON
```

Figure 106. Enable Fast Forward Timing Closure Recommendations



2. To exclude a specific hierarchy or entity from Fast Forward Compilation, set the **Enable Hyper-Retimer Fast Forward Hierarchy analysis during compilation** assignment to **Off** in the Assignment Editor, or add the following assignment to the project `.qsf` for each hierarchy or entity that you want to exclude:

```
set_global_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF \
    <INSTANCE MODULE NAME>
```

3. To include a specific hierarchy or entity from Fast Forward Compilation, set the **Enable Hyper-Retimer Fast Forward Hierarchy analysis during compilation** assignment to **On** in the Assignment Editor, or add the following assignment to the project `.qsf` for each hierarchy or entity that you want to include:

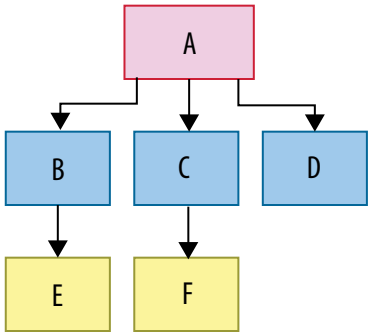
```
set_global_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY ON \
     <INSTANCE MODULE NAME>
```

4. Click the **Fast Forward Timing Closure Recommendations** stage on the Compilation Dashboard, or click **Processing ➤ Start Compilation** to run a full compilation that includes Fast Forward Compile.

You can mix ON and OFF assignments for the same instance within a single `.qsf`. If you assign mixed ON and OFF assignments to the same instance, the last assignment that appears in the `.qsf` takes precedence.

If you want to perform Fast Forward analysis for a subset of the hierarchies in your design, turn off Fast Forward analysis for all hierarchies that you want to omit from analysis. Otherwise, turn off Fast Forward analysis at the root hierarchy, and turn on Fast Forward analysis for the hierarchies that you want to analyze. The following examples show some of these assignment combinations, with respect to the *Example Design Hierarchy*.

Figure 107. Example Design Hierarchy



```
# This runs Fast Forward Compile on the entire hierarchy: A,B,C,D,E,F
# This produces the same result as if FAST_FORWARD_HIERARCHY was not set in the
QSF

set_global_assignment -name FLOW_ENABLE_HYPER_RETIMER_FAST_FORWARD ON
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY ON -to |
```

```
# Runs Fast Forward Compile on B and E only, ignores A,C,D,F

set_global_assignment -name FLOW_ENABLE_HYPER_RETIMER_FAST_FORWARD ON
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF -to |
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY ON -to B
```

```
# Runs  Fast Forward Compile on C only, ignores A,B,D,E,F

set_global_assignment -name FLOW_ENABLE_HYPER_RETIMER_FAST_FORWARD ON
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF -to |
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY ON -to C
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF -to F
```

```
# ON instance HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY takes precedence
# Fast Forward Compile runs on only C and F
# If the assignments were reversed then FFC would not run

set_global_assignment -name FLOW_ENABLE_HYPER_RETIMER_FAST_FORWARD ON
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF -to |
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF -to C
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY ON -to C
```

```
# This runs on A,B,C,F

set_global_assignment -name FLOW_ENABLE_HYPER_RETIMER_FAST_FORWARD ON
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF -to D
set_instance_assignment -name HYPER_RETIMER_FAST_FORWARD_ON_HIERARCHY OFF -to E
```

Note: Instance assignments apply to the post-fit netlist. Therefore, you may need to define design partitions. Otherwise, instance names can change during synthesis, leading to unexpected assignment results. Refer to Creating a Design Partition on page 140.

1.10.3.2. HyperFlex Settings

The **HyperFlex** settings page controls whether Fast Forward Compilation analyzes and reports results for specific logical structures in the Hyperflex architecture. You access this page by clicking **Assignments ➤ Settings ➤ HyperFlex**. Turn on **Run Fast Forward Timing Closure Recommendations during compilation** to enable Fast Forward analysis during the compilation flow by default. To access the following additional settings, click **Advanced Settings**.

Table 23. Advanced HyperFlex Settings

Option	Description
Fast Forward Compile Asynchronous Clears	Specifies how Fast Forward analysis accounts for registers with asynchronous clear signals. The options are: • **Auto**—the Compiler identifies asynchronous clears as asynchronous until they limit timing performance during Fast Forward Compilation, at which point the Compiler identifies the asynchronous clears as removed. • **Preserve**—the Compiler never assumes removal or conversion of asynchronous clears for Fast Forward analysis.
Fast Forward Compile Cut All Clock Transfers	Cuts all clock transfers in Fast Forward Compilation analysis.
Fast Forward Compile Fully Registered DSP Blocks	Specifies how Fast Forward analysis accounts for DSP blocks that limit performance. Enable this option to generate results as if all DSP blocks are fully registered.
Fast Forward Compile Fully Registered RAM Blocks	Specifies how Fast Forward analysis accounts for RAM blocks that limit performance. Enable this option to analyze the blocks as fully registered.
Fast Forward Compile Maximum Additional Pipeline Stages	Specifies the maximum number of pipeline stages that Fast Forward compilation explores.
Fast Forward Compile User Preserve Directives	Specifies how Fast Forward compilation accounts for restrictions from user-preserve directives.

1.10.4. Step 4: Review Fast Forward Results

After running Fast Forward Compilation, review the reports in the **Fast Forward Timing Closure Recommendations** folder of the Compilation Report to determine which recommendations are appropriate and practical for your design functionality and performance goals. The following section describes these reports.

Related Information

Hyperflex Architecture High-Performance Design Handbook

1.10.4.1. Clock Fmax Summary Report

The Clock Fmax Summary in the **Fast Forward Timing Closure Recommendations** report folder reports the current f_{max} and potential performance achievable for each clock domain after Hyper-Retiming, Hyper-Pipelining, and Hyper-Optimization steps. Review the Clock Fmax Summary data to determine whether each potential performance improvement warrants further investigation and potential optimization of design RTL.

Figure 108. Current and Potential Performance in Clock Fmax Summary

Viewing Clocks in the Timing Analyzer
in Hyperflex Architecture High-Performance Design Handbook

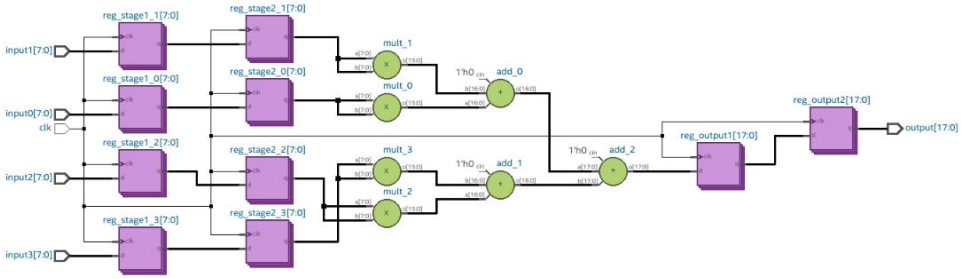
1.10.4.2. Fast Forward Details Report

The Fast Forward Details report recommends the design modifications necessary to achieve Fast Forward compilation performance levels. Some recommendations might be functionally impossible or impractical for your design. Consider the recommendations that you can implement in RTL to achieve similar performance improvement.

Click any optimization **Step** in the report to view the implementation details and performance calculations for that step.

To illustrate the effectiveness of Fast Forward Timing Closure recommendations in enhancing the timing of your design, consider the following simple design composed of adders, multipliers, and registers:

Figure 109. Simple Design with Adders, Multipliers, and Registers



Initially, this design is required to meet a maximum frequency of 800MHz. However, due to certain constraints, the maximum frequency is currently limited to 388.5MHz.

	Slack	From Node	To Node	Launch Clock	Latch Clock	Relationship	Clock Skew	Data Delay	Worst-Case Operating Conditions

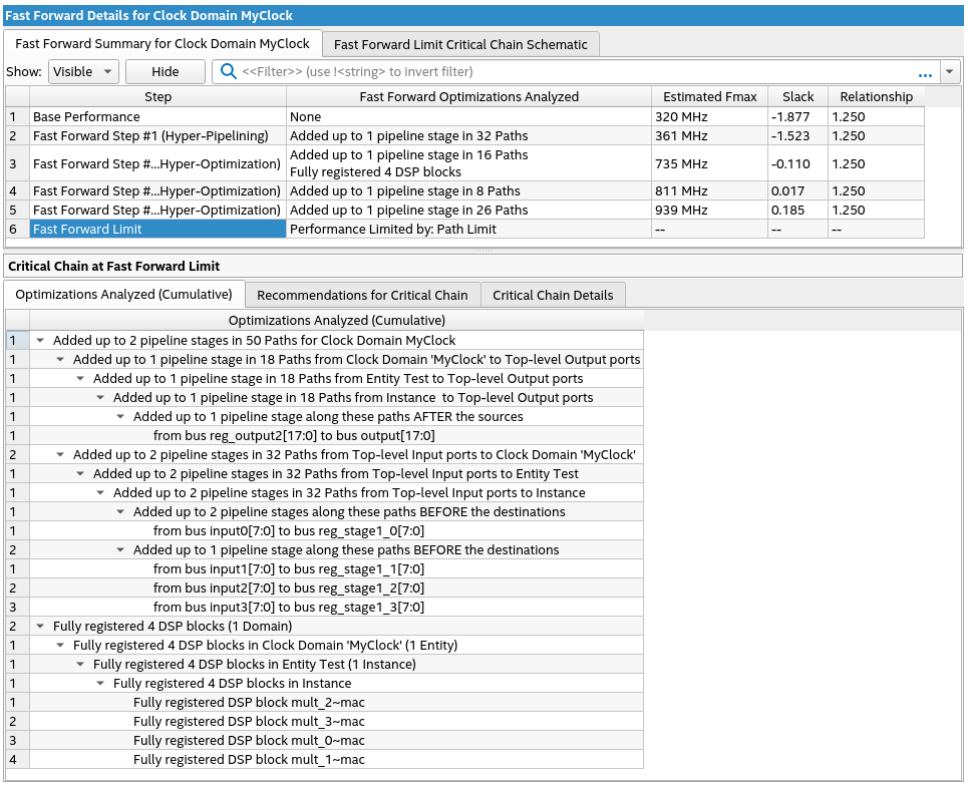
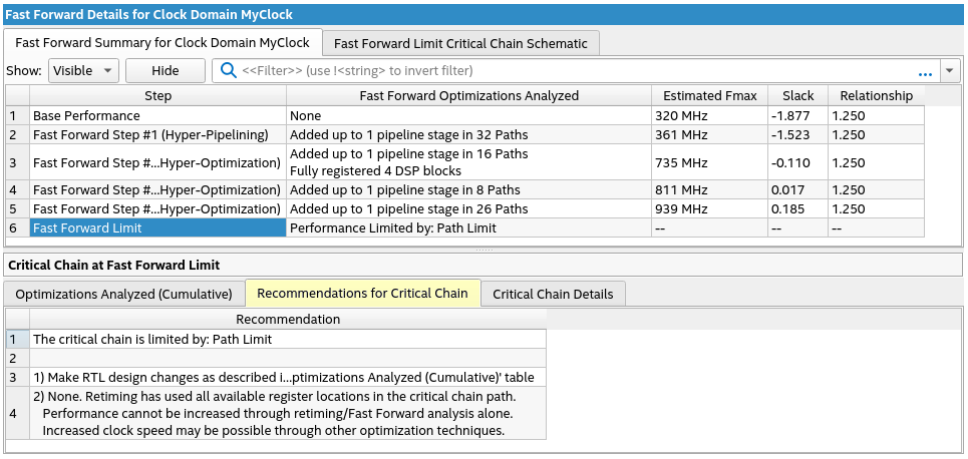
Upon executing the Fast Forward Timing Closure recommendations, proceed to review the Fast Forward Details Report. Within this report, you can find a breakdown of the optimization steps aimed at improving timing, as shown in the following image:

Figure 110. Fast-Forward Details Report



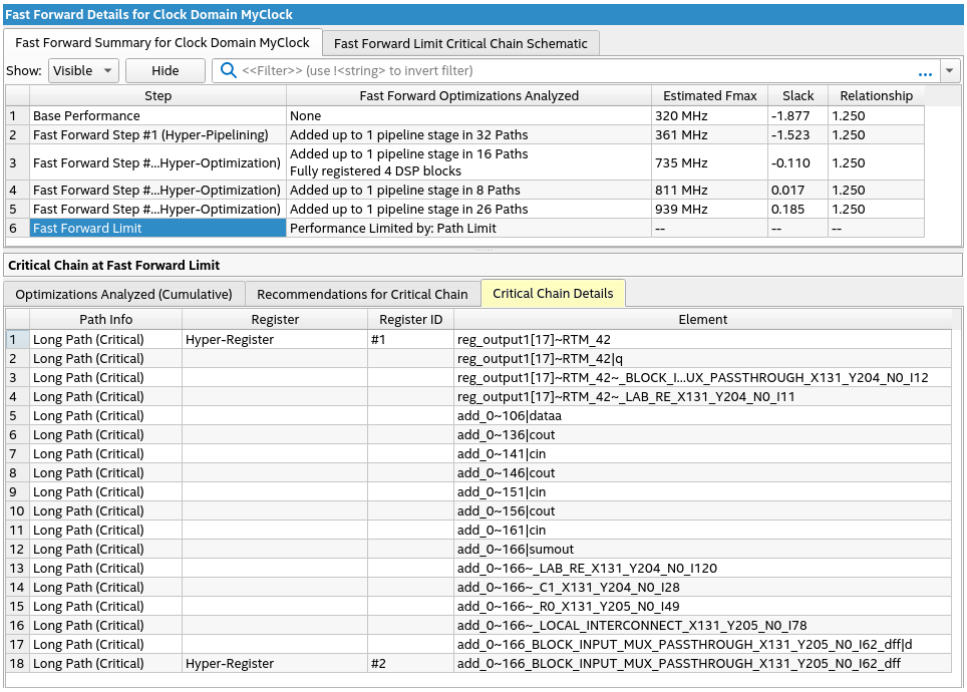
The **Optimizations Analyzed** tab shows two primary recommendations: adding pipeline stages in 50 paths and fully registering four DSP blocks. View the **Recommendations for Critical Chain** tab for specific guidance on implementing these optimizations at the RTL level.

Figure 111. Recommendations for Critical Chain



Additionally, explore the **Critical Chain Details** tab for a comprehensive description of the elements constituting the critical chain.

Figure 112. Critical Chain Details



Refer to the following table for further details on each field:

Table 24. Fast Forward Details Report Data

Report Field	Description
Step	Displays the pre-optimized Base Performance f_{MAX}, the recommended Fast Forward optimization steps, and the Fast Forward Limit critical path that prevents further optimization.
Fast Forward Optimizations Analyzed	Summarizes the optimizations necessary to implement each optimization step.
Estimated Fmax	Specifies the potential f_{MAX} performance if you implement all Fast Forward optimization steps.
Optimizations Analyzed For Fast Forward Step	Lists design recommendations hierarchically for the selected **Step**. Click the text to expand the report and view the clock domain, the affected module, and the bus and bits that require modification.
Optimizations Analyzed (Cumulative)	Accumulated list of all design changes necessary to reach the selected **Step**.
Critical Chain at Fast Forward Limit	Displays information about any path that continues to limit Hyper-Retiming even after application of all Fast Forward steps. The critical chain is any path that limits further Hyper-Retiming. Click the **Fast Forward Limit** step to display this field.
Recommendations for Critical Chain	Lists register timing path associated with the retiming limitations. Right-click any path to **Locate Critical Chain in Fast Forward Viewer**.

For a deeper analysis of the critical chains' structure, utilize the Fast Forward Viewer's cross-probing feature, as shown in the following image:

Figure 113. Locate Critical Chain in Fast Forward Viewer

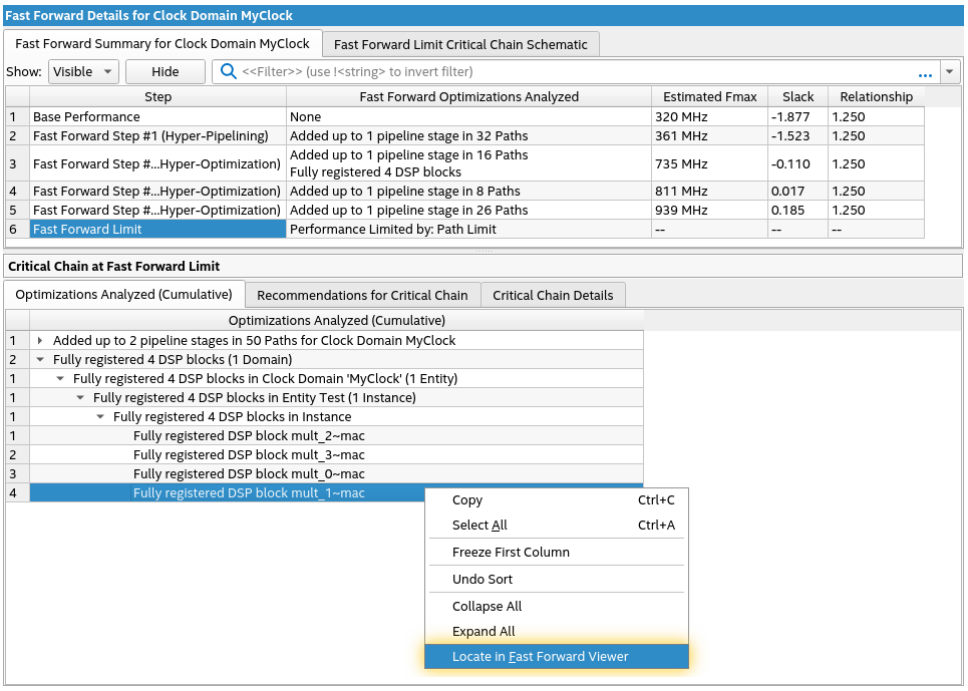


Figure 114. Fast Forward Viewer Shows Predictive Results

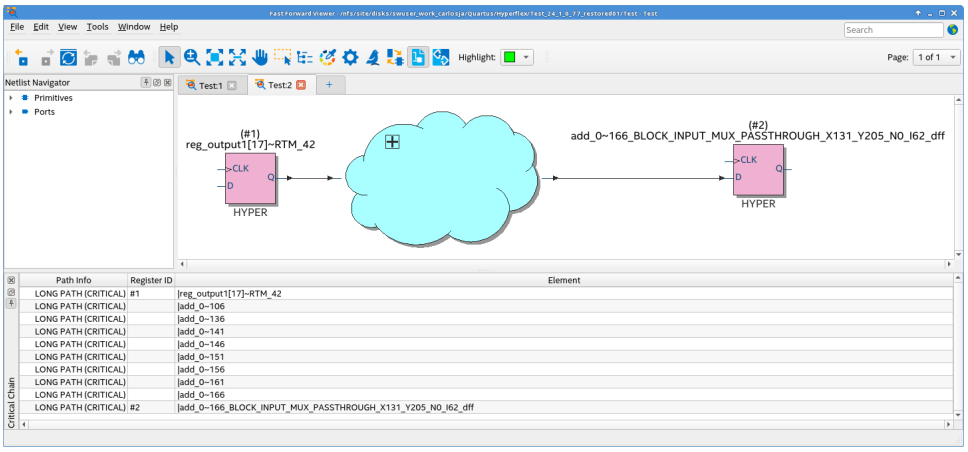
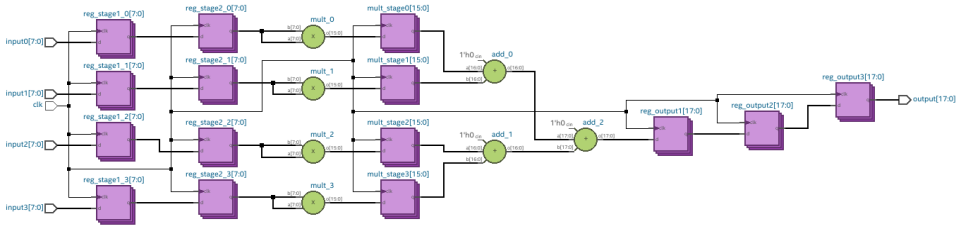


Based on the recommendations of the Fast Forward Details report, for this example, implement additional registers in the DSP blocks and an additional pipeline stage between `reg_output_2` and `output`. When you implement these modifications, the updated design takes the following form:

Figure 115. Design Modification



By repeating the compilation process and conducting a thorough analysis using the Timing Analyzer, you can observe tangible improvements in the timing performance of your designs.

	Slack	From Node	To Node	Launch Clock	Latch Clock	Relationship	Clock Skew	Data Delay	Worst-Case Operating Conditions

Although some of the Fast Forward Timing Closure recommendations may present challenges in practical implementation within complex designs, they nonetheless offer valuable insights and opportunities for analysis. These recommendations serve as a valuable addition to your design optimization, providing a fresh perspective and uncovering potential ways for enhancing timing performance.

Interpreting Critical Chain Reports
in Hyperflex Architecture High-Performance Design Handbook

1.10.5. Step 5: Implement Fast Forward Recommendations

Implement the Fast Forward timing closure recommendations in your design RTL and rerun synthesis and the **Retime** stage to perform Hyper-Retiming and realize the predictive performance gains. The amount and type of changes that you implement depends on your performance goals. For example, if you can achieve the target f_{MAX} with simple asynchronous clear removal or conversion, you can stop design optimization after making those changes. For more information, refer to Retiming Restrictions and Workarounds on page 130.

1. Implement one or more Fast Forward recommendations in your design RTL, such as any of the following techniques:

- Remove limitations of control logic, such as long feedback loops and state machines.
- Restructure logic to use functionally equivalent feed-forward or pre-compute paths, rather than long combinatorial feedback paths.
- Reduce the delay of 'Long Paths' in the chain. Use standard timing closure techniques to reduce delay. Excessive combinational logic, sub-optimal placement, and routing congestion cause delay on paths.
- Insert more pipeline stages in 'Long Paths' in the chain. Long paths have the most delay between registers in the critical chain.
- Increase the delay (or add pipeline stages to 'Short Paths' in the chain).
- Explore performance and implement the RTL changes to your code until you reach the desired performance target.

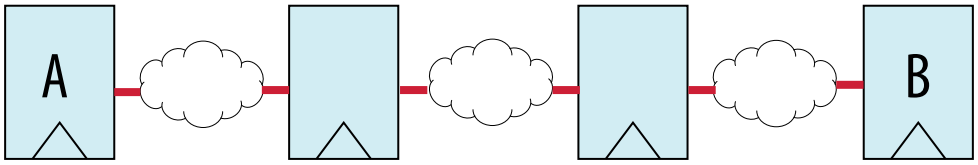
2. Implement your RTL changes and perform Hyper-Retiming by re-running the **Retime** stage on the Compilation Dashboard (which also reruns prerequisite synthesis and fitting stages).

1.10.6. Retiming Restrictions and Workarounds

The Compiler identifies the register chains in your design that limit further optimization through Hyper-Retiming. The Compiler refers to these related register-to-register paths as a critical chain. The f_{MAX} of the critical chain and its associated clock domain is limited by the average delay of a register-to-register path, and quantization delays of indivisible circuit elements like routing wires. There are a variety of situations that cause retiming restrictions. Retiming restrictions exist because of hardware characteristics, software behavior, or are inherent to the design. The **Retiming Limit Details** report the limiting reasons preventing further retiming, and the registers and combinational nodes that comprise the chain. The Fast Forward recommendations list the steps you can take to remove critical chains and enable additional register retiming.

In the diagram of a simple critical chain that follows, the red line represents the same critical chain. Timing restrictions prevent register A from retiming forward. Timing restrictions also prevent register B from retiming backwards. A loop occurs when register A and register B are the same register.

Figure 116. Sample Critical Chain



Particular registers in critical chains can limit performance for many other reasons. The Compiler classifies the following types of reasons that limit further optimization by retiming:

- **Insufficient Registers**—indicates insufficient quantity of registers at either end of the chain for retiming. Adding more registers can improve performance.
- **Short Path/Long Path**—indicates that the critical chain has dependent paths with conflicting characteristics. For example, one path improves performance with more registers, and another path has no place for additional hyper-registers.
- **Path Limit**—indicates that there are no further Hyper-Register locations available on the critical path, or the design reached a performance limit of the current place and route.
- **Loops**—indicates a feedback path in a circuit. When the critical chain includes a feedback loop, retiming cannot change the number of registers in the loop without changing functionality. The Compiler can retime around the loop without changing functionality. However, the Compiler cannot place additional registers in the loop.

After understanding why a particular critical chain limits your design's performance, you can then make RTL changes to eliminate that bottleneck and increase performance.

Table 25. Hyper-Register Support for Various Design Conditions

Design Condition	Hyper-Register Support
Initial conditions that cannot be preserved	Hyper-Registers do have initial condition support. However, you cannot perform some retiming operations while preserving the initial condition stage of all registers (that is, the merging and duplicating of Hyper-Registers). If this condition occurs in the design, the Fitter does not retime those registers. This retiming limit ensures that the register retiming does not affect design functionality.
Register has an asynchronous clear	Hyper-Registers support only data and clock inputs. Hyper-Registers do not have control signals such as asynchronous clears, presets, or enables. The Fitter cannot retime any register that has an asynchronous clear. Use asynchronous clears only when necessary, such as state machines or control logic. Often, you can avoid or remove asynchronous clears from large parts of a datapath.
Register drives an asynchronous signal	This design condition is inherent to any design that uses asynchronous resets. Focus on reducing the number of registers that are reset with an asynchronous clear.
Register has don't touch or preserve attributes	The Compiler does not retime registers with these attributes. If you use the `preserve` attribute to manage register duplication for high fan-out signals, try removing the `preserve` attribute. The Compiler may be able to retime the high fan-out register along each of the routing paths to its destinations. Alternatively, use the `dont_merge` attribute. The Compiler retimes registers in ALMs, DDIOs, single port RAMs, and DSP blocks.
Register is a clock source	This design condition is uncommon, especially for performance-critical parts of a design. If this retiming restriction prevents you from achieving the required performance, consider whether a PLL can generate the clock, rather than a register.
Register is a partition boundary	This condition is inherent to any design that uses design partitions. If this retiming restriction prevents you from achieving the required performance, add additional registers inside the partition boundary for Hyper-Retiming.
Register is a block type modified by an ECO operation	This restriction is uncommon. Avoid the restriction by making the functional change in the design source and recompiling, rather than performing an ECO.

continued...

Design Condition	Hyper-Register Support
Register location is an unknown block	This restriction is uncommon. You can often work around this condition by adding extra registers adjacent to the specified block type.
Register is described in the RTL as a latch	Hyper-Registers cannot implement latches. The Compiler infers latches because of RTL coding issues, such as incomplete assignments. If you do not intend to implement a latch, change the RTL.
Register location is at an I/O boundary	All designs contain I/O, but you can add additional pipeline stages next to the I/O boundary for Hyper-Retiming.
Combinational node is fed by a special source	This condition is uncommon, especially for performance-critical parts of a design.
Register is driven by a locally routed clock	Only the dedicated clock network clocks Hyper-Registers. Using the routing fabric to distribute clock signals is uncommon, especially for performance-critical parts of a design. Consider implementing a small clock region instead.
Register is a timing exception end-point	The Compiler does not retime registers that are sources or destinations of `.sdc` constraints.
Register with inverted input or output	This condition is uncommon.
Register is part of a synchronizer chain	The Fitter optimizes synchronizer chains to increase the mean time between failure (MTBF), and the Compiler does not retime registers that are detected or marked as part of a synchronizer chain. Add more pipeline stages at the clock domain boundary adjacent to the synchronizer chain to provide flexibility for the retiming. Alternatively, you can reduce the detection number for that particular synchronizer chain **Synchronization Register Chain Length** (default is 3). In some cases a synchronizer chain isn't necessary, and shouldn't be inferred.
Register with multiple period requirements for paths that start or end at the register (cross-clock boundary)	This situation occurs at any cross-clock boundary, where a register latches data on a clock at one frequency, and fans out to registers running at another frequency. The Compiler does not retime registers at cross-clock boundaries. Consider adding additional pipeline stages at one side of the clock domain boundary, or the other, to provide flexibility for retiming.

1.11. Full Compilation Flow

Use these steps to run a full compilation of an Quartus Prime project. A full compilation includes IP Generation, Analysis & Elaboration, Synthesis, Early Timing Analysis, Fitter, Timing Analyzer, and any optional Compiler modules you enable.

1. Before running a full compilation, specify any of the following project settings:
   - To specify the target FPGA device or development kit, click **Assignments ➤ Device**.
   - To specify device and pin options for the target FPGA device, click **Assignments ➤ Device ➤ Device and Pin Options**.
   - To specify options that affect compilation processing time and netlist preservation, click **Assignments ➤ Settings ➤ Compilation Process Settings**.

- To specify the Compiler's high-level optimization strategy, click **Assignments ➤ Settings ➤ Compiler Settings**. Specify a **Balanced** strategy, or optimize for **Performance**, **Area**, **Routability**, **Power**, or **Compile Time**. The Compiler targets the optimization goal you specify. Compiler Optimization Modes on page 149 describes these options in detail.

  For projects with a long compilation time, consider running full compilations with temporarily modified compiler optimization strategies without changing the project compiler settings. For details, see Full Compilation Flow with Temporary Optimization Mode on page 133.
- To specify synthesis algorithm and other **Advanced Settings** for synthesis and fitting, click **Assignments ➤ Settings ➤ Compiler Settings**. Turn on **Enable Intermediate Fitter Snapshots** to preserve the planned, placed, routed, and retimed snapshots by default during full compilation.
- To specify required timing conditions for proper operation of your design, click **Tools ➤ Timing Analyzer**.

2. To run full compilation, click **Processing ➤ Start Compilation**.

   Note: • To save processing time, the Compiler only preserves the planned, placed, routed, and retimed snapshots during full compilation if you turn on **Enable Intermediate Fitter Snapshots** (**Assignments ➤ Settings ➤ Compiler Settings**).

  For complete information about generating device programming files with the Assembler and running the Quartus Prime Programmer.

1.11.1. Full Compilation Flow with Temporary Optimization Mode

You can run a full compilation flow that temporarily overrides the compiler optimization mode set in the Quartus settings file (`.qsf`) for your design. The optimization mode set for your project in your settings file does not change and remains the default compilation strategy for your project.

Overriding the compiler optimization mode set in your project can be helpful when your project has long compile times and you want to quickly produce a bitstream for on-chip testing.

To run a full compilation with a temporary optimization mode, select a compilation mode from the **Processing ➤ Start Optimization Mode Compilation** menu in the Quartus Prime Pro Edition GUI.

The following temporary optimization mode compilation flows are available in the **Start Optimization Mode Compilation** menu:

- **Start Aggressive Compile Time Optimization Mode Compilation**

  In this optimization mode, the Compiler reduces its performance optimization efforts and performs minimal reporting to provide a shorter compilation time.
- **Start Fast Functional Test Optimization Mode Compilation**

  In this optimization mode, the Compiler minimizes its setup-timing optimization efforts to provide an even shorter compilation time.

The selected optimization mode is enabled only for the duration of the compilation. After the compilation completes, Quartus Prime returns to the compilation optimization strategy that is set in the project settings.

Tip: You can customize the Quartus Prime Processing toolbar to include buttons for any of these temporary optimization mode compilations.

Important: With these optimization modes, the clocks in the resulting compilation might not meet setup. You might need to slow down the clocks on your design, such as by using PLL ECOs post-compile, before generating the bitstream.

Related Information

- Compiler Optimization Modes on page 149
- Temporarily Overriding the Compiler Optimization Mode for a Compilation in *Intel Quartus Prime Pro Edition User Guide: Scripting*
- Using the ECO Compilation Flow

1.12. Compilation Monitoring Mode

You can compile your design using the command-line interface (CLI) and the interactive Quartus Prime Pro Edition GUI.

- The CLI is generally helpful when your design is part of a larger script-based environment or the compilation is expected to take a significant amount of time. A log file is produced that you can examine at a later stage. However, it is difficult to examine and scroll through the textual output generated during a very long compilation. In such cases, use the Monitoring Mode.
- The GUI presents the entire flow of a design along with tools and utilities for design, configuration, and debugging. The entire design is assumed to be contained in a single project directory.

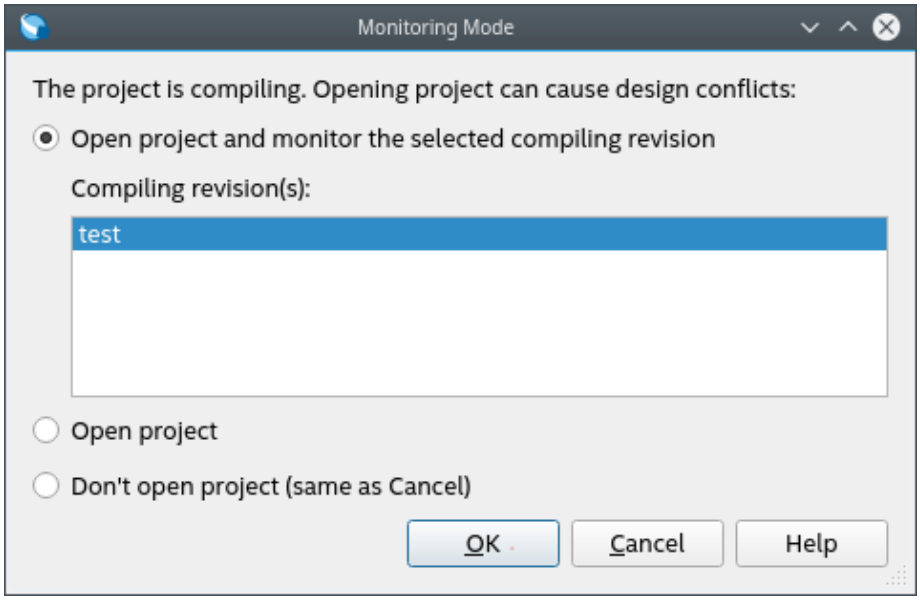
Monitoring Mode

With the "Monitoring Mode," you can bring up the Quartus Prime Pro Edition GUI, connect to a project whose compilation has already been initiated on the CLI, and monitor the execution of the compilation in the GUI. It helps examine compilation-related messages in the interactive message window of the GUI, and in general, interact with the GUI in the same way as you would in the CLI. You can also view reports, view messages, and cross-probe to source files.

To use the Monitoring Mode, perform these steps:

1. Start compiling your project through the CLI. For more information, refer to Compilation with `quartus_sh --flow` in the *Quartus Prime Pro Edition Scripting User Guide*.
2. Launch the Quartus Prime Pro Edition GUI.
3. Open the same project in the GUI that you are already compiling in the CLI. The **Monitor Mode** dialog appears, as shown in the following image:

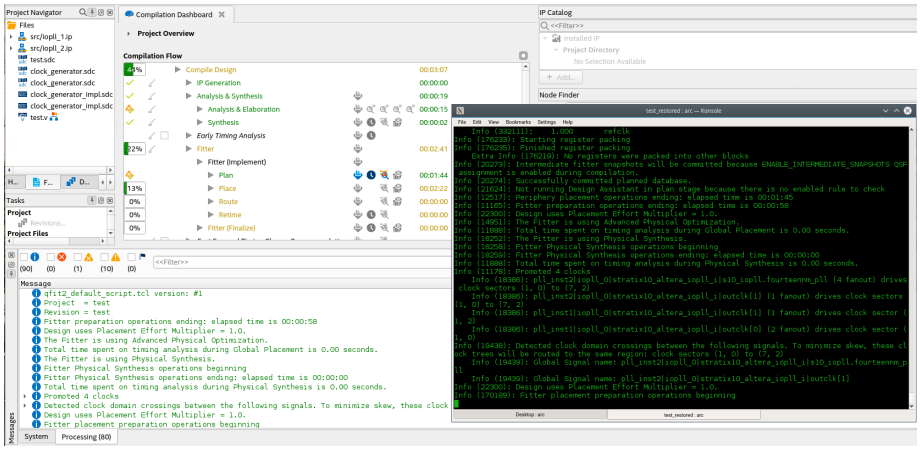
Figure 117. Monitoring Mode



4. Select **Open project and monitor the selected compiling revision** and click **OK**. The Compilation Dashboard appears, displaying the status of the compilation, as shown in the following image:

   Note: Selecting **Open project** opens the project in the non-monitoring mode, but doing so might lead to design conflicts, where the underlying database might change unexpectedly and get corrupted. Selecting **Don't open project** cancels launching the project in the GUI.

Figure 118. Monitoring the Compilation



Once the compilation ends, the **Monitoring Mode Ended** message appears on the GUI, indicating you can continue in the GUI and perform other operations on your project.

Guidelines for Using the Monitoring Mode

Consider the following when using the monitoring mode:

- You can start and exit the Quartus Prime Pro Edition GUI in monitoring mode as often as you like without affecting the progress of the compilation underway.
- If you are compiling multiple revisions of a project simultaneously, you can choose which revision compilation to monitor.
- You cannot stop a monitored compilation in the GUI. You must stop it from the CLI.
- After a monitored compilation finishes, the Quartus Prime Pro Edition GUI automatically switches out of monitoring mode. However, if a new command-line compilation for the same project and revision starts, you are prompted to reenter the monitoring mode.
- If you are currently compiling a project and revision from the CLI and open that design in the GUI without choosing the monitoring mode, you might cause design conflicts and corrupt the compilation database.
- For a project being compiled, the project shown when the GUI is not in the monitoring mode might not reflect the most recent state of the project.
- If you launch a new compilation of the project, the new compilation can corrupt the command-line compilation.

Related Information

Compilation with quartus_sh --flow in *Intel Quartus Prime Pro Edition User Guide: Scripting*

1.13. Exporting Compilation Results

The Quartus Prime Compiler writes the results to a set of database files. You can run a command to export the compilation results database as a single Quartus Database File (.qdb).

After running design compilation, the exported `.qdb` file contains the data to reproduce similar compilation results in another project, or in a later software version. You can export your project's compilation results database for import to another project or migration to a later Quartus Prime software version.

You can export the `.qdb` for your entire project or for a design partition that you define in your project. When migrating the database for an entire project, you can export the compilation database in a *version-compatible* format to ensure compatibility for import to a later software version. Although you cannot directly read the contents of the `.qdb` file after export, you can view attributes of the database file in the Quartus Database File Viewer.

Table 26. Exporting Compilation Results

To Export Compilation Results For	Method	Description
Complete Design	Click **Project ➤ Export Design**	Saves compilation results for the current project revision in a version-compatible Quartus database file (`.qdb`) that you can import to another project or migrate to a later version of the Quartus Prime software. You can export the results for the synthesized or final compilation snapshot. *Note:* Not supported for Agilex 7 devices.
Design Partition	Click **Project ➤ Export Design Partition**	Saves compilation results for a design partition as a Partition Database File (`.qdb`) that you can import to another project using the same version of the Quartus Prime software. You can export the results for the synthesized or final compilation snapshot.

1.13.1. Exporting a Version-Compatible Compilation Database

You can export a project compilation database to a format that ensures version-compatibility with a later version of the Quartus Prime software. The Quartus Prime Pro Edition software version supports export of version-compatible databases for the following software versions and devices:

Table 27. Version-Compatible Compilation Database Support

The first table column indicates the first version to support version-compatible compilation database export for the specified devices.

Note:

- Database import supports two major versions back. For example, a database that you export from version 19.3, you can then import using version 19.3, 20.1, and 20.3. However, you cannot import version 19.3 to 21.1.
- You can export from any version that follows a supported version, if the version still supports the devices.

First Version with 'Export Design' Support	Stratix 10 and Devices	Arria 10 and Cyclone 10 GX Devices
18.0	No Support.	Supports all devices.
18.1	• 1SG250L • 1SG280H_S2 • 1SG280L • 1SG280L_S3 • 1SX250L • 1SX280L • 1SX280L_S3	Supports all devices.
19.1	• 1SM16BH • 1SM21BH • 1SM16CH • 1SM21CH • 1SM21KH • 1SM16KH • 1SM21LH • 1SM16LH	Supports all devices.
19.3	• 1SG10MH_U1 • 1SG10MH_U2 • 1ST250E • 1ST280E • 1SM16E • 1SM21E • 1ST165E • 1ST210E • 1SG166H • 1SG211H	Supports all devices.
20.1	• 1SD280P • 1ST040E • 1ST085E • 1ST110E	Supports all devices.
20.3	• 1SD21BP • 1SG040H • 1SX040H	Supports all devices.
20.4	• 1SN21BH • 1SN21CE	Supports all devices.

1. In the Quartus Prime software, open the project that you want to export.
2. Generate synthesis or final compilation results by running one of the following commands:

- Click **Processing ➤ Start ➤ Start Analysis & Synthesis** to generate synthesized compilation results.
- Click **Processing ➤ Start Compilation** to generate final compilation results.

3. Click **Project ➤ Export Design**. Select the **synthesized** or **final Snapshot**.

Figure 119. Export Design Dialog Box

4. Specify a name for the **Quartus Database File** to contain the exported results, and click **OK**.
5. To include the exported design's settings and constraint files, copy the `.qsf` and `.sdc` files to the import project directory.

1.13.2. Importing a Version-Compatible Compilation Database

Follow these steps to import a project compilation database into a newer version of the Quartus Prime software:

Note: Designs exported from the Quartus Prime Pro Edition software versions 23.2 or earlier cannot be imported into version 23.3 due to the new DNI database.

1. Export a version-compatible compilation database for a complete design, as Exporting a Version-Compatible Compilation Database on page 137 describes.
2. In a newer version of the Quartus Prime software, open the original project. Click **Yes** if prompted to open a project created with a different software version.
3. Click **Project ➤ Import Design** and specify the **Quartus Database File**. To remove previous results, turn on **Overwrite existing project's databases**

Figure 120. Import Design Dialog Box

4. Click **OK**. When you compile the imported design, run only Compiler stages that occur after the stage the `.qdb` preserves, rather than running a full compilation. For example, if you import a version-compatible database that contains the synthesized snapshot, start compilation with the Fitter (**Processing ➤ Start ➤**

Start Fitter). If you import a version-compatible database that contains the final snapshot, start compilation with Timing Analysis (Signoff) (**Processing ➤ Start ➤ Start Timing Analysis (Signoff)**).

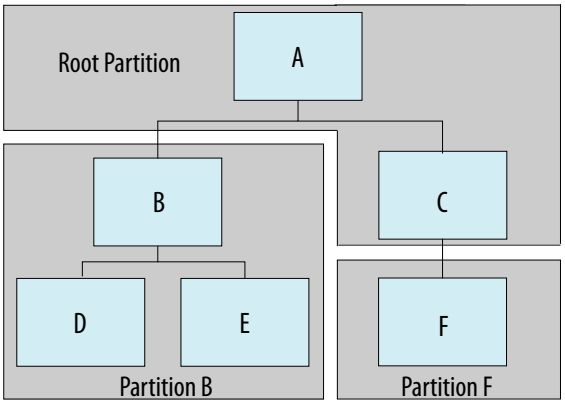
Design Netlist Infrastructure on page 10

1.13.3. Creating a Design Partition

A design partition is a logical, named, hierarchical boundary that you can assign to an instance in your design. Defining a design partition allows you to optimize and lock down the compilation results for individual blocks. You can then optionally export the compilation results of a design partition for reuse in another context, such as reuse in another project.

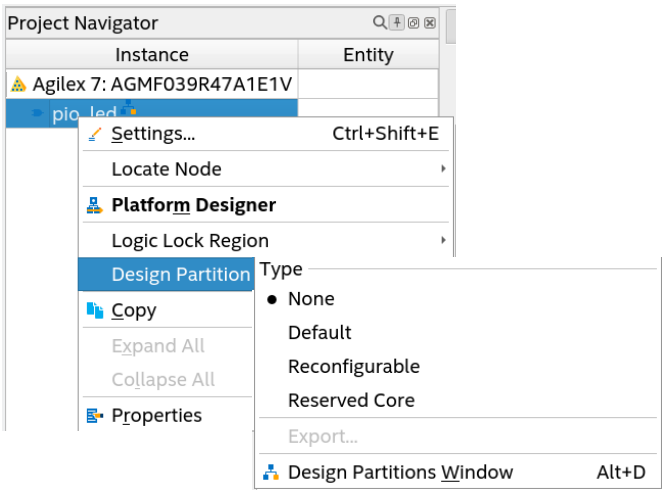
Figure 121. Design Partitions in Design Hierarchy



Follow these steps to create and modify design partitions:

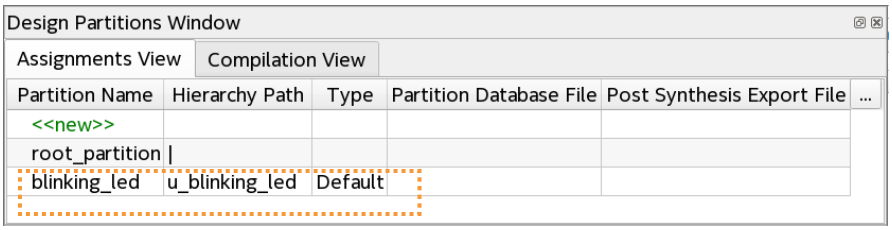
1. In the Quartus Prime software, open the project that you want to partition.
2. Generate synthesis or final compilation results by running one of the following commands:
   - Click **Processing ➤ Start ➤ Start Analysis & Synthesis** to generate synthesized compilation results.
   - Click **Processing ➤ Start Compilation** to generate final compilation results.
3. In the Project Navigator, right-click an instance in the **Hierarchy** tab, click **Design Partition ➤ Set as Design Partition**.

Figure 122. Creating a Design Partition from the Project Hierarchy



4. To view and edit all design partitions in the project, click **Assignments ➤ Design Partitions Window**.

Figure 123. Design Partitions Window



5. Specify the properties of the design partition in the Design Partitions Window. The following settings are available:

Table 28. Design Partition Settings

Option	Description
Partition Name	Specifies the partition name. Each partition name must be unique and consist of only alphanumeric characters. The Quartus Prime software automatically creates a top-level (|) "root_partition" for each project revision.
Hierarchy Path	Specifies the hierarchy path of the entity instance that you assign to the partition. You specify this value in the **Create New Partition** dialog box. The root partition hierarchy path is |.
Type	Double-click to specify one of the following partition types that control how the Compiler processes and implements the partition: • **Default**—Identifies a standard partition. The Compiler processes the partition using the associated design source files. • **Reconfigurable**—Identifies a reconfigurable partition in a partial reconfiguration flow. Specify the **Reconfigurable** type to preserve synthesis results, while allowing refit of the partition in the PR flow. • **Reserved Core**—Identifies a partition in a block-based design flow that is reserved for core development by a Consumer reusing the device periphery.
Empty	Specifies an empty partition that the Compiler skips. This setting is incompatible with the **Reserved Core** and **Partition Database File** settings for the same partition.

continued...

Option	Description
Partition Database File	Specifies a Partition Database File (`.qdb`) that the Compiler uses during compilation of the partition. You export the `.qdb` for the stage of compilation that you want to reuse (synthesized or final). Assign the `.qdb` to a partition to reuse those results in another context.
Entity Re-binding	• PR Flow—specifies the entity that replaces the default persona in each implementation revision. • Root Partition Reuse Flow —specifies the entity that replaces the reserved core logic in the consumer project.
Color	Specifies the color-coding of the partition in the Chip Planner and Design Partition Planner displays.
Post Synthesis Export File	Automatically exports post-synthesis compilation results for the partition to the specified `.qdb` file each time Analysis & Synthesis runs. You can automatically export any design partition that does not have a preserved parent partition, including the root_partition.
Post Final Export File	Automatically exports post-final compilation results for the partition to the specified `.qdb` file each time the final stage of the Fitter runs. You can automatically export any design partition that does not have a preserved parent partition, including the root_partition.

1.13.4. Exporting a Design Partition

The following steps describe export of design partitions that you create in your project.

Note: Design partitions exported from the Quartus Prime Pro Edition software versions 23.2 or earlier cannot be imported into version 23.3 or later due to the new DNI database.

When you compile a design containing design partitions, the Compiler can preserve a synthesis or final snapshot of results for each partition. You can export the synthesized or final compilation results for individual design partitions with the **Export Design Partition** dialog box.

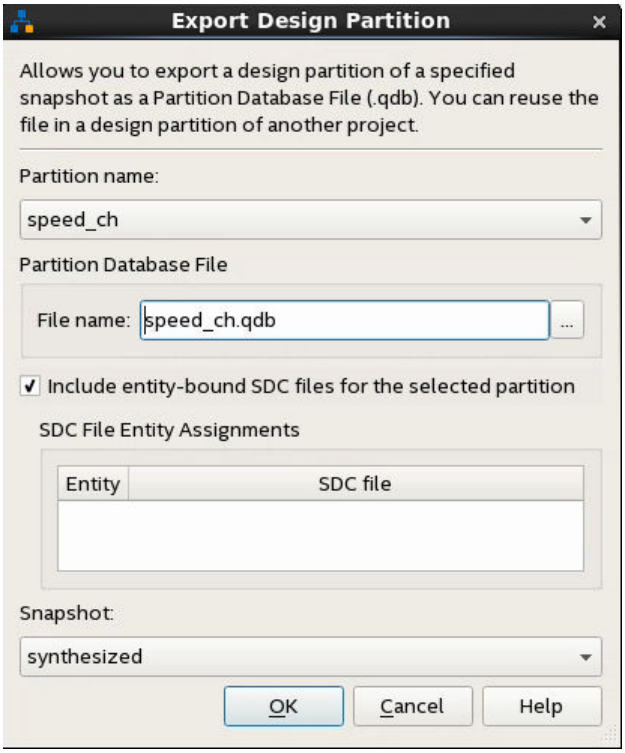
If the partition includes any entity-bound `.sdc` files, you can include those constraints in the `.qdb`. In addition, you can automate export of one or more partitions in the Design Partitions Window.

Manual Design Partition Export

Follow these steps to manually export a design partition with the **Export Design Partition** dialog box:

1. Open a project and create one or more design partitions. Creating a Design Partition on page 140 describes this process.
2. Run synthesis (**Processing ➤ Start ➤ Start Analysis & Synthesis**) or full compilation (**Processing ➤ Start Compilation**), depending on which compilation results that you want to export.
3. Click **Project ➤ Export Design Partition**, and specify one or more options in the **Export Design Partition** dialog box:

Figure 124. Export Design Partition Dialog Box



- Select the **Partition name** and the compilation **Snapshot** for export.
- To include any entity-bound `.sdc` files in the exported `.qdb`, turn on **Include entity-bound SDC files for the selected partition**.

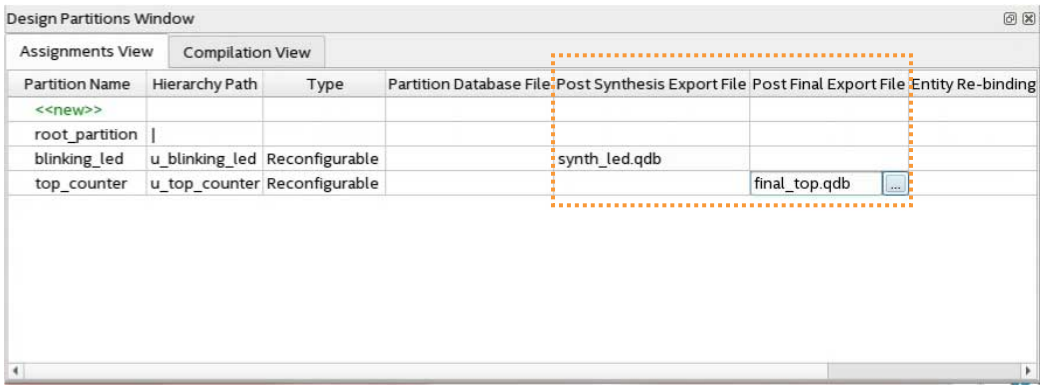
4. Click **OK**. The compilation results for the design partition exports to the file that you specify.

Automated Design Partition Export

Follow these steps to automatically export one or more design partitions following each compilation:

1. Open a project containing one or more design partitions. Creating a Design Partition on page 140 describes this process.
2. To open the Design Partitions Window, click **Assignments ➤ Design Partitions Window**.
3. To automatically export a partition with synthesis results after each time you run synthesis, specify the a `.qdb` export path and file name for the **Post Synthesis Export File** option for that partition. If you specify only a file name without a path, the file exports to the `output_files` directory after compilation.
4. To automatically export a partition with final snapshot results each time you run the Fitter, specify a `.qdb` file name for the **Post Final Export File** option for that partition. If you specify only a file name without a path, the file exports to the `output_files` directory after compilation.

Figure 125. Specifying Export File in Design Partitions Window



`.qsf` Equivalent Assignment:

```
set_instance_assignment -name EXPORT_PARTITION_SNAPSHOT_<FINAL|SYNTHESIZED> \
     <hpath> -to <file_name>.qdb
```

1.13.5. Reusing a Design Partition

You can reuse the compilation results of a design partition exported from another Quartus Prime project. Reuse of a design partition allows you to share a synthesized or final design block with another designer. Refer to *Intel Quartus Prime Pro Edition User Guide: Block-Based Design* for more information about reuse of design partitions.

To reuse an exported design partition in another project, you assign the exported partition `.qdb` to an appropriately configured design partition in the target project via the Design Partition Window:

1. Export a design partition with the appropriate snapshot, as Exporting a Design Partition on page 142 describes.
2. Open the target Quartus Prime project that you want to reuse the exported partition.
3. Click **Processing ➤ Start ➤ Start Analysis & Elaboration**.
4. Click **Assignments ➤ Design Partitions Window**, and then create a design partition to contain the logic and compilation results of the exported `.qdb`.
5. Click the **Partition Database File** option for the new partition and select the exported `.qdb` file.

Figure 126. Partition Database File Setting in Design Partitions Window

6. Specify any other properties of the design partition in the Design Partitions Window. The Compiler uses the partition's assigned `.qdb` as the source.

1.13.6. Viewing Quartus Database File Information

Although you cannot directly read a `.qdb` file, you can view helpful attributes about the file to quickly identify its contents and suitability for use.

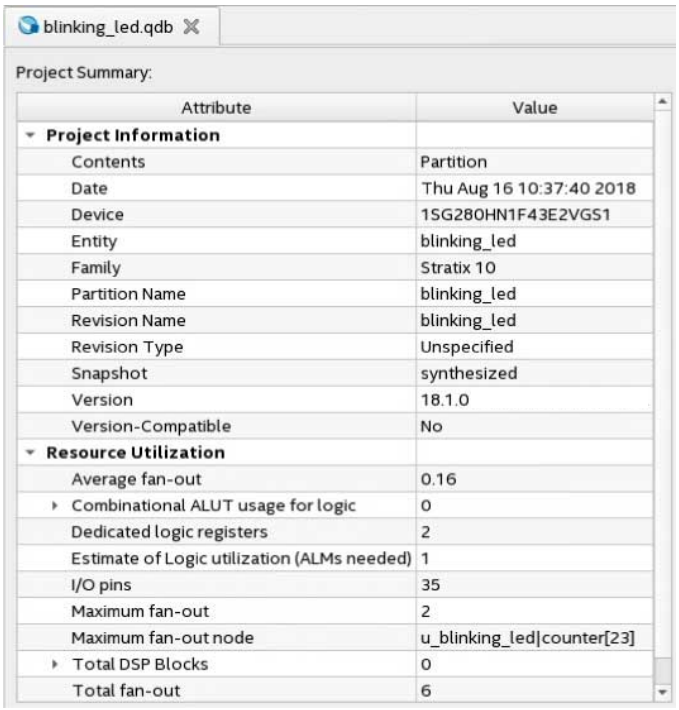
The Quartus Prime software automatically stores metadata about the project of origin when you export a Quartus Database File (`.qdb`). You can then use the Quartus Database File Viewer to display the attributes of any of these `.qdb` files.
Follow these steps to view the attributes of a `.qdb` file:

1. In the Quartus Prime software, click **File ➤ Open**, select **Design Files** for **Files of Type**, and select a `.qdb` file.
2. Click **Open**. The Quartus Database File Viewer displays project and resource utilization attributes of the `.qdb`.

   Alternatively, run the following command-line equivalent:

```
quartus_cdb --extract_metadata --file <archive_name.qdb> \
     --type quartus --dir <extraction_directory> \
     [--overwrite]
```

Figure 127. Quartus Database File Viewer



1.13.6.1. QDB File Attribute Types

The Quartus Database Viewer can display the following attributes of a `.qdb` file:

Table 29. QDB File Attributes

QDB Attribute Types	Attribute	Example
Project Information	Contents	`Partition`
	Date	`Thu Jan 23 10:56:23 2018`
	Device	`10AX016C3U19E2LG`
	Entity (if Partition)	`Counter`
	Family	`Arria 10`
	Partition Name	`root_partition`
	Revision Name	`Top`
	Revision Type	`PR_BASE`
	Snapshot	`synthesized`
	Version	`18.1.0 Pro Edition`
	Version-Compatible	`Yes`
Resource Utilization (exported for partition QDB only)	For synthesized snapshot partition lists data from the **Synthesis Resource Usage Summary** report.	`Average fan-out.16` `Dedicated logic registers:14` `Estimate of Logic utilization:1` `I/O pins:35` `Maximum fan-out:2` `Maximum fan-out node:counter[23]` `Total DSP Blocks:0` `Total fan-out:6` …
	For the final snapshot partition, lists data from the **Fitter Partition Statistics** report.	`Average fan-out:.16` `Combinational ALUTs: 16` `I/O Registers` `M20Ks` …

1.13.7. Clearing Compilation Results

You can clean the project database if you want to remove prior compilation results for all project revisions or for specific revisions. For example, you must clear previous compilation results before importing a version-compatible database to an existing project.

1. Click **Project > Clean Project**.
2. Select **All revisions** to clear the databases for all revisions of the current project, or specify a **Revision name** to clear only the revision's database you specify.
3. Click **OK**. A message indicates when the database is clean.

Figure 128. Clean Project Dialog Box Cleans the Project Database

1.14. Integrating Other EDA Tools

You can optionally integrate supported EDA synthesis, netlist partitioning, simulation, and signal integrity verification tools into the Quartus Prime design flow.

The Quartus Prime software supports input netlist files from supported EDA synthesis tools. The Compiler's EDA Netlist Writer module (`quartus_eda`) can automatically generate output files for processing in other EDA tools. The EDA Netlist Writer runs optionally as part of a full compilation, or you can run EDA Netlist Writer separately from the GUI or at the command line. The following functions are available to simplify EDA tool integration:

Table 30. EDA Tool Integration Functions

EDA Integration Task	EDA Integration Function
Specify settings for generation of output files for processing in other EDA tools.	Click **Assignments ➤ Settings ➤ EDA Tool Settings** to specify options for supported tools.
Generate output files for processing in other EDA tools.	Click **Processing ➤ Start ➤ Start EDA Netlist Writer** (or run `quartus_eda`) to generate files.
Compile RTL and gate-level simulation model libraries for your device, supported EDA simulators, and design language.	Click **Tools ➤ Launch Simulation Library Compiler** to compile simulation libraries easily.
Generate EDA tool-specific setup scripts to compile, elaborate, and simulate Intel FPGA IP models and simulation model library files.	Specify options for **Simulation** file output when generating Intel FPGA IP with IP parameter editor.
Generate files that allow supported EDA tools to perform netlist modifications, such as adding new modules, partitioning the netlist, and changing module connectivity.	Use the `quartus_eda –resynthesis` command to generate a Verilog Quartus Mapping File (`.vqm`) that contains a node-level (or atom) representation of the netlist in standard structural Verilog RTL.
Include files generated by other EDA design entry or synthesis tools in your project as synthesized design files.	Click **Project ➤ Add/Remove Files In Project** to add supported **Design File** files from other EDA tools.

1.14.1. Generating a VQM Netlist for other EDA Tools

The EDA Netlist Writer (`quartus_eda`) can generate a node-level netlist in Verilog Quartus Mapping File (`.vqm`) format for use in other EDA tools. You can process the `.vqm` netlist in other EDA tools to add new modules, partition the netlist, or change connectivity. After third-party tool changes, you resynthesize and compile the `.vqm` in the Quartus Prime software.

The `.vqm` format is standard structural Verilog RTL. The modules can be any Intel FPGA family-specific WYSIWYG type for core logic (such as, flip-flop, LUT, DSP, M20K). EDA Netlist Writer does not support `.vqm` for periphery modules (such as transceivers, memory interfaces, I/O, or IP including these). The RTL is a fully flattened representation of the entire design hierarchy or partition. The module names capture the original hierarchy, although some renaming can occur to legalize names. There is no truncation of the netlist module names.

To perform `.vqm` netlist partitioning in other EDA tools, define a design partition that includes only core logic elements. Generate the partition netlist as step 3 on page 149 describes. After processing the `.vqm` in third-party tools, resynthesize the `.vqm` files either independently or as a design partition. If including a black box module instantiation in the `.vqm`, make connections between existing logic in the `.vqm` and the black box. Prior to resynthesis, specify the source file (`.ip`, `.v`, or `.vqm`) for the black box in the project `.qsf`.

Table 31. VQM Netlist Generation Requirements and Limitations

Requirement or Limitation	Description
Design partitions must only include core logic.	Design partitions must include only flip-flops, LUTs, DSPs, and on-chip memory. The EDA Netlist Writer does not support `.vqm` output for periphery modules (such as transceivers, memory interfaces, I/O, or IP that includes these).
Analysis & Synthesis does not support some special characters in instance names that are legal in SystemVerilog.	Analysis & Synthesis resolves these characters by placing the standard escape character '\' to escape the special character present in the RTL. If any of the hierarchical constraints (for example, SDC timing constraints) explicitly reference such a special character, modify these characters manually.
Generate `.vqm` only for a synthesized netlist.	The post-fit netlist includes atoms, such as wire-luts, that are not appropriate for resynthesis.
Avoid module or entity name collisions	If you add a `.vqm`, generated from an RTL design file, to the same Quartus Prime project that generated the `.vqm`, beware of potential entity or module name collisions. Name collisions can occur if the original RTL file from which the `.vqm` derives, and the `.vqm` file itself, both specify the same entity or module name. When the RTL and `.vqm` files are both present in the project **Files** list, the Compiler uses the last entry in the list.
Partition assignments might not align with the original design.	`.vqm` generation flattens all logic within a partition unless you specify the `–exclude_sub_partitions` argument. Compiling a design that has assignments pertaining to a flattened partition causes an error.

To generate a `.vqm` for processing in other EDA tools, follow these steps:

1. In the Quartus Prime software, click **Processing ➤ Start ➤ Start Analysis & Synthesis** (or run `quartus_syn`) to synthesize the design netlist.
2. Create a design partition containing only core logic elements for the `.vqm`, as Creating a Design Partition on page 140 describes.
3. To generate the `.vqm` in the `resynthesis` directory, run any of the following commands at the command prompt:
   - To write out the entire design netlist to `.vqm`:
     ```
     quartus_eda --resynthesis=on <project_name>
     ```
   - To write out only a specific design partition netlist to `.vqm`:
     ```
     quartus_eda --resynthesis=on -partition=<name> <project_name>
     ```
   - To write out any sub partition as a black-box netlist to `.vqm`:
     ```
     quartus_eda --resynthesis=on –exclude_sub_partitions <project_name>
     ```
     You can also combine `–exclude_sub_partitions` with `-partition`.
4. View the resulting `.vqm` in the `resynthesis` directory, and specify the `.vqm` as input to your EDA tool.
5. After processing the `.vqm` in another EDA tool, add the `.vqm` as an Quartus Prime project design file by clicking **Project ➤ Add/Remove Files In Project**. Avoid module or entity name collisions, as the VQM Netlist Generation Requirements and Limitations table describes.
6. Run Analysis & Synthesis on the project, followed by the remaining Compiler stages.

1.15. Compiler Optimization Techniques

You can apply various optimization techniques via settings and entity assignments to achieve your design requirements during compilation. For example, you can specify options to preserve specific registers through synthesis processing, apply fractal synthesis, enable register retiming, and various other targeted Compiler optimizations.

1.15.1. Compiler Optimization Modes

To apply the compiler optimization settings, click **Assignments ➤ Settings ➤ Compiler Settings**. Alternatively, you can apply the optimization settings using the `OPTIMIZATION_MODE` QSF. For example:

```
set_global_assignment -name OPTIMIZATION_MODE "Aggressive Area"
```

The default value for `OPTIMIZATION_MODE` is "Balanced". For all other values, refer to the Optimization Modes table.

You can enable one of the following optimization modes to focus the Compiler's optimization effort. The settings compilation mode you select affects synthesis and fitting results.

To select an optimization mode, start with the **Balanced** setting. This mode is appropriate for many designs and provides an implementation balanced between optimization and compile time. If this setting does not meet your goals, you can try different optimization modes depending on your requirements.

If your design requires additional performance compared to the **Balanced** setting, use the **High performance effort** setting that enables additional timing optimizations during the fitting stage. You can achieve additional performance using the **Superior performance** setting that further enables additional timing optimizations during the Synthesis stage. However, these synthesis optimizations may result in increased logic area, negatively impacting designs with high utilization. Both settings increase compile time.

Alternatively, use the **Aggressive Area** setting to reduce logic area at the potential expense of performance. Similarly, use the **Aggressive power** setting to reduce dynamic power at the potential expense of performance.

If your design has difficulty routing successfully, the settings **Optimize netlist for routability**, **High placement routability effort**, and **High packing routability effort** offer a variety of optimizations to improve routability. Which optimizations work best is design-dependent, so try each if you encounter routability issues.

Finally, use **Aggressive Compile Time** and **Fast Functional Test** settings to reduce compile time. These settings reduce performance but may be helpful early in a design cycle when only functionality is being verified.

Table 32. Optimization Modes (Compiler Settings Page)

Optimization Mode	QSF Value	Description	Implications
Balanced (normal flow)	`Balanced`	The Compiler optimizes synthesis for balanced implementation that respects timing constraints.	The default setting that produces a balance between optimization effort and compile time.
High performance effort	`High Performance Effort`	The Compiler increases the timing optimization effort during placement and routing, and enables timing-related Physical Synthesis optimizations (per register optimization settings).	Increases compilation time for better performance compared to **Balanced** setting.
High performance with maximum placement effort	`High Performance With Maximum Placement Effort`	Enables the same Compiler optimizations as **High performance effort**, with additional placement optimization effort.	Increases compilation time for better performance compared to **High performance effort** setting.
High performance with aggressive power effort	`High Performance With Aggressive Power Effort`	Enables the same Compiler optimizations as **High performance effort**, while performing additional optimizations to reduce dynamic-power.	Increases compilation time for lower power compared to **High performance effort** setting.
Superior performance	`Superior Performance`	Enables the same Compiler optimizations as **High performance effort**, and adds more optimizations during Analysis & Synthesis to maximize design performance with a potential increase to logic area.	Increases compilation time for better performance compared to **High performance effort** setting. If design utilization is very high, this mode can cause difficulty in fitting, which can also negatively affect overall optimization quality.

continued...

Optimization Mode	QSF Value	Description	Implications
Superior performance with maximum placement effort	`Superior Performance With Maximum Placement Effort`	Enables the same Compiler optimizations as **Superior performance**, with additional placement optimization effort.	Increases compilation time for better performance compared to **Superior performance** setting.
Aggressive Area (reduces performance)	`Agressive Area`	The Compiler makes aggressive effort to reduce the device area required to implement the design at the potential expense of design performance.	Reduces performance for reduced area compared to **Balanced** setting.
High placement routability effort	`High Placement Routability Effort`	The Compiler makes high effort to route the design at the potential expense of design area, performance, and compilation time. The Compiler spends additional time reducing routing utilization, which can improve routability and also saves dynamic power.	Increases compilation time for better routability compared to **Balanced** setting.
High packing routability effort	`High Packing Routability Effort`	The Compiler makes high effort to route the design at the potential expense of design area, performance, and compilation time. The Compiler spends additional time packing registers, which can improve routability and also saves dynamic power.	Increases compilation time for better routability compared to **Balanced** setting.
Optimize netlist for routability	`Optimize Netlist for Routability`	The Compiler implements netlist modifications to increase routability at the possible expense of performance.	Increases compilation time for better routability compared to **Balanced** setting.

continued...

Optimization Mode	QSF Value	Description	Implications
Aggressive power (reduces performance)	`Agressive Power`	Makes aggressive effort to optimize synthesis for low power. The Compiler further reduces the routing usage of signals with the highest specified or estimated toggle rates, saving additional dynamic power but potentially affecting performance.	Reduces performance for lower power compared to **Balanced** setting.
Aggressive Compile Time (reduces performance)	`Aggressive Compile Time`	Especially useful during early design iterations, this mode reduces the compilation run time by 30% (on average) at the expense of design f_{MAX} of 15% (on average). Run time reduction occurs through reduced effort and fewer performance optimizations. This mode also disables some detailed reporting functions. This mode produces the fastest full-flow timing estimation with an approximate correlation to the high-effort modes.	• This mode reduces performance. • Reduced effort levels can cause no-fits, especially on highly congested designs. Mitigate this potential by either partitioning and constraining the placement of congested parts of design, or by using a high effort or routability mode • This mode may not identify the same critical paths as a full-effort compile (similar to Compiler seed-effects). • This mode disables some detailed reporting functions and enables `.qsf` settings that cannot be overridden by other `.qsf` settings.
Fast Functional Test (hold-timing optimization only)	`Fast Functional Test`	This mode produces a `.sof` bitstream file that you can use for on-board functional testing with minimal compile time. This mode further reduces compile time beyond Aggressive Compile Time mode by limiting timing optimizations to only those for hold requirements.	• Reduced effort levels can cause no-fits, especially on highly congested designs. Mitigate this potential by either partitioning and constraining the placement of congested parts of design, or by using a high effort or routability mode. Refer to the *Creating a Partition* topic in this document and the *Intel Quartus Prime Pro Edition User Guide: Design Constraints* • This mode can require clock speeds outside the lock range of the PLL Intel FPGA IP. Mitigate this effect by using the `adjust_pll` ECO command to update the PLL IP after fitting. • This mode disables some detailed reporting functions and enables `.qsf` settings that cannot be overridden by other `.qsf` settings.

Note: If you enable extended optimization modes for Design Space Explorer II by use of `.qsf` assignments, and then subsequently open the **Compiler Settings** tab for that project revision, the **Compiler Settings** tab indicates that the extended optimization mode reverts to one of the **Compiler Settings** tab **Optimization Modes**.

- Full Compilation Flow with Temporary Optimization Mode on page 133

1.15.2. Allow Register Retiming

The **Allow Register Retiming** option on the **Register Optimization** tab controls whether or not to globally disable retiming. When turned on, the Compiler automatically performs register retiming optimizations, moving registers through combinational logic. When turned off, the Compiler prevents any retiming optimizations on a global scale.

Optionally, assign **Allow Register Retiming** to any design entity or instance for specific portions of the design. Click **Assignments ➤ Assignment Editor** to specify entity- and instance-level assignments, or use the following syntax to make the assignment in the `.qsf` directly.

Remember: For devices that use the Hyperflex architecture (such as Agilex 7 devices), you can use the **Allow Register Retiming** optimization option alongside the Hyper-Retiming optimization.

Example 11. Disable register retiming for entity abc

```
set_global_assignment –name ALLOW_REGISTER_RETIMING ON

set_instance_assignment –name ALLOW_REGISTER_RETIMING OFF –to “abc|”

set_instance_assignment –name ALLOW_REGISTER_RETIMING ON –to “abc|def|”
```

Example 12. Disable register retiming for the whole design, except for registers in entity abc

```
set_global_assignment –name ALLOW_REGISTER_RETIMING OFF

set_instance_assignment –name ALLOW_REGISTER_RETIMING ON –to “abc|”

set_instance_assignment –name ALLOW_REGISTER_RETIMING OFF –to “abc|def|”
```

1.15.3. Automatic Gated Clock Conversion

Clock gating saves power in ASIC designs by adding more logic to a circuit to prune the clock tree. Pruning the clock tree disables portions of the circuitry so that the flip-flops are not required to switch states. When using an Quartus Prime FPGA to prototype ASIC designs, you must convert clock gates to clock enables in your design.

Table 33. Gated Clock Conversion Example

ASIC Gated Clock Example

```
module infer_enable (clk, reset, d, en, q);

input d, en, clk, reset;
output q;

wire gated_clk;
reg q;

assign gated_clk = clk & en;
always@(posedge gated_clk or reset)
 begin
               if (!reset)
                      q <= 1’b0;
              else
                      q <= d ;
              end
endmodule
```

FPGA Clock Enable Example

```
module infer_enable (clk, reset, d, en, q);

input d, en, clk, reset;
output q;

reg q;

always@(posedge clk or reset)
 begin
               if (!reset)
                      q <= 1’b0;
              else if (en)
                      q <= d;
              else
                      q <= q ;
              end
endmodule
```

Rather than manually converting gated clocks in your RTL, you can specify the **Auto Gated Clock Conversion** setting to automatically convert gated base clocks in the design to clock enables. You can apply this setting globally to all gated base clocks in the design, or to one or more specific clock signals.

Table 34. Gated Clock Conversion Settings

Setting Scope	Description
Global	Enable the **Auto Gated Clock Conversion** option at **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)**. Alternatively, add the global assignment to the project `.qsf`: `set_global_assignment -name SYNTH_GATED_CLOCK_CONVERSION on`
Instance-specific	Specify the **Auto Gated Clock Conversion** for one or more instances in the Assignment Editor (**Assignments ➤ Assignment Editor**). Alternatively, add the instance assignment to the project `.qsf`: `set_instance_assignment -name SYNTH_GATED_CLOCK_CONVERSION on -to clk_in`

Following design synthesis, view the results of gated clock conversion in the Gated Clock Conversion Details report. The report lists all converted and unconverted gated clocks with their base clocks. For unconverted gated clocks, the report specifies the reason the clock is not converted.

Note: Automatic gated clock conversion supports explicit RAMs (such as WYSIWYG RAMs and Intel FPGA memory IP), but does not support inferred RAMs.

Figure 129. Gated Clock Conversion Details Report

Gated Clock Conversion Details

	Gated Clock	Base Clock	Converted to Clock Enable	Reason not Converted
1	clk1	clk_in	No	Found register out1_dff fed by the gated clock tree has in-use clock enable
2	clk2	clk_in	No	Found unconvertable IO pin clk_out2 fed by the gated clock tree
3	clk3	clk_in	No	Found unsupported WYSIWYG wys_io fed by the gated clock tree
4	clk4~0	clk_in	No	Found unsupported gate clk4~0 in the gated clock tree
5	clk5	clk_in	No	Found dangerous cascaded clock from clk5~0 to clk5

1.15.4. Enable Intermediate Fitter Snapshots

To save compilation time, the Compiler does not save the planned, placed, routed, or retimed snapshots by default during full compilation.

However, you can turn on **Enable Intermediate Fitter Snapshots** (**Assignments ➤ Settings ➤ Compiler Settings**) to generate and preserve snapshots for the Plan, Place, Route, and Retime stages any time you run full compilation. You can also run any intermediate Fitter stage independently to generate the snapshot for that stage.

With the **Enable Intermediate Fitter Snapshots** option enabled, multiple snapshots are saved during the Fitter stages, allowing more flexible iteration of intermediate Fitter steps. For example, you can resume and rerun from the Place snapshot as opposed to starting from the Fitter Plan stage, saving compilation time. However, with this option enabled, you might incur extra runtime to write the intermediate snapshots during Fitter stage and disk space consumption is more in order to accommodate the additional snapshots.

Note: The **Enable Intermediate Fitter Snapshots** option is off by default. However, if **Run Fast Forward Timing Closure Recommendations during compilation** option is on, then the **Enable Intermediate Fitter Snapshots** option is forced enabled.

1.15.5. Fast Preserve Option

Enabling the **Fast Preserve** option on the **Incremental Compile** tab specifies that the Compiler can simplify a preserved partition to only interface logic.

Interface logic is logic at the partition boundary that interfaces with the rest of the design.

1.15.6. Fractal Synthesis Optimization

Fractal synthesis optimizations can be useful for deep-learning accelerators and other high-throughput, arithmetic-intensive designs that exceed all available DSP resources. For such designs, fractal synthesis optimization can achieve 20-45% area reduction.

Fractal synthesis is a set of synthesis optimizations that use FPGA resources in an optimal way for arithmetic-intensive designs. These synthesis optimizations consist of multiplier regularization and retiming, as well as continuous arithmetic packing. The optimizations target designs with large numbers of low-precision arithmetic operations (such as additions and multiplications). You can enable fractal synthesis globally or for specific multipliers, as Enabling or Disabling Fractal Synthesis on page 160 describes.

Project-Wide Fractal Synthesis Considerations

Note: Fractal synthesis optimization is most suitable for designs with deep-learning accelerators or other high-throughput, arithmetic-intensive functions that exceed all DSP resources. Enabling fractal synthesis project-wide can cause unnecessary bloat on modules that are not suitable for fractal optimizations. Consider the following factors before enabling fractal synthesis optimization project wide:

- Intel FPGA devices contain thousands of hard DSP blocks that are perfectly suited for arithmetic operations. If the total amount of arithmetic functions in your design is small, then there is no need to enable Fractal Synthesis. In such cases, all the arithmetic functions map directly into DSPs by default. Enable global Fractal Synthesis only if there are not enough DSP blocks available to implement all arithmetic components. Enable Fractal Synthesis only for modules that you do not want the Compiler to map into DSPs.
- In the current version of the Quartus Prime Pro Edition software, fractal synthesis optimizations target low-precision multiplication. Implement high-precision multipliers (where width of every operand exceeds 11 bits) using DSP blocks.
- If you enable project-wide Fractal Synthesis, the following information message number 20193 may generate during compilation:

  ```
  Applied dense packing to "<entity>". Area: 2 LABs. Logic density: 0.775.
  ```

  This information indicates the effort the Compiler is packing computational logic into a smaller number of LABs. If the design is already highly utilized, the Compiler can skip this stage.

  — Verify that the Area the message reports does not exceed 100 LABs. If the Area exceeds 100 LABs, divide fractal synthesis blocks to sub-blocks, and then assign the fractal synthesis optimizations to the sub-blocks independently.

  — Verify that the Logic density the message reports is greater than 0.75. If the logic density is less than 0.75, disable **Fractal Synthesis** for this entity because standard synthesis typically achieves better density.

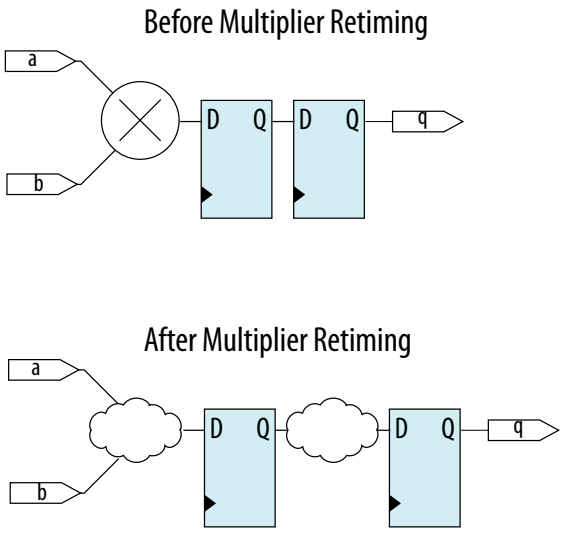
Table 35. Fractal Synthesis Area Improvement

		Area (LABs)	
Device	**Dot-product**	**Fractal Synthesis ON**	**Fractal Synthesis OFF**
Arria 10 and Cyclone 10 GX	Sum of 16 4x4sm	12	19
	Sum of 16 5x5sm	19	32
	Sum of 16 6x6sm	25	36
	Sum of 16 7x7sm	34	44
	Sum of 16 8x8sm	45	60
Stratix 10 and Agilex 7 Devices	Sum of 16 4x4sm	15	22
	Sum of 16 5x5sm	21	39
	Sum of 16 6x6sm	29	47
	Sum of 16 7x7sm	39	55
	Sum of 16 8x8sm	55	71

Multiplier Regularization and Retiming

Multiplier regularization and retiming performs inference of highly optimized soft multiplier implementations. The Compiler may apply backward retiming to two or more pipeline stages if required. When you enable fractal synthesis, the Compiler applies multiplier regularization and retiming to signed and unsigned multipliers.

Figure 130. Multiplier Retiming



Note:

- Multiplier regularization uses only logic resources, and does not use DSP blocks.
- Multiplier regularization and retiming is applied to both signed and unsigned multipliers in modules where the FRACTAL_SYNTHESIS QSF assignment is set.

Multiplier Regularization Example

The following simple, unsigned dot-product design example contains multiplication operators with 5-bit operands. These short multipliers are perfect candidates for multiplier regularization.

```
(* altera_attribute = "-name FRACTAL_SYNTHESIS ON" *)
module dot_product(
   input clk,
   input [4:0] a, b, c, d, e, f, g, h,
   output reg [11:0] out
);
reg [9:0] ab, cd, ef, gh;
reg [10:0] ab_cd, ef_gh;

always @(posedge clk)
begin
    ab <= a * b;
    cd <= c * d;
    ef <= e * f;
    gh <= g * h;
    ab_cd <= ab + cd;
    ef_gh <= ef + gh;
    out <= ab_cd + ef_gh;
end
endmodule

module top(
   input clk,
   input [4:0] a1, b1, c1, d1, e1, f1, g1, h1,
   input [4:0] a2, b2, c2, d2, e2, f2, g2, h2,
   output [11:0] out1, out2
);
dot_product core1(.clk(clk), .a(a1), .b(b1), .c(c1), .d(d1),
    .e(e1), .f(f1), .g(g1), .h(h1), .out(out1));
```

```
dot_product core2(.clk(clk), .a(a2), .b(b2), .c(c2), .d(d2),
    .e(e2), .f(f2), .g(g2), .h(h2), .out(out2));
endmodule
```

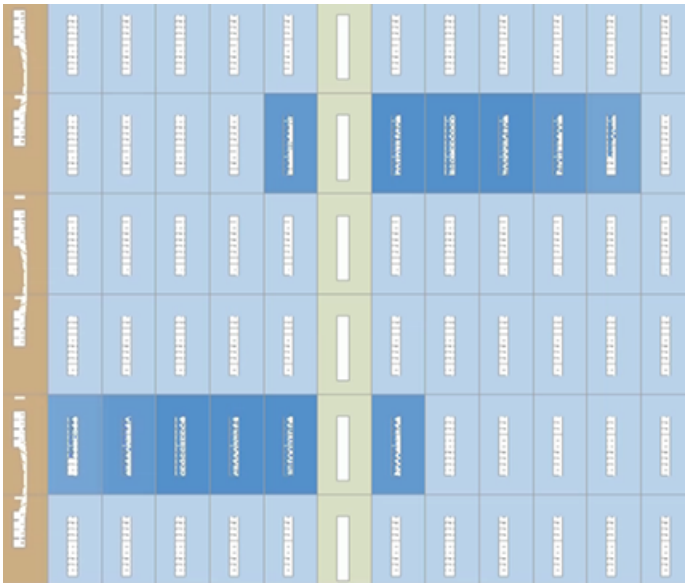
Quartus Prime synthesis prints the following messages to the console:

Figure 131. Console Messages

Message	Message ID
Inferred optimized multiplier from the following logic: "core1|mult_2"	20192
Inferred optimized multiplier from the following logic: "core1|mult_1"	20192
Inferred optimized multiplier from the following logic: "core1|mult_0"	20192
Inferred optimized multiplier from the following logic: "core2|mult_3"	20192
Inferred optimized multiplier from the following logic: "core2|mult_2"	20192
Inferred optimized multiplier from the following logic: "core2|mult_1"	20192
Inferred optimized multiplier from the following logic: "core2|mult_0"	20192
Timing-Driven Synthesis is running	286030
Applied dense packing to "core2". Area: 6 LABs. Logic density: 0.941667.	20193
Applied dense packing to "core1". Area: 6 LABs. Logic density: 0.941667.	20193

In the Chip Planner, you can observe this design having two unsigned dot-product cores. These cores are independently optimized and placed. The LAB resources are nearly 100% optimized, as the following image shows:

Figure 132. Design Placement



Signed dot-products are common for deep-learning applications. The following demonstrates an example of a signed dot-product:

```
(* altera_attribute = "-name FRACTAL_SYNTHESIS ON" *)
module dot_product(
   input signed clk,
   input signed [4:0] a, b, c, d, e, f, g, h,
   output reg signed [11:0] out
);
reg signed [9:0] ab, cd, ef, gh;
reg signed [10:0] ab_cd, ef_gh;

always @(posedge clk)
begin
    ab <= a * b;
```

```
    cd <= c * d;
    ef <= e * f;
    gh <= g * h;
    ab_cd <= ab + cd;
    ef_gh <= ef + gh;
    out <= ab_cd + ef_gh;
end
endmodule

module top(
   input clk,
   input signed [4:0] a1, b1, c1, d1, e1, f1, g1, h1,
   input signed [4:0] a2, b2, c2, d2, e2, f2, g2, h2,
   output signed [11:0] out1, out2
);
dot_product core1(.clk(clk), .a(a1), .b(b1), .c(c1), .d(d1),
    .e(e1), .f(f1), .g(g1), .h(h1), .out(out1));
dot_product core2(.clk(clk), .a(a2), .b(b2), .c(c2), .d(d2),
    .e(e2), .f(f2), .g(g2), .h(h2), .out(out2));
endmodule
```

Quartus Prime synthesis displays the following messages in the console:

Figure 133. Console Messages

Message	Message ID
Inferred optimized multiplier from the following logic: "core1|mult_2"	20192

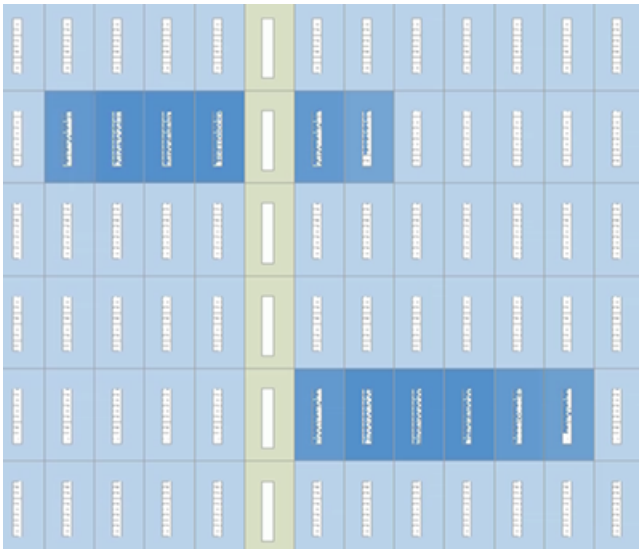
Inferred optimized multiplier from the following logic: "core2|mult_3"	20192
Inferred optimized multiplier from the following logic: "core2|mult_2"	20192
Inferred optimized multiplier from the following logic: "core2|mult_1"	20192
Inferred optimized multiplier from the following logic: "core2|mult_0"	20192
Timing-Driven Synthesis is running	286030
Applied dense packing to "core2". Area: 6 LABs. Logic density: 0.95.	20193
Applied dense packing to "core1". Area: 6 LABs. Logic density: 0.95.	20193

In the Chip Planner, you can observe this design having two signed dot-product cores independently optimized and placed:

Figure 134. Design Placement

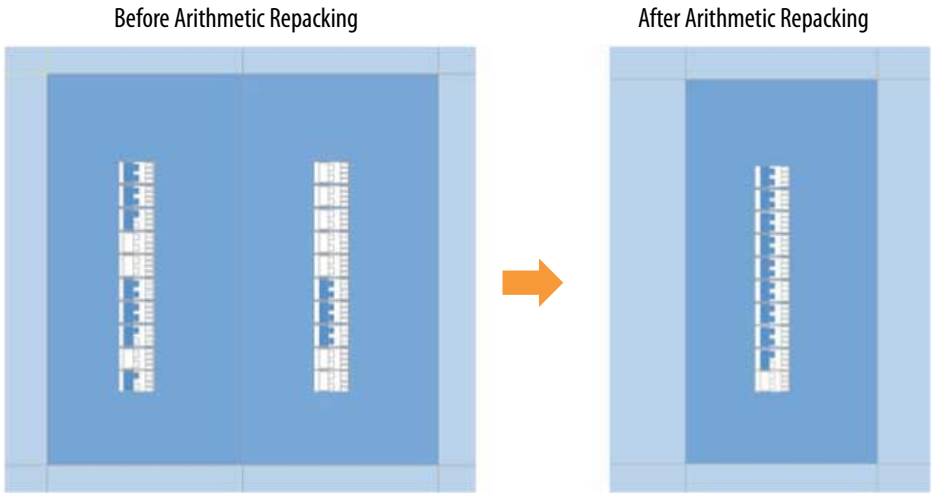


Continuous Arithmetic Packing

Continuous arithmetic packing re-synthesizes arithmetic gates into logic blocks optimally sized to fit into Intel FPGA LABs. This optimization allows up to 100% utilization of LAB resources for the arithmetic blocks.

When you enable fractal synthesis, the Compiler applies this optimization to all carry chains and two-input logic gates. This optimization can pack adder trees, multipliers, and any other arithmetic-related logic.

Figure 135. Continuous Arithmetic Packing



Note that continuous arithmetic packing works independently of multiplier regularization. So, if you are using a multiplier that is not regularized (such as writing your own multiplier) then continuous arithmetic packing can still operate.

1.15.6.1. Enabling or Disabling Fractal Synthesis

For Stratix 10 and Agilex 7 devices, fractal synthesis optimization runs automatically for small multipliers (any A*B statement in Verilog HDL or VHDL where bit-width of the operands is 7 or less). You can also disable automatic fractal synthesis for small multipliers for these devices using either of the following methods:

- In RTL, set the DSP multstyle, as "Multstyle Verilog HDL Synthesis Attribute" describes. For example:

```
(* multstyle = "dsp" *) module foo(...);
module foo(..) /* synthesis multstyle = "dsp" */;
```

- In the `.qsf` file, add as an assignment as follows:

```
set_instance_assignment -name DSP_BLOCK_BALANCING_IMPLEMENTATION \
     DSP_BLOCKS -to r
```

In addition, for Stratix 10, Agilex 7, Arria 10, and Cyclone 10 GX devices, you can enable fractal synthesis globally or for specific multipliers with the **Fractal Synthesis** GUI option or the corresponding FRACTAL_SYNTHESIS `.qsf` assignment:

- In RTL, use `altera_attribute` as follows:

```
(* altera_attribute = "-name FRACTAL_SYNTHESIS ON" *)
```

- In the `.qsf` file, add as an assignment as follows:

```
set_global_assignment -name FRACTAL_SYNTHESIS ON -entity <module name>
```

In the user interface, follow these steps:

1. Click **Assignments ➤ Assignment Editor**.
2. Select **Fractal Synthesis** for **Assignment Name**, **On** for the **Value**, the arithmetic-intensive entity name for **Entity**, and an instance name in the **To** column. You can enter a wildcard (*) for **To** to assign all instances of the entity.

Figure 136. Fractal Synthesis Assignment in Assignment Editor

1.16. Synthesis Language Support

The Quartus Prime software synthesizes standard Verilog HDL, VHDL, and SystemVerilog design files.

1.16.1. Verilog and SystemVerilog Synthesis Support

Quartus Prime synthesis supports the following Verilog HDL language standards:

- Verilog-1995 (IEEE Standard 1364-1995)
- Verilog-2001 (IEEE Standard 1364-2001)
- SystemVerilog-2005 (IEEE Standard 1800-2005)
- SystemVerilog-2009 (IEEE Standard 1800-2009)
- SystemVerilog-2012 (IEEE Standard 1800-2012)

The following important guidelines apply to Quartus Prime synthesis of Verilog HDL and SystemVerilog:

- The Compiler uses the Verilog-2001 standard by default for files with an extension of `.v`, and the SystemVerilog standard for files with the extension of `.sv`.
- If you use scripts to add design files, you can use the `-HDL_VERSION` command to specify the HDL version for each design file.
- Compiler support for Verilog HDL is case sensitive in accordance with the Verilog HDL standard.
- The Compiler supports the compiler directive `` `define ``, in accordance with the Verilog HDL standard.
- The Compiler supports the `include` compiler directive to include files with absolute paths (with either "/" or "\" as the separator), or relative paths.
- When searching for a relative path, the Compiler initially searches relative to the project directory. If the Compiler cannot find the file, the Compiler next searches relative to all user libraries. Finally, the Compiler searches relative to the current file's directory location.
- Quartus Prime Pro Edition synthesis searches for all modules or entities earlier in the synthesis process than other Quartus software tools. This earlier search produces earlier syntax errors for undefined entities than other Quartus software tools.

1.16.1.1. Verilog HDL Input Settings (Settings Dialog Box)

Click **Assignments ➤ Settings ➤ Verilog HDL Input** to specify options for the synthesis of Verilog HDL input files.

Figure 137. Verilog HDL Input Settings Dialog Box

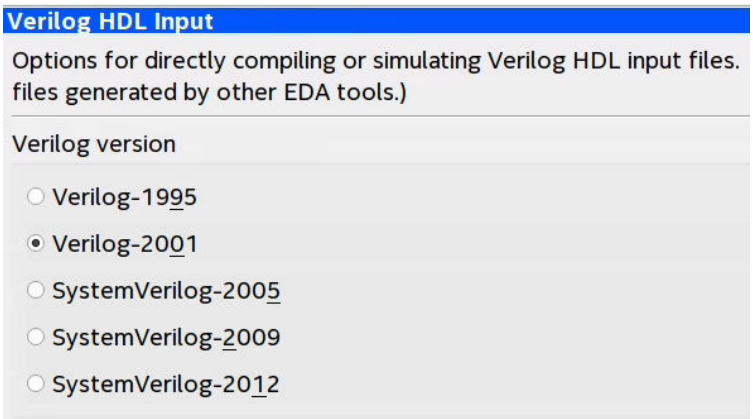

Table 36. Verilog HDL Input Settings

Setting	Description
Verilog Version	Directs synthesis to process Verilog HDL input design files using the specified standard. You can select any of the supported language standards to match your Verilog HDL files or SystemVerilog design files.
Library Mapping File	Allows you to optionally specify a provided Library Mapping File (`.lmf`) for use in synthesizing Verilog HDL files that contain non-Intel FPGA functions mapped to IP cores. You can specify the full path name of the LMF in the **File name** box.
Verilog HDL Macro	Verilog HDL macros are pre-compiler directives which can be added to Verilog HDL files to define constants, flags, or other features by **Name** and **Setting**. Macros that you add appear in the **Existing Verilog HDL macro settings** list.

1.16.1.2. Design Libraries

By default, the Compiler processes all design files into one or more libraries.

- When compiling a design instance, the Compiler initially searches for the entity in the library associated with the instance (which is the work library if you do not specify any library).
- If the Compiler cannot locate the entity definition, the Compiler searches for a unique entity definition in all design libraries.
- If the Compiler finds more than one entity with the same name, the Compiler generates an error. If your design uses multiple entities with the same name, you must compile the entities into separate libraries.

1.16.1.3. Verilog HDL Configuration

Verilog HDL configuration is a set of rules that specify the source code for particular instances. Verilog HDL configuration allows you to perform the following tasks:

- Specify a library search order for resolving cell instances (as does a library mapping file).
- Specify overrides to the logical library search order for specified instances.
- Specify overrides to the logical library search order for all instances of specified cells.

1.16.1.3.1. Hierarchical Design Configurations

A design can have more than one configuration. For example, you can define a configuration that specifies the source code you use in particular instances in a sub-hierarchy, and then define a configuration for a higher level of the design.

For example, suppose a subhierarchy of a design is an eight-bit adder, and the RTL Verilog code describes the adder in a logical library named `rtllib`. The gate-level code describes the adder in the `gatelib` logical library. If you want to use the gate-level code for the 0 (zero) bit of the adder and the RTL level code for the other seven bits, the configuration might appear as follows:

Example 13. Gate-level code for the 0 (zero) bit of the adder

```
config cfg1;
design aLib.eight_adder;
default liblist rtllib;
instance adder.fulladd0 liblist gatelib;
endconfig
```

If you are instantiating this eight-bit adder eight times to create a 64-bit adder, use configuration `cfg1` for the first instance of the eight-bit adder, but not in any other instance. A configuration that performs this function is shown below:

Example 14. Use configuration `cfg1` for first instance of eight-bit adder

```
config cfg2;
design bLib.64_adder;
default liblist bLib;
instance top.64add0 use work.cfg1:config;
endconfig
```

Note: The name of the unbound module may be different from the name of the cell that is bounded to the instance.

1.16.1.4. Initial Constructs and Memory System Tasks

The Quartus Prime software infers power-up conditions from the Verilog HDL `initial` constructs. The Quartus Prime software also creates power-up settings for variables, including RAM blocks. If the Quartus Prime software encounters non-synthesizable constructs in an `initial` block, it generates an error.

To avoid such errors, enclose non-synthesizable constructs (such as those intended only for simulation) in `translate_off` and `translate_on` synthesis directives. Synthesis of initial constructs enables the power-up state of the synthesized design to match the power-up state of the original HDL code in simulation.

Note: Initial blocks do not infer power-up conditions in some third-party EDA synthesis tools. If you convert between synthesis tools, you must set your power-up conditions correctly.

Quartus Prime synthesis supports the `$readmemb` and `$readmemh` system tasks to initialize memories.

Example 15. Verilog HDL Code: Initializing RAM with the readmemb Command

```
reg [7:0] ram[0:15];
initial
begin
$readmemb("ram.txt", ram);
end
```

When creating a text file to use for memory initialization, specify the address using the format @<*location*> on a new line, and then specify the memory word such as `110101` or `abcde` on the next line.

The following example shows a portion of a Memory Initialization File (`.mif`) for the RAM.

Example 16. Text File Format: Initializing RAM with the readmemb Command

```
@0
00000000
@1
00000001
@2
00000010
…
@e
00001110
@f
00001111
```

1.16.1.5. Verilog HDL Macros

The Quartus Prime software fully supports Verilog HDL macros, which you can define with the `'define` compiler directive in your source code. You can also define macros in the Quartus Prime software or on the command line.

To set Verilog HDL macros at the command line for the Quartus Prime Pro Edition synthesis (`quartus_syn`) executable, use the following format:

```
quartus_syn <PROJECT_NAME> --set=VERILOG_MACRO=a=2
```

This command adds the following new line to the project `.qsf` file:

```
set_global_assignment -name VERILOG_MACRO "a=2"
```

To avoid adding this line to the project `.qsf`, add this option to the `quartus_syn` command:

```
--write_settings_files=off
```

1.16.2. VHDL Synthesis Support

Quartus Prime synthesis supports the following VHDL language standards.

- VHDL 1987 (IEEE Standard 1076-1987)
- VHDL 1993 (IEEE Standard 1076-1993)
- VHDL 2008 (IEEE Standard 1076-2008)
- VHDL 2019 (IEEE Standard 1076-2019)(3)

The Quartus Prime Compiler uses the VHDL 1993 standard by default for files that have the extension `.vhdl` or `.vhd`.

(3) Only a subset of the features introduced by in VHDL 2019 are supported: Interfaces and Conditional Analysis.

Note: The VHDL code samples follow the VHDL 1993 standard.

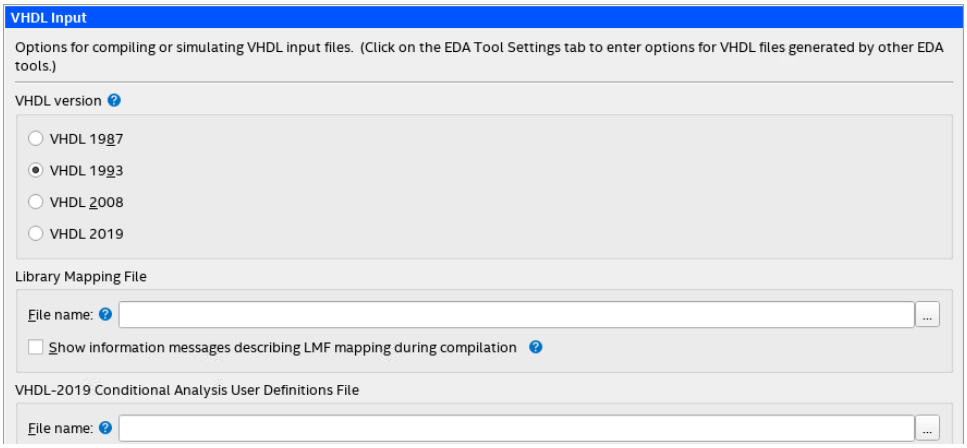
1.16.2.1. VHDL Input Settings (Settings Dialog Box)

Click **Assignments ➤ Settings ➤ VHDL Input** to specify options for the synthesis of VHDL input files.

Table 37. VHDL Input Settings

Setting	Description
VHDL Version	Specifies the VHDL standard for use during synthesis of VHDL input design files. Select the language standards that corresponds with the VHDL files.
Library Mapping File	Specifies a Library Mapping File (`.lmf`) for use in synthesizing VHDL files that contain IP cores. Specify the full path name of the LMF in the **File name** box.
VHDL-2019 Conditional Analysis User Definitions File	Specifies the `.ini` file that contains your user-defined VHDL 2019 conditional analysis identifier-value pairs.

Figure 138. VHDL Input Settings Dialog Box



Related Information

VHDL-2019 Conditional Analysis Tool Directives on page 167

1.16.2.2. VHDL Standard Libraries and Packages

The Quartus Prime software includes the standard IEEE libraries and several vendor-specific VHDL libraries. The IEEE library includes the standard VHDL packages `std_logic_1164`, `numeric_std`, `numeric_bit`, and `math_real`.

The STD library is part of the VHDL language standard and includes the packages `standard` (included in every project by default) and `textio`. For compatibility with older designs, the Quartus Prime software also supports the following vendor-specific packages and libraries:

- Synopsys* packages such as `std_logic_arith` and `std_logic_unsigned` in the IEEE library.
- Mentor Graphics* packages such as `std_logic_arith` in the ARITHMETIC library.
- Primitive packages `altera_primitives_components` (for primitives such as GLOBAL and DFFE) and `maxplus2` in the ALTERA library.
- IP core packages `altera_mf_components` in the ALTERA_MF library for specific IP cores including LCELL. In addition, `lpm_components` in the LPM library for library of parameterized modules (LPM) functions.

Note: Import component declarations for primitives such as GLOBAL and DFFE from the `altera_primitives_components` package and not the `altera_mf_components` package.

1.16.2.3. VHDL wait Constructs

The Quartus Prime software supports one VHDL `wait until` statement per process block. However, the Quartus Prime software does not support other VHDL wait constructs, such as `wait for` and `wait on` statements, or processes with multiple `wait` statements.

Example 17. VHDL `wait until` construct example

```
architecture dff_arch of ls_dff is
begin
output: process begin
wait until (CLK'event and CLK='1');
Q <= D;
Qbar <= not D;
end process output;
end dff_arch;
```

1.16.2.4. VHDL-2019 Conditional Analysis Tool Directives

Quartus Prime Pro Edition provides support for VHDL-2019 (IEEE Std 1076-2019) section 24.2 Conditional analysis tool directives.

With conditional analysis tool directives, your VHDL description can be varied according to directives stored in a separate `.ini` file.

Create the `.ini` file and specify the path in the **File name** field of the **VHDL-2019 Conditional Analysis User Definitions File** panel of the **VHDL Input** compiler settings page.

The format for the file is as follows:

- One *identifier*="*value*" pair per line
- Use ; or # characters to start line or trailing comments
- Identifiers must follow the requirements for a basic identifier as specified by the VHDL standard:
  - It must start with a letter.
  - It must contain only alphanumeric and underscore ("_") characters.
- Values must be surrounded by double quotes.

A line in the file with invalid syntax is ignored and generates a warning message. Lines that attempt to redefine the standard identifiers are ignored.

An example of a conditional analysis user definitions file is as follows:

```
USER_VAR1="ABC"
USER_VAR2 = "xyz"

# line comment
; line comment
USER_VAR3 = "TEST" # trailing comment
USER_VAR4 = "lorem" ; trailing comment

USER_VAR5=";# comment characters in quotes are ignored"
```

Standard Conditional Analysis Identifiers

Quartus Prime provides the following standard conditional analysis identifiers:

- `VHDL_VERSION = "<version>"`

  For example, `VHDL_VERSION = "2019"`. The values for <*version*> are restricted by the IEEE standard.

  `VHDL_VERSION` is set per file and can have a different value in each file.
- `TOOL_TYPE = "SYNTHESIS"`

  The values for `TOOL_TYPE` are restricted by the IEEE standard.
- `TOOL_VENDOR = "INTEL CORPORATION"`
- `TOOL_NAME = "QUARTUS"`
- `TOOL_EDITION = "PRIME PRO"`
- `TOOL_VERSION = "<major and minor version>"`

  For example, `TOOL_VERSION = "21.3.0"`

1.17. Synthesis Settings Reference

This section provides a reference to all synthesis settings. Use these settings to customize synthesis processing for your design goals.

1.17.1. Advanced Synthesis Settings

The following section is a quick reference of all Advanced Synthesis Settings. Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Synthesis)** to modify these settings.

Table 38. Advanced Synthesis Settings (1 of 13)

Option	Description
Allow Any RAM Size for Recognition	Allows the Compiler to infer RAMs of any size, even if the RAMs do not meet the current minimum requirements.
Allow Any ROM Size for Recognition	Allows the Compiler to infer ROMs of any size even if the ROMs do not meet the design's current minimum size requirements.
Allow Any Shift Register Size for Recognition	Allows the Compiler to infer shift registers of any size even if they do not meet the design's current minimum size requirements.
Allow Register Duplication	Controls whether the Compiler duplicates registers to improve design performance. When enabled, the Compiler performs optimization that creates a second copy of a register and move a portion of its fan-out to this new node. This technique improves routability and reduces the total routing wire required to route a net with many fan-outs. If you disable this option, retiming of registers is also disabled. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
Allow Register Merging	Controls whether the Compiler removes (merges) identical registers. When enabled, in cases where two registers generate the same logic, the Compiler may delete one register and fan-out the remaining register to the deleted register's destinations. This option is useful if you want to prevent the Compiler from removing duplicate registers that you have used deliberately. When disabled, retiming optimizations are also disabled. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
Allow Shift Register Merging Across Hierarchies	Allows the Compiler to take shift registers from different hierarchies of the design and put the registers in the same RAM.
Allow Synchronous Control Signals	Allows the Compiler to utilize synchronous clear and synchronous load signals in normal mode logic cells. Turning on this option helps to reduce the total number of logic cells used in the design, but can negatively impact the fitting. This negative impact occurs because all the logic cells in a LAB share synchronous control signals.

Table 39. Advanced Synthesis Settings (2 of 13)

Option	Description
Analysis & Synthesis Message Level	Specifies the type of Analysis & Synthesis messages the Compiler display. **Low** displays only the most important Analysis & Synthesis messages. **Medium** displays most messages, but hides the detailed messages. **High** displays all messages.
Auto Clock Enable Replacement	Allows the Compiler to locate logic that feeds a register and move the logic to the register's clock enable input port.
Auto DSP Block Replacement	Allows the Compiler to find a multiply-accumulate function or a multiply-add function that can be replaced with a DSP block.
Auto Gated Clock Conversion	Automatically converts gated clocks to use clock enable pins. Clock gating logic can contain AND, OR, MUX, and NOT gates. Turning on this option may increase memory use and overall run time. You must use the Timing Analyzer for timing analysis, and you must define all base clocks in Synopsys Design Constraints (`.sdc`) format.

Table 40. Advanced Synthesis Settings (3 of 13)

Option	Description
Auto Open-Drain Pins	Allows the Compiler to automatically convert a tri-state buffer with a strong low data input into the equivalent open-drain buffer.
Auto RAM Replacement	Allows the Compiler to identify sets of registers and logic that it can replace with the altsyncram or the lpm_ram_dp IP core. Turning on this option may change the functionality of the design.
Auto ROM Replacement	Allows the Compiler to identify logic that it can replace with the altsyncram or the lpm_rom IP core. Turning on this option may change the power-up state of the design.

continued...

Option	Description
Auto Resource Sharing	Allows the Compiler to share hardware resources among many similar, but mutually exclusive, operations in your HDL source code. If you enable this option, the Compiler merges compatible addition, subtraction, and multiplication operations. Merging operations may reduce the area your design requires. Because resource sharing introduces extra muxing and control logic on each shared resource, it may negatively impact the final f_{MAX} of your design.
Auto Shift Register Placement	Allows the Compiler to find a group of shift registers of the same length that are replaceable with the altshift_taps IP core. The shift registers must all use the same clock and clock enable signals. The registers must not have any other secondary signals. The registers must have equally spaced taps that are at least three registers apart.
Automatic Parallel Synthesis	Option to enable/disable automatic parallel synthesis. Use this option to speed up synthesis compile time by using multiple processors when available.

Table 41. Advanced Synthesis Settings (4 of 13)

Option	Description
Block Design Naming	Specifies the naming scheme for the block design. The Compiler ignores the option if you assign the option to anything other than a design entity.
Clock MUX Protection	Causes the multiplexers in the clock network to decompose to 2-to-1 multiplexer trees. The Compiler protects these trees from merging with, or transferring to, other logic. This option helps the Timing Analyzer to analyze clock behavior.
DSP Block Balancing	Allows you to control the conversion of certain DSP block slices during DSP block balancing.

Table 42. Advanced Synthesis Settings (5 of 13)

Option	Description
Disable DSP Negate Inferencing	Allows you to specify whether to use the negate port on an inferred DSP block.
Disable Register Merging Across Hierarchies	Specifies whether the Compiler allows merging of registers that are in different hierarchies if their inputs are the same.
Enable Formal Verification Support	Enables the Compiler to write scripts for use with the OneSpin* formal verification tool.
Enable State Machines Inference	Allows the Compiler to infer state machines from VHDL or Verilog HDL design files. The Compiler optimizes state machines to reduce area and improve performance. If set to **Off**, the Compiler extracts and optimizes state machines in VHDL or Verilog HDL design files as regular logic.
Enable SystemVerilog static assertion support	Enables immediate assertions in the Compiler for information, warning, and error messages for SystemVerilog designs.
Enable VHDL static assertion support	Enables immediate assertions in the Compiler for information, warning, and error messages for VHDL designs.
Force Use of Synchronous Clear Signals	Forces the Compiler to utilize synchronous clear signals in normal mode logic cells. Enabling this option helps to reduce the total number of logic cells in the design, but can negatively impact the fitting. All the logic cells in a LAB share synchronous control signals.
Fractal Synthesis	Turning this option **On** directs the Compiler to apply dense packing to arithmetic blocks, minimizing the area of the design for arithmetic-intensive designs.
HDL Message Level	Specifies the type of HDL messages you want to view, including messages that display processing errors in the HDL source code. **Level1** displays only the most important HDL messages. **Level2** displays most HDL messages, including warning and information based messages. **Level3** displays all HDL messages, including warning and information based messages and alerts about potential design problems or lint errors.

Table 43. Advanced Synthesis Settings (6 of 13)

Option	Description
Ignore GLOBAL Buffers	Ignores GLOBAL buffers in the design. The Compiler ignores this option if you apply the option to anything other than an individual GLOBAL buffer, or a design entity containing GLOBAL buffers.
Ignore LCELL Buffers	Ignores LCELL buffers in the design. The Compiler ignores this option if you apply the option to anything other than an individual LCELL buffer, or a design entity containing LCELL buffers.
Ignore Maximum Fan-Out Assignments	Directs the Compiler to ignore the Maximum Fan-Out Assignments on a node, an entity, or the whole design.
Ignore SOFT Buffers	Ignores SOFT buffers in the design. The Compiler ignores this option if you apply the option to anything other than an individual SOFT buffer or a design entity containing SOFT buffers.

Table 44. Advanced Synthesis Settings (7 of 13)

Option	Description
Ignore translate_off and synthesis_off Directives	Ignores all `translate_off/synthesis_off` synthesis directives in Verilog HDL and VHDL design files. Use this option to disable these synthesis directives and include previously ignored code during elaboration.
Infer RAMs from Raw Logic	Infers RAM from registers and multiplexers. The Compiler initially converts some HDL patterns differing from RAM templates into logic. However, these structures function as RAM. As a result, when you enable this option, the Compiler may substitute the altsyncram IP core instance for them at a later stage. When you enable this assignment, the Compiler may use more device RAM resources and fewer LABs.
Iteration Limit for Constant Verilog Loops	Defines the iteration limit for Verilog loops with loop conditions that evaluate to compile-time constants on each loop iteration. This limit exists primarily to identify potential infinite loops before they exhaust memory or trap the software in an actual infinite loop.
Iteration Limit for non-Constant Verilog Loops	Defines the iteration limit for Verilog HDL loops with loop conditions that do not evaluate to compile-time constants on each loop iteration. This limit exists primarily to identify potential infinite loops before they exhaust memory or trap the software in an actual infinite loop.

Table 45. Advanced Synthesis Settings (8 of 13)

Option	Description
Maximum DSP Block Usage	Specifies the maximum number of DSP blocks that the DSP block balancer assumes exist in the current device for each partition. This option overrides the usual method of using the maximum number of DSP blocks the current device supports.
Maximum Number of LABs	Specifies the maximum number of LABs that Analysis & Synthesis should try to utilize for a device. This option overrides the usual method of using the maximum number of LABs the current device supports, when the value is non-negative and is less than the maximum number of LABs available on the current device.
Maximum Number of M4K/M9K/M20K/M10K Memory Blocks	Specifies the maximum number of M4K, M9K, M20K, or M10K memory blocks that the Compiler may use for a device. This option overrides the usual method of using the maximum number of M4K, M9K, M20K, or M10K memory blocks the current device supports, when the value is non-negative and is less than the maximum number of M4K, M9K, M20K, or M10K memory blocks available on the current device.

Table 46. Advanced Synthesis Settings (9 of 13)

Option	Description
Maximum Number of Registers Created from Uninferred RAMs	Specifies the maximum number of registers that Analysis & Synthesis uses for conversion of uninferred RAMs. Use this option as a project-wide option or on a specific partition by setting the assignment on the instance name of the partition root. The

continued...

Option	Description
	assignment on a partition overrides the global assignment (if any) for that particular partition. This option prevents synthesis from causing long compilations and running out of memory when many registers are used for uninferred RAMs. Instead of continuing the compilation, the Quartus Prime software issues an error and exits.
NOT Gate Push-Back	Allows the Compiler to push an inversion (that is, a NOT gate) back through a register and implement it on that register's data input if it is necessary to implement the design. When this option is on, a register may power-up to an active-high state, and may need explicit clear during initial operation of the device. The Compiler ignores this option if you apply it to anything other than an individual register or a design entity containing registers. When you apply this option to an output pin that is directly fed by a register, the assignment automatically transfers to that register.
Number of Inverted Registers Reported in Synthesis Report	Specifies the maximum number of inverted registers that the Synthesis report displays.
Number of Protected Registers Reported in Synthesis Report	Specifies the maximum number of protected registers that the Synthesis Report displays.
Number of Removed Registers Reported in Synthesis Migration Checks	Specifies the maximum number of rows that the Synthesis Migration Check report displays.
Number of Swept Nodes Reported in Synthesis Report	Specifies the maximum number of swept nodes that the Synthesis Report displays. A swept node is any node which was eliminated from your design because the Compiler found the node to be unnecessary.
Number of Rows Reported in Synthesis Report	Specifies the maximum number of rows that the Synthesis report displays. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
Optimization Technique	Specifies an overall optimization goal for Analysis & Synthesis. Specify a **Balanced** strategy, or optimize for **Performance**, **Area**, **Routability**, **Power**, or **Compile Time**. The Compiler targets the optimization goal you specify.

Table 47. Advanced Synthesis Settings (10 of 13)

Option	Description
Perform WYSIWYG Primitive Resynthesis	Specifies whether to perform WYSIWYG primitive resynthesis during synthesis. This option uses the setting specified in the **Optimization Technique** logic option.
Power-Up Don't Care	Causes registers that do not have a **Power-Up Level logic** option setting to power-up with a do not care logic level (X). When the **Power-Up Don't Care** option is on, the Compiler determines when it is beneficial to change the power-up level of a register to minimize the area of the design. The Compiler maintains a power-up state of zero, unless there is an immediate area advantage.
Power Optimization During Synthesis	Controls the power-driven compilation setting of Analysis & Synthesis. This option determines how aggressively Analysis & Synthesis optimizes the design for power. When this option is **Off**, the Compiler does not perform any power optimizations. **Normal compilation** performs power optimizations provided that they are not expected to reduce design performance. **Extra effort** performs additional power optimizations which may reduce design performance.

Table 48. Advanced Synthesis Settings (11 of 13)

Option	Description
Remove Duplicate Registers	Removes a register if it is identical to another register. If two registers generate the same logic, the Compiler deletes the duplicate. The first instance fans-out to the duplicates destinations. Also, if the deleted register contains different logic option assignments, the Compiler ignores the options. This option is useful if you want to

continued...

Option	Description
	prevent the Compiler from removing intentionally duplicate registers. The Compiler ignores this option if you apply it to anything other than an individual register or a design entity containing registers.
Remove Redundant Logic Cells	Removes redundant LCELL primitives or WYSIWYG primitives. Turning this option on optimizes a circuit for area and speed. The Compiler ignores this option if you apply it to anything other than a design entity.
Report Parameter Settings	Specifies whether the Synthesis report includes the reports in the **Parameter Settings by Entity Instance** folder.
Report PR Initial Values as Errors	Allows you to flag explicitly defined initial values found in PR partitions as Errors instead of Warnings.
Report Source Assignments	Specifies whether the Synthesis report includes reports in the **Source Assignments** folder.

Table 49. Advanced Synthesis Settings (12 of 13)

Option	Description
Resource Aware Inference for Block RAM	Specifies whether RAM, ROM, and shift-register inference should take the design and device resources into account.
Restructure Multiplexers	Reduces the number of logic elements synthesis requires to implement multiplexers in a design. This option is useful if your design contains buses of fragmented multiplexers. This option repacks multiplexers more efficiently for area, allowing the design to implement multiplexers with a reduced number of logic elements: • **On**—minimizes your design area, but may negatively affect design clock speed (f_{MAX}). • **Off**—disables multiplexer restructuring; it does not decrease logic element usage and does not affect design clock speed (f_{MAX}). • **Auto**—allows the Quartus Prime software to determine whether multiplexer restructuring should be enabled. The **Auto** setting decreases logic element usage, but may negatively affect design clock speed (f_{MAX}).
SDC Constraint Protection	Verifies `.sdc` constraints in register merging. This option helps to maintain the validity of `.sdc` constraints through compilation.
Safe State Machine	The **Safe State Machine** option implements state machines that can recover from an illegal state. The following settings are available: • **Auto**—for Stratix 10 or Agilex 7 designs, this default setting enables **Safe State Machine** whenever the Compiler determines this setting is advantageous in state machines of 6 or less states. The setting helps to allow for unexpected initial power-up conditions. For Arria 10 and Cyclone 10 GX, the **Auto** setting is the same as **Never**. • **On**—directs the Compiler to always use **Safe State Machine**. • **Never**—never uses **Safe State Machine**.
Shift Register Replacement – Allow Asynchronous Clear Signal	Allows the Compiler to find a group of shift registers of the same length that can be replaced with the altshift_taps IP core. The shift registers must all use the same `aclr` signals, must not have any other secondary signals, and must have equally spaced taps that are at least three registers apart. To use this option, you must turn on the **Auto Shift Register Replacement** logic option.
Size of the Latch Report	Allows you to specify the maximum number of latches that the Synthesis Report should display.
Size of the PR Initial Conditions Report	Allows you to specify the maximum number of registers that the PR Initial Conditions Report should display.

Table 50. Advanced Synthesis Settings (13 of 13)

Option	Description
State Machine Processing	Specifies the processing style the Compiler uses to process a state machine. You can use your own **User-Encoded** style, or select **One-Hot**, **Minimal Bits**, **Gray**, **Johnson**, **Sequential,** or **Auto** (Compiler-selected) encoding.
Strict RAM Replacement	When this option is **On**, the Compiler replace RAM only if the hardware matches the design exactly.
Synchronization Register Chain Length	Specifies the maximum number of registers in a row that the Compiler considers as a synchronization chain. Synchronization chains are sequences of registers with the same clock and no fan-out in between, such that the first register is fed by a pin, or by logic in another clock domain. The Compiler considers these registers for metastability analysis. The Compiler prevents optimizations of these registers, such as retiming. When gate-level retiming is enabled, the Compiler does not remove these registers. The default length is set to two.
Synthesis Effort	Controls the synthesis trade-off between compilation speed, performance, and area. The default is **Auto**. You can select **Fast** for faster compilation speed at the cost of performance and area.
Synthesis Migration Check for Stratix 10	Enables synthesis checks on Arria 10 to Stratix 10 design migration.
Timing-Driven Synthesis	For Arria 10 and Cyclone 10 GX designs, allows synthesis to use timing information to better optimize the design. The **Timing-Driven Synthesis** logic option impacts the following **Optimization Technique** options: • **Optimization Technique Speed**—optimizes timing-critical portions of your design for performance at the cost of increasing area (logic and register utilization) • **Optimization Technique Balanced**—also optimizes the timing-critical portions of your design for performance, but the option allows only limited area increase • **Optimization Technique Area**—optimizes your design only for area

1.18. Fitter Settings Reference

Use Fitter settings to customize the place and route of your design. Click **Assignments ➤ Settings ➤ Compiler Settings ➤ Advanced Settings (Fitter)** to access Fitter settings.

Table 51. Advanced Fitter Settings (1 of 8)

Option	Description
ALM Register Packing Effort	Guides aggressiveness of the Fitter in packing ALMs during register placement. Use this option to increase secondary register locations. Increasing ALM packing density may lower the number of ALMs needed to fit the design, but it may also reduce routing flexibility and timing performance. • **Low**—the Fitter avoids ALM packing configurations that combine LUTs and registers which have no direct connectivity. Avoiding these configurations may improve timing performance but increases the number of ALMs to implement the design. • **Medium**—the Fitter allows some configurations that combine unconnected LUTs and registers to be implemented in ALM locations. The Fitter makes more use of secondary register locations within the ALM. • **High**—the Fitter enables all legal and desired ALM packing configurations. In dense designs, the Fitter automatically increases the ALM register packing effort as required to enable the design to fit.
Advanced Physical Synthesis	Enables the Physical Synthesis engine that includes combinational and sequential optimization during fitting to improve circuit performance.
Allow Delay Chains	Allows the Fitter to choose the optimal delay chain to meet t_{SU} and t_{CO} timing requirements for all I/O elements. Enabling this option may reduce the number of t_{SU} violations, while introducing a minimal number of t_H violations. Enabling this option does not override delay chain settings on individual nodes.

continued...

Option	Description
Allow DSP Retiming	Allow retiming through DSP blocks.
Allow Early Global Retiming in the Fitter	Allows the Compiler to run global retiming early in the Fitter.
Allow Hyper-Aware Register Chain Area Optimizations in the Fitter	Reduces ALM usage by automatically forcing some back-to-back registers into Hyper Registers. Turning on this area reduction technique may reduce performance and increase compile time.
Allow RAM Retiming	Allow retiming through RAM blocks.
Allow Register Duplication	Allows the Compiler to duplicate registers to improve design performance. When you enable this option, the Compiler copies registers and moves some fan-out to this new node. This optimization improves routability and can reduce the total routing wire in nets with many fan-outs. If you disable this option, this disables optimizations that retime registers. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
Allow Register Merging	Allows the Compiler to remove registers that are identical to other registers in the design. When you enable this option, in cases where two registers generate the same logic, the Compiler deletes one register, and the remaining registers fan-out to the deleted register's destinations. This option is useful if you want to prevent the Compiler from removing intentional use of duplicate registers. If you disable register merging, the Compiler disables optimizations that retime registers. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.
Auto Delay Chains for High Fanout Input Pins	Allows the Fitter to choose how to optimize the delay chains for high fan-out input pins. You must enable **Auto Delay Chains** to enable this option. Enabling this option may reduce the number of t_{SU} violations, but the compile time increases significantly, as the Fitter tries to optimize the settings for all fan-outs.
Auto Fit Effort Desired Slack Margin	Specifies the default worst-case slack margin the Fitter maintains for. If the design is likely to have at least this much slack on every path, the Fitter reduces optimization effort to reduce compilation time. *Note:* Only available for Arria 10 and Cyclone 10 GX devices.

Table 52. Advanced Fitter Settings (2 of 8)

Option	Description
Auto Global Clock	Allows the Compiler to choose the global clock signal. The Compiler chooses the signal that feeds the most clock inputs to flip-flops. This signal is available throughout the device on the global routing paths. To prevent the Compiler from automatically selecting a particular signal as global clock, set the **Global Signal** option to **Off** on that signal.
Auto Global Register Control Signals	Allows the Compiler to choose global register control signals. The Compiler chooses signals that feed the most control signal inputs to flip-flops (excluding clock signals) as the global signals. These global signals are available throughout the device on the global routing paths. Depending on the target device family, these control signals can include asynchronous clear and load, synchronous clear and load, clock enable, and preset signals. If you want to prevent the Compiler from automatically selecting a particular signal as a global register control signal, set the **Global Signal** option to **Off** on that signal.
Auto Packed Registers	Allows the Compiler to combine a register and a combinational function, or to implement registers using I/O cells, RAM blocks, or DSP blocks instead of logic cells. This option controls how aggressively the Fitter combines registers with other function blocks to reduce the area of the design. Generally, the **Auto** or **Sparse Auto** settings are appropriate.

continued...

Option	Description
	The other settings limit the flexibility of the Fitter to combine registers with other function blocks and can result in no fits. • **Auto**—the Fitter attempts to achieve the best performance with good area. If necessary, the Fitter combines additional logic to reduce the area of the design to within the current device. • **Sparse Auto**—the Fitter attempts to achieve the highest performance, but may increase device usage without exceeding the device logic capacity. • **Off**—the Fitter does not combine registers with other functions. The **Off** setting severely increases the area of the design and may cause a no fit. • **Sparse**—the Fitter combines functions in a way which improves performance for many designs. • **Normal**—the Fitter combines functions that are expected to maximize design performance and reduce area. • **Minimize Area**—the Fitter aggressively combines unrelated functions to reduce the area required for placing the design, at the expense of performance. • **Minimize Area with Chains**—the Fitter even more aggressively combines functions that are part of register cascade chains or can be converted to register cascade chains. If this option is set to any value but **Off**, registers combine with I/O cells to improve I/O timing. This remains true provided that the **Optimize IOC Register Placement For Timing** option is enabled.
Auto RAM to MLAB Conversion	Specifies whether the Fitter converts RAMs of **Auto** block type to use LAB locations. If this option is set to **Off,** only MLAB cells or RAM cells with a block type setting of **MLAB** use LAB locations to implement memory.
